On the 2d of February we anchored in Port Famine, and on the 10th, having obtained chronometric observations for which I went there, we sailed for the neighbourhood of the First Narrow and Lomas Bay (near Point Catherine). We often anchored thereabouts in the prosecution of our work.

On the 17th, as we ran along the curious spit or bank of shingle that fronts San Sebastian Bay, I really could not tell, though I had been in that bay before, whether I had not been

* I think that this easterly swell must have been caused by a south-east gale, though it came to us from the east.

deceived as to no channel existing,* so well defined and distinct did a wide opening appear. A few more minutes, however, undeceived me: I discerned low flat land stretching along the western horizon: and soon afterwards we anchored in the bay. The following week was occupied in surveying the north-eastern shore of Tierra del Fuego, which, except San Sebastian Bay, does not contain a port. San Vicente Cove is not worth notice as a harbour.

On the 25th, we anchored at the Hermite Islands, on the north-east side of Wollaston Island. Thence, on the 27th, we crossed Nassau Bay to Goree Road, and the following day entered the Beagle Channel.

The 1st of March passed in replenishing our wood and water at a cove, where we had an opportunity of making acquaintance with some Yapoo Tekeenica natives, who seemed not to have met white men before.

Till the 5th the Beagle was actively occupied, by day, in working to windward (westward) through the channel, and then she anchored at Woollȳa. But few natives were seen as we sailed along: probably they were alarmed at the ship, and did not show themselves. The wigwams in which I had left York, Jemmy, and Fuegia, were found empty, though uninjured: the garden had been trampled over, but some turnips and potatoes of moderate size were pulled up by us, and eaten at my table, a proof that they may be grown in that region. Not a living soul was visible any where; the wigwams seemed to have been deserted many months; and an anxious hour or two passed, after the ship was moored, before three canoes were seen in the offing, paddling hastily towards us, from the place now called Button Island. Looking through a glass I saw that two of the natives in them were washing their faces, while the rest were paddling with might and main: I was then sure that some of our acquaintances were there, and in a few minutes recognized Tommy Button, Jemmy's brother. In the other canoe was a face which I knew yet could not name. "It must be some one I have seen before," said I,—when his sharp eye

* Vol. I. p. 457-8.

© The Complete Work of Charles Darwin Online

detected me, and a sudden movement of the hand to his head (as a sailor touches his hat) at once told me it was indeed Jemmy Button—but how altered! I could hardly restrain my feelings, and I was not, by any means, the only one so touched by his squalid miserable appearance. He was naked, like his companions, except a bit of skin about his loins; his hair was long and matted, just like theirs; he was wretchedly thin, and his eyes were affected by smoke. We hurried him below, clothed him immediately, and in half an hour he was sitting with me at dinner in my cabin, using his knife and fork properly, and in every way behaving as correctly as if he had never left us. He spoke as much English as ever, and, to our astonishment, his companions, his wife, his brothers and their wives, mixed broken English words in their talking with him. Jemmy recollected every one well, and was very glad to see them all, especially Mr. Bynoe and James Bennett. I thought he was ill, but he surprised me by saying that he was "hearty, sir, never better,"* that he had not been ill, even for a day, was happy and contented, and had no wish whatever to change his way of life. He said that he got "plenty fruits,"† "plenty birdies," "ten guanaco in snow time," and "too much fish." Besides, though he said nothing about her, I soon heard that there was a good-looking‡ young woman in his canoe, who was said to be his wife. Directly this became known, shawls, handkerchiefs, and a gold-laced cap appeared, with which she was speedily decorated; but fears had been excited for her husband's safe return to her, and no finery could stop her crying until Jemmy again showed himself on deck. While he was below, his brother Tommy called out in a loud tone—"Jemmy Button, canoe, come!" After some time the three canoes went ashore, laden with presents, and their owners promised to come again early next morning. Jemmy gave a fine otter skin to me, which he had dressed and kept purposely; another he gave to Bennett.

Next morning Jemmy shared my breakfast, and then we had a long conversation by ourselves; the result of which was, that I felt quite decided not to make a second attempt to place Matthews among the natives of Tierra del Fuego. Jemmy told me that he knew very little of his own language; that he spoke some words of English, and some Tekeenica, when he talked to his family; and that they all understood the English words he used. York and Fuegia left him some months before our arrival, and went in a large canoe to their own country; the last act of that cunning fellow was to rob poor Jemmy of all his clothes; nearly all the tools his Tekeenica 'friends' had left him; and various other necessaries. Fuegia was dressed as usual, and looking well, when they decamped: her helpmate was also well clothed, and had hardly lost anything I left with him. Jemmy said "York very much jaw," "pick up big stones," "all men afraid." Fuegia seemed to be very happy, and quite contented with her lot. Jemmy asserted that she helped to "catch (steal) his clothes," while he was asleep, the night before York left him naked.

Not long after my departure in Febuary 1833, the much-dreaded Oens-men came in numbers, overland, to Woollȳa; obliged Jemmy's tribe to escape to the small islands, and carried off every valuable which his party had not time to remove. They had doubtless heard of the houses and property left there, and hastened to seize upon it—like other 'borderers.' Until this time York had appeared to be settled, and quite at ease, but he had been employed about a suspiciously large canoe, just finished when the inroad was made. He saved this canoe, indeed escaped in it, and afterwards induced Jemmy and his family to accompany him "to look at his land." They went together in four canoes (York's large one and three others) as far west as Devil Island, at the junction of the north-west and south-west arms of the Beagle Channel: there they met York's brother and some others of the Alikhoolip tribe; and, while Jemmy was asleep, all the Alikhoolip party stole off, taking nearly all Jemmy's things, and leaving him in his original condition. York's fine canoe was evidently not

© The Complete Work of Charles Darwin Online

built for transporting himself alone; neither was the meeting with his brother accidental. I am now quite sure that from the time of his changing his mind, and desiring to be placed at Woollȳa, with Matthews and Jemmy, he meditated taking a good opportunity of possessing himself of every thing; and that he thought, if he were left in his own country without Matthews, he would not have many things given to him, neither would he know where he might afterwards look for and plunder poor Jemmy.

While Mr. Bynoe was walking about on shore, Jemmy and his brother pointed out to him the places where our tents were pitched in 1833, where the boundary line was, and where any particular occurrence happened. He told Mr. Bynoe that he had watched day after day for the sprouting of the peas, beans, and other vegetables, but that his countrymen walked over them without heeding any thing he said. The large wigwams which we had erected with some labour, proved to be cold in the winter, because they were too high; therefore they had been deserted after the first frosts. Since the last depredations of the Oens-men, he had not ventured to live any longer at Woollȳa; his own island, as he called it, affording safer refuge and sufficient food.

Jemmy told us that these Oens-men crossed over the Beagle Channel, from eastern Tierra del Fuego, in canoes which they seized from the Yapoo Tekeenica. To avoid being separated they fastened several canoes together, crossed over in a body, and when once landed, travelled over-land and came upon his people by surprise, from the heights behind Woollȳa. Jemmy asserted that he had himself killed one of his antagonists. It was generally remarked that his family were become considerably more humanized than any savages we had seen in Tierra del Fuego: that they put confidence in us; were pleased by our return; that they were ready to do what we could explain to be for their interest; and, in short, that the first step towards civilization—that of obtaining their confidence—was undoubtedly made: but an individual, with limited means, could not then go farther. The whole scheme, with respect

to establishing a missionary with the Fuegians who were in England, among their countrymen, was on too small a scale, although so earnestly assisted by Mr. Wilson,* Mr. Wigram, Mr. Coates, and other kind friends.

I cannot help still hoping that some benefit, however slight, may result from the intercourse of these people, Jemmy, York, and Fuegia, with other natives of Tierra del Fuego. Perhaps a ship-wrecked seaman may hereafter receive help and kind treatment from Jemmy Button's children; prompted, as they can hardly fail to be, by the traditions they will have heard of men of other lands; and by an idea, however faint, of their duty to God as well as their neighbour.

That Jemmy felt sincere gratitude is, I think, proved by his having so carefully preserved two fine otter skins, as I mentioned; by his asking me to carry a bow and quiver full of arrows to the schoolmaster of Walthamstow, with whom he had lived; by his having made two spear-heads expressly for Mr. Darwin; and by the pleasure he showed at seeing us all again.

As nothing more could be done, we took leave of our young friend and his family, every one of whom was loaded with presents, and sailed away from Woollȳa.

On the 9th of March we were off Beauchesne Island.† Many persons have fancied that there are two islands near together in that place, having been deceived by two hummocks on the only island, which from a distance show just above the horizon like two islets. Next day we anchored in Berkeley Sound; first in Johnson Cove, and afterwards in Port Louis.

We found a state of affairs somewhat different from that of March 1833; but though more settled, in consequence of the presence of an established authority, resident at Port Louis (a lieutenant in the navy), my worst forebodings had not equalled the sad reality.

In a note to page 240, I alluded to the murder of the Buenos Ayrean commanding officer; and to that of Mr. Brisbane. A few weeks before the Clio arrived in 1833, there was a small

* Of Walthamstow. † Near the Falklands.

© The Complete Work of Charles Darwin Online

garrison at Port Louis, consisting of a sergeant's guard of soldiers, a subaltern, and a field officer. The men mutinied because their superior was thought to be unnecessarily severe, and occupied them unceasingly in drill and parade, to the prejudice of their obtaining food sufficient for health. They were obliged, in consequence of his system, to live upon worse fare than the settlers, because they could not go about to forage for themselves; and the result was that, after many threats, they murdered him. A small armed schooner* arrived a few days afterwards from Buenos Ayres, by whose officers and crew, assisted by some French sailors, the principal mutineers, nine in number, were taken and put into confinement on board. They were afterwards carried to Buenos Ayres.

On the 26th of August 1833, three 'gauchos' and five Indians† (the prisoners before mentioned), set upon and murdered Mr. Brisbane; Dickson, the man in charge of Vernet's store;‡ Simon, the capataz; the poor German; and another settler; after which atrocious acts they plundered the settlement and drove all the cattle and horses into the interior. Only that morning Mr. Low, who was then living with Mr. Brisbane, left Port Louis on a sealing excursion, with four men. Hardly was his boat out of sight, when the deceitful villains attacked Brisbane in Vernet's house: suspecting no treachery, he fell at once by the knife of Antonio Rivero. Simon defended himself desperately, but was overpowered; the others, overcome by fear, fell easy victims. The rest of the settlers, consisting of thirteen men, three women, and two children, remained with the murderers two days, and then escaped to a small island in the Sound; where they lived on birds' eggs and fish, till the arrival of the English sealer Hopeful,§ on board which was an officer of the navy, ‖ who in some measure relieved their immediate distress, but could not delay to protect them from the assaults which

they anticipated. About a month after the Hopeful sailed, H.M.S. Challenger, Captain M. Seymour, arrived, having a lieutenant of the navy and four seamen on board, who had volunteered from H.M.S. Tyne, and were duly authorized to remain at the Falklands. The following extract from a letter will show what took place on Captain Seymour's arrival.

"Captain Seymour, and the consuls, being anxious to visit the settlement of Port Louis, landed some distance from it (the wind being strong from S.S.W.), intending to walk there. About a mile from the houses they were met by an Englishman named Channon, sent by the gauchoes to see who they were, and whether the ship was a whaler in want of beef, or a man-of-war. He informed them that the gauchoes and Indians had murdered Mr. Brisbane: Dickson, who had been left in charge of the flag by Captain Onslow: Simon; and two others: and had pillaged the houses, destroying every thing in their search for money. He then pointed them out, sitting under a wall, with their horses behind the remains of the government house, ready saddled for a start on our nearer approach. They had two gauchoes, prisoners, who had not been concerned in the murders, and whom they threatened to kill, if he, Channon, did not return. He also stated that one of them was willing to turn king's evidence, and would bring back all the horses, if possible, provided Captain Seymour would ensure his pardon. The whole of them, nine in number, retreated into the interior as soon as they found out it was a ship of war, taking all the tame horses, between fifty and sixty.* As his party were not armed, Captain Seymour thought it right to return on board; but after dark, Lieutenant Smith was sent with a party of marines, and two boats, to try and take them, if they should be still about the houses, and to leave with Channon a bottle containing a crucifix, as a signal for Luna.† On their landing, Lieutenant Smith took all necessary precautions, left six men in charge of the boats, and proceeded cautiously with the

* Thirteen men and three women had escaped to an island in the Sound, as they could do nothing against the murderers, who had all the arms.

† The gaucho who offered to become king's evidence.

© The Complete Work of Charles Darwin Online

rest. He carefully searched every building in the place, without seeing even a trace of them. All was desolation; yet he learned afterwards from the two innocent gauchoes, that Antonio Rivero and another, suspecting who the party were, had watched them closely: that at one time Lieut. Smith was near treading on them; which seemed hardly credible, until the arrangements made on landing, the marching in Indian file to hide his men, &c. were mentioned. Mr. Smith left with Channon Luna's pardon, who, on the fourth day, brought in two horses—not having been able to obtain more, as the murderers were very watchful and fearful of each other, so much so, that one of them had fallen a sacrifice to suspicion; and Luna's desertion reduced their number to six. With Luna for their guide, on the sixth day Lieut. Smith, four midshipmen and twelve marines, were despatched into the interior. They were absent four days, and marched more than a hundred miles, enduring much fatigue, which was increased by the boisterous state of the weather, and by continual rain for three out of the four days. Water in ravines, which on going out hardly rose above their ankles, on their return had increased to torrents: in crossing them some nearly lost their lives, and on the bleak moors they sunk at every step knee-deep in bog. Without sleep or shelter, they lived for the last two days on beef just warmed through, by fires that it took hours to kindle. They were not successful in capturing any of the murderers, but at one time were so near, that they had the mortification to see them drive their horses away at a gallop, and having all the tame ones but two, they were quickly out of reach of musket-shot. So hasty however was their retreat, that they left their provisions behind them. Captain Seymour finding that capturing the Indians would be a tedious and uncertain task, made one of the ruined houses habitable, and leaving six marines as an additional protection to Lieut. Smith and his boat's crew, proceeded as ordered. The lieutenant endeavoured to make his abode comfortable, by clearing away rubbish and bones, and putting a garden into some order. With the two horses he succeeded in catching and taming two cows,

© The Complete Work of Charles Darwin Online

which gave about two gallons of milk daily, besides fourteen others, five or six of which were in calf. By one means or other all but one of the murderers were taken, and a cutter was hired to remove them to the flag-ship at Rio de Janeiro."

Before the Beagle's arrival Lieut. Smith had succeeded in capturing the principal murderer, and transporting him to an islet in the Sound, where he was watched, and furnished with provisions by the boat's crew. The lieutenant applied to me for assistance, and knowing that he was not safe while such a desperate character as Rivero was at large, though on an islet, and that the life of Luna (the king's evidence) was still more risked, I took those men, and one named Channon, who was said to have been an accomplice in the plot, though not an active agent, on board the Beagle. Rivero was put in irons, Channon confined to the ship, and Luna left at liberty, though watched.

When Mr. Low returned from his sealing expedition he found that his life was sought, as a friend of Mr. Brisbane; and as he could do nothing on foot against the mounted gauchoes, he retired to Kidney Islet, at the entrance of Berkeley Sound, to await the arrival of some ship. Tired, however, of inaction, he set out to go westward, in search of some whaler, and on the 6th of February, when in great distress, he fell in with our tender, the Adventure, and immediately offered his services as a pilot: they were accepted, provisionally, by Lieut. Wickham, and afterwards by me, trusting that the Admiralty would approve of my so engaging a person who, in pilotage and general information about the Falklands, Tierra del Fuego, Patagonia, and the Galapagos Islands, could afford us more information than any other individual, without exception.

Mr. William Low is the son of a respectable land-agent in Scotland; he was brought up as a sailor, and possesses strong common sense, quick apprehension, a readiness at description, and an extraordinary local memory.

On the 13th the Adventure arrived: she had almost completed her examination of the west, south, and south-east outer coasts, in a very satisfactory manner, having been greatly forwarded

© The Complete Work of Charles Darwin Online

and helped by Mr. Low's minute acquaintance with every port, and almost every danger. Our tender sailed to continue her coasting examination on the 21st. She returned on the 26th, and sailed again on the 30th. Meanwhile our own boats were constantly occupied in and near Berkeley Sound and Port William.

When I visited the settlement it looked more melancholy than ever; and at two hundred yards' distance from the house in which he had lived, I found, to my horror, the feet of poor Brisbane protruding above the ground. So shallow was his grave that dogs had disturbed his mortal remains, and had fed upon the corpse. This was the fate of an honest, industrious, and most faithful man: of a man who feared no danger, and despised hardships. He was murdered by villains, because he defended the property of his friend; he was mangled by them to satisfy their hellish spite; dragged by a lasso, at a horse's heels, away from the houses, and left to be eaten by dogs.

Besides my own acquaintance with him and opinions derived from the personal knowledge of the Beagle's officers, some of whom had known Brisbane when his vessel, the Saxe Cobourg, was wrecked in Fury Harbour (owing to no fault of his), Mr. Weddell bears testimony to his character on many occasions, particularly by an observation in page 48 (Weddell's Voyage), where he says, "I had full confidence in the care and ability of Mr. Brisbane." (1823.)

In 1830 Mr. Brisbane was wrecked on the eastern coast of Tierra del Fuego, near Policarpo Cove, (54° 38′ S.), when sealing there in partnership with Mr. Bray, who afterwards commanded the sealing schooner 'Transport,' lost in 1833, at Hope Harbour. I have a copy of their log in my possession, from which the following extracts are selected, to show with what enduring patience some of those hardy sealers bear misfortune and distress.

"Feb. 23d. Employed saving things from the wreck: six Indians came to us. 24th. Twenty-five Indians came, with their women and children. 25th. Another visit from natives: men, women, and children. 26th. Indians began to be very trou-

© The Complete Work of Charles Darwin Online

blesome. 27th. Forty Indians came to us, all armed with bows, arrows, and slings, without women or children. Some of our people employed in building a shallop out of the wreck. 28th. More Indians, with twelve strong women and eighteen children: but unarmed on this day.

"March 1st. More Indian visitors. 2d. Fifty-one natives, armed." To the 9th the crew continued to build their shallop, and were almost daily visited by natives, whom two-thirds of the party were obliged to watch with arms in their hands. On the 21st sixty-one natives visited them (these Indians always went away before dusk). On the 23d the time of high-water was observed to be 4^h. 40^m, and the rise seventeen feet, during moderate westerly wind and settled weather. Mr. Brisbane made the latitude, by observation, 54° 38′ S. and the longitude he estimated at 65°. 30′. W. "29th. Much troubled every day by natives, who tried to steal our tools; and hard pressed by hunger. No supper(*a*) the last three days.

"2d April. Four long guns were found to the eastward, lying on a piece of the forecastle of some large ship, supposed to be a large frigate(*b*), also two leaden hawse pipes attached to the woodwork. 8th. A large party of Indians, who were plaguing us, quarrelled among themselves, and had a severe fight. 9th. Our last remainder of provisions finished. 15th. Employed caulking the shallop's deck, and getting limpets from the rocks. N. B. Almost starving. 17th. Not being troubled to-day by natives, and the sea being smooth, went out in a little boat which we had saved, and caught eleven skate."

After this day several fish were caught at times, which, with shell-fish, afforded a scanty subsistence; but before this time they had been reduced to eating hide, and half putrid blubber, which they got by barter from the Indians. Mr. Bray, as well as Brisbane, told me that hunger and anxiety so wore and excited them, that they could seldom sleep more than an hour

(*a*) Supper was their principal meal; as during the day, while the Indians were about, they had no time to cook or eat. R. F.

(*b*) Perhaps the O'Higgins—(Chilian). R. F.

© The Complete Work of Charles Darwin Online

or two at night, though working all day, while they were so hard pressed for food.

"22d. Launched the shallop, or rather, hauled her down at low water, and let her float. 24th. Indians more troublesome than ever; obliged to fire at them repeatedly. 27th. Almost starved, eating bullock's hide. 30th. Nothing to eat but bullock's hide and berries. Could not get the shallop over the reef because of a heavy surf.

"May 1st. Got out to sea; found the shallop leak very much: nothing to eat but hide. 2d. Lat. 54°. 00′. Long. east. 63°. 50′. 5th. Made Cape Meredith (in the Falklands), but could not get near for want of wind. 6th. Two men gave out (*c*) for want of food: they had gone six days with but one pound of hide. 7th. A heavy gale; the shallop under bare poles, and almost sinking; sea making a clear breach over her; men quite worn out by constant pumping and baling, and by want of food: we had a very hard job to keep her from sinking: at dusk saw land through the rain and spray, half a mile to leeward; showed the head of the jib, and bore away right before the wind for the nearest part: saw a cove, ran into it, and anchored. Killed numbers of geese; thanked God for our safety. 11th. Many of our men ill from the sudden change. 17th. Went ashore in Pleasant Harbour; saw a great number of cattle; the dog caught two of them, and held them for us to kill.(*d*) 30th of May. Anchored in Port Louis, landed, and hauled the shallop ashore at high-water."

The vessel in which Brisbane and Bray were wrecked, was driven ashore in a northerly gale, while sealing near Policarpo Cove. Their crew consisted of about twenty men, most of whom had fire-arms, and plenty of ammunition. Though it will swell yet more the catalogue of his disasters, I must add that Brisbane was once wrecked on South Georgia, and escaped thence to Monte Video in a shallop, which he and his companions in distress built out of the wreck of their sealing vessel.

(*c*) Could work no longer. R. F.

(*d*) Seized them by the lip. He was a large, strong animal, between a bull-dog and a mastiff. R. F.

© The Complete Work of Charles Darwin Online

I have now by me two of the tools, almost the only ones, which they had to use: one is a cooper's adze, nearly worn down to the middle; and the other a saw, made out of a piece of iron hoop, fixed to a wooden frame.

6th April. While the Beagle was preparing for sea the body of Lieut. Clive,* late of H. M. S. Challenger, was found lying at high-water mark, in an unfrequented part of Berkeley Sound; and the following morning I buried it in a grave on shore, not far from the tomb of our regretted shipmate Hellyer. After noon, on the same day, we sailed from the Falklands, depressed more than ever by the numerous sad associations connected with their name.

* Lieut. Clive was drowned accidentally, by the upsetting of a small boat:—his body could not then be found.

CHAPTER XVI.

Soundings—Anchor in Santa Cruz—Lay Beagle ashore for repair—Prepare to ascend River—Set out—View of surrounding country—Rapid stream—Cold—Ostriches—Guanacoes—Indians—Fish—Cliffs—Firewood—Lava Cliffs—Difficulties—Chalia—See Andes—Farthest West—View round—Return—Danger—Guanaco hunters—Puma—Cat—Tides—Sail from Santa Cruz.

In working to the westward from Berkeley Sound to the River Santa Cruz, we sounded frequently, and found that the depth is nowhere much above one hundred fathoms between those places. But the water is not of so little depth between the Falklands and Cape Virgins, or Tierra del Fuego; for there we could not strike soundings in some places, towards the islands, with one hundred and fifty fathoms of line.

On the 13th we anchored in the Santa Cruz, and immediately prepared to lay our vessel ashore for a tide, to ascertain how much injury had been caused by the rock at Port Desire, and to examine the copper previous to her employment in the Pacific Ocean, where worms soon eat their way through unprotected planks. (16th.) When on the beach, at a place we afterwards called 'Keel Point,' it was found that a piece of the false keel under the 'fore-foot,' had been knocked off, and that a few sheets of copper were a good deal rubbed. By Mr. May's exertions all was repaired in one tide; and the following day we were making preparations for an excursion up the river.

17th. An examination, or rather a partial exploring, of the River Santa Cruz had long been meditated. During the former voyage of the Beagle, Captain Stokes had ascended the rapid current as far as a heavy boat could be taken; but his account served only to stimulate our curiosity, and decided my following his example.

Three light boats were prepared (whale-boats strengthened): as much provision as they could stow with safety was put into them, and a party of officers and men selected. Lieut. Sulivan,

having to take charge of the ship during our absence, could not go; neither could Mr. Stewart, or Mr. King, who were required to attend to duties on board; but Mr. Darwin, Mr. Chaffers, Mr. Stokes, Mr. Bynoe, Mr. Mellersh, Mr. Martens, and eighteen seamen and marines prepared to accompany me.

Early on the 18th we left the Beagle, and with a favouring wind and flood tide sailed up the estuary, into which the river flows. This wide and turbid estuary receives a torrent which rushes through a confined opening into the ocean, during seven hours, and is opposed and driven back by the flood tide during about five hours of the twelve. On each side of both the estuary and river lie extensive plains of arid desert land: these plains are not, however, on the same level; for, on the northern bank the land is very little raised above the level of high spring tides; while, on the southern side of the river, high, perpendicular cliffs form a striking contrast: but after ascending these heights, by any of the ravines which intersect them, one finds a dead level expanse, similar in every respect to that on the northern shore. In the horizon, another 'steppe,' or parallel plain, at a higher elevation, is seen; which, at a distance, appears like a range of hills of equal height.

Excepting in the porphyry districts, all the eastern coasts of Patagonia, and the little of the interior which I have seen, seemed to me to be a similar succession of horizontal ranges of level land varying in height, intersected here and there by ravines and water-courses. There are, certainly, hills in many places which appear when one is passing at sea, or in the distance, conical, or at all events peaked; but even those hills are but the gable ends, as it were, of narrow horizontal ridges of land, higher than the surrounding country.

The cliffs on the south side of the river have a whitish appearance; and are similar to those on the outer coast, which were said by Sir John Narborough to resemble the coast of Kent. Their upper outline, when seen from a distance, is quite horizontal. Brownish yellow is the prevailing colour, lighter or darker, as the sun shines more, or becomes obscured. Here and there, in hollow places and ravines, a

© The Complete Work of Charles Darwin Online

few shrubby bushes are seen. But over the wide desolation of the stony barren waste not a tree—not even a solitary 'ombu'*—can be discerned. Scattered herds of ever-wary guanacoes, startled at man's approach, neighing, stamping, and tossing their elegant heads; a few ostriches striding along in the distant horizon, and here and there a solitary condor soaring in the sky, are the only objects which attract the eye. Certainly, upon looking closely, some withered shrubs and a yellow kind of herbage may be discerned; and, in walking, thorns and prickles assure one painfully that the plain is not actually a desert: but I am quite sure that the general impression upon the mind is that of utter hopeless sterility. Is it not remarkable that water-worn shingle stones, and diluvial accumulations, compose the greater portion of these plains? On how vast a scale, and of what duration must have been the action of those waters which smoothed the shingle stones now buried in the deserts of Patagonia.

Fresh water is seldom found in these wastes; salinas† are numerous. The climate is delightful to the bodily sensations; but for productions of the earth, it is almost as bad as any, except that of the Arabian, or African deserts. Rain is seldom known during three quarters of the year; and even in the three winter months, when it may be expected, but little falls excepting on rare occasions, when it comes down heavily for two or three days in succession. Sea winds sometimes bring small misty rain for a few hours, at any time of year, but not enough to do good to vegetable productions. The only animals which abound are guanacoes, and they care little for fresh water, for they have often been seen drinking at the salinas. The puma probably quenches its thirst in their blood; of other animals, supposed to require much liquid, there are none in these regions.

The climate is healthy and pleasant; generally a bright, sunny day is succeeded by a cloudless and extremely clear night. In

summer the heat is scorching, but not sultry; and in winter, though the weather is sometimes searchingly cold, especially during southerly winds, the air is always elastic and wholesome. Changes of wind are sudden, and cause rapid, though not very great, variations of temperature. Sometimes the sky is slightly or partially overcast, occasionally clouded heavily; but on most days there is bright sunshine, and a fresh or strong westerly wind.

The confluence of a continental torrent of fresh water, with great tides of the ocean, which here rise forty feet perpendicularly, has embarrassed the mouth of the Santa Cruz with a number of banks. They are all composed of shingle and mud, and alter their forms and positions when affected by river-floods, or by the heavy seas caused by south-east gales.

Into the entrance of the Santa Cruz, the flood-tide sets about four knots an hour; one may say, from two to five knots, according to the time of tide, and the narrower or broader part of the opening; and outwards, the water rushes at least six knots on an average in mid-channel. There are places in which at times, when acted upon by wind or unusual floods, it runs with a velocity of not less than seven or eight knots an hour—perhaps even more; but near either shore, and in bights between projecting points, of course the strength of the outward as well as inward current is very inferior.

In such a bight, almost under some high cliffs on the southern shore, the Beagle was moored, and it is easy to conceive the different views presented in this situation, with forty feet change in the level of the water. At high water, a noble river, unimpeded, moves quietly, or is scarcely in motion: at other times, a rushing torrent struggles amongst numerous banks, whose dark colour and dismal appearance add to the effect of the turbid yellow water, and naked-looking, black, muddy shores.

The boats sailed on between some of the banks, with a fresh southerly wind, disturbing every where immense flights of sea-birds. Now and then a monstrous sea-lion lifted his unwieldy bulk a few inches from the stony bank, lazily looked

© The Complete Work of Charles Darwin Online

around, and with a snort and a growl, threw his huge shapelessness, by a floundering waddle, towards the nearest water.

As far as Weddell's Bluff* we sailed merrily; but there took to the oars, because the river makes a sudden turn, or rather, the river Santa Cruz (properly so called), enters the estuary of the same name from the south-west, as far as can be seen from Weddell's Bluff:—but a little beyond where the eye reaches, it takes a westerly direction. Another river, the Chico of Viedma, also enters the estuary at this place from the north-west. Here, a little above the Bluff, the water was fresh on the surface, and sometimes it is quite fresh, even into the estuary; but in filling casks, or dipping any thing into the stream for fresh water, it is advisable not to dip deep, or to let the hose (if one is used), go many inches below the surface, since it often happens that the upper water is quite fresh, while that underneath is salt. This occurs, more or less, in all rivers which empty themselves into the sea: the fresh water, specifically lighter, is always uppermost.

Wind failing us entirely, we pulled to the south-west. On our left, high cliffs still continued, and at their base a wide shingle beach offered tempting landing-places, with many spots extremely well adapted for laying a vessel ashore, to be repaired or cleaned; on our right, a low shore extended, rising gradually, however, in the north-west, † to cliffs like those near Keel Point.

The flowing tide favoured us until about five, when we landed on the north shore, at a spot where the rise and fall of the tide had diminished to four feet. Here the river was six hundred and forty yards in breadth, running down at the rate of about six knots during a part of the ebb, and from two to four knots an hour during the greater part of the flood-tide. It was perfectly fresh to the bottom, and in mid-channel about three fathoms deep; but this depth extended very little way

* Named after the enterprizing southern navigator.

† On the south side of the north-west arm of the Santa Cruz.

© The Complete Work of Charles Darwin Online

across, the deep channel being extremely narrow, not more than twenty yards in width.

The distinct difference between the opposite banks of the river had been diminishing, until at this spot* both sides were much alike. We had left the cliffs and salt water, and had fairly entered the fresh-water river. Instead of having a wide extent of dismal-looking banks and dark-coloured muddy shores, we were at the side of a rapid stream, unvarying in width, on whose banks shrubs and grass agreeably relieved our eyes from muddy shingle covered with hosts of crabs.

Our first night passed well, for there were plenty of bushes to supply us with fire-wood. Early next morning, some of the party went upon the nearest hills to look for guanacoes, when they saw that although the surface of the country appeared to an observer near the river to be irregular and hilly, upon ascending the heights it became apparent that the stream ran in a large valley; that the general character of the country was similar to what I have already described, and that those which had appeared to be hills were the terminating sides of extensive plains, whose level was about three hundred feet above the river. Near the fresh water, shrubs, bushes, and grass were not scarce; but every where on the higher ground a sterile, stony waste met the eye. Mr. Stokes† and I went on the heights, to obtain a view of the river; and for a considerable distance we could trace its windings, but were sorry to see a great number of small islands, thickly covered with brushwood, which seemed likely to impede our progress if obliged to track‡ the boats.

The southerly wind blew keenly over the high land, and the surface of the ground was frozen hard; but the air was healthily fresh and bracing. Where, indeed, could it be purer than on these dry hills? At first setting out we tried the oars, but very soon found them unable to contend with the

† It was his office to make a map of the country we passed through.

‡ Pull, or tow them along by a rope.

© The Complete Work of Charles Darwin Online

strength of the stream; so landing all our party, except two in each boat, we made the boats fast to one another, at a few yards apart, in a line a-head: and then taking the end of a coil of whale-line ashore, half our party fixed themselves to it by laniards of broad canvas straps, which passed across their breasts and over one shoulder, and walked together steadily along the river's bank. The bight of the line was passed round a stout mast, stepped in the headmost boat and attended by the two men, who veered away or shortened in the line as the varying width of the stream, or frequent impediments rendered necessary. In this manner, one-half of our party relieving the other about once an hour, every one willingly taking his turn at the track rope,* we made steady progress against the stream of the river, which rather increased in rapidity as we ascended, until its usual velocity was between six and seven knots an hour. While among the islands which I mentioned tracking was difficult and tedious, many were the thorny bushes through which one half of the party on the rope dragged their companions. Once in motion no mercy was shewn: if the leading man could pass, all the rest were bound to follow. Many were the duckings, and not trifling the wear and tear of clothes, shoes, and skin. At intervals stoppages were made for refreshment and observations.

Three chronometers were carried in the boats, with other necessary instruments: among them two mountain barometers, with which Mr. Darwin and myself wished to measure the height of the river above the level of the sea, and the heights of the neighbouring ranges of hills above the level of the river. This afternoon we picked up a boat-hook upon the south bank of the river, which was immediately recognized to be one which had been left by accident sticking in a mud-bank, by the party who accompanied Captain Stokes in his excursion up this river in the year 1827.

It was very cold at our bivouac this night, being a sharp

* Mr. Stokes alone being excepted, as his duty required continual attention.

© The Complete Work of Charles Darwin Online

frost: and while observing the moon's meridian altitude, dew was deposited so fast upon the roof of the artificial horizon, and froze there so quickly as it fell, that I could hardly make the observation. My sextant was injured a little by the frost, for not having been used before in very cold weather, the brass contracted so much as to injure the silvering at the back of the index glass, and slightly change the index error.

In the morning it was so cold that our usual ablutions were shunned, and all were anxious to have the first spell at the rope in order to warm themselves, though few had slept many minutes, and many had hard work the previous day. The thermometer was at 22° Fahr.—nothing,—indeed warm weather to Polar voyagers, but to us, accustomed to temperate climates, it appeared a severe degree of cold.

20th. As we were going along the bank of the river, which to our great benefit was becoming more accessible and clearer of bushes, we saw some dark coloured animals crossing the stream at a distance, but no one could guess what they were until the foremost of them reached the shore, and rising upon his stilt-like legs, showed himself to be an ostrich. Six or seven of these birds were swimming across: till then I had no idea that so long-legged a bird, not web-footed, would, of its own accord, take to the water and cross a rapid stream: this, however, was a certain proof to the contrary, for nothing had disturbed them that we could discern. As far as we could tell, at so great a distance, they seemed to be of the kind which the Spanish-patagonians call 'Avestruz-petis.' They were, however, far too wild to be approached with a gun. We saw smoke at a distance and anticipated meeting Indians, in the course of our next day's journey. The country around continued similar to that already described: but islands no longer impeded our progress, though some high cliffy banks gave us trouble. At the next place where we passed a night, Mr. Darwin tried to catch fish with a casting net, but without success; so strong a stream being much against successful fishing. A very sharp frost again this night. The net and other things, which

© The Complete Work of Charles Darwin Online

had occupied but little room in the boat, were frozen so hard as to become unmanageable and very difficult to stow.

21st. We proceeded as usual, dragging the boats up the stream (or rather torrent, for it never ran less than six knots, and in many places more) at the rate of about two miles an hour: and as we were approaching near to the smoke, we chose our position for the night, rather more cautiously than usual, upon a little peninsula.

22d. We had not advanced a mile this morning, when fresh tracks of Indians, on horseback, trailing their long lances, aroused our utmost vigilance. We thought they had been reconnoitring our party, at day-light, and perhaps such was the case. The smoke of their fires was seen behind the nearest range of low hills, on our side of the river, being then on the north bank, but the boats had been tracking on either side, as better ground for walking was found. Proceeding on, a dead animal was found in the water, which proved to be a guanaco; how it came by its death did not appear, as it showed no external wound, but some of our party, hungrier or less squeamish than the rest, immediately proposed dividing and eating it; and hunger carried the day: the dead animal was hauled on shore, cut to pieces, and distributed. The guanaco steaks were much relished by all except two or three, who could not conquer their antipathy to supposed carrion. Our meal was eaten close to the place where we thought a tribe of Indians was encamped: and, in consequence, our arms were kept in readiness, and a careful watch set. Afterwards cautiously proceeding, we arrived at the spot whence the smoke had issued, but saw no human beings: though marks of very recent fire, and numerous tracks of feet upon a soft muddy place at the side of the river, showed that a party of Indians had lately crossed over, and a smoke rising at some distance on the southern shore, pointed out where they were gone. At this spot there was about an acre of good pasture land, by the water side: and the breadth of the river itself was something less than usual, reasons which had induced the na-

© The Complete Work of Charles Darwin Online

tives to select it as a crossing place.* To pass a river running at the rate of six or seven miles an hour, and about two hundred yards in width, can be no easy task to women and children. But as we saw many prints of very small feet on the muddy bank, both women and children must have crossed at this place with the men. How did they get over? there is no wood, neither are there rushes with which they might make balsas.† Perhaps some of the women and children were put into rough, coracle-like boats, made of hides,‡ and towed across by the horses, holding by whose tails the men swam and perhaps many of the women. This method of holding by the tail, while swimming, is said to be better than resting a hand upon the horse's neck and holding by the mane. None of the Indians sit upon their horses while swimming.

This day (22d) we passed two places which we considered rapids, the stream of the river ran so violently, and we had so much difficulty in passing, even with all hands upon the rope. Besides the strength of the stream we had to contend against high cliffs, over whose upper edges it was difficult to convey the tow-line: yet we made good about twelve miles in the day. The night of the 22d was not so cold as the preceding, but we always found the nights wintry though the days were warm, so much so, indeed, that we were often annoyed by the heat of the sun. So winding was the course of the river that we certainly walked double the distance which was advanced in a direct line: yet very little of interest, as a picturesque subject, had been seen; for no country excepting a desert could wear a more triste and unvarying appearance.

Immense accumulations of shingle, rounded stones, imbedded, as before mentioned, in diluvial deposition, form the level plain, or valley, through which the river pursues its very winding course. The width of this vale varies from one mile to five miles, and the level of the shingle plain is from

© The Complete Work of Charles Darwin Online

three hundred to one thousand feet below that of the adjacent higher, but still horizontal ranges—whose broken-down ends, or sides, form the boundaries of the valley through which the river flows. Those of the higher ranges look like hills when one is in the valley, and it is not until after ascending to their summits that their real nature is seen; when, instead of being inclined to consider those heights as hills, one becomes disposed to think the valley of the river a vast excavation, cut down below the level of the neighbouring country. But on the height, or in the valley, all is an unprofitable waste. Scarcely, indeed, could we find bushes enough, even near the river, to make our nightly fires, after the third day's journey. The wiry, half-withered grass upon which the guanacoes feed is so scanty, that they are obliged to wander over much ground in search of their food. Those few stunted bushy trees which are found here and there, near the river, are a kind of thorn trees, the wood of which is extremely hard and durable.* The night of the 22d we passed by the side of a little cove, which sheltered the boats from the strength of the stream: and, as all hands were tired, we rested during the morning of the following day.

After noon (23d) we went on, and at dark stopped on the south shore. Scarcity of fuel and a cold night, made it necessary to take good care of the wood when cut. There may be honour among thieves, but there was little to be found during a cold night among our party, for the fire of those who happened to be on watch was sure to blaze cheerily, at the expense of the sleepers. A little incident occurred here very unimportant certainly to those unconcerned, yet of much consequence to us: we left our stock of salt behind, and a spade, which latter was much wanted for earthing up the sides of our tents, to keep out the cold wind.

24th. I noticed more than usual a curious effect of the river water being so much warmer than the air over it.† At

* A guanaco was shot this day by the running fire of several guns. He was soon cut up and stowed in the boats.

† The temperature of the air being 30°, that of the water 46°.

© The Complete Work of Charles Darwin Online

daybreak, and until after sunrise, the river was smoking, quite as if it were boiling. This day we passed some earthy cliffs between two and three hundred feet in height, and where they came in our way it was extremely difficult to manage the boats and tow-lines; but by veering out at those times a great length of rope, our object was accomplished without any disaster. Near these cliffs the valley of the river begins to contract and become more irregular, and the sides or breaking down of the higher ranges become more abrupt and are nearer to the river. In most places we found a cliffy side opposite to a low projecting point of shingle, but in some spots that we passed both sides were high, and we had no choice on which to take the tow-line. The difference, also, between the level of the higher ranges and that of the river, was observed to be much increased.

On this day (25th) our best shots succeeded in killing two guanacoes, but they died out of our reach, and probably became food for pumas, instead of man. The order of our march was usually one or two riflemen in advance, as scouts —Mr. Darwin, and occasionally Mr. Stokes, or Mr. Bynoe, upon the heights—a party walking along the banks, near the boats, ready to relieve or assist in tracking, and the eight or ten men who were dragging the three boats along at the rate of about two miles an hour over the ground, though full eight knots through the water. Difficult places to pass—delays caused by embarking and disembarking frequently to change banks, and avoid impediments—the necessary observations, rest, and meals, occupied so much time that we did not average more than twelve miles in one day: and even that small distance was not accomplished without making both shoulders and feet sore.

26th. In the distance some very level topped, dark looking cliffs, were seen at the summits of elevated ranges, which Mr. Darwin thought must have a capping or coating of lava. Of course we were very anxious to verify a fact so curious, and at noon were quite satisfied that it was so, having approached to the foot of a height thus capped, whose frag-

© The Complete Work of Charles Darwin Online

ments had in falling not only scattered themselves over the adjacent plain, but into the bed of the river, in such a manner as to make the passage exceedingly dangerous; because large angular masses, in some places showing above the stream in others hidden beneath, but so near the surface that the water eddied and swelled over them, menaced destruction to the boats as they were with difficulty dragged through the eddying rapid; sometimes the rope caught under or around one of those masses, and caused much trouble. Near the spot where we stopped at noon there is a glen, quite different in character from any place we had passed.* Indeed, upon entering the lava district, or that part of the country over which lava formerly flowed, there was no longer a Patagonian aspect around. Steep precipices, narrow, winding vallies, abundance of huge angular fragments of lava, a more rapid and narrower river, and plains of solid lava overlying the whole surface of the country, make this district even worse in its appearance than the eastern coast of Patagonia. Excepting in an occasional ravine nothing grows. Horses could not travel far, the ground being like rough iron; and water, excepting that of the river and its tributary in Basalt Glen, is very scarce.

The glen above mentioned is a wild looking ravine, bounded by black lava cliffs. A stream of excellent water winds through it amongst the long grass, and a kind of jungle at the bottom. Lions or rather pumas shelter in it, as the recently torn remains of guanacoes showed us. Condors inhabit the basaltic cliffs. Near the river some imperfect columns of basalt give to a remarkable rocky height, the semblance of an old castle. Altogether it is a scene of wild loneliness quite fit to be the breeding place of lions.†

No signs of human visitors were discovered: indeed, the nature of the country must almost prevent horsemen from traversing these regions, there is so little food and such bad ground: only in glens or ravines such as this can any grass or bushes be found. Guanacoes absolutely swarm upon the

heights, a consequence probably of their being undisturbed. They spread over the face of the high country like immense flocks of sheep.

During a long walk this evening Mr. Stokes and I were repeatedly disappointed by the mirage over an extensive stony plain, between two bends of the river. We were tired and very thirsty, and went from one apparent piece of water to another, only to be tantalized and to increase still more our dilemma.

27th. Similar country. On the banks of the river some drift wood was found; the trunks of trees of considerable size. Small trees had been found lying by the side of the river, from time to time, but none so large as these, some of which were almost two feet in diameter, and about thirty feet in length. The wood appeared to be 'Sauci,' of the red kind. That these trees had been drifted from a great distance was evident, because they were much water worn.

28th. In passing a rapid, whose difficulties were much increased by rugged blocks of lava lying in the bed of the river, one of our boats was badly stove and barely rescued from sinking in the middle of the stream: fortunately we got her on shore and there patched her up. There was still no change in the scenery, nor any signs of inhabitants: and our work was as monotonous as heavy.

29th. While upon a high range of lava-capped land, Mr. Stokes and Mr. Darwin descried distant mountains in the west, covered with snow. At last, then, the Andes were in sight! This was inspiriting intelligence to the whole party; for small had been our daily progress, though continual and severe the labour. The river increased in rapidity, while but little diminution had taken place in the quantity of water brought down: the breadth was rather less, certainly, but the depth in most places greater. No fish had yet been caught; indeed, only two had been seen, and those seemed to be like trout.

30th. The snowy summits of the distant Cordillera were more distinctly seen from the heights, near the river, that rise

© The Complete Work of Charles Darwin Online

about a thousand feet above its level, which, there, is about three hundred feet above that of the sea. Two guanacoes were shot with my rifle by H. Fuller,* who hastened to the boats for assistance. Some of our party went directly with him to bring in the animals, but condors and cara-caras† had eaten every morsel of the flesh of one; though the other was found untouched and brought to the boats. Four hours had sufficed to the cara-caras and condors for the cleaning of every bone.‡ When our party reached the spot some of those great birds were so heavily laden that they could hardly hop away from the place. The guanaco that was eaten by the birds must have been, by his size, at least fifty pounds heavier than any shot by us in Patagonia, therefore about 300lbs. Mr. Darwin and Mr. Stokes had much amusement with these animals, upon the heights. Being so much tamer there and more numerous, whole flocks were driven by them into narrow defiles, where dozens might have been killed had there been more people with guns, lassoes, or balls.

Though the bed of the river is there so much below the level of the stratum of lava,§ it still bears the appearance of having worn away its channel, by the continual action of running water. The surface of the lava may be considered as the natural level of the country, since, when upon it, a plain, which seems to the eye horizontal, extends in every direction. How wonderful must that immense volcanic action have been which spread liquid lava over the surface of such a vast tract of country. Did the lava flow from the Cordillera of the Andes, or was it thrown out from craters in the low country? Its position with respect to subaqueous deposits, its horizontal surface and cellular texture, are reasons, among others, for thinking that it was thrown out of the earth, while these plains were covered by a depth of sea.

The valley, or channel of the river, varies here from one mile, or less, to about three miles; but it looks narrower, owing

to the deception caused by high land on each side. Some of the views are certainly striking, and, from their locality, interesting; I could not, however, have believed that the banks of any large fresh water river could be so destitute of wood, or verdure of any kind, or so little frequented by man, beast,* bird, or fish.

May 1st. The weather was invariably fine during the earlier part of our journey; but this day it began to change, and two or three gloomy clouded days were succeeded by a few hours only of small rain, and by some strong wind. This night (1st) we slept at the foot of heights whose summits were covered with snow, but the temperature was many degrees warmer than that of the first nights, when it froze so sharply. There was no particular frost after the 21st of April.

We had great difficulty with the boats on the 2d, the river being contracted in width, without any diminution of the body of water pouring down.

On the 3d, we found a more open country, the lava-capped heights receding gradually on each side, leaving a vale of flat, and apparently good land, from five to fifteen miles in extent. The width of the river increased; on its banks were swampy spaces, covered with herbage; and low earthy cliffs, without either shingle or lava, in some places bounded the river. A little further, however, the usual arid and stony plains of Patagonia were again seen, extending from the banks of the river to ranges of hills, about fourteen hundred feet above its level, on which the horizontal lava-capping could be distinctly discerned.

In the distant west the Cordillera of the Andes stretched along the horizon. During three days, we had advanced towards those far distant mountains, seeing them at times very distinctly; yet this morning our distance seemed nearly as great as on the day we first saw their snow-covered summits. A long day's work carried us beyond the flat and into the rising country, whose barren appearance I just now mentioned.

* Excepting guanacoes.

© The Complete Work of Charles Darwin Online

We were all very tired of the monotonous scene, as well as of the labour of hauling the boats along.

4th. Our provisions being almost exhausted, and the river as large as it was beyond the lava country, our allotted time being out, and every one weary and foot-sore, I decided upon walking overland to the westward, as far as we could go in one day, and then setting out on our return to the Beagle. I was the more inclined to this step, because the river here made a southerly bend, to follow which would have required at least a day, without making much westing, and because I thought that some of our party might walk in that time at least twice as far as they could track the boats, and then return before night. To have followed the course of the river two days longer, we should have needed all the small remainder of our provisions, and probably without being enabled to see further than we might by one day's walk directly westward. Leaving those who were the most tired to take care of the boats, a party set out early, in light marching order. A large plain lay before us, over which shrubs, very small trees, and bushes were sparingly scattered; yet parts of this plain might be called fertile and woody, by comparison with the tracts between us and the eastern sea-coast.

At noon we halted on a rising ground, made observations for time, latitude, and bearing; rested and eat our meal; on a spot which we found to be only sixty miles from the nearest water of the Pacific Ocean. The Cordillera of the Andes extended along the western side of our view; the weather was very clear, enabling us to discern snow-covered mountains far in the north, and also a long way southward; hence much of the range was visible, but of the river we could discern nothing. Only from the form of the land could we conclude that at the end of the southerly reach I have mentioned, the direction of the river is nearly east and west for a few miles, and that then it may turn northward, or rather come from the north along the base of the Cordillera.

There are many reasons for inducing one to suppose that it comes not only from the north, but from a considerable dis-

tance northward. At the place where we ceased to ascend the stream, the Santa Cruz was almost as large as at the places where we passed the first and second nights near the estuary. The velocity of the current was still at least six knots an hour; though the depth remained undiminished. The temperature of the water was 45°, while that of the air was seldom so high, even in the day-time, and at night was usually below the freezing point. Trees, or rather the trunks of trees, were found lying upon the banks, whose water-worn appearance indicated that they had been carried far by the stream. The water was very free from sediment, though of a whitish blue colour, which induces me to suppose that it has been chiefly produced by melted snow, or that it has passed through lakes in which the sediment it might have brought so far was deposited. If filled from the waters of the nearer mountains only, its temperature would surely be lower, approaching that of melted snow: it would also, in all probability, bring much sediment, and would therefore be muddier, and less pure in colour.

When one considers how large an extent of country there is between the River Negro and the Strait of Magalhaens, and that through that extensive region only one river of magnitude flows, it may be difficult to account for the manner in which the drainage of the eastern side of the great Cordillera is carried off, or where the melted snow and occasional heavy rains disappear.

The Gallegos is small, though it runs into a large estuary. The Chupat river is very small: that at Port Desire is scarcely more than a brook. At times, it is true, these smaller rivers are flooded, but their floods (added to their usual streams) seem unequal to carrying off the continual drainage of the Andes. South of the Negro only the Santa Cruz flows with a full and strong stream throughout the whole year, and my idea is that the sources of the river Santa Cruz are not far from those of the southern branch of the Negro, near the forty-fifth degree of latitude; and that it runs at the foot of the Andes, southward, through several lakes, until it turns to the eastward in the parallel of fifty degrees.

© The Complete Work of Charles Darwin Online

In Viedma's Diary I find that he heard from the Indians at Port San Julian (in 1782) that the river Santa Cruz flowed from a large lake near the Cordillera of the Andes, and that there was abundance of wood on its banks. In consequence of this information, he went, in November, with a party of Spaniards and Indians on horseback, to explore this lake. In his way, Viedma crossed the river Chico, which flows into the estuary of the Santa Cruz, just above Weddell Bluff. The Chico, though small at times and then fordable, was subject, the Indians said, to great floods in the spring, when the melting snows of the Cordillera over-filled a lake, far in the north-west, whence this river ran. Afterwards, Viedma crossed the river Chalia, which they told him rose in another lake near the Cordillera, was likewise subject to floods, and emptied itself into the Santa Cruz: when he passed, it was only up to the horses' knees (after searching many leagues, however, for a ford), but at his return it was deeper. This Chalia can be no other than the stream which flows through Basalt Glen, a mere brook when we saw it in the dryest season of the year. Viedma reached the lake,* and found every thing correspond to the description; for it was deep and large, surrounded by snow-covered mountains, on which were many forests.

Some persons have doubted whether there is ever much drainage to be carried off from the eastern side of the Andes, between the parallels of forty and fifty; but if they will take the trouble to read Viedma's Diary, and some other notices to be found in the work of Don Pedro de Angelis, I think they will be convinced that there is always a considerable drainage, and that at times there are heavy floods to be carried off.†

* Called Capar, or Viedma. MS. Chart.

† As one proof of this assertion, I may quote a passage from Viedma:—"Reconocido pues todo" (all that there was to see in the neighbourhood of the lake whence the Santa Cruz flowed), "nos expusó el Indio Patricio nos debiamos apartar luego de aquí, porque con los vientos fuertes, y el sol, solia derretirse tanta nieve que era imposible vadear los arroyos para regresar, y tendriamos que pasar el verano en aquel pasage hasta que las heladas empezasen."—(Diario de Viedma, p. 57.)

© The Complete Work of Charles Darwin Online

Reference to the accompanying plan will shew our position when we halted, and I decided to return, not having explored, I should think, more than one-third of its course. At that place the level of the river was found to be four hundred feet higher than that of the sea at the entrance; and as the distance is about two hundred miles,* the average descent or fall of the water must be near two feet in a mile, which, I apprehend, is unusually great. I could not, indeed, believe that the computation and data were correct, until after repeated examination.† Two barometers were used at the river-side, and a very good one was carefully watched on board the Beagle.‡ Certainly, the rapid descent of the river, in many places, was such, that even to the eye it appeared to be running down-hill; and this remark was often made in the course of our journey.

Two days before we reached our westernmost point, many traces of an old Indian encampment were seen; but excepting at that place and at the spot which we passed on the 22d, no signs of inhabitants were any where found. Scarcity of pasture, and the badness of the ground for their horses' feet, must deter Indians from remaining in this neighbourhood; but that they frequently cross the river, when travelling, is well known.

The quantities of bones heaped together, or scattered near the river, in so many places which we passed, excited conjectures as to what had collected them. Do guanacoes approach the river to drink when they are dying? or are the bones remains of animals eaten by lions or by Indians? or are they washed together by floods? Certain it is they are remarkably numerous near the banks of the river; but not so elsewhere.

I can hardly think that the guanaco is often allowed to die a natural death; for pumas are always on the alert to seize invalid stragglers from the herd. At night the guanacoes choose the clearest places for sleeping, lying down together like sheep; and in the day they avoid thickets, and all such places as might

* Following the course of the river.

† The data will be found in the Appendix. ‡ At the level of the sea.

© The Complete Work of Charles Darwin Online

shelter their ever-watchful enemy. Condors, also, and fierce little wild cats* help to prevent too great an increase of this beautiful, inoffensive, and useful animal.

Late on the 4th we returned to our tents, thoroughly tired by a daily succession of hard work, and long walks. At this bivouac we were about one hundred and forty miles, in a straight line, from the estuary of Santa Cruz, or from Weddell Bluff; and about two hundred and forty-five miles distant by the course of the river. Our station at noon on the 4th, was eight miles in a straight line farther westward, and about thirty miles from the Cordillera of the Andes. The height of those mountains was from five to seven thousand feet above our level, by angular measurement with a theodolite. Early on the 5th we began the rapid descent. Sometimes the wind favoured, and we passed the land at the rate of ten knots an hour; sometimes dangerous places obliged us to turn the boat's head to the stream, pull against it, and so drop down between the rocks. Though easy, the return was far more dangerous than our ascent of the river.

5th. Our first day's work in returning was a distance of eighty-five miles, which had cost us six days hard labour in ascending. Next day we made good about eighty-two miles; and on the 7th we reached the salt water. Although we made such quick progress in returning, our halts for observations were similar to those made in going. While descending the rapid stream, so quickly and quietly, we saw many more guanacoes and ostriches than we had seen before; but our flying shots only frightened them, and time was too precious to admit of any delay. Only one fish was got, and that was a dead one, which had been left on the bank: it was similar to a trout. Not more than half a dozen live fish were seen, and none could be caught either with hooks or nets. Leaving a very small party near Weddell Bluff to look for guanacoes, I hastened on board with the boats; and with the ebb tide reached the Beagle before noon on the 8th. The ship being ready for sea, except-

* Though the wild cat could not injure a full-grown animal, it might destroy a young one with great ease.

© The Complete Work of Charles Darwin Online

ing a ton or two of fresh water, the yawl and cutter were dispatched to get it and bring on board the shooting party. During my absence satisfactory observations on the tides had been made, which showed that the neap tides rise about eighteen feet, and the springs from thirty-eight to forty-two feet. One day when walking through a woody ravine, not far from the anchorage, Mr. Stewart saw a puma lying under a bush, glaring at him: taking a steady aim, he fired, and laid the animal dead. It was a very large one; and the skin is now in the British Museum. The moment of thus looking a lion in the face, while taking aim, at only a few yards distance, must be somewhat trying to the nerves, I should imagine. A beautiful wild cat was also added to our collections, besides condors and foxes.

9th. The boats, and shooting party, arrived with water and two guanacoes. As the sportsmen were returning with their burthens on the preceding evening, darkness overtook them while yet distant from their tent; and they were soon made uncomfortably* conscious that an enemy was at hand, for the strong and peculiar smell of a lion warned them that one was near. They trudged on with their cargoes, talking to one another; but the scent was still strong until they approached the fire, which had been kept up by their companion, when it ceased entirely. Such a weight as a lion's, added suddenly to that of a guanaco, would have been rather distressing.

We were detained for a day or two by an overcast sky, which prevented my obtaining equal altitudes; but on the 12th the Beagle left the Santa Cruz, and stood towards the alleged place of the shoal, or rock, called 'Aigle,' not far from the westernmost of the Falkland Islands. No such danger, nor any sign of shallow water being found, but, on the contrary, no bottom with one hundred fathoms of line, we steered towards Magalhaens Strait, and on the 18th anchored off Cape Virgins. Next morning I landed on the Cape, taking Mr. Darwin and Mr. Stokes with me, and remained till after the noon observation, when, returning on board, the Beagle weighed and sailed to another station. From this time (till the 25th) we were busily em-

* Being only two in number.

© The Complete Work of Charles Darwin Online

ployed in sounding in the neighbourhood of Cape Virgins, Point Catherine, Lomas Bay, and Possession Bay.

On the 23d, at day-light, we saw the Adventure coming from the Falklands. After communicating with us, she went on to survey the portion of coast extending from Sweepstakes Foreland to Cape Monmouth; and we remained to complete our own task of sounding the banks about the First Narrow, and examining the south shore of St. Philip Bay. On the 3d of June both vessels were moored in Port Famine, preparing for their passage to San Carlos in Chiloe.

The next chapter will take the Beagle into the Pacific by a route not hitherto used, except by sealing vessels: although it possesses many advantages over either the passage round Cape Horn, or that through the western reaches of the Strait of Magalhaens. Mr. Low is said to be the first discoverer of it, and he certainly was the first to pass through in a ship; but I think one of the Saxe Cobourg's boats had passed through it previously, and I much question whether Sir Francis Drake's shallop did not go by that opening into the Strait of Magalhaens in 1578.*

Before I finally leave Tierra del Fuego, a remark or two may here be made respecting the language of the natives. 'Pichi,' in the Huilliche or Araucanian language, means 'small' or 'a little,' and 're' signifies 'only,' 'but,' 'purely,' or 'simply.' Hence, Pecheray, always uttered in a begging, or whining tone, may have some such signification. In Beauchesne's voyage it is said, that the natives in the Eastern parts of Magalhaens Strait were called 'Laguedi-che,' and those westward, 'Haveguedi-che.'† These words are to me very interesting, because I suppose the first to be a corruption of Laque-che, which means, in Araucanian, 'People with balls' (bolas), and the second is not far removed from Huapi-gulu-che, which means 'people of mountainous islands heaped together,' terms respectively most appropriate for natives of eastern and western Tierra del Fuego.

---

* See Burney, vol. i. p. 368 and p. 327, where he shows that Drake discovered Cape Horn, and anchored near it (in or near St. Martin Cove?) in 1578. Another early southern discovery is mentioned in vol. ii. p. 198, where it is stated that Dirck Gherritz discovered land in 64°. S. in 1599, (part of or near South Shetland?)

CHAPTER XVII.

Beagle and Adventure sail from Port Famine through Magdalen and Cockburn Channel — Enter Pacific—Death of Mr. Rowlett—Chilóe —Chile—Government—Adventure sold—Consequent changes—Plans —Mr. Low—Chonos—Lieut. Sulivan's party—Moraleda—Ladrilleros — De Vea — Sharp—San Andres—Vallenar—Mr. Stokes—San Estevan — Distressed sailors — Anna Pink Bay — Port Low—Potatoes— Indian names — Huafo — Volcano—Chilotes—Aborigines—Militia— Freebooters — Climate — Docks—Tides—Witchcraft — Alerse—Calbucanos—Cesares—Search for men—Meteors.

June 9th. Good equal altitudes having been obtained, after an interval of time sufficient for rating our chronometers,* we sailed from Port Famine, went down the Magdalen Channel, enjoying some fine scenery, among which Sarmiento was pre-eminent, and anchored in a cove under Cape Turn. The following day we beat to windward through the Cockburn Channel, and would have anchored at night had a safe place offered in time, but as the only cove near us at dusk was a very small one, I preferred leaving that unoccupied for the Adventure, and remaining under way in the Beagle. The night was long and very dark, small rain fell nearly all the time, and squalls from the westward were frequent. There were but four square miles in which it was safe to sail to and fro after dark, and for fourteen hours we traversed that area in every direction. It was necessary to keep under a reasonable press of sail part of the time, to hold our ground against the lee tide; but with the ebb we had often to bear up and run to leeward, when we got too near the islets westward of us. In a case of this kind a ship is so much more manageable while going through the water than she is while hove-to, and those on board are in general so much more on the alert than when the vessel herself seems half asleep, that I have always been an advocate for short tacks under manageable sail, so as to keep as much as possible near the same place, in preference to heaving-to and drifting.

* The Adventure had four chronometers.

© The Complete Work of Charles Darwin Online

When the day at last broke on the 11th, we saw the Adventure coming out to us from the cove where she had passed the night, and then both vessels sailed out of the Channel, past Mount Skyring and all the Furies, as fast as sails could urge them. At sunset we were near the Tower Rocks,* and with a fresh north-west wind stood out into the Pacific, with every inch of canvas set which we could carry.

On the 26th we were still together, in latitude 43° and longitude 75°, although gales had occasionally separated us for a few hours. After passing the latitude of 45° we had a succession of bad weather, and adverse (N.W.) winds. Trusting too much to our usual good fortune I had steered in too direct a line towards Chilóe, and in consequence all these north-west winds were against us. Had I shaped a course which would have taken us farther from the land, while we had the wind southward of west, we might have made a fair wind of these provoking north-westers, and arrived at Chilóe at least a week sooner. A few remarks upon the wind and weather, between the parallels of forty and forty-seven, off Chilóe and the Chonos Archipelago, will be found in the Appendix (No. 19).

On the 27th we witnessed the last moments of Mr. Rowlett's existence in this world. He had long been sinking under an internal complaint of which it was impossible to cure him, except by a vigorous and uniform mode of treatment to which he was not willing to conform until too late: but his illness had no relation whatever to the service in which he had been employed. He was much regretted by all of us, having been a kind, honourable friend. The following day we committed the body of our deceased companion to the seaman's grave, that "ever-changing and mysterious main." In the evening we were near the north-west end of Chilóe, and at midnight an anchor was let go in our former berth, off Point Arena. The Adventure arrived two days afterwards, her main-boom having broken in a heavy squall on the 27th, in consequence of which she got to leeward, and was prevented from sooner weathering the north end of the island. A supply of fresh provisions

* Not far from Cape Noir, on Noir Island.

and good rates for the chronometers were obtained, after which we sailed (14th July) for Valparaiso, and arrived there together on the 22d.

My first object would have been, after seeing the vessels securely moored, to go to Santiago, present my instructions in the proper quarter, and ask for the sanction of the Chilian government, in prosecuting the survey of the coasts of Chile; but I was so much in arrear with respect to computations and charts, that I could not venture to give even a week to an excursion to that agreeable place, where a thousand attractive novelties would inevitably have diverted my attention in some measure from the dull routine of calculation, and attention to the data accumulated by many months' exertion of those on board the Adventure, as well as in the Beagle; therefore I sent Lieutenant Wickham, who spoke Spanish, and had been at Santiago before, to show my instructions to the Authorities, and request their approval of our examination of the shores under their jurisdiction. Nothing could be more satisfactory than the reply (Appendix No. 20), and from that time until the Beagle left Chile she received every attention and assistance which the Chilian officers could afford.

As I proposed to remain at Valparaiso during the winter months, Messrs. Stokes, King, Usborne, and myself, whose occupation would be sedentary and would require room, as well as more light and quiet than we could always have on board, took up our quarters on shore; while those on board attended to the refit and provisioning of our vessels.

At this time I was made to feel and endure a bitter disappointment; the mortification it caused preyed deeply, and the regret is still vivid. I found that it would be impossible for me to maintain the Adventure much longer: my own means had been taxed, even to involving myself in difficulties, and as the Lords Commissioners of the Admiralty did not think it proper to give me any assistance, I saw that all my cherished hopes of examining many groups of islands in the Pacific, besides making a complete survey of the Chilian and Peruvian shores, must utterly fail. I had asked to be

© The Complete Work of Charles Darwin Online

allowed to bear twenty additional seamen on the Beagle's books, whose pay and provisions would then be provided by Government, being willing to defray every other expense myself; but even this was refused. As soon as my mind was made up, after a most painful struggle, I discharged the Adventure's crew, took the officers back to the Beagle, and sold the vessel.*

Early in November our charts of the eastern coasts of Patagonia and Tierra del Fuego, as well as those of the Falkland Islands (the work of the Adventure) were finished, and shipped off for England; and on the 10th we sailed, alone, to resume our more active occupations on the southern coasts. My former intention was to have filled up all blanks in the charts of the outer west coast of Patagonia, between the parallels of fifty-three and forty-eight, and then carried a connected survey along the coast to the equator; after which the Galapagos Islands; Dangerous Archipelago; Marquesas, Society, Friendly, and Feejee Islands; besides New Zealand; were to have had as earnest an examination as could be effected by both vessels during 1836 and part of 1837. That this plan might have been carried out by the divisions of labour and exertions of the Beagle and her tender may, I think, be inferred from what has actually been executed with inferior means and in much less time. But my reduced arrangements were on a much smaller scale: I could only look to the most useful objects that might be effected within the limited time to which I dared to look forward.

All on board partook, more or less, of the mortification caused by parting with our consort, just as she was most wanted, and most able to take an effective part; and I confess that my own feelings and health were so much altered in consequence—so deprived of their former elasticity and soundness—that I could myself no longer bear the thoughts of such a prolonged separation from my country, as I had encouraged others to think

* Though her sale was very ill-managed, partly owing to my being dispirited and careless, she brought 7,500 dollars, nearly £1,400, and is now (1838) trading on that coast, in sound condition.

© The Complete Work of Charles Darwin Online

lightly of, while I could hold out to them the prospect of seeing as well as doing a great deal among the islands of the Pacific, besides completing the surveys of Chile and Peru.

I now proposed, first, to go to San Carlos, there set two of our boats at work among the islands eastward of the large island, while the Beagle would survey the more exposed coasts, those to the west and south; then the ship was to examine the seaward shores of the Chonos archipelago, while another of her boats was employed among those islands; and, the Chonos explored, she would return to San Carlos, collect her scattered parties, and proceed along the coast, northwards, taking all the ports and islands in her way.

On the 21st we arrived at San Carlos, and were pleased to find that Mr. Low had returned safe from his difficult undertaking; and that a person (Mr. Douglas) whom I had engaged to make an excursion to Calbuco and into the forests of 'Alerse,' on the Cordillera of the Andes, had also come back with the required information, and was ready to engage himself to act as a pilot and interpreter.

When last at San Carlos I proposed to Mr. Low, then serving as pilot on board the Adventure, to pass the time of our absence at Valparaiso, in exploring part of the Chonos Archipelago with a whale-boat belonging to me, and a crew of natives (Chilotes). Low, ever restless and enterprising, entered eagerly into my views; so furnishing him with money, a chart, and a few instruments, I explained where I wished him to go, and when he should be again at San Carlos, all further arrangement being left to him.

Mr. Low hired a crew of six men,* and set out. After he had quitted the southernmost place at which provisions could be procured, called Caylin, or 'El fin de la Christiandad,' one of his men† persuaded some of the others‡ to eat up the stock

* A Welshman, two Chilotes, a Chilian, and two Sandwich Islanders who had been left at San Carlos by a whaler. † The Chilian.

‡ The Chilotes and Sandwich Islanders. Taffy remained faithful: he and Low, being able-bodied active men, frightened the rest into reluctant submission.

© The Complete Work of Charles Darwin Online

of provisions in the boat as soon as possible, in order that they might be obliged to return without going far. But Low was too much inured to hardship to be so easily diverted from his plan; he went on, directly south, even after his provisions were consumed; obliging them to live for fourteen days upon shell-fish and sea-weed. After exploring much of the Chonos Archipelago, sufficiently to facilitate our survey materially, he returned with his hungry crew to Caylin.

24th. Lieutenant Sulivan set out with the yawl and a whale-boat, to survey the east side of Chiloé and the islets in the Gulf of Ancud.* With him were Messrs. Darwin, Usborne, Stewart and Kent; Douglas as a pilot, and ten men. Two days afterwards, the Beagle sailed, to examine the western coast of Chiloé, and the Chonos Archipelago.

Dec. 2d. While standing towards distant mountainous land, about the latitude of 45°, we saw a comparatively low and level island;† considerably detached from those which seemed like Tierra del Fuego, being a range of irregular mountains and hills, forming apparently a continuous coast. This level island I have since ascertained to be that formerly called Nuestra Señora del Socorro, where Narborough anchored and landed, in 1670. It was selected in 1740, by Anson, as a rendezvous for his squadron; but no one seemed to know where to look for it: the Anna Pink having made the land in 45°. 35′, and the unfortunate Wager in 47°, near Cape Tres Montes. Narborough mentions seeing 'an old Indian hut' on this island; and in a MS. journal, written by Moraleda‡ (now in my possession) it is said that the former natives of the Chonos used to make annual excursions to that as well as other outlying islands. After witnessing the distance to which savages venture in such frail canoes as those of Tierra del Fuego, it does not surprise one to find them going fifteen or twenty miles across an open

* Orders in Appendix, No. 21.

† About three or four hundred feet in height, excepting one hill, which is seven hundred feet.

‡ MS. Diary of Moraleda's examination of Chiloé and part of the Chonos Islands in 1787-93, given to me at Lima, by a friend to whom I am much indebted for valuable information.

© The Complete Work of Charles Darwin Online

space of sea in such large canoes as those of the Chonos Indians, which are indeed boats. Fuegian wigwams have been found upon Staten Land and upon Noir Island, each of which is as far from any neighbouring coast as Socorro is from the nearest shore.

While Narborough's ship was under sail, near Socorro, he went in his boat to the island which is nearest to it, by him named Narborough Island.* There he landed, and took possession for his Majesty and his heirs.†

3d. Having passed the night quietly at single anchor, near the north-east point of Socorro, we weighed and continued our route to and fro along the coast, taking angles, soundings, and observations. On the 5th, we were near Huafo,‡ which, to our surprise, we found to be twenty-five miles farther north than the Spanish charts (following Moraleda) showed its position, yet the longitude was almost correct. In a small cove, near the south-east point of Huafo, we anchored, but broke a bower-anchor in doing so; for the cove is small—an unexpected puff of wind gave us too much way—and dropping the bower in haste, it fell upon a rock, and broke.§ Only two days before another anchor was broken, near Socorro, by the ship pitching while a short scope of cable was out, and the anchor hooking to a rock. I found, on landing, that the formation of the island, like that of Socorro and Narborough Island, is a soft sandstone, which can be cut with a knife as easily as a cake of chocolate.

* "Neither the chart in Ulloa, nor any of the Spanish charts lately in use, show the name of N.S. del Socorro to any island near the coast hereabouts. The Spanish Atlas of 1798, places an island very near the coast, in 44° 50′ S. latitude, which in shape and situation answers nearly to Narborough's description of the island, to which he gave his own name."—(Burney, vol. iii. p. 360. Note.)

† "I saw no kind of mineral in it. Not finding this island noted in any draught (chart), I called it after my own name, Narbrough Island, and took possession of it for his Majesty and his heirs."—(Narborough's Voyage to Patagonia and Chile, in 1669-1671.)

‡ Called by Narborough "No-man's Island."

§ Or between two rocks, so that the first sudden strain snapped the shank.

© The Complete Work of Charles Darwin Online

These three outlying islands are thickly wooded, rather level, compared with their neighbours, and not exceeding eight hundred feet in height. There are few, if any others, like them in the Chonos Archipelago; almost all the rest, however portions of some may resemble them, being mountainous, and very like those of Tierra del Fuego and the west coast of Patagonia, beyond 47° south; therefore I need only remark, that the vegetation is more luxuriant; that there is a slight difference in it, consequent probably upon a milder climate; that some productions, such as canes and potatoes, &c., are found there which do not grow near the Strait of Magalhaens; and that in other respects, as to appearance, nature, and climate, the Chonos Archipelago is like Tierra del Fuego in summer.

We remained a few days in San Pedro harbour; and on the 9th Mr. Sulivan and his party joined us. Next day Mr. Stokes and I endeavoured to get to the top of the mountain named Huampelen, Huamblin, or San Pedro; but after climbing, creeping, struggling, and tumbling about, among old decayed trees, strongly interwoven canes, steep, slippery places, and treacherous bog, we failed, and gave up the attempt. Mr. Darwin, Douglas, and others were with me, but we were all foiled.

11th. Having despatched Mr. Sulivan, with the same party excepting Mr. Darwin, we got under weigh, and hastened towards the middle of the Chonos group, in order to find a port whence Mr. Stokes might set out to explore northwards, while I should examine the southern half of the archipelago.

13th. We succeeded in finding a sheltered, and apparently safe anchorage in a road named by me Vallenar, because it corresponded in situation to an island so called in an old chart, said to be of the Chonos, but which bore no resemblance whatever to them. However, being anxious to remove no "neighbour's landmark," and retain original names, when they could be ascertained, I kept them wherever I was able to do so. As to the native names, those given by Indians, I had not the means of finding them out, for no inhabitants were seen; but, so far as Moraleda had collected them from his Indian inter-

© The Complete Work of Charles Darwin Online

preters, and made them known by his chart,* I have scrupulously followed him.†

16th. Mr. Stokes set out, in a whale-boat, to work northwards, as near the sea-coast as possible, and meet me at a harbour in the Huaytecas group of islands, now called Port Low. He was accompanied by Mr. Low, Mr. May,‡ and four men.§ Moraleda, in his diary and chart, describes a channel which crosses the Chonos Archipelago, and is called by the natives 'Ninualac.'‖ Through this passage the Chonos Indians used to go once or twice a year to inspect the small herds of goats, or flocks of sheep which they then had upon those outlying islands I have already mentioned, namely Huamblin¶ (Socorro), and Ipun (Narborough); as well as upon others, of which I believe Lemu, a woody island on the north side of Vallenar Road, was one. Moraleda himself explored part of the continent, and some of the islands adjacent to it (between 1786 and 1796), but he saw nothing of the sea face of the Chonos. What few notices of it existed, prior to 1834, were obtained from the voyage of Ladrilleros in 1557; from the Anna Pink in 1741; from Machado in 1769; and from the Santa Barbara in 1792; which, when compared together, tended to confuse a hydrographer more than they assisted him. In Spanish charts of the coast from Cape Tres Montes northward to Taitaohaohuon (a name long enough to perplex more verbose men than sailors) from which all others, of that coast, were copied, that portion must have been originally laid down according to mag-

* Now in my possession.

† His Huamblin and Ipun I take to be Socorro and Narborough Islands, but am not certain.

‡ Having very little occupation on board, in his own particular line, just at that time, Mr. May volunteered to take an oar, as one of the boat's crew.

§ Orders in Appendix, No. 22.

‖ "Gran Canal de Ninualac, que atraviese el Archipiélago, por el informe del practico Huenupal que casi anualmente la transita con el motivo expresado en el Diario."—(Moraleda's MS. Chart, 1795.)

¶ Huamblin, if, as I suppose it, a corruption of Huampelen, means 'on watch,' 'posted as a sentinel:' Ipun means 'swept off,' or 'swept away:' Lemu means 'wood:' names singularly applicable to each of those islands respectively.

© The Complete Work of Charles Darwin Online

netic, instead of true bearing; and the fragments of knowledge acquired, about the latitude of 46° S., from the master of the Anna Pink, the pilot Machado, and the officers of the Santa Barbara frigate, clashed so much that their result was what we see in the charts hitherto used, a dotted line, and a few straggling islands, totally unlike the truth, leading one to expect a comparatively open space, whereas there is a succession of high and considerable islands, so near one another, that from the offing they 'make' like a solid unbroken coast.

While on this subject I may remind the reader that besides the expeditions above-mentioned, the missionary voyages described by Agüeros (Appendix, No. 23), the important undertaking of Sarmiento, and the disastrous voyage of the Wager, there have been other visitors to the west coast of Patagonia, part of whose acquired information, though slight, is upon record.

In 1552, two ships, commanded by Don Francisco de Ulloa, were sent by Valdivia to gain some knowledge of the Strait of Magalhaens.* The journal of their voyage is not extant. Five years afterwards (in 1557), Don Garcia Hurtado, Viceroy of Peru, sent two vessels to examine the southern part of the coast of Chile, as far as the Strait of Magalhaens. The commander was Juan Ladrilleros, and with him were two pilots, named Hernan Gallego and Pedro Gallego. A mutiny took place, and one ship deserted, but with the other Ladrilleros persevered, passed four months in the Strait at anchor during the winter, then reconnoitred the eastern entrance, and afterwards sailed back to Chile, where he at last arrived with only one seaman and a negro, the rest of his people having perished by exposure to hardships, by scurvy, or by famine. The principal geographical information obtained at so high a price, was some slight knowledge of Chiloé, and the archipelago of islands near it.—(Burney, vol. i. p. 246-9.)

Sarmiento's expedition in 1579-1580, has already been often quoted in the first volume of this narrative.

In 1675 Antonio de Vea was sent from Peru in a ship,

* Pastene, a Genoese, was, I believe, in this expedition. His MS. Journal is said to exist in the archives of Barcelona.

© The Complete Work of Charles Darwin Online

accompanied by small barks, as tenders, to reconnoitre the Gulf of Trinidad, and the western entrance of Magalhaens Strait. De Vea made an examination of those places, and was convinced, from the poverty of the land, that no settlement of Europeans could be maintained there. One of the Spanish barks, with a crew of sixteen men, was wrecked on the small islands called Evangelists, at the west entrance of the Strait. De Vea returned to Callao in 1767.—(Burney, iv. 76.)

In 1681, the notorious Sharp anchored in a gulf, surrounded by craggy mountains, whose tops were covered with snow, in 50°. 40′. south latitude; where "the difference of the rise and fall of the tide was seven feet perpendicular." Sharp named the anchorage Shergall's Harbour, the sound he called English Gulf; and the islands adjacent "Duke of York's Islands." The account of this buccaneer's visit is sufficiently connected with the object of this volume, to warrant my inserting it in the Appendix, copied verbatim from that interesting work, invaluable to seamen and hydrographers, Burney's History of the Discoveries in the South Sea.*

18th Dec. The Beagle weighed and sailed out of Vallenar Road, after experiencing the shelter afforded by that anchorage, during a heavy gale from the south-west and southward.

At day-light on the 20th we were off Cape Tres Montes: having a fine day and smooth water, we surveyed the coast between that promontory and San Andres Bay, but it became dark before an anchorage could be gained. Next morning we anchored in a narrow creek,† close by a singular cone (1,300 feet high), an unfailing landmark. Finding it a place difficult to get out of, and not to be recommended, unless in distress, we did not stay there long, but moved to a cove at the south-west part of the bay.‡ While under sail for this purpose, advan-

* In this extract from Burney (Appendix No. 23), there is a criticism upon a hydrographical error, made by some copyist, which is interesting to me from its correspondence with what I suspect to have taken place in the old charts of Nassau Bay and Cape Horn.—(See pages 122, 123.)

† Cone Creek.

‡ Christmas Cove.

tage was taken of an interval of moderate weather to run several miles along the coast northward, and back again. Strong gales set in afterwards and kept us prisoners several days. This Christmas was unlike the last: it was a sombre period. The wind blew heavily (though we did not feel it much, being well sheltered); all looked dismal around us; our prospects for the future were sadly altered; and our immediate task was the survey of another Tierra del Fuego, a place swampy with rain, tormented by storms, without the interest even of population: for hitherto we had neither found traces,* nor heard the voices of natives.

28th. Directly the weather would admit, we weighed and coasted along till the sun was getting low, when we ran under shelter from sea and wind, and anchored in the corner of a bay which I afterwards concluded must be the bay or port called Stephens, and more properly, San Estevan. While we were furling sails, some men were seen on a point of land near the ship, making signals to us in a very earnest manner. Being dressed as sailors, it was natural for us to conclude that they were some boat's crew left there to collect sealskins. A boat was sent to them, and directly she touched the land they rushed into her, without saying a word, as men would if pursued by a dreaded enemy; and not till they were afloat could they compose themselves enough to tell their story. They were North American sailors, who had deserted from the Frances Henrietta (a whaler of New Bedford), in October 1833. When off Cape Tres Montes, but out of sight of land, and in the middle of the night, these six men lowered a boat and left their ship, intending to coast along until they should arrive at Chiloé. Their first landing was effected on the 18th, but owing to negligence the boat was so badly stove that they could not repair her, and all their hopes of effecting a coasting voyage were thus crushed in the very outset.

* With one exception. On a height near Cone Creek Mr. Darwin found, in a sheltered hollow of the rock, strewed with dry grass, what appeared to him the place on which a man had slept. For some time this puzzled us considerably: probably a sealer had slept there.

© The Complete Work of Charles Darwin Online

Finding it impossible to penetrate far into the country, on account of its ruggedness, and thick forests, which, though only trifling in height, were almost impervious, they began a pilgrimage along-shore; but it was soon evident, to their dismay, that there were so many arms of the sea to pass round, and it was so difficult to walk, or rather climb, along the rocky shores, that they must abandon that idea also, and remain stationary. To this decision they were perhaps more inclined after the death of one of their number; who, in trying to cross a chasm between two cliffs, failed in his leap, fell, and was dashed to pieces. Their permanent abode was then taken up at the point which shelters Port San Estevan, now called Rescue Point; where they passed a year in anxious hope. Of course the few provisions which their boat had carried ashore were soon exhausted, and for thirteen months they had lived only upon seals' flesh, shell-fish, and wild celery: yet those five men, when received on board the Beagle, were in better condition, as to healthy fleshiness, colour, and actual health, than any five individuals belonging to our ship. Few remarks worth noticing had been made by them, as the only experienced man (whose name was John Lawson) lost his life as above-mentioned. There was an almost continual succession of rain and wind for several months after their first landing, except from the 20th to the 29th of December, which passed without rain: in July (1834) they had an extraordinary storm from south-west, which began early one morning, after a rainy night with northerly wind: and in November (1834) there were twenty-one days successively without rain. One day (in May) they saw eight vessels sailing northwards together; excepting which, not a sail was ever seen by their aching eyes till the Beagle hove in sight. Between San Andres, near which they first landed, and San Estevan, the hull of a small vessel was found, quite bedded in sand; she seemed to be about thirty-five tons burthen, from thirty to thirty-five feet in the keel, and about sixteen broad. She was full-built; neither coppered nor sheathed. In a cave, which had been used as a dwelling, near San Andres, the skull of a man was found, and some burned wood. A bracelet of

© The Complete Work of Charles Darwin Online

beads was lying in the cave, but they noticed nothing else. The skull seemed to them to have been that of a black man. No animals were seen at any time except deer and nutria, seal and otter; the former were of a reddish colour, with short straight horns, and very rough coats: no traces of other quadrupeds were observed, nor during the whole fourteen months did they ever meet a native human being. They told me that the night tides seemed always to be a foot or more higher than those of the day, which, as they said, rose from four to seven or eight feet perpendicularly. I had intended to explore the interior of Port San Estevan; but as they had already done so, and found it terminate in a fresh water river, or rather mountain stream, I gave up that plan, and sailed next day.

29th. While examining the coast towards Cape Taytao* (I must omit haohuon), we found a very dangerous patch of rocks,† five miles from the nearest land; there are soundings near them. In the evening we dropped our anchor under Inche-mo Island; an interesting locality, because there the Anna Pink anchored before she was drifted across the adjacent bay into Port Refuge (in 1741).

30th. On landing an old wooden hut was discovered in a sheltered corner, and we found that the island was over-run with goats, which I suppose to have been left by the Santa Barbara's crew, if not by Machado's people. While Mr. Stokes and I were engaged with the instruments, and two boats sounding, a couple of guns were sent against the goats, and in consequence of their effectual employment in the hands of Mr. Bynoe and H. Fuller, all on board had a good fresh meal the next two days. After noon we sailed across the Bay,‡ and found a snug, though very small cove,§ where we moored in security, and remained till the 4th of January, exploring the neighbourhood—an unprofitable wilderness of rocky mountains, woody and swampy valleys, islands and rocks in pro-

* Cape Taytao is a high bold promontory.
† Hellyer Rocks.
‡ Now called Anna Pink Bay.
§ Patch Cove.

© The Complete Work of Charles Darwin Online

fusion, and inlets or arms of the sea penetrating in every direction.

On the 4th we moved to Port Refuge, a safe, but out of the way place. In the "narrative of what befel the Anna Pink," given in Anson's Voyage, this harbour is described in very glowing colours; but we may remember that those who discovered it, were there saved from destruction; and naturally looked upon all things around them with excited feelings.* How the officers of the Santa Barbara made their survey of this port and its neighbourhood I am at a loss to know; a mere eye-sketch, drawn upon the spot, might have been much better than that which they gave to the world as a mathematical plan. In their distorted representation of Port Refuge, many soundings have been scattered, apparently at random, and quite at variance with truth. This is so unlike most Spanish works of a similar nature, some of which are very accurate,† considering the date of their manufacture, and the means employed,—that I conclude the officers of that frigate, not understanding marine surveying, merely drew rough sketches of what they saw, which were afterwards 'cooked' into a more regular 'appearance,' by some one who was not on board with them. Had time allowed I should have explored the Gulf of San Rafael, at the back of Tres Montes Peninsula,‡ but knowing that it could only be an object of geographical, not immediately practical interest to do so, I refrained from indulging mere curiosity, much as I desired to corroborate the account of Spanish missionaries who often went there, crossing the Isthmus of Ofqui, in search of Indians among the Guaianeco islands, and even farther south, of whom they might make converts to Christianity. Doubtless some of these voyages were undertaken and completed with benevolent and single-minded intentions; but I suspect that others were conducted on a different principle; and that their chief object was to procure able-bodied slaves to be employed in the mines of

‡ Appendix, No. 24.

© The Complete Work of Charles Darwin Online

Chiloé or Southern Chile. I should be glad to learn that this suspicion is ill-founded.*

On the 7th we anchored in Port Low, and found Mr. Stokes just arrived, after a fagging cruise among the Chonos islands. His journal contains a great deal of information, from which I have extracted those passages most likely to interest the general reader.

His whale-boat was so loaded at starting (16th Dec.) that her gunwale amidships was but a foot above water. She was twenty-five feet long and six feet broad, and then carried seven men, besides instruments and a month's provisions. Of water she had only two 'barecas,' because on that coast fresh water is only too plentiful. In passing a promontory, the following day, while their boat was still deep, the swell became so great that Mr. Low said he had never before been in a boat exposed to greater danger.

In some places where they landed the woods were so thick that Mr. Stokes was obliged to climb trees to get angles; and not being able to tell previously which would answer his purpose, sometimes he made three or four useless ascents, before he could obtain a view: "but," he says "there is a pleasure I cannot express in roaming over places never visited by civilized man." On Rowlett Island potatoes were found growing wild; the largest dug up measured two inches in length, and an inch in thickness: they were quite tasteless.

At the east side of Ipun, on Narborough Island, an excellent small port was found, which was named Scotchwell Harbour. On the shore, near it, was a large bed of strawberries, like those that grow in English woods; and there was a sweet-scented pea, besides abundance of other vegetable produce, both herbage and wood, and plenty of water.

"Hitherto, all the islands we had seen were of slate-rock, some parts so soft, that I could break them easily with my finger, and I found that they blacked my hand, like plumbago;

* It is difficult to account for the present abandoned state of these regions, if no harsh usage was experienced by their former natives.

© The Complete Work of Charles Darwin Online

but Ipun is quite different in structure, being an earthy sandstone."*

Syzygial high water at Ipun takes place at noon, and the tide rises six or eight feet. The flood-tide comes from the southward.

At May Harbour (which may be the Bello Dique of the Santa Barbara), many cypress trees were noticed, for the first time hereabouts, and a surprising number of otters. The tide rose seven feet. About the Huaytecas Islands, the northernmost of the Archipelago, quantities of excellent oysters were found, quite as good as any sold in London. No quadrupeds were seen, except nutria and otters, which were numerous. Their numbers, and the quantity of birds, show that Indians do not now frequent that quarter; indeed, no traces of them whatever were found by Mr. Stokes, or any of our party, among the Chonos islands.

10th. While lying at Port Low we caught plenty of fish with the seine; we obtained oysters from neighbouring creeks, and shot ducks and geese, so there was no want of fresh provision. Some piraguas from Chiloé were in the port: the Chilotes in them were in search of otters, seals, and nutria, and had come across the gulf of Huafo, in their ill-conditioned vessels, with no little trepidation.

On an outlying islet, near Port Low, I first saw the wild potato. Next to seeing a wild man, I recollect few objects which struck me much more than that group of wild potatoes:—but I have neither inclination nor space here to speak of my own sensations. The stems, leaves, and flowers of these vegetables were as large, and appeared to be as healthy, as those in an English garden, but the potatoes at their roots were small, watery, and insipid. It ought to be recollected, however, that we saw them early in January—corresponding to July—many weeks, at least, before one could expect to find eatable potatoes in an English field.

It was remarked in the Chonos islands, as well as in Tierra del Fuego, that the trees which grow in thin soil, lying upon

* Stokes, MS.

© The Complete Work of Charles Darwin Online

slaty rocks, extend their roots so horizontally that it is not surprising to find, running through woodland, broad tracts whence the shallow-rooted trees have been swept away, partly by wind, partly by the action of mountain-torrents.* As wood grows even at the water's edge in those countries, where not exposed to the first attack of wind from seaward, and as there are so many loose overhanging masses of rock, one cannot be surprised at the vast quantities of drift-wood found in some places; or think it improbable for a quadruped to be occasionally precipitated into the sea, with a falling mass of rocks and trees, and afterwards drifted by wind and current to some other locality.

From Port Low we saw a notable mountain, one of the Cordillera of the Andes, having three points upon a small flat top, about eight thousand feet above the sea. I called it the Trident at that time; but afterwards learned that there are four peaks (one of which was hid by another from our point of view), and that it is called by the aborigines Meli-moyu, which in the Huilli-che language signifies four points.

Three other remarkable mountains, active volcanoes, are visible from the northern Huaytecas islands, as well as from Chiloé; I mean the Corcobado (hump-backed), of which I do not remember the Indian name; Yanteles (or Yanchiñu, which

* The writer of Anson's voyage, speaking of Juan Fernandez, exactly describes the loose state of trees in such places, when he says, "The northern part of this island is composed of high, craggy hills, many of them inaccessible, though generally covered with trees. The soil of this part is loose and shallow, so that very large trees on the hills soon perish for want of root, and are then easily overturned, which occasioned the death of one of our sailors; who being upon the hills, in search of goats, caught hold of a tree upon a declivity, to assist him in his ascent, and this giving way, he immediately rolled down the hill; and though in his fall he fastened on another tree of considerable bulk, yet that, too, gave way, and he fell among the rocks, and was dashed to pieces. Mr. Brett likewise met with an accident, only by resting his back against a tree, near as large about as himself, which stood on a slope; for the tree giving way, he fell to a considerable distance, though without receiving any injury."—(Anson's Voyage, 8vo. edit., p. 159.)

© The Complete Work of Charles Darwin Online

means 'having a shivering, and unnatural heat'), and Minchen-madom, which, in the Huilli-che tongue, means 'under a fire-brand'; names so expressive and appropriate as to put to shame much of our own nomenclature. Wherever I have been able to discover the aboriginal name of a place in South America, and could ascertain its meaning, I have been struck by the extreme appositeness, as well as by the copious though condensed allusion usually conveyed.

In Chiloé and about the north-eastern Chonos Islands, almost all the aboriginal names are preserved, because there interpreters could be procured; but, of course, such advantages were generally unattainable in Patagonia and Tierra del Fuego. In Chiloé, as in Araucania, every corner and every conspicuous spot, whether land or water, has a particular and expressive name, a word usually compounded of two or three others: thus, Huapi-quilan means Three Islands: Calbu-co, Blue Water; Cauca-huapi, Gull Island; Huechu-cucuy, Point Cucuy,* or Grandmother; Carel-mapu (Cara-el-mapu), Bad-city-country; Petu-cura, middle stone (a rock in Chacao Narrow), &c.

15th. We sailed from Port Low and went to Huafo once more, wishing to give Mr. Darwin an opportunity of examining it geologically. There are now no inhabitants on that island, though there are a good many sheep belonging to Chilotes, who live at Caylin. Formerly there were Indians called Huyhuen-che,† upon Huafo; but the Spaniards obliged them to quit it, for fear they should give information or supplies to English ships. Near the Beagle, when at anchor, there was a square place, like an entrance to some cave, seemingly cut by man in the soft sand-stone rock; and I have since often reproached myself for having left the place without ascertaining

* Cucuy is the name of a bird, much noticed by the aborigines because its motions are supposed to be ominous: it also means grandmother.

† The Huyhuen-che, often called Huyhuenes, were a tribe of Chonos Indians, adjoining the Pichi-huilli-che, who lived in the northern portion of Chiloé. The word Huyhuen signifies 'whistle,' or 'hiss,' or 'to whistle, or hiss.'

© The Complete Work of Charles Darwin Online

its real nature. It may be the entrance to some cave, formerly used as a burying-place, similar to those explored by Low, and by the surgeon of the Wager.

On the 17th we sailed, and next day anchored off Point Arena, in San Carlos Harbour. Lieutenant Sulivan, with his party, had arrived a few days previously, after a very satisfactory cruise. We found his boats hauled up and refitted, his people lodged under their tents, and himself with Mr. Usborne busily occupied in my little observatory, laying down the work for which they had collected materials. Thus we were again assembled in safety, after being considerably divided, and, in consequence, exposed to numerous dangers which human prudence can neither foresee nor prevent. As some soundings were still wanted near the English bank, and about the approach to San Carlos, we employed the 19th in taking them, on board the Beagle, accompanied by her boats, and returned to our usual anchorage, close to Point Arena, at dark.

When sounding on the English bank, we repeatedly tried to ascertain its nature by forcing a very long iron lance downwards as far as possible. The instrument penetrated about two feet into sand in all instances but one, when it was stopped abruptly by a substance which bent the lance and turned its point. It did not, however, feel like rock, rather, I should say, like hard wood.* This hard place was about a square yard in extent, and all around was sand.

In the night, or rather from two to three the following morning, Osorno was observed in eruption, throwing up brilliant jets of flame or ignited matter, high into the darkness, while lava flowed down its steep sides in torrents, which from our distance (seventy-three miles) looked merely like red lines. Daybreak diminished the effect, and as the light increased only a dark column of smoke could be discerned. This mountain is one of the most striking in form which I ever saw. It is not only quite conical from the base to the summit, but it is so sharply pointed that its appearance is very artificial. When seen

* Mr. Sulivan had the lance in his hand at that time.

© The Complete Work of Charles Darwin Online

from the sea, at a distance of ninety or a hundred miles, the whole of the cone, 6,000 feet in height* at least, and covered with snow, stands out in the boldest relief from among ranges of inferior mountains. The apex of this cone being very acute, and the cone itself regularly formed, it bears a resemblance to a gigantic glass-house; which similitude is increased not a little by the column of smoke so frequently seen ascending.

We remained till the 4th of February in the port of San Carlos. Mr. Darwin profited by the opportunity afforded to make an excursion into the interior of the island, while the surveying party were occupied in arranging data, in laying down chart-work, and in taking and calculating observations. I paid Douglas for his services and for a variety of information collected for me, from which—from Lieut. Sulivan's journal—and from my own notes—I shall now add such few notices of Chilóe as I think may be interesting, and which have not been already introduced in the first volume. (pp. 269—301.)

Various accounts have been given of the characters and dispositions of the Chilotes. Some have said that they are a noble, industrious, and docile race; others that they are dishonest, idle, and ill-disposed: to reconcile these contradictory accounts is, therefore, at first sight, rather perplexing. There are four distinct classes of inhabitants in Chilóe and the adjacent islands;† the aboriginal Huyhuen-che, or Chonos; the Huilli-che, who came from southern Chile; the foreigners, those neither born in Chilóe nor descended from Chilotes; and the Creoles. Of these the Chonos are now nearly lost: in consequence of disease and emigration they have by degrees abandoned not only Chilóe but the adjacent Chonos islands, and are only found southward. Some Indians to the south-west of Castro, in the interior of the island near the lake Cucao,

* The volcano of Osorno, or Purraraque, or Hueñauca, is 7,550 feet above the sea level.

† The smaller islands of the Archipelago of Chilóe, those in the gulf between Chilóe and the main-land, called the Gulf of Ancoed or Ancud.

© The Complete Work of Charles Darwin Online

are under the nominal jurisdiction of their own caciques: whether they are Chonos or Huilli-che, I did not ascertain clearly. Being a race who are naturally little inclined to cultivate the soil, and preferring a comparatively idle life among muscles, seal, and fish, to voluntary labour on their own account, with a considerable degree of compulsory toil for the Spanish Government and priests, they quitted Chiloe in successive families. From them, probably, are derived the glimmerings of religion, and the crosses among the Indians of Madre de Dios, and other parts of the west coast of Patagonia. That their canoes or rather piraguas, should be similar to those of Chiloe seems natural enough; but the fact is that the Chonos people taught the Huilli-che how to make them.* Coming from an inland district near Valdivia, the Huilli-che had never required boats, though they knew how to cultivate potatoes, maize, and beans; how to make 'ponchos,' and take care of sheep and cattle. These, though more industrious, and in some respects better members of society, are a tame and docile race compared with the Chonos, whose spirit of independence has shown itself in their migration, and impatience of mis-government.

The principal population of Chiloe is now Huilli-che, nominally Christian but painfully ignorant of pure Christianity. Abandoned to the crooked direction of ungodly pastors, intent upon their own worldly interest instead of the welfare of their flock, extorting 'primicias'† and tithes from poor Indians, whom they scarcely see once in a year (I speak advisedly)—and taught only the Romish doctrine in its worst form; can any one expect the poor Chilotes to be really religious and consequently moral? That they should be extremely superstitious is much more probable, and such is the fact. Their's is a confused demi-religion, in which a medley of ideas concerning the Virgin Mary, saints, images, and witches,‡ is found far

* These piraguas are extremely like the Madras surf-boats. (See vol. i. p. 285, for a description of the piragua.

† First fruits of everything, animal as well as vegetable.

‡ They are implicit believers in witchcraft.

© The Complete Work of Charles Darwin Online

more often than any clear reference to our Saviour or the Almighty.

In the foregoing remarks on the Roman Catholic priests at Chiloé whom I conversed with and heard much about between 1829 and 1835, I do not include all. There was certainly one man (I hope there were more) whom I believe to have been as sincerely pious, and therefore good, as any Roman Catholic, but there were others whose lives scandalized even their nominal Christianity.

The foreigners settled in Chiloé of course resemble their own countrymen as to morals and habits, not being likely to take example from the Indians: and the Creoles adopt their ideas as hastily as our milliners adopt French fashions. But there is a virtue in Chiloé, which if sins could be atoned for by the good works of man alone, would go far towards purchasing good treatment and very slight purgatory for the souls of Chilotes: I mean the warm-hearted kindness shewn to one another, and particularly to strangers. Conspicuous as such a feeling of hospitality and disinterested good-nature is among the descendants of Spaniards in South America, it is no where more to be observed than in Chiloé.

Increased intercourse with other countries is annually diminishing the local peculiarities of Chilote society, a remarkable one being that of transacting mercantile business by barter, for want of current coin. Planks of alerse, indigo, tobacco, pepper, salt, &c. were substitutes for silver and gold in 1829, excepting among a very few foreigners or comparatively rich descendants of Spaniards and Creoles. At that time it was extremely difficult to get a few dollars in exchange for a bill upon good security at Valparaiso, even at the exorbitant price of sixty-pence English for each dollar. In 1834, so much had the state of trade improved at San Carlos, that there was no difficulty in obtaining as many dollars as we wanted for forty-eight pence each.

In the first volume most of the products of Chiloé are mentioned, except fish and coal. Of the shell-fish there is a full

© The Complete Work of Charles Darwin Online

account, but I may here add that smelt, mullet, a kind of bass, and other fish are plentiful during the summer months. The natives often catch many more than they want by placing very simple weirs across creeks at high-water, with a passage in the middle, which is shut when the tide begins to ebb. Some of these weirs are rough stone walls (on a small scale), others are wattled like hurdles. The number of fish kept back by them and left dry, as the water falls, is really surprising. Seals are now rare, and whales are fast diminishing in numbers. There is a good deal of coal in Chiloé, but I am told that it is of an inferior description, like that of Concepcion. Geologists say it is not true coal: lignite would be a more appropriate term. Be this as it may I tried some of it* in my cabin stove, and found it burn readily, though what I had was a lump taken from the surface of the ground. The Chilotes scarcely noticed it then, having so much wood around them, but a day may arrive in which its value may be better appreciated.

Next to San Carlos,† in size and population, is Castro, the former seat of Government, which has dwindled to a mere village. Chacao, where the governor afterwards resided, is only a hamlet. Remains of a town, such as lines of streets and the ruins of a church, are visible, but there are now only a few straggling cottages and a ruinous chapel. It is said, on the spot, that the former church of Chacao was burned by the old Spaniards, to oblige the natives to quit the place and go to San Carlos. Castro, formerly styled a city, now consists of two or three short streets of bad wooden houses and two churches: one of which was built by the Jesuits more than a hundred years ago, and is fast decaying though 'shored up' (supported by props) on all sides.

The first discovery of Chiloé was made by Spaniards in 1558, one of whom was Ercilla. Enthusiastic in every thing, the warrior-poet tells us that he ran to a tree, half-a-mile south

* Obtained for me by Mr. Robert Williams from the neighbourhood of San Carlos.

† Described in vol. i. p. 274-5.

© The Complete Work of Charles Darwin Online

of the place where his companions halted, and cut some lines on the bark.*

The populous state of Chiloé, in 1558, when first visited by Europeans may be estimated by Ercilla's description, allowing for poetical license. All accounts agree in stating that the Chonos Indians, or Huyhuen-che, were once very numerous.

"Era un ancho archipielago poblado
De innumerables islas deleytosas,
Cruzando por el uno y otro lado
Góndolas y piraguas presurosas:
* * * * * *
Llegó una corva gondola ligera
De doce largos remos impelida."

LA ARAUCANA, Cantos xxxv and xxxvi.

That the Spaniards then with Ercilla, were thought to be deities, is shown by the following lines:—

"Hombres, o Dioses rústicos, nacidos
En estos sacros bosques y montañas,
Por celeste influencia producidos," &c.

IDEM, Canto xxxvi.

Some years afterwards (in 1566) Castro was founded, to be the capital, and Chacao for a sea-port. From this time till about 1633 mines were worked in Chiloé, but then discontinued, partly because they were less productive than those of Chile, and partly on account of the difficulty of obtaining labourers after a raging epidemic had carried off one-third of the aboriginal inhabitants; and fear of infection as well as horror of the mining slavery, had driven away a large portion of the residue.† About this time the Huilli-che were carried to

* "Aquí llegó, donde otro no ha llegado,
Don Alonso de Ercilla, que el primero
En un pequeño barco deslastrado
Con solos diez, pasó el desaguadero
El año de cincuenta y ocho entrado
Sobre mil y quinientos por Hebrero,
A las dos de la tarde el postrer dia,
Volviendo á la dexada compañia."

LA ARAUCANA, Canto xxxvi.

† These were Huyhuenes, or Chonos, whose place was afterwards supplied by Huilli-che from southern Chile.

© The Complete Work of Charles Darwin Online

Chilóe, in addition to those who had accompanied the fugitives from Osorno (in 1599—1604) to Calbuco, Carel-mapu, and thence to Chilóe; who being a docile patient race, accustomed to agriculture, increased rapidly and supplanted the Chonos emigrants.

We read in the narrative of Brouwer's voyage (1643) that the port which the Dutch called Brouwer's Haven, was by some called Chilova, and by others English Haven: and in 1624, according to Agüeros (quoting D. Cosme Bueno), Englishmen were on this coast: but I think it more probable that the Bank Ingles and Port Ingles, near San Carlos, obtained those names from William Adams, in 1599,* rather than from them. In the Dutch chart published with the journal, this island is called Chiloue, and the adjacent gulf, Ankaos, or Ancoed.† Brouwer alarmed the inhabitants of Chilóe not a little, but they were even more frightened and harassed before that time by Cordes, in 1600; Spilbergen, in 1615; and afterwards by Shelvocke, in 1719; besides others.

To guard against, or rather watch for such visitors, as well as to obtain the earliest intelligence of an enemy being on the coast, the Spaniards established look-out stations in com-

* Voyage of Five Ships of Rotterdam, Burney, vol. ii. p. 193. (supposing 46° should be 42° S.)

† I mention this to show that the accent, or stress, was then upon the second syllable of that name, not upon the third. The name Chilóe is derived from Chilue, or, more strictly speaking, from Chili-hue (see Agüeros and Molina), which means 'farther,' or 'new,' or 'the end of' Chili, and ought, by derivation, to have the accent, as Agüeros placed it, on the o. No reason can be given by a Spaniard for placing an accent on the final e of that word, yet it is almost generally placed there. My own idea is that the French traders to Chile in 1700—1780, first placed an accent on the e in writing, and that Feuillée, Frezier, and others have been followed without inquiry. Had not the stress been laid on the o, surely the natives of Chiloe would have been called Chiloetes, or Chiloenos, instead of Chilotes. As to the name Chile, every one knows it is derived from the Indian word Chili, (Herrera, Ovalle, Agüeros, Molina, &c.) but why it was altered by the Spaniards to Chile, I have never been able to discover.

manding positions and outer points, such as Cocotue heights, Guabun Head, and Point Centinela; but at the present time no such precautions being thought necessary, there is a supine indifference to molestation.

Wherever Mr. Sulivan went with our boats, nearly all the Indians showed an anxiety for the island to be again under the dominion of Old Spain, and asserted that they were much happier and more prosperous before the revolution than they had ever been since. In a place where he passed two days (Huildad) there was an unusual difficulty in obtaining provisions, and it was accounted for by the natives in the following manner: the proprietor of the tithes had just been there, and had taken from them, in sheep and pigs, the full tenth, not only of those animals, but of the growing crops of corn, apples, and potatoes. He had taken away all that the poor people could be deprived of, excepting only what was absolutely necessary as stock for next year's supply.

Lieut. Sulivan says, in his journal:—"Besides the tithes, they have also to give 'first fruits' to the priests, and so hard are they on their parishioners, with respect to tithes and first fruits, that whether the yearly produce be bad or good, the same quantity must be contributed to swell the revenue of a person whom they seldom see, except at the times of collection."

This oppression, however, is not allowed by the superiors of the Church, when it is duly represented and proved: for not long ago a curate was dismissed from his parish in Chiloé, because he was a severe extortioner: I was informed that during five years that man had amassed more than thirty thousand dollars.* Some of the natives complained bitterly to Lieut. Sulivan of the task-work they were compelled to perform.

At Lemuy he met a small piragua with only three men in it, who were on their way from Castro to Quelan. They had walked across the island from San Carlos where they had been working at the new mole, which all the 'militia'† were obliged

* The number stated to me was 35,000.

† Every able-bodied native man is enrolled in the local militia, and obliged to work thus till disabled by infirmity.

© The Complete Work of Charles Darwin Online

to do in turn, each man a fortnight: part of which time was allowed for the journey. These three had worked eight days, finding themselves in everything and receiving no pay; two were old men: one more than sixty years of age; and the third was the oldest man's son. They all declaimed against the so-called 'Patriots' (Chilians) very vehemently, and asked repeatedly when they might hope to see the Spanish flag hoisted again. The old man had been a cacique, and under the Spanish authority had charge of a watch-house and a small party of men, on Point Centinela: but directly the Spaniards were overthrown he was made a private militia-man—"not to fight," he said, "but to work." If any public work was in progress, a party of militia-men were ordered to it, in their respective turns: and if the commandant had a friend to oblige, who wanted a job done, he would order a man to work at it for a week, when another would take his place, and so on. For these services no pay was given. The old man said that they were paid in money for every service performed when under the Spaniards; and he could hardly be made to believe that there was no prospect of their returning.

There is a marked difference of climate between the east and west sides of Chilóe, as to quantity of rain and wind. A proportion of both appears to be arrested (as it were) on the windward side of the heights, so that the neighbourhood of Castro and the islands in the Gulf of Ancud, enjoy much finer weather than is met with about San Carlos. But even there the inhabitants say a change has taken place gradually, and that they have not now nearly so much rain as used to fall formerly. They attribute this to the wood being cleared away, not only on Chilóe itself, but on the neighbouring Cordillera. There is an idea prevalent in Chilóe that, after a great eruption of Osorno in particular, or indeed of any of the neighbouring volcanoes, fine weather is sure to follow. Without denying the possibility of some such correspondence, I should incline to think that there have been accidental coincidences; and that fine weather occurring about or soon after those times, has been more remarked than at other periods.

© The Complete Work of Charles Darwin Online

On the little uninhabited island, Chiut, in the middle of Ancud Gulf, Mr. Sulivan found a great number of wild strawberries: they were not very good, being unripe. Near the islands beyond Chiut (called Desertas), on the shore of the main-land, he saw several piraguas stranded, evidently during a late gale, as their crews were engaged in repairing them on the beach.

In the island Alau, Lieut. Sulivan met an old native, about 112 years of age; who had great-grandchildren about him, from twelve to fourteen years old. His eyesight and intellectual faculties were still good, and he walked firmly. From the inhabitants of Alau, Mr. Sulivan heard that an English armed brig, accompanied by a Spanish vessel of war, had anchored at that island about seventy years before 1835 (1765). Our boats visited Calbuco, and happening to arrive during the time of Mass, found nobody stirring. At last one man came out of church—ran back instantly—as if to tell the news, and immediately hundreds came pouring out to see the strangers.

Calbuco, called also El Fuerte, is much superior to Castro in appearance as well as size. It ranks next to San Carlos, in consequence to the Chilotes. Near here it was that friendly Indians helping the distressed inhabitants of Osorno to escape from the Araucanians (1599-1605), raised a cry of Calbu-co (blue water), when, emerging from the woodland, they caught a glimpse of the sea.

Our party examined places on the east coast of Chiloé, where docks might be constructed, or vessels laid ashore with much facility, as the tide rises from fifteen to twenty-five feet in several land-locked coves where the swell of the ocean never penetrates.

Round Chiloé the flood tide-streams run both ways, from the south-west; and meet in the north-west part of Ancud Gulf; the times of syzygial high water, in all the archipelago, vary only from noon to an hour and half after noon. In December and January our boat expedition found that the night tides were always higher than those of the day, and the inhabitants said that was always the case in summer. In the months of July and

© The Complete Work of Charles Darwin Online

August 1829 the day tides were higher than the night, I am quite certain; and an old Biscayan, resident near point Arena, told me that they were always so in winter: hence we may conclude they are regularly higher at that time of year.

I refrain from entering here into many very interesting customs of the Huilli-che, because they are almost the same as those of the Araucanian Indians, about whom so much has been sung or said by Ercilla, Molina, and others, because my pages are limited, there being still information of a newer character to be written; but I would ask the reader, who may feel interested about the migrations of our race, to compare such customs with those of the Polynesian islanders, especially that of the 'Minga,' and making 'Cava.'*

The superstitious ideas, arising out of a debased Romish doctrine, have not deprived the Huilli-che of their belief in witchcraft, a belief held in common with all ignorant nations. Mr. Douglas, in his MS. Journal, says:—"No Chilote doubts the existence of wizards (bruxos). When I was a magistrate, a complaint was made to me of a young woman who, they asserted, had tried to bewitch a young man. The witnesses stated that she had bought from a professed witch (bruxa) a charm (llapui), which was produced in evidence. It consisted of a piece of loadstone, with iron filings adhering to it; some fish-scales; some hair and soap suds, proved to have been on the young man's face, and sold by the barber; some parings of his nails; a small dead lizard; some slips of a peculiar tree; and many other ingredients. With this charm, with two prepared apples, and a bottle half full of a liquid mixed by the witch, she proposed to win the young man's affections to such a degree that he would give her all his property. The liquid appeared to be a decoction of the deadly nightshade, and some poisonous ferns. The witnesses stated also, that this witch had a lantern made of the skin of a still-born child, which she lighted with a candle that burned with a blue flame; and gave

* The Minga is described in Molina, and Spanish authors. For an excellent discussion respecting the Cava, see Burney—Brouwer's Voyage, 1643, vol iii. p. 137, 8, 9.

© The Complete Work of Charles Darwin Online

out sparks, when the witch flew through the air from place to place.

"I have been informed," continues Mr. Douglas, "upon indisputable authority, that such lanterns do exist; and that when two or more witches wish to communicate by signal, one of them ties a lantern to a long pole, and throws it up and down very quickly, making the sparks fly. The other then makes similar use of her lantern, at a considerable distance, and those who casually see the lights, think that a witch has flown from one place to the other. The magical art of the wizard is often exercised in a search for hidden treasure. There are some places where, in a dark night, inflammable gas, or phosphoric light, is seen, near the ground, not like a Will-o'-th'-wisp of Europe, but a clear steady light, of a white, yellow, or red colour. Popular superstition ascribes these lights to the ghosts of departed misers, watching their hidden treasure; and when one is discovered by any person, he calls a friend to assist him and watch it, about the time of new moon, until they ascertain the spot whence it proceeds; and there they dig in search of an anticipated heap of gold or silver. Not succeeding (of course), they apply to a wizard, who pretends to discover where the treasure lies, and what it is, by looking earnestly into a smooth slab of black stone (which I suppose to be basalt). The wizard may not himself find the prize, nor may he be present at the search; but, after telling the people where and when to dig, he takes good care to alarm and frighten them away in some strange manner, just at the moment they expect to grasp the store of gold. Among other devices, the wizard, or witch, pretends to cover a worsted thread with quicksilver, and holding it over the supposed place, allows the quicksilver to run off into the ground, and then he desires them to dig till they find the quicksilver, thus affording time for creating some sudden alarm, which they attribute to the 'devoto,' or familiar spirit of the deceased. It is believed by some that I am able to discover hidden treasure, and for my amusement I have more than once made an experiment before them, by sticking up two stakes in a line towards the light; then going a quarter of a circle

© The Complete Work of Charles Darwin Online

round it, I stuck up two more stakes, also in a line towards it; and next day followed the lines to their crossing, at which spot I dug, and about two feet underground found a decayed tree." (Whence a gaseous exhalation?)

Mr. Douglas's account of the life of an industrious Calbucano* is interesting. He says, that those who are called 'hombres de bien' (honest men) are generally the sons of worthy parents, and who marry, while young, some hard-working sober woman. Such a pair, as one of these men and his wife, sow some corn and plant potatoes, then leave the land, with their house, in the care of an old relation, and go to the Cordillera to work in an astillero.† If their luck is good, that is, if they find plenty of fine, straight grained trees, not farther than usual from the sea,‡ this pair will cut and bring down five hundred boards in a month; then returning home they clean the potato grounds, and attend to domestic affairs, until their feet heal, and a paralytic motion of the legs, acquired in the astillero, has ceased. When quite refreshed they go for another cargo, and work till their legs and feet can stand it no longer. A third trip is afterwards made by the husband, for about a fortnight, to a nearer astillero, where he cuts pieces of timber and plank of as large a size as he can carry (tablones y cuartones), then returns to collect his harvest, make chicha, and sow corn for next year. The winter months are passed in comparative inactivity, but not without due consumption of cider and potatoes. Occasionally the Calbucano goes to San Carlos, to sell, or rather barter his boards for indigo, tobacco, red pepper, clothes, axes, spirits, &c.; and on these occasions, as well as when they go from Calbuco to the continent, several unite together to man a piragua, in the manner described by Captain King, vol. i, p. 285-6.

Directly his children are able to walk a few miles, he takes them with him to the astillero; begins by giving them two half-boards to carry, and as they grow stronger, increases their

* Native of Calbuco.

† A timber-yard: or a place where alerse is cut down, on the flanks of the Cordillera of the Andes. ‡ From three to five miles.

© The Complete Work of Charles Darwin Online

load. At about sixteen they borrow an axe, and make the boards they afterwards carry. The alerse forests are like mines to the Calbucano; and nothing but old age or accident can check him from making boards after he has had one season of good luck. The profitable parts of the forests are now, of course, much farther from the sea than they were, owing to constant thinning. To get a load of twenty boards twice as much labour is therefore required as was necessary for a similar purpose thirty years ago. The largest alerse tree that has been found by any Calbucano during the last forty years, measured thirty feet in girth, at five feet from the ground; and more than seventy-six feet to the first branches. This famous tree gave eight lengths of boards and half a length. The two largest trees seen by Mr. Douglas, in his excursion for me, measured one twenty-four, and the other twenty-two feet round, at five feet from the ground: but these were dead trees, hollow in the centre. He saw none above ten feet in circumference, that were quite sound. Report, however, says, that in the Cordillera, out of reach of the Calbuco woodsmen, there are enormous trees, from thirty to forty feet in girth, and from eighty to ninety feet in height to the first branches, above which the heads of those giant trees are said to rise some forty or fifty feet. The alerse has short, stout branches, with leaves like those of a pine, in their bluish green colour, but shorter, being only half an inch long, and one-twentieth of an inch wide: on one stem there are four rows of these small leaves, at opposite sides.

Captain King has fully described the alerse (vol. i, p. 282-3), and the manner of making the boards. I will add a few notices of the way in which it is obtained.

In carrying his load along many miles of bad road from an 'astillero,' to the nearest water conveyance, the Calbucano wears a sheep-skin on his shoulders, under a woollen shirt, and taking a stick, with its lower end forked,* he trudges along

* To steady him across bridges of single trees, thrown over ravines, as well as to assist in supporting the load. Sometimes they climb up or down precipices with their loads, by a fallen tree, notched to receive the feet.

© The Complete Work of Charles Darwin Online

with the load on one shoulder, and on the other the stick, which partly supports the weight till one shoulder is tired; he then shifts the burthen to the other, and goes on. This half rest is called 'cantuntun.' After eight, ten, or twelve of these, according to his strength, and the road, he casts down the load, and rests about ten minutes. This is his 'descanso;' and he makes about one such every two or three miles. The astillero of Melipulli is ten 'descansos,' a whole day's journey, from the place of embarkation. In examining the different forests of alerse, Mr. Douglas saw some immense land-slips (quechi), one of which was said to have brought down one thousand alerses, some of them being five fathoms round near the roots. This land-slip measured seven hundred yards in length and three hundred yards in width.

Mr. Douglas finds much fault with the manner in which the Chilotes associate for a voyage, or any joint undertaking. He says, "their voyages being planned like a commonwealth, it follows that their government on board must be republican, and the consequence is that every thing is decided by most votes and most noise." He also complains of their extreme selfishness, and of their reluctance to do any thing, however trifling, for a neighbour, unless for a consideration; another evil consequence of democratic inclinations.

When Moraleda was about Chiloé he went across the cordillera to the lake Nahuel-huapi, in quest of information relative to the 'Cesares;' but he could hear nothing positive about any such city or people, from the Indians whom he met near that lake—well known to the Spaniards as a jesuit missionary station. Mr. Douglas's father-in-law* once commanded a party sent from Chiloé to look for this reported city of 'Cesares.'† He got over and beyond the Cordillera to an elevated plain, where he saw a very large number of Indian huts (toldos), placed so as to form regular streets. Near them were large droves of horses and cattle, and small patches of culti-

vated ground: but he had no time to make further remarks, for his party was discovered, vigorously attacked and driven back, with loss, to the sea. The old man said the climate and soil of that plain were better than those of Chilóe: and, as a proof of it, he found Indian corn with from five to nine large heads, though in Chilóe the same kind of plant only bears from one to three small heads.

A few of the remarks relative to Chilóe, contained in the preceding pages, arose out of an excursion made by me, in 1829, among the neighbouring islands: and many of the other notices mentioned by Captain King (vol. i.) or myself, and given in the narrative as they were received from our associates, were corroborated by what I then witnessed. The excursion alluded to was undertaken in consequence of two carpenters belonging to the Beagle being enticed to desert by a Roman Catholic priest named Forastes, who not only afforded them the means of travelling to Castro and Lemuy, but hid them on his own premises afterwards; and, when he heard that I was seeking for them among the islands, sent them across the gulf of Ancud, in a piragua, to remain in a cove near the Corcovado until the search should be over. One of these men was not worth taking trouble about; but the other was a man who had borne a high character, and had a wife and children in England depending upon him for support. I was satisfied that this man (Wells) had not deserted until overcome by extraordinary temptation and the evil advice of his companion, and determined to do my utmost to recover him. He had pay due for several years' service, and his 'servitude time'* was considerable.

I despatched Mr. Kirke overland to Castro for intelligence; and set out in a light whale-boat, with five men, all as eager as I was myself to rescue their shipmate from the deceitful allurements of Padre Forastes. As a carpenter, also, every one was well aware, that his recovery was of much consequence to our small vessel, in a place where we could not obtain a substitute.

* For the pension granted to seamen in the Royal Navy after twenty-one years' servitude.

© The Complete Work of Charles Darwin Online

While visiting various islands I was much struck by the good order and cheerful alertness of several schools of boys, and by the apparent respectability of their teachers: and I was informed that these schools were much fostered by General Aldunate and his worthy secretary, Forelius (a Swede).

Nothing could be more pleasing than the appearance of the islands; all highly cultivated, and thickly peopled by a quiet race of men, apparently industrious, certainly most obliging and hospitable.

At Lemuy I heard that the fugitives had just left Chelin and Quehuy, in a piragua belonging to one Antonio Vargas, and were gone to the Cordillera, somewhere near the Corcovado, to kill seals and collect oil for him and Padre Forastes, until we should leave Chiloé, when they would return and work for the priest. This information cost me an ounce of gold, given to Vargas's own brother: and for six dollars, in advance, with a promise of more, I engaged a guide (vaqueano) to go with me to the main land. This man had no idea of moving by night; but, understanding clearly that the piragua was gone to an inlet under the Corcovado Mountain, I sailed at once across the gulf, steering by the light of the volcano, much to the terror of our vaqueano, who shrunk down to the bottom of the boat, drew his poncho over his head, and kept muttering prayers, sometimes to the Virgin and his 'devoto' (patron saint), sometimes to 'bruxos;' but never ventured to look up at the large sail, or watch the boat reeling through the waves, as she sailed across with a fresh westerly wind.

After a variety of petty difficulties and disappointments, and searching every inlet within twenty miles of the Corcovado, without finding a trace of the fugitives, I at last abandoned the pursuit and returned to San Carlos; having relanded our unhappy vaqueano, who, while close to the land, had been useful; but whom we had ruined, he often asserted, by obliging him to promise away all his property in masses, in offerings to saints, and in presents to 'bruxos' for his safe deliverance from such continual peril. After hearing such a melancholy statement of his prospects, I added a present to his earnings, which

© The Complete Work of Charles Darwin Online

he assured me would amply satisfy both 'bruxos' and 'devotos,' and left him, notwithstanding his temporary fears, a happy man.

In 1834 I learned that we had actually been within a boat's length of the deserters on one occasion, and that they had made up their minds to yield unconditionally. They were hidden in some thick bushes on the borders of an inlet* under the Corcovado, and their piragua was hauled up behind a rock, out of immediate observation.

It is now high time to quit Chiloé, and proceed along the coast northward: but before I do so, let me take advantage of this opportunity to express the gratitude of those with me, as well as of myself, for a succession of private assistance and sincere kindness experienced from many persons at San Carlos, whose names I refrain from mentioning, because I have a great dislike even to the idea of publishing any thing that occurs in the unreserved intercourse of friends.

* Palbitad, or Almangrande.

Extraordinary meteoric appearances have occasionally been noticed about Chiloé, and the islands southward of it. In describing the Carelmapu earthquake, of 1633, Agüeros says that torrents of rain followed; and that on a high hill near the town was seen a globe of fire, which rose for a short interval, and then fell into the sea: the waters of which were in consequence much disturbed. A violent tempest ensued, with hail larger than musket-balls.

Another remarkable earthquake happened thereabouts on the 23d—24th of December, 1737: and on the 30th, in the early part of the evening, a great exhalation or cloud of fire was seen passing, from north to south, over all the archipelago. It fell on the Huayteca islands, covered them with ashes, and burned up the vegetation to such a degree that it was only in 1750, that the islands began again to look green.—Agüeros, pp. 102, 104, 105.

In Sarmiento's voyage an appearance of a similar nature is mentioned, as having been seen near the Strait of Magalhaens: (Viage al Estrecho de Magallanes, p. 205).—Other authorities might be quoted.

© The Complete Work of Charles Darwin Online

CHAPTER XVIII.

Leave Chilóe — Valdivia — Earthquake — Aborigines — Traditions — Words—Convicts—Tolten — Boroa — Imperial—Mocha—Shocks of Earthquake—Anchor off Talcahuano — Ruins—Account of a great Earthquake which destroyed the city of Concepcion: and was felt from Chilóe to Copiapó; from Juan Fernandes to Mendoza.

At daylight on the 5th of February the Beagle sailed from Chilóe, and passed along the coast of southern Chile, towards the port of Valdivia. This is a bold and high tract of land, without a danger for shipping to avoid; but, at the same time, without a safe anchorage between the ports above-mentioned. Soundings extend some miles into the offing, though the water is deep. At two miles westward of this shore we usually found about forty fathoms water; at three miles about sixty, and at five miles from seventy to eighty or ninety fathoms, with a soft, sandy, or muddy bottom.

Whenever, as in this case, we were obliged to carry on the survey without landing, our observations for latitude—often those for time also—were made at the opposite points of the horizon, as well as in the usual manner, when land did not intervene, and the mean results taken as the most correct. In this way, it is probable that errors occasioned by refraction were in a considerable degree avoided.*

The day before arriving at Valdivia we had a strong northerly wind, with cold, rainy weather, though the glasses were high. Such an anomaly I have elsewhere noticed, especially in Tierra del Fuego; but any attempt to explain it must be deferred. Another singularity was the temperature of the

* We had three sextants, made for me by Worthington, which had additional horizon glasses, enabling them to measure any angle less than 160°. The contrivance was my own, and found to answer. It is described in the Appendix.

© The Complete Work of Charles Darwin Online

ocean, not being higher than that near the Chonos Archipelago, and very little warmer than that of Magalhaens Strait: this fact will also be recurred to again.

Feb. 8th. We anchored in the deceiving port of Valdivia. I say deceiving, because it offers to the eye ample space and the utmost security, while, in fact, the safe anchorage is very limited; so much mud and sand being brought down by the river that extensive banks are formed, and increase yearly. We were struck by the apparent strength of the fortresses, built originally by the Dutch in 1643, but improved and increased by the Spaniards. Now, however, their strength is but apparent; for a closer inspection shows that they are almost in ruins and the guns out of order; indeed so nearly disabled, that they could hardly fire a salute without danger. Around the port are high hills, completely covered with wood; and they attract clouds so much, that almost as great a quantity of rain falls there as on the western shores of Chiloé. Several rivers empty themselves at this one mouth, which is the only opening among hills that form a barrier between the ocean and an extensive tract of champaign country,* reaching to the Cordillera of the Andes. The principal of these rivers are the Calla-calla† and the Cruces; their tributaries are very numerous, few countries being better watered by running streams than that about Valdivia.

Every facility and kindness in his power was offered to us by Don Isaac Thompson, the Yntendente:—and by his secretary, Don Francisco Solano Perez, I was presented with a rare edition of Febrés's 'Arte de la Lengua Chilena,' which has been of much use in explaining the meaning of aboriginal words and names. Don Francisco wished me to take another curious work, but I declined; and have often regretted since that I did not ask him to let me copy a map in it which contained the tracks of Spanish missionaries from Castro in Chiloé to the lake of San Rafael, isthmus of Ofqui, and archipelago of islands in latitude

* Called "Los Llanos," or the plains.

† On which is the town of Valdivia.

© The Complete Work of Charles Darwin Online

48-9° S. I thought another copy might be found at Lima, but during my subsequent stay there, not one could be discovered.

The town of Valdivia, formerly dignified by the appellation of city, disappointed our party extremely. It proved to be no more than a straggling village of wooden houses, surrounded with apple-trees; and the only building, even partially constructed of stone, was a church.* Many of us were in the town on the 20th of February, at the time of that great earthquake, which ruined so many places besides the city of Concepcion: an awful event, which will be related in the following pages.

An English carpenter, who had served on board the Beagle, in 1828, but had since settled on the banks of the river Cruces, about thirty miles from Valdivia, came on board his old ship one day, to see those whom he knew. It happened that I had formerly been of some assistance to him, and he was naturally glad to oblige me, by giving such information about the country and the natives as he was able to impart; and having lived nearly four years among them, his accounts were not only interesting, but, I think, worthy of credence.† As some of these were confirmed by what I heard from residents at Valdivia, and I have no doubt of their truth, I shall mention them without hesitation in the course of my narrative.

I was much struck by the peculiar physiognomy of those aboriginal natives whom I saw during my stay: and there must have been some ground for Mr. Darwin and myself remarking at different times, unknown at first to one another, that their countenances reminded us of portraits of Charles I. This was my impression at the first glance; but after closer examination it wore off, and I thought less of that likeness than I did of their resemblance to the Hindoo race. There was neither the open honesty of a Patagonian, nor the brutal look of most Fuegians; but there was a sombre cast of depressed

* That church and other edifices have since been laid in ruins by the violent earthquake of Nov. 7, 1837.

† He was a very intelligent, observing man, and a good workman: while belonging to the Beagle, he was rated carpenter's mate.

intelligence that at once said, " we are restrained, but not subdued." Their countenances were less wide, and more swarthy, than those to which our eyes had been accustomed; and they eyed us with a sinister although resolute glance, which seemed to ask whether we were also come to try for a share of their country. These men were of a middle stature; and formed more slightly than those of the south. They were all tolerably clothed in blue cloth of their own manufacture; and the men of different tribes were distinguished by a slight difference in dress; the Juncos, who live south of Valdivia, wearing a sort of petticoat, instead of trowsers, while the Rancos, another subdivision, wore short loose breeches. In other respects they are similar, as to outward appearance, and their language is that of all southern Chile.* These Juncos and Rancos are but portions of that collection of tribes usually known among Europeans by the celebrated name of Araucanians; but among the natives, by the terms Molu-che, Huilli-che, &c. I certainly gazed at these Indians with excessive interest, while I reflected on the multiplied sufferings undergone by their ancestors—the numbers that perished in mines—or in trying to defend their country—and the insidious attempts made to thin their numbers by frequent intoxication, if not by introducing deadly disease.†

To keep these Indians on peaceable terms, and in order to have early intelligence of any general combination, the Chilians maintain among them 'capitanes de los amigos,' whose apparent office is to take the part of an Indian, if he should be ill-treated by a Chilian (of Spanish descent), and to interpret between parties who wish to barter goods. There is also a 'comisario de los Indios,' who is a centre of reference for the 'capitanes,' and who ought to be the friend and protector of the aborigines. Many tribes, however, will have nothing to say to either the commissary or his captains, seeing through their object, and detesting even the descendant of a Spaniard too deeply to admit any one of that abhorred race into their territory. About Valdivia there are only a few leagues of ground held by Chile, excepting which all that magnificent

* The Huilli-che. † By giving them infected things.

tract of country, reaching from the Gulf of Ancud nearly to the river Bio-Bio, probably the finest district in all South America, is still kept by the brave Araucanians.

These Indians are extremely superstitious, but in their rites there are curious customs, perhaps indicative of their origin. About Valdivia, whenever an aboriginal and heathen native dies, he is buried in a small canoe, with a scanty supply of provisions and chicha,* on the bank of a river which flows to the sea. Their idea is that the spirit goes by water to that place, in the direction of the setting sun, whence their remote ancestors came. Febrés says, in his work before mentioned, that the island Mocha is the place meant: but if we reflect that Mocha is very small, only twenty miles from the mainland, and that when first discovered, early in the sixteenth century, it was inhabited by Indians who often crossed over to the continent, I think we must look much farther west for the place of departed souls to which these people refer.

The aborigines who live near volcanoes offer propitiatory sacrifices to the evil spirit, Pillan, who is said to cause earthquakes and eruptions. They sacrifice bulls and rams to him, besides offering fruit, vegetables, and chicha. On a mountain called Theghin, or Theg-theghin, (which means to crackle or sparkle like fire), these people say that their early progenitors escaped from the Deluge. There is a word in common use among them, meaning 'the great ancestor,' or 'our great ancestors,' or 'the renowned,' which is hardly to be distinguished from Shem. Febrés spells it 'Them,' but, as the th is frequently pronounced, it would sound like chem.† Can this be handed down from their ancestor of the Ark ?‡

Another word that attracted my notice particularly, was 'minga.' I have a note by me (unfortunately without the proper reference) remarking the resemblance of minga, not

* Fermented liquor made from maize, apples, or other substances.

† Molina, Hist. Civil de Chile. Vol. ii. p. 333. Falkner says that the Vuta Huilliche substitute t for ch, p. 99.

‡ I am informed by Doctor Andrew Smith, that the word Ham is still common among the nations of southern Africa, as a distinguishing appellation,

© The Complete Work of Charles Darwin Online

only in sound but in meaning, to the Hebrew word mincha. Molina (p. 333) says that these people have a nasal g, which brings the two words to an identity of sound. The Hebrew term, I am told, means an offering or collection of fruits, liquors, &c.; and the corresponding Huilli-che word means a a feast of which those partake who are about to unite in a work for the benefit of him who makes the 'minga.' In the Appendix a few Greek, Latin, and Araucanian words are arranged so as to show the remarkable similarity existing between them.

I was told by the Yntendente that some Englishmen had arrived in his district a few months before we came, whose character and business he did not understand. Rumours had reached his ears of their having escaped from one of our convict settlements, at the other side of the Pacific, and he was inclined to believe the report. Three of these men had married since their arrival, and all but one were industrious members of his community: indeed I saw two of them hard at work on a boat belonging to the Yntendente. Having however no proof of their delinquency, I did not deem myself authorized to ask him to have them arrested and delivered up to me, in order that I might convey them to the senior British officer at Valparaiso. Afterwards I learned that these men, seven or eight in number, had escaped from Van Diemen's land in a very small vessel, and sailing always eastward, had at last arrived on the coast near Valdivia, whence they were conducted by a fisherman into the port. Eventually they were made prisoners by the Chilian authorities, delivered up to our Commodore, and by him sent to England.

I was informed that there is coal in many places about Valdivia; but I did not see any. We sailed on the 22d, after receiving, on all occasions, the kindest treatment from the residents.

As we passed along the low coast about the river Tolten, numbers of Indians on horseback, and armed with lances, were seen riding along the shore, evidently watching our movements. This part of the coast is shoal, and at night would

© The Complete Work of Charles Darwin Online

be dangerous, for the low land projects considerably, and would not then be readily seen. We could not distinguish the mouths of either the Tolten or the Imperial (or Cauten) quite satisfactorily, but as they are bar rivers—useless to shipping—I would not risk anchoring on so exposed a coast, or sending a boat away into such a surf as we saw breaking, without having more time at my disposal and a higher object in view.

On the Cauten was the city called Imperial—celebrated in Araucanian story—and near its site now live the Boroa tribe, some of whom have light-coloured eyes, fair complexions, and even red hair. I saw one of these Indians at Valdivia, who had blue eyes, but dark hair. She told me that in her own country, 'Boroa,' there were many with eyes like her's; that some were 'rubios,' that is, of a red and white complexion, and that a few had red hair. Her parents had told her, she said, that those people were descended from the 'Huincas.'* How the red hair originated is rather curious; I have heard of it from good authorities at other times, while in Chile.

Late on the 24th we anchored at Mocha, and the following week was occupied in surveying its shores and the space between them and the mainland.† Shocks of earthquakes were frequently felt, more or less severely; sometimes I thought that the anchor had been accidentally let go, and the chain was running out; and while at anchor, I often fancied the ship was driving, till I saw that there was neither swell, current, nor wind sufficient to move her from the anchorage. We naturally concluded that some strange convulsion was working, and anxious for the fate of Concepcion, hastened to Talcahuano Bay as soon as our duty would allow: arriving there on the 4th of March—to our dismay—we saw ruins in every direction.

The following account of this catastrophe was subsequently obtained:—

At ten in the morning of the 20th of February, very large flights of sea-fowl were noticed, passing over the city of Con-

* An Araucanian name for the Spaniards, signifying assassins.

† I shall recur to Mocha again.

© The Complete Work of Charles Darwin Online

cepcion, from the sea-coast, towards the interior: and in the minds of old inhabitants, well acquainted with the climate of Concepcion, some surprise was excited by so unusual and simultaneous a change in the habits of those birds,* no signs of an approaching storm being visible, nor any expected at that season. About eleven, the southerly breeze† freshened up as usual—the sky was clear, and almost cloudless. At forty minutes after eleven,‡ a shock of an earthquake was felt, slightly at first, but increasing rapidly. During the first half minute, many persons remained in their houses; but then the convulsive movements were so strong, that the alarm became general, and they all rushed into open spaces for safety. The horrid motion increased; people could hardly stand; buildings waved and tottered—suddenly an awful overpowering shock caused universal destruction—and in less than six seconds the city was in ruins. The stunning noise of falling houses; the horrible cracking of the earth, which opened and shut rapidly and repeatedly in numerous places;§ the desperate heart-rending outcries of the people; the stifling heat; the blinding, smothering clouds of dust; the utter helplessness and confusion; and the extreme horror and alarm, can neither be described nor fully imagined.

This fatal convulsion took place about a minute and a half or two minutes after the first shock; and it lasted for nearly two minutes, with equal violence. During this time no one could stand unsupported; people clung to each other, to trees, or to posts. Some threw themselves on the ground; but there the motion was so violent that they were obliged to stretch out their arms on each side, to prevent being tossed over and over. The poultry flew about screaming wildly. Horses and other animals were greatly frightened, standing with their legs spread out, and their heads down, trembling excessively.

After the most violent shock ceased, the clouds of dust which

§ The direction of these cracks was not uniform, though generally south-east and north-west.

© The Complete Work of Charles Darwin Online

had been raised by falling buildings, began to disperse; people breathed more freely, and dared to look around them. Ghastly and sepulchral was the sight. Had the graves opened and given up their dead, their appearance could scarcely have been more shocking. Pale and trembling, covered with dust and perspiration, they ran from place to place, calling for relations and friends; and many seemed to be quite bereft of reason.

Considerable shocks continued to harass and alarm at short intervals. The earth was never long quiet during that or the next day, nor indeed for the three days following the great shock; and during many hours after the ruin, it was tremulous, and the shocks were very frequent, though not severe. Many of these, but not all, were preceded by a rumbling, subterranean noise, like distant thunder. Some compared the sound to the distant discharge of many pieces of artillery. These noises came from the south-west quarter, and preceded the shock by one or two seconds; sometimes, but not often, the sound was unaccompanied by any shock.

It was the general opinion that the motion was from south-west to north-east. Some whole walls, whose direction was south-east and north-west, were laid flat, the bricks still maintaining their relative position, though end-wise, without being scattered upon the ground. These walls fell, without exception, to the north-east.* Others were scattered as they fell; but still the greatest masses of brick-work were thrown towards the north-east. Walls standing in the opposite direction, north-east and south-west, suffered far less: none fell bodily or in masses; fragments were shaken or torn off; and some of the walls were very much cracked,† but others suffered little. Houses built of 'adobes,'‡ became confused heaps, and roofs fell in every where. The cathedral, whose walls were four feet in thickness, supported by great buttresses, and built of good brick and mortar,§ suffered more than other buildings. Ad-

hering to the remains of the walls were left the lower parts of some buttresses—the upper parts of others—while in one place a buttress stood on its own foundation, separated entirely from the wall.

The city of Concepcion stands upon a plain, very little higher than the level of the river Bio Bio. The soil is loose and alluvial. To the eastward and northward lie rocky irregular hills: from the foot of which the loose earth was every where parted by the great convulsion, large cracks being left, from an inch to more than a foot in width. It seemed as if the low land had been separated from the hills, having been more disturbed by the shock.

Women washing in the river near Concepcion were startled by the sudden rise of the water—from their ankles to their knees—and at the same moment felt the beginning of the convulsion. It was said that the dogs avoided the ruin, by running away before it occurred. This, though known with certainty to have been the case at Talcahuano, wants confirmation with respect to Concepcion. Of nine men who were repairing the inside of a church, seven were killed, and two severely hurt. One of these poor fellows was half-buried in the ruins, during five days, with a dead body lying across him, through which it was necessary to cut, for his release. A mother, escaping with her children, saw one fall into a hole; a wall close to her was tottering; she pushed a piece of wood across the hole, and ran on; the wall fell, covering the hole with masses of brick-work; but, next day, the child was taken out unhurt. Another woman missed a child; saw that a high wall was tottering, but ran for her son, and brought him out. As she crossed the street, the wall fell, but they were safe; when the tremendous crash came, the whole street, which she had just crossed, was filled up with part of the ruins of the cathedral. Besides a waving or undulatory movement, vertical, horizontal, and circular or twisting motions were felt. An angular stone pinnacle was particularly noticed, which had been turned half round, without being thrown down, or leaving its base.

Persons riding at the time of the great shock, were stopped

© The Complete Work of Charles Darwin Online

short; some, with their horses, were thrown to the ground: others dismounted, but could not stand. So little was the ground at rest after the great destruction, that between the 20th of February and the 4th of March, more than three hundred shocks were counted.

Much misery was alleviated by the good conduct and extreme hospitality of the inhabitants of Concepcion. Mutual assistance was every where rendered, and theft was almost unknown. The higher classes immediately set people to work, to build straw-covered huts and temporary houses of board, living meanwhile in the open air under trees. Those who soonest obtained or contrived shelter, collected as many about them as they could assist, and in a very few days all had a temporary shelter, under which they tried to laugh at their misfortunes and the shifts to which they were reduced.

At Talcahuano the great earthquake was felt as severely on the 20th February as in the city of Concepcion. It took place at the same time, and in a precisely similar manner: three houses only, upon a rocky foundation, escaped the fate of all those standing upon the loose sandy soil, which lies between the sea-beach and the hills. Nearly all the inhabitants escaped uninjured; but they had scarcely recovered from the sensations of the ruinous shocks, when an alarm was given that the sea was retiring! Penco* was not forgotten; apprehensive of an overwhelming wave, they hurried to the hills as fast as possible.

About half an hour after the shock, when the greater part of the population had reached the heights,—the sea having retired so much, that all the vessels at anchor, even those which had been lying in seven fathoms water, were aground, and every rock and shoal in the bay was visible,—an enormous wave was seen forcing its way through the western passage which separates Quiriquina Island from the mainland. This terrific swell passed rapidly along the western side of the Bay of Concepcion, sweeping the steep shores of every thing moveable within thirty feet (vertically) from high water-mark. It

* Penco, the first Spanish capital of the province of Concepcion, was overwhelmed by the sea in 1730: and old Concepcion in 1751.

© The Complete Work of Charles Darwin Online

broke over, dashed along, and whirled about the shipping as if they had been light boats; overflowed the greater part of the town, and then rushed back with such a torrent that every moveable which the earthquake had not buried under heaps of ruins was carried out to sea. In a few minutes, the vessels were again aground, and a second great wave was seen approaching, with more noise and impetuosity than the first; but though this was more powerful, its effects were not so considerable—simply because there was less to destroy. Again the sea fell, dragging away quantities of woodwork and the lighter materials of houses, and leaving the shipping aground.

After some minutes of awful suspense, a third enormous swell was seen between Quiriquina and the mainland, apparently larger than either of the two former. Roaring as it dashed against every obstacle with irresistible force, it rushed—destroying and overwhelming—along the shore. Quickly retiring, as if spurned by the foot of the hills, the retreating wave dragged away such quantities of household effects, fences, furniture, and other moveables, that after the tumultuous rush was over, the sea appeared to be covered with wreck. Earth and water trembled: and exhaustion appeared to follow these mighty efforts.

Numbers of the inhabitants then hastened to the ruins, anxious to ascertain the extent of their losses, and to save some money, or a few valuable articles, which, having escaped the sweep of the sea, were exposed to depredators.*

During the remainder of the day, and the following night, the earth was not quiet many minutes at a time. Frequent, almost incessant tremors, occasional shocks more or less severe, and distant subterranean noises, kept every one in anxious suspense. Some thought the crisis had not arrived, and would not descend from the hills into the ruined town. Those who were searching among the ruins, started at every shock, however slight, and almost doubted that the sea was not actu-

* Thieves were numerous in Talcahuano. Directly after the ruin these scoundrels set to work—though crying 'Misericordia,' and with one hand beating their breast—with the other they stole most industriously.

© The Complete Work of Charles Darwin Online

ally rushing in again to overwhelm them. Nearly all the inhabitants, excepting a few who went on board vessels in the harbour, passed the night upon the hills, without shelter: and next day they began to raise sheds and huts upon the high grounds, still dreading the sea. It was said, and generally considered certain, that every dog at Talcahuano had left the town before the shock, which ruined the buildings, was felt.

Without explanation it appears astonishing how the shipping escaped destruction. There were three large whale-ships, a bark, two brigs, and a schooner, very near the town, in from four to seven fathoms water: they were lying at single anchor,* with a good scope of cable :† one only was well moored.

With the southerly breeze, which was rather fresh at the time of the earthquake, these vessels lay to seaward‡ of their anchors, having their sterns towards the sea; and were left aground in this position. The captain of the port, D. Pablo Delano, was on board one of the whale ships at the time, with the hatches battened down, and dead lights shipped. All hands took to the rigging for safety. The first great wave came in an unbroken swell to the stern of the vessel, broke over and lifted her along without doing any material harm, more than sweeping her decks: and the slack chain dragging over the mud checked her gradually, as the first impetus of the wave diminished. Whirling her round, the water rushed out to seaward again, leaving the vessel stranded nearly in her former position. From two fathoms, when aground, the depth alongside increased to ten, as the water rose highest during the last swell. The two latter waves approached, and affected the shipping similarly to the former: all withstood their force, though the light anchors were dragged. Some of the vessels were thrown violently against others; and whirled around as if they had been in the vortex of a whirlpool. Previous to the rush of waters, the Paulina and Orion, two merchantmen, were

* Or steadied by a second anchor which was too light to withstand any great strain.

† Chain.—The holding-ground is excellent, a soft, tenacious mud.

‡ Nearly half a cable's length; or from sixty to one hundred yards.

© The Complete Work of Charles Darwin Online

lying a full cable's length apart; and after it had passed they were side by side, with three round turns in their cables. Each vessel had therefore gone round the other with each wave: the bow of one was stove in: to the other little damage was done. A small vessel* was on the stocks, almost ready for launching; she was carried by the sea two hundred yards in-shore, and left there unhurt. A little schooner, at anchor before the town, slipped her cable, and ran out in the offing as the water fell. She met the wave, unbroken, and rose over it as an ordinary swell. The Colocolo† was under sail near the eastern entrance of the bay—she likewise met the wave, as a large swell, without inconvenience.

Many boats‡ put off from the shore before the sea retired: some met the advancing waves before they broke, and rose safely over them; others, half swamped, struggled through the breakers. The fate of one little boy was extraordinary. A servant woman had taken refuge with him in a boat; the boat was dashed against an anchor, lying on the shore, and divided. The woman was drowned, but the half of the boat containing the child§ was carried out into the bay. It floated, and the boy held firmly. He was picked up afterwards, sitting upright, holding steadily with both hands, wet and cold, but unhurt. The boy's name is Hodges: his father is an Englishman, well known at Talcahuano, and was an officer in the British navy.

For several days the sea was strewed with wreck; not only in the Bay of Concepcion, but outside, in the offing. The shores of Quiriquina Island were covered with broken furniture and wood work of all kinds; so much so, that for weeks afterwards, parties were constantly at work collecting and bringing back property. During three days succeeding that of the ruin the sea ebbed and flowed irregularly, and very frequently: rising and falling for some hours after the shock two or three times in an hour. Eastward of the island of Quiriquina the swell was neither so large nor so powerful as that

* About thirty tons.
† Chilian schooner of war.
‡ Chiefly, if not all, whaleboats.
§ Only four years old.

© The Complete Work of Charles Darwin Online

which swept over Talcahuano. Having more room to expend its strength in the wider and deeper part of the bay may perhaps have been the reason why the sea swelled rapidly, without breaking, near Lirquen, in the south-east part of the bay; and why it broke over Tomé* with violence, though not so furiously as over Talcahuano. The great waves, coming from the sea, appear to have been divided, at the entrance of Concepcion Bay, by the island of Quiriquina, and turned aside both ways, one part taking its course along the Tumbes, or western shore, towards Talcahuano; the other across the eastern opening, towards Tomé. While the bay of Concepcion was agitated by the great waves, it was noticed by Captain Walford (from his house at Lirquen), that the Colocolo was swept to and fro remarkably. She was under sail near the eastern entrance of the bay. Two explosions, or eruptions, were witnessed while the waves were coming in. One in the offing, beyond the island of Quiriquina, was seen by Mr. Henry Burdon and his family, who were then embarked in a large boat, near Tomé; it appeared to be a dark column of smoke, in shape like a tower. Another rose in the middle of the bay of San Vicente, like the blowing of an immense imaginary whale: its disappearance was followed by a whirlpool which lasted some minutes: it was hollow, and tended to a point in the middle, as if the sea was pouring into a cavity of the earth. At the time of the ruin, and until after the great waves, the water in the bay appeared to be every where boiling; bubbles of air, or gas, were rapidly escaping; the water also became black, and exhaled a most disagreeable sulphureous smell. Dead fish were afterwards thrown ashore in quantities; they seemed to have been poisoned, or suffocated; and for days together the shores of the bay were covered with fine corvinos, and numerous small fish. Black stinking water burst up from the earth, in several places; and in Mr. Evans's yard, at Talcahuano, the ground swelled like a large bubble,

* Tomé is near the eastern entrance of the bay, where the wave would meet with more interruption than near Lirquen, though considerably less than in the western passage.

© The Complete Work of Charles Darwin Online

then bursting, poured forth black, fetid, sulphureous water. Near Concepcion similar outbursts of water were seen, and similarly described.

By a marked part of the wall of Captain Delano's house, it was ascertained that the body of water reached twenty-five feet above the usual level of high water. It penetrated into the 'altos,'* and left sea-weed hanging to the remains of roofs, or to the tops of broken walls. But this must not be taken as the general height of the wave. A body of water, rushing upon a sloping beach with such force, would naturally preserve its impetus for some time, and run up the inclined plane, to a great height. Those who watched the waves coming in, considered them, while beyond the shipping, about as high as the upper part of the hull of a frigate; or from sixteen to twenty feet above the level of the rest of the water in the bay. Only those parts of the wave which encountered opposition broke, until within half a mile of the beach, when the roar became appalling. Persons who were standing on the heights, overlooking both bays, saw the sea come swelling into San Vicente at the same time that it advanced upon Talcahuano. The explosion in San Vicente, and the sea advancing from both sides, made them think that the peninsula of Tumbes was about to be separated from the main land, and many ran up the hills until they had reached the very highest point.

Strange extremes of injury and harmlessness were among the effects of these overwhelming waves. Buildings were levelled, heavy twenty-four pound guns were moved some yards, and upset; yet a child was carried to sea uninjured; and window-frames, with the glass in them, were thrown ashore upon the island of Quiriquina without a pane being broken! According to a register, kept by Captain Delano, it appears that his barometer fell four or five tenths of an inch between the seventeenth and eighteenth of February, and was still falling on the morning of the eighteenth, after which it rose again. So great† and

* First floor rooms.

† In Concepcion a fall of two or three tenths indicates bad weather; four or five tenths a gale of wind, with much rain.

© The Complete Work of Charles Darwin Online

sudden a fall, not followed by bad weather, may have been connected with the cause of the earthquake; but some doubt hangs over these observations. The barometers on board the Beagle, at that time in Valdivia, did not indicate any change. Still, at so great a distance, it does not follow that the mercury should move similarly; and (notwithstanding doubts excited by persons at Concepcion who had frequently looked at Captain Delano's barometer,) I am hardly inclined to disbelieve the extract from his register which he gave me.

In a river near Lirquen, a woman was washing clothes at the time of the great shock. The water rose instantaneously, from her feet half way up her legs; and then subsided gradually to its usual level. It became very muddy at the same time. On the sea-beach the water swelled up to high-water mark, at the time of the shock, without having previously retired. It then began to retire, and continued falling about half an hour, before a great wave was seen approaching.

For some days after the devastation the sea did not rise to its usual marks, by four or five feet vertically. Some thought the land had been elevated, but the common and prevailing idea was, that the sea had retired. This alteration gradually diminished, till, in the middle of April, there was a difference of only two feet between the existing, and former high-water marks. The proof that the land had been raised exists in the fact, that the island of Santa Maria was upheaved some feet more than other places.

In going through the narrow passage which separates Quiriquina from Tumbes, the great waves had swept the steep shores to a height of thirty feet (vertically) above high-water mark; but this elevation was attained, in all probability, only at the sides of the passage, where the water met with more obstruction, and therefore washed up higher. That passage is nearly one mile in width, and has ten fathoms water in the middle; but the rocks on the western side diminish its navigable width to half a mile.

Wherever the invading waves found low land, the destruction was great, from those lands being in general well cultivated, and

© The Complete Work of Charles Darwin Online

the site of many houses. The low grounds lying at the bottom of Concepcion Bay, particularly those of the Isla de los Reyes, were overflowed, and injured irreparably: quantities of cattle, horses, and sheep were lost. Similar effects, in an equal or less degree, were felt on the coasts between the river Itata, and Cape Rumena. Large masses of earth and stone, many thousand tons in weight, were detached from the cliffs, and precipitous sides of the hills. It was dangerous to go near the edge of a cliff, for numerous chasms, and cracks in every direction, showed how doubtful was the support. When walking on the shore, even at high-water, beds of dead muscles, numerous chitons and limpets, and withered sea-weed, still adhering, though lifeless, to the rocks on which they had lived, every where met the eye—proofs of the upheaval of the land.

Besides suffering from the effects of the earthquake and three invading waves, which, coming from the west round both points of the island, united to overflow the low ground near the village, Santa Maria was upheaved nine feet. It appeared that the southern extreme of the island was raised eight feet, the middle nine, and the northern end upwards of ten feet. The Beagle visited this island twice—at the end of March and in the beginning of April: at her first visit it was concluded, from the visible evidence of dead shell-fish, water-marks, and soundings, and from the verbal testimony of the inhabitants, that the land had been raised about eight feet. However, on returning to Concepcion, doubts were raised; and to settle the matter beyond dispute, one of the owners of the island, Don S. Palma, accompanied us the second time. An intelligent Hanoverian, whose occupation upon this island was sealing, and who had lived two years there and knew its shores thoroughly, was also passenger in the Beagle.

When we landed, the Hanoverian, whose name was Anthony Vogelborg, showed me a spot from which he used formerly to gather 'choros,'* by diving for them at low tide. At dead low water, standing upon the bed of 'choros,' and holding his hands up above his head, he could not reach the surface of the water:

* A large kind of muscle.

© The Complete Work of Charles Darwin Online

his height is six feet. On that spot, when I was there, the 'choros' were barely covered at high spring-tide.

Riding round the island afterwards, with Don Salvador and Vogelborg, I took many measures in places where no mistake could be made. On large steep-sided rocks, where vertical measures could be correctly taken, beds of dead muscles were found ten feet above the recent high-water mark. A few inches only above what was then the spring-tide high-water mark, were putrid shell-fish and seaweed, which evidently had not been wetted since the upheaval of the land. One foot lower than the highest bed of muscles, a few limpets and chitons were adhering to the rock where they had grown. Two feet lower than the same muscles, chitons and limpets were abundant.

An extensive rocky flat lies around the northern parts of Santa Maria. Before the earthquake this was covered by the sea, some projecting rocks only showing themselves: after it, the whole surface was exposed; and square acres (or many quadras) of the rocky flat were covered with dead shell-fish, the stench arising from which was abominable. By this elevation of the land the southern port of Santa Maria was almost destroyed: there remained but little shelter, and very bad landing: the soundings having diminished a fathom and a half every where around the island.

At Tubul, to the south-east of Santa Maria, the land was raised six feet. The waves did not enter that river's mouth until about one o'clock; and then in greater number, but with less force, six or seven having been counted. Might not this be owing to the meeting of the divisions of the great wave which passed around Santa Maria.

At the island of Mocha the shock of the earthquake was so strong that people could not stand. The sea washed over the rocks at the end of the island, higher than it had ever reached in a heavy gale of wind. Anthony Vogelborg was on one of those rocks, or rather on an islet at the south end of Mocha, at the time, with a party who were sealing. Their boat was hauled up on the top of the rocky islet, and, expecting to be washed off, they held by it in readiness. The boat was lying

© The Complete Work of Charles Darwin Online

nearly east and west. During the earthquake some water in her bottom ran as fast from one end of the boat to the other as if some one were quickly lifting one end off the ground and letting it down again. It did not wash from side to side at any time. Two forked sticks were stuck in the ground, about three yards apart; another lay across them for hanging things to dry. These sticks also were nearly east and west of one another: and during the shock they waved to and fro till the forks touched, and the cross stick fell. Strong shocks were felt by vessels under sail near Mocha; and between Mocha and Concepcion, the same was experienced by several vessels, not only on the 20th, but during following days.

At anchor off Mocha on the 24th, a shock was felt by me, which resembled the sudden dragging of the anchor over rocks. Under way on the 2d of March, it was thought that a chain-cable was running out at the hawse. In one vessel they supposed she had run ashore: on board of another, that the ship had passed over a whale. Vogelborg thought that the land had been upheaved about two feet; and from his accuracy in other matters, I am inclined to trust to his opinion.

At Valdivia the shock began gently, increased gradually during two minutes, was at its strongest about one minute, and then diminished. The motion was undulating and regular, like waves rolling from west to east, but strong; and it lasted nearly ten minutes. There was no difficulty in standing or walking, but the houses waved and cracked. The stone church tottered, but was not injured; its roof was very light. All the dwelling-houses being strongly built of wood, withstood the shock. Most people thought the motion was from south-west to north-east, but Mr. Darwin and a person with him at the time, thought the reverse.

The river increased, or rose, at the same time, and rapidly fell again to its former height. In the port the sea swelled suddenly upon the shore to high-water mark, though it was then nearly the time of low-water, and quickly fell again. Both sea and river rose and fell frequently during the remainder of the day. The river never fell below its usual height, neither did the sea retire

© The Complete Work of Charles Darwin Online

beyond its proper place, at that time of tide; but each swelled from time to time and again sunk down. This happened once or twice in an hour. After the great convulsion, other slighter shocks occurred at intervals of a few minutes during an hour. In the afternoon, at about five, a smart shock was felt, which made the people run out of their houses.* One man and one woman were drowned by the sudden rise of the sea near Niebla: it was supposed that they were upon the rocks gathering shell-fish. Excepting in this instance, no injury was done at Valdivia. No noise preceded or accompanied any of the shocks.†

This great earthquake extended to the island of Chiloé, and probably still farther to the southward. The shock was there slight, but lasted during six or eight minutes; it was neither preceded nor followed by any subterranean noise. At about thirty-four minutes after eleven,‡ the beginning of the shock was felt. The motion was undulating and not strong. The swell of the sea was felt there, but I know not at what time. A man was going to leave the shore§ in his boat; he went a short distance to fetch something, and returning found the boat aground and immoveable: puzzled and vexed he went away, but had not gone many yards before his son called to him that it was afloat.

* Although built of wood.

† (Valdivia has since been ruined). "Valdivia, Nov. 7, de 1837.

"El gran terremoto que ha esperimentado este pueblo en la mañana de este dia, sin tocar los limites de la exajeracion, se puede asegurar sea el mayor de los hasta aqui acontecidos. Dió principio a las 8 y 5 minutos; y terminó a las 8 y quarto: advirtiendo que el movimiento de la tierra en este espacio de tiempo fué tan extraordinario que con dificultad podia un hombre sostenerse en pié. Continuó en seguida hasta las 9 y media con interrupcion solo de momentos, y desde esa hora hasta las 12 y tres cuartos que son actualmente se esperimentan los mismos movimientos, aunque no con igual fuerza. Las dos unicas iglesias que habia en este pueblo, y todos los edificios fiscales, se han arruinado completamente y si no les ha caido igual suerte a las demas casas de esta poblacion ha contribuido sin duda la circumstancia de ser ellas de madera, aunque por lo general han sufrido grande detrimento. "Isidro Vergara."

"Al Sr. Yntc. de la prov. de Concepcion, Dn. Manuel Búlnes."—Extracted from the 'Araucano' of Chile, Dec. 8, 1837.

‡ Mean time (exact?). § Point Arena—San Carlos.

© The Complete Work of Charles Darwin Online

In the small port of Coliumo, close to the northward of Concepcion Bay, the waves rose about as high as at Tomé, nearly fourteen feet before they reached the shore. The little village of Dichato shared the general calamity; but, standing rather higher and more distant from the sea than Talcahuano, it escaped the ravages of that element.

At the mouth of the Maule the force and height of the waves must have been considerably diminished; for no particular effect was noticed at the time, nor were there any marks upon the shore by which the height of the wave could be afterwards ascertained. That the sea should not there have occupied attention is not surprising, when one considers the locality of La Constitucion, as the port and town are called. On level low land, at the south side of the river, lies the town; between which and the sea there is high land, and a distance of about a mile. The river winds round the northern promontory of the high land, and then fights its way to sea over a bar, on which there are always breakers. There are no houses on the sea-shore; and, without going half a-mile up the hill, the sea cannot be seen; naturally then, for some time after the town was ruined by the earthquake, the inhabitants would be engaged in saving and sheltering their property, rather than looking at the ocean. I could not ascertain whether the river had risen or not: and having previously heard that the waves were very powerful at the mouth of the Maule, I was a good deal surprised to find they had been almost unnoticed: but all attention seemed to have been engrossed with the earthquake.

A vessel, lying close under the promontory mentioned above, was obliged to move as quickly as possible, when the shocks began, so serious was the shower of stones which rattled down the hill and fell about, and on board of her. I was assured by the governor, by the chief pilot, and by other residents, that instead of the land having been elevated at all, they considered that it had sunk about two feet. The pilot said he had found two feet more water on the bar, since the great shock, and that he was certain the banks of the river were

© The Complete Work of Charles Darwin Online

lower, though he could not say exactly how much. A rush of water might have shifted the loose sands of the bar; but whether the land had sunk seemed to me very doubtful. Certainly, however, it had not risen.

The island of Juan Fernandes was very much affected. Near Bacalao Head an eruption burst through the sea, in a place about a mile from the land, where the depth is from fifty to eighty fathoms. Smoke and water were thrown up during the greater part of the day, and flames were visible at night.* Great waves swept the shores of the island, after the sea had retired so much that old anchors were seen at the bottom of the anchorage.

This earthquake was felt at all places between Chilóe and Copiapó: between Juan Fernandes and Mendoza. On the sea-coast, within those limits, the retiring and swelling of the ocean was every where observed. At Mendoza the motion was evenly gentle. Copiapó, Huasco, and Coquimbo felt similar, although rather more forcible undulations. Towns, and houses which lay between the parallels of thirty-five and thirty-eight, suffered extremely; nearly all were ruined; but northward and southward of those latitudes, slight injury was done to any building. In the parallel of thirty-three and a-half, Juan Fernandes suffered, yet Valparaiso, opposite, escaped uninjured.

As to the state of neighbouring volcanoes, so various were the accounts of their action, both after and before the earthquake, that I had no means of ascertaining the full truth; but I heard from Valdivia that directly after the earthquake all the volcanoes from Antuco to Osorno, inclusive, were in full activity.†

* The highest summit of Juan Fernandes was "found to be burned, full of fissures and hot," in 1743. Ulloa saw a small flame there.—Voyage of Juan and Ulloa; translated by Adams.

† Of another earthquake the "Araucano," of Dec. 8, 1837, states as follows:

"Talcahuano, Nov. 7, 1837.

"Fué bastante recio y duró como cuatro o cinco minutos, con la particularidad notable de haberse advertido un pequeño retroceso de la mar á cia su centro en Talcahuano, y haber quedado interrumpido por algunos dias el flujo y reflujo de sus aguas."

CHAPTER XIX.

Mocha — Movement of Land — Penco — Ulloa — Shells — Coal — Maule — Topocalma — Aconcagua — Valparaiso — Horcon — Papudo — Pichidanque — Conchali — Herradura — Coquimbo — Wreck — Challenger — Blonde — Ride — Estate — Colcura — Villagran — Arauco — Former caciques — Colocolo — Caupolican — Scenery — Quiapo — Night travelling — Leübu — Tucapel — Valdivia — Lautaro — Challenger.

When the Beagle entered Concepcion Bay, she had only one heavy anchor left, having broken or lost the others; and as there were none fit for her at Talcahuano, it became absolutely necessary to go to Valparaiso: accordingly, on the 7th of March we left the melancholy ruins and their disconsolate tenants, and on the 11th dropped our only anchor at Valparaiso. There our wants were soon supplied, and we sailed on the 17th to revisit Concepcion.

From the 27th the time was occupied in surveying the neighbourhood of Concepcion, Arauco Bay, the island of Santa Maria, and Mocha, until the 17th of April.

Mocha is a prominent land-mark for navigators, but dangerous rocks lie about its south-west quarter, and as the current usually sets northward, a ship ought to beware of them. Previous to the eighteenth century it was inhabited by Araucanian Indians, but they were driven away by the Spaniards; and since that time a few stray animals have been the only permanent tenants. Most of the early voyagers speak of it. We found the anchorage indifferent, the landing bad, and no supplies to be obtained except wood, and, with much difficulty, water.

Our duties were greatly forwarded while about Concepcion, by the earnest and very kind assistance of the yntendente, Don José Alemparte; and the active friendliness of Mr. Rouse, the British consul. Though their houses were levelled, and they themselves without any of what most Englishmen would call comfort, we were received and attended to by them and the

© The Complete Work of Charles Darwin Online

'Penquistos,'* as cordially as if their nerves and minds had endured no strain.

Although it was indisputably proved to the satisfaction of every person in the neighbourhood, that elevations of land had occurred to the extent mentioned in the previous chapter, I strongly suspect that a sinking down has taken place since that period, to a very considerable amount, if not quite enough to counterbalance former elevation. This idea is suggested by the fact that when I was last at Talcahuano, in July 1835, only four months after the great convulsion, the shores of Concepcion Bay had regained their former position with respect to the level of the sea:†—by what the people of Tubul told me, when I rode by, of the sea having returned to its centre,‡ (meaning that it had regained its usual height),—and by what the inhabitants of Santa Maria said, when they told me that for three or four weeks immediately following the earthquake, their little port was much shallower than it was when I went there seven weeks afterwards.

Whether this conjecture be well founded a short time may show: if it should be, an explanation might thus arise of the differences of opinion respecting the permanent elevation of land near Valparaiso, where some say it has been raised several feet during the last twenty years, while others deny that it has been raised at all. It may have been elevated, or upheaved as geologists say, for a time, but since then it may have settled or sunk down again gradually to its old position. In a place like Valparaiso Bay, where dust is so much blown from the land to the water's edge, and even out to sea; and where many streams bring detritus from ravines, no decisive judgment can be formed as to the rise of land, because of the beach increasing gradually, and the water diminishing in depth.

* Natives of Concepcion: so called because they formerly lived at Penco: before that city was overwhelmed in 1730.

† Close to the landing place at Concepcion is a rock that was usually covered at high-water, previous to the earthquake (of 1835), but which was two feet above the highest tides of the next few weeks. In July, 1835, that rock was covered at ordinary high-water, as in 1834.

‡ 'Està ahora el mar à su centro.'

© The Complete Work of Charles Darwin Online

In a ride along the beach of Concepcion Bay, with Mr. Rouse, we examined the solid wall of old Penco Castle, and found on one side the date 1686 and on another 1687.

This castle and the adjoining foundations of houses, are so near the level of the sea, that I am surprised the inhabitants should not have feared being frequently inundated, even by tides only a few feet higher than usual.

If all this coast has been more or less upheaved during comparatively modern times, how is it that the foundations of Penco still stand at the water's edge, very little above the level of a high spring tide? Ulloa remarks, that "the country round the bay, particularly that between Talcahuano and Concepcion, within four or five leagues from the shore, is noted for a very singular curiosity, namely, that at the depth of one-half or three-quarters of a yard beneath the surface of the ground, is a stratum of shells of different kinds, two or three toises in thickness, and in some places even more, without any intermixture of earth, one large shell being joined together by smaller, and which also fill the cavities of the larger. From these shells all the lime used in building is made, and large pits are dug in the earth for taking out those shells, and calcining them. Were these strata of shells found only in low and level places, the phenomenon would be more easily accounted for by a supposition no ways improbable, namely, that these parts were formerly covered by the sea, agreeable to an observation we made in our description of Lima. But what renders it surprising is, that the like quarries of the same kind of shells are found on the tops of mountains in this country, fifty toises above the level of the sea. I did not indeed personally examine the quarries on the highest of those mountains, but was assured of their existence by persons who had lime-kilns there; but I saw them myself on the summits of others, at the height of twenty toises above the surface of the sea, and was the more pleased with the sight, as it appeared to me a convincing proof of the universality of the deluge. I am not ignorant that some have attributed this to other causes; but an unanswerable confutation of their

© The Complete Work of Charles Darwin Online

subterfuge is, that the various sorts of shells which compose these strata both in the plains and mountains, are the very same with those found in the bay and neighbouring places. Among these shells are three species very remarkable: the first is called 'choros,' already mentioned in our description of Lima; the second is called 'pies de burros,' asses' feet; and the third 'bulgados,' and these to me seem to preclude all manner of doubt that they were originally produced in that sea, from whence they were carried by the waters, and deposited in the places where they are now found.

"I have examined these parts with the closest attention, and found no manner of vestige of subterraneous fires. No calcinations are to be met with on the surface of the earth, nor among the shells; which, as I have already observed, are not intermixed with earth; nor are there stones, or any other heterogeneous substances found among them. Some of these shells are entire, others broken, as must naturally happen in such a close compression of them, during so long an interval of time.

"The pie de burro has its name from the fish enclosed in it, resembling, when taken out, the foot of an ass. This fish is of a dark brown colour, firm and filaceous; it is an univalve, its mouth almost circular, and its diameter about three inches. The bottom of the shell is concave within, and convex without. The colour within is perfectly white, the surface very smooth; the outside scabrous and full of tubercles. Its thickness in every part is about four or five lines; and being large, compact and heavy, it is preferred to all others for making lime.

"The bulgados, in the Canaries called bulgaos, are snails, not at all differing in their form from the common, but larger than those of the same name found in gardens, being from two inches to two inches and a-half in diameter. The shell is also very thick, rough on the outside, and of a dark brown colour; and, next to the preceding, makes the best lime.

"All these species of shell fish are found at the bottom of the sea in four, six, ten, and twelve fathom water. They are caught by drags; and what is very remarkable is, that no shells, either the same, or that have any resemblance to them, are seen either

© The Complete Work of Charles Darwin Online

on the shores continually washed by the sea, or on those tracks which have been overflowed by an extraordinary tide. They adhere to a sea-plant called cochayuyo (*a*).

"This plant divides itself into several branches, equal in dimensions to the main stem. These branches successively produce others of the same proportion, so that the produce of one single root covers a prodigious space. At the joints, where the branches spring, is found this kind of shell-fish, where they both receive their nourishment, and propagate their species."—Ulloa's Voyage, translated by Adams, vol. ii. pp. 252-254.

Not far from Old Penco is the stratum of coal about which there has lately been much discussion.

Herrera says, "There is coal upon the beach, near the city of Concepcion: it burns like charcoal."* Frezier bears witness that near Talcahuano there is good coal, which can be obtained without digging deeper than two feet; and he declares that the natives were astonished at his companions taking a substance out of the earth to burn as fuel in their forge.† Captain Basil Hall saw the place whence coal had been "worked without any trouble. The seam is thick, and apparently extensive, and might probably, with due care and skill, be wrought to any extent."‡ Captain Hall "laid in a supply of coals at this place. The coals, which were brought for us to the beach, cost twelve shillings per ton, every thing included."§ Stevenson says, "To what extent the coal reaches, has never yet been ascertained; all that has been used has been obtained by throwing aside the mould which covers the surface. This coal is similar in appearance to the English cannel; but it is reasonable to suppose that if the mine were dug to any considerable depth, the quality would be found to improve."‖

Many other authorities¶ might be cited to prove that coal exists abundantly near Concepcion, and that it has often been

(*a*) See note at end of chapter.

used. There are objections to it, by no means insuperable, which have alarmed people, and checked the working of those mines. It is said to be very bituminous—that it burns too quickly to ashes to answer well for smith's work, because it does not give heat enough—and that it is liable to spontaneous combustion. The last objection might be removed by keeping the coal under water,* and coking† would render it available for the forge. Some geologists say that it is 'mere lignite,' and think very lightly of its quantity or value; but practical men will doubtless attach some value to what has been proved by experience.

On the 17th of April, the Beagle sailed from Concepcion Bay, examined Coliumo, and, coasting along, anchored off the Maule River on the 20th. In a very thick fog, during the night of the 19th, while carrying sail to get an offing, we were within a fathom of being run down by a vessel crossing us on the opposite tack. As both ships were under all sail, and it was dark, our momentary sensations were far from agreeable.

To land here was perplexing enough, for a heavy surf broke on the bar of the river, and nearly as much along the shore; but with some risk and difficulty we effected our purpose in two light whale-boats, which could be hauled up directly they touched the beach. Nearly all the population of a thriving village, called Constitucion, came down to meet us (on the 21st), and assist in hauling our boats up the steep though yielding sand, where, for our comfort, they told us a whole boat's crew had been drowned, not long previously, in attempting to land. From a height overlooking the river, village, and neighbourhood, we enjoyed a very pleasing view, so long as we turned away from the bar of the river, and the surf. A rich country and a fine river are pleasing things at all times, but the difficult approach to Constitucion mars half its beauty. Only the smallest craft can cross the bar; it is dangerous

* I do not mean merely wet, but well saturated and covered with water till required for use.

† It has been coked, and found to answer well.

© The Complete Work of Charles Darwin Online

for boats to land on the outer beach: and difficult for them to profit by the few opportunities which occur of passing the bar without risk.

Notwithstanding these local disadvantages, Constitucion may thrive wonderfully hereafter, by the help of small steamers, for she has a most productive country around her, abounding in internal as well as external wealth, and a navigable river at command. Besides this, in 1805, a very practicable passage was discovered through the Andes, about seventy leagues south of Mendoza, not far from the latitude of the River Maule, almost entirely level, and fit for waggons—the only pass of such a description between the isthmus of Darien and Patagonia.

From the Maule we sailed along the coast northward; limited time, and work in prospect urging us to hasten more than could have been wished. The shoal, or rather rocks of Topocalma, or Rapel, were examined; some coves looked at, fit only for coasting launches, and the line of this bold, but uninteresting coast tolerably well determined. Before sunrise, on the 22d, we had a splendid view of the Andes—their range or cordillera being unclouded, and distinctly visible from south-east almost to north. The sharp summit of Aconcagua, 23,000 feet above the sea level, towered high over any other.

At noon, on the 23d, we hove-to off Valparaiso, and sent boats ashore. Mr. Darwin came on board, and among other pieces of good news, told me of my promotion. I asked about Mr. Stokes and Lieut. Wickham, especially the former; but nothing had been heard of their exertions having obtained any satisfactory notice at head-quarters, which much diminished the gratification I might otherwise have felt on my own account. Mr. Darwin returned to the shore, intending to travel overland, to meet us at Coquimbo, his very successful excursion across the Andes having encouraged him to make another long journey northward.

On the 25th, we anchored in Horcon Bay, a place (by some curious accident) entirely left out of all former charts, although there is good anchorage, and a fishing village not far

© The Complete Work of Charles Darwin Online

from a populous small place called Puchancavi. From this station we sailed to Papudo, a small port rising into repute, on account of copper-mines in its neighbourhood. It is well marked by a high-peaked hill, called Gobernador. Next to Papudo lies Ligua, a place where boats only can go; farther north, or 'down the coast' (as they say in Chile and Peru), is Pichidanque, an excellent cove, rather than port, now much used for shipping copper, and formerly a smuggling place; rendered more notorious by the murder of Burcher, the master of an English smuggling vessel called the Scorpion, who was enticed ashore and assassinated, after which his ship was seized and plundered. This took place in the present century; and an individual, who was said to have taken an active part in the tragedy, was living at Quillota, in 1835.

Close to Pichidanque is a high pointed hill, called 'Silla' (from its saddle shape), seeing which distinctly from Valparaiso, is said to be a sign of an approaching northerly wind.

I landed at Conchali after dark on the 30th, leaving the Beagle under sail in the offing. My reception was very hospitable; but the people made sure I was a smuggler; and some of the principal inhabitants rode with me several miles next morning to the place where my boat was hauled ashore, thinking all the time that I was only waiting for a favourable opportunity to tell them my secret, and make advantageous terms. All this coast, except a few corners, is bold and high, barren and uninteresting; though picturesque in outline.

May 2d. Another smuggling cove, called Quilimari, was examined by me. There is but doubtful landing, and no shelter for a vessel; balsas, however, might do a good deal of work for such a character as I was taken for at Conchali.

On the 4th, having hastily reconnoitred the coast nearly as far as Coquimbo, we ran into Herradura Cove, and moored ship securely. It was my intention to refit there thoroughly, and prepare the Beagle for receiving a large supply of stores and provisions at Valparaiso, which would enable her to run down the coast to the Galapagos, and thence cross the Pacific to Sydney in Australia. In Herradura she lay quietly close

© The Complete Work of Charles Darwin Online

to the land until the 6th of June: and all her crew were encamped on shore near the ship, while she was thoroughly cleared out, re-stowed, and painted. At Coquimbo (or Serena) we always met with a hearty welcome whenever duty required that we should go there, or when we went for our own amusement. The Yntendente, Yrrisarte, the kind-hearted Mr. Edwards and his family, and others, will not easily be forgotten by the Beagle's officers.

As another real benefactor to the public service, I may be allowed to mention Don Francisco Vascuñan, who lent me a vessel of thirty-five tons, called the Constitucion, to be employed in forwarding the survey. This craft was built in the River Maule, and bore a very high character as a sea boat. Lieutenant Sulivan, Mr. King, Mr. Stewart, and Mr. Forsyth volunteered to go in her; so giving them a boat's crew, a small boat, a native pilot with his balsa, and as good an outfit as my means would allow, I despatched this new tender to examine a portion of coast near Coquimbo, which the Beagle had not seen sufficiently, and directed Lieut. Sulivan, if he found the vessel efficient, to continue afterwards surveying along the coast of Chile, as far as Paposo, whence he was to repair to Callao.*

On the 6th of June, the Beagle left Herradura, and sailed towards Valparaiso. Anxious, however, to communicate with Don Diego Portales,† who was staying at his country-house, near Papudo, I touched there in my way; arrived at Valparaiso on the 14th of June, and immediately began the arrangements necessary for our preparations to quit Chile. The liberal assistance rendered by Don Francisco Vascuñan, in lending me his own vessel, without any kind of agreement or remuneration whatever, had enabled me to look forward to adding much of the coast of Chile to our gleanings in hydrography; for I well knew that Lieutenant Sulivan would not only make despatch, but extremely correct work.

Here I may remark, that if little is said henceforth about

* Orders in Appendix.

† Don Diego Portales, one of the ablest men in South America, was murdered, in 1837, by some of his ungrateful countrymen.

© The Complete Work of Charles Darwin Online

places so well known as the coasts of Chile, Peru, and other countries often described, it is because I feel bound to avoid mere repetition as far as possible, and because the limits of my narrative are fixed. For the present, leaving the Beagle to get her stores and provisions on board, I must turn to another scene.

16th June. By the post which arrived from Santiago this morning, an English merchant received a laconic account of the total loss of his Majesty's ship Challenger. This report spread as quickly as bad tidings are wont to do: but no official information arrived during that day, or the ensuing night. Recollecting that a Swedish ship had come lately into Valparaiso, whose officers had seen what they described as "an American brig" cast away near Mocha; I found out the ship and questioned the master and mates. They had arrived at Valparaiso on the 25th of May, and all agreed in stating that on the 20th of that month, they saw a large vessel ashore on the coast of the mainland, to the northward and eastward of Mocha. They saw her at daylight, but as they had light airs of wind and a very heavy swell until three in the afternoon, to save themselves from danger they were obliged to make all sail away from the land, and lost sight of the wreck.

The vessel looked large, with fore and main masts standing, and top-gallant masts an end until eight o'clock, when the fore-topmast went over the side, or was struck: her fore-topsail yard remained across; no main-top-gallant yard was seen; the main-top-gallant mast was standing all day, and there was a large ensign at the mast-head: white and red were seen, therefore it was thought to be American. Her bow was to seaward, as if she had anchored; her sails were loose all day; people were seen on the after part of what appeared to be a roundhouse painted green. Bulwarks very high—ports very large—no boats on deck or at the quarters—no guns on upper deck. Looking at her end on, with the masts nearly in a line—all her upper deck could be seen, though very indistinctly, owing to hazy weather, the additional haze caused by spray thrown up from a furious surf, and their own distance from the wreck; which was never less than four miles.

© The Complete Work of Charles Darwin Online

The log of the Swedish ship was produced, which exactly corroborated their statement. The master said he could not lower a boat, so great was the swell; and during five hours of almost calm, he was drifting helplessly towards the wreck, and expecting to share her fate. The two masts and red and white ensign, caused them to consider her an American brig, and as such she was reported to the consul for the United States.

A few of the preceding data convinced me they had seen the poor Challenger, but I was more strongly assured of the fact by pointing to the Conway, then at anchor near us, and asking whether she was like that ship—and near her size? Yes, sir, they replied. The green roundhouse abaft, seemed to have been a deception caused by looking at the curved green taffrail of the Challenger. I concluded that the mizen-mast had been cut or carried away; perhaps used as a raft: that the boats had been lowered, and that the ensign was St. George's, (Sir G. E. Hamond's flag being white at the mizen) but did not fly out, as there was no wind. The quarter-deck guns were close to the side, or perhaps below. Such were my thoughts, but other persons were of a totally different opinion. I was astonished that the Commodore did not hear officially from Santiago—particularly as the merchant's private notice was received through our Consul-general.

17th. At the Post-office I obtained a large packet, directed to our vice-consul, the moment the post-master opened the mail bag; and hastening to the consul's office, I was surprised to find it shut, and to hear that no one would be there for an hour or two. Such apathy—upon such an occasion! Not choosing to break the seals, though I saw by the direction what were the contents (Despatches by Challenger), I went in search of the proper person to open the packet: took the Commodore's letters, and hastened with them to the Blonde. Every doubt was then ended. The Challenger was lost on the night of the 19th of May, at the spot described by the Swede: but all her crew were saved except two; and on the 26th of that month, Captain Seymour, the officers and men were encamped near the wreck, at a place called Molguilla. The Blonde pre-

© The Complete Work of Charles Darwin Online

pared for sea: an offer of such assistance as I could render was accepted by the commodore; and, having arranged the Beagle's affairs, as far as then necessary, I went on board the Blonde, taking with me Mr. Usborne, J. Bennett, and a whaleboat. Lieut. Wickham was to forward the Beagle's duty during my absence, and take her to Copiapo, Iquique, and Callao, before I should rejoin her.

18th. Weighed at three in the morning and cleared the port before daybreak. A northerly, freshening wind favoured us much when in the offing.

21st. Anchored in the bay of Concepcion, off Talcahuano, at noon. As soon as I could get a boat I landed, and hastened to obtain information, horses, and a guide, as the commodore wished me to go to Captain Seymour, and concert measures for removing the crew and the remaining stores.

The captain of the port told Commodore Mason that the part of the coast on which the Challenger went shore, is quite inaccessible in any weather, but that boats had entered the mouth of the river Leübu, near Molguilla.

Lieutenant Collins (of the Challenger) had been at Talcahuano, trying to procure a vessel, in which the shipwrecked crew might embark by means of boats, at the Leübu, but not succeeding he had returned to his shipmates; whom he expected to find at the mouth of the river. It was said that a large body of Indians was in motion towards them, that the crew were short of provisions, and that they were becoming sickly. Assisted by the governor of Talcahuano, horses and a native guide were soon obtained; but I wanted a more energetic assistant, and engaged a Hanoverian who was used to the half Indian natives of the frontier, and well known among them. This man was Vogelberg, or Vergara, already mentioned. With orders and letters from Commodore Mason, accompanied by Vogelberg and H. Fuller, and provided with five horses, I left Talcahuano the same evening.

Being personally acquainted with the Yntendente, and his second in command, I hastened immediately to their houses at Concepcion, wishing to get an order to pass the Bio Bio River

© The Complete Work of Charles Darwin Online

that night, and to procure a circular letter to the local authorities. Not a minute was lost by either of those zealous officers in attending to and complying with my requests. Alemparte left his dinner to write a circular letter, in his own hand; and neither he nor Colonel Boza would return to their respective parties, until they had ascertained that I was properly provided with horses and a guide, and that I required no further assistance.

Although orders were issued and the ferry-boat at her station, no crew were to be found, and only those men who belonged to the boat knew how to cross over safely. Vexatious as the delay seemed, I was afterwards glad of it; for judging by the work in day-light, I doubt our having ever reached the opposite bank with our horses, in a dark night.

While talking to Colonel Boza I remarked a watchful, wild-looking, young Indian, in a Chilian half-uniform, standing in the house. Something unusual in his manner attracted my notice though hurried, and I have since regretted losing that opportunity of acquainting myself with the son of Colipi, a famous cacique, who is the principal, and a very powerful leader of the northern Araucanians, though at present a friend to the Chilians. Colipi is a very tall and unusually strong man; his onset and his yell are talked of with a shudder, by those who have suffered from Indian hostility. Educating his son at Concepcion is one of the methods used to conciliate the 'Barbaro.'

22d. Before the dawn of day we were looking for the watermen; and, as the sun rose, succeeded in getting their boat, or rather flat-bottomed barge, into motion. We rode into the river, about two hundred yards, until we reached the barge, then lying close to an overflowed bank. By some persuasion of voice, whip, and spur, the horses were made to leap out of the water, over the gunwale and into the boat. They certainly showed more sense than horses usually have, in understanding so readily how to behave; but whether their owners showed more than asses, in having so clumsy a ferry-boat, may be

© The Complete Work of Charles Darwin Online

doubted. In leaping in the horses nearly knocked down, or trod upon, those who were dismounted; and when leaping out again, they made such a splashing of the water in the leaky ferry-barge as effectually washed our faces. The river is wide, deep, and rapid; and there are many sand-banks. The boatmen use oars as well as long poles; but are slow and awkward to a degree I could scarcely have believed, had I not witnessed their progress. The breadth at the ferry is about a quarter of a mile, when the river is low, but upwards of half a mile when flooded, as at this time. The south bank is steep; and from San Pedro, a little village at the ferry, the land rises in a south-east direction, towards a lofty range of hills; but towards the south-west, it is low, level, and firm. Across this excellent galloping ground we tried our horses, and made the miles seem short, till we reached a low range of hills over Point Coronel. There, dismounting, we used our own legs until the hills were passed, and before us lay two long sandy beaches, called 'Playa Negra,' and 'Playa Blanca.'

In our gallop we passed the house of Don Juan de Dios Rivera,* whose estate on the south side of the Bio Bio is mentioned by Captain Hall as an instance of the progressive tranquillization of the Indians. Several large barn-like buildings spread over about two acres of ground, enclosed by a high fence of rough posts and rails, showed an eye accustomed to the country, that the proprietor held in his own hands a large estate: but that collection of thatched irregular roofs, and the utter absence of any thing like outward neatness or regularity, brought to my mind a very neglected rick-yard, near which not even a cottage appears.

Yet this was the house of a man of large property; and not by any means a bad one, compared with others in that country. Many reasons might be adduced to explain why Chilian gentlemen are reluctant to expend either time, trouble, or money in building good houses. Earthquakes are very frequent; property is yet insecure; and the country has been occupied,

* Yntendente of Concepcion in 1821.

© The Complete Work of Charles Darwin Online

but so lately that there has not been any leisure time in which to think of more than the first necessaries of life. Noble trees surround this 'casa de hacienda.'* No underwood impedes your riding at a rapid pace in any direction: and beyond the woody spaces, extensive plains stretch towards the sea and to the bank of the river. These plains are intersected by numerous streams, and adorned with irregular clumps or thickets of trees: smaller indeed than those which shade the 'casa de hacienda,' but of a size sufficient to shelter cattle.

This estate, which is not considered a large one in that country, comprises, besides many square leagues of wild hilly country, more than one hundred square miles of excellent land, well watered, abundantly wooded, and most pleasantly as well as conveniently situated. The owner is said to be a most worthy man, and numerous instances of his active goodness as well as excellent disposition, have been related to me at different times; one of which I must stop to relate.

My attendant, Vogelborg, passed near the door of Don Juan de Dios Rivera, while executing a commission entrusted to his most speedy despatch. Stopping a moment to ask the way, Don Juan remarked that he looked ill, and had better rest. Vogelborg thanked him, but explained the necessity of hastening onwards: in truth he was ill and very tired, though anxious to proceed. Don Juan then suggested the quicker method of forwarding the letters, entrusted to Vogelborg, by his own confidential servant, and forthwith despatched him upon one of his own horses, desiring Vogelborg to take possession of an excellent bed; where he remained two days under the kind care of Don Juan de Dios and his wife, who till that time, had never seen him.

Abreast of Negra Beach is an anchorage, sheltered from the north and north-west winds by Point Coronel, but exposed to the southerly and west winds. Here, as well as in coves further south, much smuggling was carried on in the time of the Spaniards.

Leaving the sea-shore, and some slippery rocky places over

which we were obliged to lead our horses, we ascended the heights of Colcura. For our reward, after a muddy scramble up to the top of a steep hill, we looked down upon a fine though but partially wooded country, forming an agreeable succession of valleys and high grounds; while to seaward there was an extensive view of the coast, with the island of Santa Maria in the distance.

Perched on a height overlooking the sea, and directly above a very snug little anchorage, is the hamlet called Colcura; and thither we hastened, inattentive to the complaints of our guide (who was likewise guardian of the horses), and trusting to Vogelborg's recollection of the road. Riding into a sort of field entrenchment at the top of Colcura hill, we were accosted by a sly-looking, sharp-visaged character, whose party-coloured jacket appeared to show that its owner held some office of a military nature, but whether that of 'cabo,'* or a higher, I could not determine until I heard him say he could give us a good meal, and that he had three fine horses near the house; when at once styling him 'gobernador' I rebuked myself for having thought ill of his physiognomy, and proceeded to unsaddle. Disappointed, however, by a scanty bad meal, we thought to regain our tempers upon the backs of our host's horses; but not an animal had he sent for; nor, to our further vexation, could any inducement tempt him to lend one of those fine horses, which, he still said, were close by. The Indians, he declared, were expected daily; he knew not the moment he might have to fly for his life; on no condition would he lend a horse: no, not if a fleet of ships were wrecked, and I were to offer him an ounce of gold for each mile that his horse should carry me.

Every Chilian residing on the frontier endeavours to keep by him a good horse, on which to escape, in case of a sudden attack of the Indians; for, as they never give quarter, and approach at a gallop, it is highly necessary to be always prepared. Those who can afford to do so, keep horses solely for the purpose of escape, which are the finest and the swiftest they can procure. I remember hearing, that when General

* Corporal.

© The Complete Work of Charles Darwin Online

Rosas was carrying on a war of extermination against the Pampa and Patagonian Indians, on the banks of the rivers Colorado and Negro, he had with him horses so superior, that it was said he could always ensure escape, if by chance he should be pursued: and one of them was invariably led about, saddled and bridled, near his tent.

Saddling our own steeds, and quitting the thin-faced dispenser of tough hens and sour apples, we set off at a gallop, leaving the lazy guide whom we brought from Talcahuano, to return there with the two worst animals (it was fortunate indeed we had brought with us a spare one), and in two hours we reached the foot of Villagran; that hill so famed in Araucanian story.

Being a natural barrier, it was a spot often chosen by the Araucanians, at which either to lie in ambush for the Spaniards, or openly oppose them. In one battle, the brave Villagran, after whom this ridge of hills is named, and a small Spanish force, opposed a multitude of Indians who had hemmed them in on every side. The only opening by which Villagran could escape, was stopped up with a barrier of branches and fallen trees, behind which the Indians stood discharging arrows and slinging stones. Ercilla gives an animated description of this scene; but as his book is scarce, I will attempt a free translation of that passage, lame as it must necessarily be.

——— ——— the veteran Villagran,
Heedless of any kind of death,
Hazarded all upon a cast.

He rode a stately powerful horse,
Purest of Spanish blood—
Strength and activity were well combined
In that courageous steed—
Swift and high-spirited, he yet obeyed
The slightest touch of finger on the rein.

The danger reached—instant as thought—
The warrior's spurs excite the noble brute—
He dashes on—and down the barrier goes.
A deafening crash and dire dismay
Followed, as onward tore their way
Those few determined men.

> The gallant steed unhurt appeared,
> Strove foremost in the fight, and feared
> Only to be the last!
>
> ERCILLA. Canto VI.

We ascended the heights by winding narrow paths, up which our horses were led, in order to spare them as much as possible, and met a small party of Chilians, on their way from the wreck of the Challenger towards Concepcion, from whom we heard that the wreck had been abandoned, and that the officers and crew were entrenched in a secure position, on the height of 'Tucapel Viejo,' close to the mouth of the river Leübu. We were also told that the Indians increased in number daily, and that great fears of their hostility were entertained.

From the summit of Villagran we had an extensive view, reaching from Tumbes Heights, at the west side of the Bay of Concepcion, to Cape Rumena. The low island of Santa Maria, with its sandy spit, shaped like an arm, seemed to be within a few miles of us, though distant several leagues. I could trace the long, low, and almost straight beach of Laraquete till ended by the white cliffs of Tubul: I could distinguish the height immortalized by Colocolo's name, and under it smoke arising from the classical Arauco. Southward, a large extent of fertile, level, and rather woody plains reached to distant ranges of hills, which showed only a faint blue outline. Time allowed no delay, but with a hasty glance, as we mounted our horses and cantered along the summit, I saw a schooner* in the distance, off the Paps of Bio Bio, working her way to the southward.

Descending the hill, we reached 'Chivilingo,' a village near a small river which runs through a 'hacienda' belonging to the 'Santa Maria' family. We called at the door of their large, barn-like dwelling, to ask if horses could be spared. The mistress of the house happened to be at home, having lately arrived from Concepcion; and directly she heard my story she ordered every horse to be put in requisition; but, unfortunately, two only were within reach, one of which was lame. All the others had been sent to grass at a distance. After acknowledg-

* The Carmen, with Mr. Usborne on board—see page 456.

© The Complete Work of Charles Darwin Online

ing her kindness, and paying her 'mayor domo' for the hire of the horse, we pushed on with that one and two of the least jaded of our own animals.

Between Chivilingo and the rivulet called Laraquete is a hill, unimportant at present, though it may hereafter become of consequence, as it contains coal. Some that I carried away with me was thought to be almost equal to cannel coal, which it very much resembled. The little river Laraquete, which will admit a large boat at high water, runs at the foot of the hill, and there is no surf where it enters the sea. Very glad I was then to see nothing like a hill between us and Arauco. We urged our horses along the dead level, and reached a pass of the Carampangue river as the sun was sinking below the horizon. From his sickly appearance and the black gathering clouds, I thought we should not be long without heavy rain, and that the sooner we could house ourselves the better. The Carampangue is shallow, except in the middle, but wide. Men and animals are carried over it on a 'balsa,' made of several logs of light wood fastened together, and pushed or poled across with their burdens by one man. These contrivances are very convenient where the water is shallow near the bank, and where the bank itself is low: for a horse can walk upon them from the shore without difficulty, or any scrambling; and as soon as they ground on the opposite side, it is equally easy to disembark. Where wood is not plentiful, balsas are made of rushes tied together in bundles; or of hides sewn up and inflated, or made into a rough kind of coracle.

The last few miles had been slowly accomplished by dint of whip and spur; but from the river to Arauco was a long league over unknown ground, in the dark, and while rain fell fast. Heavily we toiled along, uncertain of our way, and expecting each minute to be bogged; our horses, however, improved as we neared their anticipated resting place, and almost tried to canter as lights appeared twinkling within an open gateway in the low wall of Arauco.* We asked for the house of the 'coman-

* It is a low wall, or rather mound of earth, enclosing a number of 'ranchos' (cottages or huts).

© The Complete Work of Charles Darwin Online

dante,' and were directed to a rancho rather higher and larger than the rest. Without a question we were received, and told to make the house our own. That we were wet and tired, was a sufficient introduction to the hospitable Chilian.

Before thinking of present comfort, it was necessary to secure horses for the next day's journey, and dispose of our own tired animals; but money and the willing assistance of the comandante (Colonel Ger°. J. Valenzuela), soon ensured us both horses and a guide. In the colonel's house, a barn-like building, entirely of wood, and divided into three parts by low partitions, I was surprised to see an arm-chair of European make, which in no way corresponded to the rest of the furniture. Some large shells, not found in these seas, also caught my eye, and tempted me to ask their history. They had been brought only the previous day from the wreck of the Challenger, and were given by Captain Seymour to Don Geronimo, who had himself but just returned from assisting the shipwrecked party. His account and the chances of an attack being made by the Indians, increased our anxiety to proceed; it would, however, have been worse than useless to attempt finding our way in a dark night, while it was raining fast and blowing very hard; but at daybreak in the morning we saddled, and soon afterwards were splashing along the low flat tract of land extending from Arauco westward towards Tubul. Heavy rain during the night had almost inundated the low country, and to our discomfort appeared likely to continue during the day. In half an hour after starting we were soaked with mud and water; but being well warmed by galloping, we felt indifferent to the rain, and to a heavy gale of wind that was blowing.

Arauco, famous in Spanish song and history, is simply a small collection of huts, covering a space of about two acres, and scarcely defended from an enemy by a low wall or mound of earth. It stands upon a flat piece of ground, at the foot of the Colocolo Heights, a range of steep, though low hills, rising about six hundred feet above the sea.

In the sixteenth century, Arauco was surrounded by a fosse, a strong palisade, and a substantial wall, whose only opening

© The Complete Work of Charles Darwin Online

was secured by a gate and drawbridge. Now the ditch, dug by the old Spaniards, is filled up, and the remains of their drawbridge have disappeared, having been used probably as fuel. This was the first place assaulted by the Indians, after their grand union against the Spaniards, at the end of the sixteenth century. To relate even a part of the history of those times would be digressing too much; but an anecdote of Colocolo and the great Caupolican may shorten our journey, and divert us for a time from mud, and rain, and wind.

Ashamed at having given way to men, at first imagined to be gods, and indignant at the outrages and oppressions of their invaders, a general gathering of the Indian tribes took place near Arauco. Ercilla names sixteen caciques of renown, besides others of inferior fame, who assembled with their followers. At the feast which followed their first consultation, great disputes arose among the rival caciques. A general was to be chosen, and each esteemed himself worthy of that high distinction. Insulting words induced an appeal to arms, and desperate strife was about to commence, when Colocolo, the oldest and most respected chief, advancing hastily,* with haughty strides, exclaimed :—

"What madness is exciting you, Caciques!
Thus eagerly to rush into a war
Against the very sources of our strength—
To tear each other's entrails out, as beasts,
And utterly forget the tyrant foe?
Turn your arms and angry blows
Against those authors of your slavery,
Whose shameful inroads on our fathers' land
Heap infamy upon Arauco!
Arauco's sons yourselves display—
And cast their galling yoke away.
Husband every drop of blood,
To mingle with a Spanish flood!"

Having gained attention and temporary silence, the Araucanian Nestor continued an eloquent address to the angry

* Ercilla, canto ii.

© The Complete Work of Charles Darwin Online

chiefs, in which, after expostulating with them upon their ruinous rivalry; he exhorted them to choose a leader by some trial of ability, which should be publicly made; and suggested that the man who could bear a heavy weight for the longest time must be the fittest to endure the burthen of governing.

The caciques agreed to his proposal, and prepared a large trunk of a tree for this great trial of strength. Colocolo well knew that the qualifications of an Indian general were not bodily strength and activity, unless accompanied by qualities of mind proportionably superior; but it happened that Caupolican exceeded all his countrymen in mental, and all but Lincoya in bodily qualifications. Accident had impeded his attendance at the 'gathering,' and the object of Colocolo in proposing so tedious and otherwise absurd a trial was to gain time for Caupolican's arrival.

Fourteen chiefs successively bore the ponderous tree upon their shoulders. No one gave up the trial, until he had endured more than four hours' oppression; some even sustained the burthen six, eight, or ten hours; and one hardy mountaineer carried the tree for fifteen. But the famed Lincoya claimed the prize; confiding in his Herculean strength, he had allowed all others to precede him in the trial. When at last he threw the mantle from his Atlas shoulders, he took the tree from the ground as if it had been a stick; ran, jumped, and danced with it on his back, seeming to feel no weight; and the multitude, astonished, exclaimed, 'Lincoya shall be general! the rest are infants in comparison!' but the wise Colocolo insisted upon the completion of the trial, knowing that Caupolican would soon arrive, and that Lincoya's antics would exhaust even his great strength, and make it possible for an inferior to carry the tree longer. The crafty veteran had himself excited Lincoya to the unnecessary exertions which he knew would undermine him. From sunrise, until noon of the following day, full thirty hours, did the gigantic Lincoya sustain his immense load. While the air yet resounded to the shouts of 'Lincoya,' Caupolican arrived, and demanded to try his strength; but Colocolo interposed, saying that Caupolican had arrived from a

© The Complete Work of Charles Darwin Online

great distance, and ought to rest. Until the next morning, therefore, the trial was postponed.

During the night, great excitement animated the vast multitude. The strength and ability of Caupolican were well known; even Lincoya doubted the result; he had deemed his only rival far off; and the antics in which he had indulged had prematurely exhausted his strength. At daybreak the tribes again assembled, and as the sun rose, Caupolican lifted the tree, and quietly poised it upon his shoulder. His manner, and the ease with which he placed his burthen, excited the surprise and admiration of all, except Lincoya, whose spirits sunk as he watched the cautiously guarded manner and easy movements of his rival.

During that day and the following night, lighted by the full moon; during the whole of the next day, and throughout the second night, did Caupolican sustain that overpowering weight which men of common strength could only bear during a very few hours: and when the sun rose on the third morning, the still untired chief lifted the tree above his head, and dashed it to the ground, with an effort which showed that his powers were far from being exhausted. He was unanimously chosen general, amidst extraordinary shouting and applause: and no sooner had the other caciques acknowledged his authority, than he began to take measures for acting immediately against the Spaniards.

Arauco, their nearest strong hold, was to be attacked. Eighty chosen men approached, disguised as the serving Indians, who supplied the Spanish soldiers with firewood, and forage for their horses. Each man, with his load of fuel or grass, in which his arms were hidden, advanced unsuspected to the fort, when, by preconcerted signal, they threw down their loads and attacked the unprepared Spaniards. This assault was the signal for other Indians to rush towards the fort; but the Spaniards, although surprised, made so good a defence, that almost all the eighty chosen men were killed, and no others could gain admittance. The whole Indian multitude then surrounded Arauco; and the Spaniards, seeing that they must be

© The Complete Work of Charles Darwin Online

overpowered if they remained, opened the gate in the dead of the night and escaped. Thus began this famed insurrection, which caused the destruction of seven towns, and drove every Spaniard from Araucania.

Leaving the low land near the sea, we ascended sloping hills, and found ourselves in a beautiful country. Though I did not see it distinctly until my return, I will endeavour to describe it in this place:—the outer range of hills, near the sea, is a succession of downs, free from wood, except here and there in the valleys, and every where covered with short sweet grass:—there is no sandy or barren rocky land. Numbers of fine cattle were seen grazing in the neighbourhood, but very few sheep. In-shore of the downs is a very luxuriant country: gradually rising hills, every where accessible; extensive valleys, woods of fine timber trees, very little encumbered with underwood; spaces of clear grass-land, like fields; beautiful lakes, and numerous streams of excellent water, together with a rich soil clothed with sweet grass, disposed me to think this the finest country I had ever seen.

Generally speaking, the soil is clayey; but there is every where a layer of vegetable mould upon the surface; which indicates that the country was covered with wood until the Indians partially cleared it by burning. While they were so numerous as they are said to have been in the sixteenth century, large tracts of ground must have been cultivated by them, or cleared for their sheep. In riding across this now unemployed land, regretting at every mile that it should be so neglected, fine bullocks often crossed our path; or wild-looking, but well-conditioned troops of horses. These animals must be very nearly wild: for restrained by no fences, looked after by nobody, they are free to roam and feed where they please. Once only in a year they are driven together, if they can be found, to be counted, marked, or killed. Here and there a stray cottage, or rather hut, was seen, with a high thatched roof, like those of Chiloé. But for these cottages, and a field or two near them, this excellent country would have appeared to be quite deserted by the human race, though possessing every desirable

© The Complete Work of Charles Darwin Online

quality. We passed over no hills of any consequence as to height, though generally we were ascending or descending. An in-shore circuit was taken, to avoid crossing three rivers, which, near the sea, are difficult to pass; and having lost our way (notwithstanding the alleged excellence of our guide), a native, almost Indian, was easily prevailed upon to run by the side of our horses until he put us into the right track. Before running through the bushes, he carefully tucked up his loose trousers as high as possible; thinking, I suppose, that his skin was less likely to be torn than the trousers; and thus bare-footed and bare-legged he ran before us for several miles with the greatest ease. At the cottage from which he came, a very good horse, in excellent condition, and well cleaned, was standing in a yard. I asked the owner to let me hire or buy him, but he would consent to neither; alleging that, in the Indian country, his life depended upon having a good horse close at hand. Three thousand Indians had assembled, he told me, and were expected to make an attack upon the Chilian frontier; but on what particular part was quite uncertain. They had heard of the wreck, and were actually going to the place to plunder the crew, when accidentally met and driven back by Colipi, with his friendly tribe. Dogs seem to be kept at these cottages for the same purpose as those at the 'ranchos,' in the Pampas, namely, to give warning of the approach of enemies. Small parties of Indians seldom or ever attack a house without reconnoitring carefully; and this they cannot effect if there are many dogs about.

After our running guide had left us, though put into the right track, we were soon at a loss again; so numerous were the tracks of horses and cattle in this rich pasture land. The professed guide whom we had brought from Arauco, was more useful in recovering half-tired horses, than from knowing the way: no sooner did he get upon a horse, which one of my party could not persuade to go out of a walk, than he started off at full gallop, exulting in his skill. Perhaps his secret lay in a sharp pair of iron spurs: for the thick skin and coarse

© The Complete Work of Charles Darwin Online

hair of horses, so roughly kept as these, is proof against ordinary spurs, used with humanity.

Going very much by chance, often losing our way, and often taking a cast round to look for the most frequented track, we at last arrived at Quiapo, a hamlet consisting of five huts only, just in sight of one another on neighbouring hills. To which of them the name belongs, I know not, as 'Todo es Quiapo,' was all the answer I could get from my guide.

Riding up to the nearest hut, we tempted a young man who occupied it, to sally forth in the rain in search of fresh horses. This exertion was caused by the sure stimulant—money. We might have talked of the wreck, and the Indians, until that day month, without exciting our acquaintance to move; but the touch of dollars at once overcame the apathy with which he listened to our first request for food and horses. His wife told us to kill a fowl, if we could, for there was nothing else to be had; so forth we sallied, and as each understood that the permission applied to himself, great was the confusion among the poultry. To the dismay of our hostess, we soon reappeared, each with a fowl; but a certain silver talisman quickly hushed her scolding, and set her cooking. Meanwhile the rancho was ornamented with our wet clothes hanging about it to be dried; but rain came through the roof in so many places that our trouble was useless. Dripping wet, having been soaked since the morning, and of course cold, we could not go near the fire, because of the smoke; so with a long pole we poked a hole through the thatch, which let the smoke out, and then closing round the fire, we surprised the good woman by our attack upon her half-roasted fowls.

All these huts are much alike. Under one thatched roof, there is a place where all the family (including the dogs, cats, and pigs) eat, while sitting or lying round the fire, which is on the ground in the middle; and there is a kind of 'dais,'* where the same party afterwards seek that sound sleep from which none of the insect tribe appear to awake them, however

* Raised half a foot above the ground.

© The Complete Work of Charles Darwin Online

much they may plague others. Sometimes there is a sort of bedstead, and a slight partition for the older people; but the others take their rest upon the raised part of the floor, wrapped in sheepskins, or goat-skins, and rough woollen clothes. A large heap of potatoes occupies one corner of the hut, and another is filled by a granary, curiously contrived with stakes about six feet in length, driven into the ground in a circle of perhaps six feet diameter. Rough wicker-work unites the stakes, and forms a bottom about half a foot from the ground. Straw is then inserted into the wattled-work, until there is enough to prevent any corn from falling through. This large fixed basket is filled at harvest time, and supplies the family during the whole year: neither rat or mouse can get at it without making a rustling noise, which instantly alarms each cat and dog.

Before our host returned with horses it was evening. He would have detained us until the next morning, could his arguments have availed, but finding that with or without him, on we were resolved to go, he set out at a good pace towards Leübu. Less rain and wind encouraged hopes of a fine night, so we trotted or galloped along while day-light lasted, but as the night grew dark rain again poured down: and, obliged then to go slowly, we followed one another as close as possible, placing the guide in front with a white poncho. While in the open country we got on pretty well, but, after two hours easy work, we found that the track was taking us through thick woods. My first intimation of the change was being nearly knocked off my horse by the bough of a tree, so pitchy dark was the night; and after this I kept my head on the horse's neck, trusting to his eyes entirely, for I could see nothing. That our guide could find the way has been matter of astonishment to me ever since: he never failed once. Some of the defiles through which he led were knee-deep in clayey mud, so stiff that the horses could hardly move. Often we were set fast in such places, obliged to get off, and feel for the track,—knee-deep, and up to our elbows in mud,—for it was upon hands and knees that we went, oftener than upon our legs. Our guide knew we were in the

© The Complete Work of Charles Darwin Online

right track, but each of us was obliged to seek safe footing for himself and his horse, in the defiles among steep ravines and streams, swelled by heavy rains. Passing these streams was dangerous, and there only did the guide hang back. At one brook which seemed by the noise, to be deep and large, he refused to cross, saying his horse would not go on, and that we could not get over in the dark. However, Vogelborg was not to be so stopped. Leaving his own horse stuck fast in a slough, he scrambled through, hauling my horse after him by the bridle. Holding by my horse's long tail, and driving him on, I scrambled after: Vogelborg then went back, and with the guide brought the others over. In several places, while in the ravines, I had recourse to the tail of the guide's horse for my support and dragged my own animal after me, for it was hopeless to remain on his back, so often was he stuck fast or down in the mud. The last man, Fuller, fared the worst, as he had no one behind him to drive his horse on; and frequently we were obliged to stop and holla to one another, to avoid parting company. At last we emerged from the wood and from those horrible ravines. Before us we could then see that there was space, nothing interfering between our eyes and the clouds; but while under the trees and in the water courses, utter blackness surrounded us to a degree I never witnessed in any other place. Our eyes were not of the least use, for I could not even see the white poncho of our guide, though close before me. Feeling and hearing alone availed. Heavy rain during the whole time prevented the mud from forming too thick a coat upon us. Another hour brought our small party to an Indian settlement, near the river Leübu; and as we rode by the huts, our guide talked to those within at the utmost pitch of his voice, as if determined no one should be ignorant of his adventure. Hearing their conversation carried on in the Indian language, was rather an impressive novelty. We continued our route, and at last reached the Leübu.

The north side of this river (on which we were), is low and sandy near the sea, but the south side rises to a high, remark-

© The Complete Work of Charles Darwin Online

able headland, called the 'Heights of old Tucapel,'—('Altos de Tucapel viejo.') The breadth of the river is about one hundred yards. Tucapel was the name of one of the more powerful caciques who united under Caupolican, to resist and expel the Spaniards. In his district and near his usual residence, which bore the same name, the daring but avaricious Valdivia was overwhelmed by numbers and taken prisoner, though not until every one of his small party had desperately fought and devotedly died for the cause which many among them considered that of God and their king.

Religion had so much influence over the minds of the earlier Spaniards, and was so warped and misinterpreted by the priests of their day, that actions, in themselves most unjustifiable, found defenders and active supporters among churchmen, and energetic performers among those who trusted their consciences to other men's keeping. An enthusiastically religious feeling, strengthened them to persevere under all trials and disappointments, and helps to account for the wonderful energy and constancy, shown in discovering, exploring and subduing the New World. This high sentiment of religion, urging them to conquer in order to convert to Christianity, and to honour God by serving their king, was an impelling motive in the minds of the early adventurers, at least as strong as the desire of riches. I here allude to those leaders who first opened the roads, which crowds of inferior men afterwards followed. One proof of this feeling is the fact, that the last of Valdivia's faithful companions who fell, was his chaplain, without whom, it appears, he did not even go to battle.

Valdivia had set out in the morning with only fifty Spaniards, besides a body of friendly Indians, intending to attack and disperse the multitude of his opponents. As he approached Tucapel, some fugitive friends* entreated him not to proceed, assuring him that twenty thousand Indians were there who had sworn to take his life, or sacrifice their own. Despising the natives and used to conquer, Valdivia listened

* Friendly Aborigines.

© The Complete Work of Charles Darwin Online

to no cautions. The three thousand Indians, supposed to be friendly, accompanied him to the battle but turned against him: and his own page, Lautaro, who there immortalized his name among his countrymen, was the first to set the example and proved himself the most daring in the fight. (It should be mentioned that Lautaro's servitude was compulsory, having been brought up against his inclination, in the Spaniard's house.)* Onward dashed Valdivia, at the head of his small band, and was speedily surrounded by a countless throng. Hemmed in on every side, and overpowered by men who till then used to fly from a man in armour and mounted on a horse, all that desperate brave men could do, was done: but their horses tired, slaughter appeared to diminish neither the number nor rage of their opponents, and one after another sunk to the ground. Valdivia's chaplain fell the last, except the general himself, who fought like a lion at bay: till, seeing that he was alone, he turned and fled. The goodness of his horse enabled him to escape for a little while, but he was hunted by the swiftest and strongest, whose speed exceeded that of a tiring horse. His steed failed, and he was taken prisoner to be tortured and put to death, after suffering every torment that savage ingenuity could devise. When he was at the stake, the rage of the older Indians could not be repressed: and an aged man named Leocato, who had suffered long and severely by Spanish oppression, struck him on the head with his club, and at one blow deprived him of life.

Although surrounded by a multitude, so resolute and energetic were the companions of Valdivia, that they were actually gaining the day, until Lautaro rallied the retreating Indians, and by his heroism turned the tide of victory against the Spaniards. The natives' superstitious awe of these superior men, once thought gods, added to their being mounted on

* Lautaro was the son of an Araucanian chieftain, who fell in battle against the enemies of his race. Though brought up and educated in the family of Valdivia, from a mere child, he had never ceased to long for an opportunity of turning his forced acquirements to the disadvantage of his instructors, and revenging the death of his father.

© The Complete Work of Charles Darwin Online

horseback and clad in armour, were such immense advantages, that to oppose the progress of a few resolute Spaniards even by the numbers of a multitude, was a daring effort.

In consequence of this and many subsequent acts of valour and conduct, the young Lautaro became a most celebrated leader, and was chosen by Caupolican as his lieutenant and successor.

But I must return to the banks of the Leübu, which we were approaching as fast as our tired horses could drag their hoofs through deep, loose sand, when a solitary light moving on the dark side of the opposite high land, showed the place where our countrymen were anxiously waiting for assistance: we had heard that their encampment was under Tucapel Heights, and close to the river's mouth.

As soon as we arrived at the water side, I hailed as loudly as I could call, but no answer was returned. Again I hailed "Challenger's a-hoy," and a faint 'hallo' repaid us for every difficulty. "Send a boat!" I called. "Aye, aye!" echoed from the hills. Lights appeared directly coming down the hill: a little boat came across the river, and very soon we were embarked in the Challenger's dinghy,* the only boat saved. The master and one man were in her, from whom we heard that all the party were well, and that they had not yet been molested by natives.

Captain Seymour was at the landing place. Old friends, meeting under such circumstances, can say but little. Hastening to the encampment, where all had turned out to hear the welcome news of assistance being at hand, we made their hearts rejoice by saying that the Blonde was at Talcahuano, and coming to their relief. With the officers, I found our excellent consul, Mr. Rouse.† At the first intimation of the Challenger's loss, he had hastened to the spot without an hour's delay; well aware how useful his influence and information would prove, and supposing that the officers would not be

* At midnight. The horses were sent back to the Indian huts, with whose owners our guide held such noisy intercourse as we passed.

† H. B. Majesty's consul at Concepcion.

© The Complete Work of Charles Darwin Online

conversant in Araucanian habits and language, even if they should have made a slight acquaintance with those of Chile. His assistance proved to be of the utmost consequence, for not only did his explanations intimidate and discourage open or disguised enemies, who were not wanting, but his credit and influence procured daily supplies of provisions: while to his address and good sense every one of the shipwrecked crew was much indebted in many transactions.

Daylight found Seymour and myself still talking, though he had given me his bed. Partly at that time, and partly in subsequent conversations, he gave me the following account of the loss of the Challenger; but without mentioning his own exertions or conduct, which I heard of from his officers.

I will take this opportunity of mentioning that there is a large fox, called 'culpen,' in the Araucanian country, which was mentioned to me as being more like a wolf than a fox; but at that time I paid very little attention to the subject. Stevenson says, "the culpen is rather more foolish than daring, but not void of the latter quality. It will advance within eight or ten paces of a man, and after looking at him for some time, will retire carelessly." "Its colour is a dark reddish brown, with a long straight tail covered with shaggy hair; its height is about two feet."—Stevenson's South America, vol. i. p. 115. (Is not this like the Falkland animal?)

(Note referred to in page 423.)

(*a*) Ulloa said that the word 'cochayuyo' meant 'lake herb.' His authority is too good to be lightly questioned, otherwise I should have had no doubt that the word was derived from 'cochun,' 'salt,' or 'bitter,' and 'yu,' a thread: as the plant grows with long thread-like stalks, which taste salt, like most sea-weed: and 'lavquen' is the word generally used for 'lake,' as well as 'sea,' rather than 'cocha.'

CHAPTER XX.

Challenger sails—Sounds off Mocha—Wrecked on the main-land—Crew saved—Stores landed—Camp formed—Great exertions and excellent conduct—Mr. Consul Rouse—Leübu—Plague of mice—Curious rats—Return to Blonde—Ulpu—Araucanian dress—Arauco—'Boroanos'—Tubul—Bar rivers—Apples—Ferry—Blonde sails—Seek for the Leübu—Schooner Carmen—Errors and delay—Embark Challenger's crew—Rescue the Carmen—Talcahuano—New Concepcion—Valparaiso—Coquimbo—Challenger's sail in Conway—Reflections.

THE Challenger sailed from Rio de Janeiro on the 3d of April 1835: she had much bad weather off Cape Horn, which lengthened her passage considerably.

On the 18th and 19th of May, strong north-west winds, with thick weather and heavy rain, prevented observations being taken; except a few for time only. The ship was approaching the land, and her position estimated by dead reckoning from the last observations.

At five P.M. on the 19th, the Challenger hove-to, bent cables, unstowed the anchors, and sounded, but no bottom was found with two hundred and ten fathoms of line. This sounding was taken as a matter of form rather than utility, for no one supposed that the ship could be less than fifty miles from a steep coast, off which soundings extend a very little way. At this time, she was really about twelve miles from Mocha, which bore from S.E. to S. The weather was clear overhead, but too hazy near the horizon to see land, or any object distant more than four or five miles. Mocha is high, bold land, which in clear weather may be seen at thirty, forty, or even fifty miles distance; but soundings are no guide in its neighbourhood. They are irregular, and indeed not to be got, except very near the land.

A course was shaped for passing Santa Maria, and approaching the entrance of Concepcion Bay; and with a strong wind from W.N.W., the ship ran eight or nine knots an hour, under treble-reefed topsails, courses, and jib, steering N.b.E. until

© The Complete Work of Charles Darwin Online

eight o'clock, when it was thought prudent to haul to the wind until daylight. By many on board even this step was deemed unnecessary caution. Captain Seymour proposed putting her head to the south-west till daylight; but the master felt so confident of the ship's place, and so much disliked the idea of losing both time and ground, that his opinion was preferred, and her head was kept to the northward. About nine, or soon after that time, the Challenger was lying from N. to N. ½ E., going about four knots, under the sail before-mentioned. The wind had moderated; but a thick haze surrounded the ship, though the sky overhead was clear.

Captain Seymour had been walking the deck for some time, and had only just gone to his cabin, when a change in the appearance* of the water alongside, and an unusual motion of the ship, startled the officer of the watch, and induced him to order the 'helm' down and 'about ship,' while a midshipman was sent to tell the captain there was a suspicious alteration in the water. Just then breakers were seen by the look-out men and by the officer of the watch at the same moment; and as the captain flew up the ladder, (the ship coming round) he saw her position, and gave the order, 'mainsail haul,' as she was rising to a heavy rolling breaker. The after-yards swung round, but while bracing them up, she struck heavily; then 'hauling the head-yards,' and bracing up, she seemed to 'gather way;'—the foam alongside, from the recoiling waves, probably deceiving their eyes. A high breaking sea struck her bows—and astern upon the rocks, a helpless wreck, the proud Challenger was dashed.† Again, a great roller approached, threatening to overwhelm her; but it broke short, and only drenched her fore and aft with force sufficient to wash men overboard. While bracing-up, the topmen had been ordered aloft to shake the reefs out, and readily they went, without

* Lines of foam, and intervals of light-coloured water.

† When the ship was thus hove violently astern, her rudder, stern-post, dead-wood abaft, gun-room beams, cabin-deck, and many timbers, besides planking, crashed awfully as they broke at once before the resistless power of an ocean swell.

© The Complete Work of Charles Darwin Online

a moment's hesitation. They were, however, quickly recalled —a few moments sufficing to show that saving lives was all that could be attempted. Each succeeding sea drove the ship's stern higher than the bow* upon the shore, and along shore withal, inside some rocks, which partly deadened the fury of the great south-west swell, that rolls in directly against this part of the coast. That the sea did not break at first upon the hull of the vessel, and drive every thing before it, is accounted for by her position—with the bow to seaward—and by the defence afforded by a large rock near her bow which received the first shock of each wave.

Heavily the ship continued to beat upon the shore, reeling from side to side as seas struck her, yet her masts, though tottering at every shock, did not fall; nor did her strong hull yield to the continual striking, until hours had passed. Then, indeed, the rising of the tanks and contents of the hold showed that her frame had given way, and that the well-built Challenger would never float again. There was scarcely any wind; but the roar of the breakers and the clouds of spray would have almost stupified the crew, had not life been at stake. No land could be discerned till after the moon had risen—no one could even conjecture where the ship had struck, excepting only the master, who thought they must be on the Dormido shoal, off the island of Santa Maria. The purser collected the ship's papers, and saw them headed up in a water-tight cask: each person endeavoured to secure some valuable:—till daylight came further preparation would have availed nothing.

The captain was asked to cut away the masts; but he refused to let more than the mizen-mast be touched, because their weight, after the first few seas, steadied the ship, as she lay over, and prevented her rolling to seaward with the recoiling waves. When she first struck, he was asked to let go the anchors; another request which he wisely refused, rightly judging that having struck, anchoring could not improve their

* The peculiarity of her form—drawing as much water forward as she did abaft—may have been partly the cause of her bow remaining to seaward, which contributed so much to the preservation of lives.

© The Complete Work of Charles Darwin Online

condition, but might prevent their drifting past the rocks and nearer to the shore; both anchors, however, were kept in readiness, in case the water astern should deepen, which might have happened had they struck upon an isolated shoal, like the Dormido.

Soon after the moon rose, at about two in the morning, land was seen astern of the ship, not far distant. It seemed to be rather extensive, though not high; and as there was no longer any doubt of their having struck upon the mainland, better hopes of saving life relieved the torturing, anxious suspense they had hitherto endured. Daylight shewed them the shore on which they were. Near the ship lay an extensive sandy beach, and beyond it, gradually rising in the interior, a thickly wooded country appeared to reach to distant mountains. The mizen-mast was then used to form part of a raft; the jolly-boat was lowered over the stern; and in her Mr. A. Booth (mate), after a long struggle, reached the shore, with the end of the deep-sea lead-line. Mr. Gordon (midshipman), next tried to land in another boat, to assist in hauling a rope ashore, but the boat was upset, rolled over and over, and Mr. Gordon and one of the men were drowned. The other man was saved. Mr. Gordon was one of the most active and able young men of his age, and very much esteemed by all his shipmates.* His fellow-sufferer, John Edwards, was one of the best men in the ship.

A stream of tide or current, setting two or three knots an hour, along the shore, much increased the difficulty of reaching it, or of assisting those who were making the perilous attempt. Meanwhile, each succeeding heave of the sea forced the ship higher upon the sandy beach, and rendered the situation of those on board less critical.

The men who reached the land safely, hauled stouter ropes ashore with a line; rafts were then made; the large boats got overboard; the sick landed, and a party was sent ashore to protect them. A few Indians appeared at a distance, whose approach, with numbers of their countrymen, was a serious evil in prospect.

* He had anxiously sought to go in the first boat.

© The Complete Work of Charles Darwin Online

Before much had been done in landing stores, a great many Indians and some creole natives had assembled. Nearly all came on horseback, and many assisted in hauling the rafts ashore, or helping the people to land. Even the Indian women rode into the furious surf, and with their lassoes helped very materially: some took the boys up behind their saddles, and carried them ashore; others fixed their lassoes to the rafts. Thus instead of molesting the sufferers, these 'uncivilized barbarians' exerted themselves much for them. What a lesson to the 'wreckers' of some other coasts, whose inhabitants are called civilized!

But notwithstanding these friendly acts, Captain Seymour was too prudent to put confidence in the natives. He remembered the saying, 'Nunca, nunca fiarse à los Indios;' and forming a small encampment upon the beach, he barricaded it with spars, boats, casks, and other moveables.* There every thing was carried when landed, and put under care of the guard. All this day was anxiously occupied in landing stores and provisions. A small party remained on board; but the rest were on shore, during the night of the 20th.† Throughout the following days, some of the officers and all the men who were not on guard ashore, were constantly occupied in bringing provisions, ammunition, and stores from the wreck. Heavy and laborious as this duty proved, it was persevered in until every transportable article of value was removed. Two boat carronades were mounted on shore, which, with small arms and the barricade above mentioned, would have kept off a considerable force of Indians.

On the 21st, Lieutenant Collins and Mr. Lane (assistant-surgeon) set out to go to Concepcion: whence, directly after they arrived, Mr. Rouse set out, with horses and mules, taking such few useful things as he could carry, among which were two small tents, that had belonged to the Beagle, and were lent to Mr. Rouse, when his own house was shaken down by the destructive earthquake of February.

* The barricade was finished on the 25th.

† It was on this day that the Swede saw the unfortunate Challenger.

© The Complete Work of Charles Darwin Online

Wherever Mr. Rouse went he carried with him the thorough good-will and high respect of the inhabitants of the province of Concepcion—a feeling inestimably valuable at such a time, and totally different from the mere outward formal civility shown to him as the British consul! This feeling forwarded him on his journey, induced others to assist in earnest, and afterwards enabled him to procure a large supply of fresh provisions for the shipwrecked crew.

From Concepcion Lieutenant Collins went to Talcahuano, to hire a vessel. Only one fit for such a purpose was in the port, the Carmen, an American schooner, but her owner asked a price so utterly unreasonable, that the Lieutenant refused to engage with him, and returned to the wreck.

After Lieutenant Collins was despatched to Concepcion, Captain Seymour and the master went to examine the mouth of the river Leübu, about eighteen miles to the N.N.W. of Point Molguilla, where the ship struck. They found that boats might enter and leave the river with most winds; that there was no bar at the entrance; and that under Tucapel Heights* there was a spot very suitable for their encampment, until some means of embarkation should offer. Travelling overland so great a distance as to Concepcion, in such a country, would have been almost impracticable, except as a last resource; for it must have involved the total loss of every thing which they could not carry on their backs, and rendered useless the many days hard labour, in a raging surf, by which so much had been landed. It was therefore resolved, that as soon as all valuable stores which could be removed were landed, measures should be taken for shifting their camp to the Leübu.†

When the consul arrived his advice strengthened the opinion

* Immediately over the entrance of the river.

† While Captain Seymour was away at the Leübu, the officers availed themselves of the opportunity to get the greater part of his stores and private property, books, &c. landed; for he would not allow any of his own things to be moved, or a man to be employed about them, while an article of the ship's stores could be saved, though his private property was very valuable.

© The Complete Work of Charles Darwin Online

of Captain Seymour, and their immediate removal was decided upon. Though the Indians as yet had been inoffensive, Mr. Rouse had heard as he came of a large body who were approaching from the interior, and whose intentions he suspected to be hostile. The tribe then about Molguilla was that of an Indian cacique, in alliance with the Chilians, and therefore inclined to be civil, while the plunder was not very tempting, and while all the party were well armed and on the alert.

A few days after the ship was wrecked, this cacique gave a fine young heifer to Captain Seymour, who thanked him for his present, and expressed regret that any thing he could offer in return must be very trifling; when he was startled by a violent exclamation from the chieftain, who indignantly refused to accept any thing from men in distress. He would not take the paring of a nail from them, (biting his thumb-nail angrily as he spoke).

By Mr. Rouse's exertions and assistance, as interpreter and adviser, several yoke of oxen were procured, as well as many horses, mules, and donkeys; but even with such unhoped-for help, the removal of the heavy stores which had been saved was a tedious and difficult undertaking. Once established, however, at Leübu, they felt comparatively secure: tents were made out of sails; a palisade was fixed and a ditch dug: but the guns, spars, anchors, cables, and large boats, were left on the beach, as they were too heavy for removal overland; and to transport them by sea, from such an exposed coast, was out of the question.

Leaving their good ship a wreck upon the shore, in the hands of those who would soon destroy her, to get at the copper and iron, was to all a melancholy sensation. But the feelings of her captain at that moment—how little those who obeyed orders had to feel, compared with him who gave them!

On the 8th of June the wreck was abandoned: and the whole party were encamped at Leübu. Time passed away but no tidings of assistance arrived. Sickness began its insidious attacks: for cold wet weather had succeeded to a duration of fine dry days unusual at that time of year. Some of their

© The Complete Work of Charles Darwin Online

essential articles of provision were exhausted: inactivity and uncertainty were depressing the minds of all, and Captain Seymour had begun to concert measures for abandoning the ships' stores, which had been so painfully saved, and travelling overland to Concepcion, when the letters from Commodore Mason were given to him. It ought not to be forgotten that Mr. Rouse decided to remain with Captain Seymour, and share his fate, whatever plan he might adopt.

Among evils of magnitude trifling vexations are little noticed; an absolute plague of mice caused amusing occupation, rather than annoyance. The ground, the tents, their beds, everything and every place was infested by mice: nothing was safe from their teeth; provisions were hung up, and people were obliged to watch them. Hundreds were killed every hour, for they literally swarmed over all that part of the country, and curiously enough the old people attributed their appearance to the earthquake! Besides these mice, which had feet like those of a lizard, enabling them to climb in all directions, even along the smallest line or branch of a tree, there were animals that they called rats, about the encampment at Leübu, which deserve mention, not on account of their numbers (as there were comparatively few) but because they were formed like opossums, having a pouch to contain their young for some time after birth.

Early the next morning (24th) I went up with Captain Seymour to the heights of Tucapel, which overlook the river and command an extensive view of the sea. Flag-staffs had been erected there, and large piles of wood collected, in order that flags might be kept flying by day, and fires burning at night. The little camp below presented a regular and very respectable appearance: fourteen or fifteen tents, pitched in regular order, and surrounded by a palisade with a ditch, would have caused even a large body of Indians to hesitate before they attacked it. I was much struck by the strength of the position, and the ease with which it might be defended by a small force against numbers, and still maintain communication with the sea. There was formerly a small settlement there, called a

© The Complete Work of Charles Darwin Online

town, though in truth only a very small village: but latterly, the river Leübu has scarcely been noticed, except as the last retreat of the pirate Benavides. Nevertheless it is a situation admirably adapted for a commercial as well as agricultural settlement.

Though bread and other things were deficient, the shipwrecked party never knew the want of water, and they had always an abundant supply of a very fine kind of potato, which perhaps is hardly to be surpassed in size or quality by any in the world. Not one of the officers of the Challenger had seen its equal, and I never recollect eating any that were so good, and at the same time so large.* Neither beef nor mutton were scarce, in consequence of the 'credit' obtained by Mr. Rouse. Money was soon exhausted, but the high character of the consul was known all over the country, and the natives trusted implicitly to his word.

The report of a 'wreck' had quickly drawn numerous plunderers, even from Concepcion and Talcahuano: but those pilferers satisfied themselves secretly, I believe, without attempting any daring robbery. During the confusion of the first day no doubt much was stolen by Indians, and hidden in the neighbourhood: since many articles were sold to the Talcahuano people for spirits or tobacco, and being taken by them to that place, occasioned a report of the officers and crew having been stripped and plundered.

But it must not be supposed that Captain Seymour and his officers had no internal troubles, and that strangers were their only foes. Shameful acts of robbery were committed by some of the Challenger's own party: a very few of her marines scrupling not to rifle chests and boxes belonging to officers. This conduct, in connexion with a spirit of insubordination which began to show itself, among some of those who knew Captain Seymour the least, occasioned his calling the crew together on the beach, and causing one man to be corporally punished.

* The officers of the Blonde were of a similar opinion, after trying a great many that were sent on board from the Leübu.

© The Complete Work of Charles Darwin Online

On this trying occasion Captain Seymour animadverted on the thoughtless conduct of a few who talked of what ought to be done, as if they were on equal terms with those whose authority at such a time was more than ever necessary; and who, in their unguarded conversations, heeded not who was listening, or which of their inferiors might be influenced by their opinions. He reminded them of the treacherous and often hostile disposition of those Indians who then surrounded them, and were daily increasing in numbers; and made known not only his own determination to stay by the stores, at all hazards, but that those who attempted to desert should do so at the peril of their lives. He well knew that the majority (and that majority included all the worthiest and best) would stand by him to the last, and think little of difficulties or dangers incurred in doing their duty.

After this well-timed public admonition not a word more was heard about "abandoning the stores, and making the best of the way to Concepcion." Neither was there again occasion to inflict punishment. This one act of necessary justice, executed so properly and decidedly, was probably the means of saving much property, of upholding character, and even of preserving many lives: for when once anarchy begins, who can foretel all its consequences?

Anxious to return as soon as possible to tell the Commodore how easily the Blonde might take off both people and stores, at the mouth of the Leübu, that he might lose no time in effecting the embarkation—I recrossed the river and was galloping towards Quiapo, before noon (on the 24th) hoping to reach Arauco ere midnight; and, certain of fresh horses, I and my two companions spared neither whip nor spur. Our guide dropped behind, but as we could find the path by our tracks of the previous day, we did not wait for him. Such ravines (quebradas) as we passed: how we got through them during the black darkness of the preceding night astonished me, for we could hardly scramble along in broad daylight: and had I known the nature of those passes, I certainly should not have tried to get through, excepting by day.

© The Complete Work of Charles Darwin Online

At Quiapo we had a mixture of corn and water, which I thought tolerably good. It is a common mess among the lower class of natives in many countries besides Chile.* A few handfuls of roasted corn, roughly pounded between two stones, were put into a cow's horn, half full of cold water, and well stirred about with a stick until changed into a substantial mess of cold porridge. Our haste shortened the journey, and we should have reached Arauco in good time, had not a second guide (the man who waited at Quiapo with the Arauco horses) mistaken the road, and taken us along a track which was crossed by two rivers, not then fordable. His error was not discovered until too late, and to pass the rivers we were obliged to make a delay of several hours. The tract of country we traversed this day, was as fine as any that I have attempted to describe. I do not think we rode over or even saw an acre of unproductive land. The woody districts were very pleasing to the eye, and as specimens of a rich and fertile country almost in a state of nature, equally so to the mind. In many places our road lay through an open forest, where fine trees stood at considerable distances apart, and not being surrounded by underwood allowed us to gallop between them as we pleased. I thought of England's forests in the 'olden time.'

In one of the quiet woodland glades we passed through, some of the finest cattle I ever saw were grazing. One immense animal would have attracted admiration, even by the side of show-cattle in England. Very large, well-shaped, and extremely fat, he looked and moved as if few things had ever caused him to turn against his will. These cattle have owners, I was told, but are seldom molested: once perhaps in some years a large number may be killed for the sake of their hides and tallow; and even then so extensive and so little known are these woods, that a considerable proportion of the cattle are not seen by their indolent destroyers, nor yet at the almost nominal musters which take place annually. The

* Among the Araucanian aborigines it is made with maize, and called ulpu.

© The Complete Work of Charles Darwin Online

soil being usually of a tenacious, clayey nature, and streams of water numerous, moisture sufficient for vegetation is ensured, even at the dryest periods. Indeed, these countries never have suffered from drought; their climate being a happy mean between the dry, parching heat of Northern Chile, or Peru, and the continual wet, wind, and chilliness of Chiloe.

The first river we had to cross was not more than fifty feet wide, but the banks were hollow and rotten. Our guide looked along the stream till he found a tree which had fallen across, so as to form a bridge over two-thirds of the width: and with a pole in his hand, he climbed as far as the boughs would bear him: then finding that the water beneath was not above his middle, he waded through the remainder. Unsaddling, we sent all the gear across by help of the tree and lassoes, and turned the horses over, much against their will, for they had to plunge in and scramble out.

Again using our spurs, we hoped to pass the second river also before dark, but in vain; there was only just daylight enough left to see that it had overflowed its banks, and seemed to be wide and rapid. Even Vogelborg thought it impossible to cross before the next morning, so we turned back to look for some hut in which we might obtain shelter from heavy rain, which was beginning to pour down. The night was very dark and our prospect rather comfortless, when we were fortunate enough to find a 'rancho,' and there we gladly took refuge. Its owners were absent at a merry-making in the 'neighbourhood' (about twenty miles off!); their daughters, however, and an Indian captive (from Boroa) were not deficient in hospitality. Poor girls! they were rather frightened at first, at their house being so suddenly occupied, but our guide quieted their alarm. As soon as the horses were provided for, we looked about for food for ourselves, and could find nothing but potatoes, till, hearing Vogelborg call for help in his broken English, I ran to him thinking he was hurt or attacked. He was struggling with a sheep which he had caught, and was dragging to the hut. Greatly were the poor girls alarmed when they saw that the sheep was to be sacrificed; they ex-

© The Complete Work of Charles Darwin Online

claimed that their father would beat them terribly, that the sheep was worth eight rials!* A dollar for the sheep, and another for each of themselves, altered their tone; and before long we had such a fire and supper as the old 'rancho' had not witnessed since the wedding-day of its owners.

But what a night of penance we passed—the place swarmed with fleas, not one moment could I rest, though very tired; and it was raining too hard, and was too cold to sleep outside in the open air. These insects are the torment of travellers in Chile. The natives appear either not to feel, or not to be attacked by them, but an unlucky stranger who ventures to sleep within the walls of an inferior kind of house, or even any country house, in Chile, is sure to be their victim. When I stripped to bathe the next day, I found myself so covered, from head to foot, with flea-bites, that I seemed to have a violent rash, or the scarlet fever.

As the day broke (on the 25th) we mounted our horses, eager to get away from such unceasing tormentors: and the Indian girl undertook to show us a place where we might pass the river, even flooded as it was. By the help of fallen trees, lassoes, and poles, we conveyed ourselves and the saddles across; but to get the horses over was very difficult. The stream being rather wide and rapid, and the banks steep and rotten, occasioned so much difficulty, that two whole hours were spent in getting the animals across and out of the river. Our united strength applied to good lassoes, was barely sufficient to help the struggling and frightened creatures up the muddy broken banks. When one had passed, the others followed in their turns more readily; but I thought we should have lost one of them. From this river to Arauco was not above an hour's ride, at the pace we went, though it is called seven leagues.

During the last two days I had seen several Indians of pure Araucanian blood, in their native dress, and was much struck by the precise similarity of that worn by the women, to the dress of the aborigines of Peru, as described and figured in Frezier's voyage. The square cloak, or mantle, thrown over the shoulders,

* Or a dollar, equal to about four shillings.

© The Complete Work of Charles Darwin Online

and fastened in front by a pin with a very large flat head, the size of a dollar, or even the palm of a hand; the broad band round the waist ornamented with beads; and the beaded or brass ornaments in the hair, ears, and round the neck, caught my eye sooner than their features, which are so similar to those of the almost Indian breed who live on the borders, that at first sight the difference was hardly noticed. Perhaps the eye of one of those Indians who has never lived with civilized people, is the only feature which differs strikingly: so much have the lower classes of Chilian creoles mixed with the aborigines. In the eye of a free, wandering Indian, there is a restless suspiciousness, which reminds one of the eye of a wild animal: but this peculiar expression is soon removed by civilization.

The clothing of the Araucanians, made by themselves, is very strong good cloth. Indian ponchoes will keep out rain longer than any others. Dark blue is the usual colour of their clothes, from ponchoes to petticoats; and they are all of woollen manufacture.

The women dress their hair with some pains, and ornament it with beads, bits of brass, or large-headed pins, such as those I have described. Some few have ornaments of gold: and to see an Indian woman dressed in her national costume, with large golden ornaments, quite transports the imagination to the days of Cortes and Pizarro. I saw but one so ornamented, a fine-looking young woman, the daughter of a cacique, who had accompanied some of her tribe to look at the ship-wrecked white men. Her horse was a beautiful animal, looking as wild as herself.

At Arauco the worthy colonel welcomed me to breakfast, but regretted that I had been prevented from proceeding to the wreck: he thought some accident had happened, and hardly could believe that we had actually passed a night at the Leübu. D. Geronimo told me he had received intelligence of a large body of Indians, about three thousand strong, who were marching northward against Colipi, and his allies, the Chilians. He thought it probable that they would molest the Chal-

© The Complete Work of Charles Darwin Online

lenger's people, for the sake of plunder as well as because they had been on friendly terms with Colipi.

This hostile tribe, whose visit he was anticipating, was that called 'Boroanos,' by the Chilians ('Boroa-che,' by the Indians). I have before said that in Boroa there are fair Indians; and that I saw, when at Valdivia, one of the natives of that district. The Indian girl, whom I mentioned just now as a captive, agreed exactly in what she stated of them, with the account I had previously heard. She and the 'Boroana' at Valdivia both said, that "their fathers had told them that the 'rubios' (meaning red and white, or red-haired people) were children of the women whom their ancestors took prisoners when they destroyed the seven cities." Many of these 'rubios' had blue eyes, with rather fair complexions; and some few had red hair. If this is the true story, they must be gradually losing such striking peculiarities; and the assertion made a century ago that there were white Indians in Araucania, might well be thought erroneous now. Both of the 'Boroanos' whom I saw had dark blue or grey eyes, and a lighter complexion than other Indians; but their features were similar to those of their countrywomen, and they had long black hair.

In our way to Arauco this morning, we passed by Tubul, a place admirably adapted for a large town, but now occupied only by a few poor families living in huts. Hills surround a fine plain, through which the river Tubul winds to the sea: lying in that river, I saw the remains of a whaler (the Hersilia) captured by Benavides, when at anchor near the island of Santa Maria.* She was brought into the Tubul, plundered, and partly burned.

Some years ago, ships of two hundred tons could enter the mouth of this river, and pass up nearly a mile; but the late earthquake had raised the land so much, that only very small vessels could enter at this time. May not changes of relative level, similar to this, have occurred at the rivers

* Captain Hall's Journal, vol. i. p. 312-13.

© The Complete Work of Charles Darwin Online

Cauten, Tolten, and Bueno? The Cauten, or Imperial, is spoken of by the earlier writers on Chile, as admitting ships of burthen; but now the entrance of each of those rivers is almost closed by a bar.

In opposition to this idea it may be urged, that where a large river runs into the sea exactly against the direction of the prevailing wind and swell, a bar of sand, shingle, and mud must be formed by deposition from the opposing waters; and that it is only where a river runs uninterruptedly into the sea, protected from wind and swell by a projecting islet or point of land, that a perfectly clear entrance may be expected; and, therefore, that the Spanish accounts must have been incorrect. I suspect that they described those rivers as they found them at some distance in-land, not at the mouth.

Leaving the hospitable colonel assembling a remarkably awkward squad, whom he was anxiously preparing for the threatened attack of the 'Boroanos,' we rode away upon the good horses which, three days previously, had brought us from Concepcion.

At the Carampangue there was no balsa. What was to be done? To wait until some one brought a boat from the opposite shore might expend the day; but the river was wide and deep, and the weather too cold for so long a swim: nevertheless, five dollars excited our guide, or rather horse-keeper, to make the trial, and during several minutes I thought he must have been drowned: for, instead of slipping off the horse, and holding by the mane or tail when he began to swim, the man sat bolt upright, so that the poor horse's head was scarcely visible; and both horse and man appeared to get confused, turning round in the stream two or three times, while the current was carrying them down the river. At last they struggled out, to my infinite joy, and galloped off in search of the men whose business it was to attend at the ferry with a balsa. While we were anxiously waiting, a large party appeared on the opposite bank, with whom were the balsa-men. They had been merry-making, the previous day having been the feast of St. John; and as they had hardly recovered from the effects of 'chicha,'

© The Complete Work of Charles Darwin Online

and other favourite libations, to carry so large a number across upon a small raft, was a difficult undertaking. Talking at the pitch of their voices, laughing and tumbling about, their reaching the opposite shore without a cold-bath, was attributed by Vogelborg to the protection of the saint whose anniversary they had so dutifully celebrated. The 'chicha,'* is sometimes fermented, and then soon affects a person's head, if drank to excess: but these votaries of St. John had doubtless improved its insipid taste by aguardiente. During the chicha season, or autumn, the Indians are said to be more dangerous than at other times, as they indulge in this, their favourite beverage, to excess.

Apple trees are now abundant in southern Chile, throughout the Indian as well as Spanish territories. They were also plentiful on the eastern side of the Andes, particularly about the river Negro and the great lake 'Nahuelhuapi,' in the middle of the last century. Whether they are indigenous, or were planted by the early missionaries, has been much disputed in that country; but as the Indian name for them is 'manchana,'† I should incline to think they were introduced by the first missionaries.

Our road over the heights of Villagran was much worse than at our former passage. Heavy rain and constant traffic, in consequence of the wreck, had worn it into a curious succession of steps: and each animal endeavouring to place his feet in the holes made by those which had previously passed—the rain having filled up the hollows with mud and water—had worked the clayey track into a continuation of transverse ridges and trenches. A man might step from ridge to ridge without wetting his feet; but the horses always planted their legs, up to the knees and hocks, in the mud and water of the trenches. Their motion was just as if they were stepping over logs of timber: unpleasant enough for the rider, and extremely tiring to themselves. We helped them however as much as possible, to the surprise of our lazy guide, by dismounting and leading them up the hills as well as down.

* 'Chicha' is made with maize, apples, or other things.

† Manzana is Spanish for apple.

© The Complete Work of Charles Darwin Online

We reached 'Playa Blanca' as it got dusk. The heights near Point Coronel were difficult, in the dark, but we passed without worse disaster than a roll in the mud, from my girths breaking while struggling in a slough. Along the level lands of Don Juan de Dios Rivera we galloped briskly, until we were completely bewildered in the darkness. At last we found ourselves among enclosures, and by pulling up rails and breaking fences, made our way to a farm-house, where such information was obtained as enabled us to reach San Pedro, on the south bank of the Bio Bio, soon after midnight. No inducement could prevail upon the owner of the ferry-boat to let her take us across before daylight, so we sat down by a fire, after feeding our excellent horses, and dozed till daybreak.

With the first dawn we drove the lazy boatmen to their barge, urging them alternately with money, entreaties, reproaches, and threats. The river was exceedingly swollen by late heavy rains, so that it was almost twice as wide, and quite as rapid, as usual. Our heavy ferry-boat was 'tracked' up it until it seemed possible for us to reach the other bank before the current swept us out to sea; but the appearance of the boat and men, and the utter uncertainty caused by a very thick fog, gave me no great hopes of reaching Concepcion in any reasonable time, though a vivid expectation of passing a few hours upon a sand-bank at the mouth of the river, if we escaped being hurried into the open sea. In this clumsily-built, flat-bottomed boat (a sort of large punt) were five horses, a troublesome young bull, six men, and three nominal boatmen, one of whom merely attempted to steer. With very long poles our unwieldy craft was pushed into the stream, and while the shore could be distinguished through the fog, made progress in a proper direction, though most crab-like was the movement. When fairly out of sight of land, the boatmen became alarmed and puzzled; but just then a large bell was heard tolling at Concepcion, which served to animate them, and to ensure our trying to go in the right direction. After an hour's unpleasant work, in a very cold morning, we landed about a mile below Concepcion, having started about as much above it on the oppo-

© The Complete Work of Charles Darwin Online

site side. No time was then lost in galloping to Talcahuano, and going on board the Blonde, so that Captain Seymour's letter was delivered to Commodore Mason soon after ten.

I found that the commodore had engaged an American schooner* to go in search of the crew of the Challenger; and that Mr. Usborne had been sent in her, with the second master of the Blonde,† three seamen of that ship, my coxswain, and the whale-boat which I took from the Beagle; she was a poor craft, and wretchedly found, though reputed to have sailed well, and to have been a fine vessel in her time. They left Talcahuano on the day after a gale from the north-west (on the 24th), which, by all accounts, was one of the severest that had been experienced during many years.

The Blonde sailed from Concepcion Bay on the 27th, the morning after I arrived; but unfortunately, during all that day, thick weather and half a gale of wind from the northward, prevented our having even one glimpse of the land, as we were running towards the entrance of the Leübu.

On the 28th, thick weather kept us in the offing. On the 29th, at daylight, the schooner Carmen was seen, and soon afterwards, through the haze, we made out Tucapel Head. At this time, neither Vogelborg (who was on board as local pilot) nor I, knew that the Heights of Tucapel Viejo were identical with the headland we recognized by the name of Tucapel Head. We both thought that Tucapel Viejo was in the bay where the river 'Lebo' is placed in the old Spanish charts. This error appears almost unaccountable to me now; though both he and I were then drawn into it by a variety of reasons unnecessary to detail here, and we therefore advised the commodore to run along-shore towards the supposed place of the Leübu (or Lebo), which he did; but the weather was so unfavourable, so thick and hazy, that nothing could be seen distinctly. Scarcely indeed could we discern the line of the surf, heavily as it was beating upon the shore; and at noon we were obliged to haul off, on account of wind and rain.

* The Carmen; for which such exorbitant demands had been made in answer to Lieutenant Collins. † Mr. Biddlecombe.

© The Complete Work of Charles Darwin Online

I should have mentioned that we spoke the schooner at eight in the morning, when Mr. Usborne said they had seen nothing in their run along-shore on the 26th, the only clear day they had had. After speaking us, he kept to the northward, intending, as we concluded, to close the land about Tucapel Head, and again run along-shore to the southward. In the haze we quickly lost sight of the schooner; but thinking that we should soon meet again in clearer weather, little notice was taken of this circumstance, which was afterwards so much regretted. Continual thick weather prevented any observations being taken, as well as the land from being seen, until the 2d of July, when Tucapel Head was indistinctly made out in the distance. But strong wind and a high swell were reasons sufficient to keep the Blonde far in the offing, while thick hazy weather lasted; and after making the land we actually stood to sea again, without even attempting to show the ship to the poor fellows on shore. In the course of this night a few stars were seen; and their altitudes were the only observations that could have been obtained at any moment since we left Concepcion Bay, during six days of constantly clouded and hazy weather, in which neither sun, moon, nor stars, nor even the horizon could be seen!

On the 3d, Tucapel Head was again made out indistinctly; but nothing was done, a wide offing being still preserved.

On the 4th, the weather had improved enough to allow of a partial view of the coast between the supposed place of the Leübu and Cape Tirua; but no signal-fire, nor any thing like a flag, could be perceived on any of the heights.

Land appears so different when viewed from an offing at sea and when seen closely, especially from the land side, that it is less surprising that Vogelberg, who had visited the Leübu dozens of times by land, and also by sea in a boat, should be as much at a loss as myself to recognise the height which we had both ascended with Captain Seymour.

How it happened that I, who had surveyed this coast, should be ignorant of the real place of the Leübu, as I then certainly was, is another affair entirely, and one which I feel bound to

© The Complete Work of Charles Darwin Online

explain. A momentary reference to my instructions shows that the Beagle was only expected to "correct the outline, and to fix the positions of all the salient points"* of the coast between Chiloé and Topocalma (near Valparaiso); and the Beagle's charts of that coast prove that a great deal more was accomplished than was thought practicable when those instructions were framed.

Between Cape Tirua opposite Mocha, and Tucapel Head, the shore was laid down on our chart as determined by triangulation connected with the ship under sail, her distance from the land varying from one mile to five miles; and as no river was seen thereabouts, nor any break in the coast-line where a river's mouth could be, our chart contained merely a note, saying, "River Lebo, according to the Spanish chart." Now, the erroneous place of this Lebo (meant for Leübu) was twenty miles south of the real position, which, shut in behind Tucapel Head, could never have been seen from any vessel sailing past, however near the shore she might have been. The coast-line in the Beagle's chart was proved to be perfectly correct; but the place of the Leübu, which could only have been obtained by landing, or having a local pilot on board, was not known; and not being a navigable river, I did not deem it of sufficient consequence to be worth our delaying on an exposed coast, without an anchorage or a landing-place—so far as I then knew—while it was sought for.

Considering the multiplicity of places the Beagle had to visit subsequently, I often found it necessary to sacrifice such details as seemed to me of least consequence. Every seaman knows how very difficult it is to make out the openings of some small rivers, while he is sailing along a coast little known, and all marine surveyors know that there is seldom any way of making sure of such openings without landing; or entering them in a boat. I do not say this to excuse neglect—not feeling culpable—but simply to explain how the case stood.

On each day, when near the land, guns were fired at intervals, and sometimes three or four were fired at once; blue

* Hydrographer's Memorandum, p. 31.

© The Complete Work of Charles Darwin Online

lights also were occasionally burned during the nights, in hopes that the schooner might see them.

On the 5th of July, the day broke clearly for the first time during the longest week I ever passed, and we saw the land distinctly, from Cape Rumena to Tirua, with Mocha Island, strange to say, for the first time—near it as we had often been. Now that the tops of the hills were quite free from fog or cloud, I recognised the Heights of Tucapel at the first glance; and after looking for some minutes at their summits, through a good glass, I distinctly saw smoke rising. Standing towards them—in half an hour flags were discerned on the heights, and there was no longer any doubt; yet no steps were taken until near one o'clock, though it was a beautiful, and almost calm day. From nine in the morning until one, the Blonde lay almost becalmed, about five miles from the land. At one, three boats were sent to the mouth of the Leübu, with some money and a small supply of bread; but a current setting along the shore from the northward delayed their reaching the entrance of the river until evening.

We found the greater part of the Challenger's crew still in health; but delay and bad weather had increased the sick-list, and two of her party (the assistant-surgeon and a young midshipman) were in danger: waiting so long in uncertainty, and without employment, in a wet, dirty place, had tried all their constitutions severely. It was too late to attempt going out into the offing after the Blonde, (which was standing to sea) with the gig and cutter, two indifferent boats; so manning the barge with a double crew, one crew being men of the Challenger, and taking one of her officers (Lieutenant Collins) with me, I hastened out of the river as the sun was setting. A light breeze from the land favoured us, and though the Blonde was hull down in the south-west when we started, we were happy enough to get on board at about eight o'clock.

In going off to the ship after it became dark, we kept the end of a piece of old gun-breeching burning, held up in the bow of the boat. The light, as strong almost as that of a false fire, was seen plainly on board the ship, and then she was hove-to.

© The Complete Work of Charles Darwin Online

As soon as the barge was hoisted in, the frigate again made sail off shore; but a fortunate mistake caused the main-yard to be squared about midnight, and at daybreak next morning we were in a good position off the entrance of the river. The Blonde then steered towards the land, and at nine anchored near the River Leübu, about a mile from Tucapel Head. Every boat was hoisted out, and the work of embarkation proceeded rapidly. Though a swell made the ship roll heavily, and delayed the boats along-side, the weather was so fine and a south-east wind so favourable, that the quickness of going and returning made amends for some delay in discharging each cargo. At six in the evening, Captain Seymour came on board with the last party of his crew, and at eight, the Blonde weighed and made sail, before a fresh and favourable breeze.

Most of the tents remained standing, being of very little value, and some of the stores were left. For what was abandoned, both there and at Molguilla, the commodore appointed Vogelborg to be agent, leaving him on the spot to take charge: and he wisely asked one of the Chilians who lived in the neighbourhood, and had generally supplied the shipwrecked crew with provisions, to join him in his undertaking. Between them they might have recovered many things of value to individuals, but, to the British Government, nothing worth the great expense of carriage to Concepcion.

Mr. Rouse sent his servants back by land, with his horses and mules, and accompanied his esteemed friend, Captain Seymour, in the Blonde. The numerous Indians and others whom we left gathering round the encampment, in all probability saved Vogelborg and his partner the trouble of taking care of much of the property. They reminded me of the vultures which in those countries gather round the places where men are slaughtering cattle.

During the night of the 6th, the Blonde passed rapidly northward, running before a fresh southerly breeze; and at eleven in the morning of the 7th, she was off Point Tumbes, when seeing a dismasted vessel, with an English blue ensign hoisted, about five miles to the northward of us, the frigate stood towards

© The Complete Work of Charles Darwin Online

her, and finding that she was the schooner Carmen, closed and took her in tow. But for the Blonde's opportune arrival, she would have been drifted to the northward, and obliged to run into any port she could reach. Mr. Usborne came on board, and as soon as he had refreshed himself by a few hours' sleep, gave me the following account of his proceedings and accidents.

After leaving Talcahuano, wind and weather favoured the Carmen until she had run along the coast from Tucapel Head to Cape Tirua, at about a mile from the surf, without seeing either smoke, flags, people, or wreck; but, during one night, a fire was seen on Tucapel Head. When Mr. Usborne spoke the Blonde, on the morning of the 29th, the schooner was on her way to the place where she had seen the fire; and he would have said so when the Blonde hailed him had he had time, but as she passed on without stopping, and he felt sure that the Challenger's people were not in the direction which she was taking, he kept a different course. At about two in the afternoon of that day, while four seamen were aloft on the topsail yard, furling the topsail, the schooner gave a sudden plunge into a high swell, and away went the foremast head, fore-topmast, and topsail-yard. The four men were carried overboard, but saved; though one (James Bennett) was severely bruised. The mainmast followed, being dragged downwards and broken by the rigging attached to the head of the foremast; and in this state, a mere wreck, the Carmen drifted towards Mocha. So wretchedly was the vessel provided in every way, that the only tools which they had to cut the laniards of the rigging with, were knives and a cooper's old adze.

After clearing the wreck, they got up a small spar abaft, on which was set the Beagle's boat's sail; and by means of cleats,* Bennett and J. Nutcher (boatswain's mate of the Blonde), got to the head of the stump of the foremast, although, being loose in the step, it swayed to and fro as if it would go overboard, and fixed temporary rigging. A staysail and trysail were then set, and just saved her from going ashore upon the wea-

* To secure these cleats to the mast, they were obliged to draw nails out of the vessel's beams, having no others.

© The Complete Work of Charles Darwin Online

ther side of Mocha, while it was blowing hard, with a high sea running; and in all probability, not one person would have been saved had she struck. If Mr. Usborne had not known this land well, from his late survey, it is not likely that they would have escaped, because when they found themselves about half a mile from the breakers, the tack which appeared to the others to be by far the best, was in truth the worst: had they gone on that tack, nothing could have saved them. Mr. Usborne saw their position exactly, and knowing how the current would affect them, determined upon what they thought the wrong tack, and rescued them. I say that Mr. Usborne did this; because Mr. Biddlecombe was sick, and the master of the vessel reluctantly yielded to the person who he saw was at home, while he himself was utterly bewildered.

After this narrow escape, the schooner was drifted to the southward, as far as the latitude of Valdivia, before the southerly wind, which took the Blonde to the mouth of the Leübu, drove the Carmen back slowly to the northward. Mr. Usborne and his companions had almost entered the opening of the Bay of Concepcion early in the morning of the day on which the Blonde took them in tow, but had been drifted away again by a fresh wind, and were falling to leeward fast, for want of sail, when the Blonde arrived. Mr. Usborne recovered from his fatigue in two or three days, but Bennett was ill for a fortnight.

During the few days they were away, they suffered much. As for the ten men belonging to the vessel, they were utterly useless, being frightened or sick during the whole time; so that but for the exertion of the Blonde's seamen, of Bennett, of the master of the vessel (Mr. Thayer), of Mr. Biddlecombe, and above all, Mr. Usborne, the Carmen might have left her remains on the shore, when perhaps few, if any, would have survived to tell the fatal tale.*

The Blonde worked to windward, with the schooner in tow, during the remainder of the day and early part of the night, and at midnight they both anchored off Talcahuano.

* Mr. Usborne's narrative of this affair is in the Appendix, No. 27.

© The Complete Work of Charles Darwin Online

Until the 10th, it was necessary to remain at anchor, as there were accounts to settle between the commodore, the consul, the pursers, the officers, and the owner of the schooner; there were visits to the Authorities, to thank them for their assistance, and, as usual on board men-of-war, there was much to do in very little time. To Don José Alemparte, the yntendente of the province; to Colonel Boza, the principal military authority; to D. Miguel Bayon, the governor of Talcahuano; and to Don Pablo Delano, captain of the port, sincere thanks were really due for their earnest exertions. Mr. Rouse took his leave of us on the 10th, and we then sailed.

While the Blonde was lying off Talcahuano, I had a few opportunities of looking about, and seeing that both Concepcion and Talcahuano were rising out of their ruins, and that their unfortunate inhabitants had, at least, roofs over their heads. Concepcion was, and is still nominally, a city: but it will be long before it again appears as such to the eye of a stranger. Some idea may be formed of the low scale to which every thing was there reduced, when I mention that it was very difficult to find a carriage of any kind in which the Commodore could go to visit the Yntendente.

Great discussions had arisen on the subject of rebuilding the city. The government party wished to remove the site to a better position; but there was so strong an opposition, that the result was likely to be the gradual rebuilding of the town in the same place, while the removal was still undecided, and under consideration. Two situations were named as much more eligible than the former: one on the banks of the little river Andalien, about a mile from the old city; and the other, on a rising ground about two miles on the Talcahuano side of Concepcion. This latter position has many and great advantages, as all acknowledged; but people were reluctant to move; each one had or fancied an advantage in the old situation of his house, encumbered as it was with ruins. Besides, many more serious difficulties would arise in leaving small freeholds, and obtaining equivalents in another place: however, an active government might have accomplished so desirable a change without injuring

© The Complete Work of Charles Darwin Online

any one, by purchasing the ground, and distributing it so fairly that each man should gain rather than lose. The sum necessary for purchasing ground for a new city, would not have been greater than might have been borrowed; and repaid in ten years out of the custom-house.

Perhaps there is not a situation in the world much more advantageous to the prosperity of a commercial city than this of which we are speaking. Centrally placed between the great and navigable river Bio Bio, the port of San Vicente, the noble bay of Concepcion, and an easy communication by land with the best part of Chile, a part which may well be called one of the finest countries in the world:—with a large extent of level and fertile land on all sides—with the means of obtaining water by sinking wells to a small depth, as well as by an aqueduct from the Bio Bio—and with the blessing of an unexceptionable climate—how could the New Concepcion fail to thrive, and increase rapidly? It might be shaken down and destroyed by an earthquake as soon as built, may be said. Probably, may be replied, if the inhabitants should be so unwise as to build houses of brick and stone, one or two stories in height, and with heavily tiled roofs. But let them try another mode of building. Wood is abundant, and let them make that the only material of which either walls or roofs shall be composed. A strong frame-work, similar in some measure to that of a ship, lightly covered or ceiled with thin planks, and roofed with shingles,* would, if placed on the ground and not let into it as foundations usually are, withstand the convulsions of any earthquake which has yet happened in that tormented country. Why do not the Chilians pay more attention to the remark of the aborigines of Peru, who, when they saw the Spaniards digging deep foundations for their buildings, said, "You are building your own sepulchres?"†

The houses of the natives of Peru were in those days built without foundations, simply upon the levelled ground; and they withstood the severest shocks. No house should extend far

* Small pieces of wood, like tiles. † Ulloa, vol. i. p. 340.

© The Complete Work of Charles Darwin Online

upwards. Nothing should be above the ground floor but a light strongly-secured wooden roof: and they should be placed upon firm ground—if possible, upon rock. The principal objections against the present site of Concepcion are—that the earth upon which the houses stand is every where loose, and sandy, and that it is too near the river.

One day, while visiting a gentleman at Talcahuano, he called three little Araucanian boys into the room where Mr. Rouse and I were sitting with him, and desired them to harangue or make speeches to one another in their own way. The little fellows stepped forward boldly, and one of them spoke to the other two in a very fluent and expressive manner; but ended every marked sentence, or portion of his subject, by the singular sharp rise of the voice which has so often been noticed as a peculiarity in the oratory of Indians in this country. Another boy replied in a similar manner; and then they began to fight with their fists. This part of the display of course we stopped; but we were much interested by the composure and readiness with which the little boys spoke. One of the speakers was son of a cacique. All three had been obtained by actual (though secret) purchase from their countrymen, through the intervention of one of the 'Capitanes de los Amigos,'* one of whose offices is to take the part of and protect the natives. Perhaps, in the first instance, these boys had been stolen or taken prisoners, and were not the children of those who sold them to the 'captain of the friends.' In the family of Don —— those boys found a comfortable and a happy home; he had taken them from the rascally 'capitan de los amigos' as an act of charity, and intended to give them employment and land on his estate. I thought of Lautaro, as I noticed the bright eye of the little cacique.

When I took leave of the Yntendente, he said that he was about to make a journey to the frontier, for the sake of inspecting the outposts and securing the assistance of the friendly Indians: and this, I afterwards understood, was in consequence

* See page 399.

© The Complete Work of Charles Darwin Online

of the rumoured approach of those hostile tribes of whom Colonel Valenzuela had spoken to me at Arauco.

We sailed from Talcahuano with a fair wind, which carried us quickly and pleasantly along-shore; but crowded, and anxious as we were, the ship could not go fast enough for us. The sick people, excepting Mr. Lane, were improving when we reached Valparaiso on the 13th. Much attention and kindness were shown to Captain Seymour by his acquaintance at Valparaiso; but it could not be expected that he should be cheerful, or inclined to see people, excepting intimate friends, at that time; particularly as the death of Mr. Lane was an additional blow much felt by him. I was very glad when we weighed anchor, on the 17th, for every hour caused an increase of painful feeling.

A fresh fair wind drove us in twenty-four hours to Coquimbo, where the Conway was at anchor ready for sea. It was then arranged, that all the officers and two-thirds of the crew should go home in the Conway; and, of course, no small bustle of preparation for so many passengers was caused. Captain* and Mrs. White already occupied one-half of the captain's cabin, and their luggage a considerable space below; but as both Captain Eden and the senior lieutenant, Johnstone, were bent upon accommodating the ship-wrecked party to the utmost of their power, stowage-room was cleverly contrived.

How striking the contrast appeared between the fertility and verdure of the Concepcion country, and the dry barrenness of the naked earth or rocks about Coquimbo. Scarcely any one went on shore; a mixture of unpleasant feelings occasioned a gloomy heaviness in most of our minds.

On the 22d, both ships sailed from Coquimbo, and soon afterwards parted company. The Conway stood to the westward, 'close-hauled;' while the Blonde steered towards the north with a fresh southerly wind.

What caused the loss of the Challenger?—is a question not easy to answer with certainty. The error in her reckoning

* Then Vice-Consul at Valparaiso.

© The Complete Work of Charles Darwin Online

amounted to more than forty miles; and the only way in which I can account for it to my own satisfaction is, that while the north-west wind was blowing, a current set to the southward and eastward, for which no allowance was made, as those on board could not be aware that such a current might be found, its existence not being known. A south-east current was not to be expected thereabouts; for the general set of the waters is northerly, excepting near the land, and they thought themselves in the offing. But currents are very uncertain and treacherous in most places. Unusual winds, peculiar seasons affecting the weight of the atmosphere, and those powerful interrupters of all order—earthquakes, have immediate effect upon the great ocean, as well as upon small bodies of water, though not always so visibly.

Scarcely four months had elapsed since that tremendous earthquake, which destroyed so many towns in Chile, had altered the movements of the Pacific Ocean upon all the extent of coast which reaches from latitude forty-five to the parallel of twenty-five. Even in July, the land about Concepcion was scarcely considered to be at rest, and recovered, as it was said, from those awful convulsions. Can it then be considered improbable that the currents of that sea should have taken unusual directions, and betrayed even cautious seamen, such as Captain Seymour and Mr. Macdonald (the master) were well known to be. So much care and judgment had always been shown in conducting the Challenger, and she had visited so many places in the Atlantic, in the Pacific, and among the South Sea Islands, that of all the King's ships at that time in commission, those who sailed in her (unconnected even with her management) thought her one of the last that would end a voyage disastrously.* The surprising manner in which the hull of the Challenger held together, and so long resisted heavy shocks, reflects infinite credit upon her architect (Hayes), and upon the dockyard where she was built.

* This I have heard from several persons who were wrecked in the ship, whose opinions I have reason to respect.

CHAPTER XXI.

Andes—Aconcagua—Villarica—Islay—Powder—Callao—Rejoin Beagle —Constitucion —Plans — Wilson — Carrasco — 'Galāpagos' — Iguanas —Lava Rocks — Land-tortoises —Craters —Turtle — Shells — Dye— Volcanoes—Settlement—Albemarle Island—Cyclopian Scene—Tagus Cove —Tide Ripples — Settlers — Climate — Salt—Dampier—Birds— Transportation of Tortoises—Currents—Temperature of Water.

THE irreclaimably barren appearance of the sea coast of Northern Chile, is very repulsive to an eye accustomed to woodland scenery: yet there is an effect in its lofty mountains, which seem to rise abruptly almost from the ocean, that charms one for a time. Just before sunrise is generally the most favourable moment for enjoying an unclouded view of the Andes in all their towering grandeur: for scarcely have his beams shot between their highest pinnacles into the westward vallies, when clouds of vapour rise from every quarter, and during the rest of the day, with few exceptions, obscure the distant heights.

It has been long supposed that the Andes are higher about the equator than near or beyond the tropic; but the Beagle's measurements of Aconcagua* and Villarica,† prove that there is still much to be ascertained on this subject. Few results, depending upon angular measurement, are more difficult to obtain with accuracy than the heights of distant mountains. With respect to Aconcagua, though a variety of measurements, taken by different officers at various times, agreed together so closely as to give from 23,200 to 23,400 feet for the vertical elevation of that volcano above the level of the sea, I would not claim to be much nearer the truth than within 500 feet.

The Blonde touched at Cobija, Arica, and Islay—hapless arid dwelling-places for either man or beast, as I have ever

* Lat. 32°. 39′. S.: height, 23,000 feet above the sea level.

† Lat. 39°. 10′. S.: height, 16,000 feet above the sea level.

© The Complete Work of Charles Darwin Online

seen. Of these and other ports along the coasts of Northern Chile and Peru, nautical information will be found in the Appendix. I will only delay the general reader with one or two observations.

From near Iquique to Arica the precipitous coast is so lofty, and approaches so much to the character of enormous cliffs, about a thousand feet high, that it is really sublime. Near Islay, the land is in several places covered with a whitish powder, or dust, which lies many inches thick in hollows or sheltered places, but is not found abundantly in localities exposed to wind. Much difference of opinion has arisen about this powder. People who live there say it was thrown out of a volcano near Arequipa a great many years ago: other persons assert that it is not a volcanic production, and appertains to, or had its origin, where it is found. My own idea was, before I heard any thing of the controversy, that there could be no doubt of its having fallen upon the ground within some hundred years, for it was drifted like snow, and where any quantity lay together, had become consolidated about as much as flour which has got damp in a damaged barrel.

In one of the old voyages there is a passage which seems to throw some light upon this subject: "As they (of Van Noort's ship) sailed near Arequipa, they had a dry fog, or rather the air was obscured by a white sandy dust, with which their clothes and the ship's rigging became entirely covered. These fogs the Spaniards called 'arenales.'"—Voyage of Van Noort, in 1660, from Burney, vol. ii. p. 223.

On the 9th of August, the Blonde anchored in Callao Bay, and I enjoyed the satisfaction of finding all well on board the Beagle. She had touched at Copiapó and Iquique, for Mr. Darwin, in her way to Callao, where she arrived on the 19th of July. Lieutenant Sulivan brought his little vessel safely to an anchor near the Beagle on the 30th, having accomplished his survey in a very satisfactory manner. So well did he speak of the Constitucion, as a handy craft and good sea boat, and so correctly did his own work in her appear to have been executed, that after some days' consideration I decided to buy

© The Complete Work of Charles Darwin Online

her, and at once set on foot an examination of the coast of Peru, similar to that which Mr. Sulivan had completed of the coast of Chile. Don Francisco Vascuñan had authorized the sale of his vessel at Callao: she was purchased by me for £400, and immediately fitted out afresh.

I could not spare Lieutenant Sulivan to remain on the coast of Peru, while the Beagle would be crossing the Pacific, on her return to England by way of the Cape of Good Hope; but there was Mr. Usborne, able and willing to undertake the task, who, from his station, could be spared without prejudice to the duties yet remaining to be executed on board the Beagle, and a better man for the purpose I could not have desired. With him Mr. Forsyth volunteered to go, and Commodore Mason was prevailed upon to allow Mr. E. Davis, a master's assistant of the Blonde, to join the little expedition; who, with seven good seamen, and a boy, volunteers from the Beagle, completed Mr. Usborne's party.

A stranger might well smile at the idea of such a boat affair being started to survey, in eight or at most ten months, the whole coast of Peru, from Paposo, near Atacama, to the River Guayaquil; but the task was completed; the charts are now engraved; and very soon seamen will be able to test their accuracy.

Most people are aware that the coast of Peru is free from storms; that the wind blows moderately along the land or from it; and that there is little or no rain. Consequently, as the sea is seldom much disturbed (except by a south-west swell), and there are neither 'races' nor dangerous streams of tide, an open boat might undertake such a task, if safety alone were to be considered, provided that she did not try to land in a surf. The real impediments to surveying that coast are—the surf caused on those steep rocky shores by an occasional heavy swell, almost amounting to rollers, from the south-westward; the delays and doubts created by prevalent fogs; and the loss of positions, as well as time, consequent upon being drifted by currents during a calm. Mr. Usborne had also to prepare for, and provide against, as much as possible, difficulties of a very different nature—those arising out of the disturbed state

© The Complete Work of Charles Darwin Online

of that country—the anarchical internal dissensions which are the bane of all South America, but especially of Peru. In this respect there were so many prospective dangers, as well as difficulties, that I should not have ventured to let him encounter them, had we not had such a man as Belford Hinton Wilson* to rely upon for foresight, advice, influence, and as hearty unflinching assistance, as any one public servant could afford to another. Mr. Wilson's exertions were unceasing, until he procured every passport and document that could by any possibility be required for Mr. Usborne. He introduced him as well as myself, to the hydrographer (Don Eduardo Carrasco) who assisted us in many ways most materially; and after I left the coast he showed every possible attention and kindness to all the Constitucion's party; winding up by advancing a large sum of money out of his own purse, to forward the service in which they were engaged, and increase their comfort during a long passage to England round Cape Horn.

Captain Carrasco, formerly in the Spanish navy, and now Director of the Nautical School at Lima, gave me, and afterwards Mr. Usborne, every particle of information which he and I thought might be useful—both verbally and in writing—besides which he ransacked the archives for manuscripts, charts, and books, from which he allowed extracts to be taken or copies made, in the most truly liberal manner; and I long to see the results of our voyage, whatever they may be, laid before him and his friends, as an acknowledgment—however slight—of their free assistance and co-operation.

On the 6th of September Mr. Usborne sailed.† He was to commence near Paposo; work along the coast thence to Guayaquil, and afterwards return to Callao.

The following day the Beagle left Callao, and steered direct towards the Galāpagos Islands, of which, as they are novel ground, I shall be rather minute in my description.

15th. Uncertain of the strength, and even of the direction of the currents—though aware that at times the former is very

* Then consul-general, now chargé d'affaires of H.B.M. in Peru.

† Orders in Appendix.

© The Complete Work of Charles Darwin Online

considerable—we were anxiously looking out for land, when what appeared to be an islet was seen from the mast-head. This seeming islet turned out to be the summit of Mount Pitt, a remarkable hill at the north-east end of Chatham Island. (Charles Island of Cowley, 1684). As the breeze and current carried us onwards, the tops of other hills successively appeared, and for a short time looked very like a cluster of islets.

Gradually rising above the horizon, the greater part of Chatham Island became distinctly visible: in this neighbourhood it is not often that the air near the water is clear enough to allow of very distant high land being thus gradually raised above the horizon of an eye at the mast-head; for, in general, clouds hang about these islands, and the atmosphere itself is hazy. Towards evening the higher parts of the land were clouded over, but we were near enough to see that the island was very rugged—in some places quite barren—in others covered with a stunted and sun-dried brushwood—and that the heights, on which the clouds hung, were thickly clothed with green wood. The shores seemed to be bold, and easy to approach, though not to land upon, because of a continual high surf.

A number of little craters (as they appeared to be) and huge irregular-shaped masses of lava rock, gave a strangely misleading appearance to the lower parts of the island; and when first seen through that indistinct glimmer which is usually noticed over land on which a hot sun is shining, were supposed to be large trees and thick wood.* Hood Island, small and rather low, was seen before dusk, when we tacked and stretched to seaward for a few hours.

16th. Assisted by a current running to the westward, we worked up to Hood Island during the night, and at daylight lowered a boat down and prepared her for Mr. Chaffers,

* This glimmering haziness is at times a great impediment to making accurate measurements of an object, when both it and the observer's eye are near the ground. Raising either some few feet higher, remedies this inconvenience, which is much felt when using a micrometer for measuring a base.

© The Complete Work of Charles Darwin Online

who, with Mr. Mellersh, was to examine this island and the anchorages about it. Under the land we saw two whalers at anchor, which showed North American colours. The island is small—neither high nor low—rugged, covered with small sun-burnt brushwood, and bounded by a bold, rocky shore. Some small beaches of white sand are visible here and there.

As soon as Mr. Chaffers had set out, the Beagle steered towards Chatham Island, with a moderate breeze, which allowed us to prepare the yawl for another party, under Lieutenant Sulivan. At noon, Barrington Island was visible from the deck, and appeared to be distant about twenty miles; when with Messrs. Stewart and Johnson, and ten chosen seamen in the yawl, Mr. Sulivan left us to examine the central islands of the archipelago.

In continuing our course, we passed through several ripplings, apparently caused by the meeting of streams of current which set along the shores of Chatham Island, from the east towards the west. If not so caused, they must be the effects of currents passing over very uneven ground, but we got no bottom, with fifty fathoms of line. When such appearances are created by shoals, it should be remembered that the shallowest place is generally under the smoothest part, close to the ripple. Favoured by smooth water and fine weather, we passed close to the low south-west extreme, and anchored directly that point was found to defend us from the swell.

This part of the island is low, and very rugged. We landed upon black, dismal-looking heaps of broken lava, forming a shore fit for Pandemonium. Innumerable crabs and hideous iguanas started in every direction as we scrambled from rock to rock. Few animals are uglier than these iguanas; they are lizard-shaped, about three feet in length; of a dirty black colour; with a great mouth, and a pouch hanging under it; a kind of horny mane upon the neck and back; and long claws and tail. These reptiles swim with ease and swiftness—but use their tails only at that time. At a few yards from the water we found vegetation abundant, though the only soil seen was a little loose dusty earth, scattered upon and between the

© The Complete Work of Charles Darwin Online

broken lava. Walking is extremely difficult. A hand-barrow was lying at the landing-place, which showed that terrapin were to be got near us, though we did not then see any. The men from whalers and sealing vessels carry the large terrapin, or land-tortoises, on these barrows.

Ascending a little hill, we were surprised to find much brush or underwood, and trees of considerable size, as large in the trunk as one man could clasp. These were prickly pears, and a kind of gum-tree: how their roots are able to penetrate, or derive nourishment from the hard lava, it is hard to say; for earth there is scarcely any. Wild cotton shrubs are numerous. This first excursion had no tendency to raise our ideas of the Galāpagos Islands.

17th. Weighed and stood alongshore, sounding. There was good anchorage, until near the south-west point of Stephens Bay, off which the water is shoal, and the bottom uneven. We anchored in Stephens Bay, and found an American whaler lying there. This bay is large, and the anchoring ground generally good; but the landing is bad at low water. There is no fresh water: and it is frequently difficult to enter, as well as to leave, because usually becalmed by high land, it seldom feels the true wind. Enderby Cove is only fit for a boat; at low water it is full of rocks. The Kicker Rock is a curious mass of stone, rising almost perpendicularly from the bottom of the sea, where it is thirty fathoms deep; and in the offing is another (called the Dalrymple, by Colnett), which looks exactly like a ship becalmed, with all sail set. Seeing a remarkable hill at the north-east side of the bay, which had not an appearance like other parts of the island, I went to it in a boat, hoping to find water near the foot, and to have a good view from the summit. Disappointed in both ways, the hill being composed of a crumbling sand-stone, and almost inaccessible, I returned to the ship early next morning. Several new birds were seen by those who were on shore, and many fish were caught on board, of which the best and most numerous were a kind of rock cod, of large size.

18th. Weighed and stood alongshore until noon, when we

© The Complete Work of Charles Darwin Online

anchored close to a low rugged point, near the north-east end of the island: employed two boats in examining the shore, and landed a party to look for terrapin: Mr. Darwin and Mr. Stokes went to the top of a neighbouring hill. Throughout this day it blew so fresh a breeze, that double-reefed topsails were as much as could be carried: but I think this strength of wind only prevailed under the lee of the island, where the wind rushed down in squalls, after having been intercepted and checked by the high land. All the hills appear to have been the craters of volcanoes: some are of sandy mud, others are lava. There is plenty of wood hereabouts, though stunted and dry. On no part of this shore is there a chance of finding water; all is stony, without any soil which could either collect or carry it off.

Our party brought eighteen terrapin on board. In size they were not remarkable, none exceeding eighty pounds. This animal appears to be well defended by nature; but, in truth, it is rather helpless, and easily injured. The shell is slight, and becomes weaker (in proportion to the animal's size), as the tortoise grows older.

19th. Sailed round the north-east extremity of the island, and worked to the southward against a tide, or rather current, setting strongly to the north-west.

20th. At daylight we were off the south-east part of the island; and continued working to the south-west, during the forenoon, along a shore quite bold, excepting the small rocks above water in 'Middle' Bay. At noon, seeing a small cove, I went in a boat to examine it, and look for water. We found no signs of any in that place; but a little farther west, a fine stream was seen falling from a lava cliff, about thirty feet high. Mr. Low had described this waterfall correctly; and his account of the watering place near it was soon verified, by our discovering a cove half a mile to the westward of the cascade. We landed on a stony beach in the cove, and found a fine stream of excellent water: two others were likewise seen, but they were inaccessible. This water runs from the highest parts of the island (which are almost always enveloped in

© The Complete Work of Charles Darwin Online

clouds) down a large valley.* All this southern side of the island is well wooded; and on the higher ground the wood is very green.

Continuing our course along shore, we arrived at our former anchorage in Stephens Bay soon after dark, when Mr. Chaffers returned on board, having reached the anchorage in the morning.

22d. So generally cloudy is the weather here, that a day such as this proved to be, of hot, vertical sunshine, was much felt by every body; and to show how objectionable our anchorage was in this respect, I may mention that a fresh breeze was blowing all day in the offing; yet in the bay only light variable airs were felt.

Some fine turtle were brought on board, the first we had seen here; they are rather like the green turtle of the West-Indies, but not exactly. Among the shells found about the islands one is common, which reminded me of the purple murex, as the fish emits a strongly dyeing liquid of a similar colour.† A kind of mangrove grows near the water, on the sandy beaches of this island; and the shape and colour of that curious tree are some relief to an eye tired of looking at rugged lava or withered bushes.

23d. While becalmed we tried the clamms‡ in fifty fathoms water, and brought up as much sand as would fill a bucket, but nothing curious. Afterwards we had a breeze, and passed Barrington Island pretty closely. It is not high, yet the shores are bold and fronted by cliffs; the more elevated parts appear to be level, and rather woody. This night was spent under sail between Charles and Hood Islands.

24th. While we were endeavouring to reach the anchorage in Post-Office Bay (Charles Island), Mr. Chaffers and Mr. Mellersh went away in a boat to visit the islets that lie near the eastern side of that island: and it was found that they had all

* There is no other place in the Galāpagos where ships can water at all times of the year. † Found also on the coast of Peru (Ulloa).

‡ An indifferent contrivance of mine, made and put together by our own armourer.

© The Complete Work of Charles Darwin Online

been the summits of volcanoes. Charles Island is peculiar in its outline: for a succession of round topped hills, precisely similar in shape, though differing in size, shews on every point of view. This exact similarity is very remarkable. Must not all these volcanoes* have been thrown up under the same circumstances, such as similar action of the ocean, or even a strong wind—perhaps at the very same time? †

The highest and largest of these hills rises 1,800 feet, the next about 1,700; the rest are of various smaller heights. The northern sides of the island are wooded, but the wood looks as brown as that on the lower parts of Chatham Island. Post-Office Bay is sheltered, easy of access, has excellent anchorage, and only wants fresh-water to make it a most desirable harbour for shipping. Its name is the result of a custom established by the whalers: a box was placed on a post, to receive letters, and homeward-bound ships examined the directions, taking with them all which they might have means of forwarding; but since the island has been peopled the box has been empty, for letters are now left at the settlement.

25th. Mr. Nicholas O. Lawson, acting for the governor of this archipelago, ‡ came on board. With him and me a party went to another anchorage called Black Beach Road, landed, and walked up towards the settlement. In 1832, the republic of the 'Ecuador' decided to use these islands as a place of banishment, and sent a small colony to Charles Island. 'La Floriana' is the name given to this island by the Guayaquilians, though by the Spaniards it was once called 'Santa Maria de l'Aguada.' The governor, at the time of our visit, was Don José Villamil. There were then about eighty small houses, or huts, and nearly two hundred souls upon the island, most of whom were convicts.

After walking rather more than a mile along a good path, through the underwood (which as the ground rises becomes very thick), we reached a small spring of water, near which are a few huts, but no cultivated ground. The water from this

* For volcanoes they certainly have been. † See page 493.

‡ An officer of the republic of the Equator.

© The Complete Work of Charles Darwin Online

spring might be conveyed to shipping by means of leaden pipes, without much difficulty, but it is not of very good quality. Having ascended gradually during another half-hour's walk, we reached the ridge of that height which limited our view from the sea; when surprisingly sudden and agreeable was the change. Heated and tired by a dusty uphill walk, through sun dried trees and over rugged lava stones, our bodies were here refreshed by a cool breeze, while our eyes enjoyed the view of an extensive, fertile and cultivated plain. Surrounded by tropical vegetation, by bananas, sugar canes, Indian corn, and sweet potatoes, all luxuriantly flourishing, it was hard to believe that any extent of sterile and apparently useless country could be close to land so fertile, and yet wear the most opposite appearance. Our eyes having been accustomed to the desert shores of Peru and northern Chile, during many months, were completely dazzled by a sight so new and unforeseen.

It appears that rain falls very frequently on these higher grounds, and is absorbed by rich black mould of a nature sufficiently clayey to enable it to retain moisture. During the wet season this plain becomes quite muddy, while the little rain that falls on the lower ground is so quickly absorbed, or finds its way so soon through the loose lava stones that its effects are not there visible.

Most of the houses are in this fertile space, but it appears that a house on the dry ground, and plantations in the moist valley, would answer better: for at Mr. Lawson's house salt cannot be kept dry, books and paper become mouldy, and iron rusts very quickly. At his table we found the welcome of a countryman, and a variety of food quite unexpected in the Galāpagos Islands, but fully proving their productiveness. At the foot of a hill we saw water dropping plentifully, and from this spring, called the "Governor's Dripstone," the inhabitants obtain a certain supply throughout the year.

Although most of the settlers were sent here against their wish, there are many who do not desire to return to the continent. Some are married and have children on the island.

© The Complete Work of Charles Darwin Online

In a small cave near the "governor's dripstone," an old sailor lived during several years: he had been unfortunate, and was tired of the world. Terrapin and potatoes were his food, till a former friend, the master of a whaler, recognised him, and carried him away by force. So strongly was the old man attached to his cave, that he shed tears when taken away.

There are goats and hogs upon this island, but they are scarce and wild, not having yet had time to increase much; they are hunted with dogs, though it would be wiser to let them alone for a few years. The settlers have abundance of vegetables, and depend chiefly upon terrapin for their meat. Many of these animals being large and heavy, the people who go in search of them kill and open them on the spot, then take out the fleshy pieces and put them in a bag. Thus one man can carry away the useful parts of more terrapins than several men could lift.

The quantity of tortoise shells lying about the ground, shows what havock has been made among these helpless animals. On the lower ground, near the spring, I saw an apology for a garden, in which the large terrapin shells were used to cover young plants, instead of flower pots. In a place one has not seen before, some marked peculiarity occasionally reminds one, more forcibly than the ordinary novelties of scenery, that all around is strange and new. The palm-trees and arid appearance of St. Jago, the sedan chairs of Bahia, the boats of Rio de Janeiro, the beef carts of Monte Video, the travelling waggons of Buenos Ayres, the 'toldo' of the Patagonian, the wigwam of the Fuegian, the wooden houses and clogs of San Carlos de Chiloé, the stockades of Valdivia, the effects of earthquake at Concepcion, the concentrated bustle of Valparaiso, the quiet and uniform serenity of Coquimbo, women riding astride and troops of ill-used donkeys at Lima, are a few instances among the multitude of such local peculiarities.

Small birds are numerous on this island, and so remarkably tame that they may be knocked down with a stick. Lizards are also numerous; and there are a few small snakes, but those

© The Complete Work of Charles Darwin Online

we caught were not venomous. Among the useful vegetables we noticed the plaintain, pumpkin, yuca, Quito orange, castor oil plant and melon, besides those before mentioned.

Returning on board we met Mr. Stokes on his way from the southern parts of the island: he described the lava thereabouts as having such a form and rugged surface as the sea would present if suddenly congealed, while ruffled by a very strong wind.

26th. After completing the necessary observations in Post-Office Bay, we weighed and worked round to an anchorage off Black Beach: and at nine in the evening Mr. Chaffers returned, having been round the south side of this island after visiting the small eastern islets. He found much difficulty in landing on them, but succeeded, and from the top of Gardner Islet saw a dangerous breaker about a mile to the south eastward.

27th. Being Sunday, many of the officers and ship's company were on shore in the afternoon, and some of the officers went to the top of the highest hill, which has a crater, as have all the hills we examined about these islands; and these craters are all similarly broken down on the side towards the south.

28th. Having taken on board live pigs and a quantity of vegetables, we weighed and stood towards Albemarle Island. Four small islets, the remains of volcanoes, lie near the low south-east extreme of this island, and together with Brattle Islet, are extremely useful in warning vessels of their approach to a very dangerous piece of coast. So low are the south-eastern extremities of Albemarle Island that they are not discernible until you see the surf on the shore. A heavy swell setting towards the land, and generally light winds, add to the danger of getting near this coast; but there is anchorage in case of necessity.

Albemarle Island is a singular mass of volcanic ejections. Six volcanoes have there raised their summits from two to four thousand feet above the ocean, and from them immense quantities of lava have from time to time flowed towards the

© The Complete Work of Charles Darwin Online

sea; so that this island, large as it is, may be literally described by saying that it consists of six huge craters, whose bases are united by their own overflowed lava. The southern side, which is exposed to the trade wind, and completely intercepts it, with all the clouds it brings, is thickly wooded, very green, and doubtless has fresh water; but how is that water to be obtained where such a swell rolls upon the shore? The weather side of Chatham Island is partially protected from the great south-west swell of the Pacific by Hood Island, yet even there it is difficult to land.

We passed this night under easy sail, off the south-west extreme of Albemarle Island; and on the 29th we found a small cove, in which we anchored; but such a wild-looking place—with such quantities of hideous iguanas as were quite startling! Hence I despatched Mr. Mellersh and Mr. King, to examine the depth of Elizabeth Bay, and rejoin us beyond Narborough Island; we then weighed, and continued our examination of this unearthly shore. Passing a low projecting point, our eyes and imagination were engrossed by the strange wildness of the view; for in such a place Vulcan might have worked. Amidst the most confusedly heaped masses of lava, black and barren, as if hardly yet cooled, innumerable craters (or fumeroles) showed their very regular, even artificial looking heaps. It was like immense iron works, on a Cyclopian scale!

When this lava flowed from the heights it must have been stopped rather suddenly (cooled) by the water; for the lava cliffs are in some places twenty, and in others forty feet high, while close to them there is water so deep that a ship could not anchor there, even in a calm while the sea is quite smooth. Until we rounded this point the wind was very strong, eddying round the high south-west cape; but here we were becalmed, and passed some anxious hours, till at length light variable airs carried us off-shore.

30th. This morning we passed a remarkably fine American whaler, the Science, carrying nine whale-boats! On the south-

© The Complete Work of Charles Darwin Online

eastern height of Albemarle, smoke was seen issuing from several places near the summit, but no flame. Profiting by every breeze, we hastened towards Tagus (or Banks) Cove.

Narborough Island is exactly like a part of Albemarle—a great volcano, whose base is surrounded by an extensive field of lava: it is utterly barren and desolate. A few mangroves, on the sandy beaches near Albemarle Island, are not seen in the distance; neither are there enough of them even to diminish the dismal appearance of the island.

We entered the passage in the afternoon, and anchored in the little cove first described by Capt. Pipon, who then commanded H.M.S. Tagus. This cove is the crater of an extinct volcano, and its sides are so steep as to be almost inaccessible.*

1st October. Our first object was to find water: none could be got in the cove, but at a short distance from it a few holes were found, out of which a bottle might be filled in an hour. Around this scanty spring draining continually through the rock, all the little birds of the island appeared to be collected, a pretty clear indication of there being then no other fresh-water within their reach: yet during the rainy season there must be considerable streams, judging by gullies which are worn in the rock. All the heights hereabouts, and the sides of the craters, are composed of sandstone that looks like fine sandy mud half baked; but the low grounds are lava. The crater in which we anchored gave me the idea of its having been a mud volcano. The climate is very different from that of the Windward Islands; for wind clouds and rain appear to be obstructed in their northward passage, by the heights on the southern part of this island. The heat is here far greater than in other parts of the archipelago, and the land is more sterile. Numbers of another sort of iguana were seen for the first time, and many were killed and eaten. In size and shape they resemble the black kind, but their colour

* In 1825 H.M.S. Blonde, commanded by Lord Byron, anchored here. In her voyage (pp. 92, 93, 94) the black and the red (or brown) iguanas are described, and it is stated that a specimen of the black kind was brought to England from Mexico. Lord Byron saw a volcano burning on Narborough Island.

© The Complete Work of Charles Darwin Online

is a dirty orange red, inclining to reddish brown above and yellow beneath. These reptiles burrow in the earth like rabbits, and are not bad eating. Of the black kind a vast number run about the rocks near the sea, living either upon fish or sea-weed. As we went afterwards in a boat along the ragged irregular shore, we saw numbers of turtle. There are small sandy beaches here and there, to which these animals approach in the evenings: when, as it gets dark, they land and usually lie on the beach during the night, even if it is not the season in which they seek a place for their eggs.

From a height near Tagus Cove dismal indeed was the view, yet deeply interesting. To see such an extent of country overwhelmed by lava, to think of the possible effects of the seven dormant volcanoes then in sight, and to reflect that at some one period all was activity and dreadful combustion where we then witnessed only silent desolation, was very impressive.

2d October. We passed this day and the following night in Banks Bay. On the 3d, Mr. Mellersh returned, having examined Elizabeth Bay and the western shore of Narborough Island. We then went round the north-west end of Albemarle Island, and passed the night under sail off the north extreme. At daybreak, on the 4th, we made all sail towards Abingdon Island, which is small, rather high, and tolerably covered with stunted wood; we did not maintain a position even near where I wished to pass the night, but were carried about forty miles away, dead to leeward, during only a few hours of light wind. The current hereabouts runs between one and four knots an hour to the north-westward, yet the depth of the water is unfathomable by ordinary means: excepting for which it is like a vast river in the sea.

5th. While working to windward, endeavouring to regain our lost ground, we saw Bindloes Island: and passed through many ripplings, some of them dangerous for a boat; these were northward, and rather eastward of Abingdon. During the 6th, other indications of a strong current were noticed, besides ripplings such as these, which, in very deep water, and in the open sea, are difficult to explain: sometimes at night, while all

© The Complete Work of Charles Darwin Online

around was smooth and tranquil—a short, deep plunge suddenly startled every one: but in a minute afterwards the ship was again quiet. We continued to work to the southward in order to reach James Island, and meet Lieutenant Sulivan.

7th. While working to windward we saw Towers Island, which is different in appearance from all the other islands of this archipelago, being low and flat. We passed it about noon, and Bindloes at sunset. The latter has an irregular hilly surface, partially wooded, but like the rest is a mass of lava, and indurated sandy mud.*

8th. The Beagle was close to James Island, a high, large, and well-wooded tract of ground, or rather lava. We anchored at the northern end, and a boat came alongside loaded with fish, for there was a party of settlers here, detached from Charles Island, whose employment was salting fish and extracting oil from terrapin.† This oil is of a light colour, and exceedingly good quality, being very like pure olive oil. Lieutenant Sulivan returned with his party, and I then detached Mr. Chaffers in the yawl, accompanied by Mr. Johnson and six men, to examine Bindloes, Abingdon, and Towers Islands. As Mr. Darwin anxiously desired to see as much as possible of the productions of this central and large island, he was landed, accompanied by Mr. Bynoe, besides his servant and H. Fuller, to remain until the Beagle's return. Although there is abundance of water on the higher parts of this island, so broken and dry are the lower grounds that it does not arrive at the shore: at two places only can enough water for even a boat's crew be procured, in the dry season; and for a ship there is scarcely hope of a sufficiency. The poor fellows who brought us the fish had been living so long upon terrapin, and the produce of their lines, without any thing else, that half a bag of biscuit (50 lbs.) which we gave them, appeared to be an inestimable treasure, for which they could not sufficiently thank us. We sailed in the evening, but made very little

* Of course much of the information given in these pages was collected by the officers.

† They also salt the terrapin; or tortoise.

© The Complete Work of Charles Darwin Online

progress towards our destination (Chatham Island) this day (9th). The winds appear to be much lighter and more variable, to leeward of the archipelago, while the current is considerably stronger.* We got pretty close to Chatham Island at dusk, worked to windward during the night, and on the following morning stood along the weather shore towards the watering place.

11th. How remarkably different is the climate of the windward and leeward islands of this group! Here we were enveloped by clouds and drizzling fog, and wore cloth clothes. At Tagus Cove and James Island, a hot sun, nearly vertical, overpowered us;—while the south side of Albemarle, Charles, and Chatham Islands, were almost always overshadowed by clouds, and had frequent showers of rain. We anchored close to the watering place: but it appeared strange to remain at anchor in such a spot, only three cables' lengths from a surf breaking high upon a steep cliffy shore, with nothing but the ocean between us and the antarctic; and such was our position; yet it was a safe one, because the great south-west swell of the Pacific is interrupted by Hood Island, and the southerly trade, or perennial wind is so moderate, that it has neither power to raise a sea nor to harm a vessel lying at anchor, if her ground tackle is not defective.

The 12th was spent in filling water, washing, cutting some wood, and bringing thirty large terrapin on board. These animals abound hereabouts; and some are very large, deserving the name of elephant-tortoises. Two of our party tried to reach the higher and thickly wooded part of the island, but found their task impracticable, in so short a time as they could spare, for the wood grows impenetrably thick, though none is straight or of a large size. The upper grounds have a rich loamy soil, lying upon rock, in which the terrapin wallow like hogs, and may be found by dozens. This was a very hard day's work for so few men as were then on board our small vessel. (13th) We had some difficulty in 'casting,' so as to

clear the land, but got out of the scrape and were working towards Hood Island when the man looking out aloft reported a breaker, which proved to be on a rock at the west end of MacGowen shoal. When first seen it was on the horizon, and hardly differed from the topping of a sea;—once only in about ten minutes it showed distinctly. We steered for it, lowered two boats, and employed the rest of the day in examining this very dangerous shoal, and fixing its position. One rock at the west end is just a-wash, but there is another under water, except in the hollow of a swell, about half-a-mile to the eastward, which is exceedingly treacherous. We had two narrow escapes this day; while weighing from Chatham Island, baffling winds sent us a great deal too close to the cliffs before our anchor was up, or the ship under command; and while sounding along the edge of MacGowen shoal we were drifted so close to the second rock, mentioned above, that I was not sure on which side of us it lay.

14th. Anchored and examined Hood Harbour, having heard there was a sunken rock in it which our boat had not discovered, but we found nothing dangerous for a ship. Shoal water and large blocks of lava lie near the shore in the harbour; but a vessel must have stood too close in if she touches thereabouts. Left Hood Island at noon, and steered for the southern part of Charles Island. Having a fine breeze we rounded Saddle Point at eight, and anchored at nine off Black Beach.

15th. I went to Post-Office Bay and near the best landing place, found some excellent salt, which though but small in quantity gives a hint that more may be got elsewhere.

16th. Weighed in the afternoon, having obtained the necessary observations, and went to Black Beach Road to take in wood, potatoes, and pigs. We there found a small schooner at anchor, just arrived from Guayaquil, and having, among other things, a bag of letters from England, for the Beagle. That very evening we were to leave Charles Island; not to return! In the schooner were some emigrants; who brought cattle, and information that the governor, Villamil, might be

© The Complete Work of Charles Darwin Online

expected to arrive in a few days, with a vessel laden with animals, and supplies for the settlement. We stood across, during the night, to the four islands near Point Woodford; and at daylight next morning (17th) resumed our usual occupations, while sailing along the east side of Albemarle Island. At noon we steered for Albany Islet, to embark Mr. Darwin and Mr. Bynoe; and after our party were on board, we returned towards the shore of Albemarle Island, and there passed the night under sail, in order to start early from a particular position. Our landsmen had enjoyed their stay and profited by it, though the heat was oppressive, and the sky nearly cloudless by night and by day: how different was this from the weather we had had on board! The higher grounds of James Island are extensive, and would be adapted to cultivation if the wood, which now grows thickly, were cleared. There is a fine salt spring, or lake, in an old crater; the salt is excellent, in colour and quality: and the men employed by Mr. Lawson were using it daily for curing their fish and terrapin.

When at some height upon the island, among the thick wood, it is extremely difficult to find the way: men have been lost thereabouts, and it is said that some of the bodies never were found. The day we re-embarked Mr. Darwin there was a man missing, belonging to an American whale ship, and his shipmates were seeking for him. The master of this whaler was very obliging to our party, supplying them with water, and offering his hearty assistance in any way which lay in his power. The earnest wishes to be of use, and the attentions of North Americans to us on all occasions, have been often and gratefully remarked by many on board the Beagle.

18th. Continued our examination of Albemarle Island. When off the northern volcano, the black streams of lava, which have flowed in every direction down the sides of the mountain, looked like immense streams of ink. Thence we steered for Abingdon Island to meet Mr. Chaffers. I thought the current less strong, and setting more to the west, than when I was here on a former day.

On the 19th we were close to Abingdon Island, where there

© The Complete Work of Charles Darwin Online

is a fine bold-looking cliff, at the west side, considerably higher than any I had seen in the Galapagos. Mr. Chaffers soon came alongside after we closed the land; when, his orders being all executed, the boat was hoisted in, and we made sail to the north-west in search of Wenman and Culpepper Islets.

Next day (20th) we saw and steered for Wenman Islet, another crater of an extinct volcano. It is high, small, and quite barren: correctly speaking, there are three islets and a large rock, near each other, which, at a distance, appear as one island, but they are fragments of the same crater. We afterwards passed Culpepper Islet, which is a similar rocky, high, and barren little island. At sun-set we made all sail and steered to get well into the south-east trade wind, so as to expedite our passage towards the dangerous archipelago of the Low Islands, and thence to Otaheite (or Tahiti). While sailing away from the Galapagos, impelled westward over a smooth sea, not only by favouring easterly breezes but by a current that set more than sixty miles to the west during the first twenty-four hours after our losing sight of Culpepper Islet, and from forty to ten miles each subsequent day until the 1st of November,* I will look back at those strange islands, and make a few more remarks on them.

There are six principal ones, nine smaller, and many islets scarcely deserving to be distinguished from mere rocks. The largest island is sixty miles in length, and about fifteen broad; the highest part being four thousand feet above the sea. All are of volcanic origin, and the lava, of which they are chiefly composed, is excessively hard. Old Dampier says,† "The Spaniards, when they first discovered these islands, found multitudes of 'guanoes' and land-turtle, or tortoise, and named them the Galapagos‡ Islands." Again, "the air of these islands is temperate enough, considering the clime. Here is constantly a fresh sea-breeze all day, and cooling refreshing winds in the night; therefore the heat is not so violent here

* Lat. 10°. 14′. S. long. 120°. 35′. W.

as in most places near the equator. The time of the year for the rains is in November, December, and January: then there is oftentimes excessive dark tempestuous weather, mixed with much thunder and lightning. Sometimes before and after these months there are moderate refreshing showers; but in May, June, July, and August, the weather is always very fair."* I can add nothing to this excellent description, except that heavy rollers occasionally break upon the northern shores of the Galapagos during the rainy season above-mentioned—though no wind of any consequence accompanies them. They are caused by the 'Northers,' or 'Papagayos,' which are so well known on the coast between Panama and Acapulco. Colnett also gives a good description of these islands:—in his voyage, p. 58, he says, "I consider it as one of the most delightful climates under heaven, although situated within a few miles of the equator." The buccaneers often resorted to them for refreshments, and as a place where they might refit their vessels, share out plunder, or plan new schemes of rapine, without any risk of being molested.

Striking instances of the manner in which high land deprives air of its moisture may be seen at the Galapagos. Situated in a wind nearly perennial, those sides only which are exposed to it (the southern) are covered with verdure, and have water: all else is dry and barren, excepting such high ground as the passing clouds hang upon indolently as they move northward. In a similar manner may we not conclude that western Peru is deprived of rain—since the easterly trade wind which carries moisture, and consequent fertility, to eastern Peru, is drained, or dried, as it crosses the Andes? And may we not extend this reasoning to other countries similarly situated, such as Patagonia, perhaps Arabia, and even Africa, upon whose arid deserts no moist wind blows? Currents of air, moving from ocean to land, convey vapour; but as these currents pass over

* During the rainy season, or from November to March (which is not, however, at all to be compared to a continental rainy season) there are calms, variable breezes, and sometimes westerly winds: though the latter are neither of long duration, nor frequent.

© The Complete Work of Charles Darwin Online

high land, or even a considerable extent of low country, much if not the whole of their aqueous contents is discharged, and until such a body of air has again acquired moisture, it is found to be dry, parching, and unfavourable to vegetation.

All the small birds that live on these lava-covered islands have short beaks, very thick at the base, like that of a bull-finch. This appears to be one of those admirable provisions of Infinite Wisdom by which each created thing is adapted to the place for which it was intended. In picking up insects, or seeds which lie on hard iron-like lava, the superiority of such beaks over delicate ones, cannot, I think, be doubted; but there is, perhaps, another object in their being so strong and wide. Colnett says, p. 59, "they observed an old bird in the act of supplying three young ones with drink, by squeezing the berry of a tree into their mouths. It was about the size of a pea, and contained a watery juice, of an acid, but not unpleasant taste." "The leaves of these trees absorb the copious dews which fall during the night; the birds then pierce them with their bills for the moisture they retain, and which, I believe, they also procure from the various plants and evergreens.' "The torch thistle contains a liquid in its heart, which the birds drank, when it was cut down. They sometimes even extracted it from the young trees by piercing the trunks with their bills." For thus squeezing berries, and piercing woody fibre, or even only stout leaves, a slight thin beak would be scarcely available. Colnett* observes, that some of the birds which he saw resembled a few that he had seen at New Zealand, but as he also remarks that all the dead shells which he found upon the beach were familiar to him, I think one may suspect the accuracy of his eye, if not his memory, in those instances.

Mr. Stokes made some notes about the tortoises (terrapin), while with me, and as he and I are satisfied as to the facts, I will add them. Fresh water was first discovered on Charles and on James Islands, by following the terrapin paths. These animals visit the low, warm ground to seek for food and de-

* Colnett's Voyage to the South Seas, pages 52, 55, 57.

© The Complete Work of Charles Darwin Online

posit their eggs; but it must be a toilsome journey indeed for them to ascend and descend the rugged heights. Some that Mr. Stokes saw in wet, muddy places, on high ground, seemed to enjoy themselves very much, snuffling and waddling about in the soft clayey soil near a spring. Their manner of drinking is not unlike that of a fowl: and so fond do they appear to be of water, that it is strange they can exist for a length of time without it; yet people living at the Galapagos say that these animals can go more than six months without drinking. A very small one lived upwards of two months on board the Beagle without either eating or drinking: and whale-ships have often had them on board alive for a much longer period. Some few of the terrapin are so large as to weigh between two and three hundred weight; and, when standing up on their four elephantine legs, are able to reach the breast of a middle-sized man with their snake-like head.* The settlers at Charles Island do not know any way of ascertaining the age of a terrapin, all they say is, that the male has a longer neck than the female.† On board the Beagle a small one grew three-eighths of an inch, in length, in three months; and another grew two inches in length in one year. Several were brought alive to England. The largest we killed was three feet in length from one end of the shell to the other: but the large ones are not so good to eat as those of about fifty pounds weight—which are excellent, and extremely wholesome food. From a large one upwards of a gallon of very fine oil may be extracted. It is rather curious, and a striking instance of the short-sightedness of some men, who think themselves keener in discrimination than most others, that these tortoises should have excited such remarks as—"well, these reptiles never could have migrated

* When their long necks and small heads are seen above low bushes they look just like those of snakes.

† Their eggs were found in great numbers in cracks of a hard kind of clayey sand; but so small were the cracks that many of the eggs could not be got out without being broken. The egg is nearly round, of a whitish colour, and measures two inches and a half in diameter—which is about the size of a young one when first hatched.

© The Complete Work of Charles Darwin Online

far, that is quite clear," when, in simple truth, there is no other animal in the whole creation so easily caught, so portable, requiring so little food for a long period, and at the same time so likely to have been carried, for food, by the aborigines who probably visited the Galapagos Islands on their balsas,* or in large double canoes, long before Columbus saw that twinkling light, which, to his mind, was as the keystone to an arch. Honest Dampier immediately reverted to the tortoises of the West Indies, and of Madagascar,† when he saw those of the Galapagos. He had observed too many varieties caused by climate, soil, food, and habits, to entertain a doubt of their being other than a variety of the tortoise kind. As to the 'guanoes' they were, to his eye, familiar objects.

The currents about these islands are very remarkable, for in addition to their velocity, which is from two to five miles an hour, and usually towards the north-west,‡ there is such a surprising difference in the temperature of bodies of water moving within a few miles of each other, that this subject must be reserved for further discussion. On one side of an island (Albemarle Island) we found the temperature of the sea, a foot below the surface, 80°. Faht.; but at the other side it was less than 60°. In brief, those striking differences may be owing to the cool current which comes from the southward along the coasts of Peru and Chile, and at the Galapagos encounters a far warmer body of water moving from the bay of Panama, a sort of 'gulf stream.' The retentive manner in which such ocean rivers preserve their temperature has been frequently remarked: and must have a great effect upon the climates of countries near whose shores they flow.

* I have heard that driftwood, not the growth of these islands, is frequently found on the south-east shores. On this subject Colnett says (p. 58), "on several parts of the shore there was driftwood, of a larger size than any of the trees that grow on the island: also bamboos and wild sugar canes, with a few small cocoa nuts at full growth, though not larger than a pigeon's egg." † Dampier, vol. i. p. 102.

‡ In the twenty-four hours immediately previous to first making these islands, the Beagle was set fifty miles to the west north-west.

CHAPTER XXII.

Dangerous Archipelago of the Low Islands—Krusenstern—Squalls—Discoveries—Otaheite—Matavai—Natives—Houses—Point Venus—Theft—Singing—Pomare—Sugar—Papiete—Church—Mr. Pritchard—Thierry—Shells—Mr. Nott—Bible—Paamuto Natives—Falkner—'Ua'—Papawa—Relics—Divine Service—Hitote—Henry—Audience—Queen—Missionaries—Roman Catholics—Forming head—Meeting at Papiete—Dress—Behaviour—Eloquence of natives—Honourable feelings—Interesting discussion—Venilia.

After sailing before the wind twelve days, our approach to land was indicated by a black tern which flew past the ship.* Tropic birds were seen on the previous day (2d), but they roam farther than tern. On the 9th we saw Honden Island, one of the low coral formations, only a few feet above water, yet thickly covered with cocoa-nut trees.† Our observations corroborated the position assigned to it by Admiral Krusenstern,‡ in his excellent chart and memoir, the only documents of any use to us while traversing the archipelago of the Low Islands. This archipelago is indeed extremely deserving of its appellation, 'Dangerous;' for numerous coral islets, all low, and some extensive, obstruct the navigation, while unknown currents and strong squalls, and a total want of soundings, add to the risk of sailing there at night. Singular interruptions to the trade-wind are caused by these low lagoon§ islands; not only does the easterly wind often fail among them, but heavy squalls come from the opposite direction, and more frequently by night than by day. This is especially the case from November to March.

I have before remarked (pp. 65, 66), that extensive shallows, such as the Abrolhos and Bermudas, are liable to heavy squalls;

* 3d November, lat. 11°.45′ S., long. 126° W.

† About 110 feet from the water level to the top of the trees.

‡ Admiral Krusenstern had the kindness to send me a copy of his Atlas of the Pacific Ocean, accompanied by an elaborate memoir.

§ Most of them are little better than dry reefs encircling a shallow lake or lagoon.

© The Complete Work of Charles Darwin Online

and so far as I have heard or observed, it is usually the case that on land, a wide tract of flat country, without hills, or at sea, a considerable space of partly-covered ground, nowhere rising much above high-water, is subject to more frequent and violent blasts of wind than mountainous or even hilly regions, whether continental or island.

Clouds are certainly attracted, even if their formation be not hastened, by land; especially when it is covered by trees: and as low islands (such as those of the Dangerous Archipelago, between 14° and 20° south) have no hill or height of any kind, about which clouds attracted by the archipelago (taken together) can gather and discharge a portion of their contents, electrical as well as fluid, it may, I think, be inferred, that the want of such a conductor as would be furnished by a mountain five or six thousand feet high, is the reason why clouds in various electrical conditions unite or oppose one another, as the case may be; and, in consequence, cause rapid changes in the atmosphere around them; of which the effects are seen in squalls (sometimes with heavy rain, sometimes without), and even in whirlwinds. Where high land acts as a conductor between the earth and certain portions of our atmosphere, there may be a continual, though unperceived, electrical action. In connection with this subject I would, if I were able, consider the effects of rapidly varying temperature over land, and comparatively uniform temperature over ocean during twenty-four hours; which latter fact I might suspect to be one reason why the great Humboldt could not discover any particular electrical action, as indicated by his electrometers, while sailing from Europe to Brazil: although those same instruments were far from inactive after he landed. But I feel myself out of my depth, and will leave such speculations to those who are qualified to indulge in them.*

On the 13th, after having passed some anxious nights in very squally weather,† we were gratified by seeing an islet whose existence we had not suspected. Tairo is the name by

* See note (*a*) at the end of this chapter.

† All the squalls were from the westward.

© The Complete Work of Charles Darwin Online

which it is known to the islanders of the archipelago. A few hours afterwards we ranged along the shore of another and much larger island, or rather group of islets, till then not laid down in any chart, the native name of which is Cavahi. We saw a number of islets covered with cocoa-nut trees, surrounding a lagoon; but could not delay to examine the south side, because we had been so unexpectedly detained by contrary winds, and I was very anxious about the chronometer measurement, the interval being already considerable.

Hastening on, therefore, we passed between the Elizabeth and Wittgenstein (or Faarava) groups, which are similar to Cavahi in appearance, and carried a press of sail to reach the Society Islands. It was singular that directly we were clear of the Low Islands, we got into a steady trade-wind, such as we had enjoyed before seeing Honden Island; and were no more troubled by westerly wind, or squalls, till long after we had left Otaheite* and were approaching near New Zealand.

15th. Early this morning we saw Otaheite; but clouds hanging over the high land and a haziness about the horizon, at first disappointed our expectations. As the sun rose higher, the clouds shrunk away, vanishing as they rolled along the grandly formed mountains: high, sharp, irregular peaks, and huge masses of rock appeared between the mists, and again were hidden—deep vallies or glens showed darkly, and while the shadows passed, seemed to be denied the light of day. Strikingly different in appearance were the lower hills and dales, and the richly wooded land at the sea-side. There the bright sunshine heightened the vivid and ever-varying tints of a rich verdure. The beautiful alternation of light and shade, each moment changing as the flitting shadows passed over every kind

* Some diversity of opinion has arisen respecting the spelling of this name. No person now doubts that Tahiti is the native word, and therefore the most correct to be used when talking to Polynesian islanders, or writing for them; but as our immortal countryman, Cook, wrote Otaheite, and it is difficult to hear or see the word without thinking of him, I shall beg to be allowed the same privilege that Frenchmen claim when writing 'Londres,' or Englishmen when they write 'Sicily;' and for the future use only the word Otaheite.

of green; the groves of graceful palm-trees; the dazzling white foam of the breakers on the coral reefs, contrasted by the deep blue of the sea, combined to form a most enchanting view. At a distance in the west, Eimeo (Moorea) showed a picturesque outline, and added to the beauty of a scene which surpassed our ideas, even heightened as they had been by the descriptions of former voyagers.

Passing Point Venus, and avoiding the Dolphin Shoal, we worked up to an anchorage in Matavai Bay. No pilot appeared, but had we waited in the offing, a very good one* would have offered his services. With a fresh breeze, we gained the anchorage so quickly that few natives had time to hasten on board, as is their usual custom: only one long canoe came alongside while we sailed in: it was made of half a tree, hollowed out, with a narrow rough plank laced to each side, and an out-rigger, consisting of two crooked branches, secured to the canoe and to a long piece of light wood which floated in the water parallel to it. This out-rigger extended eight or ten feet from the ticklish conveyance, and enabled four men to sit at their ease in the narrow trunk of a tree that had never exceeded a foot in diameter.

The personal appearance of these men was to me most remarkable: tall and athletic, with very well-formed heads and a good expression of countenance, they at once made a favourable impression, which their quiet good-humour and tractable disposition afterwards heightened very much. To my eye they differed from the aborigines of southern South America in the form of their heads; in the width or height of the cheek-bones; in their eye-brows; in their colour; and most essentially in the expression of their countenances. High foreheads; defined and prominent eyebrows; with a rich, bronze colour, give an Asiatic expression to the upper part of their faces; but the flat noses (carefully flattened in infancy), and thick lips, are like those of the South Americans.

By the time the vessel was secured, a number of canoes had

* Called James Mitchell, though an aboriginal Otaheitan.

© The Complete Work of Charles Darwin Online

assembled, each containing from two to ten persons. A few, indeed, were so small that they could only hold one man each. The outriggers hindered their approach, as much as hoops impeded the motions of our maternal ancestors; but those who could not get near looked equally happy at a distance. All were cheerful, tractable, and patient, though eager to see the 'manuâ' (their corruption of man-of-war), and dispose of their merchandize (shells and fruit) to the new-comers.

The work necessary for securing the ship being completed, permission was given to admit the natives; and on board they swarmed like bees. In a minute, our deck became a crowded and noisy bazaar. 'One dălă' (dollar), and 'my ty' ('maitai,' meaning 'good, fine, agreed,' &c.) sounded in all tones, except those of women, none of whom appeared afloat. The current price of every article was 'one dala': a pig, a shell, a whole basket of shells, a roll of cloth, a heap of fruit, or a single fish-hook, of the worst description, were offered as equivalents for the coveted dollar. Old clothes, if of cloth, they would not take, unless as a gift; but linen was acceptable. Every man had a light linen or cotton garment, or the remains of one, of some kind; the more respectable wore shirts, and loose wrappers for trowsers; a few had jackets and trowsers. Many had straw hats; some had a wreath of leaves, some flowers in their hair: only a few of the youngest boys were nearly naked.

Mr. Darwin and I went to Point Venus, and landed among a mob of inquisitive, laughing, and chattering natives, most of whom were women and children. Mr. Wilson, the respected missionary, so long resident at Matavai, met us on the beach; and with him we went, attended by the younger part of the mob, to his house. Ten minutes' walk along level land, every where, except at the sea-side, covered or shaded by thick underwood, tall palms, and the rich foliage of the bread-fruit tree, brought us to the quiet dwelling. The free, cheerful manners of the natives who gathered about the door, and unceremoniously took possession of vacant seats, on chairs, or the floor, showed that they were at home with their benefactors; and that any seclusion or offensive intimation of superiority had

© The Complete Work of Charles Darwin Online

not existed in the conduct of Mr. or Mrs. Wilson. Two chiefs, of inferior rank, made acquaintance with us; they walked into the room, shook hands, sat down at their ease, and conversed with Mr. Wilson in exactly the manner of respectable English farmers. They were large, but inactive-looking men, and round-shouldered—suitably clothed, above the knees, in clean white jackets, shirts, and wrapper trowsers, with their closely-cut hair hidden by a large straw-hat—their appearance was very respectable. 'Ia-orana,' pronounced 'yoronha,' was a salutation we soon learned; but one of my younger shipmates was a little perplexed during his first excursion, "Why does every one call me 'Your honour,'" said he. Most of our officers and many of the men passed the evening on shore, and Mr. Darwin and myself rambled about until darkness summoned all on board.

Often as the native houses have been described, I found them different from the idea I had formed. Perhaps they are now rather slighter, and not constructed exactly like those of other times. Upon slight posts, placed in the ground in a long ellipse, a very light and elegant frame-work of 'purau'* is supported. This frame-work forms the low, but extensive roof; and upon it a thatch of pandanus leaves,—simply doubled upon twigs or reeds placed crosswise on the purau-wood rafters, which have their ends outwards,—forms a light covering, impervious to water, regular, indeed pretty to the eye, impenetrable by heat, and easily replaced once in eight or ten years. The middle of the roof forms an obtuse angle, as a common low roof does elsewhere; but the ends are rounded. The purau rafters are placed at equal distances around the circumference, converging as radii to the centres and central line of the ellipse. All of them are of equal length and size, and their ends are generally ornamented with a neat matting, made of a mosaic† pattern. Each line of twigs, holding the leaves, is straight and equi-distant from the next; and as, in the house, only about three inches of the smooth surface of each leaf is seen between the lines of twigs, the flat under surface, of an uniform appearance and

* The 'purau' is something like bamboo. † Or arabesque.

© The Complete Work of Charles Darwin Online

light straw colour, aids the smooth, round purau in agreeably surprising the eye of a stranger by a new kind of architecture, as admirable as it is simple. Around the house, instead of a wall, are strong canes, regularly placed between the supporting posts, at distances (one or two inches) equal to the diameter of the canes; they are driven into the ground, and secured to the roof; one opening only is left for a door. Within are some screens of native cloth, or framed bed-places, or simply mats spread upon dry grass. There are a few low stools, some baskets, joints of bamboo holding cocoa-nut oil, and calabashes with water, besides a variety of smaller things, which I had not time to examine. What house in a tropical climate could be more agreeable than one of these elegant wicker-work cottages, shaded round by large trees, and profiting by the fresh air of every breeze?

Pretty shades for the face (they cannot be called hats, as they encircle and project from, without covering the head) are made with the palm-leaves. When fresh, adorned by white, or deep red flowers, and tastefully placed, this head-dress is unique and pleasing.

Perhaps my eyes were prejudiced in favour of features and complexion; for the shambling gait and flat noses of the native women had no charms for me. I saw no beauty among them; and either they are not as handsome as they were said to be, or my ideas are fastidious. The men, on the other hand, exceed every idea formed from the old descriptions.

On this day, with us the 16th, but to agree with the reckoning of Otaheite and those who came from the west, changed to the 17th, I was fully occupied in making observations upon the spot where once stood Cook's observatory, a classical, and to us, important place. Upon the situation of this celebrated point, Venus, depend most of the geographical positions of islands in the South Sea; and its locality upon our globe has been deemed well known. Messrs. Wales, Green, and Bayley are particularly entitled to the greatest share of credit for having by their observations attained to so great a degree of accuracy.

© The Complete Work of Charles Darwin Online

While we were engaged with the instruments on shore, a crowd of natives were eagerly displaying their merchandise along side or on board the ship. From the dawn of day, until they were admitted at breakfast time, canoes had been approaching from every direction. Their occupants had heard of the dollars, and every canoe within reach had been loaded. This sort of competition could not last; so I thought it better to give them as much opportunity to dispose of their wares as our small deck allowed; and desired Lieut. Wickham to let the market be held till trade grew dull. Some wanted to build us a house; many asked to be allowed to wash our clothes. There appeared to be no want of will to work, if dollars were to be gained.

On shore it was difficult to make the required observations, among a crowd of curious observers of ourselves and our instruments; for though they readily drew back as far as we wished, it was quite impossible to keep them from running about and shaking the ground. While employed with the dipping needle under a tent, I thought myself fortified: but they besieged the small opening so closely, in their eagerness to see the sight, that the heat caused by a vertical sun was soon increased to that of an oven, from their thus blocking up the only air-hole.

At my return to the ship in the evening, I found that the fair had not lasted above an hour after breakfast. All the natives had behaved well excepting two; one of whom absconded with the top of a brass stanchion. The other tried to carry off an axe; but was detected, and pointed out to the more respectable of his countrymen, who said he should be tried, and that his sentence would probably be a fine of ten hogs.*

This evening some of our party were much pleased by hearing the pretty plaintive songs of the children, as they sat in groups upon the shore. Their voices accord in the most perfect manner; and, although the tunes are rather monotonous,

* The man who tried to steal the axe wa fined eight hogs and a large piece of cloth. Five of the pigs went to the queen, and three were sent on board the Beagle. The cloth was given to the man who caught the thief.

© The Complete Work of Charles Darwin Online

they detained us, sitting upon the sandy beach, till we could stop no longer.

18th. Mr. Wilson went with me in a boat to Papiete, the most frequented harbour of Otaheite. We passed inside the reefs, by narrow twisting passages among the coral rocks. Seeing two marks set up on an extensive rocky flat, partially covered by the water, I concluded they were placed as beacons; but was told they were tabu (taboo) marks to keep people from fishing or picking up shells upon the queen's 'preserve.' We passed the royal burying-ground, which is adorned by that peculiar tree, the aito, whose wood is so hard that it is called iron-wood. This tree looks like the English yew. It is purposely planted by the natives near their burying-grounds, and used to be considered sacred. Another remarkable tree, resembling (although larger and finer than) the ilex, also casts a solemn shade over the tomb of Pomare.*

The point of land on which the tombs and one of the royal houses stand, is one of the most agreeable places on the island, in point of position; and was a favourite residence of old Pomare. A portion of their superstition hangs about the natives yet: I could not persuade them to approach the tomb of their king, although they told me to go and look at it. The tomb is a plain mass of masonry, sheltered by a roof of wood.

At Toanoa, between this place (called Papawa) and Papiete, we saw Mr. Bicknell's sugar-mill. The sugar made there from native cane is of a very good quality, and cheap. Mr. Bicknell told me that the natives brought their canes to him; and that latterly he had given up growing and attending to them himself. Noticing a large deficiency in some lead-work, he remarked: "That lead was stolen in the last civil war; our books were then in high request, not to be read, but to make cartridges." That such a sad misapplication of numbers of books sent out by missionary societies, has also occurred in New Zealand, as well as among the eastern Indian nations, I have heard from many quarters.

* The late king.

© The Complete Work of Charles Darwin Online

Papiete is a pretty and secure little bay. Around it is low land, ornamented with trees and European as well as native houses: but immediately behind the level part, hills rise to a height of two or three thousand feet. Lying to leeward of the island it enjoys less sea-breeze, and is therefore hotter than other harbours. In the middle of the bay is a little island belonging to the queen, where the colours of Otaheite (red, white, red, horizontal) are displayed.

Several neat-looking white cottages showed that European ideas had extended their influence hither: but I was sorry to see the new church, a large wooden structure capable of holding six hundred people, covered by a partly Otaheitan roof, in lieu of one formed completely in their own style. Instead of the circular end, an ugly gable terminates a high box-shaped house, resembling a factory.

Mr. Pritchard* arrived from Eimeo as we landed. Leaving him for a short time, I went to see a person who styled himself Baron de Thierry, King of Nuhahiva† and sovereign chief of New Zealand. About the house in which resides this self-called philanthropist,—said to be maturing arrangements for civilizing Nuhahiva and New Zealand—as well as for cutting a canal across the Isthmus of Darien,—were a motley group of tattowed New Zealanders, half-clothed natives of Otaheite, and some ill-looking American seamen. I was received in affected state by this grandee, who abruptly began to question me with—"Well, Captain! what news from Panama? Have the Congress settled the manner in which they are to carry my ideas into effect?" I tried to be decently civil to him, as well as to the 'baroness'; but could not diminish my suspicions, and soon cut short our conference.

In his house was a pile of muskets, whose fixed and very long bayonets had not a philanthropic aspect. He had been there three months, and was said to be waiting for his ships to arrive and carry him to his sovereignty. Born in England, of French emigrant parents; his own account of himself was that

* Now Her Majesty's Consul. † One of the Marquesas.

© The Complete Work of Charles Darwin Online

he was secretary of legation to the Marquis of Marialva, at the congress of Vienna; and that in 1815 he belonged to the 23d Light Dragoons (English). In 1816 he was attaché to the French ambassador in London. In 1819 he was studying divinity at Oxford. In 1820-21, he was a student of laws at Cambridge. Afterwards he travelled on the continent: and lately had been sojourning in the United States. He visited and brought letters from the Governor of St. Thomas, in the West Indies. He showed papers to prove these assertions: had a wife and four children with him; and he had succeeded in duping a great many people.

Mr. Pritchard had seen the queen (by courtesy called Pomare, after her father, though her name was Aimatta) at Eimeo, the day before he arrived at Otaheite; and as she had not intimated an intention of coming thence, I agreed to go with him in a few days to pay my respects to her, and to make a formal application upon the subject of the Truro, a merchant vessel plundered and destroyed by the Low Islanders in 1830-31.* I returned to Matavai in the evening, and, after landing Mr. Wilson, remained nearly two hours listening to the natives singing. I asked them to dance; but they said it was forbidden, and that the watchman would take them to the governor of the district, who would fine them heavily. Singing, except hymns, is also forbidden to the grown people, but they seemed to like listening to the children.

This evening, before dark, there was a sight upon the Beagle's deck, which delighted us who wished to collect shells but had not time to look for them. An Englishman† had spread out a large collection which he had just brought from the Low Islands, and soon found eager purchasers.

19th. We weighed anchor, and went into the little cove of Papawa, for the sake of watering quickly, without exposing the men and boats to a heavy surf. It is easy to avoid the numerous rocky patches, while there is a breeze, and the sun

shining on either side, or astern; but if the sun is a-head, it is almost impossible to distinguish the reefs, by the colour, or relative smoothness of the water. Walking to the house of Mr. Nott, I saw an elderly native writing in a cottage, and apparently very intent upon his employment. He showed me what had engaged his attention, an Otaheitan version of the book of Jeremiah, in Mr. Nott's writing, which he was copying in a very distinct, good hand.

Mr. Nott, the senior missionary upon the island, had then almost completed a great work, the translation of the Bible.* When we consider the judgment and persevering industry required to translate the Bible from one written language into another, it becomes easier to obtain a fair conception of the labour necessary to fix, and make proper use of an unwritten, and very peculiar language, in order to effect such a work,—a work worthy of the fathers of our church. I paid my respects to the author of this immense undertaking, and asked his advice and opinion respecting the affairs in which I was instructed to take a part, while on the island.

In the course of another visit to Papiete, I again met the titular king of Nuhahiva, and told him my suspicions, so plainly, that he said he should appeal to the governor of New South Wales, to the Admiralty, and to the king of England himself, against the unjust suspicions and improper conduct of the captain of the Beagle!

Since the 17th the weather had been too cloudy, by night and by day, to admit of astronomical observations. Instead of fine clear weather, there was a thickly overcast sky, and only light and variable wind. From the latter end of December to the beginning of March cloudy weather (with much rain, and westerly winds) is usual at Otaheite. Singular interruptions to

* This noble work is completed. I have now lying by me a copy of the entire Bible, in the language of Otaheite, translated and compiled by Mr. Nott, who has just sailed from England on his return to Otaheite, carrying with him an ample number of copies of the Book of Books. I felt deeply gratified by that good man's kindness in giving me one of the first copies which were printed.

the regularity of the trade-wind occur among all the tropical islands of this ocean. One instance has already been given of the uncertain and changeable state of the weather among the Low Islands, and many more may be found in the narratives of voyages in the Pacific between the tropics.

20th. While conversing with Middleton about those Low Islands (where he had passed much time), I was very much struck by the unpleasant personal feeling shewn by him when alluding to the missionaries, and their regulations, as contrasted with the strong terms in which he mentioned the good effects of their intercourse with the Low Islanders; and how much more missionaries were required. His own words, as I find them in a paper of remarks he gave me, are, "the inhabitants (of the Low Islands) are familiarized to Europeans; and are partly civilized, owing to the Gospel having been preached to them by the missionaries." In another place he says, "there are inhabitants enough to require the constant residence of one or two missionaries. They have some books of the Gospel in their hands, but are yet too ignorant to profit by their contents." His own antipathy to the missionaries had arisen, I found, in consequence of their restraints upon his conduct, while at Otaheite.—Among other information he said that the natives of Chain Island told him frequently, that the first ship they ever saw was manned with black people; but the captain, whom the natives styled the 'King of the Spirits,' was a white man. They were much alarmed when they saw the vessel come close to their island, and their old men deemed it an omen of impending disasters. Soon after this event, the island was inundated by the sea, and many people perished. They were then cannibals, and always at war with the natives of the neighbouring islands: since that time, which was 'long ago' (how long he could not ascertain), the Chain Islanders have invaded and successively conquered the other Low Islands, invariably killing and eating the greater proportion of their captives. (The Low Islands are called Paamuto.)

Middleton arrived at Otaheite from Chain Island, only two days before this conversation took place, He came in his

© The Complete Work of Charles Darwin Online

own open whale boat, with a crew of five natives; two being Chain Islanders, one a native of the Gambier Islands, one from the Marquesas, and one from the ferocious set who live upon an island called Aura.* Knowing their habits, and understanding their language, radically the same though differing in dialect, had assisted his daring and enterprising disposition in a series of wanderings about all the islands which lie in this quarter of the Pacific. He sold me a chart, made by himself, in which, he said, every one of the Low Islands was marked, though not correctly.† From him I obtained their native names also, with the proper pronunciation. He says the natives are great talkers, and have very good memories: for hours at a time he has often listened, with the deepest interest, to their traditions, and to the terrible tales of their inhuman warfare. About the year 1800, as near as he could ascertain, a ship was cast away upon the low island Arutua:‡ her crew were Europeans (meaning white men). The people of Arutua offered no violence, but the blood-thirsty natives of Aura hearing of the wreck, repaired to the place in a body, and massacred every man.

In the year 1831, the master and mate of the unfortunate Truro, passing by Aura in a small boat, were invited ashore by many friendly signs. They suspected no danger, landed together, without arms, were instantly speared by the treacherous natives, and fell, embracing each other.§ Those islands are supposed, by Middleton, to have received their earlier inhabitants from the Marquesas; and a few, latterly, from Otaheite.

By frequent intercourse, by presents, and by some slight knowledge of medicine, Middleton thought he had established

* Excepting the savages of Aura the natives of Chain Island have conquered, successively, all the other islanders in their neighbourhood. On Chain Island there are more hogs and fruits than on any other low island.

† Some of these data were used in adding to Admiral Krusenstern's chart. ‡ I do not know its position.

§ I remarked that the heads of the Otaheitans and those few of the Chain Islanders whom I saw, were strikingly different, but truly conformable to their respective characters.

© The Complete Work of Charles Darwin Online

himself among the low islanders so securely that he scrupled not to visit any of their islands, Aura alone excepted. How necessary it must be for a missionary to have a knowledge of medicine and surgery. The Jesuit, Falkner, wandered alone in safety among the tribes of South American Indians, owing, in a great measure, to his knowledge of the healing art.*

21st. I went to see 'Ua,' an old man, who remembered 'Toote' (Cook); yet was still strong and active: he told me that in those days he was a little boy. There were many more people then in Otaheite; ten to one, as compared with the present numbers: but sickness had destroyed a great many, he thought. The island was not so healthy as in former times; and they had caught diseases, in those days unknown. Asking who brought this or that disease, he imputed the worst to the ships which came after Cook's first visit, and left men upon the island until

* "Mr. Thomas Falkner was the son of a surgeon of eminence at Manchester, and was brought up in his father's profession, for which he always manifested the most promising disposition. To complete his professional studies, he was sent to London to attend St. Thomas's Hospital; and, happening to lodge in Tooley-street, on the Surrey bank of the Thames, he made an acquaintance with the master of a ship, employed in the Guinea trade, who persuaded the young surgeon to accompany him in his next voyage in his professional capacity. On his return to England, he engaged to go in the same situation on board a merchant ship to Cadiz, from which he continued his voyage to Buenos Ayres, a Spanish settlement on the River La Plata. Here he fell sick, and was in so dangerous a state when his ship was ready to depart, as not to be in a condition to be carried on board; so she sailed without him. The Jesuits, of which there was a college at Buenos Ayres, nursed him during his illness with the greatest care and kindest assiduity; and perceiving the very great advantage which they would derive, in their missions, from possessing a brother who was so well skilled in medicine and surgery, spared no pains to win his affection and secure his confidence. In short, they so worked upon his mind, as to persuade him to enter into their college, and finally to become one of their order. He now entered upon his ministry among the Indians who inhabit the vast track of country between the River La Plata and the Straits of Magellan. His skill in the cure of diseases, and in performing chirurgical operations, together with his knowledge of mechanics, rendered his mission successful beyond example. In this country he remained near forty years, and was among the persons appointed

© The Complete Work of Charles Darwin Online

their return the following year.* Curvature of the spine, or a hump-back, never appeared until after Cook's visits; and as he had a hump-backed man in his ship, they attribute that deformity to him. 'Ua' told me that I need not yet have any anxiety about a westerly wind, or bad weather. "The wind would be light and variable during that day, but on the morrow would draw round to the eastward, and two days afterwards the sky would be nearly free from clouds." Thanking the old man with some presents, I returned on board; and the Beagle then got under weigh, 'swept' out of the harbour, and, by the sails and sweeps, alternately employed, regained her former anchorage in Matavai Bay. In the course of a walk among the cottages between Papawa and Matavai, I found numerous tokens of industry, such as I had not expected in a South Sea island. In an enervating climate, where abundance of food is easily procured, one ought not to expect the contented natives to distress their minds or bodies, with anxious and industrious endeavours to supply wants which they do not feel, in any degree like the inhabitants of cold or temperate climates; yet the men of Otaheite undergo great fatigue, and carry heavy burthens up and down most difficult tracks in the

pointed by the Spanish government to make a survey of the coasts between the Brazils and the Tierra del Fuego, Falkland Island, &c. When the society of Jesuits was dissolved, he was sent back to Spain, and after an absence of near forty years, arrived in his native country. Soon after his return to England he became domestic chaplain to Robert Berkeley, esquire, of Spetchley, near Worcester, a Roman Catholic gentleman of distinguished knowledge, most respectable character, and large fortune. There he wrote the account of Patagonia, which has been quoted in this volume, and was afterwards published, with a map corrected from that of D'Anville, according to his own observations. Mr. Falkner possessed a very acute mind, a general knowledge, and most retentive memory. Of his medical experience and practice, I have heard physicians of eminence speak in the highest terms of commendation. His manners, as may be supposed from the tenor of his life, were at once singular and inoffensive: and he retained somewhat of his Indian habits to the last. He died, as I have been informed, about the year 1781."—Colnett's Voyage, page 25, note.

* Spanish ships, from Lima, in 1774-6.

© The Complete Work of Charles Darwin Online

mountains, in a manner astonishing, if not impossible, to Europeans. Mr. Darwin, who made a three days' excursion among the wildest parts of the mountains, was quite enthusiastic in his account of the strength, activity, and above all, the excellent disposition and good conduct of the two natives who were his companions and guides.

At the door of one house I saw the owner reading a book attentively. It was the New Testament translated into his native language. His wife was rolling up some of the large green leaves which they use as substitutes for plates; and two merry little children had been running after me, singing, in hopes of a present of some trifle. The superior expression of that man's countenance, and his unaffected employment (for I came upon him suddenly, and unperceived till the children spoke), made an impression upon my mind, which, I hope, will not be forgotten.

In my way back, passing some tall palm trees, I asked a native to get me some cocoa-nuts. Putting a strip of bark between his feet, he threw off his shirt, and jumped 'at' the tree, catching the trunk with his feet and hands at the same moment; then moving his hands alternately, and his feet by short jumps, the band of bark assisting their hold on the slender trunk, in a few seconds he was at the top of a tree seventy feet in height, quite straight and perpendicular, and tapering in size from a foot to six inches in diameter.

Some curious relics of former times were found for me, which had long remained in dusty quiet; among them were tortoise-shell masks, and head pieces surmounted by feathers of the tropic bird; also an apron, ingeniously, or rather laboriously made of small pieces of mother of pearl. So long was it since they had been used, that a native about thirty years of age did not know what they were for: but from the signs and expressions of the old man to whom they belonged, I think they formed part of the dress of a priest, used when sacrificing a (perhaps human) victim.* Two English sixpences also found their way to me, bearing the date 1787; memorials of the ill-fated Bounty.

* A whole dress may be seen at the British Museum, brought to England by Cook in 1771.

© The Complete Work of Charles Darwin Online

News arrived that the queen intended to return to her head-quarters at Papiete, and that she had ordered a present of fruit and pigs to be prepared.

22d. Sunday. Early this morning a party went with me to Papiete, and others went to Mr. Nott's church, while those who could not go far from the ship attended Mr. Wilson, to hear as well as see the natives at divine service. At Mr. Pritchard's church we found an orderly, attentive, and decently dressed congregation. I saw nothing "grotesque," nothing "ludicrous," nor anything which had a tendency to "depress the spirits," or "disappoint one's expectations."*

The church was quite full and many were sitting outside; I suppose six hundred people were present besides children, who, like others of their happy age, required an occasional touch with the white wand of a most stern looking old beadle, to prevent their chattering to one another about the strangers, and their 'money.'†

Mr. Pritchard's fluent delivery in the native language surprised and pleased us much. The greater part of the natives were very attentive. Two were making notes upon paper, of the subject of his discourse. A few were careless, but only a very few; and their eye-wanderings were caused chiefly by the strangers in uniform. Where is the English congregation of five or six hundred persons, in which a captious observer could not occasionally detect inattention to the clergyman? Hymns were sung with much propriety, and a very pleasing musical effect. The language is so soft and so full of vowels, that the good voices and very correct ears of the natives succeed admirably in hymns. After the service in the native language had ended, we repaired to the English chapel with Mr. Pritchard, who performed divine service in the manner of the Independents. Occasional visitors from ships at the island, and the few European residents who are within reach, frequent this chapel.

* I had read Kotzebue's voyage a few days previously.

† All gold or silver is by them called 'money;' the gold lace on a coat, an epaulette, a gold coin, or a dollar, is 'money.'

© The Complete Work of Charles Darwin Online

It was certainly better to suppress altogether, rather than only to restrain and alter their former licentious amusements, but it seemed to me that some kind of innocent recreation was much wanted by these light-hearted islanders. There is a void in the mind where a naturally thoughtless and volatile disposition exists, which it is extremely difficult to fill with serious thoughts of any duration. To such minds "a quiet reflecting day," (as my respected and much lamented messmate in the Thetis, the Rev. Henry Hall, used to term Sunday), is, in a great measure, a vacant time of leisure, which if not occupied by innocent thoughts which interest without doing harm, is certain to be seized upon by evil imaginations and bad passions.

During the time we passed in the churches it was sufficiently plain that there was no harshness usually shewn towards the children: for they clustered round their minister so closely when he moved about, that he was obliged to push them away, good naturedly, several times. From the manner of elderly, as well as young natives, I should conclude that "Pritate,"* as they called Mr. Pritchard, was a favourite.

23d. With Mr. Henry (the son of the missionary) a well known chief, 'Hitote,' came on board to share our breakfast. Captain Beechey has introduced him in his work and described his character. Mr. Henry was born upon the island, and had never visited England, yet a more English countenance, or more genuine English ideas, I have seldom met with in any part of the world. From him I received some information, to me very interesting, and to those for whom it was my duty to collect nautical intelligence, I hope useful.† Afterwards I hastened to Papiete to pay my respects to Queen Pomare. I was in time to see her arrive from Eimeo, sitting on the gunwale of a whale-boat, loosely dressed in a dark kind of gown, without anything upon her head, hands, or feet, and without any kind of girdle or sash to confine her gown, which was fas-

* Having so few consonants in their language, obliges them to change most of our names.

† Mr. Henry's data were also used in adding to Krusenstern's chart.

© The Complete Work of Charles Darwin Online

tened only at the throat. There was no reception at landing: no attendance, no kind of outward ceremony showed that the 'Queen of the Isles' had arrived at her home.

Some time afterwards, when I heard that she was inclined to give an audience, I went to the royal cottage with Mr. Pritchard. A parcel of half-dressed merry looking damsels eyed us with an amusing mixture of shyness and curiosity. These, I concluded, were a part of the 'Queen's mob,' as our interpreter had ignorantly or democratically called the royal attendants. Only a few men were about the house, one of whom was the queen's foster-father ('feeding father' in the Otaheitan language) and another her husband.

Entering a small room, 'Ia-orana Pomare,' with a shake of the hand, was the salutation given by Mr. Pritchard, and by myself, following his example. On the only three chairs in the room we sat down, but the queen looked very uncomfortable, and certainly not at all dignified. I could not help pitying her, for it was evident she was expecting a lecture on the subject of the Truro, and felt her utter helplessness: I was therefore glad, after a few words of compliment, to see her mother, husband, and foster-father enter the room, though they sat down upon chests or the floor.

I delivered a letter from Commodore Mason, which she asked Mr. Pritchard to interpret, and sent out to her secretary. A meeting of the chiefs, herself presiding, was proposed and decided to be held on the following day. Some conversation then passed on other subjects, and we took our leave by shaking each individual by the hand. This is certainly preferable to pressing noses, but I was sorry to see that the missionaries had attended but little to the outward demeanour, to the manners, to the attendance, and to the dwelling of the sovereign of a people whose happiness and improvement would certainly be increased by raising the character, and improving the condition of their ruler. While called a queen, Pomare ought to be supported by some of those ceremonious distinctions, which have, in all ages and nations, accompanied the chief authority. That the missionaries should interfere harshly

© The Complete Work of Charles Darwin Online

or sweepingly, would doubtless irritate; but a beneficial influence, almost unnoticed except in its effects, might be exerted in these temporal, and seemingly trifling affairs, which might assist hereafter in a day of need.

I have been told that the natives have been very ungrateful to the missionaries. Perhaps they are not all aware what a debt of gratitude they owe. Certainly, the better informed and the older inhabitants understand and appreciate the kindness and the labours of their devoted teachers; but whether the younger or the lightly-disposed have, generally speaking, a kindly feeling towards them I doubt. More temporal enjoyments, and more visible or tangible benefits are asked for by the younger inhabitants, who are daily becoming more aware of the manners and habits of civilized nations. Surely the queen, a young and lively woman, is likely to compare her own habits and personal comforts, and the degrees of attention or deference shown to her, with those of foreigners, either resident in or visiting Otaheite.

Dispensing temporal benefits, with an evident desire to better their condition in every way, excites the gratitude of ignorant minds, and often paves the way towards teaching them to acquire abstract ideas, and to wage war against many of those things which they would rather do than leave undone. There is a Roman Catholic mission at the Gambier Islands, amply provided with presents and property fit for the natives, and it is said that they are succeeding well. At Otaheite the missionaries were afraid that the doctrines of the Roman church would obtain a greater influence, and agree better with the disposition of the natives than the strict discipline in which they have hitherto been held. Unless preventive measures are taken in Europe, religious strife and internal warfare may again be caused in these islands, even by those whose aim is peace. Already there is a remarkable bitterness of feeling on the subject, which is unlikely to diminish if the success of the Roman Catholic mission increases.

But I have wandered away from Pomare—her small ill-furnished room and her awkwardly-contrived house, neither Eng-

© The Complete Work of Charles Darwin Online

lish nor Otaheitan. Before she became sovereign, she was known by the name of Aimatta, which signifies 'eye-eater;'* but Pomare has since been adopted as the royal name. In affixing her signature, 'Vahine' is added, which means 'female'—thus 'Pomare Vahine.' Her husband is a young, intelligent man; but he has no share in the government, being only king-consort. This man was the only native of the island, that I saw, whose nose was sharp and projecting. It is amusing to think that they call a man 'long nose,' in this country, when they wish to wound his feelings deeply.

During the first few days after a child is born, the mother or her attendants keep pressing the back of the infant's head with one hand, and the forehead and nose with the other, to make the head high and the nose and brow flat. Children of the higher ranks undergo more compression, because they are more carefully attended.† How the queen's husband escaped, or could be chosen by her with such a nose, I am at a loss to discover.

24th. With all the officers who could be spared from the duty of the ship, Mr. Darwin and I repaired early to Papiete. Mr. Wilson, Mr. Henry, and Hitote, were of the party. Arrived at the hospitable abode of Mr. Pritchard, we waited until a messenger informed us of the queen's arrival at the appointed place of meeting—the English chapel. From our position we had just seen the royal escort—a very inferior assemblage. It appeared that the chiefs and elderly people had walked to the chapel when our boats arrived, leaving only the younger branches of the community to accompany Pomare. The English chapel is a small, wooden structure, with a high, angular roof; it is about fifty feet in length and thirty feet wide; near the eastern end is a pulpit, and at each corner a small pew. The rest of the building is occupied by strong benches, extending nearly from side to side; latticed windows admit light and air; the roof is thatched in a partly Otaheitan manner; none

* I need not remark upon the offering made to the king in the time of human sacrifice.

† Mitchell, the native pilot, described this process to me minutely.

© The Complete Work of Charles Darwin Online

of the woodwork is painted, neither is there any decoration. Entering the chapel with my companions, I turned towards the principal pews, expecting to see Pomare there; but no, she was sitting almost alone, at the other end of the building, looking very disconsolate. Natives sitting promiscuously on the benches saluted us as we entered:—order, or any kind of form, there was none.

The only visible difference between Pomare and her subjects was her wearing a gay silk gown, tied however round the throat, though entirely loose elsewhere; being made and worn like a loose smock-frock, its uncouth appearance excited more notice from our eyes than the rich material. In her figure, her countenance, or her manner, there was nothing prepossessing, or at all calculated to command the respect of foreigners. I thought of Oberea,* and wished that it had been possible to retain a modified dress of the former kind. A light undergarment added to the dress of Oberea might have suited the climate, satisfied decency, and pleased the eye, even of a painter.

Disposed at first to criticise rather ill-naturedly—how soon our feelings altered, as we remarked the superior appearance and indications of intellectual ability shown by the chieftains, and by very many of the natives of a lower class. Their manner, and animated though quiet tone of speaking, assisted the good sense and apparent honesty of the principal men in elevating our ideas of their talents, and of their wish to act correctly.

Every reader of voyages knows that the chiefs of Otaheite are large, fine-looking men. Their manner is easy, respectful, and to a certain degree dignified; indeed on the whole surprisingly good. They speak with apparent ease, very much to the

* Queen of Otaheite in 1767. "Both men and women are not only decently, but gracefully clothed, in a kind of white cloth, that is made of the bark of a shrub, and very much resembles coarse China paper. Their dress consists of two pieces of this cloth: one of them, a hole having been made in the middle to put the head through, hangs down from the shoulders to the mid-leg before and behind; another piece, which is between four and five yards long, and about one yard broad, they wrap round the body in a very easy manner."—Wallis's Voyage Round the World, 1767.

© The Complete Work of Charles Darwin Online

purpose in few words, and in the most orderly, regular way. Not one individual interrupted another; no one attempted to give his opinions, or introduce a new subject, without asking permission; yet did the matters under discussion affect them all in a very serious manner. Might not these half-enlightened Otaheitans set an example to numbers whose habits and education have been, or ought to have been, so superior?

It had become customary to shake hands with the queen, as well as with the chiefs. This compliment we were expected to pay; but it seemed difficult to manage, since Pomare occupied a large share of the space between two benches nearest to the wall, and the next space was filled by natives. However, squeezing past her, one after another, shaking hands at the most awkward moment, we countermarched into vacant places on the benches next in front of her. The principal chiefs, Utaame, Taati, Hitote, and others, sat near the queen, whose advisers and speakers appeared to be Taati and her foster-father. It was left for me to break the silence and enter upon the business for which we had assembled. Desirous of explaining the motives of our visit, by means of an interpreter in whom the natives would place confidence, I told Mitchell the pilot to request that Queen Pomare would choose a person to act in that character. She named Mr. Pritchard. I remarked, that his sacred office ought to raise him above the unpleasant disputes in which he might become involved as interpreter. The missionaries had approached, and were living in Otaheite, with the sole object of doing good to their fellow-men, but I was sent in a very different capacity. As an officer in the service of my king, I was either to do good or harm, as I might be ordered; and it was necessary to distinguish between those who were, and ought to be always their friends, and men whose duty might be unfriendly, if events should unfortunately disappoint the hopes of those interested in the welfare of Otaheite. These expressions appeared to perplex the queen, and cause serious discussions among the chiefs. Before any reply was made, I continued: "But if Mr. Pritchard will undertake an office which may prove disagreeable, for the

© The Complete Work of Charles Darwin Online

sake of giving your majesty satisfaction, by forwarding the business for which this assembly was convened, it will not become me to object; on the contrary, I shall esteem his able assistance as of the most material consequence."

The queen immediately replied, through the chieftain at her right hand, Taati, that she wished Mr. Pritchard to interpret.

Removing to a position nearer the queen and chiefs (he had been sitting at a distance), Mr. Pritchard expressed his entire readiness to exert himself on any question which might affect the good understanding and harmony that hitherto had existed between the natives of Otaheite and the British; and he trusted that those persons present who understood both languages, (Messrs. Wilson, Bicknell, Henry, and others,) would assist and correct his interpretations as often as they thought it necessary.

Commodore Mason's letter to me, authorizing my proceedings, was then read—in English, by myself—and translated by Mr. Pritchard. Next was read an agreement or bond, by which Queen Pomare had engaged to pay 2,853 dollars, or an equivalent, on or before the 1st day of September 1835, as an indemnification for the capture and robbery of the Truro at the Low Islands.

The queen was asked whether her promise had been fulfilled?

Taati answered, "Neither the money nor an equivalent has yet been given."

"Why is this?" I asked. "Has any unforeseen accident hindered your acting up to your intentions; or is it not to be paid?"

Utaame and Hitote spoke to Taati, who replied, "We did not understand distinctly how and to whom payment was to be made. It is our intention to pay; and we now wish to remove all doubts, as to the manner of payment."

I observed, that a clear and explicit agreement had been entered into with Capt. Seymour; if a doubt had arisen it might have been removed by reference to the parties concerned, or to disinterested persons; but no reference of any kind had been made, and Mr. Bicknell, the person appointed to receive the money, or an equivalent, had applied to the queen, yet had not obtained an answer.

© The Complete Work of Charles Darwin Online

I then reminded Pomare of the solemn nature of her agreement; of the loss which her character, and that of her chiefs, would sustain; and of the means England eventually might adopt to recover the property so nefariously taken away from British subjects. I said that I was on my way to England, where her conduct would become known; and if harsh measures should, in consequence, be adopted, she must herself expect to bear the blame.

These words seemed to produce a serious effect. Much argumentative discussion occupied the more respectable natives as well as the chiefs; while the queen sat in silence.

I must here remark, in explanation of the assuming or even harsh tone of my conduct towards Pomare, at this meeting, that there was too much reason for believing that she had abetted, if not in a great measure instigated, the piracy of the Paamuto people (or Low Islanders). For such conduct, however, her advisers were the most to blame. She was then very young; and during those years in which mischief occurred, must have been guided less by her own will than by the desires of her relations.

I had been told that excuses would be made; and that unless something like harshness and threatening were employed, ill effects, instead of a beneficial result, would be caused by the meeting: for the natives, seeing that the case was not taken up in a serious manner, and that the captain of the ship of war did not insist, would trouble themselves no farther after she had sailed away; and would laugh at those by whom the property was to be received.

The 'Paamuto,' or Low Islands, where the piracies have occurred, in which she and her relations were supposed to have been concerned, were, and are still considered (though nominally given up by her), as under her authority and particular influence. Her father was a good friend to all the natives of those islands; and the respect and esteem excited by his unusual conduct have continued to the present time, and shown themselves in attachment to his daughter. So much hostility has in general influenced the natives of different islands, that

© The Complete Work of Charles Darwin Online

to be well treated by a powerful chief, into whose hands a gale of wind, or warfare throws them, is a rare occurrence.

The Paamuto Isles are rich in pearl oysters. Pomare, or her relations, desired to monopolize the trade. Unjustifiable steps were taken, actuated, it is said, by her or by these relations; and hence this affair.

They soon decided to pay the debt at once. Thirty-six tons of pearl oyster-shells, belonging to Pomare, and then lying at Papiete, were to form part of the equivalent; the remainder was to be collected among the queen's friends. Taati left his place near her, went into the midst of the assembly, and harangued the people in a forcible though humorous manner, in order to stimulate them to subscribe for the queen. After he had done speaking, I requested Mr. Pritchard to state strongly that the innocent natives of Otaheite ought not to suffer for the misdeeds of the Low Islanders. The shells which had come from those ill-conducted people, might well be given as part of the payment; but the queen ought to procure the rest from them, and not from her innocent and deserving subjects. A document, expressing her intention to pay the remaining sum within a stated time, signed by herself and by two chiefs, with a certainty that the property would be obtained from the Low Islanders, would be more satisfactory than immediate payment, if effected by distressing her Otaheitan subjects, who were in no way to blame.

Taati replied, "The honour of the queen is our honour. We will share her difficulties. Her friends prefer assisting her in clearing off this debt, to leaving her conduct exposed to censure. We have determined to unite in her cause, and endeavour to pay all before the departure of the man-of-war."

It was easy to see that the other principal chiefs had no doubt of the propriety of the demand; and that they thought the queen and her relations ought to bear the consequences of their own conduct. Taati, who is related to her, exerted himself far more than Utaame, Hitote, or any of the others. This part of the business was then settled by their agreeing to give the shells already collected, such sums of money as her friends

© The Complete Work of Charles Darwin Online

should choose to contribute, and a document signed by two principal chiefs, expressing the sum already collected and paid; and their intention of forthwith collecting the remainder, and paying it before a stipulated time. Difficulties about the present, as compared with the former value of the shells, were quickly ended by arbitration; and their value estimated at fifty dollars per ton: the ready way in which this question about the value of the shells was settled, gave me a high idea of the natives' wish to do right, rather than take advantage of a doubtful point of law.

I next had to remark, that the queen had given up the murderers of the master and mate of the Truro in a merely nominal manner, and not in effect; and that she must expect to receive a communication upon that subject by the next man-of-war.

She asked me—whether I really thought they would be required from her by the next man-of-war?

I replied: "Those men were tried and condemned by the laws of Otaheite. Your majesty, as sovereign, exercised your right of pardoning them. I think that the British Government will respect your right as queen of these islands; and that his Britannic Majesty will not insist upon those men being punished, or again tried for the same offence; but the propriety of your own conduct in pardoning such notorious offenders, is a very different affair. It will not tend to diminish the effect of a report injurious to your character, which you are aware has been circulated."

After a pause, I said, "I was desired to enquire into the complaints of British subjects and demand redress where necessary. No complaints had been made to me; therefore I begged to congratulate her majesty on the regularity and good conduct which had prevailed; and thanked her, in the name of my countrymen, for the kindness with which they had been treated."

I then reminded Pomare of the deep interest generally felt for those highly deserving and devoted missionaries, whose exertions, hazardous and difficult as they had been, and still were, had raised the natives of Otaheite to their present en-

© The Complete Work of Charles Darwin Online

lightened and improved condition; and that every reason united to demand for them the steady co-operation of both her and her chiefs. Finding that they listened attentively to Mr. Pritchard's interpretation, which I was told was as good as it appeared to me fluent and effective, I requested permission to say a few words more to the queen—to the effect that I had heard much of her associating chiefly with the young and inexperienced, almost to the exclusion of the older and trustworthy counsellors whom she had around her at this assembly. To be respected, either at home or abroad, it was indispensably necessary for her to avoid the society of inferior minds and dispositions; and to be very guarded in her own personal conduct. She ought to avoid taking advice from foreigners, whom she knew not, and whose station was not such as might be a guarantee for their upright dealings: and she ought to guard carefully against the specious appearances of adventurers whose intentions, or real character, it was not possible for her to discover readily. Such men could hardly fail to misinform her on most subjects; but especially on such as interested themselves; or about which they might entertain the prejudices and illiberal ideas which are so prevalent among ignorant or ill-disposed people. I tried to say these things kindly, as the advice of a friend: Pomare thanked me, acknowledged the truth of my remarks, and said she would bear them in mind.

Turning to the chiefs, a few words passed, previous to Taati asking me, in her name, "Whether they were right in allowing a foreigner to enlist Otaheitans to serve him as soldiers; and in permitting them and other men to be trained, for warlike purposes, upon their island?"* My reply was, "If Otaheitan subjects, so trained, almost under the queen's eye, act hostilely against the natives of any other island, will not those natives deem her culpable? To my limited view of the present case, it appears impolitic, and decidedly improper to do so." After a few words with Utaame and Hitote, Taati rose and gave notice that no Otaheitan should enlist or be trained to serve as

* With reference to the so-called Baron de Thierry.

© The Complete Work of Charles Darwin Online

a soldier, in a foreign cause. By this decree de Thierry lost his enlisted troops, except a few New Zealanders, and whaling seamen.

One of the seven judges, an intelligent, and, for an Otaheitan, a very well educated man, named 'Mare,' asked to speak to me. "You mentioned, in the third place," said Mare, "that you were desired to enquire into the complaints of British subjects, and demand redress, if necessary. You have stated that no complaint has been made, and you have given us credit for our conduct: allow me now to complain of the behaviour of one of your countrymen, for which we have failed in obtaining redress." Here Mare detailed the following case of the 'Venilia,' and said that no reply to their letter to the British government, had yet been received. Mare then added, in a temperate though feeling manner, "does it not appear hard to require our queen to pay so large a sum as 2,853 dollars out of her small income; while that which is due to her, 390 dollars, a mere trifle to Great Britain, has not obtained even an acknowledgment from the British government?"

I ventured to assure Mare that some oversight, or mistake, must have occurred, and promised to try to procure an answer for them, which, I felt assured, would be satisfactory.

The letter on the subject of the Venilia, very literally translated, is as follows: it is, for many reasons, a curious document.

"Our friend, the king of Britain, and all persons in office in your government, may you all be saved by the true God!

"The following is the petition of Pomare, of the governors, and of the chiefs of Tahiti.

"A whale-ship belonging to London, has been at Tahiti: 'Venilia' is the name of the ship, 'Miner' is the name of the captain. This ship has disturbed the peace of the government of Queen Pomare the first. We consider this ship a disturber of the peace, because the captain has turned on shore thirteen of his men, against the will of the governor of this place, and other persons in office. The governor of this district made known the law clearly. The captain of the ship objected to

© The Complete Work of Charles Darwin Online

the law, and said that he would not regard the law. We then became more resolute: the governor said to the chiefs, 'Friends, chiefs of the land, we must have a meeting.' The chiefs assembled on the twenty-second day of December 1831. The governor ordered a man to go for the captain of the ship. When he had arrived on shore, the governor appointed a man to be speaker for him. The speaker said to the captain of the ship, 'Friend, here are your men, take them, and put them on board of your ship; it is not agreeable to us that they should remain upon our land.' The captain said, 'I will not by any means receive them again: no, not on any account whatever!' The governor again told his speaker to say, 'Take your men, and put them on board your ship, we shall enforce our laws.' The captain strongly objected to this, saying, 'I will not, on any account, again receive these bad men, these mutineers.' We then said, 'It is by no means agreeable to us for these men to live on shore: if they are disturbers of the peace on board the ship, they will disturb the peace on shore.' Captain Hill, who has long been a captain belonging to Britain, spoke to the captain of the ship: this is what he said to him: 'It is not at all agreeable to the laws of Britain that you should discharge, or in any manner turn away your men in a foreign land.' This is another thing Captain Hill said, 'you should write a document, stating clearly the crime for which these men have been turned on shore; that the governor and chiefs may know how to act towards them, and that they may render you any assistance.' But this was not agreeable to the captain; he would not write a document. The governor then said to the captain, 'If you will not take your men on board again, give us the money, as expressed in the law.' The captain said, 'I will not give the money, neither will I again take the men: no, not on any terms whatever; and if you attempt to put them on board the ship, I will resist, even unto death.' The governor then said, 'We shall continue to be firm; if you will not give the money, according to the law, we shall put your men on board the ship, and should you die, your death will be deserved.' When the captain perceived that we were determined

© The Complete Work of Charles Darwin Online

to enforce the law, he said, 'It is agreed; I will give you the money, three hundred and ninety dollars.'

"On the 24th of December the governor sent a person for the money. The captain of the ship said, 'He had no money.' We then held a meeting: the governor's speaker said to the captain, 'Pay the money according to the agreement of the 22d day of this month.' The captain said, 'I have no money.' The governor told him, 'If you will not pay the money we will put your men on board the ship.'

"One Lawler said, 'Friends, is it agreeable to you that I should assist him? I will pay the money to you, three hundred and ninety dollars! I will give property into your hands: this is the kind of property; such as may remain a long time by the sea-side and not be perishable. In five months, should not the money be paid, this property shall become your own.'

"Mr. Pritchard said that this was the custom among foreigners. We agreed to the proposal.

"On the 26th of December we went to Lawler's house to look at the property, and see if it was suitable for the sum of money; and also to make some writings about this property. While there, Lawler made known to us something new, which was, that we should sign our names to a paper, written by the captain, for him to show his owners. We did not agree to this proposal, because we did not know the crime for which these men were turned on shore. We saw clearly that these two persons were deceiving us, and that they would not pay the money; also that the captain would not again take his men; but we did not attempt to put his men on board the ship, because another English whaler had come to anchor. We told the captain that we should write a letter to the British government, that they might order this business to be investigated, and might afford us their assistance.

"This is the substance of what we have to say:—We entreat you, the British Government, to help us in our troubles. Punish this Captain Miner, and command the owners of the Venilia to pay us three hundred and ninety dollars for thirteen of their men having been left on our land; and also to send the wages

© The Complete Work of Charles Darwin Online

of a native man who was employed to supply the whole crew with bread-fruit while at anchor here. Let them send a good musket for this man, because the captain has not given him a good musket according to the agreement at the beginning. Captain Miner also gave much trouble to the pilot. He took his ship out himself: the pilot went after the ship to get his money, and also the money for Pomare, for anchorage. He would not give the pilot his share. After some time he gave the pilot some cloth for his share.

"In asking this, we believe that our wish will be complied with. We have agreed to the wish of the British government in receiving the Pitcairn's people, and in giving them land. We wish to live in peace, and behave well to the British flag, which we consider our real friend, and special protection. We also wish that you would put in office a man like Captain Hill, and send him to Tahiti, as a representative of the king of Great Britain, that he may assist us. If this should not be agreeable to you, we pray you to give authority to the reverend George Pritchard, the missionary at this station.

"This is the conclusion of what we have to say. Peace be with you. May you be in a flourishing condition, and may the reign of the beloved king of Britain be long! Written at Tahiti on the sixth day of January, one thousand eight hundred and thirty-two.

"On behalf of POMARE, the queen.

"Signed by APAAPA, chief secretary.
ARUPAEA, district governor.
TEPAU, district governor.
TEHORO, one of the seven supreme judges.
MARE, a district judge, (since raised to be a supreme judge)."

"Addition:—"This man, Lawler,* is an Irishman: he has

* This Lawler was so remarkably good-looking a man, that the natives used to say (literally translated) that "he was as beautiful as a glass tumbler." (Many years ago, when Wallis discovered the Society Islands, a drinking-glass excited so much notice, that ever since it has been referred to as one of the most beautiful of objects.)

© The Complete Work of Charles Darwin Online

been living at Tahiti about three months: he came from the Sandwich Islands. Of his previous conduct we can say nothing. We much wish that a British ship of war would come frequently to Tahiti to take to their own lands these bad foreigners that trouble us. It is useless for us to depend upon the consul at the Sandwich Islands. We have long known that we can obtain no assistance from him.*

"We wish to do our duty towards you Britons. You are powerful and rich—but we are like weak children.

"On behalf of POMARE, the queen.

APAAPA, chief secretary."

"Paofai (close to Papiete),
Tahiti, 7th January 1832."

This interesting letter needs no apology for its insertion at full length. Besides explaining Mare's application, it helps to give an idea of the state of Otaheite; and it appeals to our better feelings in a persuasive manner.

* The British government has since appointed Mr. Pritchard to act as Consul for the Society and Friendly Islands.

Note (*a*) referred to in page 507.

That the electric agent (whether fire or fluid) goes upward from the earth to the atmosphere, as well as in the contrary direction, showing that a mutual action takes place between air and land, many facts might be brought to prove: I will only mention two.

"On October 25th we had a very remarkable storm: the sky was all in flames. I employed part of the night in observing it, and had the pleasure of seeing three ascending thunderbolts! They rose from the sea like an arrow; two of them in a perpendicular direction, and the third at an angle of about 75 degrees."—(De Lamanon, in the Voyage of La Pérouse, vol. iii. pp. 431-2).

While H.M. corvette Hind, was lying at anchor off Zante, in 1823, in twelve fathoms water, an electric shock came in through her hawse, along the chain-cable, by which she was riding. Two men, who were sitting on the cable, before the bitts, were knocked down—felt the effects of the shock about half an hour—but were not seriously hurt. A noise like that of a gun startled every one on board; yet there was neither smell, nor smoke, nor any other visible effect. The sky was heavily clouded over; small rain was falling; and there was distant thunder occasionally, but no visible lightning. The cable was hanging slack, almost 'up and down.' I witnessed this myself.

CHAPTER XXIII.

Continuation of the Meeting at Papiete—Questions—Explanation—Meeting ends—Pilotage—Mr. Wilson—Queen's Visit—Fireworks—School Intelligence—Letters—Inhabitants—Dress—Conduct—Abolition of Spirits—Defect in Character—Domestic Scene—Aura Island—Newton at Bow Island—Pearl Oyster-shells—Divers—Steering—Queen's Letter—Collection—Sail from Otaheite—Whylootacke—Flight of Birds—Navigators—Friendly—Feejee Islands—English Chief—Precautions—La Pérouse.

Reverting to the meeting at Papiete:—The queen's secretary next asked to speak, and said that a law had been established in the island, prohibiting the keeping, as well as the use or importation of any kind of spirits. In consequence of that law, the persons appointed to carry it into effect had desired to destroy the contents of various casks and bottles of spirits; but the foreigners who owned the spirits objected, denying the right to interfere with private property. The Otaheitan authorities did not persist, as they were told that the first man-of-war which might arrive would certainly take vengeance upon them if they meddled with private property. He wished to ask whether the Otaheitans ought to have persisted in enforcing their own laws; and what I should have done, had the law been enforced with a British subject, and had he made application to me.

My answer was, "Had the Otaheitans enforced their law, I could in no way have objected. In England a contraband article is seized by the proper officers, and is not treated as private property while forbidden by the law."

Much satisfaction was evidently caused by this declaration: also, at a former part of the discussions, when a remonstrance was made against Otaheitans paying the Truro debt, the greater part of the assembly seemed to be much pleased.

A respectable old man then stood up, and expressed his gratification at finding that another of King William's men-of-war had been sent—not to frighten them, or to force them to do as they were told, without considering or inquiring into their own

© The Complete Work of Charles Darwin Online

opinions or inclinations, but to make useful enquiries. They feared the noisy guns which those ships carried, and had often expected to see their island taken from them, and themselves driven off, or obliged in their old age to learn new ways of living.

I said, "Rest assured that the ships of Great Britain never will molest Otaheitans so long as they conduct themselves towards British subjects as they wish to be treated by Britons. Great Britain has an extent of territory, far greater than is sufficient for her wishes. Conquest is not her object. Those ships, armed and full of men, which from time to time visit your island, are but a very few out of a great many which are employed in visiting all parts of the world to which British commerce has extended. Their object is to protect and defend the subjects of Great Britain, and also take care that their conduct is proper—not to do harm to, or in any way molest those who treat the British as they themselves would wish to be treated in return."

I was much struck by the sensation which these opinions caused amongst the elderly and the more respectable part of the assemblage. They seemed surprised, and so truly gratified, that I conclude their ideas of the intentions of foreigners towards them must have been very vague or entirely erroneous.

The business for which we had assembled being over, I requested Mr. Pritchard to remind the queen, that I had a long voyage to perform; and ought to depart from her territories directly she confided to me the promised document, relating to the affair of the Truro; and I then asked the queen and principal chiefs to honour our little vessel by a visit on the following evening, to see a few fireworks: to which they willingly consented: some trifling conversation then passed; and the meeting ended.

Much more was said, during the time, than I have here detailed: my companions were as much astonished as myself at witnessing such order, so much sensible reasoning, and so good a delivery of their ideas! I shall long remember that meeting at Otaheite, and consider it one of the most interesting sights

© The Complete Work of Charles Darwin Online

I ever witnessed. To me it was a beautiful miniature view of a nation emerging from heathen ignorance, and modestly setting forth their claims to be considered civilized and Christian.

We afterwards dined with Mr. Pritchard, his family, and the two chiefs, Utaame and Taati. The behaviour of these worthies was extremely good; and it was very gratifying to hear so much said in their favour by those whose long residence on the island had enabled them to form a correct judgment. What we heard and saw showed us that mutual feelings of esteem existed between those respectable and influential old chieftains and the missionary families.

It was quite dark when we left Papiete to return, by many miles among coral reefs, to the Beagle; but our cat-eyed pilot undertook to guide our three boats safely through intricate passages among the reefs, between which I could hardly find my way in broad daylight, even after having passed them several times. The distance to the ship was about four miles; and the night so dark, that the boats were obliged almost to touch each other to ensure safety; yet they arrived on board unhurt, contrary to my expectation; for my eyes could not detect any reason for altering our course every few minutes, neither could those of any other person, except the pilot, James Mitchell. Had he made a mistake of even a few yards, among so many intricate windings, our boats must have suffered (because the coral rocks are very sharp and soon split a plank), though in such smooth and shallow water, a wrong turning could have caused inconvenience only to ourselves, for there was little or no danger of more than a wetting.

The observations at Matavai being completed, I was enabled to leave the place, and invited Hitote and Mr. Henry (who had returned with us) to pay another visit to Papiete in the Beagle, and meet the royal party.

25th. At daylight this morning, while the Beagle's crew were unmooring and hoisting in the boats, I went to Mr. Wilson's school-house, then used also as a chapel—the old chapel having been blown down by a violent gale of wind. Divine service (a hymn, a long extempore prayer, and another hymn) was

© The Complete Work of Charles Darwin Online

performed. This is the established custom at all the missionary stations at Otaheite on Wednesday mornings: on other mornings one or two hours after daylight are employed in the schools. The congregation was numerous, and very attentive. I noticed that all the principal men of the district, besides Hitote who came from a distant part of the island, were present.

Mr. Wilson's manner pleased me much; it was the sincere, and naturally impressive manner of a kind-hearted, honest man, earnestly performing a sacred and paramount duty. I went to see the new chapel after the morning-service was ended; but only the floor-timbers and the posts for the roof were then fixed in their places. The natives were irregular in their work, sometimes doing much, at others little, just as they felt disposed. Being a voluntary work, they took their time about it.

Mr. Darwin and I breakfasted with Mr. Wilson at his house: it happened that Mr. and Mrs. Henry were about to make a journey to some distance; that a favourite son was undertaking a new and difficult mission at the Navigator's Islands, and that we were both about to take leave of the pious teacher of the heathen: and for each he asked a blessing, in an extempore prayer of some length, the result of unaffected, genuine piety. A kinder, or less exceptionable prayer, so far as I could pretend to judge, than that unprepared one by Mr. Wilson, I could not have wished to hear. That it was unprepared I feel certain, because he had not expected us to be present, and the manner in which our prospects were intermingled with those of the others he mentioned, showed that there was no premeditation. There was no affected expression, or unusual tone: it was the sincere devout manner of a pious plain-spoken man.

When under sail we tried to approach the entrance of Papiete Harbour, but baffling winds prevented our anchoring until three in the afternoon; and then, anticipating the royal visit, we tried to make such preparations as our little vessel could accomplish. Dressing the ship with flags, and preparing to man yards, was all we were able to do: salute we could not, on account of the chronometers.

© The Complete Work of Charles Darwin Online

We were told that the queen had walked to Papawa, distant about two miles, to inspect a quantity of fruit, cocoa-nuts, pine-apples, &c. (which she had ordered to be collected as a present to the man-of-war): and, with our glasses, we saw the royal party hastening along the beach, and in the midst of a number of women, children, and men, the queen was observed advancing at a quick walk. Soon afterwards, when it was supposed she had rested and dressed, we sent the boats. The chiefs were already on board. Mr. Pritchard undertook the troublesome offices of interpreter and master of the ceremonies, and by his assistance we saw the whole party collected on the Beagle's upper deck, while the seamen manned yards, and we all gave the queen three cheers.

A bad dinner, accepted after the four mile walk, in a manner it did not deserve,—was succeeded by a few rockets, blue lights, and false fires,—the only fireworks we possessed. Luckily the rockets were good and gave high satisfaction. Lying in the middle of a bay, whose radius, supposing it semi-circular, may be half-a-mile, our ears were startled by a thrilling outcry of delight echoing around the beach, as each successive rocket rushed into the sky and burst. This outcry from the natives on shore, who were taken by surprise (the night being very dark) showed how much they enjoyed the sight. Our visitors on board, being told what would happen, only repeated 'maitai,' 'maitai,'* with earnestness. I much wished then to have had a few good fireworks of a more artificial character. To any one about to visit distant, especially half-civilized or savage nations, let me repeat a piece of advice given to me, but which from inadvertence I neglected to follow: "take a large stock of fireworks."

Some presents to each of our guests helped to amuse them and keep up their cheerfulness. After tea I proposed hearing a few of the seamen's songs,—as some of our crew were very good singers,—not at the time thinking of their prejudices against any singing except hymns. Mr. Pritchard had no word to interpret 'song' but 'himene;' and Rule Britannia,

* Very good—beautiful.

© The Complete Work of Charles Darwin Online

with one or two other grave performances, passed off very well, but, to the perplexing of Mr. Pritchard and surprise of the Otaheitans, a merry comic song was struck up, which obliged Mr. Pritchard to answer the queen's inquiries plainly, by saying, "No, that was not a hymn," it was "sea singing." 'God save the King' sounded more gravely, and suited better.

We landed the party almost at their own doors, and if they were half as well pleased as we were, our little preparations had not been a waste of time and trouble. Their behaviour on board was extremely correct: their habits and manners perfectly inoffensive. No doubt they are improving yearly, and the example of the missionary families has an influence over them, exceeding that of very differently disposed people by whom they are too frequently visited.

26th. At daylight this morning some of us visited the school. As I had heard of 'compulsion' and other absurdities, I went early to get there before Mr. Pritchard arrived, without having hinted at such an intention.

About the large chapel or church, groups of elderly and old people were sitting by threes and fours in a place, helping each other to read the New Testament. While one read the others listened, and, if able, corrected him. One man not less than fifty years of age, was learning to read, with spectacles. Some came in, others went out, just as they chose, for there was not any one even to watch them till Mr. Pritchard came: and during about an hour after sunrise, every day, those people, both women and men, thus instructed one another, previous to beginning their daily out-of-door labours.

In the school-house I found a number of children, waiting for their teacher, who soon arrived and gave them their tasks. The greater part of them wrote sentences on slates from his dictation, with ease and correctness. One sentence he gave them was, 'the captain wishes you happiness,' which they wrote instantly, and some of their own accord added, 'and we wish happiness to the captain.' The handwriting of many, indeed most of the elder girls and boys, was very good: and to verbal questions they replied readily. They seemed to be in good discipline, and yet a merrier or more cheerful looking

© The Complete Work of Charles Darwin Online

set of children I never saw. A hymn excellently, or, I ought perhaps to say, prettily sung, ended their attendance.

Returning by way of the church, I saw Hitote, his brother, and other chiefs, engaged in eager discussion. Mr. Pritchard and I went in: "You are just come in time," said they, "we are disputing about the lightning conductors on board the Beagle, and cannot determine whether they end in the ship's hold, or whether they go through her bottom, into the water." Mr. Pritchard explained: a momentary pause ensued—each seemed trying to understand the puzzling subject; when a shrewd old man, hitherto a quiet listener, remarked—"you white men are wonderfully clever, you know and do most things, I wish some of you (passing his hand over his chin in a drolly rueful manner) I wish some of you would tell us how to rid our faces of these troublesome beards!" (He had just been shaved).

The rapidity with which intelligence is communicated among savage, or partially civilised nations, has often been remarked: but I do not remember meeting with an explanation, till Mr. Nott told me it was passed verbally—from one to another—each man calling to his neighbour. No method could be speedier, where a population is numerous; as at Otaheite or New Zealand, when Cook was there.

In the course of the morning I waited upon the queen to inform her that the Beagle was then going out of the port; and that I waited only for her commands, and the letter she had promised: upon which she sent for her secretary and the chiefs; when we left her for a time. Two of the persons who had been on board our vessel the previous evening, sent me letters this morning, which are so peculiar and interesting, in many points of view, that I here insert them.

Translation of a letter from 'Mare,' one of the seven supreme judges of Otaheite; written in a round distinct hand, in his own language, and directed to me.

"Tahiti, Nov. 26, 1835.

"To you the officer of King William!

"May the peace of God be with you. This is what I have to say to you, my dear friend. I praise you with grateful feelings in my heart for your kindness to me, an insignificant man,

© The Complete Work of Charles Darwin Online

in giving to me a box and some other things besides. I and my wife will feel grateful to you when we look at these things. This is another thing with which I feel pleased; your having shown me the many good things on board your ship; and your men; they have great excellence, and a good character.

"That you may be saved is the wish of your servant,

"MARE."

A letter from Paofai, the brother of Hitote, directed to 'Fitirai,' is similar.

"Dear Friend, "Tahiti, Nov. 26, 1835.

"Peace be unto you and your family, in the name of God. These are my words to you. I feel very much gratified by your great kindness in giving me a trunk, and several other things. For this cause I thank you with grateful feelings. My wife and family will also feel grateful to you. Dear friends may the peace of the Messiah, who is the King of Peace, be with you. Amen. "PAOFAI."*

Among the natives of Otaheite let us not overlook the sons and daughters of the earlier missionaries. Those whom we had the pleasure of seeing did credit to the country of their parents; to Otaheite; and to those excellent persons who must have taken such pains with their education. I presume not to speak from what I have seen only, but from the corresponding accounts of others, added to what I witnessed myself.

I will now make a few general remarks, previous to quitting the island. It did not appear to me that the men of Otaheite are separated visibly into two classes, as some accounts had led us to expect. All of the higher class, whom we saw, or about whom we could learn anything, certainly were large, but rather unwieldy: yet among the lower class there were numerous stout tall men, as tall as the chiefs, and more actively made. A few were of a middle size, and a very few, low in stature: but all well-proportioned and muscular; though their muscles are not hard and knotty, like those of a hard-working white man; they

* The original letters, in the hand-writing of Mare and Paofai, are in my possession.

© The Complete Work of Charles Darwin Online

are rounded, and smooth. They stride along in an imposing manner, occasionally recalling ideas of the giants of history. Although, generally speaking, they are taller than the Patagonians, they do not, to the eye, appear so large. This ocular deception must arise from the better proportion of the Otaheitans. The native of Patagonia has a large, coarse looking head, with high cheek bones, and a 'mane-like' head of hair: his shoulders are high and square; his chest very wide; while to heighten the effect of these traits, each of which gives one an idea of size, a great rough mantle, made of the woolly skin of the guanaco, thrown loosely round his shoulders, hangs almost to his feet. But the Otaheitan head is singularly well formed; and, if phrenology is not altogether a delusion, few men are more capable of receiving instruction, or doing credit to their teachers, than these islanders, so often described, yet by no means enough known. Their hands, and more especially their feet, have been said to be of the Papua form; but the shape of the latter is owing, it appears to me, to their always going barefooted: and I observed their hands particularly without being able to distinguish any peculiarity whatever in the form.

The young men frequently wear a wreath of leaves, or flowers, round the head, which, though becoming, has rather a Bacchanalian appearance. Some cut their hair short, others shave the greater part of their head, but solely from caprice: not one could give me any reason beyond that which is implied in "it is the fashion."

It is seldom that one meets a native entirely naked; I mean naked excepting the girdle which is always worn: generally they have a garment, or a piece of one, obtained from a white man. These remnants, often tattered, and, among the lower classes, always dirty, disfigure them much. Those whom I saw, with only a native girdle, but whose bodies were tattowed in the old fashion, appeared to my eye much less naked than the young men, not tattowed, and only half clothed. I shall not forget the very unpleasant impression made upon my mind, at first landing, by seeing a number of females, and children, with a few men, half dressed in the scanty, dirty, and tattered

© The Complete Work of Charles Darwin Online

scraps of clothing, which they unfortunately prefer to their native dress. A woman, who has around her waist a substantial native garment, which falls as low as the calf of the leg; and over her shoulders, folding in front across the bosom, a mantle, or cloak, of similar material—appears to the eye of a stranger much more decently dressed than the hasty lover of novelty; who seems proud of a dirty cotton gown, tied only at the neck, and fluttering in the wind. Their Sunday dresses, however, are clean and decent, though those of other days are certainly much the contrary. An under-garment alone need be added to the women's former dress of native manufacture, to make it answer every purpose. Why should not home ingenuity, and domestic industry be encouraged?

The moral conduct and character of these islanders have undergone so much discussion; so various have been the decisions, and so varying are the opinions of voyagers and residents, that I, for one, am satisfied by the conclusion, that the good and the bad are mixed in Otaheite, much as they are in other parts of the world exposed to the contamination of unprincipled people. That the missionaries have done so much, in checking and restraining depravity, is to me matter of serious reflection. But let us also remember, that the testimony of very trustworthy witnesses shews that there, even in earlier days, iniquity did not search after those who sought not her abode!*

The Beagle's stay was too short to enable us to form any

* Cook says—"Great injustice has been done the women of Otaheite, and the Society Isles. The favours of married women, and also the unmarried of the better sort are as difficult to be obtained here, as in any other country whatever. I must, however, allow, that they are all completely versed in the art of coquetry, and that very few of them fix any bounds to their conversation. It is therefore no wonder that they have obtained the character of libertines."

In the excellent descriptions of Turnbull, we read:—"Much has been said as to the licentiousness and loose conduct of the women. It is but justice to say, that I saw nothing of this. Their ideas of decency are doubtless very different from ours; they must be judged therefore by a very different standard."

© The Complete Work of Charles Darwin Online

just conclusions. I witnessed no improprieties, neither did I see any thing that would not have inclined me to suppose (had I read or heard nothing of them), that their habits are, in most ways, better than those of many civilized nations. The missionaries have succeeded in carrying attention to religion, and general morality, to a high pitch: may they continue to succeed, in future years, and become an example to larger, older, and nominally wiser nations.

Is it not a striking fact, that the people of a whole country have solemnly refrained from drinking spirits: does not this act alone entitle them to respect, and high consideration? So sincere are they on this subject, that, a short time since, when they heard that a small vessel, lying in their harbour, had on board a cask of rum, which the master intended to sell to some of the residents, they went off to the vessel, and destroyed the obnoxious liquor.

Upon enforcing their first law on this subject, every part of each house was searched. They were very minute in their scrutiny, but overlooked a bottle of brandy, which Mr. Pritchard had kept in the house for medical purposes. After their search, when leaving him, he called them back and showed the bottle, saying for what purpose it had been kept. Some said, 'keep it for that purpose;' others said 'no, it is 'ava,'* destroy it! let us make no distinction, let us utterly discard the use of so baneful a liquor! have we not other medicines, about whose use there can be no doubt?' However, the milder party prevailed, and the brandy bottle would have preserved its contents had not Mr. Pritchard poured them on the ground before their eyes.†

One horrible defect in the former character of the Otaheitans has hardly been mentioned in the earlier writers. They were

* Or cava, their word for intoxicating liquor of any kind.

† I was surprised, when I first arrived at Otaheite, by finding that none of the natives who came on board would touch spirits; and that they would drink but very little wine. Afterwards, however, one chief was noticed who seemed differently disposed.

© The Complete Work of Charles Darwin Online

unkind, and utterly inattentive to the old and infirm:—they were yet worse: they scrupled not to destroy their aged or sick, yes, even their parents, if disabled by age or by sickness.*

Mr. Wilson assured me that in former times, when a person had lingered in sickness, they would carry him to the water-side, under pretence of bathing him, dig a hole, and bury him alive! Thus they ended the life of a young man who had been servant to Mr. Wilson, until he sickened, and, by the natives, was supposed to be dying. Mr. Wilson tried all he could do, in the way of medical assistance, and had hopes of his recovery, when he suddenly disappeared: and not until a long time afterwards could he ascertain the horrid cruelty of which the natives had been guilty!

That they do not even now pay that attention to infirm old age which, in our estimation, is a sacred duty, may be inferred from the following anecdote. Mr. Stokes rambled into a secluded spot near Matavai, where, surrounded by old trees, stood a small and tottering hut. On a filthy worn-out mat, lay a venerable looking old man, hardly covered by a ragged cloth. His only friend, an aged hobbling dog, limped to his side as if hoping that his example would excite some one to show compassion to the old man, his master.

The helpless state of this poor sufferer, whose legs were swollen by elephantiasis to an unwieldy bulk, and his utter destitution, induced Mr. Stokes to make immediate inquiries, and endeavour to get him relieved from some of his misery. It was ascertained that a daughter and son-in-law were usually living with him, but the new 'manuâ' had engrossed their attention, and the poor father had been left to the care of his faithful though helpless dog!

At Matavai the memory of the captain of H.M.S. 'Racoon,' known as the 'long captain,' also as 'Tapane matapo,' or 'Captain blind eye,' is still cherished. The conduct of both him and the officers of the Racoon, seems to have highly delighted all classes. How pleasant it is to hear a countryman,

* From enquiries made among the missionaries and natives, I convinced myself of this startling fact.

© The Complete Work of Charles Darwin Online

especially of one's own cloth, spoken of in such terms of friendship and respect, and how much that pleasure is increased when one reflects, that many years have elapsed since the conduct took place which caused these sensations.

Mr. Stokes passed some nights in Otaheitan cottages. He told me that the natives, both men and women, are extremely fond of their children, and are very kind to them. Not content with nursing and amusing them, they cram them as managers of poultry cause turkeys to be crammed, not exactly with pepper corns, or walnuts,* but with bananas and other nutritive food. At each end of the houses he visited there was a small fire, one being for the elder, the other for the younger folks; this was in the evening, at their last meal time.

Breadfruit, which had been previously roasted, and wild plantains brought from the mountains, were put to the fire to be warmed. Meanwhile cocoa-nuts were opened, their milk was poured into cups, made of empty nutshells, and handed about with the nuts. Each person had a nut and a cup of the milk, or juice.† Taro-root roasted was then served, together with the bread-fruit and plantain, on leaves freshly gathered; there was also a piece of brownish yellow wood, like the rotten root of a tree, hanging up in the hut, which the people sometimes eat; it is called Ti.‡ Grace was said (a duty never omitted), and a clean, comfortable meal enjoyed by the whole party. Afterwards the fires were put out, and a queer little wooden pipe passed round. The strongest tobacco is thought the best, and they like to swallow the smoke. Sometimes, instead of tobacco, they use an indigenous herb.

Before sleeping the oldest man said prayers: one of the young men read a short portion of the New Testament, and then a hymn was sung by the whole family. A lamp was kept

* The very best things for fattening turkeys.

† Cocoa-nut milk makes an indelible black stain, and is sometimes used for dyeing.

‡ The root of the Ti plant is sweet, like sugar cane of indifferent quality. Molasses has been made from it.

© The Complete Work of Charles Darwin Online

burning all night. A curious snuff was observed by Mr. Stokes, and from the method of using or taking it, I am inclined to think it an old custom, not imported by the white men. A substance, not unlike rhubarb in its appearance, but of a very pleasant fragrance, was rubbed on a piece of shark's skin, stretched on wood; and much it appeared to please an old man, who valued this snuff-stick so highly, that he would not part with it.

The Otaheitans are fond of going to sea, and take great interest in seeing new countries. Mr. Henry said there was no difficulty in getting a crew of natives, for boats or small vessels, provided that a promise was made to bring them back to their own island. From four to six yards of ordinary linen, or cotton cloth, with good provisions, was accounted enough remuneration for the zealous services of an able-bodied active man, during one month.

While we stayed at Otaheite we were supplied with excellent beef, and passably good vegetables; the latter however happened to be scarce. Most of the cattle belonged to the missionaries, who were trying to persuade the natives to rear them, and were beginning to succeed, though the people are fonder of their horses, of which there are a good many on the island, but ill kept and little understood.

Mr. Stokes obtained another account of the murder of the master and mate of the Truro, which says: "The master and mate of the Truro had left the northern end of Aura Island, intending to go to Otaheite; the chief of the northern district having treated them very kindly, and told them to avoid the south end of the island, because bad men lived there.

"The wind would not allow them to keep a sufficient offing; and a small canoe, with only two men, approached their boat with the apparent design of offering fruit for sale; but when near the boat they threw spears with such effect, that the white men were both killed." I place more confidence in the former account.

The seizure of a ship at Bow Island (barque Newton, of

© The Complete Work of Charles Darwin Online

Valparaiso, under Chilian colours, though owned by British subjects), has by some persons been supposed to have been excited by Queen Pomare: but the following statement, from Mr. Middleton, who was pilot on board the ship at the time, gives a very different idea.

The master of that vessel (named Clarke) had employed some natives of Bow Island to dive for pearl oyster-shells on his account; he had agreed to pay them a certain quantity of cloth, and to give them so much provision per month. Repeated ill-treatment, and a miserable supply of provisions (at one time only one cocoa-nut each day, without any thing else), induced the natives to think of deserting him; yet they were unwilling to lose the reward of their labours, which had been very severe. One morning he had agreed to the pilot's earnest request that the natives should have more food, and had ordered a biscuit a-piece for them! Soon after the pilot, who was charged with the care of the natives, had delivered the biscuits, the master came on deck, affected to deny his orders, snatched the biscuits away from each of them, and threw them overboard! Sullen and fierce looks were exchanged; and the pilot warned Mr. Clarke that the natives would attack him, and take the vessel, if he did not alter his harsh conduct: to which he replied, by defying half a hundred of them!

A few words from the pilot, in their own language, appeased their resentment at the moment, and the brooding storm passed over; but in the course of that day, while Middleton was away getting shells, the master beat a chief. This was an unpardonable affront; they took possession of the vessel; bound all the white people; and carried them on shore.

What extraordinary mildness among savages!

When the pilot returned with his cargo of shells, he saw none of the crew; and at first hesitated to approach. But the natives seeing this, hailed him, saying, that they did not intend to hurt any one; that they were his friends; and had touched none of his things. This he found true. His own cabin was shut up—untouched; though every other place in the ship had

© The Complete Work of Charles Darwin Online

been ransacked, and the furniture of the hull torn to pieces. They afterwards allowed the pilot to take the vessel to Otaheite, where she was sold by auction for the benefit of those who had insured her.

Obtaining the pearl oyster-shell is well known to be a difficult and dangerous employment: though the divers at the Paamuto Islands seldom go down deeper than four or five fathoms, they remain at the bottom from one to three minutes, sometimes bringing ten shells at one time to the surface; and during four or five hours they continue this extreme labour. After a long dive, blood gushes from the ears and nose; and the poor diver is quite blind during ten or twenty minutes. He may then be seen squatting on the reef, his head between his knees, and his hands spread over his face—a pitiable object: yet for the small monthly pay of ten or twelve yards of calico, or coarse linen, do those hard-working natives endure such straining exertions!

At some of the islands, a good hatchet or axe will purchase as many shells as would fill a small canoe.

In making their voyages from one island to another, the natives steer by the stars, by the direction of the wind, and the flight of birds; but their ideas of distance are extremely vague. Those who have seen a compass used in a boat esteem it highly. Middleton, who had made many voyages among the Low Islands, in whale-boats manned solely by natives, said that they always expressed astonishment at his predicting the time at which they would arrive at their destination. Sometimes they asked if he could see the land in the compass; more than once they exclaimed, "Ah, you white men! you know every thing! What simpletons we are, notwithstanding all our canoes!" The canoe occupies so much time and labour in constructing, and is so essential to their every purpose, that a fine one is to the natives of any of these islands what a three-decker is to us.

The queen's letter being finished, and sent to me by her messenger, I will give the translation made for me on the spot by Mr. Pritchard.

© The Complete Work of Charles Darwin Online

"Tahiti, November 26, 1835.

"To the Captain of the ship of war:

"This is what I have to say to you, before you leave us, respecting the debt. We have 2,338 dollars, which we are now taking to the person who is to receive this property, who is Mr. Bicknell. We are now collecting the remainder.

"Peace be with you,

"And with your king, William,

"(Signed) POMARE VAHINE.

"(Witnessed by) HITOTE and TAATI."

Taking leave of the queen was our next engagement. At the door of her house was a table, on which the loyal and kind-hearted natives were depositing their dollars, and fractions of dollars: to enable her to pay the debt. To me it was an affecting and an unpleasing sight,—not the proofs of loyalty and affection—Heaven forbid!—but the reflection that those individuals had in no way done wrong, and that their dollars had been hardly earned and were highly prized. To show how little a metallic currency was then understood, I may mention that many individuals wished to subscribe fractions, who could not afford a whole dollar; but they were prevented, at first, because the collector knew not how to reckon a fraction of a dollar. Mr. Pritchard easily explained this, and then the smaller coins, (rials, and two rial pieces,) were soon numerous upon the table. Frequently, while walking about the island, men had asked me to give them a dollar in exchange for its value in small coin, which, to their surprise, I was always glad to do, when I had dollars with me.

About Pomare was rather a large assemblage of maids of honour, but their postures and appearance, as they sat about upon the floor, were not the most elegant. The contrast between our own neatly dressed, and well-mannered country-women, whom we had just left in the house of Mr. Pritchard, was rather striking as compared with these brown and oily Otaheitans: but our visit was not long, and we tried to make it agreeable. Returning by the beach, we talked for some time

© The Complete Work of Charles Darwin Online

with Taati, Utaame, and others. Old Ua was there also, to thank me for some trifles sent to him by one of the queen's maidens, who had attended her when on board the Beagle; and I was glad to hear that the damsel had executed her commission in a most punctual manner.*

They expressed great anxiety about the arrival of another man-of-war, with, perhaps, harsher orders: and were very desirous to know when I should arrive in England, and when they would hear from me. I endeavoured to satisfy them on these points, before Mr. Darwin and I wished them farewell (in the most earnest meaning of the word) and, after taking leave of Mr. Pritchard's family, embarked. Mare and Mr. Pritchard accompanied us to the vessel, then under sail outside the reefs, —wished us a great deal more happiness than most of us will probably enjoy, and returned with Mr. Henry and the pilot in their own boats. We made all sail, and soon lost sight of this beautiful island.

Easterly winds swept us along a smooth sea for many days, after leaving Otaheite.† At daylight on the 3d of December we saw Whylootacke (or Wailutaki) a small group of islets encircled by a coral reef, from four to eight miles in diameter. The principal one is 360 feet high, and nearly four miles long. There was a native missionary upon it, educated at Otaheite. On the 11th a few white tern were seen near the ship, (in lat. 28°. S. and long. 180°.) and as she was about 120 miles from any land then known, this notice may help to show within what limits the sight of those birds may be considered to indicate the vicinity of land. I am not at all surprised that the early voyagers should have taken so much notice of the appearance and flight of birds, when out of sight of land; since in my very short experience I have profited much by observing them, and I am thence led to conclude that land, especially small islands or reefs, has often been discovered in consequence of watching

* She was his grand-daughter.

† We sailed with the land breeze, which at Otaheite is so regular that a ship might sail round the island (in successive nights) with the wind always a-beam, and off the land!

© The Complete Work of Charles Darwin Online

particular kinds of birds, and noticing the direction in which they fly, of an evening, about sunset. Short winged birds, such as shags or boobies, seldom go a hundred miles from land, and generally return to their accustomed roosting place at night; and even those with longer wings which fly farther, do not habitually remain on the wing at night, though they are known to do so sometimes, especially if attracted by a ship, on which, doubtless, they would perch if she were to remain motionless, and her crew were to be quiet for a short time. Mistakes may occur in consequence of floating carcases, trunks of trees, wrecks of vessels, or drifting seaweed, all which attract birds and afford them rest at night; but, generally speaking, if there is land within fifty miles of a vessel, its existence will be indicated, and the direction in which to look will be pointed out by birds. Decided oceanic fowl, such as albatrosses and all the petrel family, sleep upon the surface of their favourite element; therefore the flight of that description of bird can be no guide whatever, except in the breeding season, when they frequent the vicinity of land.

Until I became aware of these facts, the discovery of the almost innumerable islands in the great ocean of Magalhaens, (erroneously, though now probably for ever called Pacific,) caused great perplexity in my mind. That Easter Island, for instance, such a speck in the expanse, and so far from other land, should have been—not only discovered—but repeatedly visited and successively peopled, by different parties of the human family, seemed extraordinary, but now, connecting the numerous accounts related by voyagers of canoes driven hundreds of miles away from their desired place, with these facts respecting birds, much of the mystery seems unravelled.

Every one is well aware that uncivilized man is more attentive to signs of weather, habits of animals, flight of the feathered tribe, and other visible objects, important to his very existence, than his educated brother,—who often diminishes the perceptive faculties of the mind, while he strengthens the power of reflection and combination.

© The Complete Work of Charles Darwin Online

Before arriving at New Zealand I will add a very brief remark or two about the Navigators, the Friendly, and the Feejee Islands. At the first mentioned, where De Langle and Lamanon were massacred, there is now a prosperous mission established by the exertions of the London Missionary Society, and I hear that a large proportion of the islanders are no longer blood-thirsty savages. At the Friendly Isles much opposition had been encountered, chiefly in consequence of former hostilities brought on by a runaway convict, who excited the natives to murder the first missionaries who went there: and the prejudices then caused are scarcely yet removed. Mariner's account of the Tonga, or Friendly Islands, is considered by English residents at Otaheite, to be a very accurate one,* and is full of interesting information. I obtained a few notices of the Feejee group from the owner of a schooner that was lost there; and as they are comparatively little known, my mite may as well be contributed in this place to the general fund.

The whole group of islands called Feejee, or Fidji, by Europeans, but of which the native name is, I believe, Navihi—is of very dangerous navigation: not only on account of coral reefs, scarcely hidden by a few feet of water, but because the natives are ferocious and treacherous cannibals. My informant† said, that the master of his schooner‡ (who was long detained a prisoner among them, his life being spared in hopes of obtaining a large ransom), was an unwilling participator in a cannibal feast on some prisoners of war, taken in an attack on a neighbouring island. That they have an idea of the superiority of white men may be inferred from a message sent previous to this battle, saying, "We shall kill and eat you all—we have seven white men to fight for us!" Although many unfortunate seamen have fallen victims to the thoroughly savage Feejee Islanders, a few whites have not only escaped death,

* Among a variety of very curious facts mentioned by Mariner, one may be noticed here, because I shall have to refer to it in a future page. I mean the rat shooting practised by the chiefs as an amusement.

† Mr. Green, of Valparaiso.

‡ 'The Terrible;' Clark, master.

© The Complete Work of Charles Darwin Online

but have established themselves in some authority among the natives. A man known by the name of Charles, was more respected than almost any of their own chieftains, on account of his extraordinary valour: and so highly was he considered by all of them, that he was allowed to have a hundred wives.*

No small vessel ought to venture near any of the Feejee islands without being armed, and prepared to act defensively. Boarding nettings, if she has them, should be triced up; and no professions, or appearance of friendship, ought ever to put strangers off their guard. In case of an unavoidable rupture, a chief, the highest in rank that can be secured, should, if possible, be made prisoner—by force if fair means fail; and he should be made to understand that his life depended upon the conduct of his countrymen. Of course no right-minded man would act otherwise than to avoid or prevent any hostilities with ignorant savages, so long as he could do so without risking the lives of his own countrymen; but he must remember that, in hand to hand fighting, a band of fierce savages, armed with a variety of weapons, are more than a match for seamen unused, perhaps, to muskets, and equally awkward with pistols or swords: however brave and determined they may be, if dispersed, as usually happens, they are sure to be by far the greatest sufferers. I here allude to those savages who are really warriors. At some islands, and other places, they are comparatively timid, though seldom less treacherous.

Remarking on the criticisms of such as have animadverted on officers who found themselves obliged to take harsh measures in self-defence—La Pérouse, whose humanity and good sense not one individual among the nations who regret his untimely loss, ever questioned, says, "I am, however, a thousand times more angry with the philosophers who extol the savages, than with the savages themselves. The unfortunate Lamanon, whom they massacred, told me the very

* Only chieftains of note are able to maintain many wives: very few had so large a number as that man: scarcely any had more.

evening before his death, that the Indians (meaning the natives of the Navigator Islands) were worthier people than ourselves!

"Observing rigidly the orders I have received, I have always treated them with the greatest mildness; but I confess to you, that if I were to undertake another voyage of the same kind, I would demand different orders.

"A navigator, on quitting Europe, ought to consider the savages as enemies, very weak indeed, and whom it would be ungenerous to attack and barbarous to destroy, but whose assaults he has a right to prevent when authorised to do so by well-grounded suspicions."—Voyage of La Pérouse, vol. iii. p. 413.

When a vessel approaches the Feejee Islands, numberless canoes put off, and soon surround her so closely, that unless the wind is pretty fresh, she is placed in no slight jeopardy. At such a time the principal chief ought to be invited on board; and presents should be given to him, while he is made to understand that it is necessary he should order the canoes to keep off. His commands will be implicitly obeyed; and while he is on board, and well treated, there will be less risk; but he must not be relied on implicitly.

Some of the canoes are very long, from sixty to eighty feet in length: and when two such are fastened together, with a light structure erected upon them, the men who stand on their raised deck are above the level of a small vessel's bulwark.*

* Heaps of stones form not only ballast but ammunition for these formidable canoes. Indeed, among all savage nations, a stone held in the hand, or thrown, perhaps from a sling, is a common, and by no means despicable weapon. These easily collected missiles, and the manner of using them, recal to mind the victory gained by the English fleet over that of France, off Sluys, on the 22d of June 1340; in which "though the battle was fought on the sea, it could scarcely be called maritime; for little depended on the accidents of winds and waves, or on the skill of a commander in availing himself of them. Piles of stones on the deck formed a part of the magazines. The archers of both nations used their crossbows as if they had been on land. They employed grappling irons for boarding, and came to such close quarters as to exhibit a succession of single combats."—Mackintosh, vol. i. p. 294.

© The Complete Work of Charles Darwin Online

At the time that Mr. Clark was a prisoner among them, a musket was considered to be a fair ransom for a white man; and (perhaps fortunately for him) they had then an idea that the flesh of white men was not wholesome.

They have many articles of trade, such as shells, tortoise-shell, coral, spermaceti, whales' teeth, 'bicho de mar,' mats of exquisite workmanship, fruit, and provisions: among the latter are pigs and 'iguanas.' Excepting a great alligator, the Feejee men never saw an animal on their island larger than a dog or a pig. The monster just mentioned made its appearance on the island Pau, the largest of the group, some years ago, to the extreme consternation of the natives, who thought it was a sea-god. After destroying nine people, at different times, the 'enormous lizard,' as they called it, was caught by a strong noose passed over the bough of a large tree, the other end of the rope being held at a distance by fourteen men, who lay concealed, while a daring old man offered himself as a bait to entice the brute to run into the snare.*

Mr. Mariner supposed that this alligator, or crocodile, had made its way from the East Indies; a curious instance of the manner in which occasional migrations take place. On an island in that neighbourhood, called Lotooma, Mariner heard of two enormous bones, not at all like any human bones, nor resembling those of a whale. The natives of the island have a tradition that they belonged to a giant, who was killed in former ages by the united attack of all the population.†

On the 16th of December indications of a westerly wind appeared; and for the next three days we were buffeted by a hard gale from south-west to south-east. This was the more annoying on account of the chronometer measurement, because it was accompanied by a sudden change of temperature, which I thought would alter their rates. During the twenty-four hours previous to this southerly gale commencing, we found the current setting northward, about a mile an hour; but after the

* A feat hardly surpassed by Mr. Waterton.—Mariner's Tonga Islands, vol. i. pp. 268, 269, 270, in Constable's Miscellany, vol. xiii.

† Ibid. vol. i. p. 262.

© The Complete Work of Charles Darwin Online

hardest part of the gale was over, it set to the south-west, at about the same rate.

Both before and during these three days, I was struck by the precise similarity of the clouds, sky, peculiarities of wind, and weather, to what we had been accustomed to meet with off the coast of Patagonia: and I may here remark that, throughout the southern hemisphere, the weather, and the turn or succession of winds, as well as their nature and prognostications, are remarkably uniform.

On the 19th we made the northern hills of New Zealand; but tantalized still by adverse winds, all the next day was spent in beating to windward, and not till the 21st could we succeed in obtaining access to the Bay of Islands.

We were all a good deal disappointed by the view. After Otaheite, the northern part of New Zealand had, to our eyes, a very ordinary appearance.

DEC. 21. At daylight we were about four miles from Cape Brett, and nearly the same distance from Point Pococke; while in the north-west the Cavalle islands showed themselves indistinctly. A light easterly breeze enabled us to steer towards the Bay of Islands.—Few places are easier of access than this bay: excepting the Whale-rock, whose position is well ascertained, there are no hidden dangers: and within the line of the heads, there is little or no current deserving notice: outside that line, the current generally sets to the south-east about a mile an hour.

Compared with mountainous countries, the northern parts of New Zealand are not high; but they cannot be described as low land. Perhaps the expression, 'moderately high land,' may convey an idea of such as is more than two hundred, but less than twelve hundred feet above the level of the sea; which are the limits I have in view. In distant profile the land inclines too much to regular and convex outlines to be picturesque. It is only along the sea-coast that steep cliffs, and a more broken boundary, cause enough variety to please the eye of a lover of landscape. Approaching nearer, the interior of the country, varied by hill and valley, with an agreeable mixture of woodland and cleared ground, makes a favourable impression upon the mind, from the natural association of ideas of capability and cultivation; but whether it pleases the eye, as a picture, must depend probably as much upon the kind of scenery lately viewed, as upon preconceived ideas. With us the recent im-

© The Complete Work of Charles Darwin Online

pressions caused by Otaheite, rendered the view of New Zealand, though novel, rather uninteresting.

Cape Brett is a bold promontory, higher than any neighbouring land. When first seen from a distant offing, while no other land is in sight, it makes like a quoin-shaped island. As the sea around is free from danger, it is an excellent landfall for shipping approaching this part of the coast. Detached from, but near the cape, is the rock, with a hole or archway through it, named by Cook, 'Piercy Islet.'

Point, or rather Cape Pococke, is a steep cliffy headland, of a dark colour, rather picturesque in its appearance: near it there is a conical rocky islet. Numerous islands, small and large, are scattered over the bay; an expanse of water really about ten miles square, though to the eye it appears much smaller, because so many islands intercept the view.

Near the middle of the west side of the bay is the opening of Kororareka Harbour, a secure but shallow port; better adapted to merchant shipping than to the use of men-of-war.

After passing Cape Pococke, and advancing about a mile, a small settlement appeared in the northern bight of the bay; and the English look of the houses was very gratifying to us. This, I found, was Tipuna, or Rangihoua, the place where the first settlement of white men was made upon the shores of New Zealand. On the farther side of Kororareka other houses were then seen—neat, and apparently comfortable dwellings, well situated under the lee of the western hills, while close by, on our right hand, a curious line of flat-topped black rocks, a few feet only above the water, reminded us of the remains of a great mole.

Within the line from Cape Pococke to Cape Brett there is not more than thirty fathoms of water; and every where, excepting close to the rocks, the bottom is soft and tenacious, so that an anchor may be let go in any part. We saw small straggling villages of native huts in many places, and around each of them a substantial fence of palisaded posts and rails. These fences, and the cultivated spots of ground which appear as you proceed up the bay, might give a more favourable idea of the

© The Complete Work of Charles Darwin Online

native habits than they yet deserve; for the fences are fortifications—defences against intruding men, not cattle.

In a conspicuous solitary position, opposite to the entrance of Kororareka harbour, a single English house, without another building within a mile of it, nor any protection except that of a tall staff, on which waved the British Union-jack, presented a contrast to the fortified villages; and forcibly impressed one's mind with a conviction of the great influence already obtained over the formerly wild cannibals of New Zealand.

The entrance to the harbour is narrow, even to the eye, but it is still more confined by shoal water. In entering or leaving it, a ship ought to keep close to Kororareka Point: after rounding that point, at the distance of a cable's length, the sheltered part of the port is seen, looking like the mouth of a navigable river. On the western side, the native village of Kororareka, a straggling collection of low huts, strongly palisaded; on the eastern, three or four English houses, the head-quarters of the missionaries; on the rising ground, near the water, far up the harbour, several more houses and villages—gave an appearance of population and successful exertion as surprising as satisfactory. Near a detached house of European form, a large white ensign excited our curiosity; and we found it was the flag of New Zealand; differing only from the ensign of St. George in the upper 'canton,' next the staff, where, instead of a Union-jack, there is a red cross on a blue field; each quarter of the blue field being 'pierced' by a white star.

We anchored between Kororareka and Paihia (the missionary settlement): farther up the harbour were several whale-ships which had anchored there, I was told, in order to avoid the spirit-shops of Kororareka.

From this anchorage the view on all sides is pleasing. An appearance of fertility every where meets the eye; but there are no grand or very remarkable features. There is nothing in the outward character of the country corresponding to the ferocious sanguinary disposition of its aboriginal inhabitants. The British resident, some English settlers, and two of the

© The Complete Work of Charles Darwin Online

native chiefs came on board during the afternoon; and in the evening I made acquaintance with Mr. Baker, a missionary residing at Paihia. The resident's boat was manned by young Zealanders, whose smooth faces, cropped hair, Scotch caps, and jackets and trowsers, were much approved of (perhaps hypocritically), by a chief whose long war-canoe was well-manned by athletic savages with half-naked figures, faces deeply-scarred —rather than tattowed—and long curly hair.

We were amused by finding that the Beagle had been mistaken for a ship of the (so called) Baron de Thierry. Her small size; the number of boats; and her hoisting a white ensign (thought to be that of New Zealand), so completely deceived them all, that one boat only approached reluctantly, after we had anchored, to reconnoitre; but as soon as it was known that the expected intruder had not arrived, visitors hastened on board. Had he made such an experiment, he would hardly have escaped with life, so inveterate and general was the feeling then existing against his sinister and absurd attempt. He would indeed have found himself in a nest of hornets.

In walking about the missionary establishment at Paihia, I was disappointed by seeing the natives so dirty, and their huts looking little better than pigstyes. Immediately round the dwellings of the missionaries I expected a better state of things; but I was told, that their numerous and increasing avocations engrossed all their time; and that the native population were slow in adopting habits, or even ideas, of cleanliness.

My first impression, upon seeing several New Zealanders in their native dress and dirtiness was, that they were a race intermediate between the Otaheitans and Fuegians; and I afterwards found that Mr. Stokes and others saw many precise resemblances to the Fuegians, while every one admitted their likeness to the Otaheitans. To me they all seem to be one and the same race of men, altered by climate, habits, and food; but descended from the same original stock.

Of a middle size, spare, but strong frame, and dark complexion, the New Zealander's outward appearance is much in his favour; hardiness and activity, as may be expected, he

© The Complete Work of Charles Darwin Online

eminently possesses. The expression of his features indicates energy, quickness of apprehension, without much reflection; and a high degree of daring. Ferocity is a striking trait in the countenances of many among the older men, and it is increased considerably by the savage style in which their faces are disfigured, or, as they think, ornamented by lines cut in the skin with a blunt-edged iron tool, and stained black. These lines are certainly designed with as much taste, even elegance, as could possibly be exerted in such disfiguring devices. The expression which, it appears, is anxiously desired, is that of a demon-warrior. All their old ideas seem to have had reference to war. Well might the Spanish poet's description of the Araucanians have been applied to the New Zealanders in their former condition:—

> "Venus y Amor aqui no alcanzan parte,
> Solo domina el iracundo Marte!"

The lines upon the face are not, however, arbitrary marks, invented or increased at the caprice of individuals, or the fancy of the operator who inflicts the torture; they are heraldic ornaments, distinctions far more intelligible to the natives of New Zealand than our own armorial bearings are to many of us, in these unchivalric days. Young men have but few: slaves, born in bondage, or taken young, have scarcely any marks; but the older men, especially the more distinguished chiefs, are so covered with them that the natural expression of face is almost hidden under an ornamented mask. One object of the tattowing, is to prevent change of features after middle age. Some of the women, whom the missionaries endeavoured to persuade not to follow this practice, said, "Let us have a few lines on our lips, that they may not shrivel when we are old."

Every one has heard of, and many people have seen the war-dance. What exaggerated distortions of human features could be contrived more horrible than those they then display? What approach to demons could human beings make nearer than that which is made by the Zealanders when infuriating, maddening themselves for battle by their dance of death!

© The Complete Work of Charles Darwin Online

The hair of a New Zealander is naturally luxuriant, though rather coarse; its rough, free curliness in an unadorned, almost untouched state, heightens that expression of untameable ferocity which is so repulsive in the older men, especially in those of inferior degree. Many of the young women are good-looking; and they dress their hair with some pains, and not a little oil.

Although cannibalism and infanticide have ceased in the northern parts of New Zealand, the aboriginal race is decreasing. The natives say frequently, 'The country is not for us; it is for the white men!' and they often remark upon their lessening numbers. Change of habits, European diseases, spirits, and the employment of many of their finest young men in whale-ships (an occupation which unhappily tends to their injury), combine to cause this diminution. Wearing more clothes (especially thick blankets), exposes them to sudden colds, which often end fatally. We were surprised at seeing almost every native wrapped up in a thick blanket, perhaps even in two or three blankets, while we were wearing thin clothing.

The countenances of some of the men (independent of the tattowing) are handsome, according to European ideas of line beauty. Regular, well-defined, and high features are often seen; but they are exceptions, rather than the usual characteristics. Generally speaking, the New Zealander has a retreating and narrow forehead—rather wide, however, at the base; a very prominent brow; deeply-sunk black eyes, small and ever restless; a small nose, rather hollow, in most cases, though occasionally straight or even aquiline, with full nostrils; the upper lip is short, but that and the lower are thick; the mouth rather wide; white and much blunted teeth; with a chin neither large nor small, but rather broad. Some have higher and better heads, and a less marked expansion of brow, nostrils, and lips; others, again, are the reverse: usually, their eyes are placed horizontally; but some are inclined, like those of the Chinese, though not remarkably; indeed not so much so as those of a Scotchman whom I met there. Among the women I noticed a general depression of the bridge of the nose, and a flat frontal region.

© The Complete Work of Charles Darwin Online

Few engravings, or paintings, show the real expression, features, or even colour of the Polynesian tribes. They give us a half naked, perhaps tattowed* man or woman; but the countenance almost always proves the European habits of the artist. The features have a European cast, quite different from the original, and the colouring is generally unlike; especially in coloured engravings.

The general complexion of both women and men is a dark, coppery-brown; but it varies from the lightest hue of copper to a rich mahogany or chocolate, and in some cases almost to black. The natural colour of the skin is much altered by paint, dirt, and exposure. Before closing this slight description of the personal appearance of the Zealanders, I must allude to the remarkable shape of their teeth. In a white man the enamel usually covers all the tooth, whether front or double; but the teeth of a man of New Zealand are like those of the Fuegians, and at a first glance remind one of those of a horse. Either they are all worn down—canine, cutting-teeth, and grinders—to an uniform height, so that their interior texture is quite exposed, or they are of a peculiar structure.†

The New Zealanders' salutation has often been talked of as 'rubbing noses,' it is, in fact, touching, or crossing them; for one person gently presses the bridge of his nose across that of his friend. Mr. Darwin informed me that when a woman expects to be saluted by a person of consequence, in the 'nose pressing' manner, she sits down and makes a droll grunting noise, which is continued, at intervals, until the salute has been given.

The usual manner of the native is very inferior. Accustomed to a low, wretched dwelling, and to crouching in a canoe, his

* Amoco is the native word for the tattow marks.

† This apparent wearing away of the teeth is not found in the Zealanders alone. The Fuegians, Araucanians, and Society Islanders show it more or less, and it is very remarkable among the natives of New Holland. I have also seen some white men (Europeans) with similar teeth, but they were all elderly; whereas in some young savages I have noticed incisors shaped rather like those of a horse.

© The Complete Work of Charles Darwin Online

habitual posture of rest is squatting on his hams, or upon the ground, with his knees up to his chin; hence, also, his limbs are rather inferior in their shape. But arouse his spirit, set him in motion, excite him to action, and the crouching, indolent being is suddenly changed into an active and animated demoniac. The Zealander is extremely proud; he will not endure the slightest insult. A blow, even in jest, must be returned!

Every one has seen or heard so much of their weapons and canoes, that it is almost superfluous to speak of them; yet, in examining one of their larger canoes—seventy feet in length, from three to four in width, and about three in depth—I was much interested by observing what trouble and pains had been taken in building and trying to ornament this, to them, first-rate vessel of war. Her lower body was formed out of the trunk of a single tree—the New Zealand kauri, or cowrie—the upper works by planks of the same wood; the stem and stern, raised and projecting, like those of the gallies of old, were carved and hideously disfigured, rather than ornamented, by red, distorted faces with protruding tongues and glaring mother-of-pearl eyes. Much carving of an entirely different and rather tasteful design* decorated the sides. Beneath the 'thwarts,' a wicker-work platform, extending from end to end, served to confine the ballast to its proper position, and to afford a place upon which the warriors could stand to use their weapons. From forty to eighty men can embark in such canoes. But their day is gone! In a few years, scarcely a war-canoe will be found in the northern district of New Zealand.†

Judging only from description, the largest canoes ever seen by the oldest of the present generation, must have been nearly ninety feet in length; formed out of one tree, with planks attached to the sides, about six or seven feet wide, and nearly as much in depth. Several old men agreed, at different times, in this account; but perhaps each of them was equally inclined to magnify the past.

* Arabesque, like the ornaments at Otaheite.

† North of latitude 38° S.

New Zealand much requires assistance from the strong but humane arm of a powerful European government. Sensible treaties should be entered into by the head of an over-awing European force, and maintained by the show, not physical action, of that force until the natives see the wonderful effects of a changed system. Finding that their protectors sought to ameliorate their condition, and abolish all those practices which hunger, revenge, and ignorance probably caused, and alone keep up; that they neither made them slaves, nor took away land without fair purchase; and that they did no injury to their country, or to them, except in self-defence—even then reluctantly—would give the natives satisfaction and confidence, and might, in a few years, make New Zealand a powerful, and very productive country. I say powerful, because its inhabitants are very numerous, and have in themselves abundant energy, with moral, as well as physical materials; productive also, because the climate is favourable; the soil very rich; timber plentiful, and very superior; minerals are probably plentiful; flax is a staple article; corn and vines are doing well; and sheep produce good wool.

While our thoughts are directed to the natives of New Zealand, let us refer to what Sir James Mackintosh says of the former savages of our own island.

"B.C. 54.—At the time of Cæsar's landing, the island of Great Britain was inhabited by a multitude of tribes, of whom the Romans have preserved the names of more than forty. The number of such tribes living in a lawless independence, is alone a sufficient proof of their barbarism. Into the maritime provinces southward of the Thames, colonies probably recent from Belgic Gaul began to introduce tillage; they retained the names of their parent tribes on the continent; they far surpassed the rest in the arts and manners of civilized life. The inhabitants of the interior appear to have been more rude and more fierce than any neighbouring people. The greater part of them raised no corn; they subsisted on milk and flesh, and were clothed in the skins of the beasts whom they destroyed for food. They painted and punctured their bodies, that their

© The Complete Work of Charles Darwin Online

aspect might be more horrible in war. The use of carriages in war is a singular instance of labour and skill among such a people. Their domestic life was little above promiscuous intercourse. Societies of men, generally composed of the nearest relations, had wives in common. The issue of this intercourse were held to belong to the man (if such there should be) who formed a separate and lasting connexion with their mother. Where that appropriation did not occur, no man is described as answerable for the care of the children."

Again, Sir James says—

"The Britons had a government rather occasional than constant, in which various political principles prevailed by turns. The power of eloquence, of valour, of experience, sometimes of beauty, over a multitude, for a time threw them into the appearance of a democracy. When their humour led them to follow the council of their elders, the community seemed to be aristocratic. The necessities of war, and the popularity of a fortunate commander, vested in him in times of peril a sort of monarchical power, limited by his own prudence, and the patience of his followers, rather than by laws, or even customs. Punishment sprung from revenge: it was sometimes inflicted to avenge the wrongs of others. It is an abuse of terms to bestow the name of a free government on such a state of society: men, in such circumstances, lived without restraint; but they lived without security. Human nature, in that state, is capable of occasional flashes of the highest virtues. Men not only scorn danger, and disregard privation, but even show rough sketches of ardent kindness, of faithful gratitude, of the most generous self-devotion. But the movements of their feelings are too irregular to be foreseen. Ferocious anger may, in a moment, destroy the most tender affection. Savages have no virtues on which it is possible to rely."

Speaking of missionaries, the same historian states, that—

"Our scanty information relating to the earliest period of Saxon rule, leaves it as dark as it is horrible. But Christianity brought with it some mitigation. A.D. 596. The arrival of

© The Complete Work of Charles Darwin Online

Augustine in Kent, with forty other missionaries, sent by Gregory the Great to convert the Saxons, is described in picturesque and affecting language by Bede, the venerable historian of the Anglo-Saxon church. It cannot be doubted that the appearance of men who exposed themselves to a cruel death for the sake of teaching truth, and inspiring benevolence, could not have been altogether without effect among the most faithless and ruthless barbarians. Liberty of preaching what they conscientiously believed to be Divine truth, was the only boon for which they prayed."

22d. On the little island of Paihia, where our instruments were landed for observations, the remains of half-burned human bones were found: and as the dead are not burned in this country, they must have been the remains of a former meal. It was difficult to decide upon the time which had elapsed since that feast was made, by the appearance of the bones. They might have been covered by earth for some time, and only lately exposed; or they might have been the remains of a very modern feast, indulged in upon a little island to which it was not probable that a missionary, or any one who might give information to him, could approach unperceived.

We were much struck by the beautiful appearance of an evergreen tree, resembling an ilex, or a large myrtle, when seen from a distance; whose bright red flowers, in large clusters, upon the dark green foliage, gave an effect which I longed to see transferred to an English garden. This tree seemed to be common. After landing, the fern attracted more notice than any other vegetable production: every where in New Zealand this useful plant is found. Why useful? may be thought. Because it was one principal article of food, before the introduction of potatoes. Owing to its abundance, and to the edible, as well as tolerably nutritious, nature of its roots, no man can ever starve in New Zealand who is able to gather fern: but that it is not a pleasant food may be inferred from the fact that no native eats fern-roots when he can get potatoes. Where the fern grows thickly, and high, the soil is known to be

© The Complete Work of Charles Darwin Online

rich: where it is small, and scarce, the land is not worth cultivating.*

Mr. Williams, the elder, formerly a lieutenant in the navy, was absent on an exploring and negociating expedition to the southern parts of the island. I much regretted having missed seeing him, as he was considered the leading person among the missionary body in New Zealand; and was said, by every one, to be thoroughly devoted to the great cause, in which he was one of the first, and most daring. I walked with Mr. Baker about the little village, or hamlet, of Paihia. A substantial stone building I thought must be the church; but was a good deal disappointed at being shown a small low edifice, as the place of worship; and hearing that the large stone house was the printing establishment. This I did not like; for I thought of the effect produced on ignorant minds by the magnificence of Roman Catholic churches. No doubt education overcomes superstitious ideas and observances; and the devotion of an enlightened man is not increased or diminished by the style, or by the decorations of a building: in him probably no building made by hands would excite such emotions as the starry temple of a cloudless sky. But ought he, therefore, to despise, or think lightly of those outward forms, and ceremonious observances, which influence ignorant people, who see without thinking; and are too much guided by that which makes a vivid impression. Would a little outward show do any harm among such ignorant human beings as the savages of New Zealand; or among Fuegians, and New Hollanders? And may one not expect that an intelligent native should notice that the 'House of God' is in every respect inferior to the other houses which they see erected by Christians?

Paihia is a pretty spot. The harbour of Kororareka lies in front; and an amphitheatre of verdant hills forms the back ground. But it must be hot during the summer, as it is in a hollow, facing the sun. A visit to Mr. J. Busby, the 'British

* Humboldt mentions fern-roots being used for food near the Orinoco.

© The Complete Work of Charles Darwin Online

Resident,' at his house (protected by the flag, as I have already mentioned) occupied Mr. Darwin and myself some time. Like most of the missionary dwellings, it is a temporary boarded cottage, intended only for present purposes. Mr. Busby was taking great pains with his garden; and among other plants he anticipated that vines would flourish. Those at Waitangi (the name of his place) are favoured by climate, as well as by the superintendance of a person who so thoroughly understands their culture. At a future day not only New Zealand, but Van Diemen's Land, and all New Holland, will acknowledge the obligation conferred upon them by this gentleman, who made a long and troublesome journey through France and Spain solely for the purpose of collecting vines for Australia, his adopted country.

Mr. Busby's official occupations at New Zealand appeared to me of a very neutral character. An isolated individual, not having even the authority of a magistrate, encircled by savages, and by a most troublesome class of his own countrymen, I was not astonished at his anxiety to receive definite instructions, and substantial support; or at the numerous complaints continually made by the English settlers.

Afterwards we went to Kororareka. On a sandy level, narrowly bounded by a low range of hills, or rather rising grounds, stands the principal assemblage of houses in the island; or as the missionaries say, 'in the land'. I have said assemblage of houses, because it did not agree with my ideas of a town, a village, a hamlet, or even an Indian encampment. Near the beach were a few small cottages which had once been whitewashed. At the foot of the hills were two or three small houses of European build; but the remaining space of ground appeared to be covered by palings, and pig-styes. The temporary enclosures which are made in a market-place, for cattle, might give an idea of the appearance of these sadly wretched dwelling places. The palings, or palisades, are intended to be fortifications: they are high, sometimes eight or ten feet; and, almost encircling the whole, a stronger palisade is fixed, but so inefficiently that either strength, an axe, or fire, would ensure

© The Complete Work of Charles Darwin Online

an entrance to resolute men. There is neither embankment nor ditch. Within the small square spaces, enclosed by the slighter palings, are the huts of the natives: the angular, low thatched roofs of which are scarcely set off from the ground by walls a foot or two in height. These roofs slope downwards, lengthwise as well as sideways; so that the front of the hut is the highest part. The upper point of the roof may be eight feet from the ground; the space of ground occupied, about ten square feet; seldom more, indeed usually less. Besides the door, through which a man cannot pass excepting upon his hands and knees, there is neither window, nor aperture of any kind. The New Zealand 'order of architecture,' is marked by two wide planks placed edgeways in front, joined together at the top by nails or pegs, and forming a wide angle, in which the space is filled up, excepting a door-way two feet square, with materials similar to those of the walls and roof, namely wicker work, or 'wattling,' covered by a thatching of broad flag leaves or rushes. The eaves of the roof project two or three feet beyond the front; so likewise do the side walls. In this sort of porch the family sit, eat, and, in the daytime, often sleep. At night most of them huddle together, within what, in every respect, deserves the name of a sty: even a Fuegian wigwam is far preferable, for as that is frequently left vacant during many successive weeks, heavy rains and a cold climate are antidotes to any particular accumulation of dirt. In a fine climate, surrounded by beautiful trees and luxuriant herbage, can one account for human nature degrading itself so much as to live in such a den? Is it not that the genuine, simple beauties of Creation are understood, and enjoyed, only in proportion as man becomes more refined, and as he differs more from his own species in what is falsely called a state of nature.

I was inquisitive about the large planks, generally painted red, which appeared in front of every house. The natives told me that such boards had always been made by their ancestors, before tools of any metal were seen in the land: they were from twelve to twenty feet in length, about two feet in breadth, and two inches thick: and they seemed to have been 'dubbed'

© The Complete Work of Charles Darwin Online

down to a fair surface; but I am inclined to think that the wood is of a kind that splits easily into plank, like the alerse of southern Chile.* Being the evening meal time, some women, and male slaves, were removing the cinders from holes in the earth, whence steam was issuing profusely, under a shed, near the house I was examining. The shed was a light roof, upon upright poles, covering the cooking place—a few square yards of cinder-covered ground. Out of each hole dirty looking bunches of fish and leaves were raked with fingers and sticks. Hot stones were at the bottom of the hole, placed in the usual Polynesian and Chilote method. The fish had been wrapped in the leaves, but taking it out of the oven in such a manner had displaced the leaves, and substituted a coating of ashes and cinders. Potatoes, raked out of another hot hole, looked more eatable: but leaving the natives to their dirty food, we walked to the new church. A slightly built edifice of bricks, and light frame work, with an abundance of bad glass windows, gave me the idea of a small methodist meeting-house, or an anabaptist chapel, rather than an episcopal church. A good deal of money having been subscribed by residents, and visitors, specially for this church, it might be wished that a portion of it had been employed in obtaining a better design, and better materials, as it stands in a very conspicuous situation. To place a church in a stronghold of iniquity, such as Kororareka, the resort of the worst disposed inhabitants of New Zealand, native and foreign, was a daring experiment: yet notwithstanding the ill-will entertained towards the missionaries, by their 'spirit-selling' countrymen; by native chiefs, whose pandering trade was yearly lessened; and by the evil disposed of every description, no molestation had been offered, and not a plane of glass had been broken! neither had the church service been performed in vain to inattentive hearers.

Returning to the beach, we saw some of the fine canoes I have already mentioned: we then paid a formal visit to one of the chiefs; and for another, who was not at home, I

* Kauri? or some other pine?

© The Complete Work of Charles Darwin Online

thought I could not do better than leave a present: his wife, or rather one of his wives, was pointed out to us, as the sister of the notorious Shunghi. 'Titore' was the absent chief's name. He was out in the country, with a hundred well-armed followers, cultivating, as we were told, his yam and potato grounds. We next saw a burying place, or rather a place where the dead are exposed, upon a raised platform, to the wind and sun. Wrapped in cloth of the country, the bodies are placed upon small square platforms of boards, which are fixed upon single central posts, ten feet high. Bushes were growing, unmolested, in the enclosure (or 'Marae'), no foot entering to tread them down. Among these thickets I saw several large boards standing upright like gravestones, some of which were painted red, and uncouthly carved. Returning to our boat, the chief whom we had visited presented me with a garment of the country manufacture: his assumed haughtiness was amusing, from being characteristic. Our evening was passed in very interesting conversation with Mr. W. Williams, and Mr. Baker;* the former had just arrived from Waimate, an agricultural settlement, lately established by the missionaries, in the interior.

Of the difficulties encountered and surmounted by the first missionaries in New Zealand full accounts have been lately published: the little we then heard strongly excited our curiosity. Mr. Marsden appeared to have been the originator, as well as the main instrument, in forwarding the great work.

On the 23d, I went with Mr. Baker to Tipuna, the place where the first missionaries, Mr. King and Mr. Kendal, established themselves in 1813. Mr. King was absent, but I saw his wife and son, who told me that he was travelling about among the natives, and would not return for several days; he was on horseback, his son said, but quite alone. Mrs. King described the former state of things which she had witnessed herself in strong terms; she could not look back to those days

* I learned that de Thierry was sometime resident in the King's-bench, and that his alleged purchase of land, in New Zealand, was a theme of ridicule among the aborigines.

© The Complete Work of Charles Darwin Online

without shuddering. Being told in the evening, that "before morning their house would be in flames;" and that "stones were heating for the oven in which they themselves were to be cooked," was a quieting farewell, from a mob of angry natives, on more than one occasion. But Mr. King always found a trusty friend in a chief, whose name has been often noticed—'Waripoaka.' I met him near the house, in company with a young chief, whose sense of propriety was so delicate that he would not appear before Mrs. King, because he was not dressed 'well enough!' Waripoaka was satisfied with his own attire, and went with us. To my prejudiced eye, the dress of the young man, a mat, or mantle of the country, loosely wrapped around a fine figure, appeared far more suitable than the long-tailed old coat, thread-bare pantaloons, and worn-out hat, which utterly disguised and disfigured the old chief.

Mr. King's son talked of his sheep, and I found that though not more than eighteen or twenty, he was already a farmer, possessing land and a flock of sheep. Returning by a different route, we landed upon an island lately bought from the natives by two persons who had been masters of whale-ships.

This island, purchased for a trifling price, will become very valuable, as the trade to the Bay of Islands increases; and I regretted to see a spot of such future consequence in the hands of men, whose verbal attacks upon the missionaries, and illiberal aspersions of Mr. Busby's character, disgusted me so much that I had hardly patience to make the inquiries which were the object of my visit; or to wait while Mr. Baker told them of a plan which was in contemplation among the settlers, for the prevention, or at least restriction, of the sale of spirits.

Such men as these, strongly prejudiced, deaf to reason, and too often habitually vicious; run-away convicts, whose characters may be imagined; and democratic seceders from regular government, cause the principal difficulties against which honest, upright settlers, and the whole missionary body, have to contend. One of the men, whose share in the property of the island I have been regretting, was partly intoxicated while we were with him; but Waripoaka, who accompanied us, significantly warned me of his state as I entered the house.

© The Complete Work of Charles Darwin Online

24th. I went with Mr. Baker to a scattered village, called Cawa-cawa. Leaving the ship early, we followed the windings of an estuary which forms Kororareka Harbour, until its shores contracted it to the limits of a fresh-water river. Three good houses on the eastern shore, lately built by respectable English settlers, attracted our notice in passing; and afterwards the 'Pah'* of Pomare,† a well-known chief, appeared like a cattle-enclosure upon a hill. Pomare is the man who killed and ate a part of his female slave, when Mr. Earle was there; he has still large possessions, and had larger, but has sold much for ammunition, muskets, and spirits. His honourable office at this time was that of supplying the numerous whale-ships which visited the harbour with his slaves; and he found such an employment of his female vassals answer better than the horrible one well described by Mr. Earle. Dismal alternative! On board each of the ships we passed there were many of these women; but before we notice the 'mote,' let us consider the great 'beam,'—think of what our own seaports were in times of war, and be charitable to the South Sea Islanders.

Pomare was heard to say that his son would be a greater man than himself: and the New Zealanders in general are impressed with the idea that their sons will be better, or greater men, than themselves.

The estuary, or arm of the sea, whose windings we were following, forms an excellent harbour for ships not larger than third-class frigates; or to speak in a more definite manner, for those which do not draw more than seventeen feet of water. On each side the land rises to five or six hundred feet, sheltering the anchorage without occasioning those violent squalls alternating with calms, that are found under the lee of very high land, over which strong wind is blowing. As far as I know, there are very few shoals or banks in the wide space which forms the inner harbour. A slight stream of current and

* Or Paa; by Cook called Hippah.

† This chief said that his father had adopted the name of 'Pomare,' because he had heard of a very distinguished warrior at Otaheite, who bore that appellation.

© The Complete Work of Charles Darwin Online

tide runs outwards during about seven hours, and the tide sets inwards about five, though with still less strength. At times, the outward stream may run about two knots in the narrow places. Mr. Mair's house and shipping-yard, Mr. Clendon's establishment, and the pleasantly-situated house and garden of Mr. Wright gave an English aspect to the eastern side of the harbour; while boats passing and ships lying at anchor in an estuary, much resembling one in our own country, prevented the frequent occurrence of a thought, that we were near the Antipodes; and that on the western side of the harbour is the place where 'Marion' and so many of his crew were massacred, and afterwards eaten! That horrid catastrophe is now said to have been caused by mutual ignorance of language. The Frenchmen not understanding that the spot was tabooed, persisted in fishing there, and endeavoured to maintain their intrusion by force.

Canoes met and passed us as we proceeded. It was pleasant to witness the cordial greetings exchanged between most of their occupants and Mr. Baker. All these canoes were going to Kororareka, to sell their cargoes of firewood, potatoes, yams, or pigs. Here and there, by the water-side, we saw a house, or rather hut, with a patch of cleared and cultivated ground, a great pile of firewood, ready for sale, and perhaps a canoe close by, which the native owners were loading with the marketable produce of their land. When the estuary had diminished, and we found ourselves in a fresh-water river, there was much resemblance to parts of the river at Valdivia; but the amount of ground under cultivation, and the number of huts scattered over the face of the country and along the banks of the river, were less near Valdivia, exclusive of the town itself, than in this so lately a cannibal country.

Though on a small scale, the banks of this river are interesting and picturesque. On each side, the soil is extremely good on the low grounds, and the hills are well clothed with wood; they are not high, but approach the river rather closely in some places, so that the winding stream, spaces of level and partially cultivated land, and woody heights, are agreeably

© The Complete Work of Charles Darwin Online

mingled, and formed a rapidly varying view as we proceeded.

Mr. Baker had been urged by the natives of Cawa-cawa to visit them, and endeavour to settle a dispute which had arisen with a neighbouring village, or rather tribe. He also wished to gain more advocates for the abolition of spirits; and I was glad to profit by the opportunity of seeing a little of the natives and their habits, in a place said to be Christianized, and uncontaminated by the spirit-sellers.

A few of our own countrymen were employing themselves as sawyers, on the banks of the river, near the village of Cawa-cawa; but neither their huts, their mode of living, nor their outward appearance, caused any feeling of good-will towards them on my part.

Having ascended the stream, as far as the boat could go, which was about four miles from the salt-water, we landed, and walked towards the village of Cawa-cawa, escorted by several elderly and a mob of young natives. Our way led through open underwood, maize-grounds, and damp swampy soil, in which I saw plenty of the plant called 'flax,' supposed, a few years since, to be very valuable, and now probably much undervalued. Across a stream the natives seemed delighted to carry us; indeed, I may say once for all, that at this village their whole behaviour was affable, friendly, and open, to a degree nearly approaching that of the merry Otaheitans.

Under the shade of a large tree, the inhabitants of the widely-scattered huts soon assembled. For me they brought a chair out of a cottage; but for themselves their native soil offered a sufficient place of rest. In all positions, half-enveloped in blankets or coarse country mattings, with their rough, curly hair protecting their heads from the sun's rays, and almost shading their tattowed faces, about a hundred men, women, and children surrounded their apparently most welcome friend 'Payka,' as they called Mr. Baker. Many fine forms and most expressive countenances were there. Such heads, indeed I may say, such a group for a painter! I had sufficient leisure to admire them; for it is etiquette in New Zealand to sit in silence

© The Complete Work of Charles Darwin Online

during some minutes, previous to commencing any conversation. Engrossed by the fine, the grand heads of some of the old warriors, whose amply tattowed features had withstood the ravages of time more successfully than their once dark hair, and by the graceful figures of the younger women, I was sorry when the ceremonial silence was ended. By turns the principal men discussed with Mr. Baker (whose speaking appeared to be to the purpose, as well as fluent), the business for which they had assembled.

I could understand few words used, but the gestures of the natives were sufficiently expressive to give a general idea of their meaning. Mr. Baker's interpretation to me afterwards was to this effect:—"A neighbouring tribe has encroached upon the district which this tribe claim as hereditary property. These men prove their right to it by bringing forward several of their elders, who have at various times killed and eaten 'rats' upon it."

In other days, the war-club and the patoo-patoo—a sanguinary contest to determine whose should be the land and whose bodies should fill the ovens—would have been the unfailing mode of decision. "What would Mr. Baker recommend them to do, now that they had become Christians?" was their question. He recommended arbitration, each party to choose a 'wise man;' and if the two wise men disagreed, they should refer the question to the deliberation of the missionaries, at their next general meeting. He also promised to visit the other tribe, enquire into the case, and exert himself for the sake of both parties, who were equally his friends, and whose interest, as well as duty, it was to remain at peace.

By temporising, talking to each party, and inducing one to meet the other half way, Mr. Baker had no doubt of amicably arranging the affair.* Is it not extremely gratifying to find the missionaries thus appealed to, and acting as mediators and peacemakers?

The singular reason for laying claim to this land, appears less extraordinary when explained. Formerly there were no wild

* Before the Beagle sailed it was settled.

© The Complete Work of Charles Darwin Online

quadrupeds, excepting rats, upon New Zealand: and while so destitute of animal food, a rat was considered 'game' by the natives; and no man would attempt to kill his neighbour's rats, or those which were found on his territory, without intending, or declaring war against him. Had not the rats, eaten by the older men of Cawa-cawa, belonged to them, the lawful or understood owners of the rats would long since have made war upon the people of Cawa-cawa. Rats having been there killed, and war not having been consequently declared, were irresistible arguments in the minds of those men, who never forgot, and who knew not how to forgive an injury.* Some of us are apt to think modern game laws harsh inventions, and the result of civilization. Yet if, in our own history, we look back seven hundred years, we find that human lives were then forfeited for those of beasts of the chase: and if we look at this country, which may be supposed two thousand years behind our own, in point of civilization, we find, that to kill a rat upon a neighbour's land, is an offence almost sufficient to cause a general war.

The precise manner in which territory is divided among these savages surprised me not a little: I thought land was but slightly valued by them. Though sold to Europeans for what we consider trifles, the sale is, to them, matter of high importance, in which every free man of the tribe ought to be consulted. Uncleared land is supposed to belong to the tribe, collectively. Cultivated spots, and houses, are private property, but cannot be sold, or given away, out of the tribe, without the consent of the whole community. This division of land among small tribes,† looks much like a comparatively late appropriation of the country. To make a purchase of land in New Zealand, in a manner which will ensure quiet and unquestioned possession, it is necessary to assemble all the tribe of

* In Mariner's Tonga Islands a full description is given of the manner in which the Friendly Islanders shot rats: as an amusement.

† There are several varieties of the human race in New Zealand; differing from one another as much as the lightest olive-coloured Otaheitan differs from the 'brown-black' New Hollander.

owners, or as many as can come; a few absentees, of little consequence, not being thought about. The goods intended to be given, as an equivalent for the land, are then spread out for inspection; and if the contracting parties agree, their word is given, and their marks are perhaps put to a deed which they cannot read,* but whose purport they are told. The goods are forthwith carried away; each man appropriates what he chooses, and it often happens that the chief men of the tribe receive the smallest portion of the purchase goods.

One, among many objections alleged against the purchase of land, said to have been made by de Thierry, was, that he could not have bought land in New Zealand, while absent, because, in order to make a purchase valid, it is necessary to buy from the tribe, not from individuals.

Mr. Stokes was informed that when a tribe is utterly vanquished, the conqueror generously gives the survivors a grant of land, and even slaves. I do not see how to reconcile this act of generosity with the blood-thirsty warfare which has usually ended in indiscriminate slaughter, and cannibal feasts.

Satisfied, for the time, on the principal subject:—the much desired abolition of the use and importation of ardent spirits, was discussed. An old man, named 'Noah,' spoke to the tribe; and after alluding to the disgraceful and unfortunate events, caused by drinking, which had happened to their friends, and to neighbouring tribes, since the white men had introduced the vice of intoxication, old Noah ended a short but eloquent harangue, by saying, "expel the liquid fire." Noah is a Christian: his name was his own choice, when baptized, some years ago. The principal men, eight in number, signed, or made marks upon the paper, which contained the resolutions agreed to by acclamation. Noah wrote his name in a distinct hand: each of the others made marks resembling a small part of the tattowed lines upon their faces. One man imitated the mark upon the side of his nose; another that near his eye. Baked potatoes were afterwards brought to us; and a curious wine, of which I had not

* A few natives can now read and write.

© The Complete Work of Charles Darwin Online

heard. It was dark coloured, and not unlike good elderberry wine. It is made from the small currant-like fruit of a shrub, which the settlers call 'native vine;' but the resemblance to a vine is about as evident as that of a common elderberry bush. The fruit grows in clusters, much like small elderberries in appearance, but it contains stony kernels, which are said to be unwholesome, if not poisonous. Women collect the juice by squeezing the bunches of fruit with their hands. I have heard that it is used after fermentation as well as in its pure juicy state, but some assert the contrary: it might then assuredly cause intoxication; I doubt, however, their often obtaining, or keeping, a sufficient quantity. It dyes the hands of the women and children who collect the juice, so deeply, that they cannot efface the stain for many days afterwards.

Instead of rubbing, or rather pressing, noses, these people have adopted the custom of shaking hands: every one expects to have a shake. Yet with all their asserted equality, and democratic ideas, there must be a considerable distinction of rank, and difference of occupation, among them; for I particularly noticed that two chief persons of this tribe, who rather resembled the higher class at Otaheite, had far less swarthy complexions, and less hardened extremities, than the others: one of them, considered by Mr. Baker to be the head of the tribe, was more like an Otaheitan 'Eri,' and less like the ordinary New Zealanders than any other native I saw, while at their island. From the meeting place under the large tree, we went to see a chapel which the natives were building, by their own free will and labour; and in our way we passed through yam and potato grounds, so neatly kept, that no gardener need have hesitated to commend them.* The intended chapel was a lightly framed building of wood, with a thatched roof. The natives seemed to be very proud of it, and were much gratified by our praises. Some large oxen, in a pen, were feeding on young branches, and leaves of trees, gathered for them by the

* Cook speaks in strong terms of the neatness and regularity of their cultivated grounds.

© The Complete Work of Charles Darwin Online

natives, which they appeared to relish as much as hay: they were called 'booa-cow.'*

At the door of a house, or rather in the porch (before described), I saw a woman reading: she was sick, Mr. Baker told me, one of a long list of invalids, who frequently applied to the missionaries for advice and medicine. I looked at her book, it was the Gospel of St. Matthew, printed at Paihia, in the New Zealand language. Now, certainly, there was neither constraint, nor any thing savouring of outward show, in this woman's occupation, for my seeing her was sudden, and quite accidental, arising from my going out of the usual path to look at the oxen. Mr. Baker told me, that one of the most troublesome, though not the least gratifying duties, of the missionaries, was that of attempting to act as medical men. No regularly educated practitioner having at that time established himself in the land, every complaint was entrusted to the kind attention, and good will, but slight medical knowledge of the missionaries. We saw several nets for fishing placed in separate heaps, each upon a small platform, at the top of a post eight or ten feet in height: in a similar manner yams and potatoes are preserved from the rotting influence of the damp earth. The nets are made with the split leaves of the 'flax' plant, not merely with the fibres, and last for many years: both they and the food, thus exposed to the air, are thatched, like the houses, with the broad leaves of an iris-like rush, or flag, which grows abundantly by the river sides, and in marshy places. I was here informed, that after the bodies of the dead (which are exposed to the air, on platforms similar to those I have just mentioned), are thoroughly dried, the bones are carried away, and deposited in a secret burying place.

25th. Being Christmas-day, several of our party attended Divine service at Paihia, where Mr. Baker officiated. Very few natives were present; but all the respectable part of the

* Literally cow-pig. Before white men brought others, pigs were the only domestic animals known in Polynesia besides dogs:—and when a cow first appeared in a ship, she was called cow-booa, or booa-cow.

© The Complete Work of Charles Darwin Online

English community had assembled. Instead of performing the whole service first in one language, and afterwards in the other, as at Otaheite, the two entire services were mixed, and the whole extended to such a length that had even the most eloquent divine occupied the pulpit, his hearers could scarcely have helped feeling fatigued. Mr. Baker appeared to be more fluent in the language of New Zealand, than in his own, a fortunate circumstance for the natives, though not for the English who attend his church. In the mere glimpse which I had of the missionary body at New Zealand, it appeared to me that they rather undervalued their white congregations. They say, "We are sent to the heathen, it is to their improvement that every effort should be directed." "This is true," may be replied; "but does not the example of respectable settlers, or visitors, assist the influence of missionaries?" Would not the natives take notice if foreigners whom they see in the land refused, generally speaking, to conform in their habits and conduct, to the principles so earnestly insisted upon by the missionaries? But unless Divine service is performed in a manner which will, at the very least, increase respect for it, and give rise to no feelings of slight towards those who, from the nature of their highly responsible office, are expected to perform it tolerably well—it does not seem likely that such as are only sojourners in the land, will be seen at the church as often as might be desirable; thus a part of their example, so beneficial to the great cause, will perhaps be lost.

A very correct musical ear seems to be as general among the people here, as among those of Otaheite. The responses of thirty natives, women and men, were made so simultaneously, and so perfectly in harmony, that I could no more distinguish the different voices, than I could those of a number of good choristers singing together. Their singing was equally melodious, yet neither I nor others were disposed to think it equal to that of Otaheite.

26th. Disputes between masters of whale ships and their crews, and between both these classes and the New Zealanders, obliged me to meddle, though very reluctantly, in their affairs.

© The Complete Work of Charles Darwin Online

to show what anarchy has been caused in this country, by the partial, half measures, which have been taken, I will try to describe the state of things, at the Bay of Islands, as we found them.

I will not attempt to give the slightest sketch of events which had occurred anterior to the Beagle's visit, full and authentic details being accessible in other publications; farther than to say that the rumoured approach of de Thierry had stimulated Mr. Busby (holding the undefined office of British resident) to take measures adverse to such foreign intruders, by issuing a public announcement,* and by calling together the principal chiefs of tribes inhabiting the districts of New Zealand, north of the Thames, with a view of urging them to frame a sort of constitution,† which should have a steadying influence over their unwieldy democracy, and leave them less exposed to foreign intrusion.

Thus much had been done by words and on paper; the chiefs had departed, each to his perhaps distant home, and the efficiency of their authority, in a 'collective capacity' was yet to be discovered. No 'executive' had been organized; the former authorities—each chief in his own territory—hesitated to act as they had been accustomed, owing to a vague mystification of ideas, and uncertainty as to what they really had agreed upon, while the authority of Mr. Busby was absolutely nothing, not even that of a magistrate among his own countrymen; so of course he could have no power over the natives. To whom then were the daily squabbles of so mixed and turbulent a population, as that of the Bay of Islands and its vicinity, to be referred?

Late events had impressed the natives with such a high idea of King William's men-of-war, that even the little Beagle was respected by them, and, in consequence, appeals were made to me—by natives, by men of the United States of America,

* Appendix, No. 35.

† A copy of the constitution, or form of government, decided upon at a meeting of all the chiefs of the northern districts (excepting two or three of minor consequence), is in the Appendix, No. 36.

© The Complete Work of Charles Darwin Online

and by British subjects; but, not then aware of the peculiarity of Mr. Busby's position, I referred them to him, under the idea that his office was of a consular nature, and therefore that I ought not to act in these cases, excepting as his supporter. Finding him unwilling to take any steps of an active kind, not deeming himself authorised to do so: and the aggrieved parties still asking for assistance, I referred them to the only real, though not nominal, authority, in the place, that of the missionaries. By the active assistance of Mr. Baker, the more serious quarrels were ended without bloodshed, and those of a more trifling nature, in which the natives were not concerned, were temporarily settled: but I doubt not that in a few days afterwards anarchy again prevailed.

To give an idea of the nature of some of these quarrels, and of the serious consequences they might entail, I will describe briefly two or three cases which were referred to me.

Pomare had been beaten while on board a whale ship, by some of her crew. No New Zealander will submit to be struck, but thus to treat a chief is unpardonable. Burning with indignation he maltreated the first Englishman whom he met on shore, and was concerting serious measures of revenge, when the master of the ship, and a number of his men, came to ask for assistance and protection.

Again; a chief, whose name I do not know, had been refused admittance on board a whale ship, where he had heard that one of his female slaves was living. He did not wish to injure her, or even take her away. His only motive, in asking admittance, was to satisfy himself that she was there. Highly affronted at the refusal, he spoke to me, (as he said) previously to collecting his warriors and attacking the ship.

Another case was unconnected with the natives, but tended to expose a fraudulent system, and to show the necessity of arming British authorities, in distant parts of the world, with a definite degree of control over the licentious, or ill-disposed portion of their own countrymen, who, in those remote regions, are disproportionably numerous, and now able to do pretty much what they please.

© The Complete Work of Charles Darwin Online

A person who stated himself to be the master of an English whaler, lying in the harbour, came on board the Beagle, accompanied by a man said to be the third mate. The former complained of the mutinous state of his crew, who had ill treated this third mate, and then refused to work or obey any orders. Inquiry on board the whaler, showed that the crew had been ill-used, especially as to provisions: and that not only the nominal master, but the chief as well as the second mate were North Americans, (U.S.) The legal master, it appeared, was the so-called third mate, an Englishman. His name appeared in the ship's papers as master; that of the person who had been acting as master did not appear at all. But the acting master, who before me styled himself 'supercargo,' produced a power of attorney from the owners of the vessel,* which appeared to authorise him to control the proceedings of the vessel, as he thought proper; to displace the master and appoint another person in his stead, and in every way to act for the owners, as if he, the American, were sole owner. Nearly all the seamen were British subjects. How far his power of attorney might carry weight against the spirit and intent of the navigation laws, I had much doubt; but as it appeared to me that the owners in such cases, ought to know their own interest better than other persons could; and that in suiting their own interest they certainly would add their mite towards the general interest of their country; and as the supercargo had a circular letter from the Commander-in-chief on the West-India and North American station, asking for the assistance of any King's ship he might meet (with the view of encouraging the whale fishery out of Halifax); I refrained from doing what my first impulse prompted—putting an officer on board, and sending the ship to the nearest port (Sydney), in which correctly legal measures might be adopted, if necessary. Meanwhile as the British resident did not think himself authorised to interfere, and disorder, with 'club-law,' were prevailing and likely to continue, in the Rose, I went on board, accompanied by Lieutenant Sulivan and Mr. Bynoe.

* The 'Rose' of Halifax.

© The Complete Work of Charles Darwin Online

After examining the provisions and all the ship's papers, I spoke to the crew (every man of whom wished to leave the vessel) and to the nominal master; obtained an assurance, in their hearing, that their future allowance of provisions should be unobjectionable, and, for the time, restored order. But I felt that the calm was unlikely to last, and two days afterwards fresh appeals were made, to which I could not attend, being in the act of leaving the port.*

The laws which regulate our merchant shipping, especially sealers and whalers, do not appear to extend a sufficient influence over the numerous vessels, which, with their often turbulent inmates, now range over the vast Pacific. For many years past, Great Britain and the United States have annually sent hundreds of large whale ships into the Pacific: during late years, Sydney has sent forth her ships, amounting at present in number to more than sixty, most of which are employed in whaling or trading in the Pacific: and be it remembered that their crews are not the most select seamen—the nature of many of them may easily be imagined—yet in all this immense expanse of ocean, little or no restraint except that of masters of vessels, on board their own ships, is imposed either upon Americans or British subjects! There is the nominal authority of a consul at the Sandwich, and Society Islands: and occasionally a man-of-war is seen at the least uncivilized places. But how inefficient is so widely separated, and so nominal a control? When ships of war visit the less frequented parts of the Pacific, they are too much in the dark, as to the state of things, to be able to effect a tenth part of what might be done, in equal time, by a ship employed solely on that ocean. In so peculiar a portion of the world as Polynesia, it takes some time to learn what has been taking place: and what ship of war has stayed long enough for her captain to lose the sensation of inexperience—which must embarrass him if called upon to decide and act, in cases where he really is about the most ignorant person (as regards the special case) of any one

* Afterwards (at Sydney) I heard that the men had all left the vessel, and were living among the natives.

© The Complete Work of Charles Darwin Online

concerned with it? In consequence of that ignorance, he must inevitably be more or less guided by the advice of parties, of whose individual interest in the matter so short an acquaintance cannot give him a proper idea.

A great deal of prudence, and good management, is required in the commander of a man-of-war, who has any business of consequence to transact with the natives of Polynesia, or who has to deal with his own countrymen in that distant region. A single ship, assisted perhaps by tenders, might, if well commanded, do more good in a few years among the islands of the Pacific, than can now easily be imagined. But then she must be stationary; not that she should remain in one place—far from it—her wings should seldom rest; I mean only that she should stay in the Pacific during three or four years. In that time so much information might be gained, and so much diffused among the natives; such a system of vigilant inspection might be established, and so much respect for, and confidence in the British nation, be secured—that our future intercourse with Polynesia would, for a length of time, be rendered easier and infinitely more secure, as well as creditable.

The few ships of war which have remained during any length of time among the islands, have been occupied by exploring and surveying, to an extent that has interfered with the earnest consideration of other matters. But in a ship, employed as I have described, a surveyor might be embarked, who would have ample opportunities of increasing our knowledge of that ocean. And if a sensible man, whose natural ability had been improved by an education unattainable by sailors, could be tempted to bear the trials and losses of a long sea voyage, in a busily employed ship, how much might Science profit by the labours of three or four such years?

Having thus entered freely into ideas which I have so often dwelt upon that they are become familiar, I will venture to suggest the kind of ship which would do most, in my humble opinion, at the least ultimate expense consistent with efficiency. Moral influence over the minds of natives, as well as over wanderers from our own or other countries, is a pri-

© The Complete Work of Charles Darwin Online

mary object, and that influence might be at once obtained by the mere presence of a large ship.

Compare the manner in which the natives of the Marquesas behaved to the Tagus and Briton frigates, with their hostility to vessels whose appearance did not overawe them. An outward show of overpowering force would often prevent a struggle, and probably loss of life, which, however justifiable, cannot too anxiously be avoided. From what I have seen and heard, I feel authorised to say that one ship of force, well-manned, and judiciously commanded, would effect more real good in the Pacific than half-a-dozen small vessels.

Frigates have already been seen among some of the islands of Polynesia, and heard of in the greater number. To send a ship of a lower class to establish a general influence over the Polynesians, and our own wandering countrymen, as well as for the purposes I have previously mentioned, would be to treat the business so lightly that, for the credit of our country, it would perhaps be better let alone; particularly as a frigate does occasionally go from the South American station, and a sloop from Australia, or the East-Indies. No European or American nation has now a duty to perform, or an interest to watch over, in the Pacific Ocean, equal to that of Great Britain. The North Americans are increasing their connections, and consequently their influence, rapidly. Russia has extended her arm over the Northern Pacific. France has sent her inquiring officers, and Roman Catholic missionaries* are sowing the seeds of differences, if not discord, among the islanders, in the Gambier Islands and elsewhere.

Independent of expense, what are the principal local objections to employing a frigate in such a duty? In the first place, among the islands there would be risk of getting ashore, increasing with the size of the ship:—in the second; it might be difficult to obtain supplies, and in the event of losing spars she might be obliged to return; perhaps to England:—in the third; to get ashore, in a ship drawing so much water, would

* Sent out immediately after the first circulation of Captain Beechey's interesting work.

© The Complete Work of Charles Darwin Online

be a much more serious affair than a similar accident happening to a smaller vessel: and, by obliging her to return to England, or go to an East-Indian dockyard, would upset all plans and expose Polynesia to greater irregularities and less control than ever, until new arrangements could be made.

To the 'risk of getting ashore,' I answer: large ships are in general more efficiently officered and manned than small ones, and they are less likely to get into danger, because they are consequently more carefully managed. The Pacific is, technically speaking, a 'deep water' ocean: all its coral reefs are 'steep-to.' Sand or mud banks are unknown, except near the shores of continents, and even there they are rare, unless on the Japanese and Chinese shores. Small ships attempt to sail in intricate passages, and get ashore:—large vessels use warps, or await very favourable opportunities, and are not risked. Secondly: supplies may now be obtained in any quantity on the coast of South America, as well as in Australia; and fresh provisions can be obtained by regular, reasonable purchase, at the principal islands. New Zealand, Norfolk Island, the north-west coast of America and other places, are stocked with the finest spars: and lastly: a large ship, well provided, has the resources of a small dock-yard within herself.

An East-India trader of eight hundred tons, was hove down by her own crew, and the natives, at Otaheite. Cook laid his ship ashore for repair in Endeavour River, on the north-east coast of New Holland; where the rise and fall of tide is very great. Sydney is an excellent place for heaving down and repairing a ship of any size. Guayaquil has a great rise and fall of tide. Lima, or rather Callao,—and Coquimbo, are good places for a ship to refit in. But Sydney is superior to all as a rendezvous, and any repairs may be effected there.

Large ships are able to do all their own work, while small vessels are frequently obliged to ask for the help of their neighbours, when they get into difficulty, or want repairs. These considerations, however, should not prevent a frigate from having a good tender, for much risk would then be

© The Complete Work of Charles Darwin Online

avoided: and although the large ship might be repairing, the knowledge that she was in the Pacific* would be quite sufficient, if she had only established such a character as that which was borne by many a British frigate during the last general war. Such a ship could detach efficient boats for surveying, or other purposes; she could carry animals, seeds, plants, and poultry, to those islands which have none; and by her countenance and protection, she could assist and encourage the missionaries in their all-important occupation.

* No accident need oblige her to quit that ocean. Many large ships are built there, and never leave its waters.

CHAPTER XXV.

Waimate—Cultivation—Flax—Apteryx—Gardens—Missionaries—Farm—Barn—Mill—Grave of Shunghi—Horses—Kauri Pine—Keri-keri—Children—Waripoaka—La Favorite—Political condition—Relics—Images, or Amulets—Mats—Leave New Zealand—Remarks—Intercourse—Convicts—Effects of Missionary exertion—Irregular Settlements—Trade—Residents and Consuls—Missionary Embarrassments—Society's Lands—Discontent of Settlers—Purchase of Land—Influence of Missionaries—Their sphere of action.

28th. Accompanied by Mr. Baker, I set out to go to Waimate, a settlement formed by the missionaries with the view of introducing agriculture and mechanical arts among the natives, in addition to the truths of the Gospel. Entering one of the numerous creeks (Waitangi) by which the north-eastern shores of New Zealand are intersected, we went a little way in a boat, then landed and got on horseback.* Two natives, who had been waiting with the horses, ran by their side during the rest of the day with much ease, though we trotted or cantered rather fast. One of them even carried a bundle weighing about thirty pounds. The men did this by choice, for the sake of riding back from Keri-keri, a place we were afterwards to visit, and whence Mr. Baker and I would return by water. While running thus easily and cheerfully, by the side of our horses, they reminded me of men at Madeira; and still more of the Maltese, whom they both resembled in feature, figure, and colour. To see fern every where, was a remarkable peculiarity. In some places it grew thickly, and to the height of a man, in others it was scantily scattered. It is said to be an index to the quality of the soil, which is productive in proportion to the quantity of fern. After ascending the first low hills, I was a little disappointed by the uniform and unpicturesque appearance around me. A rather level or irregularly undulating country, in which extensive plains were more

* A few horses had been brought over from Sydney.

© The Complete Work of Charles Darwin Online

remarkable than hills—every where verdant, in many places wooded, and intersected by numerous streams of water—pleased by its supposed capabilities, though not by the picturesqueness of its appearance. From seeing the remains of forest, or rather irregular-looking woods, in a variety of situations—at the summits of hills, as well as in the hollows of vallies; and from the prevalence of fern instead of grass, I was led to think that the whole land had once been thickly wooded, but that the natives had cleared away the trees by burning.

We passed by a native village, around which were many acres of well cultivated ground, with maize and potatoes in a thriving state. They were planted in little heaps of earth (like mole-hills), at exact distances, laid out by line. For planting the sweet potato (cumera), a kind of yam (taro), or the lately introduced potato, a wooden stake is used as a substitute for a spade, in preparing the ground. The natives acknowledge themselves much indebted to the white men for pigs and potatoes; but they speak angrily of the 'liquid fire'—and diseases which they brought. One old native also made a shrewd remark about certain seven-barrelled guns sent among them by some of our countrymen, even while others were preaching the gospel of peace, and trying to check their inclination to quarrel.

Abundance of the flax plant was growing on the low moist ground, and also on higher, apparently dry soil. I was told that the flax plant does not like a swamp, but thrives where the ground is rather moist. With leaves like those of an iris or large lily, whence the fibres are obtained which are 'called' flax, this plant has always been of great consequence to the natives. Those immense nets which are mentioned in the faithfully descriptive accounts of Cook, are made with the leaves split into long narrow shreds, not scraped or peeled. For the manufacture of smaller cordage and thread, the leaves are scraped by a shell, which removes the upper or green part and leaves the strong white fibres, that run longitudinally along the under side. With these fibres, in less or greater numbers, and twisted more or less, the New Zealand cordage has been made, which was so much liked at its first intro-

© The Complete Work of Charles Darwin Online

duction, but is now said to be of a quality very inferior to that made with European, or even Chilian, hemp. The principal objection I have heard urged against the New Zealand rope is, that it does not endure frequent bending; not being sufficiently tenacious if used where its pliability is much tried. In sailor's language, 'it soon goes in the nip.' Perhaps this objection might be removed by a peculiar mode of treating the plant, or by another way of seasoning and preparing the fibres. Very fine mats for clothing are made with these fibres, which, when properly prepared, are of a fine silky texture, extremely durable, and capable of withstanding a great deal of washing and wear. I have one by me which has been in constant use sixteen years, and frequently washed. This being the case with respect to the mats, how does it happen that rope made by white men, of the very same material, has not been found to answer? Surely, it can only be because the material has not been properly treated by those who are, perhaps, little acquainted with its nature, with the best season for cutting it, and with other peculiarities probably well known to the natives. Do not many of our own handicraftsmen make a mystery of their art, and, in consequence, are not the secrets of most trades hidden to those who have not learned them, and cannot read?

An open-sided house, or rather shed, standing apart from the little village, I was told was a chapel, which the natives had lately built of their own accord, and without telling the missionaries of their intention: when it was completed they applied to Mr. Williams for a teacher.

A very fine-looking native passed us, whose air and manner of carrying his gun reminded me of an Albanian's. Every man now carries a gun or musket, who, a few years since, would have been armed with a war club, or patoopatoo, and a mieri.*

So accessible is the country between Waimate and the Bay of Islands, that, except across a few small ravines, which require log bridges, a cart might travel easily; though there was at this time no road: water conveyance also is every where at hand, so

* Or mearee (spear).

© The Complete Work of Charles Darwin Online

intersected is the land by arms of the sea. Fresh water, in rivers, brooks, and springs, is plentiful, and never fails.

There is a rare and curious bird in New Zealand, which few persons have seen. It is shy, and seldom visible in the day-time: the natives are said to chase it by moonlight. It is of the bustard or emu kind, unable to fly, though provided with short wings; it is said to be more hairy than feathery, and about the size of a small emu.*

On rather a high plain, or very flat-topped hill, stands Waimate—the agricultural establishment of the Church Missionary Society. After so long an absence from every similar sight, and in New Zealand, the sudden appearance of three English houses, surrounded by outhouses, gardens, and cultivated fields, was striking and delightful; I looked at it as a fragment of Old England, small indeed, but apparently genuine. About twenty acres of land, judging only by eye, seemed to be cultivated. Corn was in full ear, and looked well. The buildings showed at a distance to greater advantage than on a nearer approach; because they are built in the form of gentlemen's cottages, but entirely of wood, and were then unfinished. There were also nice gardens, which had evidently profited by much industrious care, and knowledge of gardening: my hasty survey was however stopped by the approach of a person, whose appearance and manner showed that he was an essential actor in this English scene; and whose intelligent, kind, and truly respectable demeanor was of that description which at once excites esteem and goodwill. This was Mr. Davis, the superintendant of the farming establishment. He told me that Mr. Wm. Williams (the brother of Henry Williams) and Mr. Clarke, were gone to Hokianga, at the opposite side of the island, to attend the last hours of a young Wesleyan missionary.

I have hitherto spoken of missionaries in general terms, as if they formed a distinct and undivided class. That as a body they are distinct, in the scale of worldly divisions, is true; their self-devotion, their habits of life, peculiar education, and inces-

* This bird (Apteryx Australis) has lately been described by naturalists, therefore I say no more about it.

© The Complete Work of Charles Darwin Online

sant anxiety, attach them to a class, of which the good, and therefore truly great Bishop Heber was one of the leading members. But of course they are separated, among themselves, by distinctions which are a natural result of more or less education and of early habits.

The Church Missionary Society have distinguished by the term 'missionary' only those educated, well-informed men who have taken holy orders, and they are styled 'reverend.' Those who are not in orders are termed 'catechists.' Without an idea of finding fault with the present conduct of any individual belonging to either of those two classes, it has occurred to others as well as to me, that a third class might be added advantageously, that of 'visiting' or 'inspecting missionaries.' A clergyman of Heber's character, embarked on board a man of war, might advise and assist those who are now too much on an equality to give free advice to one another, or readily to see the small defects from which no human beings or institutions ever can be free.

Human nature, tried during a long course of years, has seldom steered a uniformly steady course; and may not slight defects, if unnoticed, increase into real blemishes? Difficulties have arisen in New Zealand, as well as in other parts of the Pacific, unnoticed by many people, because, till lately, they were but little felt. These difficulties particularly interfere with the missionaries, and if not remedied by timely measures, will lead to continual embarrassment.

To return from this digression. Near the houses a number of sheep were grazing: plenty of fowls, geese, and pigs; some cattle and horses; and several calves and colts, added to the comfortable, farm-like appearance. We accompanied Mr. Davis into his house for a few minutes, walked over the garden and farm, looked at the farm-yard, barn, and mill, and returned to dinner. The house was well constructed of wood; and though unfinished had a remarkably clean and neat appearance. The compact manner in which the walls were boarded or wainscotted struck me particularly, from being such a contrast to the manner in which a South American carpenter would have con-

© The Complete Work of Charles Darwin Online

structed a house of similar size. A little room, used by Mr. Davis, pleased me much; for, in addition to clever contrivances and good carpentry, it contained a collection of excellent books, and a frame on which an unfinished plan of the Society's farm bore testimony to the nature of the in-door occupations of our host. I did not expect to see much indication of reading, certainly none of drawing, in a newly-built house, standing in the midst of a tract of New Zealand, which two years previously was covered with fern.

In the garden, European vegetables seemed to thrive, and the farm-yard was quite English; a large barn, built entirely by natives, under Mr. Davis's direction; a blacksmith's shop; carts and farming implements, successively engaged our attention. In the barn, a surprising work for the New Zealanders, two natives were thrashing, and a winnowing machine was attended by a third. The mill and mill-dam were well worth examination, as good works of their kind, independent of the interest occasioned by their locality. An embankment (made entirely by natives) had changed the upper part of a small valley into a large pond; and on the middle of the pond-head, or embankment, stood the mill.

A powerful water-wheel, equal to the performance of far more work than the mill required, seemed to be easily turned by only a part of the stream admitted through the mill-dam or sluice. In answer to a remark upon the surplus power, Mr. Davis said that the Society contemplated erecting a thrashing machine, and that Mr. Coates* had encouraged him to anticipate its arrival. A thrashing-machine might be worked easily, in addition to the mill, and yet there would be power to spare.† When embanking the pond, an unfortunate accident occurred, which almost stopped the work: one of the natives, incautiously digging under an overhanging mass of earth, was smothered by its sudden fall. Superstitious and easily excited, the natives abandoned their allotted tasks, and not without

* Secretary to the Church Missionary Society.

† The Church Missionary Society have sent out the thrashing machine, and probably it is now in full operation.

© The Complete Work of Charles Darwin Online

much difficulty could the missionaries induce them to resume their employment. When at last the mill was finished and in full operation, nothing could exceed the surprise and delight of the natives, especially those who had assisted in the work. They called it a 'ship of the land.' "Wonderful white men!" said they; "fire, water, earth, and air are made to work for them by their wisdom; while we can only command the labour of our own bodies!"

Many natives have visited Sydney; some have been round the world; and, of course, their ideas and descriptions have been imparted to their countrymen; but nothing, not even that, to a savage, awfully-mysterious object, a steam-vessel, has yet effaced their early-formed opinion, that a large ship of war is the greatest wonder of the world.

Returning from the mill, Mr. Davis showed me where Shunghi was buried. No monumental mark indicates the tabooed place in which the remains of the slaughter-loving cannibal were deposited; a few dark-leaved trees and some thickly-growing fern alone point out the spot.

While looking about, highly gratified by all we saw, we met Mr. W. Williams, who had just returned from his attendance upon the young Wesleyan before-mentioned. The sufferer had been released from painful illness by death.

A thriving young English oak, near Mr. Davis's house, augured well; for where English oaks succeed, many other useful trees will certainly grow. Several younger saplings, just fit for transplanting, occupied a part of Mr. Williams's well-stocked garden; and these interested me more than all the other plants and trees in the garden taken together. Englishmen one now meets every where; but a living, healthy, English oak was a sight too rare, near the Antipodes, to fail in exciting emotion.

I was much struck by the harmony and apparent happiness of those families whose cheerful hospitality I was enjoying. An air of honesty, and that evident tranquillity of mind which can only be the result of a clear conscience, offered a forcible contrast to the alleged gloom and selfishness of which some

© The Complete Work of Charles Darwin Online

missionaries have been accused by those whose society was not, perhaps, even tolerable to them, because of their vicious habits and indulgences. It was also very gratifying to me to mark the lively interest taken by Mr. Williams, Mr. Davis, and Mr. Baker in every detail connected with the Fuegians, and our attempt to establish Richard Matthews in Tierra del Fuego. Again and again they recurred to the subject, and asked for more information; they would not hear of my calling the attempt 'a failure.' "It was the first step," said they, "and similar in its result to our first step in New Zealand. We failed at first; but, by God's blessing upon human exertions, we have at last succeeded far beyond our anticipations." Their anxiety about the South American aborigines generally; about the places where missionaries might have a chance of doing good; and about the state of the islands in the Pacific Ocean, gave me a distinct idea of the prevalence of true missionary spirit.

In the minds of Mr. Williams and his brother I should have expected high and generalizing ideas, similar in a great degree to those of the 'Apostle of the South'—the 'heroic Marsden,' as he has been most deservedly styled; but I was unprepared to find all the members of this missionary body anxious to hear about, and talk of Fuegians and other distant tribes of savages, rather than to draw attention to themselves, to their troubles, and ultimate success, or to their own interests.

At this interview it was fully decided that Richard Matthews should remain with his brother, a respectable young missionary mechanic, established at the northern end of the island, and lately married to Mr. Davis's daughter. Among many subjects of conversation we discussed the dress of the natives; and Mr. Williams assented fully to the inconvenience of their present awkward mode, and expressed an intention of trying to introduce something like the poncho and 'chilipā'* dress of South America. With sincere regret I took leave of the residents at Waimate. Instead of hours, I could have passed days

* The chilipā is a kind of loose breeches.

© The Complete Work of Charles Darwin Online

with them, had other duties allowed of following my own inclination.

Riding across a valley close to Waimate, we passed some young horses of a good breed, though fitter for the saddle than for agricultural purposes. They were the produce of mares brought from Sydney. A picturesque wooden bridge, which had been thrown across the stream at the bottom of the valley, reminded me strongly of one well-known in England; and caused that rush of associated ideas sure to follow an unexpected meeting with the semblance of an object familiar in other days.

In a large wood I saw the noble cowrie (kauri) pine. The trunk of this gigantic offspring of New Zealand is in size and shape like an immense antique column. From the ground to the lower branches, more than ninety feet have been measured; and around the trunk, at a yard from the ground, more than forty feet; while thirty feet in circumference is not an uncommon size. But the upper portions are comparatively meagre, and utterly devoid of any of the beauties so remarkable in our English oaks, cedars, and firs. The woods of New Zealand have rather a naked appearance; for the branches seem inclined to grow upwards instead of spreading, or feathering.

Cantering along, across an open easy country, passable for wheel carriages, we soon approached Keri-keri. A deep ravine, into which a considerable stream falls over a precipice about a hundred feet in height, was pointed out to me as the limit of an arm of the sea which penetrates from the Bay of Islands. The waterfall is rather picturesque. Passing on over rounded hills covered with fern, I almost started at a thoroughly English scene suddenly exposed. In the valley beneath, a quiet little village; a church-like building of stone, with a clock on the tower; an English cutter at anchor, with her ensign flying, in the arm of the sea before-mentioned, close to the village; gardens full of flowers, surrounding the neatly-built and white-washed cottages; cattle grazing about the surrounding hills; and a whole school of little English children, hallooing and screaming to one another as they played in a

© The Complete Work of Charles Darwin Online

field, quite transported me in imagination to the other side of the world. Recalled to the truth by our pedestrian companions asking us to stop for them, I enquired of Mr. Baker how long that respectable church had been built? and was disappointed to hear that the fancied church was a store-house. A small, low building, which he pointed out, was the chapel—it looked much more like a small school-house.

I was glad to see that our native companions took pains to dress themselves decently before they entered the village; as, while running along the road, they had carried their clothes in their hands; but of their own accord they put them on as soon as the houses were seen.

In the village of Keri-keri we found an English welcome, and an abundance of happy-looking, healthy children. Their parents seemed to bear the Church missionary character, open integrity, and the outward indications of a sincere wish to do that which is right. It may seem absurd to speak thus decidedly upon a hasty glance and first impression; but there is a talisman in a truly honest face, and a charm in the manner of one who 'thinketh no evil,' that to me is irresistible; and I have never yet found cause to think lightly of 'ten minutes sight.'

At about ten o'clock, Mr. Baker and I embarked in my boat, to return to Paihia. As we passed down a river-like arm of the sea by moonlight, but little idea of the country on either side could be formed. What I could distinguish was undulating, and rather low land. We were four hours on the water, though the boat moved fast with a fair wind.

I was glad to learn from all quarters that the natives are very fond of the white children. Mr. Davis told me, that his sons could engage the attention and assistance of natives a great deal more easily than he could himself. Speaking the native language more fluently may assist the young people in their intercourse; but they are liked chiefly because born in the land, and because of the naturally kind disposition of the New Zealanders. Many instances have proved that they are kind by nature, and that their feelings are keenly sensitive, as

© The Complete Work of Charles Darwin Online

well as very strong. But there are opposing feelings, each powerful, in the same individuals; and upon education, habit, and the accidents of moments, depend their development and the ascendancy which either may obtain.

On the following day (29th), Waripoaka visited the Beagle; he was accompanied by a mixed assemblage of men, women, children, pigs, dogs, and fowls, all in one large canoe. His own appearance, a spare figure and tattowed face, ill-dressed in a shabby old suit of European clothes; and the disorderly group in his train, formed an unfavourable outward contrast to the warlike array of a heathen New Zealand chief. Waripoaka seemed to be very intelligent and unassuming; perhaps his manner to white men was too humble. It did not agree with pre-conceived ideas of an independent, haughty New Zealander, to see bows and awkward grimaces (intended for good manners) made by a man whose eye and aspect at once precluded the idea of any approach to refined habits.

During our stay at New Zealand we heard much of the zealous activity of the officers of 'La Favorite'—a French surveying ship—which had lately visited, and made a minute plan of the Bay of Islands. They must have examined every corner and ascended every hill, by the accounts we received; but neither natives nor English settlers seemed able to comprehend the principle which animated Captain La Place and the officers of La Favorite to take so much trouble in a foreign country for no good to themselves alone. I was able to explain this to some of them by instancing my own occupation on the shores of South America, and showing that nations acted upon grander principles than individuals. I was told that M. La Place had likewise examined, with much care, a considerable extent of the eastern sea-coasts of the northern large island (Eaheinomawe, or Yahinomaui).

The term Rangatira, Rangateeda, or Rangatida, has spread among all classes, excepting only the slaves, who are prisoners taken in war or their descendants. Every free Zealander now styles himself rangatira.

At Otaheite there is a very limited number of raatiras, as

© The Complete Work of Charles Darwin Online

the secondary chiefs are there called; and each of those so styled is really a person possessing a considerable estate, and having influence over his neighbours. There can be little doubt that originally the words were alike; or rather there was but one word which expressed either 'freeman' or 'privileged person;' and that the first people of New Zealand were animated by the spirit of equality and apparent liberty, which is seen to prevail in most colonies. Is not this the natural spirit of an association of adventurers, whose objects are similar, whose origin, individually, as to birth and place in the parental society does not differ much—if it does, the difference is unnoticed when not upheld by accidental circumstances—and whose property is very similar?

Democratic, essentially democratic, is the present political state of the New Zealanders; and one cannot help pitying their short-sightedness in exposing themselves to the caprice and dissensions of the many who obtain temporary influence, and to the wars, harsh slavery—for in the heathen districts the life of a slave depends upon the caprice of his master—and dreadful consequences. But this shocking existence, so utterly repugnant to our ideas of happiness, excited and still excites the New Zealander to animal enjoyments, and a sort of pleasure resulting from the gratification of his horrible propensities, which is almost incomprehensible to us, however intelligible it may have been to our earlier ancestors. Do not let us entirely forget the painted savages who opposed Cæsar—or the sacrifices of the Druids!

Some of the Zealanders have amulets and other similar trifles hung around their necks. Small uncouth images, much like the Burmese or Chinese 'josses,' formed out of a very hard stone ('jade'?), are so highly prized by them that they are, generally speaking, very reluctant to part with any. I got one from the daughter of Shunghi, but could not obtain a second, though she had several. I was told that they value them as hereditary relics, as well as supposed charms. Many nations, even at the present day, put faith in relics, some more especially in such as have a word or words upon

© The Complete Work of Charles Darwin Online

them, which it is supposed the evil spirit would not like to see or to hear, and therefore would avoid. Particular figures and shapes also are considered to be disagreeable to the author of evil and his agents.* Surely the New Zealanders must have tried thus to frighten Satan by their hideous images, and by the uncouth, horrible faces which they delight in making. The little images, or amulets of jade, are formed in a similar fashion!

These small idols, or talismans, seem to me to have been cut into the rude likeness of an ape, or a 'ribbed-nosed baboon.'† Yet, excepting the face, they resemble figures of Hindoo gods! What time and pains must have been bestowed in working such hard pieces of stone, unless indeed, a method of acting upon them by fire or chemistry was known; or that when first taken from the ground they were softer.‡

Besides the use which the natives make of the flax for clothing by day, a mat, coarsely woven of its fibres, is tied at night, or while it rains, round the neck, and forms a sort of thatch, under which the owner squats upon his heels, and, at a little distance, looks very like a bee-hive. The rough tuft of coarse and curly black hair, which shows at the top of the conical roof, does not at all injure the resemblance; and in this manner a great number of the natives pass their nights, especially if there is the least chance of a surprise or attack from an enemy. I was told that they sleep as well in this way as if they were lying down, but I doubt it much, and think that only a part of the whole number at any place, keep watch, or remain ready in this manner, while others sleep lying down, though frequently in the open air. A more watchful way of resting could not well be devised.

30th. Unpleasant discussions, on the local discordances I have already mentioned, obliged me to delay sailing for some hours: but at last I escaped, happy to disentangle myself from a maze of disagreeable questions, in which it was not

my proper business to interfere, though unavoidably I had become involved in them. By evening we had gained a good offing, and profited by it in the night, during a strong gale of wind from the eastward, with a lee current, setting to the north-west, about a knot an hour. When we sailed there was every appearance of a gale coming on, but all our necessary operations were completed, and to have stayed an hour longer in that place would have been far worse than passing some hours in a gale of wind at sea.

That the few notices here given of a small part of New Zealand are scanty and quite insufficient for those who seek general information, I am well aware: but the Beagle's stay was very short, and I have made it a principle in this narrative to restrict myself to writing what I or my companions collected on the spot: admitting a few quotations from other authorities, only where they seemed to illustrate or explain a particular subject, without requiring much space. To those interested about this important and rising country, I need hardly mention the volume of evidence taken before the House of Lords, as the latest,—and Cook's account as the earliest, —as well as best sources of information.

I will now endeavour to draw attention to a few of the difficulties against which missionaries have to contend, while anxiously labouring in their holy cause among Polynesian, Australian, and European infidels. It may be supposed that population and occasional intercourse had every where extended, even before the ever-memorable epoch, when the 'Victory' was steered by the daring Magalhaens across an unexplored ocean: but since that time, intercourse with Polynesia has so much increased, that the most interesting islanders—those of Otaheite and the Sandwich Islands—are already more civilized than the natives of some of the Spanish settlements in America.

The New Zealanders are improving; so likewise are the natives of many other islands, which have been visited by missionaries: but those islanders who have been altered only by the visits of whalers, sealers, and purveyors for Chinese epicures, have in no way profited. On the contrary, they have

© The Complete Work of Charles Darwin Online

learned to show less respect to their own ordinances, and have been taught no others in stead. The most abandoned, profligate habits and ideas, have been encouraged by the latter classes of visitors. By their fire-arms, ammunition, and spirituous liquors,—exchanged every where for provisions, and for the gratification of their animal inclinations,—lamentable effects have been caused.

Some men-of-war have allowed an unrestrained intercourse with the natives, receiving them on board, and permitting them to remain, as is still usual among the whalers. Others have not admitted any on board, excepting visitors who were formally received, and did not remain. Such, for example, as the Queens of the Sandwich Isles or Otaheite, with their attendants. But although in that respect men-of-war may have to plead guilty, they are free from any charge of exciting mutual hostility between neighbours; of taking any part in hostilities which were being carried on between rival tribes at the times of their visits; or of acting in any manner which could be likely to lower Europeans in the estimation of the natives, or to excite a feeling of animosity against white men in general.

Stray, or rather escaped convicts, are the chief draw-back. Unrestrained by any religious, or even mere moral principle, those abandoned men have done vast injury, but have frequently fallen victims to the just indignation of the provoked islanders, whose hospitality they abused. Convicts are seldom brave, but usually unprincipled, designing, and cunning; can one then wonder at the natives of some South Sea islands taking an aversion to white people, if their only acquaintance with them has been through such characters, transported to Australia for life, in consequence of felony: who have again, perhaps, been banished from Australia to the doubly penal settlement of 'Norfolk Island;' and have thence escaped to wander through those countries in which they have the strongest hope of avoiding apprehension.

It is little known, and difficult to estimate, how much anarchy, tumult, and destruction of human life have been

© The Complete Work of Charles Darwin Online

prevented by the presence and active exertions of missionaries, during the last twenty years, in which French, Russian, American, and English intercourse with the Pacific, has so much increased. Under the colours of the United States, and of our own country, more than five hundred sail of vessels have been annually employed in the Pacific, during late years. To obtain refreshments and supplies, such as I have mentioned, only those islands on which there are white or native missionaries, are considered safe for single merchant ships. But even while profiting by the influence of the missionaries, and assisted by them in their intercourse with the natives, men who belong to those very ships hesitate not, in many instances (but not in all), to ridicule the means by which the missionary has gained his influence—to encourage immorality, and the use of ardent spirits, and to seek for faults in a system, as well as in the behaviour of individuals according to that system, because it has a tendency to limit the indulgence and expose the impropriety of their own unrestrained misconduct. If the opponents of missionaries could be prejudiced so far as to allow no other good character to have been earned by those hardworking men, they can never deny them that of peace-makers.

Many sailors have left their ships, and settled for life, upon various islands. Though generally immoral, some of these men have established a character among the islanders, so very different from that of the convicts, that persons who understand the native descriptions are seldom deceived in their estimation of a man who, they hear, has recently settled in any place.

Some of these seamen have astonished the New Zealanders, and even men of the Feejee Islands, by hardy courage in warlike enterprises. One, known by the name of Charles, has been already mentioned as having distinguished himself so much by his activity and daring in wars with other islanders, that he was treated as a chief of very high rank, and allowed to have a hundred wives: while the greatest chieftains had from fifty to a hundred and fifty, according to their rank. There are now said to be upon the southern large island or

© The Complete Work of Charles Darwin Online

middle island of New Zealand, settlements supposed to be formed by some two or three hundred abandoned characters, European, Australian, and American. These outcasts, of whom a proportion are convicts, have established a sort of system amongst themselves, in order to regulate their intercourse with the natives. I was told that they were living with native women, and, at that time, cultivated the soil; but, what will be the consequence of such a colony, if left to their own devices in that distant corner of the world? Yet, again, where could outcasts, whose state of exile (if they may be supposed to have good feelings) would be as insupportable to themselves as pitiable in the minds of others—where could such unhappy wretches be placed more appropriately than at the Antipodes? They should, however, be frequently watched, to check any approach to piratical preparations, as well as to give timely notice of such an intention.

Settlements of a different character are elsewhere forming, and the establishments of individuals are increasing in North New Zealand, at Otaheite, and in the Sandwich Islands. Between these establishments, small vessels are always in motion: and not trifling is the trade in oil (cocoa-nut oil), arrow-root, and sugar, between Otaheite and Sydney: in flax, spars, potatoes, and whale-oil, between New Zealand and Sydney; in sandal-wood, bicho-do-mar, nut-oil, pearl-oyster-shells, and curiosities (such as native arms, implements, and clothing) between other islands, and Australia, Tasmania,* the East-Indies, China, and South America.

Thus surrounded by those who are engaged in a commerce annually increasing; unavoidably involved in local dissensions; referred to on all occasions as interpreters or as peace-makers; and I may say, as the consular agents of white men of all nations;† it argues very favourably for the missionaries that they have as yet upheld the character of their sacred office, though sneered at by nominal friends, censured by enemies, and always struggling against opposition. I have said that at the Sandwich Islands there is a consul; on those islands

* Van Diemen's Land. † At Otaheite and Owyhee excepted.

© The Complete Work of Charles Darwin Online

there are missionaries from the United States, but none from England. At Otaheite, also, there is now consular authority. At New Zealand there are two officers, holding the indefinite station of 'Resident.' One of these officers had a salary, but denied having any authority to act as a consular agent, or even as a magistrate. The other resident (who lived at Hokianga) was not in the receipt of any salary; his appointment having been given for the reasons stated in a letter from the Colonial Secretary at Sydney, dated 29th June 1835, of which a copy is inserted in the Appendix (No. 37), accompanied by extracts from an excellent letter addressed to Mr. Busby. (No. 38.)

Upon reading these statements, it will not be difficult to form an idea of some of the embarrassments of a secular nature, which perplex the missionaries, after having overcome all the primary dangers and difficulties of establishing themselves in savage—even cannibal countries. Although they are now able to assist their own countrymen, who have eagerly profited by their exertions,—settling in every direction upon those very lands to which access was obtained by their hardy, daring enthusiasm, and is preserved by the united efforts of the supporters of missionary societies, assisting and encouraging individual exertion,—their own strength is failing!

Embarrassments of many kinds are arising; one, jealousy of that influence which has enabled even those who are jealous to approach the spot upon which they now stand, and oppose the missionary as he exerts himself to suppress licentious habits and the use of ardent spirits. While assisting their early settlement, the missionaries were the best friends of those adventurers who sought a livelihood among the islands of the Pacific—in New Zealand especially. But when once established, ingratitude and utter want of reflection became too prevalent among the worst sort of settlers, whose only occupations were those of publicans and especial sinners. The few respectable settlers—men of character and property—such as Mr. Clendon and Mr. Mair at New Zealand, Mr. Bicknell and Mr. Henry (junior) at Otaheite, have acted—I rejoice to say—in the most honourable and praiseworthy man-

© The Complete Work of Charles Darwin Online

ner. Their conduct deserves unanimous applause. To many it appears, that the respectable support and steady countenance of these upholders of the real character of Britons have, in a quiet, unpretending manner, much assisted the progress of the missionaries, and the spread of incipient civilization which must accompany the sacred truths of the gospel. If a few such men had not appeared upon that side of the world, how low might the character of Englishmen have fallen there. A few isolated missionaries would have been always opposed by numerous reprobates.

By such men as those who are jealous of the influence of the missionaries, an outcry has been raised against their "attempts to monopolize the lands." Said those men, "Why should a missionary be allowed to purchase so much land as to prevent people who come afterwards from obtaining an eligible piece of ground near a frequented port?" "Why should Mr. —— be allowed to try to prevent Waripoaka and his tribe from selling me that piece of ground, because he thinks that I shall sell spirits, or build a public-house? Have not the missionaries already monopolized the best land in the finest situations?"

In answer to this, lest the reader should think that the missionaries have been covetous, and have taken undue advantage of their influence (gained, it ought to be remembered, at the imminent risk of life, and when no ordinary men dared to stop in the land), I will explain — that a large extent of land in New Zealand was long ago purchased by the missionaries, on behalf of the Church Missionary Society: and that many of the outcriers supposed that land to be the private property of individuals. And I will ask for attention to the too little considered fact, that these unjustly blamed individuals have (by their engagements) divided that tie which once held them to a country whose inestimable value can only be fully felt by those who have long been wanderers in other lands. New Zealand, or Otaheite, or a less known island, is now their home; and there are around them a host of little children whose smiling healthy looks would interest even strangers in their behalf,

© The Complete Work of Charles Darwin Online

whose country is that adopted by their parents, and to whom every good father would anxiously desire to leave a sufficient maintenance, such as his own honourable exertions could procure. Shall the missionaries be debarred from providing in a proper manner for the future welfare of their own children? If a missionary and a more recent settler are each in treaty for a particular piece of ground, and the former obtains it upon easier terms than the latter, is it not a natural consequence of the good-will entertained towards him by the natives; many of whom understand and appreciate his motives, and are themselves very fond of the little white children, considering them as belonging to their country? The missionaries have bought land, as opportunities offered; and they, of course, from their residence upon the spot, have had better opportunities than occasional visitors or late settlers.*

If anathemas, indulgences, or excommunications were in vogue among British missionaries, one might have a suspicion of undue influence; but as such engines of spiritual, or indeed temporal power, have not, as yet, travelled out of the coral circle of the Gambier islands, I think we need not impugn the characters of highly religious men, by puzzling ourselves to learn how protestant ministers—unassisted by artifice, supported by no temporal power, except that of public opinion, excited by their own good conduct — could have obtained so great an influence over tribes of New Zealanders, as to induce them to part with their paternal lands upon terms which the natives thought unfavourable, or less advantageous than those offered by other persons.

In opposition to such an idea as that of their eagerly grasping at territory, and using undue means to procure it, I know with certainty, that the Rev. Henry Williams, and his brother William, exerted all their real influence—that of advice—in pointing out the consequences which would result to

* After a purchase of land has been made by a settler (or immigrant, as the colonists say), he is considered to be under the protection of the chief of the tribe from whom the purchase was effected.

© The Complete Work of Charles Darwin Online

some tribes who were inclined to part hastily with extensive tracts of valuable pine forests. The real value of those trees was explained to the natives; and they were shown distinctly how a careful management of such stores of spars would ensure a future property, and sufficient maintenance for the native children who would otherwise be deprived of their birthright. Did this show a desire to monopolize?

But I must hasten to a conclusion of the subject. When authorized agents of European or American governments assume active functions in New Zealand (where at present they are little more than cyphers), I hope they will have the good sense to ask for advice from the missionaries; who, no doubt, will duly remember, that, however they may have been called upon to act during emergencies, the duties of their office are, or ought to be, separated as much as possible from affairs of a secular nature. Neither in politics, nor in any kind of hostilities or dissensions, ought they to take a part, excepting as peace-makers, if an officer or authorized executive agent of government is within their reach.

Among many omissions which I am obliged to make in the subsequent chapter, are the following:—On the 7th of January, while more than two hundred miles from any known land, we saw a boatswain-bird and two white tern. To those who are interested about the distances to which birds fly from land, this remark may be worth notice: as some persons say that tern never fly far.

Mr. Chaffers obtained the jaw of a huge blue shark, at Hobart Town, which had been killed by the boat's crew of Mr. James Kelly's whaling vessel. The extreme length of the monster was thirty-seven feet. Its jaw is now in the United Service Museum.

About Van Diemen's Land, the barometer ranged higher than I had witnessed in the southern hemisphere.

CHAPTER XXVI.

North Cape of New Zealand — Superstitions — Cook's great Lizard — Traditions — Currents — Thermometer — Sydney — Dr. Darwin — Drought — Aqueduct — Position — Disadvantages — Ill-acquired wealth of Convicts, or Emancipists — Hobart Town — Advantages of Van Diemen's Land — King George Sound — Natives — Dance — Keeling Islands — Tides — Soundings — Coral formations — Malays — Fish — Weather — Mauritius — Cape of Good Hope — St. Helena — Ascension — Bahia — Pernambuco — Cape Verde Islands — Azores — Arrive in England.

On the last day of this year (1835) we passed the north cape of New Zealand, and steered for Port Jackson. It has been said that the New Zealanders entertain vague ideas about the spirits of their dead hovering near this north cape. I had no opportunity of inquiring into this superstition, but as other authorities besides Cook mention it, no doubt there is some such belief among those who have not acquired different notions from foreigners To my mind it is interesting in two points of view; one, as showing their belief in a future state of existence; and the other, as indicating the quarter whence New Zealand was first peopled; for it appears to be an impression common to many savage nations, that their souls should go to the land of their ancestors. This is particularly remarkable among the South American aborigines. It is not easy to imagine any motive for the New Zealanders supposing that spirits hover about the North Cape, in preference to any other promontory of New Zealand, unless in connexion with the idea that from the point nearest to the country whence those people formerly migrated, the souls of the deceased would, after a time perhaps, depart to their permanent abode.

In taking leave of this interesting country I will refer to Cook once more, for a curious notice, given in his third voyage, respecting great lizards in New Zealand, which have not, so far as I am aware, been lately described, or even met with. 'Taweiharooa' gave an account of snakes and lizards of an enormous size: "he describes the latter as being eight feet in length,

© The Complete Work of Charles Darwin Online

and as big round as a man's body. He said that they sometimes seize and devour men; that they burrow in the ground; and that they are killed by making fires at the mouths of the holes. We could not be mistaken as to the animal; for, with his own hand, he drew a very good representation of a lizard on a piece of paper; as also of a snake, in order to show what he meant."—(Cook's third Voyage, chap. VII.) Perhaps this huge kind of lizard has become extinct; but it is possible that it yet exists on the southern (or middle) island. In its burrowing we are reminded of the great lizard, or iguana, of the Galapagos Islands; but the assertion that it sometimes seizes men seems to refer to an alligator, or crocodile. Cook heard of it shortly after leaving Queen Charlotte Sound, from a native of the southern large island.* If such a reptile ever existed upon the northern island it must have been exterminated by the earliest aboriginal settlers, as they have now no tradition of any animals except dogs, pigs, rats, mice, and small lizards. Pigs and dogs, say the natives, were brought from the north, in canoes.

On New Year's day, while in sight of the islets called Three Kings, we passed through several tide 'races,' one of which was rather 'heavy,' and would have been impassable for a boat. These races moved towards the north while we could trace their progress. The temperature of the water fell six degrees after passing through the principal one. Next day, at noon, we found that during the past twenty-four hours we had been set as many miles southward (S.S.E.), and hence I am inclined to infer that we were influenced by regular tide-streams, rather than by currents setting always in one direction. To the succeeding day at noon (3d) we were set only seven miles, by the water, and that due east. Afterwards, in our passage to Port Jackson, we had alternately northerly and south-easterly currents of about ten miles a day, and it was easy to tell which current we were in, by the temperature of the sea:—while the stream set from the north, the water thermometer showed about 72°; but when the current

* At New Zealand the southern large island is usually called the Middle Island.

© The Complete Work of Charles Darwin Online

was running from the southward, the temperature of the ocean, a foot below, as well as at, the surface,* was only 67°. I ought to have remarked elsewhere, if I have not already done so, that the thermometer may be used at sea to detect and trace currents; but little, if any, confidence can be placed in its indications as a guide to the approach of land. Icebergs may indeed affect it, but they will affect the temperature of the air probably sooner than that of the ocean.

Near midnight, on the 11th, we saw the red, revolving light of Sydney Light-house, and next day entered Port Jackson, and anchored in Sydney Cove. Much as I had heard of the progress and importance of this place, my astonishment was indeed great, when I saw a well-built city covering the country near the port. Not many days previously I had been reading the account of Governor Phillip's voyage to Botany Bay in 1787-8, and little did I think that, in forty-eight years from the first discovery of Port Jackson, a city, upon a large scale, could have arisen out of a wilderness so near our antipodes. In the account just mentioned it is stated that "from a piece of clay imported from Sydney Cove, Mr. Wedgwood caused a medallion to be modelled, representing Hope, encouraging Art and Labour, under the influence of Peace, to pursue the means of giving security and happiness to the infant settlement. The following lines, in allusion to this medallion, were written by Dr. Darwin."

"Where Sydney Cove her lucid bosom swells,
Courts her young navies and the storm repels,
High on a rock, amid the troubled air,
Hope stood sublime, and wav'd her golden hair;
Calm'd with her rosy smile the tossing deep,
And with sweet accents charm'd the winds to sleep;
To each wild plain, she stretch'd her snowy hand,
High-waving wood, and sea-encircled strand.
'Hear me,' she cried, 'ye rising realms! record
Time's opening scenes, and Truth's unerring word.—
There shall broad streets their stately walls extend,
The circus widen, and the crescent bend;

* For no difference could be detected, under ordinary circumstances.

© The Complete Work of Charles Darwin Online

There ray'd from cities o'er the cultur'd land,
Shall bright canals, and solid roads expand.—
There the proud arch, Colossus-like, bestride
Yon glittering streams, and bound the chasing tide;
Embellish'd villas crown the landscape scene,
Farms wave with gold, and orchards blush between.—
There shall tall spires, and dome-capt towers ascend,
And piers and quays their massy structures blend;
While with each breeze approaching vessels glide,
And northern treasures dance on every tide!"
Here ceased the nymph—tumultuous echoes roar,
And Joy's loud voice was heard from shore to shore—
Her graceful steps descending press'd the plain;
And Peace, and Art, and Labour, join'd her train."

When I was at Sydney in 1836, all that was foretold in this allegory had come to pass, with one exception only, that of canals. It was always a country comparatively dry; and unfortunately the more wood is cleared away, the drier both climate and soil become, therefore it is unlikely that canals should ever be made there. This want of fresh water is the only drawback to the future prosperity of this mushroom city; which is now dependent upon a supply brought through iron pipes from a distance of several leagues. Mr. Busby, father of the resident at New Zealand, was the projector and executor of this aqueduct, but,—like many other really valuable things,—his useful work as ably planned as it was perseveringly carried on against uncommon difficulties, is but little appreciated, even by those who daily drink the pure water which it supplies.

It is difficult to believe that Sydney will continue to flourish in proportion to its rise. It has sprung into existence too suddenly. Convicts have forced its growth, even as a hot-bed forces plants, and premature decay may be expected from such early maturity. Other rising colonies have advantages in point of situation and climate, which the country about Sydney does not possess; and if our government establishment should be withdrawn, from that day the decline of the city would commence, because its natural advantages are not sufficient to enable it to compete with other places in those regions,

© The Complete Work of Charles Darwin Online

excepting while fostered by the presence of regularly paid government officers, troops, and a large convict establishment.

There must be great difficulty in bringing up a family well in that country, in consequence of the demoralizing influence of convict servants, to which almost all children must be more or less exposed. Besides, literature is at a low ebb: most people are anxious about active farming, or commercial pursuits, which leave little leisure for reflection, or for reading more than those fritterers of the mind—daily newspapers and ephemeral trash. It was quite remarkable to see how few booksellers' shops there were in Sydney, and what a low class of books — with some exceptions — was to be found in them. These few exceptions were the works usually called 'standard,' which some persons who buy books, for show as furniture, rather than for real use, think it necessary to purchase. Another evil in the social system of Sydney and its vicinity, is the rancorous feeling which exists between the descendants of free settlers and the children of convicts. Fatal, indeed, would it be to the former, if the arm of power were removed; for their high principles and good feelings would be no match for the wiles and atrocities of such abandoned outcasts as are there congregrated, and almost rejoice in their iniquity. Money is gained by such people by any and every means, save those of honest industry. By selling spirits, frequently drugged—by theft—by receiving and selling stolen goods—by the wages of iniquity—and by exorbitant usury—fortunes have been amassed there in a few years which would make an honest man's hair stand on end. But do such men enjoy their wealth? Does it benefit them or their children? No. Their life is a miserable scene of anxiety, care, fear, and generally penuriousness; they die without a friend and without hope.

The Beagle sailed from Sydney on the 30th, and anchored off Hobart Town (or Hobarton) on the 5th of February. The change of scene was as striking as a view of Gibraltar or Madeira after leaving the Downs. Comparatively speaking, near Sydney all was light-coloured and level; while in Van Diemen's Land we almost thought ourselves in another Tierra

© The Complete Work of Charles Darwin Online

del Fuego. But this was only a first impression, on a blustering wet day. Fields of ripe corn, dotted, as it were, about the hilly woodlands, told us that the climate must generally be favourable; and the number of red brick cottages, thickly scattered about, though apparently at random, proved an extent of population incompatible with an unproductive place.

During a few days' stay in Sullivan Cove, the chief anchorage, we had opportunities of going to some distance into the country, and seeing things which led me to think that there is a more solid foundation for future prosperity in Van Diemen's Land than can be found near Sydney. Natural advantages are greater; and likely to increase as the country is cleared and inhabited—because rain is now almost too plentiful, though corn ripens well and is of excellent quality. As a convict colony, it of course partakes of the evils I have mentioned; but it does so in a far less degree, partly because the convicts sent there were of a less profligate and more reclaimable class than those landed at Sydney, and partly because an excellent local government restrained the licentious, and encouraged the moral to a far greater extent than was, or perhaps could be effected among the more numerous and dispersed population of Sydney and its environs.

On the 17th, we sailed out of the picturesque Derwent, an arm of the sea extending inland many miles beyond Hobart Town, and thence worked our way southward round the Land of Van Diemen. We then steered westward, or as much so as the contrary winds would admit, until we made the land off King George Sound on the 6th of March; and a few hours afterwards moored in the principal anchorage, called Princess Royal Harbour; a wide but shallow place, with a very narrow entrance. The country round King George Sound has a dull, uniform aspect; there are no mountains or rivers;* few trees are visible; white, sandy patches; scrubby bushes; bare masses of granite; and a slightly undulating outline meet and disappoint the eye of a stranger.

* Unless a few brackish, indeed salt-water, brooks can be termed rivers.

© The Complete Work of Charles Darwin Online

A few straggling houses, ill-placed in an exposed, cheerless situation, were seen by us as we entered the harbour; and had inclination been our guide, instead of duty, I certainly should have felt much disposed to 'put the helm up,' and make all sail away from such an uninviting place.

Next day, however, we found that appearances were worse than the reality; for behind a hill, which separates the harbour from the sound, a thick wood was discovered, where there were many trees of considerable size; and in the midst of this wood I found Sir Richard Spencer's house, much resembling a small but comfortable farm-house in England. This sort of isolated residence has a charm for some minds; but the loss of society, the numerous privations, and the vastly retrograde step necessarily taken in civilized existence by emigrating to perfectly new countries, are I think stronger objections to the plan than usually occur to persons who have not seen its consequences in actual operation.

At this time there were about thirty houses, or cottages, in the neighbourhood of the sound and harbour; some had small gardens; but, generally speaking, there was no appearance of agriculture, excepting immediately around Sir Richard's house, where a few fields had been cleared and cultivated in the midst of the wood.

There is an extraordinary degree of local magnetic attraction about this place. We could not ascertain the amount of variation with any degree of accuracy until our compasses were placed upon a sandy beach of considerable extent, near the sea. Wherever there was stone (a kind of granite) near the instruments, they were so much affected as to vary many degrees from the truth, and quite irregularly: those on board were not influenced, at least not more than a degree. We were also perplexed by the irregular and peculiar tides; but as they are mentioned elsewhere, I will refrain from farther remark on them here.

We had a good opportunity of seeing several of the aborigines; for not only were there unusual numbers of neighbouring natives then about the settlement, but a strange tribe,

© The Complete Work of Charles Darwin Online

called 'Cocotu,' had lately arrived from a distance, and as the residents wished to conciliate them, a 'corobbery' was proposed, and Mr. Darwin ensured the compliance of all the savages by providing an immense mess of boiled rice, with sugar, for their entertainment.

About two hours after dark the affair began. Nearly all the settlers, and their visitors, had assembled on a level place just outside the village, while the native men belonging to both tribes were painting, or rather daubing and spotting their soot-coloured bodies with a white pigment, as they clustered round blazing fires. When all was ready —the fires burning brightly—the gloom at a little distance intense, by contrast, and the spectators collected together —a heavy tramp shook the ground, and a hundred prancing demon-like figures emerged from the darkness, brandishing their weapons, stamping together in exact accordance, and making hoarse guttural sounds at each exertion. It was a fiendish sight, almost too disagreeable to be interesting. What pains savage man takes—in all parts of the world where he is found—to degrade his nature; that beautiful combination which is capable of so much intelligence and noble exertion when civilized and educated. While watching the vagaries of these performers, I could not but think of our imprudence in putting ourselves so completely into their power: about thirty unarmed men being intermixed with a hundred armed natives. The dancers were all men; a short kangaroo-skin cloak was thrown about their hips, and white feathers were stuck round their heads: many were not painted, but those who were had similar figures on their breasts; some a cross, others something like a heart. Many had spears, and all had the 'throwing-stick'; and a kind of hatchet,* in a girdle round the waist. Much of the dancing was monotonous enough, after the first appearance, reminding me of persons working in a treadmill; but their imitation of snakes, and

* This hatchet is made of two pieces of stone, joined together by a lump of gum, almost as hard as the stone: it is used for notching trees, that the men may climb after opossums.

© The Complete Work of Charles Darwin Online

kangaroos, in a kind of hunting dance, was exceedingly good and interesting. The whole exhibition lasted more than an hour, during most of which time upwards of a hundred savages were exerting themselves in jumping and stamping as if their lives depended on their energetic movements. There was a boy who appeared to be idiotic, or afflicted with a kind of fit; but the man who was holding him seemed to be quite unconcerned about his convulsive efforts, saying, "by and bye he would be a doctor" (as I was told by a resident who understood the language), which reminded me of what Falkner says of the Patagonians.* After the corobbery the natives collected round the house where the feast was preparing; and it will not be easy to forget the screams of delight that burst from old and young as they looked in at the door and saw the tub in which their rice was smoking. Before the food was distributed they were told to sit down, which they immediately did, in a circle round the house. They separated, of their own accord, into families, each little party lighting a small fire before them. Their behaviour, and patience, were very remarkable and pleasing. One family had a native dog, which in size, colour, and shape, was like a fox, excepting that the nose was not quite so sharp, nor the tail so bushy.

Most of the aborigines had rather good countenances, and well-formed heads, as compared with those about Sydney, or in Van Diemen's land. The lathy thinness of their persons, which seemed totally destitute of fat, and almost without flesh, is very remarkable. I have since seen some drawings of South African aborigines, executed under the critical eye of Doctor Andrew Smith, by the correct hand of Mr. Charles Bell, which are so like the natives who live near King George Sound in colour, as well as countenance, and extraordinary shape, that they might be taken for full-length portraits of the latter instead of Africans.

Many of these natives have features smaller and less marked than are usual among savages; but their foreheads are higher and more full: they are not tall, few exceeding five feet eight

* Page 163.

© The Complete Work of Charles Darwin Online

inches in height: and the women are wretched objects. Some of the men had pieces of bone stuck through the cartilage of the nose, which, I heard, was to prevent their being killed by another tribe, who were seeking to revenge the death of one of their own party. I was told also, that when any death occurs in one tribe, the first individual of another that is encountered is sacrificed by the bereaved party, if strong enough; but I suspect my informant confused revenge for manslaughter with the strange story—that for every death in one tribe, however caused, a life must be taken from another. Should it be true, however, the scarcity of aboriginal population would have an explanation in addition to those which various writers have given. These natives bury their dead in a short grave; the body being laid on its side, with the knees drawn up to the chin.

During our stay at this place we caught plenty of fish, of twenty different kinds, with a seine; yet with such an abundant supply close at hand, the settlers were living principally on salt provisions.

Before quitting King George Sound I must add my slight testimony to the skill and accuracy with which Flinders laid down and described those parts of New Holland and Van Diemen's Land that I have seen. His accounts also of wind, weather, climate, currents, and tides, are excellent; and there are other points of information in his large work, useful to many, but especially to seamen, which would be well worth separating from the technicalities among which they are almost lost in the present cumbersome volumes.

March 13th. We sailed, and advanced towards Cape Leuwin, but it was the 18th before our little ship was sufficiently far westward of that promontory to steer for my next object, the Keeling Islands.

From the 27th to the 30th we had a severe gale of wind, when near the situation of those remote isles, and on the 31st were in much doubt whether they lay eastward or to the west of us. There was most reason to induce me to steer eastward—indeed I was about to give orders to that effect just as the sun was setting, (no land being seen from the mast-

© The Complete Work of Charles Darwin Online

head, though the horizon was clear)—when a number of gannets flew past the ship towards the west. We steered directly after them, and early next morning (after making but little way during a fine night) saw the Keelings right ahead, about sixteen miles distant.

A long but broken line of cocoa-palm trees, and a heavy surf breaking upon a low white beach, nowhere rising many feet above the foaming water, was all we could discern till within five miles of the larger Keeling, (there are two distinct groups) and then we made out a number of low islets, nowhere more than thirty feet above the sea, covered with palm-trees, and encircling a large shallow lagoon.

We picked our way into Port Refuge (the only harbour), passing cautiously between patches of coral rock, clearly visible to an eye at the mast-head, and anchored in a safe, though not the best berth. An Englishman (Mr. Leisk) came on board, and, guided by him, we moved into a small but secure cove close to Direction Island.

Many reasons had induced me to select this group of coral islets for such an examination as our time and means would admit of; and, as the tides were to be an object of especial attention in a spot so favourably situated for observing them, a tide-guage was immediately placed. Its construction was then new, and, being found to answer, I will describe it briefly. Two poles were fixed upright, one on shore (above high water mark, and sheltered from wind), the other in the sea beyond the surf at low water. A block was fastened to the top of each pole, and a piece of well-stretched log-line 'rove' through them.* One end of the line was attached to a board that floated on the water; the other suspended a leaden weight, which traversed up and down the pole, on shore, as the float fell or rose with the tide. Simple as this contrivance was, and useful as we should have found it in many places where the surf or swell made it difficult to measure tides at night, without using a boat, I never thought of it till after we left King George Sound.

* A very small metal chain would be better, because a line, however stretched, will shrink after being wetted by rain, and give out again as it dries.

© The Complete Work of Charles Darwin Online

Until the 12th every one was actively occupied; our boats were sent in all directions, though there was so much wind almost each day as materially to impede surveying. Soundings on the seaward sides of the islands could seldom be obtained; but two moderate days were eagerly taken advantage of to go round the whole group in a boat, and get the few deep soundings which are given in the plan.* The two principal islands (considering the whole southern group as one island,) lie north and south of each other, fifteen miles apart; and as soundings were obtained two miles north of the large island, it may be inferred, I think, that the sea is not so deep between the two as it is in other directions. Only a mile from the southern extreme of the South Keeling, I could get no bottom with more than a thousand fathoms of line.

The southern cluster of islets encircle a shallow lagoon, of an oval form, about nine miles long, and six wide. The islets are mere skeletons—little better than coral reefs, on which broken coral and dust have been driven by sea and wind till enough has been accumulated to afford place and nourishment for thousands of cocoa-palms. The outer edges of the islands are considerably higher than the inner, but nowhere exceed about thirty feet above the mean level of the sea. The lagoon is shallow, almost filled with branching corals and coral sand. The small northern island is about a mile in diameter; a strip of low coral land, almost surrounding a small lagoon, and thickly covered with cocoa-nut trees.

These lonely islands (also called Cocos,) were discovered in 1608-9 by Captain William Keeling, who was in the East India Company's service, and held a commission from King James I.† Little or no notice was taken of them from that

* This plan of the Keeling Islands will be found in the third (Mr. Darwin's) volume.

† Of these facts I was credibly informed, on the authority of the late Captain Horsburgh; and presumptive evidence of their reality is afforded by the following extract from the work of a well-known historian.

Extract from a Summary of Universal History, translated from the French of M. Anquetil, First Edition, page 50. London, 1800—

In the reign of Queen Elizabeth, a Venetian galley, deeply laden,

© The Complete Work of Charles Darwin Online

time till 1823, when one Alexander Hare, a British subject, established himself and a small party of Malays, upon the

was driven on shore at the Isle of Wight. The sight of the riches it contained excited a desire of attempting to open a trade with Turkey, through which the merchandize of India was transported. The advantages arising from this Turkish trade to the Eastern merchants shewed that it might be rendered still more lucrative if it were carried on by a direct route. In order that no measures of prudence which seemed likely to ensure success to this grand enterprise might be omitted, the queen sent to explore the two routes already opened, that of the Cape of Good Hope, by Captain Stephens, in 1582, and that of the Strait of Magellan, in 1587. From the reports which they made, it was conceived impossible for England to appropriate to itself, by means of single ships, a part of that commerce, to the prejudice of two nations, jealous, and well established; and, that, while it employed all the exertions of industry, it would be necessary also to show a respectable force. These considerations, highly judicious, gave rise to the East India Company, which sent out its first adventure with a capital of £74,000, and four ships equipped from that sum. In 1601 the company was established under the auspices of the state, which granted it a charter of protection for a time limited.

Lancaster, who commanded this squadron, behaved like a private merchant, entered into a treaty of commerce with the King of Achen, and found means to establish a small factory, but not without experiencing some marks of displeasure from the Portuguese. He took on board a considerable quantity of pepper and other spices. His successful return encouraged the company to send out three ships under the command of Henry Middleton. The latter, however, began to assume a higher tone than that of a plain merchant. He found the Dutch and Portuguese engaged in war; not on their own account, as appeared, but as auxiliaries, the one of the King of Ternate, and the other of the King of Tidore. It seemed most advantageous to Middleton at that period to espouse the part of the Portuguese. The Dutch were incensed, and threw impediments in his way, which, however, did not prevent him from returning with a very rich cargo; but the company sent out another squadron under Edward Michael Bourne, who assumed with the Dutch that air of superiority which his force authorized, and threatened open hostilities in case they interrupted the English commerce. To support these threats, William Keeling arrived, in 1608, with a body of regular troops. The Dutch made no resistance, and even applied to the English to defend them against the inhabitants of Banda; but after this service they behaved with duplicity to their benefactors, and fettered their commerce: yet Keeling found means to return with a very rich cargo, and, what is remarkable, without the loss of a single man.

© The Complete Work of Charles Darwin Online

Southern Keeling Island, which he thought a favourable place for commerce, and for maintaining a seraglio of Malay women, whom he confined to one island,—almost to one house.

In 1826, or within a year of that time, Mr. J. C. Ross, some time master of a merchant ship, took up his abode on the south-eastern islet of the group; and in a very short time Hare's Malay slaves, aggrieved by his harsh treatment of them, especially by his taking away the women, and shutting them up on an island which the Malay men might not approach, deserted in a body, and claimed protection from Mr. Ross. Hare then left the Keelings, and about a year afterwards was arrested in his lawless career by death, while establishing another harem at Batavia.

From that time Mr. Ross and the Malays lived peaceably, collecting cocoa-nut oil, turtle, tortoise-shell, and bicho do mar; and occasionally sailing to the Mauritius, Singapore, or Batavia, to dispose of them, and buy necessaries with their produce. Another Englishman, Mr. C. Leisk, who had served as mate of Mr. Ross's ship, lived with him, and they both had wives (English) and children, the whole party residing together in a large house of Malay build—just such a structure as one sees represented upon old japanned work. At the time of our visit Mr. Ross was absent on one of their trading excursions, and his deputy, Leisk, was left in charge of everything.

By some strange misconception, not intentional act of injustice, Mr. Ross had refused to give Hare's slaves their freedom, for fear that the executors of that man should demand their value from him; but he paid them each two rupees a week, in goods (at his own valuation), provided that they worked for him, both men and women, as he thought proper. Mr. Leisk told me this, and said that "many of the Malays were very discontented, and wanted to leave the island." "No wonder," thought I, "for they are still slaves, and only less ill used than they were by the man who purchased them."

These Malays were allowed to rear poultry, which they sometimes sold to shipping. They were also allowed to have the produce of a certain number of cocoa-nut trees, and might catch fish and turtle for their own use; but the sale of

© The Complete Work of Charles Darwin Online

turtle to shipping, when they touched there, and the immense crops of cocoa-nuts which are produced annually on all the islets of the group were monopolized by Mr. Ross for his sole advantage. One daily task imposed upon the Malay women was to "husk" a hundred nuts, collected for them by the men, who extract a gallon of oil from every ten.

Another kind of oil, said to be very good, is derived from the fat tail of a large land-crab, which feeds on cocoa-nuts. About a pint and a half may be obtained from one crab. The manner in which these creatures—nearly the size of a large cray-fish—tap the nuts in order to get at their contents is curious. Numbers of windfall nuts, in a comparatively soft state, are always to be found lying about under the trees: a crab seizes one of these, and pegs away at the eyes (each nut has three eyes) with one of its claws, that is long and sharp, purposely, it would seem, until it opens a hole, through which the crab extracts the juice, and some of the solid part.

The manner of ascending tall palm-trees is similar to that described at Otaheite, and requires strength as well as agility: both which are also shown by these Malays in their chases after turtle among the shallows and coral 'thickets' of the lagoon, where they abound. A party of men go in a light boat and look for a fine turtle in some shallow place. Directly one is seen, they give chase in the boat, endeavouring to keep it in a shallow, and tolerably clear place, till it begins to be tired by its exertions to escape; then, watching a favourable moment, a man jumps out of the boat and seizes the turtle. Away it darts, with the man on its back grasping its neck until he can get an opportunity, by touching ground with his feet, to turn it over, and secure his prize. Only the more active men can succeed well in this sort of fishing.

Other unusual things were seen by us at this place, one or two of which I will mention. There are fish that live by feeding upon small branches of the coral, which grows in such profusion in the lagoon. One species of these fish is about two feet and a half long, of a beautiful green colour about the head and tail, with a hump on its head, and a bony kind of mouth,

© The Complete Work of Charles Darwin Online

almost like that of a turtle, within which are two rows of saw-like teeth.—Mr. Stokes saw a dog, (bred on the island), catch three such fish in the course of a few hours by chasing them in shallow water, springing after them, almost as a kangaroo springs on land. Sometimes one would take shelter under a rock, when the dog would drive it out with his paw, and seize it with his mouth as it bolted.

Among the great variety of corals forming the walls around the immediately visible basement, and the under-water forests of the Keeling islands, there is more difference than between a lily of the valley and a gnarled oak. Some are fragile and delicate, of various colours, and just like vegetables to the eye, others are of a solid description, like petrified tropical plants; but all these grow within the outer reef, and chiefly in the lagoons.*

The wall, or outer reef, about which so much has been said and thought, by able men, without their having arrived at any definite conclusion, is solid and rock-like, with a smooth surface; and where the surf is most violent, there the coral is fullest of animated matter. I was anxious to ascertain if possible, to what depth the living coral extended, but my efforts were almost in vain, on account of a surf always violent, and because the outer wall is so solid that I could not detach pieces from it lower down than five fathoms. Small anchors, hooks, grappling irons, and chains were all tried—and one after another broken by the swell almost as soon as we 'hove a strain' upon them with a 'purchase' in our largest boats. Judging however, from impressions made upon a large lead, the end of which was widened, and covered with tallow hardened with lime, and from such small fragments as we could raise, I concluded that the coral was not alive at a depth exceeding seven fathoms below low water. But this subject has been, or will be, fully discussed by Mr. Darwin, therefore I need say no more.

* One kind of coral, while alive, stings human flesh painfully when touched by it. Another kind is so hard that it gives sparks when struck by steel.

© The Complete Work of Charles Darwin Online

As if in speaking of these singular, though so small islands, —where crabs eat cocoa-nuts, fish eat coral, dogs catch fish, men ride on turtle, and shells are dangerous man-traps,*— any thing more were necessary to ensure the voyager's being treated like the old woman's son who talked to her about flying-fish,—it must yet be said that the greater part of the sea-fowl roost on branches, and that many rats make their nests at the top of high palm-trees.

Except sea-fowl and the domestic creatures† which have accompanied man to the Keelings, there is no bird or animal; but a kind of land-rail, which is numerous. Besides the palm there are upon the largest islets other trees, particularly a kind of teak, and some less valuable wood, from which a vessel was built.

Fresh water is not scarce on the larger islets of the group, but it is only to be got by digging wells in the coral foundation, covered as it is by vegetation. In these wells, about six feet deep, the water rises and falls as the tide of the ocean flows and ebbs; which I believe to be the case at most other coral islands where there is fresh water. It appears that the fresh water of heavy rains is held in the loose soil, (a mixture of coral, sand, and decayed vegetable substances,) and does not mix with the salt water which surrounds it, except at the edges of the land. The flowing tide pushes on every side, the mixed soil being very porous, and causes the fresh water to rise: when the tide falls the fresh water sinks also. A sponge full of fresh water placed gently in a basin of salt water, will not part with its contents for a length of time if left untouched. The water in the middle of the sponge will be found untainted by salt for many days; perhaps much longer, if tried.

A word about the inhabitants, and I leave the Keelings. No material difference was detected by me between the Malays on these islands, and the natives of Otaheite or New Zealand. I do not mean to assert that there were not numbers of men

* Chama gigantea. There is a large one in the United Service Museum.

† Rats and mice included; which swarm on those islands.

© The Complete Work of Charles Darwin Online

at each of those islands to whom I could not trace resemblances (setting individual features aside,) at the Keelings; I merely say that there was not one individual among the two hundred Malays I saw there whom I could have distinguished from a Polynesian Islander, had I seen him in the Pacific.

Two boys attracted my notice particularly, because their colour was of a brighter red* than that of any South American or Polynesian whom I had seen, and upon enquiry I found that these two boys were sons of Alexander Hare and a Malay woman.

Excepting the two English families I have mentioned, all on the Keelings in 1836, were Mahometans. One of their number officiated as priest; but exclusive of an extreme dislike to pigs, they showed little outward attention to his injunctions. As no Christian minister had ever visited the place, and there was no immediate prospect of one coming there, I was asked to baptize the children of Mrs. Leisk. So unusual a demand occasioned some scruples on my part, but at last I complied, and performed the appointed service in Mr. Ross's house; where six children of various ages were christened in succession. This and other facts I have mentioned respecting these sequestered islands shew the necessity that exists for some inspecting influence being exercised at every place where British subjects are settled. A visit from a man of war, even once only in a year, is sufficient (merely in prospect) to keep bad characters in tolerable check, and would make known at head quarters the more urgent wants of the settlers.

In observing the sun's meridian altitude at this place, the sextants were used, which I have adverted to before (p. 396), and the latitude deduced from their results only differed two or three seconds from that obtained by stars, without using the additional glass: I forgot to say, in speaking of the Galapagos, how useful those instruments were there; enabling us to measure the sun's meridian altitude in an artificial horizon when nearly eighty degrees high. I would not say this in favour of

* Brighter by comparison; their colour was that of copper in its very reddest state—without any tinge of yellow.

© The Complete Work of Charles Darwin Online

my own invention, if I did not feel certain that seamen will find it useful, and that somebody ought to tell them of it, for their own sake. (These sextants were made by Worthington.)

I was informed by the residents that between October and April, they are occasionally visited by severe gales of wind, at times almost hurricanes, so strong as to root up trees, strip the leaves off others, and unroof or blow down houses. These storms begin between south-east and south, and when they abate draw towards the west (by the south) there ending. For those who take interest in the course of storms I subjoin extracts from Mr. Ross's Journal given to me by Leisk.* Earthquakes have been felt several times, I was told by Mr. Leisk, but I could get only one extract from the Journal which mentioned a shock.†

On the 12th we sailed, carrying a good sea-stock of cocoanuts, pigs, poultry, pumpkins, and turtle. Maize and sugarcane might have been had, if wanted. We first went round the northern Keeling:—on this island, about a mile across and but a few feet above the ocean, two English vessels have been lost since 1825, and probably other ships met a similar fate

* "April 4th, 1835. Wind south, blowing very hard all day, with a hard cloudy sky. 5th. Blowing heavily from the same point; with rain. 6th. Wind S.E. still blowing heavily, with rain. 7th. Wind increasing, at midnight the tops of many trees blown off; trees falling, and roofs of houses suffering, wind still S.E. At two A.M. on the 8th wind south; several houses laid flat; excessive thunder and lightning, with torrents of rain. About three A.M. the storm abating, and drawing to the west; at four, moderate west wind. 9th. N.W. light breeze, clear weather; went with a party (Mr. Ross, Leisk, &c.) to South-East Bay (inside South-East Island), found the bay strewed with dead fish of all sorts and sizes, which we supposed to have been killed by the fresh water. Numbers of trees blown down every where, and the earth cut through in many places by the runs of rain-water." On the 26th of November 1835, a south-east gale increased almost to a hurricane, causing similar effects, though less in number, because it lasted only two hours, and then ended by shifting to the westward, and moderating.

† That notice says, "May 25, 1830, weather calm and sultry, light N.E. breeze: about 1·30 A.M. an earthquake, of a rocking description, was felt. It continued about three minutes, and made our wooden house reel and strain considerably."

© The Complete Work of Charles Darwin Online

there in earlier years, when its existence was hardly known. We found the current setting towards the north-west, as I had been led to expect; but, from what I could observe, during our stay, as well as from oral information, I am led to believe that the current only sets strongly during about the last half of the flood tide, and the first half of the ebb; and that during the other six hours there is little or no current; as is the case off Cape Horn, and in many other places.*

Our passage to the Mauritius was slow, but in smooth water. Tropic birds, a few terns, and gannets were seen, at intervals, when passing the neighbourhood of the Chagos Islands, and at our approach to the island Rodriguez. We anchored in Port Louis, at the Mauritius, on the 29th of April: sailed thence on the 9th of May: passed near Madagascar—thence along the African shore—and anchored in Simon's Bay, at the Cape of Good Hope, on the 31st. From that well-known place we went to St. Helena, Ascension, Bahia, Pernambuco, the Cape Verde Islands, and the Azores; and anchored at Falmouth, on the 2d of October, after an absence of four years and nine months from England.

From Falmouth we went to Plymouth; and thence, calling at Portsmouth, to the Thames. On the 28th our anchor was let go at Greenwich; and, after the chronometer rates were ascertained, the Beagle dropped down to Woolwich, where she was paid off on the 17th of November.

Greenwich was the last station at which observations were made; and, singularly enough, Mr. Usborne and his companions came on board as we anchored there. Independent of the gratification of meeting them again, after so wide a separation, it may be supposed how my mind was relieved by his safe return from a very successful expedition, in which he had surveyed the whole coast of Peru, from Atacama to Guayaquil, without loss or accident. Although his own life was seriously risked on two or three occasions, by shots fired under misapprehension; I must not omit to mention that hostilities

* Varying from three parts, to one-quarter of a tide difference between the time of low water and the beginning of flood stream.

© The Complete Work of Charles Darwin Online

were suspended for a whole day, at Arica, between the land-forces and an attacking squadron, in order that Mr. Usborne might carry on his operations. Throughout the survey of the Peruvian coast, the cordial assistance of Mr. Wilson, Chargé d'affaires at Lima, was found to be of paramount consequence.

I would now speak of the steady support and unvarying help which I received from the officers of the Beagle: but where all did so much, and all contributed so materially to the gatherings of the voyage, it is unnecessary to particularise, farther than by saying that Mr. Stokes's services hold the first place in my own estimation.

In this long voyage, rather exceeding that of Vancouver, fatal disease was unknown, except in the lamented case of the purser, and in that mentioned at Rio de Janeiro; neither of which had the least reference to the particular service on which the Beagle was employed: and it is perhaps remarkable, that while the Beagle was in commission, between February 1829 and November 1836, no serious illness, brought on or contracted while on service, happened on board; neither did any accident of consequence occur in the ship; nor did any man ever fall overboard during all that time.

The freedom from illness must be attributed, under Providence, to active employment, good clothing, and wholesome food,* in healthy, though sometimes disagreeable climates: and our immunity from accident† during exposure to a variety of risks, especially in boats, I attribute, referring to visible causes, to the care, attention, and vigilance of the excellent officers whose able assistance was not valued by me more than their sincere friendship.

* See Appendix, No. 48.

† Excepting that mentioned in vol. i. p. 445.

CHAPTER XXVII.

REMARKS ON THE EARLY MIGRATIONS OF THE HUMAN RACE.

HAVING ended my narrative of the Beagle's voyage, I might lay down the pen: but there are some reflections, arising out of circumstances witnessed by myself, and enquiries since made respecting them, that I feel anxious to lay before those who take interest in such subjects; and who will detect fallacies which I, in a purblind search after truth, may have overlooked.

A few of these reflections bear on the origin and migration of the human race: and, deeply feeling the difficulty of the subject, as well as my comparative ignorance and inability, I would beg that my remarks may be viewed solely as those of a sailor who writes for the younger members of his profession —not as the scheme of a theorist.

Before mentioning the particular facts which have fallen under my own observation, and made most impression on me, in connexion with this subject, it may be well to defend myself from any imputation of indulging hastily formed or capricious ideas, by saying that from boyhood I have always taken interest in observing the various countenances, heads, shapes, sizes, colours, and other peculiarities of the human race; especially of those varieties in which education has not masked the mind, by teaching man to restrain or conceal his emotions. The result of this attention to outward tokens, occasionally retained more distinctly in my recollection by sketches, has been a conviction that external form, especially of the head and features, is exceedingly dependent upon mind; and that as the human being is more or less educated, accustomed to better or worse

© The Complete Work of Charles Darwin Online

habits, more or less obliged to think and act for himself; so will his external appearance vary for better or worse, and become, in a great degree, the index of his mental quality. This power of mind over matter exists in each individual, who besides may receive from his parents, outward peculiarities, and general inclinations, but in a modified degree: since the child partakes of the nature of both father and mother, (perhaps even, slightly, of that of a foster mother, if one is employed). That such hereditary peculiarities are not to be quickly or easily altered, every one will admit; but that they may be gradually changed, and in a few generations altogether obliterated, by pains being taken with successive children, many facts have been published which seem to prove incontrovertibly. This ought to give great encouragement to the exertions of parents in educating their children,* since exterior expression, if not feature, as well as the infinitely more important result, actual character, may depend so much upon training the mind aright. Supposing this to be the case, it is not surprising to find savages so very different from civilized men in outward feature, as well as in mind; or to see them, where civilization has not been known, precisely in the same condition now, as that in which we learn they were several centuries ago.

Some years since I read a long article in the "Dictionnaire Classique" under the head of "Homme," which described a great many distinct races of men—at least thirteen: and at the same time I saw a map which professed to show the geographical distribution of those several distinct races. Almost the first spot which my eye rested on was Tierra del Fuego, coloured black, to indicate that its inhabitants were black; and upon reference to the "Dictionnaire Classique" I found

* Not in overburthening their tender minds with the contents of books, or over exciting them with a whirl of ideas calculated to rouse even the listless spoiled child of fortune from his apathetic indifference—but in a wholesome mixture of general education, bodily as well as mental, adapted to their years, and calculated to prepare them, in their respective stations, for doing their duty happily to their Maker, and to their fellow-men.

© The Complete Work of Charles Darwin Online

that the Fuegians were there described as being black, like the natives of Van Diemen's Land. This mistake, so extraordinary considering the numerous voyagers who have seen the natives of Tierra del Fuego during the last three hundred years, stimulated me to inquire further into the data upon which that division of the human family into separate 'races' was founded. The more I have sought, the more evidence has appeared to demonstrate the erroneous nature of such a view; and the probability, nay certainty, that all men are of one blood.

In the course of years spent in various quarters of the world, I have had opportunities of leisurely considering people from all the principal countries. I have read much of what has been written, during late years, on the subject of their resemblance, or difference; and the conclusion to which I have been obliged to come is—that there is far less difference between most nations, or tribes (selecting any two for the comparison), than exists between two individuals who might be chosen out of either one of those nations or tribes; colour and hair alone excepted.

In the city of Lima there are now at least twenty-three distinct varieties of the human race, which are not only recognised and well known in that capital, but have been carefully enumerated and described by Stevenson, in the following table. All these varieties have arisen from the intermarriages of three, the Spaniard, the aboriginal Peruvian, and the negro: and among their descendants almost any coloured skin, or kind of hair, may be matched. It may be observed that although negro and white produce the zambo, which is a dark copper; and although it may be inferred from the table that zambo and some lighter variety would produce a lighter shade of copper-colour —there is still the long black hair, and scarcity of beard, observed in most American aborigines, to be accounted for. This peculiarity, however, may be derived from white and negro: and I think it would not be difficult to show that every variety of hair and colour might be produced from these two originals only.

Colours are classed according to appearances: a child receives more of the colour of the father than of the mother.*

* Stevenson's South America, vol i. p. 286.

© The Complete Work of Charles Darwin Online

That colour is not alone dependant upon, or caused by climate, however much it may be altered by exposure to sun and wind, or by seclusion, no person can doubt who has at all attended to the subject, and read the opinions of men who have made it their study: but that its various hues may be derived from intermarriage, without any change of climate, this table goes far to prove.*

Having seen how all the varieties of colour may be produced from white, red, and black, we pause, because at fault, and so we should remain, did we rely on our own unassisted reason. But, turning to the Bible, we find in the history of those by whom the earth was peopled, after the flood, a curse pronounced on Ham and his descendants; and it is curious that the name Ham should mean "heat—brown—scorched," while that of Cush his son, means "black:" that Japheth should imply "handsome," and that Shem, from whose line our Saviour was descended, should mean "name—renown—he who is put or placed." I cannot myself read this explanation of Cush, and the denunciation "Cursed be Canaan—a servant of servants shall he be unto his brethren," without believing that Cush was a negro, and that from the intermarriages of his descendants with those of Shem and Japheth, came hosts of mulatto, copper, or dark-coloured men who peopled a great part of Asia, Polynesia, America, parts of Africa, and part of Australia. According to this view the black descendants of Cush overspread part of Africa, Australia, and Van Diemen's Land, New Guinea, and portions of other islands: while white families, children of Japheth and Shem, spread over Asia Minor, the Caucasian district, great part of Northern Asia, and the whole of Europe.

We read, in another place, that Abraham gave gifts to the sons of his concubines, and sent them away eastward from Canaan, unto the east country: many years before this separation, Ishmael, the son of Hagar, an Egyptian slave belonging to Abraham, was established in the country next to the

* It did not, however, satisfy me as to the production of a bright red copper colour; but of that I afterwards saw an excellent example at the Keeling Islands. See page 636.

© The Complete Work of Charles Darwin Online

eastward of Canaan; and as his descendants were "not to be numbered for multitude," it follows that those of some of the sons above mentioned must have migrated to a great distance.* It is likely that some of Abraham's bond-women were either black or mulatto, being descendants of Ham; perhaps of Cush: and it is hardly possible that Hagar should not have been dark, even black, considering her parentage;† in which case Ishmael would have been copper-coloured, or mulatto,‡ and some, if not all of Abraham's sons by concubines, would have been of those colours. If this be assuming too much, there can be no doubt that in the next generation Esau, or Edom, was a red man, and that his descendants, the numerous Edomites, or Idumeans, were also red: now as Esau married the daughter of Ishmael, we have, in this case, distinct evidence of the origin of a race of red, or copper-coloured men. Had the common colour of the human race been at that time red, Esau's colour would not have been remarked: had it been black, Cush would have been no distinctive appellation. It must then have been originally fair, as no colours are mentioned in the Scripture, with reference to the human race, except fair, red, and black.

A rapid increase of flocks and herds, as well as population; a consequent diminution of vegetable food; jealousies and disputes between the children of bond-women and those of the free, and the comparative indifference of fathers to the offspring of their slaves, must have stimulated migration in every direction; and, when once begun, no doubt the love of novelty, and desire of finding countries still better than those yet explored, increased, and eventually perpetuated that passion for wandering which we see to this day in the Arab, the migratory Malay, the roving Tartar, and the ever-restless South American Indian.

* See Genesis, Chap. xiii. for evidence of the necessity there was to emigrate in those early times. † Herodotus, lib. ii.

‡ The Arabs, next to the Jews the most marked people on earth, who have preserved their genealogies in an unbroken line, assert that they are descended from Ishmael; their colour is the same as that of the Malays, the Polynesian islanders, and the Americans.

© The Complete Work of Charles Darwin Online

Climate, habits, and food operate to cause a considerable change in the form and size, though their permanent effect on the colour of the human race is slight. The effect of climate, considered alone, may be seen in the descendants of English families settled in some parts of North America, in Australia, or Van Diemen's Land; countries where neither habits nor food differ much from those of England. We see there that our sturdy thick-set labourer's son becomes a tall lathy youth, though perhaps none of his family while in England exceeded the middle height: and not only does the form alter, but the gait and voice acquire peculiarities which mark the American born, the Australian, or the Tasmanian. Exposure to cold, wet, and wind, together with but little walking exercise, shortens the legs, and increases the stoutness of body, as may be seen in the Fuegian, the Esquimaux, and the Laplander, —in fishermen, sailors, coachmen, and others; but, activity on foot, warmth, and a fine climate, have contrary effects, which may be shown by the youth above mentioned, by the African Negro, by the Indian, by the South Sea Islander, and others. Habits require little notice, for we can hardly look around us without seeing many instances of faculties or forms altered in one way or other, by exercise or the want of it, or by certain customs: porters, smiths, dancers, grooms, jockeys, are remarkable instances. That food is a material agent in affecting the human form I think no one can doubt; and when all three combine to cause alterations, how considerable must be the change effected. That colour may be altered a little by seclusion and particular diet, or by exposure to wind and sun, need not be remarked, except for the purpose of adding that a change so caused is not permanent, or transmitted to children, like peculiarity of form. The Otaheitans used to shut themselves up for a month at a time, and eat only particular food, in order to become fairer; yet their descendants are as dark at this day as their fathers were when Wallis first discovered them in 1786.

I will now endeavour to point out those lines of communication across the oceans which appear to me, as a seaman, the

© The Complete Work of Charles Darwin Online

most likely to have been followed by the earliest wanderers. Of overland routes I say nothing, because where land extends, in the vicinity of water, there is no obstacle sufficient to prevent the migration of animals, as well as men; neither need I notice intervals of sea which can easily be crossed.

Wandering eastward, from Asia Minor, roving tribes may have begun to people Eastern Asia and the Indian Archipelago, while other parties were exploring Africa; and while the sons of Japhet were advancing northward, and towards the west. A slight acquaintance with ancient history informs us at how early a period extensive commerce was carried on by ships,—to Britain in the west, and to the Indian Archipelago in the east; before which time it is obvious that those extreme regions must have been tolerably well peopled: but it is not possible that they could have been so without the employment of ships, boats, canoes, or rafts. The earliest explorers of unknown lands must have been naturally enterprising, and habitually disposed to wander. Children brought up under such instructors as their migratory parents, always eager to seek for new countries, would increase their roving inclinations; and as long as another region could be found, doubtless they would try to explore it, partly from a ruling passion and habit, partly for the sake of procuring food with greater ease, and partly in consequence of feuds among themselves, which, in such a state of society, must end in the defeat and expulsion, if not subjugation or destruction of the weaker party. Add to these motives, those which I mentioned in a previous page, consequent upon intermarriage between various castes or colours, the desire of independence, or the love of wealth,* and more than enough reasons appear to account for the early dispersion of the human race, provided they possessed the means of migration.

That in the early ages large trees were more abundant near the water side in many countries than they now are, appears indisputable; but even as we see them in many uncivilized though inhabited countries, how numerous are huge trunks, out

* Real wealth—not money, its symbol and equivalent now.

© The Complete Work of Charles Darwin Online

of which canoes might be formed, with fire, with stones, and with shells. Considering the abundance of trees once standing in places, perhaps easy of access, whence the hand of man may have long since cleared them away, and the quantity of animal,* as well as vegetable food which may have abounded where then there had been no arch-destroyer, — how easy, comparatively speaking, may it have been, in those early ages, to fell, hollow out, and launch great trunks of trees, which, secured two and two, and covered over, would form excellent vessels. Like the double canoes of modern Polynesians, they might have carried a platform, above the reach of common waves, on which families and their provisions could voyage in security. Neither refined art nor any tool would have been required in the construction : with fire to hollow and to divide, stones, shells, and bones would have sufficed for so simple a work, and thus enabled the least informed savages to make seaworthy and even burthensome vessels.

Unlike some modern canoes, however, these primitive vessels would have been capable of sailing only before the wind, or nearly so, and would therefore have been almost at the disposal of every breeze, when once at sea. Hence, in attempting to follow their course, we must attentively consider prevailing winds, and by no means omit to regard currents, of which the first sailors could have known nothing, and which must have caused the mis-direction, if not loss, of many early adventurers.

In alluding to easily constructed rafts, and double canoes, I do not for an instant dream of excluding better vessels, which no doubt, were soon constructed after men began to roam by sea ;† but I wish to show, so far as I am able, how readily means of transport were accessible to the first wanderers.

* For proofs of the extraordinarily rapid manner in which animals multiply when comparatively unmolested by man, we need only turn to South America.

† The Piragua now used at Chilóe, and by the savages of the Chonos Archipelago, exactly resembles in every minute detail the Maseulah boat of Madras. Its ' sacho,' or wooden anchor with a stone in the middle, is precisely like that used in Chinese and Japanese Junks: but doubtless these coincidences may be accidental.

© The Complete Work of Charles Darwin Online

I must pause for a moment to explain why I consider these explorers as savages, although they were spoken of before as descendants of Abraham and his countrymen, who were civilized. Let us suppose, for illustration, that a party of men and women left Asia Minor in a civilized state. Before they had wandered far, no writing materials or clothes would have remained (had they even possessed them), and their children would have been taught only to provide for daily wants, food, and perhaps some substitute for clothes, such as skins. Their grand-children would have been in a still worse condition as to information or traces of civilization, and each succeeding generation would have fallen lower in the scale, until they became savages in the fullest sense of the word; from which degraded condition they would not rise a step by their own exertions; so long as they received no assistance, no glimmerings of intelligence, from others who had branched off from the main trunk at a much later period, and had means of preserving more knowledge. The degree of degradation would depend upon climate, disposition, description and quantity of food, recollection of origin and traditions, keeping up old observances, and intercourse with other families, tribes, or nations, among whom more traces of their common origin and descent might have been preserved. Were a dozen men and women now cast away upon unknown land—supposing that not one of the party could read or write—that there was no substance with which they could clothe themselves except the skins of animals—that the climate was variable—that they had neither tools nor arms—that the extent of habitable land admitted of their wandering—that it had no other human inhabitants, and that it should be visited by none for the space of some hundred years after the arrival of this party,—in what state would their descendants be found by the next adventurers who might land on the shores of that country?

India, China, Mexico, Peru, regions separated from the central seat of population, but advanced in civilization at the earliest period of their history with which we are acquainted, preserve traditional accounts of superior men who arrived

© The Complete Work of Charles Darwin Online

there, and first began to improve the condition of their people, but we are not told whence those men came. No one, however, can read about those countries, as well as Tartary, Japan, and Polynesia, without being struck by the traces of Hebrew ceremonies and rites, by the evidences of the worship of Baal, or by remains of Arkite observances, scattered through the more populous, if not through all the nations upon earth.

That man could have been first created in an infant, or a savage state, appears to my apprehension impossible; (for a moment taking a view of the case, unaided by Scripture;) because—if an infant—who nursed, who fed, who protected him till able to subsist alone? and, if a savage, he would have been utterly helpless. Destitute of the instinct possessed by brutes,—with organs inexperienced (however perfect), and with a mind absolutely vacant; neither his eye, his ear, his hand, nor his foot would have been available, and after a few hours of apathetic existence he must have perished. The only idea I can reconcile to reason is that man was created perfect in body, perfect in mind, and knowing by inspiration enough for the part he had to perform;—such a being it would be worse than folly to call savage.

Have we a shadow of ground for thinking that wild animals or plants have improved since their creation? Can any reasonable man believe that the first of a race, species, or kind, was the most inferior? Then how for a moment could false philosophers, and those who have been led away by their writings, imagine that there were separate beginnings of savage races, at different times, and in different places? Yet I may answer this question myself; for until I had thought much on the subject, and had seen nearly every variety of the human race, I had no reason to give in opposition to doubts excited by such sceptical works, except a conviction that the Bible was true, that in all ages men had erred, and that sooner or later the truth of every statement contained in that record would be proved.

To return to the lines and means of communication:—

Following the various routes of population into the Indian

© The Complete Work of Charles Darwin Online

Archipelago, to Japan, to Kamschatka, and to Australia, we are stopped by the vast Pacific—except at one point, Kamschatka, and there, by the Aleutian isles, is an easy road to America. Now it is not probable that intercourse should have been begun by water, between various points on those extensive shores, (reaching from 60°, N. lat., to 40°, S. lat.), without numerous accidents happening, such as vessels, boats, canoes, or rafts being carried out of sight of land by storms; when, ignorant how to steer as their crews must have been, they were driven before the wind till they reached some unknown land, or were engulfed in ocean.

Many such vessels, out of the numbers which must have been tempest-tost among currents and dangers of every kind incident to navigation, may have failed in finding land before their store of provision was consumed, and their crews reduced to the horrible necessity of feeding upon human flesh. When once the natural antipathy to cannibalism was overcome, recurrence to similar food would have been less revolting on other occasions; especially if, excited by rage or animosity, and deprived of animal food, men had accustomed themselves to anticipate satisfying their hunger by the flesh of a miserable slave, or even of a late friend whom accident had estranged and turned into a blood-thirsty enemy.

Looking over a modern chart of the Pacific we see a multitude of islands scattered, like stars over the sky, from the Indian archipelago to Salas y Gomez;* whence to Mas-a-fuera, on the South American coast, the distance is not fourteen hundred miles; and to the main land itself, about eighteen hundred. It is possible that other islands may have existed, but we now find a comparatively short distance between Easter Island and South America; besides favouring circumstances of wind and weather which lead me to believe that a line of population went in that direction. It is not impossible that vessels should have crossed from New Zealand to South America, running always before the fresh westerly winds so prevalent southward of 38°; neither is it at all unlikely, on the

* Near Easter Island.

© The Complete Work of Charles Darwin Online

contrary it is highly probable, that Chinese or Japanese Junks were driven to the Sandwich Islands; perhaps across to the North American coast.

Between the tropics in the Pacific an easterly trade wind is found during more than half the year; but it is not generally known (except by readers of voyages) that from November to March there is much west wind, rain, and occasional tempest, between the vicinity of the equator, and about fifteen degrees south. This westerly monsoon, for such in fact it is, sometimes is steadily regular, and at others interrupted by calms, storms,* or heavy rains. The eastern limit to which it usually reaches is about 110° W. long., but there is reason to suppose, that it extends at times, irregularly, to the Galapagos Islands, if not to the adjacent continent, when Guayaquil is suffering from heavy torrents of rain. While the sun is far south, this westerly monsoon extends to the tropic of Capricorn, between the meridians of 150° E. and 120° W. longitude. At other times of the year the tropical regions of the Pacific are refreshed by pleasant easterly winds, varying in moderate strength, and in their direction from the northward or southward of east.

Beyond the region of tropical or trade winds, an almost continual succession of westerly winds is found to prevail. In those middle latitudes easterly winds sometimes blow; but their amount is not more than one-fifth that of the west winds, throughout the year.

In the Southern Atlantic and Southern Indian ocean similar winds prevail, between the parallels of 30° and 60°. Instances in profusion may be found in narratives of voyages, where very small vessels, boats, or canoes, have made long passages across an open ocean, or have passed months in ignorance of their geographical situation, enduring the most dreadful privations. In the event of a float, whether raft, canoe, or rudely constructed vessel, being carried out of sight

* During these storms, which begin very suddenly, not only vessels are driven out of their course, but birds, insects, and seeds are carried to great distances.

© The Complete Work of Charles Darwin Online

of land by current or wind, or by both, and taken into a steady trade, or lasting westerly wind, it would be impossible for her to struggle against it for many days; she must eventually run before it as the last expedient, with the hope, often forlorn, of falling in with some land to leeward.

When we reflect on the tedious coasting voyages undertaken formerly, even in historical times; and on the quantities of provision embarked for those long passages; may we not infer that the earliest explorers would take as much food with them as their rafts or vessels could carry; and therefore, that if driven out to sea, they were capable, in some instances at least, of holding out for a considerable length of time without having recourse to the last alternative.

If a vessel were drifted from Easter Island* by a north-west wind (occasional in July, August, or September,) she would be carried towards the coast of Chile; she might be drifted directly there, or she might be driven eastward for a time, and then, in consequence of wind changing, drifted towards the north; so that it would be uncertain whether Chile, Peru, the Galapagos Islands, Mexico, or the wide ocean would receive the lost wanderers. It is also possible that a vessel may have been driven to South America from the neighbourhood of New Zealand; but this does not appear nearly so probable as the former conjecture. That the Araucanians about Valdivia originally arrived in that country by water, from the west, is I think indicated by what is stated in page 400 of this volume.

But while man was thus spreading eastward across the Pacific, are we to suppose that no vessel was ever blown off the coast of Africa, or that of Spain, and drifted by easterly winds across the Atlantic? How easy is the voyage, before a steady trade wind, from the Canary or Cape Verde Islands to the West Indies or Brazil; from the west coast of Africa to the

* At Easter Island in 1722, Roggewein found idolaters and fire-worshippers, and he says that one of the chief idols was called Dago. In 1774, people differently disposed, were found there by Cook; the idols still remained, but no traces were observed of fire-worship.

© The Complete Work of Charles Darwin Online

east coast of America. Tradition in Brazil says that such arrivals took place there, and certainly there is a resemblance in some points between the Patagonians and what history states of the Guanches.

Let us now turn to the Negro population, descendants of Cush. Spreading to the south and west, they may have overrun extensive regions in Africa, but by no means to the exclusion of the mixed varieties of men, who also explored and colonized that continent, chiefly towards the northern and central regions. From the coast opposite Madagascar a party of negroes might have embarked to cross the Mosambique Channel, or they might have been driven off by a storm while coasting along near Algoa Bay, in which cases the current, always setting south-westward along that coast, would have hurried them into the region of strong westerly winds, by which they must have been carried, if their vessel and provisions held out, to the coast of New Holland, or to Van Diemen's Land. Now it is worth notice that the men of the south-western quarter of Australia are exceedingly like some of those who frequent the countries near Algoa Bay—and that the native dances and superstitions are very similar; while the aborigines of Van Diemen's Land, though of like colour, are shorter, stouter, and have coarser features; differences which might be expected to result from living in a wetter, windier, and colder climate. That other negroes arrived on the northern shores of Australia, brought there as slaves by red men, or making their escape from Asiatic masters, is probable: and from one or other source, if not from each, the black men in Australia and Van Diemen's Land may have been derived. That red men must have landed in Australia, we now know by the notices of late travellers, and their presence accounts for the colour observable in many of the so-called blacks, whose actual hue, when washed, is a deep brown—next to black, certainly, but with a perceptible red tinge. They are nearly the variety which would be produced by the intermarriage of a Negro and a Chino (see table, page 643,) called Zambo-chino in Lima: but there are gradations of colour, as might be expected, and va-

© The Complete Work of Charles Darwin Online

rieties of hair; some being more or less woolly, others frizzled, almost like that of a mulatto.*

The occasional peculiarities of outward form, on which so much stress has been laid, to the prejudice of the Hottentots especially, are considered by able anatomists whom I have consulted to be of no more real consequence than that existing in a six-fingered family. On their authority it may be shown that such occasional deviations from ordinary conformation, which are sometimes continued in particular families, and therefore might be found in a whole tribe who were originally but one family, in no degree constitute distinct species. From them we learn also that all varieties of the human race are alike in their anatomical structure, and that intermarriage between any two varieties whatever is productive of a prolific offspring.

Considerable stress has been laid on language as a means of tracing affinities or descents; but with great deference for the

* Of the natives of Van Diemen's Land Cook remarks that their hair differed in texture from that of the natives of New South Wales, being in Adventure Bay as woolly as that of any native of Guinea, while that of the aborigines of New South Wales was naturally long and black, though cropped short.—Cook's Voyage, 1769-71.

Bligh says that the aborigines of Van Diemen's Land are black, and that their hair, "which resembled the wool of the Caffres," was separated into shreds, and powdered with red ochre. They were generally slender, tolerably well made, kept their shoulders back, and upon their prominent chests several had marks raised in the skin.—Bligh's Voyage—Adventure Bay, 1788-1792.

Flinders saw only one native of this country, but his appearance much resembled that of the inhabitants of New South Wales. He had also marks raised upon the skin, and his face was blackened, and hair ruddled, as is sometimes practised by them. The hair was either cropped close, or naturally short, but it had not the appearance of being woolly.

In Marion's voyage a skirmish with the natives of Van Diemen's Land took place, after relating which, the writer says, "on entering among the trees they found a dying savage. This man was a little more than five feet seven inches in height, (French measure). His breast was marked like those of the Mosambique Caffres, and his skin appeared as black; but, on washing off the soot and dirt, his natural colour appeared to have a reddish tinge."

© The Complete Work of Charles Darwin Online

learned men who have devoted so much time to following its intricate traces, I would ask whether, when a language was not written, or in any manner fixed, it was not liable to vary continually as fresh separations of families into tribes occurred; and whether therefore it is possible to do more than classify unwritten languages, following some few traces of resemblance which may occasionally be marked, and detecting the root, though not the branch? In such an interesting pursuit, however, every sign, even the faintest, is valuable;—but only men of deep research and extensive learning can advantageously pursue this method of inquiry into the migrations and early history of our race.

I believe it will be found that the remarks I have ventured to make in the preceding pages, are by no means at variance with most of their deductions; and I much regret that our opportunities of collecting words, and modes of expression, were not such as to enable me to add many to their collections.

CHAPTER XXVIII.

A VERY FEW REMARKS WITH REFERENCE TO THE DELUGE.

To account for offering a few remarks on a subject so important and difficult as that of the Deluge, I beg to say that reflections, arising out of facts witnessed during the Beagle's voyage, have occasioned them; and, as results of that expedition, it has appeared to me that they are neither irrelevant to the narrative, nor likely to be altogether uninteresting to young men in the navy.

I suffered much anxiety in former years from a disposition to doubt, if not disbelieve, the inspired History written by Moses. I knew so little of that record, or of the intimate manner in which the Old Testament is connected with the New, that I fancied some events there related might be mythological or fabulous, while I sincerely believed the truth of others; a wavering between opinions, which could only be productive of an unsettled, and therefore unhappy, state of mind. Some young men, I am well aware, are in a similar condition, while many others are content to set aside all reflection, and do as the world does; or rather, as those do among whom they generally live. Natural affection and respect for good parents, relations, and elders, never can lead a young man astray; but there is, perhaps, no guide more fallible or dangerous than the common custom of those inexperienced persons who associate together, chiefly for lack of fixed occupation; and whose principal object is to drive away self-examination, or prolonged thought, by a continual succession of idle amusement, or vivid excitement.

Wholesome and necessary as amusement and recreation are, both for mind and body, every one knows how insipid, even painful their excess becomes; and external evidence shows but

© The Complete Work of Charles Darwin Online

too plainly where the happiness, the blessings, and the comfort men might enjoy, have by themselves been slighted, or destroyed, from forgetting the line between using, and abusing; and by turning a deaf ear to the reflection that they are but 'tenants at will.'

Much of my own uneasiness was caused by reading works written by men of Voltaire's school; and by those of geologists who contradict, by implication, if not in plain terms, the authenticity of the Scriptures; before I had any acquaintance with the volume which they so incautiously impugn. For geology, as a useful branch of science,* I have as high a respect as for any other young branch of the tree of knowledge, which has yet to undergo the trial of experience; and no doubt exists in my own breast that every such additional branch, if proved by time to be sound and healthy, will contribute its share of nourishment and vigour to the tree which sprung from an immortal root. For men who, like myself formerly, are willingly ignorant of the Bible, and doubt its divine inspiration, I can only have one feeling—sincere sorrow.

Few have time, as well as inclination, to go far into both sides of any question; but truth can hardly be drawn out of the well unless some exertion be made, in examining each argument, or in selecting a well-tried and experienced guide. It is idle to say, as I have heard asserted, that such works as those above-mentioned do little harm; experience proves the contrary; of which I am made painfully aware, not only by my own conscience, but by conversation with friends.

While led away by sceptical ideas, and knowing extremely little of the Bible, one of my remarks to a friend, on crossing vast plains composed of rolled stones bedded in diluvial detritus some hundred feet in depth, was "this could never have been effected by a forty days' flood,"—an expression plainly indicative of the turn of mind, and ignorance of Scripture. I was quite willing to disbelieve what I thought to be the Mosaic account, upon the evidence of a hasty glance, though knowing next to

* By which word I mean 'Knowledge,' in its most comprehensive signification.

© The Complete Work of Charles Darwin Online

nothing of the record I doubted:—and I mention this particularly, because I have conversed with persons fond of geology, yet knowing no more of the Bible than I knew at that time. Thus much I feel it necessary to say, in accounting for my own approach to a subject in which all men feel deeply interested; and which has therefore been so well treated of, that these remarks would be useless, were it not that they may reach the eyes of young sailors, who have not always access to works of authority.

The Mosaic account of the Creation is so intimately connected with that of the Deluge that I must ask my young reader (whom alone I presume to address on this subject) to turn to the first chapter of Genesis, and refer to a few verses with me. We soon find a remarkable fact, which shows to my mind that the knowledge of Moses was super-human: his declaration in an early age that light was created before the sun and moon, which must till then have appeared to be the sources of light. In the fourth verse it is stated that "God divided the light from the darkness." This may have been effected by a rotation of the earth on its axis, turning each side in succession to the light; otherwise, had the earth remained stationary, light must have been destroyed to admit darkness, and there must have been repeated creations of light. The light was called day—"and the evening and the morning were the first day." Of course there could have been no morning previous to the creation of light; and the first portion of time, consonant to our present expressions, would have been that which elapsed between light and darkness, or evening. The length of a day being determined by the rotation of the earth on its axis; turning round once, so as to make an evening and a morning to each spot on the globe; the time occupied by that rotation is a natural object of interest. In the 12th verse it is said that grass, herbs, and trees, were brought forth; in the 14th and 16th, that lights were made to divide the day from the night; and that the greater light was to rule the day. It is known that neither trees, herbs, nor grass can exist long without the light and heat of the sun, therefore the

© The Complete Work of Charles Darwin Online

rotation of the earth between the third day, when vegetation was produced, and the fourth, could not have been very different, in velocity, from its present rotation. Some men, of rare abilities, have thought that the "days" of creation were indefinite periods, notwithstanding the statement in verse 14, which affirms that the lights in the firmament of heaven were to divide the day from the night; and to "be for signs, and for seasons, and for days, and years." In this one verse do we not see that the day was less than a year (signs and seasons, days and years); for had the day there meant been more than a year would not the words have been differently placed, namely —signs and seasons, years and days? Can we think that day means one space of time in the former part, and another space of time in the latter part of that one verse? Another indication that the word day, used in the first chapter of Genesis, does not mean a period much, if at all, longer than our present day, is—that it is spoken of as alternating with night. Although the word day is used in other chapters of the Bible, even so soon as the 4th verse of the 2d chapter of Genesis, to express a period, or space of time longer than our present day, the word night is never so applied:—hence, as the earth turns uniformly on its axis, and, so far as we can reason from analogy, must have turned uniformly, while turning at all, the word night in the 5th verse interprets the length of a day.

Some have laid stress upon the declaration that a thousand years are with the Lord as one day:—but what is the context? * To lengthen the day to a thousand years, on account of this and a similar expression, is not more reasonable than it would be to reduce it to a night-watch. What is a watch in the night when passed?—next to nothing:—so are a thousand years with the Almighty. These considerations tend to show how, without Chaldee or Hebrew learning, a man, with a common English education, may convince himself of a fact which has lately been so much controverted.†

* "A thousand years in thy sight are but as yesterday when it is past, and as a watch in the night."—Ps. xc. ver. 4.

† I may, however, here remark to my young sailor friends, that the Jews,

© The Complete Work of Charles Darwin Online

Partly referring to such indefinite periods as we have been discussing,—and partly to reasoning unaided by revelation,—some geologists have said that there were successive creations, at intervals of vast duration. They have imagined an age in which only the 'so-called' lowest orders of animated creatures existed,* an age of fishes, an age of reptiles, an age of mammalia, and an age in which man appeared: statements which have obtained much attention. Fossil fishes and shell mollusca† have been found in coal measures, and in subjacent formations:—how could this have happened if vegetables had been produced first; then swept away and converted into coal, and that afterwards the lower orders of animals had appeared? We know that the fossil plants of the coal formations are similar in structure to vegetables now growing on the earth, which cannot flourish without warmth, and the light of the sun. Vegetation was produced on the third day, the sun on the fourth. If the third day was an age, how was the vegetable world nourished? But anomalies such as these appear to be endless in most geological theories: I will leave them for the present and continue my course.

Jews, who perform their worship in Hebrew, and are naturally at least as much interested in the Old Testament as any people, use and prefer our authorised English translation.

* In classing one order of creatures above or below others, we may perhaps consider them as they appear to our apprehension, in comparison with others, but we must beware of thinking them more or less imperfect. Every creature is perfectly adapted to the condition and locality for which it is designed, and absolutely perfect (speaking generally). Some that are intended to live in the dark; or some that are to exist under pressure; may at first sight appear to us imperfect; perhaps shapeless, unsightly objects: but, after examination into their natural history, our hasty remark is succeeded by expressions of astonishment at such wonderful arrangements of Providence as are shewn—even in the most shapeless sea slug.

Multitudes of creatures exist now, especially in the sea, quite as apparently imperfect as those of the so called lowest order of animated creation, whose impressions are found in solid rocks. There may also be animals in deep waters that could not exist except under pressure.

© The Complete Work of Charles Darwin Online

In the 16th verse it is said that "God made two great lights; the greater light to rule the day, the lesser light to rule the night: the stars also;" that is, he made the stars also.

It is not stated here that the Almighty made all the stars at that time; nor can I, after consulting very able men, find any passage of such an import. That all the stars dependant upon, or connected with, our solar system, namely, the planets and their satellites, were then created, seems to be evident from the fact of their revolving round our sun; but farther than this, it is not thought necessary (may we not presume) for man to know; therefore it is not revealed to us. In the ancient book of Job, the creation of the world is thus alluded to. "Who laid the corner stone thereof, when the morning stars sang together, and all the sons of God shouted for joy."* But the earth was finished, and vegetation produced, before the creation of stars mentioned in Gen. i. 16; therefore, unless the 'corner-stone' alludes to man, it may be inferred that there were stars in existence besides those made on the fourth day. Of course, the 'singing of the stars' is a figurative expression; but as we do not meet with any similar metaphor in the Bible, unconnected with some object that we know exists; we may infer that stars existed when the allegorical, or mystical corner-stone was thus laid.†

In verses 29 and 30, the food for man and beast is mentioned, and with reference to the Deluge this should be borne in mind. It may be said that the teeth of some animals are so formed as to be fit only for grazing, or browzing; that beasts of prey have teeth adapted to tearing and gnawing; and that man requires meat; but we must remember that dogs and wild beasts thrive upon a vegetable diet, and that some men never touch meat, even in the present state of the world: very

* Job. xxxviii. 6, 7.

† Much must depend upon the limit attached to the meaning of the word Heaven in the 1st Chapter of Genesis, and Heavens in the 2nd; viewed in connection with verses 1, 6, 7, 8, 9, 14, 15, 17, and 20 of Chap. i.; 1, 4, of Chap. ii.; verses 5, 7, 10, 13 of 2 Peter iii.; and very many other passages; not omitting the Lord's prayer.

© The Complete Work of Charles Darwin Online

different probably from its condition before the flood, as may be concluded from the inferior duration of human life.

The 2d and 3d verses of chap. ii. recall to mind the wonderful fact that the seventh day has been a marked division of time from the earliest period of historical record.*

It is now well known that all nations, and almost all tribes of the human race, preserve traditions of a great flood in which nearly all men were destroyed :† and it is also established as a fact, that nearly all parts of the earth, hitherto examined, bear witness to their having been at some time covered by the ocean. Instead of ascribing these effects to the universal deluge, many geologists say that the earth is in a continual, though gradual state of change; that in consequence of this general mobility, places now far above the sea were once beneath it; that districts, or countries, may have been inundated in one quarter, and other regions elsewhere, but that an universal deluge never could have happened. This is implied plainly enough, if not asserted, in several geological works.

In the Beagle's examination of the southern parts of South America, I had opportunities of observing immense tracts of land composed, solely, of fossil shells, bones, and an earth which looked like dried sandy mud :—extensive ranges of country where no solid rock could be found, only rolled or shingle stones, embedded to a great depth in earth, exactly like that described above ;—and a wide district, at least fifty miles across, covered with lava of which the surface was nearly horizontal. (San José, San Julian, Santa Cruz.)

I brought to England many specimens of these shells, which, although taken from within a few feet of the surface of the land, were found to have been pressed together, crushed, and penetrated by mud, in a manner that never could have been caused by the weight of earth then lying above them, because, though solid, it could neither have mashed the shells, nor worked into their inmost recesses. It seems evident to me

* We find it ordained in Gen. ii. 3; alluded to by Noah, chap. viii. ver. 10, 12; and afterwards observed regularly, down to the present time.

† Sharon Turner, Harcourt, &c.

© The Complete Work of Charles Darwin Online

that those shells have undergone enormous pressure beneath an ocean, when they were surrounded with mud.* But previous to such pressure, the shells must have grown naturally somewhere:—certainly not at the bottom of an ocean; because they are shells of a comparatively delicate structure which are

* On this subject, the pressure of an ocean, Mr. Lyell remarks, (Elements of Geology, 1838, pp. 7, 8, 9.) "When sand and mud sink to the bottom of a deep sea the particles are not pressed down by the enormous weight of the incumbent ocean; for the water, which becomes mingled with the sand and mud, resists pressure with a force equal to that of the column of fluid above." "Nevertheless if the materials of a stratum remain in a yielding state, and do not set or solidify, they will be gradually squeezed down by the weight of other materials successively heaped upon them, just as soft clay or loose sand on which a house is built may give way. By such downward pressure particles of clay, sand, and marl may become packed into a smaller space, and be made to cohere together permanently."

"But the action of heat at various depths is probably the most powerful of all causes in hardening sedimentary strata."

In reflecting upon these passages it appears to me that Mr. Lyell has supposed what may not always take place in a deep sea, namely—that sand and mud sink to the bottom.

Whenever particles of sand and mud are at the bottom, they must be lower than contiguous particles of water, or they could not be at the bottom; therefore those particles of sand and mud have water above, while resting upon some other substance below. Pressure there can be none, excepting of some earthy particles upon others, while the specific gravity of the sand and mud exceeds that of the displaced fluid. But, if the depth of water be increased, and its specific gravity at the bottom augmented, the sand and mud at the bottom must rise, if they do not cohere together, and to the surface on which they lie; in which case the increasing weight and density of water would tend to compress and make them cohere still more.

The smaller kinds of sea shells are very little heavier than sea water. This would prevent their being carried by the action of the sea to great depths, even if it were possible for them to be so rolled over rocks, sand, or mud, in which they would stick, or be buried, before they had been moved many miles from the place where they grew. These two considerations may help to account for the fact that seamen do not find impressions of shells, on the 'arming' of the lead, when sounding in very deep water, at a considerable distance from any shore where they grow. Sea-shells, I need hardly remark, grow only in comparatively shallow water.

© The Complete Work of Charles Darwin Online

usually found within a few feet of low water; some at least of the number being identical with living species.

If the square miles of solid land in which those myriads of shells are now embedded, had been upheaved (as geologists say), either gradually, or rapidly, shells could not be found there in their present confused and compressed state. Had the land sunk down many thousand feet with shells upon it, they might have been covered with mud, and on being afterwards upheaved again they would have appeared embedded regularly where they grew, in a matrix which, with the pressure of a superincumbent ocean, might have flattened and penetrated them: but they would not have been torn away from their roots, rolled, broken, mashed, and mixed in endless confusion, similarly to those now in my possession.

There is also another consideration: geologists who contend for the central heat of the earth assert that substances subjected to great pressure under the sea become altered: hence, in conformity with their theory, these shells could not have been long buried under a deep ocean, and afterwards raised in their pristine state. So little changed are these shells, except in form, that they appear as if they had been heaped

water. The specific gravity of oyster shell, when dead, is about twice that of sea-water (2092,1028). Most other shells are much lighter, and but few at all heavier than the oyster.

Before ending this note I must remark that the horizontal movement of water near the bottom, though gentle, may tend to press together and smooth any loose sand, mud that sinks, oazy clay, or fragments of shells, before many of their particles travel far. Water in rapid motion is known to hold sand as well as mud in suspension, but not shells, unless the current is very strong. To such a constant agitation of the sea, oscillating gently with each tide, we may perhaps ascribe the comparatively level and smoothened state of the bed of the ocean, where it has hitherto been sounded. Excepting near irregular, rocky land, one finds, generally speaking, no ravines, no vallies, no abrupt transitions in the bottom of the sea. For miles together there is an almost equal or gradually altering depth of water: and little similarity can be traced between the contour of the bed of a sea and the neighbouring dry land, until you are near the shore, where the sea acts differently, and irregular bottom is as frequent as it is usually dangerous for shipping.

© The Complete Work of Charles Darwin Online

together and squeezed in mud within a few years from the present time.

One remarkable place, easy of access, where any person can inspect these shelly remains, is Port San Julian. There, cliffs, from ten to a hundred feet high, are composed of nothing but such earth and fossils; and as those dug from the very tops of the cliffs are just as much compressed as those at any other part, it follows that they were acted upon by an immense weight not now existing. From this one simple fact may be deduced the conclusions—that Patagonia was once under the sea; that the sea grew deeper over the land in a tumultuous manner, rushing to and fro, tearing up and heaping together shells which once grew regularly or in beds: that the depth of water afterwards became so great as to squeeze or mass the earth and shells together by its enormous pressure; and that after being so forced down, the cohesion of the mass became sufficient to resist the separating power of other waves, during the subsidence of that ocean which had overwhelmed the land. If it be shewn that Patagonia was under a deep sea, not in consequence of the land having sunk, but because of the water having risen, it will follow as a necessary consequence that every other portion of the globe must have been flooded to a nearly equal height, at the same time; since the tendency to equilibrium in fluids would prevent any one part of an ocean from rising much above any other part, unless sustained at a greater elevation by external force; such as the attraction of the moon, or sun; or a strong wind; or momentum derived from their agency. Hence therefore, if Patagonia was covered to a great depth, all the world was covered to a great depth; and from those shells alone my own mind is convinced, (independent of the Scripture) that this earth has undergone an universal deluge.

The immense fields of lava, spoken of in a preceding page (633), and which to an ordinary observer appear to be horizontal, are spread almost evenly over such an extent of country, that the only probable conclusion seems to be, that the lava was ejected while a deep sea covered the earth, and

© The Complete Work of Charles Darwin Online

that tidal oscillations,* combined with immense pressure, spread and smoothed it, while in a rapidly cooling though viscous state, over the surface of the land.

The vast quantity of shingle, or rounded stones of all sizes, may be accounted for in a manner unconnected with that of water acting upon a shore; though doubtless a great proportion of the shingle we see has been rounded in that manner. Melted stone, thrown out of a volcano, and propelled through water with great velocity, might be rounded and cooled as shot are when dropped into water from a tower. In modern volcanoes we observe that some matter is thrown into the air, while other, and the greater quantity, runs over the edges of a crater, overflowing the adjacent tracts of land.

Proceeding to the west coast of South America, we find that near Concepcion there are beds of marine shells at a great height above the level of the sea. These, say geologists, were once under the ocean, but, in consequence of the gradual upheaval of the land, are now far above it. They are closely compressed together, and some are broken, though of a very solid and durable nature; and being near the surface of the land are covered with only a thin stratum of earth. They are massed together in a manner totally different from any in which they could have grown, therefore the argument used in Patagonia is again applicable here. But in addition to this, there is another fact deserving attention: namely, that there are similar beds of similar shells, (identical with living species) about, or rather below the level of the present ocean, and at some distance from it.†

In crossing the Cordillera of the Andes Mr. Darwin found petrified trees, embedded in sandstone, six or seven thousand feet above the level of the sea: and at twelve or thirteen thousand feet above the sea-level he found fossil sea-shells, limestone, sandstone, and a conglomerate in which were pebbles of the "rock with shells." Above the sandstone in which the petrified trees were found, is "a great bed, apparently about one thousand feet thick, of black augitic lava; and over this there

* See remarks on tides in the Appendix. † Pages 421, 2, 3.

© The Complete Work of Charles Darwin Online

are at least five grand alternations of such rocks, and aqueous sedimentary deposits, amounting in thickness to several thousand feet."* These wonderful alternations of the consequences of fire and flood, are, to me, indubitable proofs of that tremendous catastrophe which alone could have caused them;—of that awful combination of water and volcanic agency which is shadowed forth to our minds by the expression "the fountains of the great deep were broken up, and the windows of heaven were opened."

The upheaval of the island of Santa Maria has been quoted by geologists, from my statement; and it will be interesting to learn whether that island has remained at its new elevation, or whether, like the shore at Talcahuano,† it has sunk down again. If the coast in that neighbourhood has been gradually rising, it is strange that old Penco Castle should still stand so low (p. 421).

In Mr. Lyell's Elements of Geology,‡ he mentions Mr. Darwin having found, near Callao, "at the altitude of eighty-five feet above the sea, pieces of cotton thread, plaited rush, and the head of a stalk of Indian corn, all of which had evidently been imbedded with the shells" (marine). "At the same height on the neighbouring mainland, he found other signs corroborating the opinion that the ancient bed of the sea had there also been uplifted eighty-five feet, since the region was first peopled by the Peruvian race." The neighbourhood of Lima has suffered from immense waves caused by earthquakes, and the relics found among the shells may have been scattered by one of those waves. The bed of shells may have been disturbed by the earthquake and its consequences, the ground may have been rent, and afterwards closed again, or the opening may have been filled up by loose earth and anything lying on it, as has taken place at Concepcion. That the country near Callao, or Lima, has not been upheaved, to any sensible amount, since the last great earthquake, which was accompanied by a wave that

* Mr. Darwin's letters to Professor Henslow: printed for the Cambridge Philosophical Society—1835.

† See pages 420-1. ‡ 1838, pp. 295-6.

© The Complete Work of Charles Darwin Online

swept over and destroyed Callao, is evident from the present position of a pillar erected soon after that event to mark the place to which the waves advanced inland.* This pillar now stands so low, that waves, such as those which ruined Talcahuano, would inevitably reach its base; again destroying the whole of Callao, still situated on a flat, very few feet above the sea, near where old Callao stood.

I have now mentioned the principal facts connected with the Beagle's voyage, which I am desirous of noticing with reference to the Deluge. Want of space prevents my adding others: I have hardly room left to lay before my young readers some general considerations, arising partly out of these facts, which I hope may interest—perhaps be useful to them.

When one thinks of the Deluge, questions arise, such as "where did the water come from to make the flood; and where did it go to after the many months it is said to have covered the earth?" To the first the simplest answer is "from the place whence the earth and its oceans came:"—the whole being greater than its part, it may be inferred that the source which supplied the whole could easily supply an inferior part:—and, to the second question,—"part turned into earth, by combination with metallic bases; part absorbed by, and now held in the earth; and part evaporated."† We know nothing of the state of the earth, or atmosphere surrounding it, before the Flood; therefore it is idle and unphilosophical to reason on it, without a fact to rely on. We do not know whether it moved in the same orbit; or turned on its axis in a precisely similar manner;—whether it had then huge masses of ice near the poles;—or whether the moon was nearer to it, or farther off. Believers in the Bible know, however, that the life of man was very much longer than it now is, a singular fact, which seems to indicate some difference in atmosphere, or food, or in some other physical influence. It is not so probable that the constitution of man was very different (because we see that human peculiarities are transmitted from father to son), as it is to suppose that there was a difference in the region where he existed.

* In 1746.

† Electricity may have acted a prominent part in these changes.

© The Complete Work of Charles Darwin Online

It is easy to settle such speculations by the reflection—"It was the will of Him who is Almighty;" but as in most cases we see that secondary causes are employed to work out His will, we may imagine that the extraordinary prolongation of man's existence was effected by such means.

Connected with these questions respecting the additional quantity of water is the reflection that the amount must have been very great. This may be placed in another light. Sir John Herschel says,* "On a globe of sixteen inches in diameter such a mountain (five miles high) would be represented by a protuberance of no more than one hundredth part of an inch, which is about the thickness of ordinary drawing paper. Now as there is no entire continent, or even any very extensive tract of land, known, whose general elevation above the sea is any thing like half this quantity, it follows, that if we would construct a correct model of our earth, with its seas, continents, and mountains, on a globe sixteen inches in diameter, the whole of the land, with the exception of a few prominent points and ridges, must be comprised on it within the thickness of thin writing paper; and the highest hills would be represented by the smallest visible grains of sand."—Such being the case, a coat of varnish would represent the diluvial addition of water; and how small an addition to the mass does it appear!

Let us now refer briefly to the recorded account of the Flood. Without recapitulating dates and events, I will at once advert to the ark:—an immense vessel,† constructed of very durable wood,‡ and well stored with vegetable provision for all that it contained. Some cavillers have objected to the heterogeneous mixture of animals embarked; on the ground that they could not have been assembled; and would have destroyed one another. We may reply: He who made, could surely manage. But, without direct miraculous interposition (though we should never forget that man is a miracle, that this world is a miracle, that the universe is a miracle), imagine the effect that would be produced on the animal creation by the approach of such a war

* Treatise on Astronomy, Cabinet Cyclopædia, page 22.

† Sharon Turner, Harcourt, Burnett, &c.

‡ Some of our English ships have lasted more than a century.

© The Complete Work of Charles Darwin Online

of elements. Do we not now find animals terrified by an earthquake—birds shunning the scene of violence,—dogs running out of a town,* and rats forsaking a sinking ship? What overcoming terror would possess the animated beings on an island, if it were found to be rapidly sinking while worse than tropical torrents, aggregated water-spouts, thunder and lightning, earthquakes and volcanic eruptions united to dismay, if not to paralyse, the stoutest human heart: yet such probably would be but a faint similitude of the real deluge. Those who have themselves witnessed the war of elements, in some regions of our globe, are perhaps more able to conceive an idea, however inadequate, of such a time, than persons who have scarcely travelled beyond Europe, or made more than ordinary sea voyages. Happily for man, hurricanes or typhoons occur but rarely: earthquakes, on a great scale; their overwhelming waves; and devastating eruptions of volcanoes, still less often. That the approach of a general calamity would have affected animals, what we now see leads us to infer, and that many would have fled to the ark, is only in accordance with the wonderful instinct they are gifted with for self-preservation. Proud man would, in all probability, have despised the huge construction of Noah, and laughed to scorn the idea that the mountains could be covered, even when he saw the waters rising. Thither, in his moral blindness, he would have fled, with numbers of animals that were excluded from the ark, or did not go to it; for we do not see all animals, even of one kind, equally instinctive. As the creatures approached the ark, might it not have been easy to admit some, perhaps the young and the small, while the old and the large were excluded?† As we do

* Concepcion and Talcahuano, pp. 403, 5.

† The small number of enormous animals that have existed since the Deluge, may be a consequence of this shutting out of all but a very few. We are not told how many creatures died in the ark; some of those least useful to man may have gone: but, even if none died, the few that quitted the ark could hardly have long withstood the rapid increase of enemies, unless their increase had been proportionably quick. Whether Job had himself seen, or only heard of, the leviathan and the behemoth, does not appear; but that those monsters were the megalosaurus and the iguanadon

© The Complete Work of Charles Darwin Online

not know what was the connection or partition of land, before the deluge; how the creatures were distributed; or, what was the difference of climate between one region and another; we cannot say that any particular kind could not have been near the ark because of crossing the sea, or having far to travel.

There is abundant proof that animals have changed their habits, shape, coat, colour, or size, in consequence of migration, or transportation to different climates; therefore we cannot tell, from what is now seen, what alterations have taken place since their second dispersion.

Many able men* have pointed out how water penetrating to metallic bases, may cause volcanic eruptions; how matter thrown up, and materials torn or washed off the earth may have combined, mechanically as well as chemically; how gases may have assisted the transformations: how creatures may have been instantaneously overwhelmed, or gradually entombed; how lime may have been one among many powerful agents; how seeds, and spawn, and the germs of insects may have been preserved; and why, among such multitudes of fossil remains as we now find, only in a few places are there remains of man incontrovertibly fossil.†

don there seems to be little doubt (Burnett, p. 67.) Excepting the serpent in Africa, which opposed the passage of Regulus and a Roman army, I am not aware whether profane history mentions any well-authenticated instance of such enormous reptiles; but I cannot look at our representations of dragons, wyverns, griffins, &c. without thinking that, at least, tradition must have handed down the memory of some such monsters; even if a stray one here and there did not actually live in the earlier historical ages: pterodactyles, plesiosauri, ichthyosauri, &c. are too like them, in general figure, to admit of this idea being treated as altogether chimerical. Tradition, no doubt exaggerated by imagination, may have handed down the fact of such creatures having once existed: indeed the casual finding of a skeleton might confirm reports, if not originate them.

* Davy, Sharon Turner, Fairholme, Burnett, Granville Penn, Sumner, Young, Rhind, Lyell, Cockburn, &c.

† These fossil remains of man are not only mixed with those of animals, or fish; but in some cases they are buried at a distance beneath fossil bones of animals.—See Fairholme on the Mosaic Deluge, pp. 41—52; Miers's Chile, vol. i. p. 455, &c.

© The Complete Work of Charles Darwin Online

Still there are some points but lightly touched, or unnoticed, by any person whose works bearing particularly on this subject I have yet seen. One is the rapidity with which certain substances combine under water, and form stone; such, for instance,* as those used in Roman cement:—another is the possibility of fragile substances, such as shells, small creatures, leaves, corallines, branches, &c., being enveloped in a muddy matrix, while floating at various depths, according to their specific gravities; and the precipitation (chemically speaking) or consolidation, or simple deposition of such cohering masses.†

The similarity of coal to asphalte inclines one to suspect an identity of origin; and that coal, in a fluid state, enveloped quantities of vegetable matter—was for some time agitated by the continual tides and tidal currents of the diluvial ocean, and afterwards hardened by cooling, by pressure, or by chemical change; if not by all three. We find the impressions of leaves, stems, and branches—and even large woody trunks embedded in coal: but that the matrix, in which the leaves were enveloped and subjected to pressure, was not triturated vegetable matter is probable, because the casts of delicate vegetable substances found in it show few, if any, signs of friction or maceration. The impressions are as beautifully perfect as those of shells in fossils where the shell itself has disappeared. Might we not as well say that limestone was formed out of decomposed or pulverised shells, as assert that coal was formed out of the luxuriant herbage, the ferns and the palms, of a former state of the world?

Asphalte is at first buoyant; that trees and other vegetable productions are so I need not remark; but coal sinks in water, and asphalte may be altered chemically so as to sink like coal. Experiments on the asphalte of the famous lake at Trinidad have proved that there is so very close an analogy between that substance and coal, that a gas, exactly resembling coal gas, and

* Lyell, Elements of Geology, 1838, p. 75-6.

† The simplest experiments with pulverised, or numerous minute substances in water, shew that they attract one another mutually, and then cohere.

© The Complete Work of Charles Darwin Online

burning equally well; a bituminous oil; a substance like coal-tar; and a residuum, similar to coke; result from its distillation.

Electricity may have been a powerful agent in crystallization; in the rapid deposition of strata;* in the formation of mineral veins;† in earthquakes and volcanoes; in the formation or decomposition of water; and in other ways of which we are yet, and perhaps ever shall be, totally ignorant.

Successive strata may have been rapidly deposited by tidal oscillations and currents, aiding chemical or mechanical combinations.

The depth to which bodies would sink in an ocean several miles deep has not been proved, and there is reason to think that it is much less than people generally imagine. An eminent man has said that a knowledge of "the depression of the bed of the ocean below the surface, over all its extent, is attainable (with whatever difficulty and however slowly) by direct sounding;"‡ and, in consequence of a conversation on this subject with him in 1836, he wrote to me, suggesting a mode which might be tried. I consulted with a friend as to the possibility of success, and his letter,§ taken in connection with the facts

* Crosse. † Fox.

‡ Treatise on Astronomy, by Sir John Herschel—Cabinet Cyclopædia—page 154.

§ "I return Sir John Herschel's letter on deep-sea sounding. Anything from him is sure to be interesting and instructive; but there is a circumstance unnoticed in his communication which might obstruct the descent of a sounding apparatus to very great depth.

"Mr. Perkins found that at a depth of only 3,000 feet, sea-water was compressed 1-27th of its bulk at the surface. (Libʸ. of Useful Knowledge, vol. 1. Art. Hydrostatics.) Hydrostatic pressure has usually been estimated from depth alone, assuming that the density of the fluid was uniform; such, however, cannot be the case in an elastic fluid like water, for at great depths, being in a compressed state, it is more dense than at the surface.

"In estimating the amount of hydrostatic pressure at great depths, we should know the vertical height of the column and mean density of the fluid; and since density increases with depth, by reason of superincumbent pressure, the water at great depths must be enormously compressed, and,

© The Complete Work of Charles Darwin Online

related by Scoresby;* with what has been found by those who have sounded to great depths; and with my own practical experience in sounding—has induced me to think that man never will reach the lowest depths of the deepest oceans by any method his ingenuity may contrive;—because the water increases in density with the depth, in a ratio perhaps more than arithmetical. Every seaman knows that in sounding at great depths very heavy leads must be used with ordinary lines, or very thin lines with ordinary leads; the object being the same—that of overcoming the augmenting buoyancy of the line by a weight unusually heavy. But line, such as is used for sounding, is not buoyant at the surface of the sea; a coil of it thrown overboard sinks directly. Then what is it that causes any weight attached to a sounding-line to sink slower and more slowly,

and, consequently, in a very dense state. Let us now inquire how increasing density (from compression alone) might affect an apparatus sent down by a weight, in order to reach the bottom, presuming that the solids composing the float and sinker were incompressible, and retained their form and magnitude during the operation.

"Let bees'-wax be a float, and cast-iron a sinker, and let each, for illustration, be one cubic foot in dimensions. Let it be possible that at some depth water may be compressed into one-fourth of its bulk at the surface, and still retain the properties of a fluid; let it also be granted that a solid will swim if specifically lighter than the contiguous fluid, and sink if heavier than an equal volume of the fluid. The specific gravity of bees'-wax is stated to be 964; that of cast iron, 7248; and that of sea-water at the surface, 1028: hence the buoyancy of wax immersed in sea-water at the surface, may be called 64, and the tendency of cast-iron to sink, from the same surface, 6220. Deducting 64, we have 6156 as the whole tendency of the mass (wax attached to iron) to sink from the surface. Let us now suppose that the machine has attained a depth where the water is compressed into a four-fold density, represented by 4112 for a cubic foot; and we have 3148 for the tendency of the wax to float, but only 3136 for the tendency of the iron to sink: and the inclination to ascend rather than descend, might be represented by 12. Thus we see that an apparatus may not be certain of arriving at the bottom of an ocean: as in an opposite manner, a balloon may not reach the highest regions of the atmosphere. Either machine could only attain a position where there would be no tendency either to descend or ascend.

Plymouth, 24th Feb. 1837. "WILLIAM WALKER."

* Scoresby's Arctic Regions.

© The Complete Work of Charles Darwin Online

after the first few hundred fathoms, the deeper it penetrates; if not the increased resistance to sinking, found by the weight and line? "Friction, caused by passing through the water," I may be told. Can that friction be compared with the augmented tendency to sink that would be given by the continually increasing weight of line, if the water did not increase in density?

The pressure of the column of water over any weight, after it has been sunk some hundred fathoms, is shown by the time and exertion required to haul it up again. The operation of sounding in very deep water, with any considerable weight, occupies several hours, and a great number of men. That water is elastic has been proved by Canton's experiments as well as others: but there are familiar illustrations of this fact visible in ricochet shot, in 'ducks and drakes,' in the splashing of water, and in the rebounding of rain-drops from water. Being elastic, and the lower strata being under enormous pressure, it follows that those strata of water must be more dense than the body above them. No one doubts that the lower regions of the atmosphere are denser than the higher; yet air is but a rarer and much more elastic fluid than water. That which takes place in air, to a great extent, may be expected to occur in a very diminished degree with water. If it were not so, why should stones be blown up, casks violently burst, or rocks suddenly torn asunder by the application of the principle usually described as the hydrostatic paradox? If the water were not highly compressed before the explosion takes place, would there not be a gradual yielding, a tearing asunder by degrees, instead of a sudden and violent bursting?

The object of this digression is to show that although bodies which are not buoyant may sink to a considerable depth, it does not follow that they must sink to the bottom. Each separate thing may sink a certain distance, in proportion to its specific gravity, and there remain. The greatest depths ever reached by heavy weights, attached to lines, do not exceed a mile and a-half; a small distance, probably, compared with the depth of the diluvial flood.

Although metals, stone, rock, or coal may have sunk deeply in

© The Complete Work of Charles Darwin Online

the waters, other substances, such as earth, mud, bones, animal and human remains, &c., may have been held at various depths until decomposed by water; or combined and consolidated by volcanic gases, or electric currents. In this manner the preservation of delicate corallines, shells, skeletons of animals, &c., may be accounted for. Suspended in water, surrounded by earth in a dissolved state, combined by chemical agency, deposited on land, and consolidated by pressure, by volcanic or by latent heat, they may have become fossils. Thick skinned animals may have floated longest, because their hides would have buoyed them up for a greater length of time,* hence their remains should be found near, or upon the surface of the ground, in some cases water-worn, in others uninjured, according as they had been strewed among shingle, or deposited in a yielding mass. That bones were not rolled about much among the stones in which they are found,† is evident from the fact that bones, if so rolled among them, would soon be ground to powder. It is clear that, however much the bones may have been water-worn before deposition on land, both they, and the adjacent shingle, must have been deposited there nearly about the same time.

Tripoli stone, and other substances composed chiefly, if not entirely, of microscopic insects, may have been formed by the accumulation and cohesion of myriads of such minute creatures, swept together off the land, like swarms of locusts, aggregated by the rolling of the waves, agglutinated, deposited on the land, and afterwards heavily compressed. Or they may have been insects bred in water; such as those which Mr. Darwin calculated to amount to "one hundred thousand in a square inch of surface;" while the sea was streaked with them for a great distance.‡ Microscopic objects such as these may have been killed by some gas rising from a volcano beneath; then drawn together by mutual attraction, rolled over and

* When 'blown' after putrefaction began.

† Those, for instance, of Blanco Bay, p. 112.

‡ Darwin's Letters to Professor Henslow, printed for private distribution among the members of the Cambridge Philosophical Society: in 1835.

over, and landed among other recent compositions. In what other way could such a mass of these animalcules be heaped together?

There are also effects of existing causes which authors have only mentioned by name, in reference to the Deluge, without explaining that the effects alluded to would have been enormously increased at that time;—I mean the tides.—In the Appendix to this volume is a short statement of the manner in which tides may act—upon the principles of the ocean oscillating in its bed; and of tides being caused, partly by the water being elevated by the moon and sun, partly by a westward momentum given to it by their attraction, and partly by the oscillation caused by the return of the fluid after being elevated. If this globe were covered with water to the height of a few miles above the present level of the ocean, three more particular effects would take place: an enormous pressure upon the previously existing ocean, and on all low land; a diminished gravity in the uppermost waters, resulting from their removal from the earth's centre; and immense tides, in consequence of the increased depth of the mass, the diminished weight of the upper fluid, and the augmentation of the moon's attraction. As the waters increased on the earth, the tides would also increase, and vast waves would rush against the sides of the mountains, stripping off all lighter covering, and blowing up,* or tearing down, enormous masses of rock. Similar effects would take place as the diluvial ocean decreased, until it became bounded by its proper limits. Such oscillations I conceive to be alluded to by the words "going and returning,"† and by the expression, "they go up by the mountains; they go down by the valleys;"‡ which exactly describes the rushing of enormous waves against high land. When a wave strikes against a rock, it dashes up every projection that opposes it; but—its impetus at an end—down the water runs

* By the extraordinary power, or principle, called the hydrostatic paradox.

† Gen. viii., v. 5, marginal translation.

‡ Psalm civ. ver. 8.

© The Complete Work of Charles Darwin Online

again through cavities and hollows: such, on a grand scale, would be the effect of a diluvial wave urged against a mountain side.

In such a war of waters, earth, and fire; a buoyant, closed-in vessel—without masts, rudder, or external 'hamper' to hold wind, or catch a sea—might have floated uninjured; and the fewer openings, of any description, in her cover, or sides, the better for her security. Seeing nothing of the conflict around might have diminished the excessive terror which must have been felt by those that were within, except the confiding Chief. We do not find that the largest or highest 'swell' injures a good 'sea-boat,' when in deep water, and far from land: the foaming 'breakers' alone destroy. But, after all, such conjectures as these are vain, we cannot now know how far miraculous interposition extended—how far secondary causes were employed.

The landing of the ark on a mountain of middle height appears remarkable; because the climate of the highest, on which we might naturally suppose the ark rested, did we not know to the contrary, might have been insupportable during the time that Noah waited for the recess of the waters.* Reasoning from existing circumstances, the temperature of the surface of the ocean would have been nearly that of the contiguous air: but after the waters had receded, high mountain tops would have gradually acquired their present frozen state.

Here the reflection arises—when did icebergs begin to appear? Was not the climate equable and temperate all over the world for some time after the Deluge, in consequence of the slow drying and warming of tropical regions, and gradual formation of ice near the poles? Such a condition of climate would have favoured the distribution of animals. Those who oppose

* The Deluge began in the six hundredth year of Noah's life, in the second month, and seventeenth day of the month (Gen. vii. 11),; and Noah quitted the ark in the six hundred and first year, in the second month, and twenty-seventh day of the month (Gen. viii. 14), making a period of twelve months and ten days. Noah waited in the ark nearly five months after it grounded on Ararat.

© The Complete Work of Charles Darwin Online

the idea that animals migrated to various quarters of the globe, surely do not reflect that the swallow, the wild swan, the wild goose, the wild horse, the Norway rat, and numerous other creatures, now migrate periodically in search of food or a better climate. Similar instinct may have taught animals to wander then, till they reached the places suited to them;* and there the same instinct would retain them. Want of proper food, or climate; or the attacks of enemies,† may have destroyed stragglers who did not migrate; therefore, when we find no kangaroos in Europe, it is no proof that kangaroos did not once exist there. Elks are now found in North America—we know they were formerly in Europe—is that race here now? During the first few hundred years after the flood, extraordinary changes may have taken place in the geography of the world, in consequence of the drying and altering of various portions; also from the effects of volcanic eruptions and earthquakes, occasioned perhaps by electric action on newly-exposed land, as well as by other causes. Many places, now islands, may have been united to a continent for a considerable period after the deluge; much land may have sunk down, much may have risen up, in various parts of the world. Such changes are said to be going on even now, though on a small scale (Lyell, Darwin, &c.); what may they not have been during the first few centuries after the flood? Volcanic eruptions, such as those of the Galapagos, Andes, Etna, Auvergne, Indian Islands, &c., were then perhaps in such activity as they have never shown since.

What the division in the earth was, in the days of Peleg, does not distinctly appear: but it could only have been a separation from the true faith; a partition of territory among men; or some mighty convulsion, some rending or contraction,

* We see abundant evidence that either living creatures are adapted to particular climates and localities, or that climates and localities are adapted to particular creatures; which latter, it has been proved by many authors, are altered by any material change of the former.

† It should be remembered, that man was allowed to eat flesh after the flood. Gen. ix. ver. 3.

© The Complete Work of Charles Darwin Online

as it were, of the earth, which was so general as to have occasioned a marked and unqualified record, as of an event well known to all.

Many philosophers think that the world has a central region of surpassing heat, and that the greater part of the interior of the globe is in a state of incandescence, if not of fusion. That small portion which they call the crust of the earth is supposed to be the only cooled part; and they differ merely as to the degree of fluidity in the central region. I take it for granted that they have duly estimated the moon's tendency to cause tides in a fluid mass, within her influence:—if there were no crust, of course she would cause such an effect, but a well hardened case, we must suppose, can resist any such movement in the central fluid mass. Upon the principle of the arch, it would be easier to imagine resistance to pressure from without than from within; but the case or crust of our globe must be so solid that it neither yields nor vibrates to an internal expansive force.

This theory, however, is unsupported by any satisfactory evidence. Men of character and attainments have advocated it, although resting on conjecture: but when we look back along the roll of history, and discover so few philosophers who have not greatly erred, although famed in their day, it is natural to pause, and not acquiesce hastily in mere human assertion unsubstantiated by proof. Boring the ground, or examining the temperature of the bottom of a deep mine, affords no estimate for that of the central regions:—Sir John Herschel says,* that "the deepest mine existing does not penetrate half a mile below the surface; a scratch or pin-hole duly representing it on the surface of such a globe, (sixteen inches in diameter), would be imperceptible without a magnifier." As our globe is about eight thousand miles in diameter, and external influence may be supposed to penetrate some distance, we can draw but unsatisfactory conclusions from experiments at depths not nearly so great even as that to which

* Treatise on Astronomy; Cabinet Cyclopædia, p. 22, Art. 30.

© The Complete Work of Charles Darwin Online

the ocean descends, and made chiefly in temperate or cold climates.

Having no pretension to more knowledge than any observant seaman may acquire in the course of a few years active employment afloat, it would be as vain as presumptuous in me, were I to offer any conjecture about the central mass of the earth. Perhaps, at a future day, when the nature of aerolites; the agency of electricity; and of electric communication through the superficial, if not through the interior regions of the globe, are better known, other opinions, respecting this wonderful world which we inhabit, may be formed by philosophers.

I have now fulfilled my intention of endeavouring to be useful, in however small a degree, to young persons of my own profession. If the few remarks laid before them, in this and the preceding chapter, at all increase their interest in the subjects spoken of; and tend, even in the least, to warn them against assenting hastily to new theories—while they induce a closer examination into the Record of truth—my object in writing them will be fully attained.

1829), 393-395 — expeditions under Lieut. Sulivan, Mr. Chaffers and Mr. Mellersh at Galapagos, 485, 486, 489-497.

Boroa Indians, light-coloured, origin, 402—further notices, 465.

Brett Cape, 564, 565.

Brightman Inlet, fish, 295.

Brisbane, Mr. 270—account of ruin of Port Louis, 271—murdered, 327, 328—burial, character, shipwreck, 332-335.

Butterflies, singular flight of, 117.

Button Island, 223.

Bynoe, Mr. Benjamin, 19, 21—skill and kindness, 77, 78 — accompanies Fuegians on shore, 127—anecdotes, 180, 181—account of Indians near Gulf of Trinidad, 197, 198—remarks on Easter Bay, large deserted canoes and wigwams, 199—various notices, 200—at Woollya, 320—River Santa Cruz, 337-356 — lands on James Island, Galapagos, 497—weather during stay, 500.

Calbuco, meaning of word, 377—origin of name, 387.

Calbucanos, mode of life, 390—alerse planks, astillero, 391 — loads, landslips, 392.

Callao, 482.

Camarones Bay, wood, water, grass, Indian tombs, 305.

Carlos, San, 363—climate, 386.

Carmen, Del, Nuestra Señora, Patagonians near, 145—situation, houses, 298—fort, inhabitants, 'Estancia del Rey,' settlers, Indians, 299—anecdotes, 300—customs and manners, trade, coal, 301 — Paz and Liebre there, 311—wild fowl, hunting, Indian attack in 1783, 313, 314.

———, American schooner, hired to go for Challenger's crew, 468—met dismasted, 473 — sketch of cruise, 474, 476.

Carrasco, Don Eduardo, Hydrographer at Lima, renders material assistance to Expedition, 484.

Castro, 382—climate, 386.

Catharina, Santa, good harbour, inhabitants, 83.

Cattle, wild, hunt, at Falklands, 279-281.

Cavahi Island discovered, 508.

'Cesares, Los,' rumours of settlement, 287—Spaniards' visit and description of it, 392, 393.

Chaffers, Mr. 270—sails in Adventure, 274—at Gorriti, 284—examines inlet and river at Port Desire, 316, 317—ascends River Santa Cruz, 337—examines Hood Island, and other places in Galapagos Islands, 485, 497.

Challenger, H.M.S. at Falklands, 328—search for murderers, 329, 331—report of loss, 428—confirmed, 429—Blonde sails to assist, 430—party go over land, 431 — ferry, estate, Don Juan Rivera, 432, 433—Colcura, 434—Villagran, Chivilingo, 436—coal, Carampangue, 437—Arauco, 437-442—country, Indians, 443—Quiapo, 444—bad travelling, 445, 446—Tucapel, Valdivia, 447, 448 — Leübu, party reach Challenger's crew, 449—account of wreck and subsequent events, 451-460 — party's return, Quiapo, 'Ulpu,' cattle, 461 — river, rancho, 462—Araucanians, 463, 464—Boroanos, Tubul River, 465—journey, 466, 467—Blonde, 469—goes to relieve Challenger's crew, 469—delays, mistake, 470, 471—reach Leübu, 472—embarkation, 473 — Talcahuano, 475—H.M.S. Conway receives crew and sails, 479—causes of wreck, 480.

Chiloé, inhabitants, 379—Indians, religion, 380—foreign settlers, kindness, barter, 381—fish, coal, towns, discovery, 382 — population, decrease, mines, 383—early notices, name, pirates, Spaniards, 384 — Indians' regret of Spanish government, tithes, oppression, 385 — anecdote, tasks, patriots, climate, 386—good sites for docks, tide-streams, 387 — Chilote voyages, 392—deserters, Padre Forastes, expedition, 394—'vaqueano,' search, 395 — meteoric appearances (note), 395—earthquake, 416.

Chiut Island, strawberries, 387.

Chonos Indians, 130-142—boy on board Adeona, cannibalism, hostilities, 189—'Niqueaccas,' quickness, religious ideas, ceremony, 190—burial-places,

© The Complete Work of Charles Darwin Online

anecdote, 'cubba,' 191—charm, sagacity, local knowledge, pilotage, 192, 193—mode of declaring war, honesty, anecdotes, 195, 196—at Chiloé, 380—former numbers, 383.

Chonos Archipelago explored, 363-366—notices, early voyages, 367-369—further remarks, 374-377.

Chupat River, discovered, 306 — described, Spaniards, cattle hunts, 307—entrance, 308, 309, 353.

Clive, Lieut., burial, 335.

Clouds, remarks on, 65, 66, 502—over low land, 506, 507, 563.

Cobija, 481.

Cockburn Channel, bad weather, Beagle under sail in, 359.

Colcura, heights of, hamlet, 434, 435.

Coliumo, 417, 424.

Colorado River, wolf seen near, 251, 295, 296 — communication with Union Bay, 296—gale, 'freshes,' 302.

Concepcion, earthquake, preceding signs, 402—destruction of city, 403, 404—situation, anecdotes, 405 — mutual assistance, 406 — waves, 413-417 — elevation and depression of land, 420—fossil shells, 421-423—coal, 424—re-visited, re-building, houses, Peruvians, 476, 477—country, 479.

Conchali, smuggling, 426.

Constitucion, vessel lent by Don Francisco Aguilar, goes with Mr. Usborne, 283, 284.

———, another vessel so named, lent by Don Francisco Vascuñan at Coquimbo, surveys coast, 427 — at Callao, usefulness, 482 — bought to survey coast of Peru, 483—sails, 484—(for proceedings see Sulivan, and Usborne).

Conway, H. M. S., passing through quantities of pumice-stone and ashes, 108, 109—receives crew of H.M.S. Challenger, 479.

Coquimbo, 427-479.

Corcovado, volcano, 376, 394.

Corrientes, Cape, rocks, 99 — reported shoal, 292.

Cruz, Santa, capital of Teneriffe, appearance, 48.

———, river, explored, 336 — estuary, banks, 'steppes,' cliffs, 337 barrenness, animals, climate, 338—mud-banks, tides, views, 339—water, 340—change of scenery, cold, 341—tracking, instruments, 342—frost, ostriches swimming, 343 — rapidity of stream, smoke, Indian tracks, 344—'Indian Pass,' rapids, windings, quantities of shingle, 345—heights, wastes, want of fuel, 346—temperature of air and water, earth cliffs, progress, lava cliffs, 347 — lava district, 'Basalt Glen,' wild scene, 348—mirage, drift-wood, boat stove, Andes, 349—guanacoes, birds of prey, bed of river, 350—views, weather, country, 351—walking party, direction of river, 352 velocity, trees, water, colour and temperature, drainage of Andes, sources, 353—Lake Viedma, or Capar, rivers, floods, 354—level of river, bones, 355—wild cats, return, mountains, rapid descent, fish, 356.

Currents near Bahia, 60, Abrolhos, 64—near Cape Frio, 70, 71—in Plata, 93, 226—from Tierra del Fuego and Staten Land to Falklands, 242, 243—near Mocha, 419 — extraordinary, 480—near Galapagos, 484, 486, 488, 496—and temperature, 505, 562—Bay of Islands, 563—on passage from New Zealand to Port Jackson, temperature of water, 621—near North Keeling Island, 638.

Cutfinger Cove, striking scenery, immense canal, 202.

Dangerous Archipelago (see Low Islands).

Darwin, Mr. Charles, volunteers as naturalist, 18, 19 — fossils near Point Alta, 106 — pumice-stones, 108—accompanies party with Fuegians on shore, 127—goes in westward exploration, 215—saves boats, 217—at Maldonado, 284—plans, 286—at Argentina, 288—River Negro, 312—obtains interesting account of Indian attack on Carmen, 314 — search for fresh water at Port San Julian, 320 — ascends Santa Cruz, 327—goes away at Chiloé with Lieut. Sulivan, 364—rejoins Beagle, 366—excursions, 379-425 — lands on James Island, 497-500—at Otaheite, 510-512—notices of natives, 522, 527, 543, 557—at New Zealand, 570—arrival in England, 638.

Tahiti (see Otaheite).

Tairo Island, discovered, 508.

Talcahuano, 402 — great earthquake, rise of sea, effects, 406, 407 — dogs, shipping, 408—anecdotes, motion of sea, 409—sub-marine explosions, fish killed, 410—height of wave, contrasts, 411—Araucanian boys, 478.

Taytao, or Taytaohaohuon Cape, rocks, 372.

Teneriffe, view of Peak, 47—measurements from thence, quarantine, 48.

Thetis frigate, account of her loss, 66-70—causes, 70, 71.

Tide in Plata, 89, 93—near Point Rubia, 116—near Cape San Diego, 120—in S.W. arm of Beagle Channel, 219—stream of tide near Falklands, 226 — strength, direction, times, height, 241, 242 — off Point Rasa, 297—rise in St. George Bay, 304—off Ship Island, and Cape Dos Bahias, race near New Bay, 305—Valdes Creek, 309 — terrific 'races' there, 310—ripplings and races near Port San José, 311, 312—in First Narrow, 321 — in Santa Cruz, 337, 339 — velocity of river, 340, 344, 351—at Ipun, May Harbour, 375—near Chiloe, 387, 388—off 'Three Kings,' direction, temperature, 620.

Tolten River, Indians, coast near, bar, 402.

Toriano, an Araucanian cacique, death of, 106.

Tosca, 99, 100.

Topocalma shoal, 425.

Trinidad, Gulf of, natives, a fine race, feathers, paint, 197 — plank canoes with oars, arms, 198.

Tubul River, 414.

Tucu-tucu, the, 313.

Tuyu, mud-bank, 292.

Unicorn schooner, 273 — considerations, purchased, named Adventure, (see Adventure).

Union Bay, 286, 287.

Usborne, Mr. Alexander Burns, 20—goes in 'Constitucion' to assist Mr. Stokes, 283—returns to Beagle, 288, 314, 315—goes away in boats, 364—at San Carlos, 378—takes command of Carmen schooner to Leübu river, meets Blonde, 469—bad weather, adventures, 474 — escape, skill, 475—takes command of another vessel called 'Constitucion,' plan of expedition, 483—receives kind assistance, 484—return to England, having completed his survey, 638, 639.

Valdes Creek, entrance, 98 — tides, shifting bar, dangers, 309, 310.

Valdivia, port, forts, rivers, 'Yntendente,' secretary, 397—town, aborigines, 398-401—convicts, 401—great earthquake, motion, 415 — shocks, 416.

Vallenar Road, 366, 369.

Ventana Mount, mines, 105 — height, 109, 295.

Verde, Cape, Islands, observations on anchoring, gales, 51, 52—exports, 53—'orchilla' weed, vegetables, sickly season, 54—dust, 55.

Vernet, Louis, appointed 'comandante' at Falklands, proceedings, 238, 239, 255—settlement, 266—delusion, 267—ruined 268.

Video, Monte, mutinous negroes, 95.

Villagran, battle, Ercilla, 435, 436.

Villarica mountain, height, 481.

Villarino, 314.

Virgins, Cape, 222, 357.

Waimate, 598 — situation, appearance, corn, gardens, farm, 601—cattle, poultry, houses, 602—barn, water-wheel, 604—mill, Shunghi's grave, English oaks, missionary families, 604—spirit, 606—valley, Kauri pine, woods, 606.

Water, white, extraordinary space of sea, supposed cause, 118.

Weddell Bluff, 340.

Whale-boat Sound, 218.

Wickham, Lieut. John Clement, 14, 21—takes command of Paz and Liebre, 111, 112, 116, 117—examines Indian graves, 168—cattle-hunt, 280-282—arrives to take command of Adventure at Gorriti, 284 — proceedings in Liebre, 295 — remarks on coast near Point Rasa, 297—Rio Negro,

© The Complete Work of Charles Darwin Online

298—Del Carmen, 299—on Indians and Spanish settlers, 300, 301—in Blanco Bay, River Negro, 302—at Port Desire, 303—discovers Chupat River, 306, 307—in great danger, 310—plans, 322—meets Mr. Low, engages him as pilot, at Port Louis, 331—sails again, 332—in Port Famine, 358, 360—at Valparaiso, Santiago, 361—returns to Beagle, 362—arrives in England, 638.

Wigram, Rev. Joseph, kindness to Fuegians, 10, 11.

William, Port, (Falklands) 227—tides, 242—suggestions for a settlement, advantages, 261, 262—accessibility, exports, 263.

Whylootacke, or Wailutaki, 557.

Williams, Corporal, drowned, 282, 302.

Wilson, Rev. William, admits Fuegians into infant school at Walthamstow, 10—kindness, 11, 12—letter, 14—selects missionary to go out with them, 15, 16.

Wilson, Belford Hinton, effective assistance, 484.

Windhond Bay, 225.

Wolf near Colorado River, 296.

Wollaston Island, 225.

Wood Mount, 319.

Woollÿa, pleasant situation, natives, arrangements, 208, 209—wigwams and gardens made, natives assist, 210—fair prospects, curiosity of natives, 211, 212—boats depart, 214—re-visited, 220—events during absence, 221—missionary removed, difficulties, 222—re-visited, pleasing scene, occurrences, 224—events there, 323-327.

Zealand, New, 564—Kororareka, Tipuna, 565—natives' flag, 566—Paihia, natives, 568—decrease of population, 569—colour, salutation, manner, war-canoes, 571—prospects of country, former savages of Britain, 572, 573—bones, tree, fern, 574—church, 575—British Resident's house, vines, Kororareka, 576—huts, 577—cooking, church, burying-places, 579—anecdotes, Waripoaka, island, 580—Cawa-Cawa, Pomare, estuary, 581—pleasing scenes, traffic, 582—flax, meeting, chiefs, 583—curious dispute, rats, game, 584—precise division of territory, purchase of land, 585, 586—spirits, 'Noah,' native wine, church, 586, 587—oxen, sick, preserving food from damp, nets, burial, 588—Christmas, Divine service, remarks, singing, 589—state of the place, measures, 590—causes of disturbance, 591, 592—suggestions, influence of ships of war, 593—Polynesian interest, resources in Pacific, 594, 597—excursion to Waimate, Waitangi Creek, running guides, activity, country, 599—woods, native village, agriculture, flax, manufacture, 599—chapel, fine-looking native, country easy of access, 600—curious bird, 601—Waimate, 601-606—valley, horses, bridge, woods, Keri-keri waterfall, beautiful scene, 606—English children, natives fond of them, 607—Waripoaka visits Beagle, 'La Favorite,' Rangateedas, 608—political condition, relics, 609, 610—departure from, 611—remarks, 612, 613—settlements, trade, 614, 615—discontent of settlers, 616—pine-forests, 618—North cape—singular superstition, great lizards, 619, 620.

ADDENDA.

In the eighth chapter of this volume, I have omitted to mention that there are meetings held among the Patagonians which might be termed 'courts of justice!'

One such meeting was described to me by an eye-witness:—'Capitan Chico' presided at it, on horseback: he was the only person mounted. The older men of the tribe sat in a ring, upon the ground, as judges (or rather as a council, or as a jury). Within the circle were four prisoners, and twelve witnesses. The trial lasted a whole day: but my informant did not see or hear the result.

The same individual told me that the Patagonians often played at a game like hockey.

These things, among others, call to mind Molina's account of the Araucanians, which some think much exaggerated. Disorganised, dispirited, and exceedingly diminished in numbers, the Araucanians, as we now see them, are scarcely to be compared to those of Ercilla's poem, who are also described by many authors besides Molina.

PART OF
TIERRA DEL FUEGO
from
H.M.S. Beagle
1834
Note. Staten Land from H.M.S. Chanticleer and part of the Strait of Magellaens from H.M.S. Adventure.
This is a partially wooded country, hills of moderate height alternating with extensive valleys.
It is high water in the Strait of Le Maire at five but the flood tide continues to run northward until about six P.M. on the day of new moon. The flood tide is much stronger than the Ebb along all this Coast and it sets from the Westward: but Northward of Staten Island, and the Strait of Le Maire, the flood tide runs North-westward.
Although five and six are the average times, the tides vary much; being sometimes nearly an hour earlier, & sometimes as much later; on the day of full or new moon.
Longitude West from Greenwich
Published according to Act of Parliament by Henry Colburn 1839.

MEMORANDUM.

The greater number of the articles in this Appendix are placed as required for reference while reading the volume to which they belong (vol. ii.); and the arrangement, or rather non-arrangement, of the rest, depended upon circumstances which I could not alter; though quite aware how disorderly the group of documents would appear.

If they should ever require to be reprinted, or even if a part should demand further attention from me, it will be easy to dispose them differently.

* Taken carefully at 9·30 A.M. 9th June, because the ship passed through a meeting of tides between Cape Froward and Magdalen Channel.

† 16th, lost Water Thermometer overboard; and employed another agreeing with Six's Self Registering.

While the Beagle was at Plymouth, in 1831, an excellent marine barometer, made by Jones, (with an iron cistern) was sent by water from the maker's hands. This instrument was suspended in my cabin, with the cistern at the level of the sea (excepting during the first eight months, when it was placed six feet higher), and by it all the barometrical observations recorded in this table were taken or corrected.

In 1836, while conveying the same barometer by land from Woolwich to London, it was seriously injured, and therefore, to give value to its indications while on board the Beagle, I annex some corresponding observations, made at the Royal Observatory, and at Somerset House.

FIGURES USED TO DENOTE THE FORCE OF THE WIND.

0 Calm.

1 Light Air .....Or just sufficient to give steerage way.

2 Light Breeze .....
3 Gentle Breeze .....
4 Moderate Breeze ...
Or that in which a man-of war, with all sail set, and clean full, would go in smooth water from
1 to 2 knots.
3 to 4 knots.
5 to 6 knots.

5 Fresh Breeze .....
6 Strong Breeze .....
7 Moderate Gale .....
8 Fresh Gale .....
9 Strong Gale .....
Or that to which a well-conditioned man-of-war could just carry in chase, full and by
Royals, &c.
Single-reefed topsails and top-gall. sails.
Double-reefed topsails, jib, &c.
Treble-reefed topsails, &c.
Close-reefed topsails and courses.

10 Whole Gale .....Or that with which she could scarcely bear close-reefed main-topsail and reefed fore-sail.

11 Storm .....Or that which would reduce her to storm stay-sails.

12 Hurricane .....Or that which no canvass could withstand.

LETTERS DENOTING THE STATE OF THE WEATHER.

b Blue sky; (whether clear, or hazy atmosphere).
c Clouds; (detached passing clouds).
d Drizzling rain.
f Foggy——f Thick fog.
g Gloomy (dark weather).
h Hail.
l Lightning.
m Misty (hazy atmosphere).
o Overcast (or the whole sky covered with thick clouds).
p Passing (temporary showers).
q Squally.
r Rain (continued rain).
s Snow.
t Thunder.
u Ugly (threatening appearances).
v Visible (clear atmosphere).
w Wet dew.
. Under any letter, indicates an extraordinary degree.

By the combination of these letters, all the ordinary phenomena of the weather may be expressed with facility and brevity.

Examples:—Bcm, Blue sky, with passing clouds, and a hazy atmosphere.

Gv, Gloomy dark weather, but distant objects remarkably visible.

Qpdlt, Very hard squalls, with passing showers of drizzle, and accompanied by lightning with very heavy thunder.

From Callao to Guayaquil the longitudes depend upon Mr. Usborne's survey, in the Constitucion. He had three chronometers fixed on board the vessel, and one which was used for observations; all four were good watches. If his whole meridian distance between Guayaquil and Callao is incorrect, the error, whatever it may be, must be distributed equally along that portion of coast, but I do not think there is an error of two miles; probably, indeed, there is not near so great a deviation from truth, as Mr. Usborne landed for observations continually, and carried a connected triangulation from Callao to Puná.

Keeling Islands—Direction Island—west point	12 05 22	96 54 45	1 12	5 27	5 N.W.
Mauritius—Port Louis—Observatory	20 09 25	57 31 30	11 18	1 02	2 N.W.
Cape of Good Hope—Simons Bay—east end of Dock Yard	34 11 24	18 25 45	28 30	2 30	5
Royal Observatory		18 28 30			
		WEST.			
St. Helena—high water mark, in the meridian of Observatory	15 55 15	5 42 45	18 00	4 50	3W. N.W
Ascension—Barrack Square	7 55 33	14 24 15	13 30	5 30	2 W.
By the Beagle's Chronometers, the meridian distances between Falmouth, Plymouth, Portsmouth, and Greenwich, are as follows:—					
Portsmouth Observatory—R.N. College—from Greenwich Observatory		1 06 07·5			
Devonport (Government House) — from Portsmouth Observatory		3 03 49·5			
Pendennis Castle—Falmouth—from Devonport (Government House)		0 52 46·5			
And Falmouth—Pendennis Castle—west of Greenwich		5 02 43·5			

N.B.—These are identical with the measures of Dr. Tiarcks.

In the foregoing Table, every position, variation, and notice of tide, is the result of observations made by officers of the Adventure or the Beagle, therefore they are, strictly speaking, original, and have no reference whatever to observations made by other persons.

An explanation of the methods and instruments used, and of the basis on which the longitudes, especially, are founded, is given, in an abridged form, at the end of the Appendix.

The positions of those points only are given which are considered to be, generally speaking, satisfactorily ascertained by actual observation on shore, or well connected by triangulation to those stations at which the artificial horizon was used.

Where tidal notices are given opposite to summits of mountains, or other places at some distance from the sea, it is to be understood that they refer to a point at which the sea approaches nearest to that specified.

All the observations for variation, afloat, were taken with a very good Gilbert's compass, placed on a stanchion above the poop, where it was found, by trials in various latitudes, to be nearly free from any effect of local attraction.

APPENDIX.

No. 1.

SIR: March 19, 1831.

Accompanying this letter, I have the honour to transmit to you, for their Lordships' information, six charts and sixteen plans of harbours and portions of the coast of Tierra del Fuego, the results of Commander Fitz-Roy's surveys in H.M.'s sloop Beagle, between April 1829 and June 1830.

Their Lordships will, I trust, permit me, as the senior officer of that expedition, to state the peculiar nature and extent of this service, as well as the complete manner in which it has been effected.

On the melancholy occasion of Commander Stokes's death, I was fortunate, through the Commander-in-chief Sir Robert Otway's just discrimination of Commander Fitz-Roy's qualifications, on account of which alone he was selected, to receive him as my colleague, in the command of the Beagle.

In April I detached the Beagle, and Adventure's tender, to complete portions of the Strait of Magalhaens that were then imperfect; and by him, and under his superintendence and able direction, the Magdalen and Barbara Channels through the Tierra del Fuego were surveyed; a considerable portion of the interior sounds on the western coast was examined; and the discovery of the Otway and Skyring Waters was made, by Commander Fitz-Roy himself, in the depth of the severe winter of that climate, and on which he was absent from the ship thirty-three days in an open whale-boat.

In August the Beagle joined me at Chiloe, and sailed again early in November following, with a view to examine the outward or sea-

© The Complete Work of Charles Darwin Online

coast of Tierra del Fuego, from its westernmost extremity to the Strait Le Maire, including Cape Horn and the islands in the vicinity.

The difficulties under which this service was performed, from the tempestuous and exposed nature of the coast, the fatigues and privations endured by the officers and crew, as well as the meritorious and cheerful conduct of every individual, which is mainly attributable to the excellent example and unflinching activity of the commander, can only be mentioned by me in terms of the highest approbation.

For the results of the voyage, and the services of Commander Fitz-Roy, I beg to refer their Lordships to their Hydrographer and the charts herewith transmitted, which I hope will be satisfactory.

I trust their Lordships will permit me once again to express how much I feel that Commander Fitz-Roy, not only from the important service he has rendered, but from the zealous and perfect manner in which he has effected it, merits their distinction and patronage; and I beg leave, as his late senior officer, to recommend him in the strongest manner to their favourable consideration.

I have, &c.

PHILLIP P. KING, Captain.

To the Hon. GEORGE ELLIOT,
Secretary of the Admiralty, &c. &c. &c.

No. 2.

SIR, London, May 23, 1831.

Enclosed is a copy of the letter sent to Captain P. P. King (then commanding H. M.'s sloop Adventure), by the Secretary of the Admiralty, relative to the natives of Tierra del Fuego, who were brought to England in the Beagle; and I have to request that you will honour me by submitting the enclosed copy, and the purport of this letter, to my Lords Commissioners of the Admiralty.

The proper season for the return of these Fuegians is now drawing near. They have been with me fourteen months, and at least five months more must elapse before they can reach their own shores.

© The Complete Work of Charles Darwin Online

They have always expected to return during the ensuing winter (summer of their country), and should they be disappointed, I fear that discontent and disease may be the consequence.

Having been led to suppose that a vessel would be sent to South America to continue the survey of its shores, and to explore parts yet unknown, I hoped to have seen these people become useful as interpreters, and be the means of establishing a friendly disposition towards Englishmen on the part of their countrymen, if not a regular intercourse with them.

By supplying these natives with some animals, seeds, tools, &c., and placing them, with some of their own tribe, on the fertile country lying at the east side of Tierra del Fuego, I thought that, in a few years, ships might have been enabled to obtain fresh provisions, as well as wood and water, during their passage from the Atlantic to the Pacific Ocean, on a part of the coast which can always be approached with ease and safety.

If their Lordships should so far approve of these ideas as to grant me any assistance in carrying them into execution, I shall feel deeply gratified, and shall exert every means in my power; but should they not be thought worthy of attention and support, I humbly request that their Lordships will grant me twelve months' leave of absence from England, in order to enable me to keep my faith with the natives of Tierra del Fuego, by restoring their countrymen, and by doing them as much good as can be effected by my own very limited means.

I have, &c.,

ROBERT FITZ-ROY, Commander.

To the Hon. GEORGE ELLIOT,
Secretary to the Admiralty, &c. &c. &c.

In June I received twelve months' leave of absence from England, and made the following agreement with Mr. Mawman, a shipowner, of London.

No. 3.

MEMORANDUM of Agreement made the eighth day of June, in the year of our Lord one thousand eight hundred and thirty-one, between John Mawman, of Stepney Causeway, London, merchant,

© The Complete Work of Charles Darwin Online

owner of the brig or vessel called The John, of two hundred tons register burthen, now lying in the London Dock, whereof John Davey is Master, on the one part, and Robert Fitz-Roy, a Commander in His Majesty's Royal Navy, of the other part.

The said John Mawman agrees with the said Robert Fitz-Roy, in manner following :—

That the said master, or such other master as the said John Mawman shall appoint, shall receive the said Robert Fitz-Roy and his friends and servants, not exceeding in the whole six persons, on board the said brig or vessel, and proceed with them forthwith to South America, to such one or two port or ports, or place or places, as the said Robert Fitz-Roy shall order and direct, such port or ports, or place or places, not to be north of Valparaiso ; and at the first port or place, or so near thereto as the said vessel may safely get, to be named by the said Robert Fitz-Roy, to land the said Robert Fitz-Roy and his said friends and servants, or such of them as the said Robert Fitz-Roy shall require, and receive them, or such of them as the said Robert Fitz-Roy shall require, on board again ; and thence forthwith to proceed to the second port or place, or so near thereto as the said vessel may safely get, to be named by the said Robert Fitz-Roy, there to land such of them, the said Robert Fitz-Roy and his friends and servants, as shall not have been already landed at the said first-named port or place, and receive the said Robert Fitz-Roy, and such other or others of the last-mentioned persons, as he shall require again on board the said vessel, and forthwith proceed to and land him or them at Valparaiso.

That the said Robert Fitz-Roy shall be at liberty to put on board stock and provender, at such places as may be agreed upon, port charges and pilotage being paid by the said Robert Fitz-Roy.

That John Mawman will find and provide the said Robert Fitz-Roy, and the said other persons, with all suitable and proper customary provisions, stores, wines, beer, and spirits.

And the said Robert Fitz-Roy agrees with the said John Mawman, his executors and administrators, as follows :—

That he will not detain the said brig or vessel at either of the ports or places to be named by him, as hereinbefore mentioned, any longer than shall be reasonably necessary to enable him and the said other persons safely to land, re-embark, and finally land at the said ports respectively.

© The Complete Work of Charles Darwin Online

That he will pay to the said John Mawman, his executors or administrators, as the compensation for the agreement hereinbefore contained on the part of the said John Mawman, the sum of one thousand pounds sterling, to be paid down prior to embarkation.

As witness the hands of the said parties.

Witness,
W. H. Woollett.
W. Wackerbarth.

Robert Fitz-Roy.
John Mawman.

No. 4.

Salisbury Square,
November 10, 1831.

My dear Sir,

Matthews left town this morning to join the Beagle at Plymouth, being detained till to-day for the steamer.

We have provided Matthews with all such articles as appeared to be necessary for him, and which could be most advantageously supplied in this country. These had all been completed before I learned from Mr. Wilson that you are short of stowage. I hope, however, they will not be found to amount to a quantity to occasion you inconvenience; and I think you will be of opinion that no part of his outfit could, with propriety, be dispensed with, in case Matthews becomes a permanent resident in Tierra del Fuego.

Mr. Wilson and myself concurred in opinion that a letter should be addressed by us to Matthews, in reference to the undertaking on which he is about to enter. This I have drawn up at Mr. W.'s request, and hoped to have procured the addition of his signature to it; but a pressure of other engagements has compelled me to drive it off till it is too late to send it to him for that purpose. I have no doubt, however, that it expresses his general views on the subject. If you should think I have dwelt too much on the religious bearing of Matthews's future labours, you must kindly call to your recollection that I am a Missionary Secretary, and could not altogether divest myself of that character on the present occasion. The letter is enclosed, and we shall feel obliged by your giving it to Matthews, when he comes on board. You will, of course, take a copy of it, if you wish to do so.

© The Complete Work of Charles Darwin Online

I much regret that we could not meet with a suitable companion for Matthews. I trust, however, you will find him to possess many valuable qualifications for the undertaking.

With very cordial wishes for your safety and welfare,

I remain, &c.

D. COATES.

To Capt. FITZ-ROY, R.N.
&c. &c. &c.

No. 5.

Salisbury Square, London,
Nov. 10, 1831.

DEAR MR. MATTHEWS,

The friends by whose means you are enabled to proceed to Tierra del Fuego cannot suffer you to depart without offering to you some suggestions and counsel with regard to your future course.

The undertaking in which you are about to be engaged springs from the benevolent interest taken by Captain Fitz-Roy in the natives of the island of Tierra del Fuego, with whom he became acquainted during his survey of that part of the coast of South America, in which he was employed by His Majesty's Government. Some of them were brought hither by Capt. F. on his return home, about twelve months ago. These individuals, through Capt. F.'s kind exertions, were, during their stay in England, placed under circumstances to receive instruction in the English language, in the principles of Christianity, and in some of the most simple arts of civilized life.

These natives will be your companions on board the "Beagle," a passage to Tierra del Fuego having, at the instance of Capt. F., been granted to them and to you on board that ship, by the liberality of the Lords of the Admiralty.

Some Christian friends having become acquainted with these foreigners, and with Capt. Fitz-Roy's solicitude to promote their welfare and that of the tribes with which they are connected, have supplied the means of providing the outfit, which was requisite to

© The Complete Work of Charles Darwin Online

enable you, advantageously, to enter on the work before you. Among these friends you are especially indebted to the kindness and liberality of the Rev. W. Wilson. His solicitude to forward Capt. Fitz-Roy's views has been manifested toward these Fuegians, as well as yourself, by his having had them under his immediate care at Walthamstow for many months, in order to impart to them such knowledge and information as seemed calculated to promote their present and eternal welfare, and by contributing largely to the fund raised for your use.

From what has been just stated, you will perceive the peculiar obligations under which you lie to Capt. Fitz-Roy and to Mr. Wilson, and the interest which they both take in your undertaking. You will especially consider yourself as bound to act under the superintendence and direction of Capt. Fitz-Roy. We earnestly recommend you to consult Capt. F. on all your plans and proceedings, and ever to act toward him with entire openness and unreserve. He is cordially desirous to promote the welfare of the Fuegians, and is possessed of information and experience, authority and influence, calculated, under the Divine blessing, powerfully to advance the object you have in view. To him, therefore, you will do well to refer on all occasions, and cheerfully conform to his wishes.

We trust that, in entering on this undertaking, you have been influenced by a sincere desire to promote the glory of God and the good of your fellow-creatures. These are the ends which those friends have in view who have assisted you, and these they trust that you, by the grace of God, will ever steadily keep in view yourself. The means to be employed for the attainment of these ends may be summed up in very few words: it is to make it your study and endeavour to do these poor creatures all the good in your power in every practicable way. By evidencing this to them in the whole of your spirit and conduct, you will gain their confidence and obtain influence over them, without which you cannot expect to succeed. But it is not easy, steadily and consistently, to maintain a line of conduct like this. To enable you to do it, you must be "strong in the grace which is in Christ Jesus," and this grace must be sought by diligent prayer and a constant reading and meditating on the word of God. Here lies your strength, and hence, under God, must your success be derived. "Draw nigh to

© The Complete Work of Charles Darwin Online

God, and He will draw nigh to you." Walk closely with Him, and his name will be glorified in you. Pursuing this course, you will be sure of enjoying His blessing, and may cheerfully leave all events in His hands.

Your first object must be to acquire the language of the Fuegians. To this you must apply with the utmost diligence, fully availing yourself for this purpose of your intercourse with the natives on the voyage; as, till this point is gained, you can hold no free communication with the tribes on the island. In prosecution of this object, we recommend you carefully to note down in writing every new word which you hear. These vocabularies you will, at your leisure, classify and reduce to order, to form the basis of a grammar and dictionary, and ultimately of translations into the language. In prosecution of this design, it will be requisite that you should ascertain, if practicable, which dialect is most extensively used in the island, if it should be found that there are more than one; as it is obviously desirable that you should fix that which is most extensively used.

In imparting religious instruction to the natives, you will make the Bible the basis of all your teaching. You must never lose sight of that great theological principle laid down in the sixth article of the Church of England:—"That Holy Scripture containeth all things necessary to salvation; so that whatsoever is not read therein, nor may be proved thereby, is not to be required of any man that it should be believed as an article of the faith, or be thought requisite or necessary to salvation." By this sound and salutary principle, let the whole of the religious instruction which you impart to the natives be governed. And we earnestly pray that God may give you a mouth to speak, and them ears to hear, that they may so "know the Holy Scriptures that they may be made wise unto salvation through faith in Christ Jesus."

In your intercourse with the Fuegians, you will bear in mind that it is the temporal advantages which you may be capable of communicating to them that they will be most easily and immediately sensible of. Among these may be reckoned the acquisition of better dwellings, and better and more plentiful food and clothing. Consequently, you will consider it a primary duty to instruct them in cultivating the potato, cabbage, and other vegetables; to rear pigs, poultry, &c., and to construct a commodious habitation, &c. You

© The Complete Work of Charles Darwin Online

will probably find in this, as well as in more important things, that example is the most influential instructor. You must therefore take care to have a comfortable habitation yourself, furnished with all necessary articles for use, and kept clean and orderly. You will also fence in a piece of ground for a garden, and get it well stocked with the most useful vegetables; and also surround yourself as quickly as possible with a plentiful supply of pigs, poultry, goats, &c. This, indeed, you will find absolutely necessary for your own future subsistence, as well as with a view to the civilization and comfort of the natives.

Captain Fitz-Roy will, we doubt not, afford you assistance in selecting a proper spot for your residence, and raising a dwelling upon it; and also in procuring the requisite seeds and animals for your subsistence, and for the successful prosecution of your work. A very liberal supply of European clothing, implements and tools, ironmongery, earthenware, &c., is included in your outfit.

We trust that these general hints, with the information and assistance which you may acquire from Captain Fitz-Roy and the books with which you are supplied, will suffice to enable you to carry on your work with comfort and efficiency.

You will have the kindness to write to Mr. Wilson, with full particulars of your proceedings and prospects, by every practicable opportunity, sending your letters to Buenos Ayres, or any other point where they may be likely to get into a channel to reach England.

In conclusion, I have only to add that Captain Fitz-Roy has very kindly and considerately offered to bring you back with him to this country, should circumstances, contrary to our anticipations, turn out to be such that you should deem it unadvisable to remain at Tierra del Fuego.

Earnestly praying that the blessing of God may rest on you and your important and interesting labours,

I remain, truly yours,

D. Coates.

Memorandum of Agreement made this eleventh day of September, one thousand eight hundred and thirty-two, between Mr. James

© The Complete Work of Charles Darwin Online

Harris, resident at the River Negro, and Robert Fitz-Roy, Commander of His Britannic Majesty's surveying sloop Beagle.

Mr. James Harris will provide and furnish two decked schooner-rigged vessels, with their rigging, sails, masts, and all other things necessary for their use and safety, both at sea and in harbour; also, sufficient crews and two pilots, together with provisions for the said pilots, their crews, and eight other persons.

The said Mr. James Harris hereby agrees that the said schooner-rigged vessels, and all on board of them, shall be under, and obey the directions of, the said Robert Fitz-Roy, or those whom the said Robert Fitz-Roy may appoint; and that the said vessels shall continue to perform this expressed service during eight lunar months from the date of this agreement, unless the said Robert Fitz-Roy shall end this agreement at an earlier period; and the said Robert Fitz-Roy shall be at liberty to put an end to this agreement at th end of any month after December of this year.

In consideration of the above useful service to be thus rendered to His Britannic Majesty and the public, the said Robert Fitz-Roy hereby agrees and promises to pay to the said Mr. James Harris, his executors or administrators, the sum of one hundred and forty pounds sterling per lunar month, during the whole time that the said schooners are employed as herein agreed.

As witness the hands of the said parties,

JAMES HARRIS, Resident at the Rio Negro.
ROBERT FITZ-ROY, Commander.

Witnesses to the signatures and agreement.

J. C. WICKHAM, Senior Lieutenant.
B. J. SULIVAN, Second Lieutenant.

No. 7.

ROBERT FITZ-ROY, Esq., Commander of H.M.S. Beagle, Dr. to Mr. James Harris, for the hire of two schooner-rigged vessels, &c., as per annexed agreement, £1,680 sterling.—11th August, 1833.

Received from Robert Fitz-Roy, Commander of H.M.S. Beagle, the sum of £1,680 sterling, in full payment for the hire of two

© The Complete Work of Charles Darwin Online

schooner-rigged vessels, &c., as per annexed agreement, dated 11th July, 1832.

JOHN HARRIS.

H.M.S. Beagle, at Sea,
15th Sept., 1833.

No. 8.

By Robert Fitz-Roy, Commander of His Britannic Majesty's surveying ship Beagle.

YOU are hereby required and directed to take command and charge of the two vessels, "La Paz" and "La Liebre," and of all on board of them.

They are engaged by me upon the terms specified in the accompanying agreement.

With these vessels you will execute as much of the survey, herein pointed out, as your means and other circumstances will allow.

Between Blanco Bay and New Bay the sea-coast should be accurately examined and charted.

Particular plans should be made of the entrances to False Bay, Brightman Inlet, Union Bay, the Bay of San Blas, and the River Negro.

The plans already made of Port San Josef and Port San Antonio should be verified.

The sea-coast ought to be completed before you undertake any examination of the interior waters; and I have to request that you will be cautious of information which may be coloured or exaggerated by individual interest.

As you are well acquainted with the excellent Memoir, drawn up by the Hydrographer for our guidance, I need only recall your attention to the accompanying extracts.

I wish you to be at the Bay of San Blas on the 10th of November, and there to await my arrival.

ROBERT FITZ-ROY, Commander.

Blanco Bay, 19th Sept., 1832.

To Lieut. J. C. WICKHAM,
Senior Lieutenant of H. M. S. Beagle.

No. 9.

(MEMORANDUM.)

H. M. S. Beagle, Blanco Bay,
19th September, 1832.

It is my direction that you take command and charge of the hired vessel "La Paz," and of all on board of her.

You will be extremely careful to keep company with Lieutenant Wickham, unless otherwise directed; and you will obey his orders, and assist him in carrying my orders into execution.

ROBERT FITZ-ROY, Commander.

To Mr. J. L. STOKES,
Assistant-Surveyor, H.M.S. Beagle.

No. 10.

H.M.S. Beagle, off San Blas Bay, Coast of Patagonia,
SIR, 4th December, 1832.

As you have already executed a considerable part of the service pointed out to you in my order, dated September 1832, and are ready for a more arduous task than I had supposed your limited means could undertake, you are hereby required and directed to examine and survey as much of the sea-coast between Port Desire and Blanco Bay as time and your means will allow.

In the first instance, you will hasten to Blanco Bay, and deliver the accompanying despatches to the Commandant of the Buenos Ayrean settlement.

Afterwards, your route will be that which appears to you the most proper for the verification of the charts with which you are furnished, and for the execution of the above-mentioned service.

You will endeavour to pass the month of March in the River Negro, and, if we do not meet sooner, you will look for the Beagle in Blanco Bay at the beginning of July.

Should she not arrive there in July, you will go with both vessels to Monte Video. I have, &c.,

Lieut. J. C. WICKHAM, ROBERT FITZ-ROY.
Commanding the hired Schooners
"La Paz" and "La Liebre."

Extract from Falkner, pp. 61, 62, 63.

I shall here give an account of a strange amphibious animal, which is an inhabitant of the river Parana, a description of which has never reached Europe; nor is there even any mention made of it by those who have described this country. What I here relate is from the concurrent asseverations of the Indians, and of many Spaniards, who have been in various employments on this river: besides, I myself, during my residence on the banks of it, which was near four years, had once a transient view of one; so that there can be no doubt about the existence of such an animal.

In my first voyage to cut timber, in the year 1752, up the Parana, being near the bank, the Indians shouted, "yaquaru!" and looking, I saw a great animal, at the time it plunged into the water from the bank; but the time was too short to examine it with any degree of precision.

It is called yaquaru, or yaquaruigh, which (in the language of that country) signifies the water tiger. It is described by the Indians to be as big as an ass, of the figure of a large overgrown river-wolf or otter, with sharp talons and strong tusks, thick and short legs, long shaggy hair, with a long tapering tail.

The Spaniards describe it somewhat differently:—as having a long head, a sharp nose like that of a wolf, and stiff erect ears. This difference of description may arise from its being so seldom seen, and, when seen, so suddenly disappearing; or perhaps there may be two species of this animal. I look upon this last account as the most authentic, having received it from persons of credit, who assured me that they had seen this water-tiger several times. It is always found near the river, lying on a bank, from whence, on hearing the least noise, it immediately plunges into the water.

It is very destructive to the cattle which pass the Parana, for great herds of them pass every year; and it generally happens that this beast seizes some of them. When it has once laid hold of its prey, it is seen no more, and the lungs and entrails soon appear floating upon the water.

It lives in the greatest depths, especially in the whirlpools made by the concurrence of two streams, and sleeps in the deep caverns that are in the banks.

Extract of a Letter from Thomas Pennant, Esq. to the Hon. Daines Barrington. (Written in 1771.)

Dear Sir:

I now execute the promise I made in town some time ago, of communicating to you the result of my visit to Mr. Falkner, an antient Jesuit, who had passed thirty-eight years of his life in the southern part of South America, between the river la Plata and the Straits of Magellan. Let me endeavour to prejudice you in favour of my new friend, by assuring you, that by his long intercourse with the inhabitants of Patagonia, he seems to have lost all European guile, and to have acquired all the simplicity and honest impetuosity, of the people he has been so long conversant with. I venture to give you only as much of his narrative as he could vouch for the authenticity of; which consists of such facts as he was eye-witness to, and such as will (I believe) establish past contradiction the veracity of our late circumnavigators, and give new lights into the manners of this singular race of men. It will not, I flatter myself, be deemed impertinent to lay before you a chronological mention of the several evidences that will tend to prove the existence of a people of a supernatural height, inhabiting the southern tract. You will find that the majority of voyagers who have touched on that coast have seen them, and made reports of their size, that will very well keep in countenance the verbal account given by Mr. Byron, and the printed, by Mr. Clarke; you will observe, that if the old voyagers did exaggerate, it was through the novelty and amazement at so singular a sight; but the latter, forewarned by the preceding accounts, seem to have made their remarks with coolness, and confirmed them by the experiment of measurement.

A.D. 1519. The first who saw these people was the great Magellan;—one of them just made his appearance on the banks of the river La Plata, and then made his retreat; but, during Magellan's long stay at Port St. Julian, he was visited by numbers of this tall race. The first approached him singing, and flinging the dust over his head, and shewed all signs of a mild and peaceable disposition: his visage was painted; his garment, the skin of some animal, neatly

© The Complete Work of Charles Darwin Online

sewed; his arms, a stout and thick bow, a quiver of long arrows feathered at one end, and armed at the other with flint. The height of these people was about seven feet (French); but they were not so tall as the person who approached them first, who is represented to have been of so gigantic a size that Magellan's men did not, with their heads, reach as high as the waist of this Patagonian. They had with them beasts of burden, on which they placed their wives. By Magellan's description of them, they appear to have been the animals now known by the name of Llama. These interviews ended with the captivating two of the people, who were carried away in two different ships; but, as soon as they arrived in a hot climate, each of them died. I dwell the longer on this account, as it appears extremely deserving of credit; as the courage of Magellan made him incapable of giving an exaggerated account through the influence of fear; nor could there be any mistake about the height, as he had not only a long intercourse with them, but the actual possession of two for a very considerable space of time.* It was Magellan who first gave them the name of Patagons, because they wore a sort of slipper made of the skin of animals. "Tellement," says M. de Brosse,† qu'ils paroissoient avoir des pattes de bêtes." In 1525 Garcia de Loaisa saw, within the Straits of Magellan, savages of a very great stature, but he does not particularize their height. After Loaisa, the same Straits were passed in 1535 by Simon de Alcazova, and attempted in 1540 by Alphonso de Camargo, but without being visited by our tall people. The same happened to our countryman, Sir Francis Drake; but, because it was not the fortune of that able and popular seaman to meet with these gigantic people, his contemporaries considered the report as the invention of the Spaniards.

In 1579, Pedro Sarmiento asserts that those he saw were three ells high. This is a writer I would never venture to quote singly, for he destroys his own credibility by saying the savage he made prisoner was an errant Cyclops. I only cite him to prove that he fell in with a tall race, though he mixes fable with truth. In 1586 our countryman, Sir Thomas Cavendish, in his voyage, had only

† This account, as well as the others where I do not quote my authority, are taken from that judicious writer, M. de Brosse.

© The Complete Work of Charles Darwin Online

opportunity of measuring one of their footsteps, which was eighteen inches long: he also found their graves, and mentions their customs of burying near the shore.* In 1591, Anthony Knevet, who sailed with Sir Thomas Cavendish in his second voyage, relates that he saw, at Port Desire, men fifteen or sixteen spans high, and that he measured the bodies of two that had been recently buried, which were fourteen spans long.† In 1599, Sebald de Veert, who sailed with Admiral de Cordes, was attacked in the Strait of Magellan by savages whom he thought to be ten or eleven feet high. He adds, that they were of reddish colour, and had long hair.‡

In the same year, Oliver Van Noort, a Dutch admiral, had a rencontre with this gigantic race, whom he represents to be of a high stature, and of a terrible aspect.

1614.—George Spilbergen, another Dutchman, in his passage through the same Strait, saw a man, of a gigantic stature, climbing a hill as if to take a view of the ship.§ 1615.—Le Maire and Schouten discovered some of the burying-places of the Patagonians beneath heaps of great stones, and found in them skeletons ten or eleven feet long.‖

Mr. Falkner supposes that formerly there existed a race of Patagonians superior to these in size; for skeletons are often found of far greater dimensions, particularly about the river Texeira. Perhaps he may have heard of the old tradition of the natives mentioned by Cieza,¶ and repeated from him by Garcilasso de la Vega,** of certain giants having come by sea, and landed near the cape of St. Helena, many ages before the arrival of the Europeans.

1618.—Gracias de Nodal, a Spanish commander, in the course of his voyage, was informed by John Moore, one of his crew, who landed between Cape St. Esprit and Cape St. Arenas, on the south side of the Straits, that he trafficked with a race of men taller, by the head, than the Europeans. This and the next are the only instances I ever met with of the tall race being found on that side of the Strait.

** Translated by Ricaut, p. 263.

© The Complete Work of Charles Darwin Online

1642.—Henry Brewer, a Dutch admiral, observed, in the Strait Le Maire, the footsteps of men which measured eighteen inches. This is the last evidence, in the seventeenth century, of the existence of these tall people. But let it be observed, that out of the fifteen first voyagers who passed through the Magellanic Straits, not fewer than nine are undeniable witnesses of the fact we would establish.

In the present century, I can produce but two evidences of the existence of the tall Patagonians; the one in 1704, when the crew of a ship belonging to St. Maloes, commanded by Captain Harrington, saw seven of these giants in Gregory Bay. Mention is also made of six more being seen by Captain Carman, a native of the same town, but whether in the same voyage, my authority is silent.*

But as it was not the fortune of the four other voyagers† who sailed through the Straits in the seventeenth century, to fall in with any of this tall race, it became a fashion to treat as fabulous the account of the preceding nine, and to hold this lofty race as the mere creation of a warm imagination. In such a temper was the public, on the return of Mr. Byron from his circumnavigation, in the year 1766. I had not the honour of having personal conference with that gentleman, therefore will not repeat the accounts I have been informed he had given to several of his friends; I rather chuse to recapitulate that given by Mr. Clarke,‡ in the Philosophical Transactions for 1767, p. 75. Mr. Clarke was officer in Mr. Byron's ship, landed with him in the Straits of Magellan, and had for two hours an opportunity of standing within a few yards of this race, and seeing them examined and measured by Mr. Byron.

He represents them in general as stout and well-proportioned, and assures us that none of the men were lower than eight feet, and that some even exceeded nine, and that the women were from seven feet and a half to eight feet. He saw Mr. Byron measure one of the men, and, notwithstanding the Commodore was near six feet high, he could, when on tip-toe, but just reach with his hand the top of

* Frezier's Voy. p. 84.

© The Complete Work of Charles Darwin Online

the Patagonian's head; and Mr. Clarke is certain that there were several taller than him on whom the experiment was made, for there were about five hundred men, women, and children. They seemed very happy at the landing of our people, and expressed their joy by a rude sort of singing. They were of a copper colour, and had long lank hair, and faces hideously painted. Both sexes were covered with skins, and some appeared on horseback and others on foot.

A few had on their legs a sort of boot, with a sharp-pointed stick at the heel, instead of a spur. Their bridles were made of thong, the bit wood; the saddle as artless as possible, and without stirrups. The introduction of horses into these parts by the Europeans introduced, likewise, the only species of manufacture they appear to be acquainted with. All their skill seems to extend no farther than these rude essays at harness, and to equip themselves for cavaliers. In other respects they would be in the same state as our first parents, just turned out of paradise, clothed in coats of skins; or, at best, in the same condition in which Cæsar found the ancient Britons; for their dress was similar, their hair long, and their bodies like those of our ancestors, made terrific by wild painting. These people, by some means or other, had acquired a few beads and bracelets; otherwise, not a single article of European fabric appeared among them. These they must have gotten by the intercourse with the other Indian tribes; for had they any intercourse with the Spaniards, they never would have neglected procuring knives, the stirrups, and other conveniences, which the people seen by Mr. Wallis had.

I should have been glad to have closed, in this place, the relations of this stupendous race of mankind, because the two following accounts, given by gentlemen of character and abilities, seem to contradict great part of what had been before advanced, or at least serve to give scoffers room to say, that the preceding navigators had seen these people through the medium of magnifying glasses, instead of the sober eye of observation. But before I make my remarks on what has been before related, I shall proceed with the other navigators, and then attempt to reconcile the different accounts.

In 1767 Captain Wallis, of the Dolphin, and Captain Philip Carteret, of the Swallow sloop, saw and measured with a pole several of the Patagonians who happened to be in the Straits of

© The Complete Work of Charles Darwin Online

Magellan during his passage.* He represents them as a fine and friendly people, clothed in skins, and on their legs a sort of boots; and many of them tied their hair, which was long and black, with a sort of woven stuff of the breadth of a garter, made of some kind of wool; that their arms were slings, formed of two round balls fastened one to each end of a cord, which they fling with great force and dexterity. He adds: "They hold one ball in their hand, and swing the other, at the full length of the cord, round their head, by which it acquires a prodigious velocity; they will fling it to a great distance, and with such exactness, as to strike a very small object." These people were also mounted on horses; their saddles, bridles, &c., were of their own making; some had iron, and others metal bits to their bridles, and one had a Spanish broad-sword; but whether the last articles were taken by war, or procured by commerce, is uncertain; but the last is most probable. It seems evident that they had intercourse with Europeans, and had even adopted some of their fashions, for many had cut their dress into the form of Spanish ponchos, or a square piece of cloth with a hole cut for the head, the rest hanging loose as low as their knees; they also wore drawers.—So these people had attained a few steps farther towards civilization than their gigantic neighbours; others, again, will appear to have made a far greater advance, for these still devoured their meat raw, and drank nothing but water.

M. Bougainville, in the same year, saw another party of the natives of Patagonia. He measured several of them, and declares that none were lower than five feet five inches French, or taller than five feet ten; i. e. five feet ten, or six feet three, English measure. He concludes his account with saying, that he afterwards met with a taller people in the South Sea, but I do not recollect that he mentions the place.

I am sorry to be obliged to remark, in these voyages, a very illiberal propensity to cavil at and invalidate the account given by Mr. Byron, but at the same time exult in having had an opportunity given me by that gentleman of vindicating his and the national honour. M. Bougainville, in order to prove that he fell in with the identical people that Mr. Byron conversed with, asserts that he saw numbers of them possessed of knives of an English manufactory, certainly given them by Mr. Byron. But he should have considered

* Phil. Trans. 1770, p. 21. Hawkesworth's Voy. vol. i. 374.

© The Complete Work of Charles Darwin Online

that there are more ways than one of coming at a thing—that the commerce between Sheffield and South America, through the port of Cadiz, is most uncommonly large—and that his Indians might have got their knives from the Spaniards, at the same time that they got their gilt nails and Spanish harness. But for farther satisfaction on this subject, I have liberty to say, from Mr. Byron's authority, that he never gave a single knife to the people he saw—that he had not one at that time about him—that, excepting the presents given with his own hands, and the tobacco brought by Lieutenant Cummins, not the least trifle was bestowed. I am furnished with one other proof that these lesser Indians, whom Mr. Wallis saw, were not the same as those described by Mr. Byron, as has been insinuated; for the first had with him some officers who had been with him on the preceding voyage, and who bear witness not only to the difference of size, but declare that these people had not a single article among them given by Mr. Byron.* It is extremely probable that these were the Indians that Mr. Bougainville fell in with; for they were furnished with bits, a Spanish scymeter, and brass stirrups, as before-mentioned.

My last evidence of these gigantic Americans is that which I received from Mr. Falkner: he acquainted me that, about the year 1742, he was sent on a mission to the vast plains of Pampas, which, if I recollect right, lie to the south-west of Buenos Ayres, and extend near a thousand miles towards the Andes. In these plains he first met with some tribes of these people, and was taken under the protection of one of the caciques. The remarks he made on their size were as follows:—that the tallest, which he measured in the same manner that Mr. Byron did, was seven feet eight inches high—that the common height, or middle size, was six feet—that there were numbers that were even shorter—and that the tallest woman did not exceed six feet; that they were scattered from the foot of the Andes over that vast tract which extends to the Atlantic Ocean, and are found as far as the Red River, at Bay Anegada, lat. 40°. 1′; below that the land is too barren to be habitable, and none are found, except accidental migrants, till you arrive at the river Gallego, near the Straits of Magellan.

" M. Frezier was assured by Don Pedro Molino, Governor of

* See Mr. Byron's letter at the end.

© The Complete Work of Charles Darwin Online

Chiloe, that he once was visited by some of these people, who were four varas, or about nine or ten feet high; they came in company with some Chiloe Indians,* with whom they were friends, and who probably found them in some of their excursions."

"Those whose height is so extraordinary as to occasion a great disbelief of the accounts of voyagers, are indisputably an existent people; they have been seen by Magellan, and six others, in the sixteenth century, and by two, if not three, in the present."

THOMAS PENNANT.

Copy of a Paper transmitted from Admiral Byron to Mr. Pennant, through the hands of the Right Reverend John Egerton, late Bishop of Durham, after he had perused the manuscript of the foregoing account.

"The people I saw upon the coast of Patagonia were not the same that were seen the second voyage. One or two of the officers that sailed with me, and afterwards with Captain Wallis, declared to me that they had not a single thing I had distributed amongst those I saw.

"M. Bougainville remarks, that his officers landed amongst the Indians I had seen, as they had many English knives among them, which were, as he pretends, undoubtedly given by me. Now it happened that I never gave a single knife to any of those Indians, nor did I even carry one ashore with me.

"I had often heard from the Spaniards that there were two or three different nations of very tall people, the largest of which inhabit those immense plains at the back of the Andes: the others, somewhere near the river Gallegos. I take it to be the former that I saw, and for this reason:—returning from Port Famine, where I had been to wood and water, I saw those people's fires a long way to the westward of where I had left them, and a great way inland, so, as the winter was approaching, they were certainly returning to a better climate. I remarked that they had not one single thing amongst them that shewed they ever had any commerce with Europeans. They were certainly of a most amazing size: so much were

their horses disproportioned, that all the people that were with me in the boats, when very near the shore, swore that they were all mounted upon deer; and, to this instant, I believe there is not a man that landed with me, though they were at some distance from them, but would swear they took them to be nine feet high. I do suppose many of them were between seven and eight feet, and strong in proportion.

"Mr. Byron is obliged to Mr. Pennant for the perusal of his manuscript, and thinks his remarks very judicious."*

No. 13.

Extracts from "Diario de Antonio de Viedma, 1783."

Communicated by Don Pedro de Angelis to Sir Woodbine Parish, F.R.S., and by him to Capt. Fitz-Roy, in 1837.

Los Indios todos son de una misma nacion en esta vecindad: su estatura es alta, de dos varas á nueve palmos por lo comun en los hombres, siendo muy raro el que pasa de esta talla. Las mugeres no son tan altas, pero lo bastante con proporcion á su sexo. Todos son de buenos semblantes, y entre las mugeres las hay muy bien parecidas y blancas, aunque curtidas del viento y del sol como ellos. No se encuentra hombre ni muger flaco, antes todos son gruesos con proporcion á su estatura: lo que y usar las ropas del cuello á los pies, habrá contribuido á que algunos viageros los tengan por gigantes.

Su idioma es gutural, y repiten en sus conversaciones una misma voz muchas veces. No interrumpen al que está hablando, aunque su oracion dure todo el dia: comunmente habla uno de mas autoridad ó el mas elocuente. Las mugeres no hablan entre los hombres sin ser preguntadas, y entonces solo contestando á la pregunta: los que hablan mucho sin ocasion ni asunto, no tienen partido entre ellos, ni se les oye.

El vestido de los hombres es un cuero de guanaco, zorillo ó liebre,

* Extract from Pennant's Literary Life, p. 47 to 69.

© The Complete Work of Charles Darwin Online

de dos varas en cuadro, el pelo para adentro, y la tez pintada de colorado, verde ó amarillo: este los cubre desde el cuello á los pies con tal arte y manejo, que raramente se les vé parte alguna de su cuerpo, excepto los brazos, y estos, cuando usan de ellos para algo. Llevan ademas otro cuero muy sobado, atado á la cintura con una correa por debajo de aquel, con que tapan el vientre y hasta la mitad de los muslos, descendiendo desde aquí en punta hasta los tobillos. En los pies se atan con unas correillas unos cueros de buey, si le tienen ó de caballo ó del cuero de los guanacos grandes, formando á manera de sandalias. Para andar á caballo usan de botas que hacen de los garrones ó piernas de los mismos caballos ó guanacos grandes; y las espuelas son se madera, que labran ellos con bastante primor. Se ciñen la cabeza con una cinta de lana como de dos dedos de ancho, tegida por ellos de varios colores, con que se sugetan el pelo doblado por arriba, con las puntas al aire como plumage por el lado izquierdo, dándose con la cinta seis ó ocho vueltas, y colgando las puntas de ella con unos cabetes de metal amarillo ó laton. Para montar á caballo sujetan el cuero grande con una correa, que se rodean por encima de todo á la cintura, de la cual cuelgan las bolas y daga, que son las armas que generalmente traen: y cuando necesitan de los brazos para usarlas, dejan caer por las espaldas el cuero sobre las ancas del caballo, quedándose desnudos de medio cuerpo arriba, y hacen de este modo buena vista cuando van de huida ó en seguimiento de la caza, porque el cuero cubre las ancas del caballo, y ofrece á los ojos el pelo que tiene por dentro de varios colores. El aparejo de montar es á manera de un albardon, sin pretal ni grupa, hecho tambíen de cuero de guanaco grande, reenchidos los bastos de paja fuerte. Los estribos labrados por ellos de madera, y tan pequeños, que tasadamente cabe el dedo pulgar del pié. Se ponen mal á caballo, pero son muy firmes en él, y lo mismo corren cuesta abajo que cuesta arriba. El freno del caballo se compone de un palito, ó hueso de canilla de avestruz, labrado con dos perillas á los estremos, tan largo como ancha la boca del caballo, y en dichas perillas están sujetas las riendas y dos correitas que atan en la barbada, con lo que queda seguro para que no se le salga de la boca. Las riendas son cordones de ocho ramales, de correitas de cuero muy sobadas.

Las mugeres tienen el vestido de la misma especie de cueros, puesto del mismo modo, con sola la diferencia de que sobre el pecho

© The Complete Work of Charles Darwin Online

lo sugetan, pasándole dos agujetas de á tercia de largo, hechas de madera ó de fierro, quedando las puntas del cuero colgando como las faldillas de los capingotes, hasta lo bajo de la cintura. Las otras dos puntas les cuelgan, y arrastran atras como media vara, estando suelto, pero para andar se lo recogen y afianzan con la mano izquierda, de la que no hacen mas uso que este, y el de cubrirse con ella en alguna urgencia sus partes. Encima de estas llevan debajo de aquel cuero una especie de mandil cuadrado, que cuelga hasta mas de las rodillas; de bayeta, paño ú otro género si le pueden haber, y sino, de cuero sobado muy bien, el cual atan con un cinto de lo mismo que las rodea el cuerpo, el que guarnece las de alguna autoridad entre ellas, con abalorios. No llevan sandalias en los pies como los hombres, pero cuando montan á caballo, calzan botas como ellos. Llevan descubierta la cabeza, dividido el pelo en dos partes, y de cada una hecha una coleta, que baja por las orejas y hombros hasta el pecho y cintura; cuya cinta es de lana parda de dos dedos de ancho, guarnecida, si es muger rica, en dias de gala con abalorios, y lo mismo las mugeres de alguna autoridad.

Tambien se ponen los abalorios en las agujetas con que sujetan el cuero en el pecho, y en las cañas de las piernas como pulseras, y en el cuello por gargantillas de cualesquiera colores. En las orejas llevan zarcillos de laton, y lo mismo los hombres. Los arreos de las caballerías en que las mugeres montan, que por lo comun son yeguas, se componen de unos sillones de vaqueta ó de zuela, (si la pueden conseguir) muy bien hechos, claveteados con clavitos de laton amarillo, guarnecidos sus extremos con abalorios de diferentes colores, (cuando los tienen) formando dibujos ó labores á su modo y fantasía. La cincha tiene tres argollas, la una en un extremo, y las otras dos en cada tercio una; la evilla con que la abrochan ó ciñen es muy grande. El freno se compone de cabezada, bocado y riendas: la cabezada es rica, guarnecida de abalorios, ó de cuantas cosas tienen ó pueden adquirir al propósito: las riendas y el bocado son del mismo modo que los que usan los hombres. Ponen á la yegua un collar al cuello que cae hasta las rodillas, con cuantos cascabeles y colgajos pueden conseguir. Estos arreos son para gala y fiestas, pero en sus marchas ordinarias no usan estos adornos, y en lugar de dicho collar ponen un cordon de lana azul ó colorado, de un dedo de grueso, con el cual dan tres vueltas al cuello de la caballería, y les sirve tambien de estribo para montar en el sillon, donde

© The Complete Work of Charles Darwin Online

se asientan con la cara á la cabeza del caballo, recogiendo las piernas arriba sobre las faldillas del mismo sillon, en una postura muy violenta y trabajosa, que solo la costumbre puede hacerles sufrir; por lo que están espuestas á muchas caidas. Parar andar á caballo y para montar guardan suma honestidad, no permitiendo que se les vea parte alguna de su cuerpo. Las mugeres de alguna autoridad llevan en las marchas sombreros de paja, que vienen á ser un redondel con cabo, sin copa, que se lo atan por debajo de la barba con cualesquiera cosa; y con esto se cubren del sol y agua cuando van á caballo.

El egercicio ó ocupacion ordinaria de los hombres es cazar, para mantener con las carnes sus familias, y hacer del cuero los toldos ó chozas en que viven, y todos sus vestidos: cuidan tambien de los caballos que tienen, y trabajan todos sus arreos. Sus divertimientos se reducen á jugar á los dados y la perinola, y egercitarse en su modo de batallar y correr parejas á caballo.

Las mugeres tienen obligacion de guisar la comida, traer el agua y la leña, armar y desarmar el toldo en las marchas, y cargarlo y descargarlo: sin que para nada de esto le ayude el hombre, aunque esté elle enferma, porque ha de sacar fuerzas de flaqueza. Ademas de esto ha de coser el toldo, que es siempre de cuero de guanaco grande, y tambien ha de coser todos los demas cueros de cama y vestidos, que regularmente se componen de cueros de liebre, zorrillo y guanacos nonatos, ó recien nacidos, de los que hacen prevencion y cosecha en la primavera, para con los sobrantes comerciar con los indios del Rio Negro, por caballos, ropas, frenos abalorios y dagas, que aquellos adquiren del comercio, é invasiones que hacen en las fronteras de Buenos Aires: porque los indios, de que aquí se vá hablando, jamas han tratado españoles hasta ahora, ni han visto ninguna de sus poblaciones, ni estas costas tienen fierro, metal, laton, herramientas ni armas; todas estas piezas y géneros las adquieren mediante dicho comercio. Para coser estas mugeres los expresados cueros, usan de alesnas, que forman del fierro que les dan los referidos indios del Rio Negro, y en lugar de hilo emplean nervios, que adelgazan, segun necesitan, de las piernas de los avestruces.

El cacicazgo es hereditario, su jurisdiccion absoluta en cuanto á mudarse de un campo á otro en seguimiento de la caza, que es su subsistencia. Cuando al cacique le parece tiempo de mudar el campo, el dia antes al ponerse el sol hace su platica á grandes voces desde su toldo: todas le escuchan con suma atencion desde los suyos. Les

© The Complete Work of Charles Darwin Online

dice se ha de marchar al otro dia: les señala hora para recoger los caballos, batir los toldos, y empezar á marchar: nadie le replica, y á la hora señalada todos están prontos como se les ha mandado. Las mugeres van por veredas que hay hechas para todas las aguadas donde deben parar: son las conductoras de todo el equipage. Los hombres, luego que las mugeres empiezan la marcha, se van apostando en el campo para cercar los guanacos y bolearlos á la travesia: porque son tan violentos en la carrera, que ningun caballo ni perro les puede alcanzar: cuando están con las bolas enredados, les sirven los perros para acabarlos de rendir. El mismo cacique señala los puestos de la batida, por lo que, y en testimonio de señorio, el tributan parte de la caza: asi nunca corre, ni hace otra cosa mas que andar de apostadero en apostadero: sus jornadas mas largas son de 4 leguas. En llegando al destino que está asignado, arman las mugeres los toldos, recogen leña, y lo tienen todo pronto para cuando los hombres vengan: estos al ponerse el sol marchan á sus toldos, sin que jamas se verifique llegue á ellos ninguno, obscurecida la noche. Si se ha de continuar la marcha al otro dia, hace el cacique la misma arenga y prevenciones; y si no dice nada, ya saben que por entonces han de permanecer allí, y esta mansion por lo comun es adonde saben que se ha retirado la caza. Aquí, cuando el cacique vé que están escasos de carne, al ponerse el sol, y en la misma forma que para las marchas, les dice recojan los caballos á la hora que señala para el dia siguiente, lo que egecutan sin falta: luego que tienen los caballos en los toldos, les hace otra plática, paseándose á caballo, y señalándoles los apostaderos con lo que cada cuadrilla debe egecutar. Van con ellos algunas mugeres para cargar la caza, porque ni aun este trabajo quieren los hombres hacer: los toldos quedan armados, y en ellos las restantes mugeres, muchachos é impedidos. Al ponerse el sol se retiran otra vez á sus toldos, reduciéndose á solas estas funciones todo el mando de este cacique, el cual por ningun delito castiga á sus indios, aunque en los puntos de obediencia que van expresados jamas se verifica le falten á ella. Cuando quiere hacer guerra á sus vecinos, ó á algunos otros de que hayan recibido agravio, ha de ser con aprobacion de su indios principales, para lo cual se juntan en el toldo del cacique: este pondera y explica los agravios y modo de vengarlos; fuerzas, facilidad ó inconvenientes que hay en hacer la guerra. Los de la junta confieren sobre el asunto, y aprueban ó reprueban lo

© The Complete Work of Charles Darwin Online

propuesto por el cacique: este no se agravia. La guerra, por lo regular, se aprueba, y solo ventilan el modo de hacerla, y cuando; y suele tardar esta resolucion algunos dias. Luego que están convenidos en salir á campaña, el cacique tres noches seguidas desde su toldo á grandes voces les hace saber á todos los indios la declaracion de la guerra, el tiempo para cuando está resuelta, la forma en que ha de hacerse enemigos contra quien, y su motivo; avisan que esten prevenidos.

Una de las principales causas que tienen para declarar guerra es, que como cada cacique tiene señalado el terreno de su jurisdiccion, no puede ninguno de sus indios entrar en el terreno de otro sin pedirle licencia para ello. El indio que vá á pedirla ha de hacer tres humaradas, y hasta que le correspondan con otras tres no puede llegar á los toldos: en ellos dá razon á aquel cacique del motivo que le trae, ya sea de paso, ó ya porque pretenda permanecer allí. Si al cacique le parece, consiente en su pretension, y si no, le manda salir inmediatamente de sus terrenos y dominios. Si el indio vá como embajador de su cacique ó de otros indios, bien pidiendo paso por aquel terreno, ó bien para comerciar con ellos ó para visitarlos, se le señala por el cacique el tiempo, y por donde deben entrar, camino que han de tomar para seguir su viage, ó terreno que han de ocupar donde hagan su comercio. Luego hacen sus tres humaradas, y en habiéndoles correspondido los indios del terreno, entran todos en este, y á cosa de una legua de la tolderia, se detienen todos los hombres, y pasando adelante las mugeres y criaturas, arman sus toldos á donde se les señala, y en estándolo, todos llegan á ellos los hombres. Nadie sale á recibirlos, quedándose así á la vista unos de otros, hasta que despues de mucho rato vá el cacique, ó cualquiera otro que haga cabeza entre los forasteros, á visitar y cumplimentar al del pais, que le recibe en su toldo acompañado de sus principales indios, que acuden allí luego para cortejar al forastero. Esta visita suele durar todo un dia, porque como cada uno habla sin que nadie le interrumpa, si el forastero trae muchas noticias y quiere enterarse de las del país, suele durar la oracion de cada uno, dos ó tres horas, y aun mas, porque tambien repiten muchas veces ciertas voces. El que oye, y los demas estan con grande atencion, diciendo con frecuencia, á, á, que quiere decir sí, sí; y con ninguna otra voz interrumpen al que habla. En estas juntas se hacen las alianzas, se otorgan amistades amplias, y otros contratos, acuerdos ó convenios, para todo lo cual tienen los caciques facultades absolutas. Cuando

© The Complete Work of Charles Darwin Online

para entrar en terreno ó tolderia agena, no se observan las expresadas formalidades, es señal de mala fé, y en consecuencia se toca luego al arma.

Tambien se declaran á menudo guerra por robarse algunos caballos, de cuyas resultas quedan los vencidos á pié, y cautivas del vencedor las mugeres mozas, y muchachos; que á las viejas y los hombres no se les dá cuartel, como no lo consigan en la fuga.

El cacique tiene obligacion de amparar y socorrer á los indios de su dominio y territorio en sus necesidades, y por lo tal es mas estimado, tiene mas partido entre ellos, y mas preferencia para cacique el que es mas dispuesto á socorrerlos, mas galan, y mas inteligente en la caza; porque si le faltan estas calidades, se van á buscar á otro que las tenga, dejándolo solo con sus parientes, y expuestos á continuas invasiones de sus vecinos: bien que no pierde aquella familia el derecho del terreno, y con el tiempo suele haber otro que restablece la tolderia que su padre, abuelo ó hermano ha destruido por su desgracia, ó mala conducta. Cuando está viejo el cacique, y en estado que por falta de fuerzas no puede cumplir con las obligaciones de su ministerio, deja el mando en el sucesor.

Los casamientos se hacen por compra que el hombre hace de la muger al padre, ó cualquiera otro á cuyo cargo está ella, que segun su calidad, buen parecer, conducta, &c., es mas cara ó mas barata, sin que pueda oponerse á la venta que celebre su padre ó su tutor, quienes no cuentan con su voluntad para otorgarla. Puede cada hombre tener una, dos ó mas mugeres propias, segun tengan haberes para comprarlas, pero raramente tienen mas de una, á menos de ser cacique ó indio de grande autoridad. El que mas llega à tener son tres mugeres, y todo marido tiene facultad de vender las suyas á otros, cuya segunda venta hace poco apreciable á la muger, y se dá por lo mismo en muy poco precio, comprándolas solamente los pobres que se surten de este modo, porque carecen de medios con que adquirirlas de primera mano. No hay tampoco inconveniente en venderlas á cualquiera pariente, como no sea hijo ó hermano de la vendida, porque todos los demas grados los tienen dispensados. Son muchos los casamientos que hacen de esta especie, por lo caro que cuestan las mugeres solteras, las cuales, interin son mozas, y tienen esperanza de casarse guardan la virginidad; pero en perdiendo aquella esperanza, se entregan á todos. Las casadas, cuyo marido que les trató su padre ó tutor ha sido de su gusto, le guardan suma fide-

© The Complete Work of Charles Darwin Online

lidad, pero en las que no, hay muchos trabajos ; bien que el adulterio no es delito, como no sea á vista del marido, y en este caso culpan al adultero y no á ella : y tampoco así se castiga, pues por medio de algun corto interes perdona este agravio el marido. El cacique siempre tiene por muger una hija ó hermana de otro cacique ; la cual es la principal entre las demas mugeres suyas, y estas la sirven en todo. Aunque se halle cansado de ella no la puede vender, porque seria agravio y motivo de romper una guerra con sus parientes. Todas estas cacicas manifiestan gravedad, hablan poco, se están recogidas en su toldo, ocupadas en algun trabajo correspondiente á ellas, y no intervienen en las vulgares conversaciones de las demas indias. Los hombres por ningun motivo castigan de obra á las mugeres, excepto cuando están borrachos ; y aun entonces el cacique á la cacica preferente jamas le pega, aunque las otras lleven todas golpes. Las ceremonias del casamiento solo se reducen, una vez ajustada la muger, llevàrsela su padre al novio á su toldo, á menos que ella no se adelante á irse con él sin que la lleve nadie, que en esto no hay inconveniente. Entonces el novio hace matar uno ó dos yeguas, segun tenga de ellas, y convida á los parientes y parientas, amigos y amigas de la novia y suyos, y comiendo todos de aquella carne, queda concluido el casamiento. Así hombres como mugeres son muy celosos y amantes de sus hijos, à quienes luego que nacen atan con muchas fajas de cuero que tienen preparadas, muy sobadas y suaves, contra una à manera de tabla, que forman, porque no las tienen, de palitos cruzados y atados, forrados con fajas de cuero, en donde los tienen sugetos mas de un mes, dándoles el pecho sin desatarlos de allí. Así dicen que se crian derechos, y efectivamente tanto ellos como ellas son todos muy derechos, tienen buenos cuerpos, y no se vè uno que sea cargado de espaldas. En quitándolos de estas ataduras, los traen regularmente siempre consigo las madres, metidos en las espaldas entre su carne y el cuero con que van vestidas, con la cabeza sacada por el cogote de la madre. Cuando van de marcha, hacen de cuero y unos palitos una especie de cuna, atumbada y cerrada por todas partes, menos por los pies y la cabeza, las cuales forran y adornan con bayeta, paño ò lo que tienen, guarneciéndolas con abaloríos, cascabeles, &c., segun pueden, y las aseguran encima de las ancas del caballo, donde va la madre. Entre estas gentes se vé que los muchachos nunca lloran, sino llevan golpes ó alguna caida.

© The Complete Work of Charles Darwin Online

Su religion viene à ser solamente una especie de creencia en dos potencias; la una benigna que solo gobierna el cielo, independiente y sin poderio en la tierra y sus habitantes, de la cual hacen muy poco caso; y la otra á un tiempo benigna y rigorosa, la cual gobierna la tierra, dirige, castiga y premia á sus habitadores, y à esta adoran bajo cualquiera figura que fabrican, ó que se hayan hallado en las playas, procedidas de algunos navios nàufragos; como son mascarones de proa, ó figuras de las aletas de popa, y estas son las que estiman y prefieren para sus cultos por suponerlas aparecidas. A esta deidad dan por nombre el Camalasque, que equivale á "poderoso y valiente." De estas figuras, cada uno que la tiene defiende y cree ser aquella la verdadera deidad, y que las de los otros son falsas, aunque no llega el caso de empeñar estas disputas, ni armar quimeras sobre ello, porque se persuaden que la misma deidad vengará sus agravios con las supersticiones que se figuran: creyendo que las enfermedades y las muertes son venganzas de estas deidades, á menos de suceder en los ya muy viejos, que solo entonces las tienen por naturales. Estas figuras las guardan en sus toldos, muy cubiertas y liadas con cuero, paño, bayeta ò lienzo, segun cada uno puede, y no se descubre à nadie sin dictàmen del santon ò hechicero, que puede ser muger ú hombre. Tiene de continuo dias en que debe egercer su oficio, cantando à la deidad al son de dos calabazas con chinas dentro,—mùsica tan desagradable como su misma voz. Tambien hace en esta forma rogaciones, por que la deidad enferme ó mate à los que tienen por enemigos: pero esto suele salirles muy mal à los tales hechiceros, porque si acaso tienen sus enemigos algun contagio, ó muere algun indio principal ó cacique, procuran por todos los medios posibles haber á las manos á los referidos hechiceros, y los hacen màrtires del diablo. Tambien deben cantar á la deidad estos hechiceros por los enfermos de sus tolderias, para contradecir á los otros hechiceros sus enemigos, y sino consigue el alivio el enfermo, suelen tambien los amigos de este darle su merecido á aquellos, á lo menos quitándoles el empleo, y tratándole en adelante como á infame: y si la muerte ha sido de muger ò hijo del cacique, suele pagar con la vida el hechicero su mala cura, que solo se reduce al canto, porque no usan de otras medicinas en sus enfermedades. Y por tanto tienen muchos contratiempos estos médicos cantores, siendo pocos de ellos los que mueren de muerte natural: pero siempre sobran pretendientes para este empleo, porque tienen facultad de usar de las mugeres de los indios,

© The Complete Work of Charles Darwin Online

si ellas consienten, ó de ellos, si el hechicero es muger. De estos hechiceros casi hay tantos como familias, ó como ídolos, porque regularmente cada cabeza de familia tiene su ídolo en su toldo, y si la tolderia se compone de cuatro, cinco ò mas familias, hay otros tantos ídolos y otros tantos hechiceros ó santones: en la inteligencia de que una familia entre ellos se compone no solo del marido, muger è hijos, sino tambien de todos los parientes del dicho marido, que es cabeza y gefe de esta familia, en la cual viene á ser como un cacique subalterno, del que tiene el general gobierno de todos, y derecho en propiedad de aquel terreno.

Cuando enferma alguno en la familia, acude el santon de ella à cantarle al oido, con voces tan fuertes y desentonadas, y tan desagradables, que ellas por sì solas bastarian à matarle. Si se agrava, convida à los demas de su oficio, y à todas las viejas, para que le ayuden á cantar, á fin de que de noche y de dia no cese el canto: pero nadie queda responsable si el enfermo muere, porque este cargo es solo del hechicero. Cuando el enfermo està ya enteramente postrado, si es doncella y jóven, le forman un toldo de ponchos, separado de la tolderia, la ponen en él, y allí es el canto mas fuerte; porque todas cuantas viejas hay, van á cantarle, y una de ellas arma en un palo todos los cascabeles que puede juntar, y haciendo con ellos gran ruido, da una vuelta al rededor del toldo de cuando en cuando, à cuyo tiempo esfuerzan las de adentro su griteria. Durante la enfermedad se matan yeguas y caballos, en ofrenda ó sacrificio al ídolo para que mejore el enfermo; pero esta ofrenda se la comen entre el mismo enfermo y los cantores. Si el enfermo muere, bien sea en el nuevo toldo de ponchos, siendo doncella, ò en el suyo mismo, siendo hombre ò muger casada, se trae al toldo el caballo mas estimado, lo aparejan, y poniéndole encima todas las alhajas del difunto, montan en él un muchacho, y le hacen dar una vuelta al rededor del toldo, donde está el cadáver: bajan al muchacho y ponen al cuello del caballo un lazo, de cuyos dos cabos tiran dos indios hasta que lo ahogan. Tienen ya prevenida una hoguera, donde van arrojando à quemar el aparejo y alhajas que lleva el caballo; y la persona que hace cabeza de duelo se va quitando el vestido y cuanto tiene puesto, y lo va arrojando tambien al fuego; como tambien todos los parientes y amigos echan una prenda cada uno, que al efecto traen de sus toldos ó se quitan de su vestidura, compitiéndose en entregar al fuego las mejores, en que denotan mas

© The Complete Work of Charles Darwin Online

obligaciones al muerto, ò mas amistad, amor, &a. Luego desuellan el caballo ahogado, y se reparte su carne entre todos los que echaron sus prendas al fuego. La doliente se està en su toldo muy tapada y sin hablar una palabra. Todas las mugeres parientas y amigas las van á hacer compañia, y para ello se cortan del pelo unos mechones, de modo que les caiga por la frente hasta las cejas, se arañan la cara, se sajan los carrillos, y lloran aunque no tengan gana, con unos gemidos y estilo tan lamentable y lastimoso, que parece se les arranca el alma. A la noche se entregan las viejas del cadáver, y ellas lo entierran donde les parece, sin que lo sepan dolientes ni otro alguno, porque ni se les pregunta, ni ellas pueden decirlo á nadie. Sigue el duelo por quince dias, con los mismos gemidos, y se van matando cada dia caballos del difunto hasta no dejar ni uno, porque todos sus bienes han de quedar destruidos sin que puedan darse á nadie, ni menos habria quien los admitiese, sabiendo que eran del muerto, porque este es un sagrado para ellos inviolable. Todas las lunas se repite un dia el duelo y llanto, y se mata caballo ò yegua si hay amigo ò pariente que quiera darlo, porque al difunto ya no le ha quedado ninguno. Cumplido el año, se repite el duelo por tres dias, con llantos, hoguera, arrojar en ella prendas, y demas ceremonias, cuantas pueden hacer para que se renueve el funeral, como en el dia de la muerte. Despues de estos tres dias, ya no vuelven á acordarse mas del difunto para nada. Toda esta fúnebre pompa y ceremonias se hacen solo por jòvenes ó personas de buena edad y robustas, pues á los que mueren viejos ni se les hace duelo ni se les llora, ni se acuerdan mas de ellos, creyendo que su muerte era precisa, y se contentan con matar en ella un caballo, el peor ó mas desechado que tenga.

Se matan caballos por casamientos y muertes, por la salida de los dientes á los muchachos, cuando comienza la menstruacion á las mugeres, por cualquiera leve mal, por aplacar al ídolo enojado, que creen lo està cuando tienen enfermedades, cuando les cuesta mucho trabajo el tomar la caza, cuando otros indios los hostigan y no tienen fuerzas suficientes para hacerles guerra, porque en este caso aguantan las injurias que les quieran hacer: y toda esta matanza de caballos é yeguas es la causa de no estar toda la costa poblada de este ganado; pues aunque las yeguas paren todos los años, con todo, como dejan pocas, no hay suficientes caballos para surtirlos, sino fuera por los que los indios Pampas de Buenos Aires les

© The Complete Work of Charles Darwin Online

cambian por los cueros que les llevan cuando bajan al Rio Negro, de que resulta tener los de San Julian menos ganado de este que los del golfo de San Jorge y Santa Elena, porque no pueden bajar al Rio Negro con la continuacion que estos.

Creen en la transmigracion del alma, y que las de los que mueren pasan á los que nacen en la familia, en esta forma: el que muere viejo transmigra el alma sin detencion, y por eso no se le llora ni hacen sentimiento, porque dicen vá aquella alma à mejorar de puesto: pero la del que muere jóven ò robusto, queda detenida debajo de tierra, sin destino hasta que se cumple el tiempo que le faltaba para ser viejo, que entonces pasa al primero que nace, y por esta detencion, en que juzgan está comprimida y violenta, le hacen todos los sacrificios al ídolo, para que le dé algun desahogo, interin llega el tiempo decretado. Y son tan supersticiosos en esta materia, que unos se persuaden es conveniente poner en el sepulcro à los difuntos alguna comida y alhajas para que coman sus almas y se diviertan, y otros lo tienen esto por ocioso, creyendo que el ídolo les darà todo lo necesario. Esta materia se gobierna en cada familia segun el modo de pensar del embustero santon, que se engaña y los engaña como quiere, sin que se repare en sus inconsecuencias, aun cuando sus pensamientos y sus disposiciones varíen á cada paso. Estos embusteros les hacen creer que el ídolo hace gestos y habla, haciéndolos ellos conforme les dicen que les vieron hacer; y aunque los mismos indios se hallen presentes al tiempo que el santon descubre el ídolo, y con sus mismos ojos vean que es mentira, como el santon diga que hablò ò hizo gestos, basta para que ellos lo crean así ciegamente.

Júzganse incapaces de poder ofender con alguna de sus operaciones á la deidad que adoran, y así creen que los contratiempos ò castigos que les envia, no es porque ellos los merezcan por sus delitos, sino porque le dà gana al ídolo de tratarlos mal. Así la benignidad de esta potencia consiste en tener buenos caballos, salud y paz, hallar mucha y buena caza, y lograr fidelidad de parte de sus vecinos.

El número de indios que se hallan aquí establecidos, seràn hasta 4,000 personas: ocupan el terreno de la costa que queda señalado. No pueden salir de él, impidièndoselo por el E la mar, por el N el Rio Negro è indios Pampas de Buenos Aires, y por el O y S la Cordillera, imposible de pasar aquí por su altura, y por hallarse

© The Complete Work of Charles Darwin Online

en todo tiempo cubierta de nieve, sin que se verifique la habitan en estos parages ni aun las aves.

En sus batallas pelean à pié, dejando á las mugeres en custodia de los caballos, y se ponen unas como camisas de hombre con mangas cerradas, hechas de diez ó doce cueros de venado, bien sobados, que no los puede pasar el sable ni la daga. En la cabeza se ponen una especie de sombrero, ó casco hecho tambien de cuero de buey ó de caballo, con cuyos resguardos procuran tirarse las cuchilladas á las piernas por ser mas fácil herir en ellas, cortando las botas. Son muy firmes y constantes en la batalla, y no la dejan, una vez que entran en ella, hasta ser vencidos ó muertos. Usan tambien de las bolas, y todo partido que es vencido, ordinariamente son muertos, porque se ensangrientan de manera que ninguno huye: y esta es la causa de no ser mucho mas poblados estos terrenos, porque las mugeres son muy fecundas, y padecen muy pocas enfermedades.

Los toldos los ponen clavando en tierra dos palos de dos ó tres varas de alto, y una y media distantes uno de otro; al lado de cada palo, y á igual distancia clavan otros dos mas cortos, y al O de los seis, clavan otros seis mas cortos à la misma distancia, y al O de estos con igual distancia otros seis de poco mas de media vara de largo. Sobre estos diez y ocho palos echan el cuero con el pelo para afuera, y lo aseguran á las cabezas de todos los palos, de los cuales cuelgan como cortinas de cuero por dentro, que forman las divisiones segun las necesitan, atàndolas de alto abajo à los mismos palos á manera de mamparos firmes: por afuera llega el cuero hasta el suelo por el NO y S, dejàndole siempre la puerta al E de toda la anchura del toldo, el cual queda como si fuese una cueva ovalada. A la puerta no se le pone cosa alguna con que cerrarla, sino en el rigor de los yelos, que la tapan, colgando de ella otro cuero. Las separaciones interiores las acomodan desde el centro hasta el fondo para cada matrimonio, y los hijos y demas familia y parentela duermen todos revueltos en el resto, que queda franco hasta la puerta, uniéndose aquí viudos, viudas, solteros, solteras, parientes, criados y esclavos, y en fin, cuantos dependen ò tienen relacion con la cabeza principal ò amo del toldo. Las doncellas aqui, sin embargo de esta ocasion, procuran, como queda dicho, guardar su virginidad, mientras

© The Complete Work of Charles Darwin Online

tienen esperanza de casarse : pero si llegan à perderla se dan à cualquiera, y tanto ellas como las vuidas pasan buena noche, acomodàndose indistintamente con el que primero se les acerca á dormir con ellas.

Las querellas de los hombres dentro de una misma tolderia se deciden entre ellos à moquetes, sin que puedan usar para ello de otras armas, ni que se atreva nadie á separarlos hasta que ellos se rinden ò separan, y los demas estàn mirando, celebràndolos ó riéndose. Las mugeres cuando riñen se estan muy asentadas, diciéndose palabras ofensivas, hasta que la una echa mano à deshacerse las trenzas del pelo con mucha flema, lo que igualmente hace la otra con la misma, continuando en los improperios : y en teniendo ambas el pelo todo suelto, se lo sacuden, se levantan y se arremeten furiosas, dàndose buenos tirones de él, en que se quitan una á otra cuanto pueden sacar, enredado en las uñas, y las demas mugeres y hombres se las estan mirandò, sin que se atreva nadie à separarlas ; hasta que ellas mismas se apartan en estando cansadas, y se quedan tan amigas de resultas de esto, como si nunca hubiesen reñido, permaneciendo todo aquel dia con el pelo suelto : y en la querella no pueden darse como los hombres moquetes, ni tirarse à romper el vestido, sino solamente el pelo, siendo de lo contrario corregidas de las circunstantes espectadoras. En tiempos de duelo, en marchas, en dias de mucho viento, muchos frios ó heladas, se pintan el rostro de negro ò morado, tanto hombres como mugeres, para que no se les corte el cutis.

Generalmente tienen estos indios índole muy dulce è inocente, y me tomaron tanto afecto y trataron con tanta sencillez, principalmente el cacique de San Julian, que si hubieramos tenido caballos bastantes, pienso no quedaria un palmo de aquellos terrenos que no pudiese registrar en su compañia.

ANTONIO DE VIEDMA.

No. 14.

Extract from Byron's Narrative of the Loss of the Wager.

"These people* were of a small stature, very swarthy, having long, black, coarse hair, hanging over their faces. It was evident, from their great surprise, and every part of their behaviour, as well as their not having one thing in their possession which could be derived from white people, that they had never seen such. Their clothing was nothing but a bit of some beast's skin about their waists, and something woven from feathers over the shoulders; and as they uttered no word of any language we had ever heard, nor had any method of making themselves understood, we presumed they could have had no intercourse with Europeans. These savages, who, upon their departure, left us a few muscles, returned in two days, and surprised us by bringing three sheep." . . . . "At this interview we bartered with them for a dog or two, which we roasted and eat."

"In one of my walks, seeing a very large bird of prey upon an eminence, I endeavoured to come upon it unperceived with my gun, by means of the woods which lay at the back of that eminence; but, when I had proceeded so far in the wood as to think I was in a line with it, I heard a growling close by me, which made me think it advisable to retire as soon as possible: the woods were so gloomy I could see nothing; but, as I retired, this noise followed me close till I had got out of them. Some of our men did assure me, that they had seen a very large beast in the woods; but their description of it was too imperfect to be relied upon."†

"The first night we put into a good harbour, a few leagues to the southward of Wager Island; where, finding a large bitch big with puppies, we regaled upon them. In this expedition we had our usual bad weather and breaking seas, which were grown to such a height the third day, that we were obliged, through distress, to push in at the first inlet we saw at hand. This we had no sooner entered than we were presented with a view of a fine bay, in which, having secured the barge, we went ashore, but the weather being very rainy, and finding nothing to subsist upon, we pitched a bell tent, which we had brought with us, in the wood opposite to where the barge lay. As this tent was not large enough to contain us all, I proposed

* Natives of the Guaianeco Islands.

† Showing that the puma crosses arms of the sea.—R. F.

© The Complete Work of Charles Darwin Online

to four of the people to go to the end of the bay, about two miles distant from the bell tent, to occupy the skeleton of an old Indian wigwam, which I had discovered in a walk that way upon our first landing. This we covered to windward with sea-weed; and, lighting a fire, laid ourselves down in hopes of finding a remedy for our hunger in sleep; but we had not long composed ourselves before one of our company was disturbed by the blowing of some animal at his face; and, upon opening his eyes, was not a little astonished to see by the glimmering of the fire, a large beast standing over him. He had presence of mind enough to snatch a brand from the fire, which was now very low, and thrust it at the nose of the animal, who thereupon made off." . . . . "In the morning, we were not a little anxious to know how our companions had fared; and this anxiety was increased upon our tracing the footsteps of the beast in the sand, in a direction towards the bell tent. The impression was deep and plain, of a large round foot well furnished with claws. Upon acquainting the people in the tent with the circumstances of our story, we found that they too had been visited by the same unwelcome guest, which they had driven away by much the same expedient. We now returned from this cruise, with a strong gale, to Wager's Island; here we soon discovered, by the quarters of dogs hanging up, that the Indians had brought a fresh supply to our market. Upon inquiry, we found that there had been six canoes of them, who, among other methods of taking fish, had taught their dogs to drive the fish into a corner of some pond, or lake, from whence they were easily taken out by the skill and address of these savages."

"Upon returning up the Lagoon,* we were so fortunate as to kill some seal, which we boiled and laid in the boat for sea-stock. While we were ranging along-shore in detached parties, in quest of this and whatever other eatable might come in our way, our surgeon, who was then by himself, discovered a pretty large hole, which seemed to lead to some den, or repository, within the rocks. It was not so rude, or natural, but that there were some signs of its having been cleared and made more accessible by industry. The surgeon for some time hesitated whether he should venture in, from his uncertainty as to the reception he might meet with from any inhabitant; but his curiosity getting the better of his fears, he determined to go in; which he did upon his hands and knees, as the

* Holloway Sound—near Port Otway.

© The Complete Work of Charles Darwin Online

passage was too low for him to enter otherwise. After having proceeded a considerable way thus, he arrived at a spacious chamber; but whether hollowed out by hands, or natural, he could not be positive. The light into this chamber was conveyed through a hole at the top; in the midst was a kind of bier, made of sticks laid crossways, supported by props about five feet in height. Upon this bier, five or six bodies were extended, which, in appearance, had been deposited there a long time; but had suffered no decay or diminution. They were without covering, and the flesh of these bodies was become perfectly dry and hard; which, whether done by any art or secret the savages may be possessed of, or occasioned by any drying virtue in the air of the cave, could not be guessed. Indeed, the surgeon finding nothing there to eat, which was the chief inducement for his creeping into the hole, did not amuse himself with long disquisitions, or make that accurate examination which he would have done at another time; but, crawling out as he came in, he went and told the first he met of what he had seen. Some had the curiosity to go in likewise. I had forgot to mention that there was another range of bodies, deposited in the same manner, upon another platform under the bier. Probably this was the burial-place of their great men, called caciques; but from whence they could be brought, we were utterly at a loss to conceive, there being no traces of any Indian settlement hereabout. We had seen no savage since we left the island, or observed any marks in the coves or bays to the northward, where we had touched, such as fire-places, or old wigwams, which they never fail of leaving behind them; and it is very probable, from the violent seas that are always beating upon this coast, its deformed aspect, and the very swampy soil that every where borders upon it, that it is little frequented."

"A few days after our return, the mystery of the nailing up of the hut, and what had been doing by the Indians upon the island in our absence was partly explained to us; for about the fifteenth day after there came a party of Indians to the island in two canoes, who were not a little surprised to find us here again. Among these was an Indian of the tribe of the Chonos, who live in the neighbourhood of Chiloe. He talked the Spanish language, but with that savage accent which renders it almost unintelligible to any but those who are adepts in that language. He was likewise a cacique, or

© The Complete Work of Charles Darwin Online

leading man of his tribe, which authority was confirmed to him by the Spaniards; for he carried the usual badge and mark of distinction by which the Spaniards and their dependents hold their military and civil employments, which is a stick with a silver head."

"This report of our shipwreck (as we supposed) having reached the Chonos by means of the intermediate tribes, which handed it to one another, from those Indians who visited us; this cacique was either sent to learn the truth of the rumour, or, having first got the intelligence, set out with a view of making some advantage of the wreck."

"Having understood my necessities, they (the two women) talked together some little time; after which, getting up, they both went out, taking with them a couple of dogs, which they train to assist them in fishing. After an hour's absence, they came in trembling with cold, and their hair streaming with water, and brought two fish, which, having broiled, they gave me the largest share; and then we all laid down, as before, to rest."

"After rowing some time, they (the women) gained such an offing as they required, where the water was about eight or ten fathoms deep, and there lay upon their oars. And now the youngest of the two women, taking a basket in her mouth, jumped overboard, and diving to the bottom, continued under water an amazing time; when she had filled the basket with sea-eggs, she came up to the boat-side, and delivering it so filled to the other women in the boat, they took out the contents, and returned it to her. The diver then, after having taken a short time to breathe, went down and up again, with the same success; and so several times for the space of half an hour. It seems as if Providence had endued this people with a kind of amphibious nature, as the sea is the only source from whence almost all their subsistence is derived. This element, too, being here very boisterous, and falling with a most heavy surf upon a rugged coast, very little, except some seal, is to be got any where but in the quiet bosom of the deep. What occasions this reflection is, the early propensity I had so frequently observed in the children of these savages to this occupation, who, even at the age of three years, might be seen crawling upon their hands and knees among the rocks

© The Complete Work of Charles Darwin Online

and breakers, from which they would tumble themselves into the sea, without regard to the cold, which is often intense, and showing no fear of the noise and roaring of the surf."

"The water was at this time extremely cold, and when the divers got into the boats, they seemed greatly benumbed; and it is usual with them, after this exercise, if they are near enough to their wigwams, to run to the fire, to which presenting one side, they rub and chafe it for some time; then turning the other, use it in the same manner, till the circulation of the blood is restored. This practice, if it has no worse effect, must occasion their being more susceptible of the impressions of cold than if they waited the gradual advances of their natural warmth in the open air. I leave it to the decision of the gentlemen of the faculty, whether this too hasty approach to the fire may not subject them to a disorder I observed among them, called the elephantiasis, or swelling of the legs. The divers having returned to their boats, we continued to row till towards the evening, when we landed upon a low point. As soon as the canoes were hauled up, they employed themselves in erecting their wigwams, which they despatch with great address and quickness. I still enjoyed the protection of my two good Indian women, who made me their guest here as before. They first regaled me with sea-eggs, and then went out upon another kind of fishery, by the means of dogs and nets. These dogs are a cur-like looking animal, but very sagacious, and easily trained to this business. Though, in appearance, an uncomfortable sort of sport, yet they engage in it readily, seem to enjoy it much, and express their eagerness by barking every time they raise their heads above the water to breathe. The net is held by two Indians, who get into the water; then the dogs, taking a large compass, dive after the fish, and drive them into the net; but it is only in particular places that the fish are taken in this manner."

"I now understood that the two Indian women with whom I sojourned were wives to this chieftain, though one was young enough to be his daughter; and as far as I could learn, did really stand in the different relations to him both of daughter and wife. It was easy to be perceived that all did not go well between them at this time; either that he was not satisfied with the answers they returned

© The Complete Work of Charles Darwin Online

him to his questions, or that he suspected some misconduct on their side; for, presently after, breaking out into savage fury, he took the young one up in his arms, and threw her with violence against the stones; but his brutal resentment did not stop here, he beat her afterwards in a cruel manner. I could not see this treatment of my benefactress without the highest concern for her, and rage against the author of it; especially as the natural jealousy of these people gave occasion to think that it was on my account she suffered. I could hardly suppress the first emotions of my resentment, which prompted me to return him his barbarity in his own kind; but, besides that this might have drawn upon her fresh marks of his severity, it was neither politic, nor, indeed, in my power, to have done it to any good purpose at this time."

"Our untoward circumstances now found some relief in the arrival of the Indians we waited for; who brought with them some seal, a small portion of which fell to our share. A night or two after they sent out some of their young men, who procured us a quantity of a very delicate kind of birds, called shags and cormorants. Their manner of taking these birds resembles something a sport called 'Bat-fowling.' They find out their haunts among the rocks and cliffs in the night, when, taking with them torches made of the bark of the birch tree, which is common here, and grows to a very large size (this bark has a very unctuous quality, and emits a bright and clear light, and in the northern parts of America is used frequently instead of candle), they bring the boat's side as near as possible to the rocks, under the roosting places of these birds; then, waving their lights backwards and forwards, the birds are dazzled and confounded so as to fall into the canoe, where they are instantly knocked on the head with a short stick the Indians take with them for that purpose. Seals are taken in some less frequented parts of these coasts with great ease; but when their haunts have been two or three times disturbed, they soon learn to provide for their safety, by repairing to the water upon the first alarm. This is the case with them hereabouts; but as they frequently raise their heads above water, either to breathe or look about them, I have seen an Indian at this interval throw his lance with such dexterity as to strike the animal through both its eyes at a great distance; and it is very seldom that they miss their aim."

© The Complete Work of Charles Darwin Online

"These Indians are of middling stature, well set, and very active; and make their way among the rocks with an amazing agility. Their feet, by this kind of exercise, contract a callosity which renders the use of shoes quite unnecessary to them. But before I conclude the few observations I have to make on a people so confined in all their notions and practices, it may be expected I should say something of their religion; but as their gross ignorance is in nothing more conspicuous, and as we found it advisable to keep out of their way when the fits of devotion came upon them, which are rather frantic than religious, the reader can expect very little satisfaction on this head. Accident has sometimes made me unavoidably a spectator of scenes I should have chosen to have withdrawn myself from; and so far I am instructed. As there are no fixed seasons for their religious exercises, the younger people wait till the elders find themselves devoutly disposed, who begin the ceremony by several deep and dismal groans, which rise gradually to a hideous kind of singing, from which they proceed to enthusiasm, and work themselves into a disposition that borders on madness; for suddenly jumping up, they snatch fire brands from the fire, put them in their mouths, and run about burning every body they come near: at other times, it is a custom with them to wound one another with sharp muscle-shells till they are besmeared with blood. These orgies continue till those who preside in them foam at the mouth, grow faint, are exhausted with fatigue, and dissolve in a profusion of sweat. When the men drop their part in this frenzy, the women take it up, acting over again much the same kind of wild scene, except that they rather outdo the men in shrieks and noise. Our cacique, who had been reclaimed from these abominations by the Spaniards, and just knew the exterior form of crossing himself, pretended to be much offended at these profane ceremonies, and that he would have died sooner than have partaken of them. Among other expressions of his disapprobation, he declared, that whilst the savages solemnized these horrid rites, he never failed to hear strange and uncommon noises in the woods, and to see frightful visions; and assured us, that the devil was the chief actor among them on these occasions."

"Here I must relate an anecdote of our nominally Christian cacique. He and his wife had gone off, at some distance from the shore, in their canoe, when she dived for sea-eggs; but not meeting with

© The Complete Work of Charles Darwin Online

great success, they returned a good deal out of humour. A little boy of theirs, about three years old, whom they appeared to be doatingly fond of, watching for his father and mother's return, ran into the surf to meet them: the father handed a basket of eggs to the child, which being too heavy for him to carry, he let it fall, upon which the father jumped out of the canoe, and catching the boy up in his arms, dashed him with the utmost violence against the stones. The poor little creature lay motionless and bleeding, and in that condition was taken up by the mother; but died soon after. She appeared inconsolable for some time; but the brute, his father, shewed little concern about it."

"The first thing that the Indians did in the morning, was to take their canoes to pieces: and here, for the information of the reader, it will be necessary to describe the structure of these boats, which are extremely well calculated for the use of these Indians, as they are frequently obliged to carry them over-land a long way together, through thick woods, to avoid doubling capes and head-lands, in seas where no open boat could live. They generally consist of five pieces, or planks; one for the bottom and two for each side; and as these people have no iron tools, the labour must be great in hacking a single plank out of a large tree with shells and flints, though with the help of fire. Along the edges of the plank they made small holes, at about an inch from one to the other, and sew them together with the supple-jack, or woodbine; but as these holes are not filled up by the substance of the woodbine, their boats would be immediately full of water if they had not a method of preventing it. They do this very effectually by the bark of a tree, which they first steep in water for some time, and then beat it between two stones till it answers the use of oakum, and then chinse each hole so well, that they do not admit of the least water coming through, and are easily taken asunder and put together again. When they have occasion to go over-land, as at this time, each man or woman carries a plank, whereas it would be impossible for them to drag a heavy boat entire."

"Quite worn out with fatigue, I soon fell asleep, and awaking before day, I thought I heard some voices at no great distance from me. As the day appeared, looking further into the wood, I per-

© The Complete Work of Charles Darwin Online

ceived a wigwam, and immediately made towards it; but the reception I met with was not at all agreeable; for stooping to get into it, I presently received two or three kicks in my face, and at the same time heard the sound of voices seemingly in anger, which made me retire and wait at the foot of a tree, where I remained till an old woman peeped out, and made signs to me to draw near. I obeyed very readily, and went into the wigwam: in it were three men and two women; one young man seemed to have great respect shewn to him by the rest, though he was the most miserable object I ever saw. He was a perfect skeleton, and covered with sores from head to foot. I was happy to sit a moment by their fire, as I was quite benumbed with cold. The old woman took out a piece of seal, holding one part of it between her feet, and the other end in her teeth, and then cut off some thin slices with a sharp shell, and distributed them about to the other Indians. She then put a bit on the fire, taking a piece of fat in her mouth, which she kept chewing, every now and then spirting some of it on the piece that was warming upon the fire; for they never do more with it than warm it through. When it was ready, she gave me a little bit, which I swallowed whole, being almost starved. As these Indians were all strangers to me, I did not know which way they were going; and, indeed, it was now become quite indifferent to me which way I went, whether to the northward or southward, so that they would but take me with them, and give me something to eat. However, to make them comprehend me, I pointed first southward, and after to the lake, and I soon understood they were going to the northward. They all went out together, excepting the sick Indian, and took up the planks of the canoe, which lay near the wigwam, and carried them upon the beach, and presently put it together; and, getting everything into it, they put me to the oar. We rowed across the lake to the mouth of a very rapid river, where we put ashore for that night, not daring to get any way down in the dark, as it required the greatest skill, even in the day, to avoid running foul of the stumps and roots of trees, of which this river was full.* I passed a melancholy night, as they would not suffer me to come near the wigwam they had made; nor did they give me the least bit of any one thing to eat since we embarked. In the morning we set off again. The weather proved extremely bad the whole day. We

* In March—April: beginning of autumn.—Caño de Perdon?—R. F.

© The Complete Work of Charles Darwin Online

went down the river at an amazing rate; and, just before night, they put ashore upon a stony beach. They hauled the canoe up, and all disappeared in a moment, and I was left quite alone: it rained violently, and was very dark. I thought it was as well to lie down upon the beach, half-side in water, as to get into a swamp under a dropping tree. In this dismal situation I fell asleep, and awaked three or four hours after in such agonies with the cramp, that I thought I must die upon the spot. I attempted several times to raise myself upon my legs, but could not. At last, I made shift to get upon my knees, and, looking towards the wood, I saw a great fire at some distance from me. I was a long time crawling to it; and when I reached it, I threw myself almost into it, in hopes of finding some relief from the pain I suffered. This intrusion gave great offence to the Indians, who immediately got up, kicking and beating me till they drove me to some distance from it; however, I contrived, a little after, to place myself so as to receive some warmth from it; by which I got rid of the cramp. In the morning, we left this place, and were soon after out of the river. Being now at sea again, the Indians intended putting ashore at the first convenient place to look for shell-fish, their stock of provisions having been quite exhausted for some time. At low water we landed upon a spot that seemed to promise well; and here we found plenty of limpets. Though at this time starving, I did not attempt to eat one, lest I should lose a moment in gathering them; not knowing how soon the Indians might be going again. I had almost filled my hat, when I saw them returning to the canoe. I made what haste I could to her; for I believe they would have made no conscience of leaving me behind. I sat down to my oar again, placing my hat close to me, every now and then eating a limpet. The Indians were employed the same way, when one of them seeing me throw the shells overboard, spoke to the rest in a violent passion; and, getting up, fell upon me, and seizing me by an old ragged handkerchief I had about my neck, almost throttled me; whilst another took me by the legs, and was going to throw me overboard, if the old woman had not prevented them. I was all this time entirely ignorant by what means I had given offence, till I observed that the Indians, after eating the limpets, carefully put the shells in a heap at the bottom of the canoe. I then concluded there was some superstition about throwing these shells into the sea, my ignorance of

© The Complete Work of Charles Darwin Online

which had very nearly cost me my life. I was resolved to eat no more limpets till we landed, which we did some time after, upon an island. I then took notice that the Indians brought all their shells ashore, and laid them above high-water mark. Here, as I was going to eat a large bunch of berries I had gathered from a tree, for they looked very tempting, one of the Indians snatched them out of my hand and threw them away, making me to understand that they were poisonous. Thus, in all probability, did these people now save my life, who, a few hours before, were going to take it from me for throwing away a shell."

"One day, we fell in with about forty Indians, who came down to the beach we landed on, curiously painted.* Our cacique seemed to understand but little of their language, and it sounded to us very different from what we had heard before. However, they made us comprehend that a ship had been upon the coast not far from where we then were, and that she had a red flag: this, we understood some time after, to have been the Anna Pink, whose adventures are particularly related in Lord Anson's voyage; and we passed through the very harbour she had lain in."†

* Probably in the neighbourhood of the 'Estero de Aysen.' in lat. 45° S —R. F.

† No—not through the harbour, but within twenty miles of it, I should suppose.—R. F.

No. 16.

Remarks on the Structure of the Fuegians.

The general form of the Fuegians is peculiar; the head and body being particularly large, and the extremities unusually small: but the feet are broad though short. This peculiarity, no doubt, is owing to their mode of life: being a people who take little exercise, but sit constantly huddled together in their canoes or wigwams; the blood, the source of nourishment, can only circulate freely, and must in greater quantity, in the head and trunk, from the obstruction to its passage into the limbs, owing to their bent position. From the same cause, the want of exercise, this is the form of the Esquimaux and Laplanders.

A man whom I examined was of the middle size, five feet seven inches, and his muscular power about a medium; the circumference of the—

© The Complete Work of Charles Darwin Online

I consider that this man was about the average stature of the Fuegians: they are generally short and broad.

The Fuegian, like a Cetaceous animal which circulates red blood in a cold medium, has in his covering an admirable non-conductor of heat; the corpus adiposum envelopes the body to preserve that temperature necessary to continue the vital functions and circulation of the fluids. In this individual it was particularly thick over the abdomen and dorsum; on the hips it formed a perfect cushion, and filled up the interstices between the muscles in general. Unlike the limbs of porters, smiths, and other athletæ in Europe, where the form and size of each muscle may be traced while in action, the limbs of these people are round and smooth, like the female sex, or the child in infancy. The quantity of fat is to be imputed to their diet; their food is shell-fish and birds, but the greatest dainty is fat of all kinds, that of the seal and penguin in particular; as for vegetable aliment they have none,* nor any taste for it. The muscles were soft, and the viscera (in particular the heart, liver, and lungs,) in good order, —a circumstance which but rarely occurs: the bones were well-formed, with their processes, foramina, and sutures complete.

The complexion of this man was dark; his skin of a copper colour, the native hue of the Fuegian tribes; the eyes and hair black (this is universal, as far as I have seen, and predominates throughout all the aborigines of America, from the Fuegians to the Esquimaux); the epidermis is thicker than in white men; but in the rete mucosum I saw no difference, the copper hue arising from the vessels of the cutis, shining through a thickened scarf-skin, and from its incorporating the particles of smoke and ochre with which their bodies are continually covered.

The hair on this man's head was jet-black, straight, long, and luxuriant, but scanty on other parts of the body. The Fuegians have little beard and no whiskers.

The features of this individual were rounder than they generally are among those of his nation; the form of whose countenance resembles that of the Laplanders and Esquimaux; they have broad faces with projecting cheek-bones; the eyes of an oval form, and drawn towards the temples; the tunica sclerotica of a yellow-white, and the iris deep black; the cartilage of the nose broad and de-

* Mr. Wilson was not aware that they eat birch excrescences, and berries.—R. F.

© The Complete Work of Charles Darwin Online

pressed; the orifice of the mouth large, when shut forming a straight line, when open an ellipsis. The head is bulky, and the hair straight.

The phrenological marks in the skull (said by some persons to include corresponding organs in the brain,) taken on the spot, were as follows:—

THE PROPENSITIES.

Amativeness—full.
Philoprogenitiveness—moderately full.
Concentrativeness—ditto.
Adhesiveness—full.
Combativeness—large.
Destructiveness—very large.
Constructiveness—small.
Acquisitiveness—small.
Secretiveness—large.

Comparison—small.
Wit—ditto
Form—small.
Number—very small.
Language—full.
Causality—small.
Imitation—ditto

The facial angle, according to Camper, 74°, the occipital, 80°.

The warlike propensities in this man were large, agreeing with the little which I know of his history. Taking a general view of the head, the Propensities (the organs most exercised by a barbarian) are large and full; the Sentiments small, few of which are ever called into action, except cautiousness and firmness, which are large; finally, the Intellectual organs, which are chiefly used by man in a civilized state, are small.

The teeth are perfect, and of the usual number; the incisores flat and apparently worn down; other instances of which I have seen. From this it is probable they are sometimes used as grinders.* The reverse of this has been frequently noticed among savages; some, it is said, file their teeth to render them more terrible in battle, while others pull out the two centre incisores, or the cuspidati, by way

* This man could not have been more than forty: probably he was many years younger.—R. F.

© The Complete Work of Charles Darwin Online

of ornament. Their teeth are generally good, regular, and healthy, arising in all probability from the system being free from any constitutional taint.

The viscera of the thorax were healthy, the heart particularly so, with its valves and columna carnosa in good order; the lower part of the thorax and the whole parietes of the abdomen were unusually expanded; the liver very large though healthy, occupying the right hypochondriac and lumbar, the epigastric, and left hypochondriac regions; the spleen remarkably small; the stomach of a moderate size, and containing some muscles and limpets in a half-digested state; the intestines were filled with flatus, which probably took place after death. The large size of the abdomen is to be referred to the squatting position these people assume, the knees and thighs being brought up against the lower part of the belly, force the viscera and intestines upward and forward, thereby distending the lower part of the thorax and front of the abdomen. Here is a peculiarity from habit becoming inherent in the constitution, and descending to posterity, as the children, male and female, are born with large bellies. In like manner Chinese children, from their parents' custom of compressing the feet, are born with them remarkably small.

Besides distending the abdomen mechanically—to this bent position is to be traced the enlarged state of the abdominal viscera, the passage of blood to the extremities being obstructed; an unusual quantity is thereby determined to, and circulated in, the cœliac and mesenteric arteries; the want of support from dress is also to be taken into account. From this stretched and distended state of the abdomen, separating the fibres of the oblique and transverse muscles, and the open state of the inguinal rings, these people must be peculiarly liable on any exertion to ventral hernia: these passages I found open in this individual; and they appeared to be in the same state in other men whom I examined. Cardiac affections mostly prevail among those who are subject to violent exercise, as porters, carriers, and artillerymen. The healthy state of this heart, which it is probable will be generally the case among the Fuegians, is to be imputed to their moderate exertions. In their canoes they are employed fishing or paddling; in their wigwams, which are seldom many yards from the beach, cooking or making small wares of the bones or skins of beasts. The cremaster muscle was strong and

© The Complete Work of Charles Darwin Online

fleshy; the lower extremities were short and ill-proportioned; the thigh of a moderate size, but from the smallness of the muscles of the leg in general, and gestatorii in particular, it looked large; the calf of the leg was very small. The diminutive size of these muscles must be referred to the cause already mentioned—the want of a due circulation in these parts, produced by a cramped position and want of exercise. Having the feet broad and short is common to all who do not wear shoes, the bones being somewhat separated, the ligaments stretched, and the muscles flattened from constantly sustaining the weight of the body unsupported by any covering to the feet. The kidneys were healthy, but unusually destitute of fat. There was no tunica adiposa; the adeps, in this instance, was chiefly collected on the surface, but little in the internal parts. If this is universally the case, it is a wonderful provision of nature to protect their bodies from the inclemency of this inhospitable region. This is the method adopted by nature during the first years of infancy, to habituate the constitution to the vicissitudes and variations of the atmosphere, which otherwise would be incompatible with existence. The arms were better proportioned than the lower extremities; and this is general throughout the Fuegian tribes; the muscles being firmer, and better formed, from the more constant use of these parts, paddling in their canoes, climbing, and making their wigwams. The muscles in general, throughout the body, were healthy, but soft and flabby, unlike the firm sinewy muscle of hardy mountaineers: and the bones less indented than is usual in those who have been accustomed to vigorous exertion.

In another Fuegian, whom I examined, the marks of the Phrenological organs, as taken from the skull, were as follows:—

THE PROPENSITIES.

Amativeness—small.	Destructiveness—full.
Philoprogenitiveness—very large.	Constructiveness—small.
Concentrativeness—full.	Acquisitiveness—full.
Combativeness—very large.	Secretiveness—large.

THE SENTIMENTS.

Self-esteem—very large.	Veneration—full.
Love of approbation—full.	Hope—small.
Cautiousness—large.	Ideality—small.
Benevolence—small.	Firmness—large.

© The Complete Work of Charles Darwin Online

THE INTELLECTUAL ORGANS.

Form—small.	Colouring—small.
Size—large.	Locality—ditto.
Weight—small.	Order—ditto.
Time—very small.	Number—ditto.
Tune—ditto	Language—ditto
Comparison—small.	Wit—ditto
Causality—ditto	Imitation—ditto

The facial angle, 76°, the occipital, 82°.

In this skull also, the propensities were large; the moral sentiments larger than in the former, but the intellectual organs equally small. Destructiveness, secretiveness, and cautiousness, large—faculties, as I have remarked, necessary to a savage warrior: the more refined sentiments, as benevolence, ideality, and conscientiousness were small, with nearly all the intellectual organs.

In this man, also, the teeth were complete; but the incisores not worn down, as in the former: their general regularity and good arrangement were greatly owing to the expanded state of the jaws, giving good space for their growth and shedding. In those persons who have sharp features, where the sides of the face meet at an acute angle, the teeth are often small; or, if large, from want of room, they overlap each other, or push one another out of the natural positions. The broadness of the face and features is owing to the breadth of the base of the cranium, which gives shape and form to the bones of the face. With respect to the arms and legs of this man, I have only to remark, that they agreed exactly with those of the other, in the largeness of the thigh compared to the leg, breadth of the feet, and better proportion of the upper extremities.

JOHN WILSON, (d) Surgeon.

No. 17.

Phrenological Remarks on three Fuegians.*

Yokcushlu, a female, ten years of age.

Strong in attachment.

If offended, her passions strong.

A little disposed to cunning, but not duplicity.

She will manifest some ingenuity.

She is not at all disposed to be covetous.

Self-will at times very active.

Fond of notice and approbation.

She will show a benevolent feeling when able to do so.

Strong feelings for a Supreme Being.

Disposed to be honest.

Rather inclined to mimicry and imitation.

Her memory good of visible objects and localities, with a strong attachment to places in which she has lived.

It would not be difficult to make her a useful member of society in a short time, as she would readily receive instruction.

Orundellico, a Fuegian, aged fifteen.

He will have to struggle against anger, self-will, animal inclinations, and a disposition to combat and destroy.

Rather inclined to cunning.

Not covetous; not very ingenious.

Fond of directing and leading.

Very cautious in his actions: but fond of distinction and approbation.

He will manifest strong feelings for a Supreme Being.

Strongly inclined to benevolence.

May be safely intrusted with the care of property.

Memory, in general, good; particularly for persons, objects of sense, and localities.

To accustomed places he would have a strong attachment.

Like the female, receiving instruction readily, he might be made a useful member of society; but it would require great care, as self-will would interfere much.

* Made in London, in 1830.

© The Complete Work of Charles Darwin Online

El'leparu, about twenty-eight.

Passions very strong, particularly those of an animal nature; self-willed, positive and determined.

He will have strong attachment to children, persons, and places.

Disposed to cunning and caution.

He will show ready comprehension of things, and some ingenuity.

Self will not be overlooked, and he will be attentive to the value of property.

Very fond of praise and approbation, and of notice being taken of his conduct.

Kind to those who render him a service.

He will be reserved and suspicious.

He will not have such strong feelings for the Deity as his two companions.

He will be grateful for kindness, but reserved in showing it.

His memory, in general, good: he would not find natural history, or other branches of science, difficult, if they can be imparted to him; but, from possessing strong self-will, he will be difficult to instruct, and will require a great deal of humouring and indulgence to lead him to do what is required.

No. 17 (*a*).

Instrument executed by Mons. Louis de Bougainville for the delivering up of the Malvinas.

"I, Monsieur Louis de Bougainville, colonel of his most Christian Majesty's army, have received six hundred and eighteen thousand one hundred and eight livres, thirteen sols, and eleven deniers, being the amount of an estimate that I have given in, of the expenses incurred by the St. Malo Company in equipments for founding their *intrusive* establishments in the Malvina Islands, *belonging to his Catholic Majesty*, in the following manner:—

"Forty thousand livres delivered on account to me in Paris, by his Excellency the Count de Fuentes, ambassador of his Catholic Majesty to that court, for which I gave the proper receipt.

"Two hundred thousand livres, which are to be delivered to me at the same court of Paris, according to bills drawn in my favour by

© The Complete Work of Charles Darwin Online

the Marquess of Zambrano, treasurer-general of his Catholic Majesty, upon Don Francisco Ventura Llorena, treasurer-extraordinary of the same; and sixty-five thousand six hundred and twenty-five hard dollars, and three-fourth parts of another, which are equivalent to the three hundred and seventy-eight thousand one hundred and eight livres three sous and eleven deniers, at the rate of five livres per dollar, which I have to receive in Buenos Ayres, on account of bills which have been delivered to me, drawn by his excellency the Baylio Fray, Don Julian Arriaga, secretary of state for the general department of the Indies and navy of his Catholic Majesty.

"In consideration of these payments, as well as in obedience to his Most Christian Majesty's orders, I am bound to deliver up, in due formality, to the court of Spain, those establishments, along with the families, houses, works, timber, and shipping built there, and employed in the expedition; and, finally, every thing therein belonging to the St. Malo Company, as included in the accounts which are so settled, and to his Most Christian Majesty, by this voluntary cession, making void for ever all claims that the company, or any person interested therein may have, or might produce, upon the treasury of his Most Catholic Majesty; nor can they henceforth demand more pecuniary, or any other compensation whatsoever. In testimony whereof, I set my name to this present instrument and voucher, as one principally interested, as well as authorized to receive the whole of this sum, agreeably to a registry in the department of state in St. Ildefonso, 4th October, 1766.

(Signed) "Louis de Bougainville."

Viscount Palmerston to M. de Moreno.

Foreign Office, January 8, 1824.

The undersigned, &c. has the honour to acknowledge the receipt of the note of M. Moreno, &c. dated the 17th of June last, in which he formally protests, in the name of his government, "against the sovereignty lately assumed in the Malvina (or Falkland) Islands, by the crown of Great Britain."

Before the undersigned proceeds to reply to the allegations advanced in M. Moreno's note, upon which his protest against this act on the part of his Majesty is founded, the undersigned deems it proper to draw M. Moreno's attention to the contents of the protest which Mr.

© The Complete Work of Charles Darwin Online

Parish, the British Chargé d'Affaires, at Buenos Ayres, addressed, in the name of his court, to the Minister for Foreign Affairs of the Republic, on the 19th of November 1829, in consequence of the British Government having been informed that the president of the United Provinces of the Rio de la Plata had issued decrees, and had made grants of land, in the nature of acts of sovereignty over the islands in question.

That protest made known to the government of the United Provinces of the Rio de la Plata :—

1st. That the authority which that government had thus assumed, was considered by the British Government as incompatible with the sovereign rights of Great Britain over the Falkland Islands.

2dly. That those sovereign rights, which were founded upon the original discovery and subsequent occupation of those islands, had acquired an additional sanction from the fact, that his Catholic Majesty had restored the British settlement, which had been forcibly taken possession of by a Spanish force, in the year 1771.

3dly. That the withdrawal of his Majesty's forces from the Falkland Islands, in 1774, could not invalidate the just rights of Great Britain, because that withdrawal took place only in pursuance of the system of retrenchment adopted at that time by his Majesty's Government.

4thly. That the marks and signals of possession and of property, left upon the islands, the British flag still flying, and all the other formalities observed upon the occasion of the departure of the governor, were calculated not only to assert the rights of ownership, but to indicate the intention of resuming the occupation of the territory at some future period.

Upon these grounds Mr. Parish protested against the pretensions set up on the part of the Argentine Republic, and against all acts done to the prejudice of the just rights of sovereignty heretofore exercised by the crown of Great Britain.

The Minister for Foreign Affairs of the Republic acknowledged the receipt of the British protest; and acquainted Mr. Parish that his government would give it their particular consideration, and that he would communicate to him their decision upon the subject, so soon as he should receive directions to that effect.

No answer was, however, at any time returned, nor was any objection raised, on the part of the government of the United Provinces of

© The Complete Work of Charles Darwin Online

the Rio de la Plata, to the rights of Great Britain, as asserted in that protest; but the Buenos Ayrean government persisted, notwithstanding the receipt of that protest, in exercising those acts of sovereignty against which the protest was specially directed.

The government of the United Provinces of the Rio de la Plata could not have expected, after the explicit declaration which had been so formally made of the right of the crown of Great Britain to the islands in question, that his Majesty would silently submit to such a course of proceeding; nor could that government have been surprised at the step which his Majesty thought proper to take, in order to the resumption of rights which had never been abandoned, and which had only been permitted to lie dormant, under circumstances which had been explained to the Buenos-Ayrean government.

The claim of Great Britain to the sovereignty of the Falkland Islands having been unequivocally asserted and maintained, during those discussions with Spain, in 1770 and 1771, which nearly led to a war between the two countries, and Spain having deemed it proper to put an end to those discussions, by restoring to his Majesty the places from which British subjects had been expelled, the government of the United Provinces could not reasonably have anticipated that the British Government would permit any other state to exercise a right, as derived from Spain, which Great Britain had denied to Spain herself; and this consideration alone would fully justify his Majesty's Government in declining to enter into any further explanation upon a question which, upwards of half a century ago, was so notoriously and decisively adjusted with another government more immediately concerned.

But M. Moreno, in the note which he has addressed to the undersigned, has endeavoured to shew that, at the termination of the memorable discussions referred to between Great Britain and Spain, a secret understanding existed between the two courts, in virtue of which Great Britain was pledged to restore the islands to Spain at a subsequent period, and that the evacuation of them, in 1774, by his Majesty, was the fulfilment of that pledge.

The existence of such a secret understanding is alleged to be proved; first, by the reservation, as to the former right of sovereignty over the islands, which was contained in the Spanish declaration, delivered at the time of the restoration of Port Egmont and its dependencies to his Majesty; and, secondly, by the concurrent description

© The Complete Work of Charles Darwin Online

of the transaction, as it took place beween the parties, given in certain documents and historical works.

Although the reservation referred to cannot be deemed to possess any substantial weight, inasmuch as no notice whatever is taken of it in the British counter-declaration, which was exchanged against it; and although the evidence adduced from unauthentic historical publications cannot be regarded as entitled to any weight whatever with a view to a just decision upon a point of international rights; yet as the allegations above-mentioned involve an imputation against the good faith of Great Britain, to which his Majesty's Government cannot but feel sensibly alive, the undersigned has been honoured with the King's commands to cause the official correspondence with the court of Madrid, at the period alluded to, to be carefully inspected, in order that the circumstances which really took place upon the occasion might be accurately ascertained.

That inspection has accordingly been made, and the undersigned has the honour to communicate to M. Moreno the following extracts, which contain all the material information that can be gathered from that correspondence relative to the transaction in question :—

The Earl of Rochford to James Harris, Esq.

" St. James's, 25th January 1771.

" I enclose to you a copy of the declaration signed on Tuesday last by Prince Masserano, with that of my acceptance of it in his Majesty's name."

Spanish Declaration.

" Sa Majesté Britannique s'étant plainte de la violence qui avoit été commise le 10 Juin de l'année 1770, à l'Ile communément appelée la Grande Maloüine, et par les Anglais dite Falkland, en obligeant par la force le Commandant, et les sujets de sa Majesté Britannique, à évacuer le port par eux appelé Egmont, démarche offensante à l'honneur de sa Couronne, le Prince de Masseran, Ambassadeur Extraordinaire de sa Majesté Catholique, a reçu ordre de déclarer, et déclare, que sa Majesté Catholique, considérant l'amour dont elle est animée pour la paix, et pour le maintien de la bonne harmonie avec sa Majesté Britannique, et réfléchissant que cet évènement pourroit l'interrompre, a vu avec déplaisir cette expédition capable de la troubler; et dans la persuasion où elle est de la réciprocité de ses senti-

© The Complete Work of Charles Darwin Online

mens, et de son éloignement pour autoriser tout ce qui pourroit troubler la bonne intelligence entre les deux Cours, sa Majesté Catholique désavoue la susdite entreprise violente, et, en conséquence, le Prince de Masseran déclare, que sa Majesté Catholique s'engage à donner des ordres immédiats pour qu'on remette les choses dans la Grande Maloüine, au port dit Egmont, précisément dans l'état où elles étoient avant le 10 Juin 1770, auquel effet sa Majesté Catholique donnera ordre à un de ses officiers, de remettre à l'officier autorisé par sa Majesté Britannique, le fort et le port Egmont, avec toute l'artillerie, les munitions, et effets de sa Majesté Britannique et de ses sujets, qui s'y sont trouvés le jour ci-dessus nommé, conformément à l'inventaire qui en a été dressé.

" Le Prince de Masseran déclare en même tems, au nom du Roi son Maitre, que l'engagement de sa dite Majesté Catholique, de restituer à sa Majesté Britannique la possession du port et fort dit Egmont, ne peut ni ne doit nullement affecter la question du droit antérieur de souveraineté des Iles Maloüines, autrement dites Falkland.

" En foi de quoi, moi, le susdit Ambassadeur Extraordinaire, ai signé la présente Déclaration de ma signature ordinaire, et à icelle fait apposer le cachet de nos armes. A Londres, le 22 Janvier 1771.

(L.S.) (Signé) " Le Prince de Masseran."

British Counter Declaration.

" Sa Majesté Catholique ayant autorisé son Excellence le Prince de Masserano, son Ambassadeur Extraordinaire, à offrir, en son nom royal, au Roi de la Grande Bretagne, une satisfaction pour l'injure faite à sa Majesté Britannique, en la dépossédant du port et fort du port Egmont; et le dit ambassadeur ayant aujourd'hui signé une Déclaration, qu'il vient de me remettre, y exprimant, que sa Majesté Catholique, ayant le désir de rétablir la bonne harmonie et amitié que subsistoient ci-devant entre les deux couronnes, désavoue l'expédition contre le port Egmont, dans laquelle la force a été employée, contre les possessions, commandant, et sujets de sa Majesté Britannique, et s'engage aussi que toutes choses seront immédiatement remises dans la situation précise dans laquelle elles étoient avant le 10 Juin 1770; et que sa Majesté Catholique donnera des ordres en conséquence à un de ses officiers de remettre à l'officier, autorisé par

© The Complete Work of Charles Darwin Online

sa Majesté Britannique, le port et fort du Port Egmont, comme aussi toute l'artillerie, les munitions, et effets de sa Majesté Britannique, et de ses sujets, selon l'inventaire qui en a été dressé; et le dit ambassadeur s'étant de plus engagé, au nom de sa Majesté Catholique, que le contenu de la dite déclaration sera effectué par sa Majesté Catholique, et que des duplicatas des ordres de sa dite Majesté Catholique à ses officiers seront remis entre les mains d'un des Principaux Secrétaires d'Etat de sa Majesté Britannique, dans l'espace de six semaines; sa dite Majesté Britannique, afin de faire voir les mêmes dispositions amicales de sa part, m'a autorisé à déclarer, qu'elle regardera la dite déclaration du Prince de Masserano, avec l'accomplissement entier du dit engagement de la part de sa Majesté Catholique, comme une satisfaction de l'injure faite à la Couronne de la Grande Bretagne. En foi de quoi, moi, soussigné, un des Principaux Secretaires d'Etat de sa Majesté Britannique, ai signé la présente de ma signature ordinaire, et à icelle fait apposer le cachet de nos armes. A Londres, ce 22 Janvier 1771.

(L.S.) (Signé) "Rochford."

James Harris, Esq. to the Earl of Rochford.

"Madrid, 14th February 1771.

"They keep the declaration here as secret as possible. I do not find any to whom they have shown it, except those to whom they are obliged to communicate it. They also report that we have given a verbal assurance to evacuate Falkland's Island in the space of two months."

The Earl of Rochford to James Harris, Esq.

"St. James's, 8th March 1771.

"His Majesty has been pleased to order the Juno frigate of thirty-two guns, the Hound sloop, and Florida store-ship, to be prepared to go to Port Egmont, in order to receive the possession from the Spanish commander there; and as I have spoken so fully to Prince Masserano on the manner of its being executed, it is needless for me to say any more to you upon it.

"I think it right to acquaint you, that the Spanish ambassador pressed me to have some hopes given him of our agreeing to a mutual abandoning of Falkland's Islands, to which I replied, that it was impossible for me to enter on that subject with him, as the restitution must precede every discourse relating to those islands.

© The Complete Work of Charles Darwin Online

"You will endeavour, on all occasions, to inculcate the absurdity of Spain having any apprehensions, from the state in which Port Egmont was before its capture, or the force now sent out, of his Majesty's intending to make use of it for the annoyance of their settlements in the South Sea, than which nothing can be farther from the King's inclination, who sincerely desires to preserve peace between the two nations."

The EARL of ROCHFORD to the LORDS of the ADMIRALTY.

"St. James's, 15th March 1771.

"Your lordships having acquainted me that, in consequence of his Majesty's pleasure, signified in my letter of 22d last, you had ordered the Juno frigate, the Hound sloop, and Florida store-ship, to be prepared to proceed to Falkland's Islands, I am commanded to signify to your lordships his Majesty's pleasure, that you order the commander of the said frigate, as soon as those ships are ready for sea, to repair directly with them to Port Egmont, and presenting to Don Felipe Ruiz Puente, or any other Spanish officer he finds there, the duplicates of his Catholic Majesty's orders sent herewith, to receive, in proper form, the restitution of possession, and of the artillery, stores, and effects, agreeably to the said orders, and to the inventories signed by the Captains Farmer and Maltby (copies of which are annexed), and that you direct him to take an exact account of any deficiency which there may be of the things mentioned in the said inventories, in order that the same may be made good by his Catholic Majesty; giving a copy of the said account, signed by himself, to the Spanish officer, and desiring an acknowledgment under his hand of the same being a true account.

"After the said restitution shall have been completed, it is the King's pleasure that Captain Stott should return immediately to England with the Juno frigate and the Florida store-ship, unless he find it necessary to leave the latter behind; and that the Hound sloop should remain stationed in the harbour till his Majesty's further orders.

"Your lordships will direct Captain Stott to behave with the greatest prudence and civility towards the Spanish commander and the subjects of his Catholic Majesty, carefully avoiding any thing that might give occasion to disputes or animosity, and strictly

© The Complete Work of Charles Darwin Online

restraining the crews of the ships under his command in this respect; but if, at or after the restitution to be made, the Spanish commander should make any protest against his Majesty's right to Port Egmont, or Falkland's Islands, it is his Majesty's pleasure that the commander of his ships should answer the same by a counter-protest, in proper terms, of his Majesty's right to the whole of the said islands, and against the right of his Catholic Majesty to any part of the same.

"In case, from any accident or otherwise, Captain Stott should not, on his arrival at Port Egmont, find any officer there on the part of the King of Spain, your lordships will direct him (supposing he should find it necessary to put any of his men on shore) to avoid setting up any marks of possession, or letting his Majesty's colours fly on shore, as it is for the King's honour that the possession should be formally restored by an officer of his Catholic Majesty; and for that reason it will be proper that the King's commanding officer should keep a good look-out, and, upon perceiving the approach of any vessel of his Catholic Majesty, should re-embark any of his men who may at that time be on shore, that the possession may be indisputably vacant.

"If it should happen that after the King's ships shall have remained as late as all October, no Spanish officer should yet appear, your lordships will direct Captain Stott, in such case, either to proceed himself, or send an officer to Soledad, to deliver his Catholic Majesty's orders to the Spanish commander there, taking care not to salute the fort as a Spanish garrison, and making a protest, in civil terms, against that settlement of his Catholic Majesty's subjects in an island belonging to his Majesty.

"If, within a reasonable time after the delivery of the said order to the Spanish commander, at Soledad, there still shall not arrive at Port Egmont any officer of his Catholic Majesty to make the restitution, it is the King's pleasure that the commanding officer of his ships should then draw up a protest of the inexecution of his Catholic Majesty's late declaration, and should take formal possession, in his Majesty's name; hoisting his Majesty's colours on shore; and that, leaving there the Hound sloop, and Florida store-ship (if the latter is necessary), and sending a duplicate of his protest to the Spanish officer at Soledad, he should proceed to England to lay before your lordships, for his Majesty's information, his report of the manner in which he has executed his commission.

© The Complete Work of Charles Darwin Online

"Your lordships will take care that a sufficient quantity of provisions and necessaries of all kinds may be sent out in the said three vessels; and will, at a convenient distance of time, despatch another store-ship for a further supply.

"P.S. I also enclose to your Lordships the copy of his Catholic Majesty's order to Don Felipe Ruiz Puente, with its translation."

ORDER of the KING of SPAIN.

(Translation.)

"It being agreed between the King and his Britannic Majesty, by a Convention signed in London on the 22d of January last past, by the Prince of Masserano and the Earl of Rochford, that the Great Malouine, called by the English Falkland, should be immediately replaced in the precise situation in which it was before it was evacuated by them on the 10th June last year; I signify to you, by the King's order, that, as soon as the person commissioned by the Court of London, shall present himself to you with this, you order the delivery of the Port de la Cruzada or Egmont, and its fort and dependencies, to be effected, as also of all the artillery, ammunition and effects, that were found there, belonging to his Britannic Majesty and his subjects, according to the inventories signed by George Farmer and William Maltby, Esqs., on the 11th July of the said year, at the time of their quitting the same, of which I send you the enclosed copies, authenticated under my hand; and that, as soon as the one and the other shall be effected with the due formalities, you cause to retire immediately the officer and other subjects of the King which may be there. God preserve you many years. Pardo, 7th February 1771.

"The BALIO FRAY, DON JULIAN DE ARRIAGA.

"To Don Felipe Ruiz Puente."

CAPTAIN STOTT to the ADMIRALTY.

"Juno, Plymouth, 9th December 1771.

"I must beg leave to refer their lordships to the letter I had the honour of writing you from Rio de Janeiro, the 30th of July last, for the occurrences of my voyage to that time; from whence I sailed, with his Majesty's ships under my command, the next day, and arrived at Port Egmont the evening of the 13th of September following. The next morning, seeing Spanish colours flying, and

© The Complete Work of Charles Darwin Online

troops on shore, at the settlement formerly held by the English, I sent a lieutenant to know if any officer was there on behalf of his Catholic Majesty, empowered to make restitution of possession to me, agreeably to the orders of his Court for that purpose, duplicates of which I had to deliver him: I was answered, that the commanding officer, Don Francisco de Orduna, a lieutenant of the royal artillery of Spain, was furnished with full powers, and ready to effect the restitution. He soon after came on board the Juno to me, when I delivered him his Catholic Majesty's orders. We then examined into the situation of the settlement and stores, adjusted the form of the restitution and reception of the possession—instruments for which were settled, executed, and reciprocally delivered (that which I received from the Spanish officer, and a copy of what I gave him, are here enclosed). On Monday, the 16th of September, I landed, followed by a party of marines, and was received by the Spanish officer, who formally restored me the possession; on which I caused his Majesty's colours to be hoisted and the marines to fire three volleys, and the Juno five guns, and was congratulated, as were the officers with me, by the Spanish officer, with great cordiality on the occasion. The next day Don Francisco, with all the troops and subjects of the King of Spain, departed in a schooner which they had with them. I have only to add, that this transaction was effected with the greatest appearance of good faith, without the least claim or reserve being made by the Spanish officer in behalf of his Court."

LORD GRANTHAM to the EARL of ROCHFORD.

"Madrid, 2d January 1772.

"I have received the honour of your lordship's despatch, containing the agreeable intelligence of the restitution of Port Egmont and its dependencies, with the due formalities. On receiving this notice I waited on the Marquis de Grimaldi, to assure him of his Majesty's satisfaction at the good faith and punctuality observed in this transaction. M. de Grimaldi seemed aware of the intention of my visit, and was almost beforehand with me in communicating notice of this event's being known in England. He seemed well pleased at the conclusion of this affair, but entered no further into conversation upon it."

© The Complete Work of Charles Darwin Online

The LORDS of the ADMIRALTY to the EARL of ROCHFORD.

"Admiralty Office, 15th February 1772.

"Having received by the Florida store-ship, lately arrived at Spithead, a letter from Captain Burr, of his Majesty's sloop the Hound, dated at Port Egmont, in Falkland's Islands, the 10th of November last, giving an account that, in the preceding month, two Spanish vessels had arrived there with the artillery, provisions, and stores, which had been taken from thence by the Spaniards, and that he had received the same from a commissary appointed by Don Philip Ruiz Puente, to deliver them up to him; we send your lordship herewith a copy of Captain Burr's said letter, together with a copy of the inventory of the artillery, provisions, and stores, which he had received as aforesaid, for his Majesty's information."

The EARL of ROCHFORD to LORD GRANTHAM.

"St. James's, 6th March 1772.

"It may be of use to inform your Excellency, that his Majesty has determined to reduce the force employed at Falkland's Island to a small sloop with about fifty men, and twenty-five marines on shore, which will answer the end of keeping the possession: and, at the same time, ought to make the court of Spain very easy as to our having any intention of making it a settlement of annoyance to them."

The EARL of ROCHFORD to LORD GRANTHAM.

"St. James's, February 11th, 1774.

"I think it proper to acquaint your Excellency that Lord North, in a speech some days ago in the House of Commons, on the subject of the Naval Establishment for this year, mentioned the intention of reducing the naval forces in the East Indies, as a material object of diminishing the number of seamen; and at the same time hinted, as a matter of small consequence, that, in order to avoid the expense of keeping any seamen or marines at Falkland's Island, they would be brought away, after leaving there the proper marks or signals of possession, and of its belonging to the Crown of Great Britain. As this measure was publicly declared in Parliament, it will naturally be reported to the Court of Spain; and though there is no necessity of your Excellency's communicating this notice offi-

© The Complete Work of Charles Darwin Online

cially to the Spanish ministers, since it is only a private regulation with regard to our own convenience; yet, as I am inclined to think, from what passed formerly upon this subject, that they will rather be pleased at this event, your Excellency may, if they mention it to you, freely avow it, without entering into any other reasonings thereon. It must strike your Excellency that this is likely to discourage them from suspecting designs, which they must now plainly see never entered into our minds. I hope they will not suspect, or suffer themselves to be made believe, that this was done at the request, or to gratify the most distant wish, of the French court; for the truth is, that it is neither more nor less than a small part of an economical naval regulation."

M. Moreno will perceive that the above authentic papers, which have been faithfully extracted from the Volumes of Correspondence with Spain, deposited in the State Paper Office, contain no allusion whatever to any secret understanding between the two Governments, at the period of the restoration of Port Egmont and its dependencies to Great Britain, in 1771, nor to the evacuation of Falkland's Islands, in 1774, as having taken place for the purpose of fulfilling any such understanding. On the contrary, it will be evident to M. Moreno, that their contents afford conclusive inference that no such secret understanding could have existed.

The undersigned need scarcely assure M. Moreno, that the correspondence which has been referred to, does not contain the least particle of evidence in support of the contrary supposition, entertained by the Government of the United Provinces of the Rio de la Plata, nor any confirmation of the several particulars related in M. Moreno's note.

The undersigned trusts, that a perusal of these details will satisfy M. Moreno, that the protest which he has been directed to deliver to the undersigned, against the re-assumption of the sovereignty of the Falkland Islands by his Majesty, has been drawn up under an erroneous impression, as well of the understanding under which the declaration and counter-declaration relative to the restoration of Port Egmont and its dependencies were signed and exchanged between the two courts, as of the motives which led to the temporary relinquishment of those islands by the British Government; and the

© The Complete Work of Charles Darwin Online

undersigned cannot entertain a doubt but that, when the true circumstances of the case shall have been communicated to the knowledge of the government of the united provinces of the Rio de la Plata, that government will no longer call in question the right of sovereignty which has been exercised by his Majesty, as undoubtedly belonging to the Crown of Great Britain.

The undersigned requests, &c.

(Signed) PALMERSTON.

Foreign Office, January 8th, 1834.

No. 18.

By Robert Fitz-Roy, Commander of H. M. sloop "Beagle," off Watchman Cape, on the coast of Patagonia, 22d January 1834.

You are hereby required and directed to proceed in his Majesty's schooner, Adventure, under your command, to survey the Falkland Islands.

New Island appears to me an eligible place for beginning your operations.

Proceeding round the southern coasts, you will endeavour to meet me, in Berkeley Sound, early in March.

After meeting me, or after the twenty-fifth of March, you will proceed to the northern shores of the Falkland Islands, and into Falkland Sound.

If, after going round the islands, you have time enough to make particular plans of any of the best harbours, you will do better than I now anticipate.

All that I think time and weather will allow you to accomplish is a coast survey on a scale of one quarter of an inch to a mile of latitude.

You will time your departure from the Falklands, so as to meet me at the west end of Elizabeth Island, in the Strait of Magalhaens, on or before the first day of next June.

R. F.

To Lieut. J. C. WICKHAM,
commanding H. B. M. schooner "Adventure."

No. 19.

Winds, Weather, and Currents off Chiloé and the Chonos Archipelago.

So much has been stated by Captain King (vol. i.) respecting the weather at Chiloé; and also with regard to that of the Gulf of Peñas, and neighbouring coast, that I need make but few remarks.

There is much less difference between the climate; the prevailing winds, and the order in which they follow; the tides; and the currents on the outer coast of Chiloé, and at the west entrance of Magalhaens Strait, including the intermediate coasts, than persons would suppose who judge only by their geographical positions. North-westerly winds prevail, bringing clouds and rain in abundance. South-westers succeed them, and partially clear the sky with their fury; then the wind moderates, and hauls into the south-east quarter, where, after a short interval of fine weather, it dies away. Light airs spring up from the north-east, freshening as they veer round to north, and augment the store of moisture which they always bring; from the north they soon shift to the usual quarter, north-west, and between that point and south-west they shift and back sometimes for weeks before they take another round turn. When the wind backs (from south-west to west-north-west, &c.), bad weather and strong winds are sure to follow. On that coast wind never backs suddenly, but it shifts with the sun (with respect to that hemisphere) very suddenly, sometimes flying from north-west to south-west or south in a most violent squall. Before a shift of this kind there is almost always an opening, or light appearance, in the clouds towards the south-west, which the Spaniards call an eye (ojo), and for that signal the seaman ought to watch carefully. As the sudden shifts are always with the sun, no man ought to be taken aback unexpectedly; for so long as a north-wester is blowing with any strength, accompanied by rain, so long must he recollect that the wind may fly round to the south-west quarter at any minute. It never blows hard from east; rarely with any strength from north-east; but an occasional severe gale from south-east may be expected, especially about the middle of winter (June, July, August). In the summer southerly winds last longer and blow more frequently than they do in winter, and the reverse. The winds never go completely

© The Complete Work of Charles Darwin Online

round the circle; they die away as they approach east; and after an interval of calm, more or less in duration, spring up gradually between north-east by east and north. Heavy tempests sometimes blow, from west-north-west to south-west; and those winds blowing directly on shore are most to be guarded against. As to the tides, they are simple and uniform in the extreme. High water, at full and change, takes place within half an hour of noon, from Valdivia to Landfall Island; and the rise of tide is every where, on the outer coasts within those limits, nearly the same, namely, from four to eight feet. In the offing no stream of tide is any where discernible, and even close to the land it does not exceed one knot, or at most two knots an hour. On this extent of coast what little current is felt, sets southward, except during or before strong or lasting southerly winds: its influence is, however, but trifling, upon a ship out of soundings.* A heavy swell, from the westward, drives in upon all the coast. A barometer is invaluable.

como tres leguas, ó poco ménos, se halla el Puerto donde ancló el Pingue-Ana de la Esquadra de Anson: tiene varias Islitas á entrada: la mayor es la del S. donde dexa un canal de 10 brazas de agua.

Este Puerto se compone de una ensenada ácia el S. S. O. y un estero al S. E. por qualquiera parte de las Islitas que tiene en la boca se puede entrar: es buen Puerto, manso, y seguro para qualquier embarcacion. Desde la punta que avanza mas E. O. como una y media legua del estero de Diego Gallegos, que se ve desde San Fernando al S. corre la Costa al N d. haciendo como ensenada, y en ella está la dicha Isla de Inche, que es el principio del Archipiélago de los Chonos, entre la qual y la Tierra-Firme está otro de Farallones grandes, y pequeños. Los vientos que se experimentáron por tiempo de 17 dias por el mes de Enero fuéron S. O. y O. que es el que llaman Travesía, y regularmente viene con zerrazon.

La Tierra-Firme es de serranía alta, y pelada, de piedra áspera, color de ceniza, y en las faldas y quebradas bosque, que me parece nada cultivable: todo es península que cercan los dos mares: por la parte del N. termina en un golfito casi circular, que llaman la laguna de San Rafael, y por el S. da principio al golfo de San Estevan donde desemboca el rio de San Tadeo; de uno á otro mar habrá de 2 á 3 leguas, aunque lo navegable del rio pasa de 5, por las vueltas y revueltas, que son muchas. De la dicha laguna al embarcadero del mismo rio habrá como 20 quadras; y éste es el Istmo que llaman de Ofqui, y vulgarmente por otro nombre el Desecho. Este rio de San Tadeo baxa de una cordillera, cuya abra se ve muy cerca de la laguna, y desemboca, como he dicho, en el golfo de San Estevan, cuya boca es algo peligrosa porque tiene poco fondo, y estrecha tanto que solo se puede entrar ó salir quando el mar está tranquilo. Al frente de su boca al S. como 4 leguas está la Isla de San Xavier, y al S. O. de 2 ½ à 3 leguas una punta ó península donde hay varias ensenadas, y caletas que son buenos Puertos; y de estos N. O. un bello estero directo mas de 2 leguas, muy sereno, de suficiente fondo, y bueno; pero con un pequeño baxo que tiene en su entrada del medio al S.: se le puso el nombre de San Quintin.

De la expedicion que los Padres Fr. Benito Marin, y Fr. Julian Real, Misioneros del Colegio de Ocópa, y destinados á las Misiones

© The Complete Work of Charles Darwin Online

del Archipiélago de Chiloe, hiciéron á últimos del año de 1778, y principios del de 1779, á los Archipiélagos de Guaitécas, y Guaianeco, al Sud de aquella Provincia, en solicitud de los Indios Gentiles.

El 10 se hiciéron á la vela, y con viento favorable navegáron casi todo el golfo que media entre Chayamapu, y Tagau, y llegáron por la tarde al Puerto de Tualad.

Surgiéron de éste al amanecer, (11) no obstante que el N. estaba considerablemente fresco, y que les ponia en cuidado, porque permaneciendo anclados conocian mayor riesgo; y lográron en pocas horas anclar en Charraguel, aunque habian ántes arribado á Tagau para comer; y para seguir desde éste el rumbo para el otro dexáron el canal que se dirige á la laguna de San Rafael, y tomáron el de Aú, cuya boca tiene como un quarto de legua de ancho por el O. E. Tomáron este rumbo con el fin de reconocer si habia otra salida mas fácil para el mar de Guaianeco: y diéron fondo en Yepusnec, en donde por la noche estuviéron en manifiesto peligro, porque sentándose la piragua grande sobre una piedra luego que la vaciante tomó su curso, se bolcó por un costado; pero mediante el favor de Dios, y patrocinio de María Santisima, cuyo nombre tenia la embarcacion, y poniendo por su parte las diligencias que en tan arriesgado caso eran necesarias, consiguiéron salir libres en todo, y sin daño alguno en la piragua.

Enderezada ésta, y viéndola ya voyante saliéron de aquel Puerto, y fuéron á comer á otro llamado el Obscuro. (12) Surgiéron luego, y continuáron la navegacion por el mismo canal, dexando al E. otros dos pequeños con rumbo al S. y llegáron á hacer noche en Tucúa: y porque entráron en el canal la víspera de San Diego, y navegáron por él todo el dia de este glorioso Santa, le tituláron con su nombre.

El siguiente dia no pudiéron salir por la mañana por lo mucho que llovió, pero aprovecháron la tarde saliendo para otro sitio, que halláron muy incómodo por la fuerza de la corriente que en él experimentáron llevaban las aguas.

De éste surgiéron á la mañana siguiente (14) con el fin de entrar por la primera boca de los dos referidos canales; y habiendo navegado hora y media con este designio, no pudiéron romper contra la fuerza de las corrientes que halláron, viendose obligados á arribar: á pocas horas se volviéron á levar, y navegáron por la primera boca; pero encontrándose despues con otra, que tampoco les fué posible

© The Complete Work of Charles Darwin Online

romper contra su corriente impetuosa, y arribáron á una ensenada para esperar proporcion favorable. Por la tarde fuéron algunos marineros, y un práctico con el Padre Fr. Benito á reconocer la boca que esperaban pasar; y regresáron asombrados de haber visto lo encrespado, y entumecido de las olas por el encuentro de unas con otras, todo lo que les causó considerable horror, y llenó su corazon de temor al considerar les era forzoso haber el pasar por tan manifiesto peligro.

Luego que dixéron Misa, (15) y estando el mar en creciente, saliéron de la ensenada, y no obstante el sobresalto que todos llevaban lográron pasar con felicidad la boca: continuáron navegando, y diéron fondo ántes de medio dia. Experimentáron allí el lleno de las aguas entre una y dos de la tarde, siendo en el mar á las nueve.

Prosiguiéron su viage, y viéron el fin de un grande estero. (16) Regresáron, y aunque al O. E. encontráron otro canal no entráron á reconocerle por no perder tiempo, y poder llegar adonde estuviesen asegurados para desembocar por la arriesgada boca referida.

Este dia entre dos y tres de la tarde consiguiéron pasarla felizmente, y fuéron á anclar en un pequeño canal que se dirige al Desecho. (17)

Prosiguiéron la navegacion, y halláron el canal principal que va al Desecho, nombrado Celtau, y llegáron á hacer noche en el Puerto Mosado. (18)

Saliéron de éste, y ántes que principiase la vaciante ganáron la boca de Celtau, lo que no hubieran conseguido con corta detencion que hubiesen tenido, como sucedió á una de las piraguas pequeñas, que se quedó fuera por su demora.

Al siguiente dia navegáron un pequeño golfo que se encuentra ántes de la boca de la laguna de San Rafael, y tomando Puerto ancláron en el, y permaneciéron toda la mañana del otro dia, esperando terminase la vaciante, no obstante haber viento N. claro, y favorable. (21)

Continuáron su derrota, y desembocáron en dicha laguna, la que rebalsáron con tiempo apacible, y tambien lo era su vista por los muchos farallones de nieve que en ella halláron, unos grandes, otros pequeños, y medianos otros. Está situada entre los 46 gr. 55 min. y 47 gr. 5 min. de latitud. Diéron fondo á las nueve de la mañana en el Puerto de San Rafael, el que solamente está resguardado por el S. y O. E. Pasáron luego los prácticos, y el Piloto Oyarsum á reconocer el Desecho, y regresáron con las funestas noticias de que

© The Complete Work of Charles Darwin Online

el palo donde se enganchaba, y afianzaba el aparejo para subir las piraguas se habia ya caido, y que el rio San Tadeo habia rebentado, y formado varios brazos, y diversos rumbos.

Este dia fuéron los Pilotos, (23) con lo mas de la tripulacion, ésta con herramientas para abrir el camino, y aquellos para reconocer, é informarse si era ó no transitable dicho rio: y juzgándose conveniente que todo esto lo presenciase uno de los Religiosos, fué el Padre Fr. Benito con los referidos al reconocimiento. Hecho éste se resolvió continuar el viage. Despues de puesto el sol amenazó el tiempo de borrasca, la que se verificó, y llegó á tanto, que pasáron la noche con mucha afliccion y temores, sin poder descansar en toda ella. Resultó de esta tormenta, que de las dos piraguas pequeñas, la una perdió el codaste, y la otra quedó tan maltratada, que solo su plan y una falca quedáron servibles. Continuó el tiempo en esta disposicion hasta el dia 28.

En este, aunque ayudó poco, pasáron hasta el principio del Desecho, y luego diéron disposicion, y probáron á subir la piragua entera; pero habiendo conseguido llegase su proa á lo último de la escalera, faltó el puño de la garita, y descendió precipitada al principio, pero sin daño alguno.

Este dia, (29) aunque festivo por Domingo, considerando por suficiente y justa causa la notable necesidad en que se hallaban, le empleáron en trabajar, y prevenir lo necesario para subir la piragua: y al siguiente despues de la Misa se principió la maniobra; pero aun con las muchas y eficaces diligencias que hiciéron no pudiéron conseguir el fin que deseaban, y resolviéron quitar las falcas á la piragua, con lo que lográron su deseo, y la subiéron hasta lo mas penoso.

Conseguido esto empleáron este dia (Dic^{e}. 1°.) en que algunos de la tripulacion fuesen á trabajar para levantar nueva piragua, y otros á conducir las cargas: y el dia 2 despacháron la piragua Santa Teresa á la Ciudad de Castro para que diese noticia de quanto hasta este dia les habia acaecido.

El 3 pasáron á pie el Desecho, y baxáron al rancho que ya estaba prevenido en la playa del rio de San Tadeo. Permaneciéron allí hasta que se aprestáron con todo lo necesario las dos piraguas. El dia 17 continuáron el viage navegando rio abaxo. Padeciéron algunos peligros y aflicciones por haberse quebrado las piraguas, y con especialidad la San Joseph; pero pudiéron llegar á la boca, ó desembocadero del rio San Tadeo en el golfo de San Estevan, y tomar Puerto en un estero estrecho y largo.

© The Complete Work of Charles Darwin Online

(A la vuelta.)

Al siguiente dia* emprendiéron la subida por el rio, y logrando la creciente favorable hiciéron buen viage; y el 16 llegáron á comer al Desecho, en donde dentro de un rancho halláron una carta del P. Fr. Francisco Menendez, por la que viéron les esperaba en la laguna de San Rafael: gozosos con tan plausible noticia pasáron por la tarde el Desecho, y encontráron á dicho Religioso en la escalera.

Los dos siguientes dias permaneciéron allí, empleando la tripulacion en conducir á la laguna lo que venia en las piraguas (las que dexáron en piezas en el rancho del embarcadero del rio) y pusiéron boyante la piragua del Patrocinio.

El dia 19 saliéron despues de comer, y navegando á remo toda la tarde llegáron al anochecer á tomar Puerto; pero ántes de dar fondo se asentó la piragua, y pasáron en ella la noche, hasta que con la creciente á la madrugada pudiéron lograr que boyase; y no obstante que habia N. se aprovecháron de la vaciante, y pasáron la segunda boca. Refrescó el viento, y continuáron navegando el golfo atracados al E., y fuéron á comer en el Puerto llamado Chauguaguen, y de allí se leváron, y siguiéron por el E. hasta cerca de la boca de Celtau, donde pasáron la noche. (20)

Segunda Expedicion.

Hecha á los referidos Archipiélagos de Guaitécas, y Guaianeco, por los Religiosos Misioneros P. Fr. Francisco Menendez, y P. Fr. Ignacio Bargas, en solicitud de la reduccion de los Gentiles, á fines del año de 1779, y principios del de 1780.

Primeramente, nuestro viage hasta la laguna† (es la de San Rafael) fué feliz, sin otra novedad que algunos sustos á la salida del golfo: llegamos el dia de los Difuntos despues de haber dicho los dos Misa en Vicuñamo al Desecho.‡ Descargóse en la escalera el mismo dia, y por la tarde se sacó la piragua el Patrocinio hasta media quilla del agua: y al otro dia de mañana se aseguró del todo, y por la tarde la otra. Intentamos hacer otra piragua mas, y por haber caido enfermos cinco marineros no se concluyó; quedó hecho el plan, y costados. El Viérnes siguiente (5) comenzáron los temporales, y continuáron con algunas nevadas, hasta que se hallaba el bastimento en el embarcadero del rio, y las piraguas ya levantadas, que fué á los 24 dias de nuestra llegada.

* Febº. 15, 1779. † Octº. 11, 1779. ‡ Novº. 2.

© The Complete Work of Charles Darwin Online

Parecia que el tiempo se oponia todo á la expedicion. Para botar las piraguas se secó el rio, y comenzó el S.; todo nos iba en contra; pero su Divina Magestad permitió que con buen tiempo creciese el rio, y á los 26 dias, el de San Jacome de la Marca, y primera Dominica de Adviento, baxamos el rio, y fuí á decir Misa á la boca del rio San Tadeo. (Nov^{e}. 28.)

* * * * * *

Uno de los Gentiles nos dixo habia visto por aquellos parages Huampus mas grandes, que andaba la gente por las bergas, y falcas mayores que las nuestras: todas noticias deseadas; pero no lo quieren averiguar.

Nuestro Señor guarde á V. R. muchos años, Castro y Marzo 14 de 1780.

* * * * * *

Huampus es nombre propio del idioma Veliche, y significa qualquiera embarcacion; y en esté dicho dió á entender aquel Gentil á los Religiosos que en aquella altura habia visto navíos, como claramente se infiere de expresar que la gente andaba por las bergas.

No. 23.

EXTRACT from Burney's History of the Discoveries in the South Sea. Vol. iv. p. 118, &c.

Oct. 11th, 1681, they* were in latitude 49° 54′ S., and estimated their distance from the American coast to be 120 leagues. The wind blew strong from the S.W. and they stood to the S.E. On the morning of the 12th, two hours before day, being in latitude by account 50° 50′ S., they suddenly found themselves close to land. The ship was ill prepared for such an event, the fore-yard having been lowered to ease her, on account of the strength of the wind. "The land was high and towering; and here appeared many islands scattered up and down." They were so near and so entangled, that there was no possibility of standing off to sea; and, with such light as they had, they steered as cautiously as they could in between some islands and along an extensive coast, which, whether it was a larger island, or part of the continent, they could not know. As the day advanced, the land was seen to be mountainous and craggy, and the tops covered with snow.

* The buccaneers under Sharp.

© The Complete Work of Charles Darwin Online

Sharp says, "we bore up for a harbour, and steered in northward about five leagues. On the north side there are plenty of harbours." "At eleven in the forenoon they came to an anchor in a harbour in forty-five fathoms, within a stone's cast of the shore, where the ship was land-locked and in smooth water. As the ship went in, one of the crew, named Henry Shergall, fell overboard as he was going into the spritsail top, and was drowned; on which account this was named Shergall's Harbour."

The bottom was rocky where the ship had anchored; a boat was therefore sent to look for better anchorage. They did not, however, shift their berth that day; and during the night, strong flurries of wind from the hills, joined with the sharpness of the rocks at the bottom, cut their cable in two, and they were obliged to set sail. They ran about a mile to another bay, where they let go another anchor, and moored the ship with a fastening to a tree on shore.

They shot geese, and other wild-fowl. On the shores they found large muscles, cockles like those in England, and limpets: here were also penguins,* which were shy, and not taken without pursuit; "they paddled on the water with their wings very fast, but their bodies were too heavy to be carried by the said wings." The first part of the time they lay in this harbour, they had almost continual rain.

On the night of the 15th, in a high north wind, the tree to which their cable was fastened gave way, and came up by the root, in consequence of which, the stern of the ship took the ground and damaged the rudder. They secured the ship afresh by fastening the cable to other trees; but were obliged to unhang the rudder to repair.

The 18th was a day of clear weather. The latitude was observed 50° 40′ S. The difference of the rise and fall of the tide was seven feet perpendicular: the time of high-water is not noted. The arm of the sea, or gulf, in which they were, they named the English Gulf; and the land forming the harbour, the Duke of York's Island; "more by guess than any thing else; for whether it were an island or continent was not discovered."

Ringrose says, "I am persuaded that the place where we now are, is not so great an island as some hydrographers do lay it down, but rather an archipelago of smaller islands. Our captain gave to them the name of the Duke of York's Islands. Our boat which went eastward found several good bays and harbours, with deep water close to the shore; but there lay in them several sunken rocks, as there did

* Steamer ducks. Penguins swim like fish.—R. F.

© The Complete Work of Charles Darwin Online

also in the harbour where the ship lay. These rocks are less dangerous to shipping, by reason they have weeds lying about them."

From all the preceding description, it appears that they were at the south part of the island named Madre de Dios in the Spanish atlas; which island is south of the channel, or arm of the sea, named the Gulf de la S^ma^ Trinidada; and that Sharp's English Gulf is the Brazo de la Conçepçion of Sarmiento.

Ringrose has drawn a sketch of the Duke of York's Islands, and one of the English Gulf; but which are not worth copying, as they have neither compass, meridian line, scale, nor soundings. He has given other plans in the same defective manner, on which account they can be of little use. It is necessary, however, to remark a difference in the plan which has been printed of the English Gulf, from the plan in the manuscript. In the printed copy, the shore of the gulf is drawn in one continued line, admitting no thoroughfare; whereas, in the manuscript plan, there are clear openings, leaving a prospect of channels through.

Towards the end of October, the weather settled fair. Hitherto they had seen no inhabitants; but on the 27th, a party went from the ship in a boat on an excursion in search of provisions, and unhappily caught sight of a small boat belonging to the natives of the land. The ship's boat rowed in pursuit, and the natives, a man, a woman, and a boy, finding their boat would be overtaken, all leaped overboard and swam towards the shore. This villanous crew of buccaneers had the barbarity to shoot at them in the water, and they shot the man dead; the woman made her escape to land; the boy, a stout lad about eighteen years of age, was taken, and with the Indian boat, was carried to the ship.

The poor lad thus made prisoner had only a small covering of seal skin. "He was squint-eyed, and his hair was cut short. The doree, or boat, in which he and the other Indians were, was built sharp at each end and flat bottomed: in the middle they had a fire burning for dressing victuals, or other use. They had a net to catch penguins, a club like our bandies, and wooden darts. This young Indian appeared by his actions to be very innocent and foolish. He could open large muscles with his fingers, which our buccaneers could scarcely manage with their knives. He was very wild, and would eat raw flesh."

By the beginning of November the rudder was repaired and hung. Ringrose says, "we could perceive, now the stormy weather was

© The Complete Work of Charles Darwin Online

blown over, much small fry of fish about the ship, whereof before we saw none. The weather began to be warm, or rather hot; and the birds, as thrushes and blackbirds, to sing as sweetly as those in England."

On the 5th of November, they sailed out of the English Gulf, taking with them their young Indian prisoner, to whom they gave the name of Orson. As they departed, the natives on some of the lands to the eastward made great fires. At six in the evening the ship was without the mouth of the gulf: the wind blew fresh from the N.W., and they stood out S.W. by W., to keep clear of breakers, which lie four leagues without the entrance of the gulf to the S. and S.S.E. Many reefs and rocks were seen hereabouts, on account of which they kept close to the wind till they were a good distance clear of the land. Their navigation from here to the Atlantic was, more than could have been imagined, like the journey of travellers by night in a strange country without a guide. The weather was stormy, and they would not venture to steer in for the Strait of Magalhaens, which they had purposed to do, for the benefit of the provision which the shores of the strait afford, of fresh water, fish, vegetables, and wood. They ran to the S. to go round to the Tierra del Fuego, having the wind from the N.W., which was the most favourable for this navigation; but they frequently lay to, because the weather was thick.

On the 12th, they had not passed the Tierra del Fuego. The latitude, according to observation that day, was 55° 25′, and the course they steered was S.S.E.

On the 14th, Ringrose says, "the latitude was observed 57° 50′ S., and on this day we could perceive land, from which at noon we were due W." They steered S. by E., and expected that at daylight the next morning they should be close in with the land; but the weather became cloudy, with much fall of snow, and nothing more of it was seen. No longitude or meridian distance is noticed, and it must remain doubtful whether what they took for land was floating ice; or their observation for the latitude erroneous, and that they saw the Isles of Diego Ramirez?

Three days afterwards, in latitude 58° 30′ S., they fell in with ice islands, one of which they reckoned to be two leagues in circumference. A strong current set here southward. They held on their course eastward so far, that when at last they did sail northward, they saw neither the Tierra del Fuego nor Staten Island. (End of November 1681.)

© The Complete Work of Charles Darwin Online

No. 24 (*a*).

EXTRACT from the Voyage of Lionel Wafer in 1686, describing the Island of Santa Maria, under the mistaken name of Mocha.

" The island afforded both water and fresh provision for our men. The land is very low and flat, and upon the sea coast sandy; but the middle ground is good mould, and produces maize, wheat, and barley, with variety of fruits, &c. Here were several houses belonging to the Spanish Indians, which were very well stored with dunghill fowl. They have here also several horses: but that which is most worthy of note, is a sort of sheep they have, which the inhabitants call ' carnero de tierra.' This creature is about four feet and a half high at the back, and a very stately beast. These sheep are so tame that we frequently used to bridle one of them, upon whose back two of the lustiest men would ride at once round the island, to drive the rest to the fold. His ordinary pace is either an amble or a good hand-gallop; nor does he care for going any other pace during the time his rider is upon his back. His mouth is like that of a hare; and the hare-lip above opens as well as the main-lips, when he bites the grass, which he does very near. His head is much like an antelope, but they had no horns when we were there; yet we found very large horns much twisted, in the form of a snail-shell, which we suppose they had shed; there lay many of them scattered upon the sandy bays. His ears resemble those of an ass, his neck is small, and resembling a camel's. He carries his head bending and very stately, like a swan; is full-chested, like a horse, and has his loins much like a well-shaped grey-hound. His buttocks resemble those of a full-grown deer, and he has much such a tail. He is cloven-footed, like a sheep, but on the inside of each foot has a large claw, bigger than one's finger, but sharp, and resembling those of an eagle. These claws stand about two inches above the division of the hoof; and they serve him in climb-ing rocks, holding fast by whatever they bear against. His flesh eats as like mutton as can be: he bears wool twelve or fourteen inches long upon the belly; but it is shorter on the back, shaggy, and a little inclining to curl. It is an innocent and very serviceable beast, fit for any drudgery. Of these we killed forty-three; out of the maw of one of which I took thirteen bezoar stones, of which some were ragged, and of several forms; some long, resembling coral; some

© The Complete Work of Charles Darwin Online

round, and some oval, but all green when taken out of the maw; yet by long keeping they turned of an ash colour."

No. 25.

By ROBERT FITZ ROY, Captain of H.M. Surveying Sloop Beagle.

You are hereby required and directed to take charge and command of the schooner Constitucion, and the party placed by me under your orders.

Directly the vessel is ready for sea, you will proceed to survey those parts of the coast of Chile which lie between the parallels of thirty-one and thirty-five: and on or before the 31st of July, you will endeavour to meet me in Callao Roads.

MEMORANDA:

At this time of year, unfavourable foggy weather may be expected to impede your progress very materially; but successful, or the contrary, you must endeavour to be punctual at your rendezvous.

At many places the landing will be bad. Do not on any account land then in a boat. Go near only in a boat; land on a balsa.

On so straight a coast, subject to a continuance of cloudy weather, views of the land may be particularly useful. Mr. King is added to your party, because he draws such views very correctly.

Do not delay in attempting to get deep-sea soundings, when not hove-to for other purposes.

Be very particular in noticing characteristic appearances of the land about anchorages; and such peculiarities of marks, or otherwise, as may help to guide a stranger.

Notice where and how wood and water are to be procured.

Let Mr. King keep a journal for you, to be given afterwards to me. No log will be required by me; but let that journal contain every note which you consider likely to be useful.

I shall be anxious to send away a tracing of your work, as soon as possible after your arrival at Callao.

Remember that Paposo is the northernmost inhabited place over which the government of Chile has authority. In approaching vessels or places on the coast of Peru, be particularly on your guard.

Inquire about the earthquake and waves of the 20th of February.

At each place make the chief Authority acquainted with your busi-

© The Complete Work of Charles Darwin Online

ness, and the accompanying letter from the government of Chile, as soon as possible.

H.M. sloop Beagle, in Port Herradura, Coquimbo,
6th day of June 1835.

To Lieutenant B. J. SULIVAN, R. F.
H.M.S. Beagle.

No. 26.

By ROBERT FITZROY, Captain of His Majesty's Surveying Sloop Beagle.

You are hereby required and directed to take charge and command of his Majesty's surveying sloop Beagle, until I rejoin you at Callao.

You will conform your conduct, in all respects, to the instructions sent to me for my guidance by the Lords Commissioners of the Admiralty.

You will sail from Valparaiso on the 28th of this month, or as soon after as possible, and proceed direct to Copiapo.

Thence you will proceed to Callao, calling at Iquique, if circumstances are favourable ; and at Callao you will await my arrival.

H.M. sloop Beagle, in Valparaiso Bay,
18th of June 1835. R. F.

To Lieut. J. C. WICKHAM,
H.M.S. Beagle.

N.B. Remember that Peru is in a state of anarchy.

No. 27.

JOURNAL of the Proceedings on board the hired schooner, Carmen, in search of the crew of his Majesty's late ship Challenger.

June 22d, 1835.—H.M.S. Blonde's boats getting the schooner Carmen ready for sea; at thirty minutes past eight, P.M. went on board the schooner with the Beagle's whale-boat and surveying instruments.

Tuesday, 23d. Blowing a strong gale from the northward all day, with very heavy rain; a great deal of surf on the beach, made it impossible to land; therefore nothing was done to forward the schooner's sailing.

Wednesday, 24th. More moderate, but very unsettled weather; Blonde's boats preparing schooner for sea; at four, weighed and ran

© The Complete Work of Charles Darwin Online

under the commodore's stern. Asked the commodore for some ballast, a few muskets, and a little powder; was refused. Thirty minutes past four, received final orders; made all sail, with the wind fresh from the southward, and ran through the small passage.

On board the Carmen were:

Mr. Wm. Thayer, master of the vessel.

George Biddlecombe,	2d master of	H.M.S. Blonde.
Alex. B. Usborne,	2d assist. surveyor,	,, Beagle.
James Bennett,	gunner's mate,	,, Beagle.
John Nutcher,	boatswain's mate,	,, Blonde.
John MacIntosh,	A.B.	,, Blonde.
John Mitchell,	A.B.	,, Blonde.

and ten men hired at Talcahuano, who were of very little, indeed almost no use as seamen.

At about ten, P.M. the wind died away to nearly a calm, which continued throughout the night.

Thursday, 25th. Daylight. Saw the Paps of Bio Bio E.S.E. by compass, nine miles distant; light, variable airs from the northward throughout the day. Sun-set: north end of St. Mary S.b.W. six miles, calm all night.

Friday, 26th. Daylight. North end of St. Mary S.E. five miles; light winds from the northward, until four, P.M., when the wind freshened from north-north-west, with heavy squalls of wind and rain; sun-set, Carnero Head, E. distant five miles. At thirty minutes past six, observed a fire on Tucapel Head, bearing south-east; burnt a blue light, supposing it might be part of the Challenger's crew on their road to Concepcion; but finding no alteration in the size of the fire, and it not corresponding with the signal agreed on, continued our course towards the supposed place of the Lebu, or Leübu.

Saturday, 27th. Strong winds from the northward, and squally weather, with heavy rain; stood off and under foresail until two, P.M., when the weather cleared a little; made all possible sail, and stood in for the point on which the Challenger was lost. At three, Molguilla Point E. two miles and a half distant, saw nothing of the wreck; bore up, and stood along the land toward the southward, from one to two miles off shore, in search of the river Lebu. At five, P.M., having run ten miles south of Point Molguilla, and five miles south of the supposed place of the Lebu, and not seeing any thing of the wreck or crew of the Challenger, hauled off, and hove-to; at

© The Complete Work of Charles Darwin Online

this time any people on the shore could have seen the vessel five miles north or south of her, she not being more than a mile and a half from the beach, and having a large blue ensign at the fore-top-gallant-mast-head.

At six, fired a rocket, as a signal to the shore; no answer of any description being made, filled and stood off and on, to keep our position during the night; fresh winds and squally, with heavy rain.

Sunday, 28th. Strong winds from north-west, and squally weather, with heavy rain; shortened sail to foresail, and headed to the westward; thirty minutes past ten, saw the island of Mocha south, distant eight miles, sounded in fifteen fathoms; wore to north-east, and carried all possible sail to get out of the bight; fresh gales and squally, with a heavy cross sea.

Monday, 29th. More moderate, but wind still from the northward. At nine A.M. spoke the Blonde, on her way to the supposed place of the Lebu; kept our wind, endeavouring to fetch Tucapel Head, where we had seen the fire three days before; noon, Tucapel Point east-north-east, three-quarters of a mile distant; observed two fires on Tucapel Head; tacked to the westward, to fetch the Head.

At thirty minutes past two, Tucapel Point east-north-east, nine miles; while four men were aloft (James Bennett, gunner's mate, Beagle; John Nutcher, boatswain's-mate; John MacIntosh, A.B.; John Mitchell, A.B., of Blonde), bending the fore-topsail, which had been split the previous night, the vessel gave a very heavy pitch, which sprung the foremast, a little below the cross-trees; and on her recovering herself, the head of the mast snapped short off, a foot below the fore-yard, bringing with it all above, and also the four seamen who were aloft; the mainmast, having no support left from the tryatic stay, and the deck-stay being aft, ready for tacking, the great weight of the main-boom, added to the pressure of the wind on the mainsail, brought the mainmast by the board, fore-and-aft the deck, striking the taffrail in its fall, which again carried it away, leaving the head of the mast hanging by the rigging over the stern, striking heavily against the rudder and the middle-piece in midships on the deck. Fortunately, none of the seamen were seriously injured, as they resolutely kept their hold of the topsail-yard, and were carried with it into the sea, out of which they soon escaped by means of the rigging that was hanging over the side.

Every effort was immediately used to clear the wreck, and get

© The Complete Work of Charles Darwin Online

the temporary rigging up, to secure the stump of the foremast which had carried away the wedges in the partners, and had about three inches play in the step, from the heel of the mast being decayed; nearly the whole of the standing rigging was lost, from night coming on, and it being necessary to get the wreck clear of the vessel as soon as possible, lest it should carry away the rudder, and otherwise damage the hull of the vessel.

Not having an axe, or any thing but a cooper's drawing-knife, that would cut the rigging in the eyes, which had hide on them that had been placed there several years before, we were obliged to haul it up taut and cut on the rail, thereby rendering it useless for any thing but junk.

There were scarcely any nails on board the vessel; and it was with the greatest difficulty we succeeded, by shifting two cleats up a slippery mast, in getting a tackle each side for shrouds, and a hawser for a stay. At eight, P.M., observed the Blonde north-west one mile; fired a rocket, and burnt three blue lights; no answer returned.

At about midnight we set the jib, peak of foresail, and Beagle's boat sail for a main-sail; during the whole of this time it was blowing fresh from the north-west, with heavy rain and a cross sea, which caused the vessel to roll her gunwale under each time; every one was quite exhausted, particularly those men who had been hanging on the mast, getting the tackles secured, the watch therefore was set until daylight.

Tuesday, 30th. Employed getting the foremast better secured, by raising sheers with fore-yard and jib-boom, and placing a pair of shrouds on each side, about twenty feet from the deck, and an extra stay to set a stay-sail on, the whole kept up by a few spikes *drawn out of the beams*. At ten, A.M. strong winds from the westward, with heavy rain; saw the north-west extreme of Mocha, bearing south-south-east, three miles distant; wore to the north-east, to give time to get more sail on the vessel, intending to weather the island, if possible; if not, to run to leeward, and then stretch off to the southward and westward. Noon; wore, strong winds and squally, with a heavy head sea; at two, set foresail, double-reefed; observed the north-west extreme of Mocha, south by east, one mile and a quarter distant. At three, P.M., when the north-west extreme bore north-east, the wind changed suddenly to south-west, bringing the rocks off the

© The Complete Work of Charles Darwin Online

south-west extreme of the island about four points on the lee-bow; but the wind increasing and giving the vessel more way, enabled her to pass about three-quarters of a mile to windward of the outer breaker, on which the sea was breaking furiously; the island itself was only visible at intervals, owing to the thickness of the weather, and constant, heavy rain.

At five, the weather being a little clearer, saw the island, its centre bearing north-east, four miles distant; stood to the southward during the night, fresh breezes from south-west throughout.

Wednesday, July 1st. Daylight, employed rigging the fore-yard as a jury main-mast; calm, with drizzling rain and a heavy swell; by noon got the jury main-mast up, and set fore stay-sail for a main-sail, secured the boat's mast to the taffrail, and set the sail for a mizen. At five, a light air from the southward, stood to the westward during the night (no stars visible).

Thursday, 2d. Strong winds from west-north-west; stood to the south-west; at thirty minutes past eight, observed a schooner west, standing to the northward; hoisted the ensign union down in the fore-rigging; but she passed within a mile to windward, and took no notice of us. Noon, weather the same; wore to north-west; thirty minutes past four, observed the land east-north-east, supposed Cocale Head; wore, and stood to the south-west; fresh breezes and squally, with rain at times; no stars visible throughout the night. Midnight, wore to the northward.

Friday, 3d. Moderate from the westward, with rain at times, employed setting up rigging and securing masts; latitude observed (within a few miles) 39° 23′ S.

Repaired the Beagle's boat, which had been badly stove by the fall of the masts, as well as our means would allow. Moderate from the westward, until two, A.M., when the wind shifted to the northward; wore to the westward.

Saturday, 4th. Moderate, with rain at times, wind north-west; employed as most necessary, fitting grummets for sweeps, in case of a calm, and being drifted near the land. Latitude observed nearly 38° 40′. S. P.M. Employed as before; at eight o'clock, wore to the northward; moderate throughout the night.

Sunday, 5th. Light winds from north-west, and fine clear weather; employed repairing sails, chafes, &c. Latitude observed, 38° 35′ S. At one, P.M., observed the island of Mocha, south extreme bearing

© The Complete Work of Charles Darwin Online

north-east about twenty miles; at five, the south extreme bore north fifty-six east, and by the angle to the north extreme eighteen miles distant. Light airs from north-west and fine weather; at nine, the wind shifted to south; trimmed and steered north by west; midnight, strong winds and fine.

Monday 6th. Strong breezes from south-south-east; at daylight, Tucapel Head north-north-east; hauled up for it; at ten, observed a vessel in shore; but suddenly lost her, and could not again get sight of her.* Noon, Carnero Head east (true), distant ten miles; found a strong current setting along shore to the southward, with at times a heavy ripple, until one, P.M., when it changed and set to the northward, and off-shore withal; at six, Dormido Rocks south-south-east, distant two miles; steered north-east by north for the Paps of Bio Bio; but found it necessary to haul up north-east, and latterly north-east half-east, owing to a strong current setting to the northward and westward; at thirty minutes past nine, Paps of Bio Bio south-south-east, distant three miles; and at two, A.M. (Tuesday, 7th), the north point of Quiriquina bore south one cable distant; stood into the bay, hoping to fetch 'Tomé,' there to anchor, until the wind came more favourable for Talcahuano; but the wind being scant, were obliged to wear (as the vessel would not stay), thereby losing more than she gained on each tack. At eleven, saw H.M.S. Blonde coming down to us; at one, we were taken in tow by the Blonde, and carried into Talcahuano Harbour, at the south-west corner of the bay of Concepcion; and at midnight we anchored.

A. B. USBORNE, July 7th, 1835.

No. 28.

WINDS AND WEATHER.

On the southern coasts of Chile, winds from the southward, or from the northward, prevail more than those from the west; and very much more than those few which come from the east.

From south-south-east to south-west, and from north-west to north (magnetic) are the points whence the wind usually blows—with less or more strength, according to the time of year.

During the summer months, or from September to March, southerly

* The Blonde, shut in by a point of land.—R. F.

© The Complete Work of Charles Darwin Online

winds are prevalent, almost always. They are frequently strong in the afternoon, and sometimes during a part of the night. Towards morning, and during the early part of the day, moderate winds, light breezes, or calms, are to be expected.

Near the land, it is generally calm at night, excepting about once or twice in a month, when the wind blows strongly from the southward until about midnight. Occasional northerly winds are experienced, it is true, during the summer; but they are usually so moderate, during that season, that they pass almost unheeded.

About the end of March, the 'northers,' as they are called, begin to remind one that fogs, heavy and frequent rains, thick gloomy weather, and strong winds, often trouble the southern coasts of Chile.

During a part of March, and throughout April, May, and June, foggy weather is frequent; and although it is not often that a thick fog lasts longer than a few hours, a day, even two days, of continued thick fog, is not an unknown occurrence.

With northerly and north-west winds the sky is overcast, the weather unsettled, damp, and disagreeable. These winds are always accompanied by clouds, and usually by thick rainy weather. From the north-west the wind in general shifts to the south-west, and thence to the southward. Sometimes it flies round in a violent squall, accompanied by rain, thunder, and lightning. At other times it draws gradually round. Directly the wind is southward of west, the clouds begin to disperse, and as a steady southerly wind approaches, the sky becomes clear and the weather healthily pleasant.

A turn of fresh southerly wind is usually followed by a moderate breeze from the south-east, with very fine weather. Light variable breezes follow, clouds gradually overspread the sky, and another round turn is generally begun by light or moderate north-easterly breezes, with cloudy weather, and often rain.

This is the general order of change. When the wind shifts against this order, or backs round, bad weather with strong wind may be expected.

Lightning is always a sign of bad weather. It accompanies or precedes a change for the worse; which, however, is usually a prelude to clearing up. Squalls are rare, excepting at the shift from north-west to south-west, already mentioned. From the westward (south-west by west to north-west by west) the wind does not usually, if ever,

© The Complete Work of Charles Darwin Online

blow nearly so strong as from north-west to north, or from south-west to south.

Currents.

Near the island of Mocha, and to the westward of Cape Rumena, the current usually runs to the north-west, from half-a-mile to one mile and a half, each hour. Distant in the offing, more than twenty or thirty miles from land, this set of current is so diminished that it is hardly sensible; but near Mocha, and especially near the very dangerous out-lying rocks off the south and south-west extreme of that island, it is increased to two, and, at times, even three miles an hour.

From the great river Bio Bio, and from other rivers in the vicinity, floods, escaping to seaward, often cause strong and irregular currents which set to the southward—passing the island of Santa Maria, sweeping round Point Lavapié, and Cape Rumena, and Tucapel Point—into the bay where his Majesty's ship Challenger was wrecked.

These southerly currents are usually found to set strongly along-shore, but seldom reach an offing of six miles to the westward of Cape Rumena.

A very intelligent Hanoverian, Anthony Vogelborg, employed during several years upon these coasts, was once drifted in a small vessel, from six miles south of the Paps of Bio Bio, to the rocks off the north end of the Island of Santa Maria, in one night, during a dead calm.

After the great earthquake of the 20th of February, which affected all the coast about Concepcion, and especially the Island of Santa Maria, the currents set to the south-eastward so strongly, that a boat belonging to the above-mentioned Anthony Vogelborg (which he was steering) running near the Island of Mocha, under sail, with a fresh southerly breeze, could hardly make head against the strong stream that was passing along shore from the north-westward. It is, therefore, to be apprehended, that the strength and direction of the currents in the neighbouring ocean are unsettled and extremely uncertain for some time after a serious earthquake.

No. 29.

Santiago, 12 de Agosto de 1835.

Señor:

He instruido al Presidente del contenido de la carta de V.S. de ayer, en que me incluye una copia de los resultados del viaje de observacion del Capitan FitzRoy, de la fragata de S.M.B. Beagle, en cuanto a la parte de la costa de Chile comprendida en el.

Su E. ha recibido esta prueba de la atencion del Capitan FitzRoy, con el mayor interes y reconocimiento, y me encarga rogar a V.S. se lo manifieste de su parte.

Reitero a V.S. las espresiones de mi mayor consideracion y estimacion; y tengo la honra de ser su mas atento,

Seguro servidor,

(Firmado) JOAQUIN TOCORNAL.

Señor CONSUL JENERAL,
de S.M.B.

No. 30.

By ROBERT FITZ-ROY, Captain of His Britannic Majesty's Surveying Sloop Beagle.

You are hereby required and directed to take upon yourself the charge and command of the schooner Constitucion (tender to the Beagle), and all on board of, or belonging to her.

As soon as you are ready for sea, you will proceed to that part of the coast of Chile, near the Desert of Atacama, at which the survey of Lieut. B. J. Sulivan ended.

From that part you will coast along and survey the shores northward towards Callao, and thence toward Puná, near Guayaquil.

At Puná your survey is to terminate.

You will thence return to Callao in the schooner Constitucion, or you will sell the said schooner, and, with your party, make your way to Callao, by the means which you consider best for his Majesty's service: combining economy with efficiency.

If opportunity should offer, a measurement from Puná to the Galapagos would be very desirable.

© The Complete Work of Charles Darwin Online

On arriving at Callao, from Puná, you will wait upon his Majesty's Consul-general, and request him to assist in procuring a passage to England, for yourself and your party, at the least expense to the public which will be consistent with the necessary accommodation which you will require, in order to prosecute your work during the homeward passage.

When you arrive in England, you will repair with your party to Plymouth, there report yourself to the Commander-in-chief, and request him to inform the Lords Commissioners of the Admiralty.

You will also request him to allow your party to be borne, for victuals only, on the books of one of his Majesty's ships, until the arrival of the Beagle, or the receipt of orders from the Admiralty.

You will endeavour to leave Callao finally before the month of June, and arrive in England before the month of October 1836.

You are furnished with the documents herein named:

Copy of my instructions.
Letter from the President of Chile.
Circular letter from the Government of Peru.
Copies of correspondence with his Majesty's Consul-general in Peru.
Letter to the Bolivian authorities.

And with instruments, stores, and provisions sufficient to last for eight months.

Money for the purchase of fresh provisions is supplied to you; and you will keep a minute account of all money which passes through your hands on account of Government.

When no longer wanted for the survey, the schooner is to be sold, and the produce of her sale carried to your contingent account.

Previous to sale, you will hold a survey on the vessel, her boat, and all such stores as you cannot advantageously carry with you to England; taking to your assistance in the survey the most competent persons whom you can obtain.

Clear reports of survey, and accounts of sale will be required.

You will not on any account take part in, or in any way interfere with any disturbance or disagreement of any kind, which may arise or be pending in your neighbourhood, bearing always in mind that the exclusive object of your mission is of a scientific nature.

You will not on any account, or for any reason whatever, allow a passenger, letters, effects of any kind, gold, silver, or jewels, to be

© The Complete Work of Charles Darwin Online

received or carried on board of the schooner Constitucion, or in her boat, excepting what actually belongs to your own party.

Remembering how frequent and uncertain are political changes, you will be very guarded in your conduct. You will show your instructions; explain distinctly that you are detached from the Beagle in her tender, for the purpose of continuing the survey of the coast of Peru; and you will most carefully avoid every act which might unnecessarily offend.

You will communicate frequently with his Britannic Majesty's Consul-general in Peru, whose influence and zealous support will be of the utmost consequence; and you will endeavour upon all occasions, to follow his advice as exactly as possible.

Given under my hand on board his Majesty's Sloop Beagle, in Callao Bay, this 24th day of August 1835.

R. F.

To Mr. Alex. B. Usborne, Master's Assistant, H.M.S. Beagle.

No. 31.

Ministerio de Relaciones Esteriores del Peru.

Palacio del Gobierno, en Lima,

Señor; Setiembre 4 de 1835.

El Infrascrito Ministro de Relaciones Esteriores tiene la honra de acompañar al Señor Consul Jeneral de S. M. Britanica los documentos que ha credido necesarios para que la "Constitucion" practique sin inconveniente en la Costa del Peru el Viage y esploracion cientifica á que está destinada.

Dichos documentos son, unas Ordenes libradas por el Ministerio de la Guerra á las Autoridades de su Dependencia, áfin de que no impiden el aceso a cualquier punto de la Costa del Buque Espedicionario, ni el desembarco de las personas que conduce, y se faciliten en lo posible sus trabajos:

Ordenes del mismo tenor de la prefectura de este departamento à los funcionarios locales subalternos suyos, y finalmente un amplio pasavante para todas las Autoridades Civiles y Militares del litoral de la Republica.

© The Complete Work of Charles Darwin Online

Tiene el Suscrito la complacencia de dar con estas medidas un Testimonio del Interes que Su Gobierno tomà en el ecsito de la ilustrada empresa del Gobierno Britanico; y de Suscribirse.

Su Muy Atento Servidor,

(Firmado) M. FERREYROS.

Señor CONSUL JENERAL de S.M. Britanica.

Republica Peruana.

Ministerio de Estado del Despacho de Relaciones Esteriores.

Palacio del Gobierno en Lima á 22 de Julio de 1835, 16°.

Señor;

Ha sido muy satisfactorio para el Infrascrito impartir á los Prefectos de este Departamento y del de la Libertad, la Orden que acompaña en Copia á esta comunicacion, relativa al permiso y ausilios que el Señor Consul Jeneral de S.M. Britanica solicita en su apreciable nota de 20 del que exije, se franqueen á los Oficiales del Bergantin "Beagle" para el desempeño de la Comision cientifica que se les ha confiado.

Ya que las Ciencias practicas que mas conspiran á la prosperidad y adelantamiento del Genero humano deben al Gobierno Britanico una proteccion tan decidida, no seria conforme, con los principios ni con los intereses del Gobierno Peruano negarse á dar las facilidades que puede franquear á los Marinos Comisionados para absolver la importante Comision de rectificar al mapa y á contribuer del modo que le es dado á dilatar los limites de la Ciencia, y asegurar el ecsito del Comercio Universal.

Se han hecho prevenciones semejantes al ministerio de Guerra y al de Hacienda para que las trasmita á sus subordinados, y espera el Infrascrito que el Señor Consul Jeneral le indique si aun seran necesarias recever disposiciones que librará gustoso para la consecucion de tan util trascendencia.

Acepte el Señor Consul Jeneral la distinguida consideracion con que es:—

Su Atento Servidor

(Firmado) M. FERREYROS.

Señor Consul Jeneral, de S.M. Britanica.

© The Complete Work of Charles Darwin Online

Ministerio de Estado de Despacho del Relaciones Esteriores,
Palacio del Gobierno á 22 de Julio de 1835. 16°.

A los Señores Prefectos de los Departamentos de Lima y de la Libertad.

Señor;

Se halla surto en el Puerto del Callao y puede ser que recorra al litoral de este Departamento el Bergantin de S.M. Britanica "Beagle" que ha venido al Pacifico espresamente con el designio de determinar con exactitud la posicion geografica de los Puntos principales de la Costa para corregir cualquier error que hubiese en los Mapas y perfeccionar por este medio la ciencia de la navegacion de que dependen en gran manera las seguridades y ventajas del Comercio. Deseando vivamente S.E. contribuir por su parte al bien exito de esta espedicion cientifica en que la humanidad y la civilizacion se interesan al mismo tiempo y dar al Gobierno de S.M. Britanica una muestra de consideracion me ha ordenado prevenir a V.S., bajo de la mas estricta responsabilidad, que permita acercar y desembarcar sin el menor embarazo en cualquier punto de la Costa de su mando á los oficiales del "Beagle" para que puedan hacer con sus instrumentos todas las Observaciones Astronomicas y cientificas que quisieran practicar; y que ademas se les proporcionen todas los auxilios y recursos que puedan necesitar, y pidieren V.S. quien deberas recomendarlos á sus subordinados con la eficacia y esmero que merecen por su carácter y por la grande importancia de su comision. Digolo a V.S. de Orden Suprema á fin de que sin la menor demora espida la necesaria á su cabal cumplimiento.

(Firmado) M. Ferreyros."

A todas las Autoridades civiles y militares de la costa de Yquique y provincia de Tarapaca hasta Puná.

Palacio del Gobierno en Lima.

Sabed: que la Goleta Constitucion construida en Maule y del porte de treinta y cinco toneladas, patache del Bergantin de S.M.B. "Beagle" conduce á su bordo Oficiales de la Marina Real Inglesa, encargados por S.M.B. de recorrer las costas del Pacifico é islas adyacentes, con el fin de rectificar los Mapas hidrográficos. El Gobierno de la República, no solo les hà permitido toda libertad en la práctica

© The Complete Work of Charles Darwin Online

de sus observaciones, sino que quiere y manda bajo de la mas estricta responsabilidad á las autoridades litorales de cualesquiera clase y rango que sean, que no les pongan embarazo alguno para acercarse á todos los puntos de la costa sin ecepcion; permanecer en ellos el tiempo que crean conveniente, y desembarcar y morar en tierra á cualquiera hora, y ademàs, que les ministren todos los ausilios que pudieren. A este fin me ordena expedir este documento ligando á su observancia á los funcionarios á quienes se presentare, y recomendándoles muy encarecidamente que si en el distrito de su mando ecsisten algunos planos geográficos de la costa, trabajados en el Perú, interesen á su nombre á los que los posean para que se sirvan mostrarlos á los referidos Oficiales, á fin de que puedan llenar más cumplidamente el importantísimo objeto de su comision. Dado de órden suprema en el Palacio del Gobierno en Lima á 1° de Setiembre de 1835.

(Firmado) M. Ferreyros.

No. 33.

(Duplicado.)

El Ciudadano Mariano de Sierra, Jeneral de Brigada de los Ejercitos Nacionales, Benemerito a la Patria, Ministro de Estado, Secretario Jeneral de S.E. el Presidente de la Republica, &c.

A las autoridades Civiles y Militares de las Costas de la Republica.

Sabed; Que la Goleta "Constitucion" patache del Bergantin de S.M. Britanica Beagle, construida en Maule del porte de veintecinco toneladas, conduce á su bordo Oficiales de la Marina Real de su Nacion con el objeto de recorrer las costas del Pacifico é Yslas adyacentes para la rectificacion de las cartas hidrograficas, que les há sido encargado por S.M. Britanica, y habiendo el Supremo Gobierno de la República permitidoles la necesaria libertad en la practica de sus observaciones, quiere que las Autoridades litorales no les pongan impedimento ni embarazo alguno en la aprocsimacion á los puertos, desembarque y permanencia en ellos por el tiempo que creyesen conveniente los referidos Oficiales Ingleses, y que les proporcionen los ausilios que pidiesen en el orden debido.

A este objeto es que S.E. me ordena espedir el presente documento,

quedando legada su observancia bajo responsabilidad á los funcionarios á quienes estas letras se presentasen. Dado en la Casa del Supremo Gabierno en Lima à 18 de Enero de 1836. 17o de la Independencia: 15° de la República.

El Ministro Secretario Grâl.

MARIANO DE SIERRA.

No. 34.

That multitude of islands, of which the native name is Paamuto, to us more commonly known as the Dangerous Archipelago of the Low Islands, may be said to lie strewed between the parallels of thirteen and twenty-five south, and the meridians of 120 and 150 west: though stricter limits would be 13° and 22° S.; 135 and 150 west; because some of those south of 22, and east of 135, are high islands, and but rarely have communication with the groups in a lower latitude.

Easter Island, though without the boundaries specified, is but an outpost, as it were, of the Dangerous Archipelago; and, no doubt, was first peopled from that extensive region of (generally speaking) low coral islands. The high, or rather hilly exceptions, such as Gambier, Osnaburgh, Pitcairn, Easter, &c. are few, in comparison with the seventy or eighty groups of islets which surround lagoons, besides many mere dry reefs.

By far the larger number of the lagoon islands have at least one harbour in each cluster accessible to shipping; and a considerable trade has been carried on with the natives for pearl oyster-shells.

What the number of inhabitants may be, who are dispersed through the Archipelago, it is exceedingly difficult to estimate, for two reasons: we know very little of them; and they are migratory. From the little I have learned on the subject, I think they cannot be less than ten thousand, nor more than thirty thousand, exclusive of children.

Fish, and shell-fish, hogs, and cocoa-nuts, are the principal subsistence of the Low islanders; but the natives of Gambier, and a few other hilly islands, have plenty of vegetable food in addition.

Those Paamuto islands which are not very remote from Otaheite, affect to receive laws from her sovereign: they have, however, no resident authority among them, except the head of each family.

© The Complete Work of Charles Darwin Online

The language of these islanders differs from that of the Otaheitans so much that they do not easily understand each other: yet I believe that both are radically the same. Taata is man, at Otaheite; in Paamuto, Tanaka; which is almost the same as Kanaka, the word for man in the Sandwich Islands; and not very different from Tangata in New Zealand. Some of the Low islanders say their ancestors came from the south-eastern islands; others say from the Marquesas; again there are some who assert that their forefathers arrived from islands to the westward: so that no reliance can be placed upon the little yet known of their origin. There is, however, reason for supposing that the earlier inhabitants were not of one family, or tribe; but that they were emigrants from more than one quarter.

In most of the entrances to harbours in the lagoon islands, there is a strong current of tide, which sets in and out alternately, about six hours each way. The tide rises nearly two, or at most three, feet. It is high water at about one, on the days of full and new moon, among the western groups of islands, and from half an hour to an hour later among those which lie towards the south-east. The currents which do not appear to be caused by tide are irregular; and, as yet, too little is known of their usual direction to enable any one to say more than that during settled weather, and a steady trade wind (south-easterly), the surface waters in general move westward from five to twenty miles a day; and that in the rainy season, from October to March, when westerly winds, squalls, and rain are frequent, the currents vary most, and occasionally set eastward, at the rate of from half a mile to two miles an hour.

Numerous instances are upon record of canoes being drifted out of their course—even several hundred miles—by currents and westerly winds: few narratives of voyages in the Pacific are without a notice of them: and they materially assist in explaining how remote, and perhaps very small, islands, may have been first peopled from the west: against the direction of the generally prevalent wind.

No. 35.

The British Resident at New Zealand, to His Britannic Majesty's Subjects, who are Residing or Trading in New Zealand.

The British Resident announces to his countrymen that he has received from a person who styles himself "Charles, Baron de

© The Complete Work of Charles Darwin Online

Thierry, sovereign chief of New Zealand, and king of Nuhahiva," (one of the Marquesas Islands) a formal declaration of his intention to establish in his own person an independent sovereignty in this country, which intention he states he has declared to their Majesties the Kings of Great Britain and France, and to the President of the United States; and that he is now waiting at Otaheite the arrival of an armed ship from Panama, to enable him to proceed to the Bay of Islands with strength to maintain his assumed sovereignty.

His intention is founded upon an alleged invitation given to him in England by Shunghi and other chiefs, none of whom as individuals had any right to the sovereignty of the country, and, consequently, possessed no authority to convey a right of sovereignty to another. Also, upon an alleged purchase made for him in 1822, by Mr. Kendall, of three districts on the Hokianga River, from three chiefs who had only a partial property in these districts, parts of which are now settled by British subjects, by virtue of purchase from the rightful proprietors.

The British Resident has also seen an elaborate exposition of the views of this person, which he has addressed to the missionaries of the Church Missionary Society, in which he makes the most ample promises to all persons, whether whites or natives, who will accept his invitation to live under his government; and in which he offers a stipulated salary to each individual missionary in order to induce them to act as his magistrates. It is also supposed, that he may have made similar communications to other persons or classes of his Majesty's subjects, who are hereby invited to make such communications, or any information on this subject they may possess, known to the British Resident, or to the additional British Resident at Hokianga.

The British Resident has too much confidence in the loyalty and good sense of his countrymen, to think it necessary to caution them against turning a favourable ear to such insidious promises. He firmly believes that the paternal protection of the British government, which has never failed any of his Majesty's subjects however remote, will not be withheld from them, should it be necessary to prevent their lives, liberties, or property, from being subjected to the caprice of any adventurer, who may choose to make this country, in which British subjects have now by the most lawful means acquired so large a stake, the theatre of his ambitious projects: nor, in the British Resident's opinion, will his Majesty, after having acknow-

© The Complete Work of Charles Darwin Online

ledged the sovereignty of the chiefs of New Zealand in their collective capacity, by the recognition of their flag, permit his humble and confiding allies to be deprived of their independence upon such pretensions.

But, although the British Resident is of opinion that such an attempt as is now announced must ultimately fail, he, nevertheless, conceives, that if such a person were once allowed to obtain a footing in the country, he might acquire such an influence over the simple-minded native as would produce effects which could not be too much deprecated or too anxiously provided against; and he has therefore considered it his duty to request the British settlers of all classes, to use all the influence they possess with the natives of every rank, in order to counteract the efforts of any emissaries which may have arrived or may arrive amongst them: and to inspire both chiefs and people with a spirit of the most determined resistance to the landing of a person on their shores, who comes with the avowed intention of usurping a sovereignty over them.

The British Resident will take immediate steps for calling together the native chiefs, in order to inform them of this proposed attempt upon their independence, and to advise them of what is due to themselves and to their country, and of the protection which British subjects are entitled to at their hands. And he has no doubt that such a manifestation will be exhibited of the characteristic spirit, courage, and independence of the New Zealanders as will stop at the outset such an attempt upon their liberties by demonstrating its utter hopelessness.

JAMES BUSBY,
British Resident.

British Residency, at New Zealand,
Bay of Islands, 10th Oct. 1835.

No. 36.

DECLARATION of the Independence of New Zealand.

1. We the hereditary chiefs and heads of the tribes of the northern parts of New Zealand, being assembled at Waitangi in the Bay of Islands, on this 28th day of October 1835, declare the Independence of our country; which is hereby constituted and declared to be an independent state, under the designation of "THE UNITED TRIBES OF NEW ZEALAND."

© The Complete Work of Charles Darwin Online

2. All sovereign power and authority within the territories of the United Tribes of New Zealand is hereby declared to reside entirely, and exclusively, in the hereditary chiefs and heads of tribes in their collective capacity: who also declare that they will not allow any legislative authority separate from themselves in their collective capacity to exist; nor any functions of government to be exercised within the said territories, unless by persons appointed by them, and acting under the authority of laws regularly enacted by them in congress assembled.

3. The hereditary chiefs and heads of tribes agree to meet in congress at Waitangi, in the autumn of each year, for the purpose of framing laws for the dispensation of justice, the preservation of peace and good order, and the regulation of trade; and they cordially invite the southern tribes to lay aside their private animosities, and to consult the safety and welfare of our common country, by joining the confederation of the United Tribes.

4. They also agree to send a copy of this declaration to his Majesty the king of England, to thank him for his acknowledgment of their flag: and in return for the friendship and protection they have shewn, and are prepared to shew to such of his subjects as have settled in their country, or resorted to its shores for the purposes of trade, they entreat that he will continue to be the parent of their infant state, and that he will become its protector from all attempts upon its independence.

Agreed to unanimously on this 28th day of October 1835, in the presence of his Britannic Majesty's Resident.

Here follow the signatures, or marks, of thirty-five hereditary chiefs and heads of tribes, which form a fair representation of the tribes of New Zealand, from the North Cape to the latitude of the river Thames.

English witnesses,

(Signed) Henry Williams, Missionary C. M. S.
Geo. Clarke, C. M. S.
James C. Clendon, Merchant.
Gilbert Main, Merchant.

I certify that the above is a correct copy of the declaration of the chiefs, according to the translation of missionaries who have resided

© The Complete Work of Charles Darwin Online

ten years and upwards in the country, and it is transmitted to his most gracious Majesty the King of England, at the unanimous request of the chiefs.

JAMES BUSBY,
British Resident at New Zealand.

No. 37.

Colonial Secretary's Office, Sydney,
29th June 1835.

SIR:

I am directed by the governor to inform you that he has received a despatch from the right honourable the Secretary of State for the Colonies, communicating the representation made by you of the advantages which would result to you personally, as well as to other Europeans who have settled in the district in which you reside, by your being invested with an appointment corresponding to that lately conferred upon Mr. James Busby:—the extreme distance of that gentleman from the quarter in which you and other European settlers reside, preventing him from rendering that assistance which he might otherwise be expected to afford:—and I am accordingly commanded by Sir Richard Bourke to acquaint you, that in pursuance of the authority thus conveyed, his Excellency has been pleased to nominate you to be an "Additional British Resident" at New Zealand.

The creation of the appointment held by Mr. Busby originated in the desire of checking the atrocities and irregularities committed at New Zealand by Europeans, and of giving encouragement and protection to the well-disposed settlers and traders from Great Britain and this colony; and as the general rules by which it is the wish of this government that the British resident should regulate his proceedings, should also guide you in cases in which you may feel yourself called upon to act—

I am directed by his Excellency to transmit to you the enclosed extract of the instructions (13th April 1833) issued to Mr. Busby on his departure to assume the duties of his office.

By an adherence to the principles laid down in these orders, and their discreet application to circumstances, it is hoped that you will not be disappointed in your expectation of being enabled to benefit

© The Complete Work of Charles Darwin Online

not only yourself, but others, and it will, his Excellency conceives, be unnecessary to do more than impress upon you the importance of obtaining the objects you seek by a moral influence over chiefs and natives.

It should further be your particular study not only to act in concert with the British resident, but to maintain with him that good understanding which is necessary to give effect to your appointment, and to preserve the influence of both.

The British resident will be requested to make known your appointment to masters of vessels, and others resorting to New Zealand; and, on your arrival at your destination, you will take such measures as your own experience, and that of any missionaries who may be on the spot, may suggest as the best for apprising the British settlers and the natives, of the nature of your office and objects.

Upon this subject Mr. Busby, to whom I have the honour of transmitting you a letter of introduction, will no doubt be able to afford you valuable information.

The Secretary of State has intimated that you have disclaimed all desire of emolument in soliciting the appointment now conferred upon you.

I have the honour to be,
Sir,
Your most obedient servant,
(Signed) ALEXANDER M'LEAY,
Colonial Secretary.

To THOMAS M'DONNELL, Esq.,
Additional British Resident
at Hokianga, in New Zealand.

No. 38.

EXTRACT from the Instructions of his Excellency, the Governor of New South Wales, to James Busby, Esq., British Resident at New Zealand, dated 13th April 1833.

To check as much as possible the enormities complained of, and to give encouragement and protection to the well-disposed settlers and traders from Great Britain and this colony, it has been thought proper to appoint a British subject to reside at New Zealand, in an accredited character, whose principal and most important duty it will

© The Complete Work of Charles Darwin Online

be to conciliate the good will of the native chiefs, and establish upon a permanent basis that good understanding and confidence which it is important to the interests of Great Britain, and of the colony, to perpetuate.

It may not be easy to lay down any certain rules by which this desirable object is to be accomplished; but it is expected, by the skilful use of those powers which educated man possesses over the wild or half-civilized savage, an influence may be gained, by which the authority and strength of the New Zealand chiefs will be arranged on the side of the resident for the maintenance of tranquillity throughout the islands.

It will be fitting that you explain to the chiefs the object of your mission, and the anxious desire of his Majesty to suppress, by your means, the disorders of which they complain; you will also announce your intention of remaining among them, and will claim the protection and privilege which you will tell them are accorded in Europe and America to British subjects, holding, in foreign states, situations similar to yours.

You will find it convenient to manage this conference by means of the missionaries, to whom you will be furnished with credentials, and with whom you are recommended to communicate freely upon the objects of your appointment, and the measures you should adopt in treating with the chiefs.

The knowledge which the missionaries have obtained of the language, manners, and customs of the natives may thus become of service to you. Assuming, however, that your reception will be as favourable as has been anticipated, I will endeavour to explain to you the manner of proceeding, by which I am of opinion you may best succeed in effecting the object of your mission; you will at the same time understand, that the information I have been able to obtain respecting New Zealand is too imperfect to allow of my presenting you with any thing more than a general outline for your guidance, leaving it for your discretion to take such further measures as shall seem needful, to arrest British subjects offending against British or colonial laws in New Zealand.

By the 9th of George IV., chap. 83, sec. 4, the Supreme Court in New South Wales and Van Diemen's Land have power to enquire into, hear and determine all offences committed in New Zealand, by

© The Complete Work of Charles Darwin Online

the master and crew of any British ship or vessel, or by any British subject living there; and all persons convicted of such offences may be punished as if the offence had been committed in England. The law having thus given the court the power to hear and determine offences, it follows, as a necessary incident, that it has the power of bringing before it any person against whom any indictment should be found, or information filed, for any offences within its jurisdiction.

I would here observe, that I can propose no other means by which you can secure the offender, than the procuring his apprehension and delivery on board some British ship, for conveyance to this country, by means of the native chiefs with whom you shall be in communication. It is well known, that amongst those Europeans who are leading a wandering and irregular life at New Zealand, are to be found transported felons, and offenders, escaped from this colony and Van Diemen's Land. It is desirable that opportunities for the apprehension and transmission of those convicts to either colony should be promptly embraced.

The chiefs are, it is said, well acquainted with the descriptions of the different Europeans residing in their country, and will be found able and willing to point out and secure, at a convenient time, those whom they know to be fugitives from the Australian colonies. You will be furnished from the office of the principal superintendant, with the names and descriptions of those convicts from New South Wales who are known or suspected to be concealed in the islands of New Zealand; and you will use your discretion as to the fittest time for causing their apprehension, and removal of such as may be within your reach, or are guilty of any offence against the peace and tranquillity of the country. You will, of course, take every precaution to avoid the apprehension of a free person in mistake for a convict, as an action for damages would probably follow the commission of such an error.

This government will indeed be disposed to save you harmless in all such cases, where becoming circumspection has been used.

When any of his Majesty's ships are off the coast, you will request the commander to receive the convict, or other person, arrested by your means, for conveyance to this place.

I would further observe, that, by means of the information which you are likely to receive from the chiefs, you may become acquainted

© The Complete Work of Charles Darwin Online

with the criminal projects of Europeans before their execution; and by a timely interference you may be able altogether to prevent their mischievous designs, or render them abortive.

In the character which you hold you will be justified in addressing any British subject, to warn him of the danger to which he may be exposed, by embarking or persevering in any undertaking of a criminal or doubtful nature.

In the manner I have now described, and by proceedings of a similar character, it may be possible to repress the enormities which have heretofore been perpetrated by British subjects in New Zealand. It may also happen that this salutary control will not affect British subjects only, but that the knowledge of there being a functionary stationed in New Zealand, through whom offences committed by the subjects of any other State against the people of that country will be made known to the British Government, and through that Government to the other European and American powers, may induce the subjects of those powers to adopt a less licentious conduct towards the New Zealanders, and other inhabitants of the South Sea Islands.

There is still another form in which the influence, it is hoped, the British Resident may obtain over the minds of the New Zealand chiefs, may be more beneficially exhibited.

It is possible, by your official moderation, that the evils of intestine war between rival chiefs or hostile tribes may be avoided, and their differences peaceably and permanently composed. It is also possible, that at your suggestion, and by the aid of your councils, some approach may be made by the natives towards a settled form of government; and that by the establishment of some system of jurisprudence among them, their courts may be made to claim the cognizance of all crimes committed within their territory: and thus the offending subjects, of whatever state, may be brought to justice by a less circuitous and more efficient process than any which I have been able to point out.

If, in addition to the benefits which the British missionaries are conferring on those islanders, by imparting the inestimable blessings of Christian knowledge and a pure system of morals, the Zealanders should obtain through the means of a British functionary, the institutions of courts of justice, established upon a simple and comprehensive basis, some sufficient compensation would seem to be rendered for the injuries heretofore inflicted by our delinquent countrymen.

© The Complete Work of Charles Darwin Online

Having thus explained to you, generally, the course of proceeding by which I think your residence in New Zealand may be made conducive to the suppression of the enormities which British subjects, and those of other states, have been in the habit of committing in these islands, I have only further to observe, that it will be your duty to assist, by every means in your power, the commercial relations of Great Britain and her colonies with New Zealand. It would indeed be desirable that you should become the medium of all communications between the New Zealand chiefs and the masters of British or colonial vessels frequenting the coasts, and the merchants and settlers established in the islands. This arrangement will probably grow out of your residence in the country, and you should keep it in view as an important object. You will be pleased to forward by every opportunity a shipping report, setting forth the names, masters, number of crew, tonnage, and countries, of vessels arriving at the Bay of Islands, or other parts of New Zealand, whence you can obtain correct accounts; with the cargoes of such vessels, their objects in touching at New Zealand, as far as you are informed; and any other particular concerning them that may be worthy of notice.

I beg to call your attention to the strange and barbarous traffic in human heads, which certainly did exist to some extent, but which, I am given to understand, is now nearly abandoned. Should it be found to continue or revive, some legislative act may be necessary to prohibit, in this colony, the crime and disgrace of participating in so brutalizing a commerce.

Having already mentioned the assistance which I anticipate you will receive from the missionaries, I have now only to impress on you the duty of a cordial co-operation with them in the great objects of their solicitude, namely, the extension of Christian knowledge throughout the islands, and the consequent improvement in the habits and morals of the people.

RICHARD BOURKE.

No. 39.

The modes of surveying coasts, where there is anchorage, and water smooth enough to admit of boats being frequently employed, have been so often detailed, that, without repeating what is said in every treatise on the subject, I will only try to describe in this

© The Complete Work of Charles Darwin Online

place the methods adopted by the officers of the Beagle, in the examination of a wild sea-coast—such, for example, as that of the south-western part of Tierra del Fuego.

On that coast the weather was so continually bad, there was so much swell, and the water near the steep precipitous shores always so deep, that anchorage (except in harbours) was impracticable: boats were seldom able to assist (while under way), and the bearing compass, though particularly good, and well placed, was of very little use: it was therefore never trusted in important bearings. Another impediment, and not a slight one, was the current; which set irregularly from one knot to three knots an hour, along the shore.

But there are seldom evils, unbalanced by remedies. The stormy and desolate shores of Tierra del Fuego are broken into numerous islands, about which anchorages are abundant, and they are excellent, when once a vessel is in them. To find, and enter, or leave them in most instances, was troublesome, and often dangerous. But, with the help of those havens, and the distinct marks afforded by a high rocky shore; and by the sharp peaks of more distant heights, a correct survey was effected.

Beginning at the western extreme, near Cape Pillar (because the prevailing winds are westerly, and the current sets to the eastward), our first object was to find a safe harbour in which to secure the ship. There we made observations for latitude, time, and true bearing; on the tides, and magnetism. We also made a plan of the harbour and its environs; and triangulations, including all the visible heights, and more remarkable features of the coast, so far as it could be clearly distinguished from the summits of the highest hills near the harbour. Upon these summits a good theodolite was used, which was set, invariably, to a well-defined mark, near the observatory; from which mark the true bearings of the stations on the summits of the hills were ascertained by observations of the sun made with a theodolite.

Many leagues of exposed, and difficult coast, were looked down upon, in this manner; and, at the least, their exact bearings from one fixed spot ascertained. But if more than one height afforded a round of angles with the theodolite, and the position of each of those heights was accurately known by triangulation depending upon a base measured at the harbour, then the positions of various other hills or marks were ascertained; and so much easier became

© The Complete Work of Charles Darwin Online

the sea-work afterwards executed in the ship. I need hardly allude to the facilities, afforded by heights, for making eye sketches of the coast line, and other details, such as the ranges of hills, forms of banks, &c. Ascending heights near the sea is advantageous in another point of view; for not a rock or a shallow escapes notice, if the day is tolerably clear. While in harbour, every place in the vicinity which could be examined in boats, or overland excursions, was explored, as far as our means and time would allow.

Before I speak of the sea-work, it may be useful to say a word about 'bases,' of four kinds, arranged according to their relative value.

The first are those derived from good astronomical or chronometrical observations, made at two stations several miles apart.

The second are deduced from angular measurements of small spaces exactly known.

The third are obtained by actual measurement with a chain, with rods, or with a line:—

And the fourth are the rather uncertain bases obtained by sound.

This statement of the relative value of bases, is only meant to refer to their employment in sea-surveying. I need hardly remind the reader of these notes, that the third description of bases, however exact nominally, requires a host of minute precautions, in addition to what I never found between Valdivia and Cape Horn, namely, a nearly level and accessible space, of considerable length, on which to measure.

To attain the utmost precision is a laudable endeavour, no doubt, when carrying on extensive trigonometrical operations on land; but it should be borne in mind, that every hour employed in what is commonly called 'hair-splitting'—in minute details that do not affect the chart or plan which is the result of a sea-survey, is not only an hour lost, but an hour taken away from useful employment.

The second kind of bases are so quickly and easily measured, either with a sextant or micrometer, across any kind of land or water, and have been so repeatedly proved in every part of the Beagle's surveys, that I consider them unobjectionable, when used for such limited operations as making plans of harbours, or fixing the positions of objects only a few miles distant. By multiplying bases, which with such easy methods is soon effected; and by a frequent use of the sextant, artificial horizon, and chronometer, material errors may be

© The Complete Work of Charles Darwin Online

kept out of the work of a practised surveyor. With a sextant, horizon, and chronometer (in a sheltered spot), a micrometer and board,* a theodolite, and intelligent assistants, much work may be done in a short time.

When ready to proceed, the chronometer rates being ascertained, and the weather glasses affording reasonable hope of a day or two without a gale of wind, we started at day-light, and worked against time. Those officers who were engaged particularly with the survey, did not take part in the routine duties of the vessel. One attended to the bearing compass, and usually wrote the various angles and bearings, taken by others as well as himself, in a bearing-book. Another officer took angles. A third attended to the ship's course, the soundings, and the patent log. When many angles were required at one time, or when observations for time, latitude, or true bearing, were made while taking a round of angles, other officers assisted.

If the bearing compass was steady enough it was used, even when true bearings were obtained; or when, if cloudy, the triangulation was carried on by points fixed from the last harbour. As the compass was so placed as to be uninfluenced by local attraction, the bearings it gave, when steady, were satisfactory; yet it was never trusted implicitly; nor at all in matters of consequence. Its use was as an auxiliary; not as a principal. Bearings, or angles, of the highest points, or of marks so well defined as not to be mistaken in consequence of a change of the place of an observer, were, of course, always selected, if such were visible: and vertical angles of all notable heights were not omitted.

For the sake of perspicuity, we considered that positions, fixed points, or marks, were separated into three classes. In the first class, were observatories or places at which the latitude, longitude, and true bearing, were accurately ascertained; besides those high peaks, or other well-defined objects which could be seen at a distance of some leagues, and whose exact places were known by a triangulation which connected them with an observatory; and the highest points of islands, which were neither low, nor small enough for the eye to overlook them at the first glance.

* A board some feet long, painted black on one side, white on the other; exactly measured, and suspended horizontally, at right angles to the observer.

© The Complete Work of Charles Darwin Online

In the second class we considered all the minor fixed points which were included in the triangulation, excepting the details of the coast, and 'boundary lines,'* which belonged to the third class.

We supposed that the ship had sailed from the 'first' harbour.† At six, in the morning, (marked 6) the position of the vessel was fixed by two or more angles between marks, already fixed, upon the land. At 6·30, and at 7 similar means were used to fix the ship's place. Soundings were taken, and laid down by proportioning to the times of each sounding, the portions of distances run between the two stations, as shewn by patent log, by bearings of a mark, such as 6 (in the figure) while sailing from 6·30 to 7: by independent double angles, (two angles between three marks), or by simple cross-bearings.

Transit bearings were always sought for, by compass as well as by noting when marks were 'on;' or, in a line, one with another, without reference to the compass. We endeavoured to ascertain (or fix) the ship's position at the same moment, by the most available of the numerous methods so readily occurring while the log was going, the time noted carefully (as often as angles or bearings were taken), and several first class marks in sight. Transit bearings were useful in the details of the coast line, as may be seen by the lines drawn from 6·30, 7 and 8; and they corroborated the correctness of the triangulation, when applied to first and second class marks.

By a judicious selection of objects, and a clever application of transit bearings, I have seen extensive and correct triangulations carried on from data, obtained at sea, which appeared utterly inadequate.‡ I do not imply that the absolute position of any one point was independently correct, because all depended at first upon observations at sea; but that the points of the triangulation were all so correct, relatively, that, upon after examination, when the regular routine of harbour work had been combined with the data obtained afloat, and their truth ascertained by connection with the previous observatory, no alteration was found necessary.

Perhaps I should explain, that in the plan of the 'first' harbour all depended upon the base Ab; by which also were fixed B and C. From the summits B and C;—G, D, E, F, were fixed, as well as a

* By 'boundary lines' I mean limiting outlines of shoals, or rocky places. † See figure. ‡ By Mr. Stokes.

number of inferior marks; by a 'round' of angles taken with a theodolite, at each station (B and C), the instrument being in each case set to A. From A, the true bearings of B and C were ascertained astronomically. When the position of L was exactly determined by latitude, and distance from the meridian of A, the long and accurate base AL became known. With that, as a foundation, the work was laid down: and by that base, if necessary, the former positions of G, D, E, and F, were corrected. But so well did angular measures answer, that it was scarcely ever requisite to make such corrections.

It has been shewn that the log served only to place soundings, or help to fill up a space, while clouds obscured marks. I should add that it was serviceable in ascertaining the direction and strength of currents. Currents altering in strength, as well as in direction, prevented our applying the patent log to other uses, although we had every reason to put implicit confidence in its indications, and have often proved their value in the still waters of a deep sound, where no stream of tide, or current, existed: as well as in harbours, where angular bases were measured for the special purpose. Views of the lands, both in plan and profile, were very frequently taken. When boats could be lowered, and a sufficient object demanded their employment (as at 11, of the first day, and at 10 of the second day) they did not hang idly at their davits.

In the example I have given, circumstances conspired in our favour, a rare event in Tierra del Fuego, or on any similar coast, exposed to the prevailing westerly winds of high latitudes; but when we failed to find anchorage, the triangulation was carried on by first class marks; and by the ship's positions, when fixed by good observations at sea. But however well such a method may answer in a fine climate—on that coast it was in general unsatisfactory, and very inferior to that of going from one harbour to another.

Among many kinds of notation useful in surveying, the annexed sketch shews a method used by Mr. Stokes, which I had not then seen adopted. It is very convenient, and assists the memory more than any other. In figure 2, A and B are stations, at which the angles specified were taken right and left of a mark, whose bearing was ascertained. Or, the angles only were taken, and the triangles afterwards calculated, or protracted, by reference to the base upon which they depended, such as A B. A sketch on this principle, how-

© The Complete Work of Charles Darwin Online

ever slightly made, brings the place to mind in an instant, and avoids any necessity for names* or letters.

No. 40.

Nautical Remarks on the Northern Coast of Chile.

Scarcely any extensive coast less requires particular description than that of Chile. With a tolerable chart, and the lead going, a stranger may sail into, or out of, almost any Chilian port without hesitation. As there are, however, some anchorages and landing-places hitherto little known, except to coasters, it may be useful to give a few notices of them.

Valparaiso, and the ports southward, have been described so often, that I will not occupy any of these crowded pages with remarks on such well-known places; although in another publication, strictly nautical, they will appear.

Quintero, Horcon, and Papudo, have no hidden dangers. The two former lie to the southward and northward, respectively, of a straggling cluster of black rocks, above water: the first is now little frequented, being rather shallow, and out of the way: the second is a summer roadstead, with a good landing-place, and easy communication thence to Puchancavi. Papudo is a small open bay, with a good landing-place. Northerly winds throw in a heavy swell. Its situation is pointed out by a high, peaked hill, called Gobernador, immediately over the port.

Pichidanque, sometimes called Herradura, has a rock near the middle, on which, at low tide, there are but fifteen feet of water: it is in a line between the north end of the little island in front of the harbour, and a gully at the north-east side, through which a river runs from Quilimari, and four cables' lengths from the island. The tide rises five feet, and syzygial high water is at nine. The Silla, over Pichidanque, I have already mentioned (p. 426).

Conchali is an exposed roadstead, seldom used but by smugglers. The landing is everywhere bad, excepting in one little cove at the north side of the bay.

* Short characteristic names are preferable to letters, or numbers, because they help the memory so much.

© The Complete Work of Charles Darwin Online

Maytencillo is a little cove, fit only for a boat to land in at particular times.

The next opening in this high rugged coast is that of the river Limari, which looks large from seaward, but is inaccessible. The coast near Limari is steep and rocky. Two miles from the entrance of the river, there is a low, rocky point, with a small beach on which boats sometimes land; but a heavy surf breaks on it. Near a mile from the coast the land rises suddenly to a range of hills, about one thousand feet high, which runs parallel to the coast, and extends two or three miles north and south of the river; the summits of the hills to the northward are covered with wood. The north entrance point is low and rocky; the south is a steep slope, with a remarkable white sandy patch on the side of it. The river at its mouth is about a quarter of a mile wide; but the surf breaks heavily right across; inside it turns a little to the north-east, and then runs to the eastward through a deep gully in the range of hills before-mentioned. Mount Talinay is a remarkable hill, 2,300 feet high; it is three miles from the coast, and seven miles southward of the river; it is thickly wooded on the top; the sides are quite bare. Ten miles southward of Mount Talinay lies a deep valley, with a remarkable sandhill on its north side, close to the coast; at the mouth of the valley there is a small sandy beach. Within five miles of Maytencillo there is a point with several rocks, running off it about a quarter of a mile; from which to Maytencillo the coast is composed of blue rocky cliffs, about one hundred and fifty feet high; the land above the cliffs rises to between three and four hundred feet; and then about three miles in shore the range of hills runs from three to four thousand feet high.

About fourteen miles northward of Limari is a small bay, with a sandy beach in the north corner; but a heavy surf. From this bay northward the coast is rocky and much broken: about eight miles southward of Point Lengua de Vaca is a small rocky peninsula, with a high, sharp rock in the centre of it, southward of which lies a small, deep cove, with a sandy beach at the head; but the entrance is nearly blocked up by small islets, and rocks both above and below water. The entrance is too bad for the smallest vessel; though in fine weather boats can land in the cove. The outer breaker is not more than two cables from the shore; but when calm the swell sets directly on it. This cove is Tortoral de Lengua de Vaca.

© The Complete Work of Charles Darwin Online

Point Lengua de Vaca is a very low, rocky point, rising gradually in-shore to a round hummock, about a mile to the southward of the Point. There are rocks nearly awash about a cable's length from the Point, and at two cables' lengths distant there are but five feet. After rounding Point Lengua de Vaca, the coast runs to the south-east, and is rocky and steep for about two miles from the Point, where there are fifteen fathoms about half a mile from the shore. About three miles from the Point, a long, sandy beach commences, which extends the whole length of the large bay as far as the island or peninsula of Tongoy. The south part of the beach is called Playa de Tanque, the north and north-east side of the bay Playa de Tongoy. Off the south-west extreme of the beach there is anchorage about half a mile from the shore, in from five to seven fathoms; the bottom is a soft, muddy sand in some places, but in others it is hard. With a southerly wind it is very smooth, and the landing is very good, but a heavy sea sets in with a northerly breeze. This is an anchorage that was once frequented by American whalers. The village, which is called the Rincon de Tanque, consists of about a dozen 'ranchos.' The only water to be got is brackish; about two miles and a half to the E.N.E.* where there is good water, the landing is generally very bad, and the water is some distance from the beach.

From Tanque to the peninsula of Tongoy there is anchorage in any part of the bay, at from one to two miles from the shore, in from seven to ten fathoms, sandy bottom. There is good anchorage with a northerly wind for small vessels, to the southward of the peninsula, abreast of the small village on the Point, with the outer Point bearing W.N.W. in four fathoms sandy bottom, with clay underneath it; but no vessel, however small, should go into less than four fathoms, as the sea breaks a little inside that depth when blowing hard from the northward. Large vessels would also find a little shelter with the wind to the northward of north-west. With a strong southerly breeze a vessel would not be able to remain at anchor to the southward of the peninsula; but there is a small bay on the north side, which is completely sheltered from southerly winds. In the south-east corner of this bay there is a small creek, into which, when smooth, boats can go; it runs about a mile inland, and near the head there is fresh water for which the whalers sometimes send their boats.

* All bearings are magnetic, unless otherwise specified.

© The Complete Work of Charles Darwin Online

The village of Tongoy consists of half a dozen small houses, built on a high point at the south side of the peninsula.

The coast on the west side of Huanaquero Hill is broken and rocky, affording no shelter for any thing but a boat; to the northward there is a deep bay, well sheltered from southerly and westerly winds, but open to the northward: between this and Port Herradura there is no place fit for a vessel.

Herradura and Coquimbo are well known. Teatinos is a bold rugged point, the land behind it rising in ridges, which gradually become higher as they recede from the coast to Copper Hill, which is 6,400 feet high. The point which makes as the north extremity of the bay, in coming from the northward, is a low rocky point, called Poroto; about four miles to the northward of Point Poroto, is the port of Arrayan, or Juan Soldado; but it does not deserve the name: it is merely a small bight behind a rocky point, scarcely affording shelter for a boat from southerly winds, and entirely open to northerly. A little to the northward of Copper Hill is another hill, on the same range and about the same height: the north side of the hill is steep, and at the foot of it is the small Bay of Osorno, which is about half a mile long, but not deep enough to afford any shelter for the smallest vessel. About half a mile to the northward of the bay there is a hamlet, consisting of a few small houses, called Yerba Buena.

The Pajaros Islands are two low rocky islands, lying about twelve miles from the coast; the northern is much smaller than the southern, and, as far as could be seen from the shore, there is no danger round or between them. A little to the northward of Yerba Buena there is a small island, called Trigo, separated from the shore by a channel about a cable's length broad; but it is only fit for boats: the island, except when very close, appears to be only a projecting point; there is a large white rock on the west point of it.

About three miles to the northward of Trigo Island, is the Port of Tortoralillo, which is formed by a small bay facing the north, with three small islands off the west point. In coming from the southward, the best entrance for small vessels is between the southernmost island and the point, where there is a channel about a cable's length wide, with from eight to twelve fathoms water. The dry rock off the point on the main land, should not be approached nearer than half a cable, as a sunken rock lies nearly that distance from it. There

© The Complete Work of Charles Darwin Online

is no channel between the northern and middle islet, as it is blocked by breakers: a vessel may anchor about half a mile from any part of the beach in from six to eight fathoms, sandy bottom. The landing is not good, the best is on the rocks near the entrance; but nothing could be embarked from there: the east end of the beach is the best for that purpose. From the land to the northward, running so far westward, it is not likely that a heavy sea would be caused by a northerly gale.

Tembladar is a small cove in the east side of Tortoralillo, but the landing there is worse than on the other beach, and it is not so well sheltered.

About three miles to the northward of Tortoralillo, there is the small island of Chungunga; it is about a mile from the shore, and is a good mark for knowing the port: there is a rocky point a-breast of it; a little in-shore of which there is a remarkable saddle hill, with a nipple in the middle, which, to a person coming from the southward, appears as the extreme of the high range, that runs thence to the eastward of Tortoralillo, and is from two to three thousand feet high.

A little to the northward of Point Chungunga, there is a large white sand-patch, which is seen distinctly from the westward; it is at the south end of the Choros beach, which runs for seven or eight miles to the north-west, to Point Choros; a heavy surf always breaks upon it.

Off Point Choros there are three islands, the inner one is low and nearly joins the shore; nothing but a boat can pass inside it. About a mile to the westward of this island, there is another small island; between them the channel is clear of danger. To the south-west of this island about a mile, is the largest of the Choros islands; it is about a mile long, the top is very much broken, and at the south-west end it very much resembles a castle: there is a small pyramid off the south end, and rocks break about a quarter of a mile from the shore. The channel between the two outer islands is clear of danger; but about half a mile to the westward of the small island, there is a rock nearly awash. Five miles to the south-east of the southern Choros Island, there is a very dangerous reef of rocks only a little above the water.

Point Carrisal is a low rocky point, about five miles to the northward of Point Choros, with a remarkable round hummock; to the

© The Complete Work of Charles Darwin Online

southward of it is the small cove of Polillao, where there is shelter for small vessels, but the landing is bad: there are two small rocky islets off the south point of the cove. To the northward of Point Carrisal is the bay of the same name, but it is not fit for vessels; at the bottom of the bay a heavy surf breaks about half a mile from the shore. The north side of the bay is formed by a rocky point, with outlying rocks and breakers about a quarter of a mile off all sides of it. There is a landing-place in the bay, near the south-east corner, where the rocky coast joins the beach, but in bad weather the surf breaks outside it.

Nearly one mile to the northward of the north point of Carrisal Bay is the Port of CHANERAL; it is well sheltered from northerly and southerly winds, but the swell sets in heavily from the south-west, which makes the landing bad; the best is in a small cove on the north side of the port, near the beach at the head of it: there is also a landing-place on the south side, but it is bad when there is any swell. On the beach at the head of the port there is always too much surf to land, except after very fine weather. About four miles and a half to the westward of it is the Island of Chañeral; it is nearly level, except on the south side, near which there is a remarkable mound with a nipple in the centre of it. There are rocks nearly half a mile from the south point of the island, and one about the same distance off the north-west point. On the north side there is a small cove, where boats can land with the wind from the southward; there is anchorage close off it, but the water is deep. An American sealing schooner was lost there a few years ago, from a norther coming on while she was at anchor.

The land round Chañeral is low, with ridges of low hills running from the points, the tops of which are very rugged and rocky, and the land is sandy and very barren; the range of high hills is several miles from the shore at this part, but between the range and coast there are several smaller hills rising out of the low land. The village of Chañeral is about three miles from the port, and is said to consist of about twenty houses. There are no houses near the port. We were told by some of the people that came off, that the only vessel that had ever been here was a small schooner, called the Constitucion (our vessel), which had taken a cargo of copper to Huasco. There was a large quantity of copper, said to belong to Mr. Edwards, ready to be embarked.

© The Complete Work of Charles Darwin Online

To the northward of Chañeral Bay the coast is low, and projects to the N.W. for about ten miles. The extreme west point, Point Pajaros, has a small rocky islet off it, about two cables from the shore: the land in-shore rises gradually to a low ridge, about half a mile from the coast, the high range is about three miles in-shore. To the northward of Point Pajaros the coast runs to the East, forming a small bay, open to northerly, but well sheltered from southerly winds; there is anchorage in from eight to twelve fathoms, about one-third of a mile from the shore, but the landing is bad.

About four miles N.E. of Point Pajaros is another point, with a high rock off it, to the northward of which is the Bay of Sarco, in which there is also shelter from southerly winds. A deep gully runs inland from the S.E., corner of the bay, at the mouth of which is a sandy beach, with anchorage about one-third of a mile off, in from eight to twelve fathoms, but the landing is not good. There are two or three small huts close to it. To the northward of Sarco the high land runs close to the coast, the sides of the hills are covered with yellow sand, the summits are rocky, and the whole coast has a miserably barren appearance. To the northward of the deep gully about four miles, there is a projecting rocky point, at the foot of a high range of hills, with a very remarkable black sharp peak near its extreme, the coast to the northward of this runs nearly north and south, and is very rocky for about eight miles, when it turns to the westward, forming a deep bay, in the N.E. corner of which is a small beach called Tongoy. To the northward of the bay a high range runs out towards Point Alcalde, the extreme point of the bay, which is nearly seven miles to the southward of Huasco; the point is very rocky with small detached rocks close to it: in-shore it rises a little, and there are several small rocky lumps, running out of the sand, one of which, from the southward, shows very distinctly: it is higher than the rest, and forms a sharp peak; a little in-shore of which the land rises suddenly to the extreme of the high range. About seven miles to the northward of Point Alcalde, is the point forming the Port of Huasco, it is a low rugged point, with several islands off it, one of which only is of any size, it is separated from the main by a very narrow channel, and appears from sea-ward to be the point of the main; it is covered with low rugged rocks, one of which on its north side is much higher than the rest, and shows distinctly coming from the southward, but from the northward it is

© The Complete Work of Charles Darwin Online

mixed with the other rocks behind it; to the south-west of this island there are several other small rocky islets, which appear as two small islands when seen from a distance. A little in-shore of the extreme point there is a short range of low hills, forming four rugged peaks, which show very distinctly from the southward and westward: the land falls again inside them for a short distance more, and then rises suddenly to a high range running east and west, which is directly to the southward of the anchorage. The top of the range forms three round summits, the easternmost of which is a little higher, and the middle a little lower than the other.

Nearly three miles to the N.E. of the anchorage, there is another range of hills about 1,400 feet high: on the south slope of which there is a sharp peak, from which it slopes to the valley that the river runs through. The river is small, and a heavy surf breaks outside it, the water however is excellent; there is another lagoon small river in the valley, nearer the port, but the water is very brackish. The anchorage is very much exposed to northerly winds, and a heavy sea then rolls in, but a heavy norther does not occur more than once in two or three years. The village consists of about a dozen small houses, scattered among the rocks on the point dividing the old and new ports. The country round presents a more barren and miserable appearance than any part even of this desolate coast: the ground is composed of a mass of small stones mixed with sand, out of which project masses of rugged, craggy rocks. A little in-shore the stony ground is changed for a loose yellow sand, which covers the sides and bases of nearly all the hills round: the summits are stony without any appearance of vegetation; but in the low grounds a few stunted bushes grow among the stones, and after rain (a rare blessing) they look much fresher than might be expected in such soil, and then the valley through which the river runs also appears green, forming a striking contrast to the country around.

Point Lobo, about ten miles to the northward of Huasco, is rugged, with several small hummocks on it; to the southward of this there are several small sandy beaches with rocky points between them, but a tremendous surf breaks on them, allowing no shelter even for a boat. A little in-shore of the point, there are two low hills, and within them the land rises suddenly to a range about 1,000 feet high. In the bay to the northward of Point Lobo, there

© The Complete Work of Charles Darwin Online

are several small rocks, and about six miles from it there is a reef which runs perhaps half a mile off a low rocky point: the outer rock is high and detached from the others.

About eleven miles to the northward of Point Lobo, is a very rugged point, with several sharp peaks on it, about half a mile to the northward of which is the small port of HERRADURA, which can hardly be distinguished till quite close to it. Off the rugged point, and between it and the entrance to Herradura, there are outlying rocks and breakers, about a quarter of a mile from the shore: off the south entrance point there is a patch of low rocks, which in coming from the southward appear to extend right across the mouth of the port. The entrance faces the N.W., and is between this low patch of rocks, and a small islet to the N.E. of it: there is no danger within half a cable of either point. The port runs in about three-quarters of a mile to the eastward of the islet, and is sheltered from both northerly and southerly winds, but with a strong northerly breeze a swell rolls in round the islet. It is rather small for large vessels, and they would not be able to lie at single anchor in the inner part of the cove, but there is quite room enough to moor across it, about a quarter of a mile above the islet, in four fathoms, fine sand. In this place an American ship, the Nile, of 420 tons, was moored during a northerly gale, which blew very heavily; and she was perfectly sheltered. The landing is better than in any place between it and Coquimbo: but there is a very serious inconvenience in the want of water. There is a small lagoon about a mile from this place, in the valley at the head of Carrisal Cove, but it is worse than brackish; yet the 'peones,' who are at work shipping the ore, make use of it. A deep valley runs in from the head of the cove, separating the high ranges of hills, and is a good mark to know it by. The range to the southward of the valley is the highest near the coast, and is distinctly seen from both the northward and southward; there is a small nipple in the highest part of it. CARRISAL is a small cove about a mile to the N.E. of Herradura, well sheltered from southerly winds, but as it is so close to Herradura, which is so much superior, it is not likely to be of much use.

To the northward of Carrisal the coast is bold and rugged, with outlying rocks a cable's length off most of the points. About nine miles to the northward of Herradura there is a high point with a

© The Complete Work of Charles Darwin Online

round hummock on it, and several rugged hummocks a little in-shore. To the northward of this there is a cove, sheltered from the southward, where small vessels may anchor, but it is not fit for large vessels; there is another cove similar to it about a mile to the northward of it. A little to the northward of the second cove, there is a high rocky point, which is the termination of the high part of the coast; to the northward of the point there is a small port, which from the chart appears to be Tortoralillo: it is well sheltered from southerly winds, and the landing is good. In the inside part of it a vessel, not drawing more than ten or twelve feet, might moor sheltered from northerly winds, in three and four fathoms, but with a northerly wind there would be a heavy swell in: there is anchorage farther out under the point, in from eight to ten fathoms; but a vessel should not go nearer the shore than eight fathoms, as the bottom inside is rocky.

During the summer months this would be a very good port for small merchant vessels; but there is no appearance of water near. Abreast of it the high range of hills recedes from the coast, which is low, with some low rocky hills a little in-shore.

About two miles to the northward of Matamores there is a low rocky point, a little to the northward of which there is a small deep bay, at the mouth of a valley, in which, apparently, there is anchorage for a vessel; but there was a heavy surf on the beach, and as the landing was bad we did not wait to examine it. To the northward of this the low hills are not so rocky, but are covered with yellow sand, except near the summits, where they are stony.

About six miles to the northward of this bay there is a remarkable rocky point, with a detached white rock off it, and a lump with a nipple on it, a little in-shore. About half a mile to the northward of this, is the small port of Pajonal, which, in coming from the southward, may be easily known by this nipple, and a small island, with a square topped lump in the centre of it, which is off the point to the northward of the port. A range of hills, higher than any near, rises directly from the north side of the port; and in the valley, about a mile from it, there is a range of small and very rugged hills rising out of the low land.

The anchorage is better sheltered from southerly winds than any to the southward, except Herradura, and there would not be much swell, as the point and island to the northward project considerably

© The Complete Work of Charles Darwin Online

to the westward. The southerly swell rolls into the mouth of the port, but on the south shore it is smooth, and the landing pretty good: there is a dangerous breaker about a quarter of a mile to the south-west of the south extreme point, which only shows when there is much swell. The best anchorage is about half way up the cove, near the south shore, in five fathoms: near the head it is very flat. We found a cargo of copper ore ready to be shipped here, but no vessel had ever been in the port: there is no water within two miles, and there it is very bad indeed. The name of Pajonal was told to us by a young man who was getting the ore down, but he appeared to know scarcely anything of the coast, and there were no inhabitants near the place.

About a mile and a half to the northward of the island before mentioned, there is another point, with an island and several rocks off it; both the islands may be passed within half a mile, but there is no passage inside them. To the northward of the northernmost island, the coast runs to the eastward, forming a large and deep bay, which at a distance looks very inviting; but before we were within a mile of the depth of it, we were in three fathoms, with rocks all round us, some above and others a little below water. From the bay being well sheltered from the southward, they do not show till close to, except two patches which are off the north point, and are always uncovered. A mile to the northward of these rocks there is another bay, which is quite clear of danger; and in the south corner of it, a small cove, there is good anchorage in seven fathoms, well sheltered from southerly winds, but very open to northerly. The water is perfectly smooth with a southerly wind, and no swell could ever reach it unless it blew from the northward. There is a small bay, half a mile to the northward of this, where a vessel may anchor, but it is not so well sheltered; there were no signs of inhabitants, nor the least appearances of water in the valleys. The land at the back of the bay is low, but to the northward of the north bay it rises to a ridge of sand hills, running east and west, and terminating in a steep rocky point, with a cluster of steep rocky islets off it. To the northward of this point the coast is rocky and broken, with rocks a short distance from the shore for about four miles, where there is a rugged point with a very high, sharp-topped hill a little in-shore, which from the southward shews a double peak; directly to the northward of this point, there is a deep rocky

© The Complete Work of Charles Darwin Online

bay, with a small cove close to the point where we anchored in five fathoms, but half a cable off shore on either side: it is not fit for a vessel. The bay is partly sheltered from northerly winds, but a northerly swell rolls in, and it does not appear to be a proper place for a vessel to enter.

From an old fisherman, who was living in a hut, we learned that the name of the place is BARRANQUILLA DE COPIAPO, and to our surprise saw a cargo of copper prepared for shipping. He also told us that another cargo had been shipped from the same place about a year before; though the cove is too small for any vessel to anchor in with safety, and outside it the water deepens very suddenly. There is no anchorage in the cove at the head of the bay, and the landing there is very bad; in the small cove the landing is good. There is no fresh water nearer than the river of Copiapo, which is about fifteen miles off.

The deep bight to the southward of this, in which are the three bays before mentioned, is called Salado Bay; the south point of it, with the island off it, is Point Cuernos. No vessel had ever been in either of these bays, but the middle one is much superior to Barranquilla, and might be a much better place to embark the ores.

From Barranquilla to Point Dallas the coast is rocky and broken, without any place sufficient to shelter the smallest vessel. Point Dallas is a black rocky point, with a hummock on its extreme, which, coming from the southward, appears to be an island; the land rises to a range of low sandy hills, with rocky summits.

The Caxa Grande is a small sharp-topped rock, which is the only one of the reef that shows above water; the patch near the point was a-wash when we passed.

The channel between it and Point Dallas appears to be wider than it is given in former charts, but the reef off the point projects much farther. The sea was high, and there was occasionally a breaker above a quarter of a mile from the point; at about that distance from the breakers on the reef, the least water we had was eleven fathoms; when the swell is not high, the breaker off the point would not show; it appeared to be detached from the reef which joins the point.

COPIAPO is a very bad port; the swell rolls in heavily, and the landing is worse than in any port to the southward; it may easily be known by the Morro, to the northward, which is a very

© The Complete Work of Charles Darwin Online

remarkable hill, nearly level at the top, but near the east extreme of it there are two small hummocks; the east fall is very steep, the end of another range of hills shews to the northward. To the S.W., apparently forming part of the same range, is another hill, the west side of which forms a steep bluff; in coming from the southward, these hills will be seen in clear weather, before the land about the port can be made out. From a fisherman, who knew the coast to the southward, we learned that the small port we passed the night in, to the northward of Port Herradura, is called Matamores; the high point to the southward of it is Point Matamores. Tortoral, or Tortoral baxo, is the bay between it and Pajonal. He described it as having always a heavy surf in it, and the landing bad. The south point of the Bay of Salado, with the islet off it, is called Point los Cachos. He was in the vessel that took the cargo of copper from Barranquilla. She was a large brig of 300 tons, and was anchored off the mouth of the cove. The island to the north of Copiapo Bay, called Isla Grande, is very remarkable; it has a small nipple on each extreme, that on the eastern is the highest: to the westward of the middle of the island, there is another small round nipple.

The channel between Isla Grande and the main is clear of danger in the middle; but such a heavy swell rolls through, that it is scarcely fit for any vessel. Off the north extreme of the island there is a reef under water, projecting two cables to the eastward; at a cable's length distance from the reef we had eight fathoms; the point on the main appeared to have no danger off it; the rocks to the southward of it are inside the line of the points. The swell in the channel was by far the worst we had experienced on this coast: to the northward of the island there are several small rocks, one of which is high. There is no danger within a quarter of a mile of them.

The point on the main, to the northward of the island, is very rocky; on the S.W. point there are two rugged hummocks, and several rocks and islets close to the shore, but no danger outside them: from this to Point Morro, the shore is steep and cliffy, with remarkable patches of white rock in the cliffs to the south of the point, which is steep, with rugged lumps on its summit. The Morro rises suddenly, a little in-shore.

On rounding the point, you open a deep bay which runs in to the

© The Complete Work of Charles Darwin Online

S.E.; there are several small rocky patches in it, and at the north end of the long sandy beach there is a piece of rocky coast, the north extreme point of which has a small island off it. The entrance to Port Yngles is to the southward of this point, round a low rocky point, to the southward of which, close in-shore, there is a small island off a sandy cove; there is a rock a-wash at high-water, about a cable's length to the N.W. of the south extreme point, but it always shows; after passing this rock the point is steep-to, and may be approached within a cable's length. The harbour inside forms several coves, in the first of which, on the starboard hand going in, there is anchorage for small vessels, but the bottom is stony and bad. There is a low island to the S.E. of this cove, above which is the best anchorage, with southerly winds. About half-way between it and a projecting rocky point on the east shore, small vessels may go much closer into the cove, to the southward of the island, where the landing is very good. The bay in the N.E. corner is well sheltered from northerly winds, and no sea could ever get up in it; but the landing is not so good there, the best is at a rocky point at the south end of the northernmost beach, where there is a small cove among the rocks perfectly smooth: it is by far the best harbour, but there is no fresh water near. The cove at the head of the harbour is very shoal; no vessel should go higher up than abreast of the projecting rocky point on the east shore, where she would have four and five fathoms in mid-channel. The bottom is hard sand, and may be seen in twelve fathoms water, which makes it appear very shallow. In the entrance there are eighteen fathoms close to the shore on both sides.

Port Caldera is close to the northward of Port Yngles, and is directly round the point with the small island off it; it is a fine bay, well sheltered, but the entrance more open than Port Yngles, and the landing not so good. There was a cargo of copper ore ready to be shipped in the south corner of the bay; but no vessel had then ever taken a cargo away. There were a few fishermen living in a hole in the cliff during the fishing season: the only vessel they had ever seen in the port was a brigantine, with provisions for the mines. No vessel had ever been in Port Yngles. There is water near the beach, on the east side, but it is very salt; it appears wonderful how they can make use of it, but they have no other nearer than Copiapo. The land is entirely covered with loose sand, except a few

© The Complete Work of Charles Darwin Online

rocks on the points; the bottom of the bay is low, but the hills rise a little inland, and the ranges become higher as they recede from the coast: the first hill to the eastward is a very remarkable sharp-topped hill, the sides of which are covered with sand, with two low paps to the eastward of it. They have had strong northers here for two days, and sometimes a good deal of sea in the south corner of the bay; but in the north-east corner, which they call Calderillo, it is then smooth; they very seldom have heavy northers. There are fish to be got in the bay, but only with a net: in all the ports we visited we caught none alongside. Near the outer points of the ports there are rock fish to be caught, but there is always a heavy swell in such places.

Point Cabeza de Vaca is a remarkable point, about twelve miles to the northward of Caldera: it has two small hummocks near its extreme; inside them the land is nearly level for some distance in-shore, where it rises to several low hills, which form the extremity of a range. The coast between Caldera and the point forms several small bays, with rocky points between them, off all of which there are rocks a short distance: there is no danger within a quarter of a mile from Point Cabeza de Vaca. To the northward of the point there is a small rocky bay, called Tortoralillo, off the north entrance point of which there is a reef of rocks, with a high rock at the extreme of it, which extends above a quarter of a mile from the shore: about half a mile to the north-west of this there is a heavy breaker when there is much swell.

To the northward of this the coast is steep and rocky for three or four miles, with a high range of hills running close to the shore; then there is a small cove, called Obispito, with a white rock on the south point of it: to the northward of this the land is low and very rocky, with breakers about a quarter of a mile from the shore. About two miles from the cove there is a point, with a small white islet off it; to the northward of which the coast trends to the eastward, and forms the small cove of Obispo, in which we anchored, but it is not fit for any vessel. There was a fire on shore in the night, but we saw no ore, and as the landing was bad we did not attempt it. There is a very high sand hill, with the summit stony, a little in-shore of the cove, and to the northward of it a higher range of stony hills running close to the

* For more information respecting the vicinity of Copiapo, see pages 229 and 230.

© The Complete Work of Charles Darwin Online

coast for about seven miles, where it terminates in low rugged hills a little in-shore of a brown rugged point, with a large white patch on its extreme, which is an islet, but does not show as one from the sea. To the northward of this point there is a fine bay, in which we anchored, and, from a fisherman who came off, learned that it is FLAMENCO: it is a very good port, well sheltered from southerly winds, and better from northerly, as the point projects far enough to prevent a heavy sea getting up. The landing is good in the S.E. corner of the bay, either on the rocks, or on a beach in a small cove in the middle of a patch of rocks, a little more to the northward, where there are a few huts, in which two brothers, with their families, were living; their chief employment was catching and salting fish, called congre, and drying them to supply Copiapo. In one day they had caught four hundred. They appeared to live in a miserable way, in huts made of seal and guanaco skins, much worse than a Patagonian "toldo"; the only water they had to drink was half salt, and some distance from the shore. They sometimes get guanacoes, that they run down with dogs, of which they have a great number.

The only vessel they had ever seen here, was a ship which anchored one night, on her way to Las Animas for copper ore, six years ago; they described Las Animas as a very bad place, not fit for any vessel, and in consequence no cargo had ever been shipped again, but taken to Chañeral, which was better, but not so good as Flamenco. There are no mines so near Flamenco as to Chañeral.

Flamenco may be known by the white patch on the brown rugged point, to the southward of which, in-shore, there are low rugged hills, rising to a high range. On the north side of the bay the land is very low: the north point is a low rocky point, with a detached hill rising out of the low land a little in-shore. To the northward there is another hill very much like it; in the depth of the bay the land is very low, and a deep valley runs back between two ranges of rugged hills. The hills are all covered with yellow sand near their bases, and to about half way up their sides, the tops are stony, with a few stunted bushes.

In the bay, to the northward of Flamenco, in which Las Animas was said to be, we could see no place fit even for a boat to land; the whole bay is rocky, with a few little patches of sand, and a heavy surf was breaking on the shore. The north point of this bay is

© The Complete Work of Charles Darwin Online

low, but a little in-shore there is a high range of hills, the outside of which is very steep: to the northward of this point there is a small rocky bay, which appears to answer better to the description of Las Animas than the other; it did not appear a fit place for vessels, and the landing was bad. The north point of this bay is a steep rocky point, with a round brown hill rising directly from the water's edge; the sides of the hills are crossed by dark veins, running in different directions, which are very remarkable. To the northward of this point there is a deep bay, which, from the description, must be Chañeral: the south side of it is rocky with small coves, but the landing appeared to be bad; the east and north shores of it were low and sandy, and a heavy surf was breaking on the beach. We could see no signs of any people, or piles of ore, along the coast; and as it did not appear a good place for vessels, and our time was short, it was not thought worth a more particular examination. The north point of the bay is low and rocky, with a high range a little in-shore. To the northward of this point the hills and coast are both composed of brown and red rocks, with a few bushes on the summits of some of the hills: the sandy appearance the hills have to the southward ceases, and the prospect is, if possible, more barren.

Nearly nine miles to the northward of the point of this bay is Sugar Loaf Island, which is about half a mile from the shore; in coming from the southward, there is a high sugar loaf hill on the main, a little to the southward of the island, for which it may be mistaken, but the island is not so high and the summit is sharper. Between Sugar Loaf Island and Chañeral, the coast is rocky and affords no shelter: there is a small bay to the southward of the passage, between the island and the main, which would afford shelter from northerly winds, but with southerly it is exposed, and the landing is very bad. In the middle of the passage there are five fathoms in the shallowest part: the water in the northern end of it is smooth, and a vessel might anchor off the point of the island, sheltered from southerly winds, in six or seven fathoms; but after eight fathoms it deepens suddenly to thirteen and twenty fathoms, about half a mile from the island. There is a small bay on the main, to the northward of the channel, where a vessel would be sheltered from southerly winds, but we did not examine it.

About twenty miles to the northward of the Sugar Loaf Island

© The Complete Work of Charles Darwin Online

there is a projecting point, with some small rocky islets off it, which we supposed to be Point Ballena, from the description given at Port Caldera. Between the point and the Sugar Loaf Island, the coast runs back a little, and is rocky, with a high range of hills running close to the shore. A little to the northward of Point Ballena there is a small bay, with a rocky islet about half a mile off the south point of it; the top of the islet is white, and answers the description given to us of a port called Ballenita: but it is not worth the name of a port; it is very rocky, with two or three small patches of sandy beaches, in which a heavy surf was breaking; the hills run close to the water, and have a very rugged appearance. A little to the northward of this there is another bay, which seemed to be Lavata: the south point has several low rugged points upon it, and in-shore the hills rise very steep. There is a small cove with excellent landing, directly behind this point, on which we anchored; there was a better-looking port inside, but it was so far from the outer coast, that our time would not allow more than a hasty glance.

The inner cove of the bay in which we anchored appeared to afford good shelter from southerly winds, and the water was very smooth. A little to the northward of this bay there is a point, which, till close, appears to be an island: but it is joined to the shore by a low shingle spit: the summit of it is rugged, with several steep peaks on it: several rocky islets lie scattered off the point.

Near three miles and a half to the northward of this, there is another point, very rugged, and with a high round hummock a little in-shore: to the southward of this point there is a deep bay, in which we expected to find Paposo, as we were some distance to the northward of its position in the old charts, but there were no appearances of any houses or inhabitants: the bay is very rocky, and does not afford good anchorage; several rocks lie off the south point, and a little inside it there is a reef running half-a-mile from the shore: in the bottom of the bay there are several small white islets; and two or three small sandy coves, which are not large enough to afford shelter for a vessel. This bay is called Isla Blanca.

About three miles from the north point of the bay, there is a white islet, with some rugged hummocks upon it: a little in-shore there is a hill of a much lighter colour than any round it; to the northward of this there is a deep bay, in which we were certain of finding Paposo, and, as we were becalmed, I went in a boat to search for it;

© The Complete Work of Charles Darwin Online

on landing at the point we saw a smoke on the east side of the bay, and, on pulling over there, found two fishermen, who told us that the place was Hueso Parado, and that Paposo was round another point about eight miles to the northward. On inquiring for water, they brought us some, which was better than what was used in some other places to the southward, but it was still scarcely fit for use; they said it was similar at Paposo, and they thought it very good. In the south corner of the bay there appeared to be fit anchorage for vessels, and the landing good, but very open to northerly winds. No vessel had ever been there in the recollection of the men that we spoke to, neither had they heard of any; they described Paposo as having only four 'ranchos' and a few fishermen: the port not good. The bay that Paposo is in they called Nuestra Señora, the north point of the bay Point Rincon, and the south, Point Grande; the projecting point, answering to the Point Nuestra Señora of the Spanish charts, they called Point Plata. The bay to the northward of Point Ballena, is Ballenita; the bay in which we anchored to the northward of it is called Lavata; the point, with the peninsula, is Isla de las Tortolas: the point to the northward of it Point San Pedro; the bay which we were in afterwards is Isla Blanca, and the point of Hueso Parado Bay, Point Taltal.

The only place at which we observed the time of syzygial high-water, quite satisfactorily, was Huasco,* where it is 8.30, and the rise four feet at neap tides; at springs, it rises about two feet more. From the swell on all this coast, it is very difficult to get the time of high-water at all near the truth; the rise and fall appeared to be five or six feet on all parts of the coast. The only perceptible current we experienced was in the channel between Sugar Loaf Island and the main, where there was a very slight one to the northward, not more than a quarter of a mile an hour; and this was after a fresh breeze from the southward for several days. It is said, however, by coasters, that there is usually a set, towards the north, of about half a mile an hour.

* And here the tide was very carefully observed in a cove, where there was no swell; yet from the small rise, the exact time could not be taken within a few minutes. The water remained at the same level about half an hour.

Winds on the Coast of Chile.

Very few words will suffice to give strangers to the coast of Chile a clear idea of the winds and weather they may expect to find there, for it is one of the least uncertain climates on the face of the globe.

From the parallel of 35° S., or thereabouts, to near 25° S., the wind is southerly, or south-easterly, during nine months out of twelve; in part of the other three there are calms, or light variable breezes, and the remainder is really bad weather: northerly gales and heavy rain prevailing, not only on the coast, but far across the ocean in parallel latitudes.

From September to May is the fine season, during which the skies of Chile are generally clear, and, comparatively speaking, but little rain falls. I do not, however, mean that there are not occasional exceptions to the general case: strong northers have been known (though rarely) in summer; and two or three days of heavy rain, with but little intermission, now and then disturb the equanimity of those who have made arrangements with implicit confidence in the serenity of a summer sky. These unwelcome interruptions are rarer, and of less consequence, northward of 31° than they are to the south of that parallel: so nearly uniform, indeed, is the climate of Coquimbo, that the city is called 'La Serena.'

In settled weather a fresh southerly wind springs up a little before noon (an hour sooner or later), and blows till about sunset, occasionally till midnight. This wind is sometimes quite furious in the height of summer; so strong, indeed, that ships may be prevented from working into anchorages, especially Valparaiso Bay, although they may take every previous precaution, by sending down top-gallant yards, striking top-gallant masts, and close-reefing their sails. But the usual strength of the southerly sea-breeze (as it is called, though it blows along the land from the south) is such as a good ship would carry double-reefed top-sails to, while working to windward.

This is also nearly the average strength of a southerly wind in the open sea, between the parallels above-mentioned, and there it is neither so strong by day, nor does it die away at night. Within sight of the land a ship finds the wind freshen and diminish,

© The Complete Work of Charles Darwin Online

nearly as much as in the ports of this coast, where the nights are generally calm, till a land breeze from the eastward springs up. This light message from the Cordillera is never troublesome, neither does it last many hours. With these winds the sky is almost always clear; indeed, when the sky becomes cloudy it is a sure sign of little or no sea breeze in summer, and probably a fall of rain: in the winter it foretels an approaching northerly wind, with rain.

In summer, ships anchor close to the land, to avoid being driven out to sea by strong southerly winds; but as the winter approaches a more roomy berth is advisable, though not too far out, because near the shore there is always an undertow, and the wind is less powerful. Seamen should bear in mind that the course of the winds on this coast, as in all the southern hemisphere, is from north to south, by the west: that the hardest northerly blow, with most sea, comes from the westward of north, and that, therefore, they should get as much as possible under the shelter of rocks or land to the westward of them, rather than of those which only defend from north winds. 'Northers,' as they are called, give good warning: an overcast sky; little or no wind unless easterly; a swell from the northward; water higher than usual; distant land remarkably visible, besides being raised by refraction; and a falling barometer; are their sure indications: but all northers are not gales: some years pass without one that can be so termed; though few years pass in succession without ships being driven ashore on Valparaiso beach. Thunder and lightning are rare: wind of any disagreeable strength from the east is unknown. West winds are only felt while a 'norther' is shifting round, previous to the sky clearing and the wind moderating. The violence of southerly winds lasts but a few hours: that of a northerly gale seldom continues beyond a day and a night, generally, indeed, not so long.

Some persons say that the strength of northerly winds is not felt to the northward of Coquimbo, but I have evidence of gales, with heavy seas, at Copiapo: and Captain Eden informed me that he had a very heavy gale of wind in H.M.S. 'Conway,' in latitude 25° S., and longitude 90° W., where such an interruption to the usual southerly winds was little expected.

How to make passages is easy to tell, for there are but two ways. When going northward, steer direct to the place, or as nearly so as is consistent with making use of the steady winds which prevail in

© The Complete Work of Charles Darwin Online

the offing: and if bound to the south, steer also direct to the place, if fortunate enough to have a wind which admits of your doing so; but if not, stand out to sea, by the wind, keeping every sail clean full: the object being to get through the adverse southerly winds as soon as possible, and reach a latitude from which the ship will be sure of reaching her port, on a direct course. Every experienced seaman knows that no method is more adverse to making quick passages than that of 'hugging the wind,' as it is called. When Sir Thomas Hardy was on this coast, he used to cross the southerly winds with a topmast studding-sail set, as many men cross the trades, his object being to get into other winds. The current on the coast of Chile is northerly, about half a mile an hour; varying a little with the wind.

The idea some persons have of Copiapo being a difficult place to make is rather unfounded; the following is the manner in which we made it in the Beagle, when strangers to that part of the coast.

July 3. A dull gloomy day, wind moderate from the southward; at 10 A.M. we were thirty miles south of Copiapo, by the dead reckoning from noon yesterday; but being aware of the northerly set, which near the shore is half a mile an hour, we steered an E.N.E. course in for the land; at noon it was in sight, forming two long rounded-topped hills: the northern one was the highest, it ended in a bluff, with a low point sloping off it; this we rightly supposed was the Morro of Copiapo, it bore N.E.; and the other which was a-head the high land of Tortoral; this had a gradual slope to seaward. A round and rather peaked black rock, about ten feet high, a little open, of a low level (eighty-five feet high) of a light brown colour, with some remarkable white patches on it, was seen at three; and a little before it, about a point south of the Morro, was a low, black, rocky island. The latter was Isla Grande, and the former the Caxa Grande rock, with the west point of the anchorage cove, on which there is a flag-staff: as we neared the land the wind gradually left us; and, as the day closed, we were four miles from the Caxa Grande. The clouds that covered the high land in-shore of Copiapo, lifted off a little in the evening, showing us two remarkable hills, one with a notched top, and the other like a sugarloaf, with rather a flat top; this was in a direction a little south of the Caxa Grande, and

© The Complete Work of Charles Darwin Online

the other nearly over Isla Grande. (Head to the westward during the night with light variable airs.)

July 4. A perfect calm all day, and no observation: we were drifted abreast of the bluff under the Morro by the afternoon; it has some very curious white patches, which are seen at some distance; indeed the whole of the land is very remarkable. Plyed to the southward during the night, wind light.

July 5. Wind light from the N.N.E., and gloomy weather; at 10 A.M., passed one mile to the N.E. of the reef; north of the Caxa Grande rock we had eighteen fathoms, between it and the Isla Grande, with fifty-seven outside, and sixteen in. As we stood in we could not, from the mast-head, see any thing of the breakers said to be off the Caxa Grande rock: as the breakers ran high on the other reefs; had there been any thing of the sort there, we should most likely have seen it: all the information we have been able to get on the subject denies their existence. Detached, but close to the N.E. part of the anchorage point, are two black rocks, ten feet high; they show well from the northward. About twenty-five miles to the N.E. of the Morro, are two singular peaks: they are higher than any of the other land; the summit of the northern one is very pointed, and the southern is rather saddle-topped; these, it would seem, must be very remarkable from seaward. We anchored in seven fathoms, Caxa Grande rock bearing S. 67° W., distant three cables from the two rocks before-mentioned.

As Iquique is situated on a part of the coast where calms are frequent, and exposed to a constant swell from the westward, there may perhaps exist some difficulty in finding it; indeed, from this very circumstance, persons do not go sufficiently near the shore, although the position of the spot is nearly correct in the common charts.

The centre of the island lies in lat. 20° 12′ 30″ S. and long. 70° 15′ W. The slight indentation the bay makes in this high precipitous coast is not perceptible from an offing of nine or ten miles, neither is the collection of sand behind and south of the bay likely to catch the eye of a stranger: should there happen to be a vessel there, her dark masts against the white sand make an excellent mark; without which, there is nothing to guide a stranger until he gets within sight of the church steeple, or some white patches in the cliffs under Ta-

© The Complete Work of Charles Darwin Online

rapaca Mountain; the latter will probably be seen first; they are nine miles to the southward of the anchorage.

The houses in the village, when first seen, have just the appearance of so many black rocks on a sandy beach. The anchorage is very tolerable, as it is sheltered from the S.W. swell by the island; which is surrounded by numerous small detached rocks, particularly on the N.E. and W. sides; therefore it should not be approached nearer than half a mile.

This island was once much higher; the many cargoes of birds' dung* it has afforded have reduced it to its present low state. The landing is bad at the best time, as you have to thread your way among patches of sunken rocks; on which the sea breaks with great violence at the full and change of the moon: several boats have been knocked to pieces, and lives lost. In the summer it is a calm nearly all night, sometimes there is a light air from the land. The sea breeze sets in from the southward or south-west about ten or eleven in the forenoon; it seldom blows fresh, but lasts until eight or ten at night. In the winter, calms, hazy weather, and light northerly winds are common.

The only trade now to Iquique is for saltpetre; the rich silver mines formerly worked are exhausted.

The water the inhabitants use is brought from Pisagua, a small bay thirty miles to the northward, for which they pay dearly, brackish as it is. Forty houses and an old church, situated on a bare sandy flat, without a vestige of verdure of any kind near, are the features Iquique presents; in vain does the eye wander for something green to rest upon—extreme desolation reigns every where, from shore to summit.

No. 41.

Remarks on the Coast of Peru.

All the bearings are magnetic.

From Point San Pedro (the south point of the bay of Nuestra Señora), at the distance of twenty miles, is Point Grande, the north point of the before-named bay. This point, when seen from the S.W., appears high and rounded, terminating in a low rugged

* Called 'guano:' it is a valuable manure.

© The Complete Work of Charles Darwin Online

spit, with several hummocks on it, and surrounded by rocks and breakers to the distance of a quarter of a mile. N. 21° W., nine miles and a quarter, is Point Rincon, having a large white rock off it; between these two points, in the latitude of 25.02 S., lies the village of Paposo, the most northern village on the coast of Chile. This is a miserable place, containing about 200 inhabitants, under an Alcalde; the huts are scattered, and difficult to distinguish, from their being the same colour as the hills at the back of them. Vessels touch here occasionally for dried fish and copper ore: the former plentiful but the latter scarce. The mines lie in a S.E. direction, seven or eight leagues distant: but are very little worked. Wood and water may be obtained on reasonable terms; the water is brought from wells two miles off, and is difficult to embark. Vessels bound for this place should run in on a parallel of 25.05., and when at the distance of two or three leagues, the white islet off Point Rincon will appear, and shortly after the low white head of Paposo. The course should be immediately shaped for the latter; for with that head bearing S.S.E., distant half a mile, is the anchorage, in from fourteen to twenty fathoms, sand and broken shells. Should the weather be clear (which is seldom the case), a round hill, higher than the surrounding ones, and immediately over the village, is also a good guide.

North twenty-three degrees west from Point Grande, at the distance of twenty-three miles, is Point Plata, similar in every respect to Point Grande, terminating in a low spit, off which lie several small rocks, forming a bay on the northern side, with from seventeen to seven fathoms water; rocky, uneven ground.

From this point to Point Jara, which lies north ten degrees west, fifty-two miles, the coast runs in nearly a direct line, a steep, rocky shore, surmounted with hills, from 2,000 to 2,500 feet high, and without any visible shelter, even for a boat.

Point Jara is a steep, rocky point, with a rounded summit, and has on its northern side a snug cove for small craft; it is visited occasionally by sealing vessels, who leave their boats to seal in the vicinity. Water is left with them; and for fuel they use the kelp, which grows in great quantity, as neither of these necessaries of life are to be had within twenty-five leagues on either side ofthem.

Nearly four miles due north from this point is the south point of the large bay of Moreno, or Playa brava, high and rocky, with a

© The Complete Work of Charles Darwin Online

black rock lying off it; and N. 26° W., twenty-two miles distant, is Point Davis (the south-west point of Moreno peninsula), which slopes gradually from Mount Moreno, and has two nipples on its extreme.

Mount Moreno, formerly called George Hill, is the most conspicuous object on this part of the coast; its summit is 4,060 feet above the level of the sea, sloping gradually on the south side to Point Davis, where it terminates; and on the north more abruptly towards the barren plain on which it stands. It is of a light brown colour, without the slightest sign of vegetation, and has a deep ravine on its western side.

Immediately under Mount Moreno is Constitucion Harbour, a small but snug anchorage, formed by the main land on one side and Forsyth Island on the other. Here a vessel might careen and undergo repairs without being exposed to the heavy rolling swell which sets into most of the ports on this coast; and the landing is excellent: the best anchorage is off a sandy spit at the north-east end of the island, in six fathoms water, muddy bottom; farther out the holding ground is bad; it would be advisable to moor ship securely, as the sea-breeze sometimes sets in strong. In running in, the island, or weather side, should not be hugged too close, as a number of sunken rocks lie off the low cliffy points—some only being buoyed by kelp. A mid-channel course would be the best, provided the wind allowed of reaching the anchorage before-mentioned: neither wood nor water are to be found in this neighbourhood—therefore provision must be made accordingly.

N. 8° W., twelve miles from this harbour, is Moreno Head, a steep bluff, the termination of a range of table land, which runs in a line from Mount Moreno; on the northern side of this head is Herradura Cove, a narrow inlet, running in to the eastward, without affording any shelter.

N. 4° W., nine miles from this head, lies Low Point, with some sunken rocks lying off it, and five miles farther on is Leading Bluff; this is a very remarkable headland, and with the hill of Mexillones, which lies a few miles south of it, is an excellent guide for the port of Cobija; it is about one thousand feet high, and facing the north is entirely covered with guano, which gives it the appearance of a chalky cliff. There is an islet about half a mile to the north-west, attached to the main by a reef of

© The Complete Work of Charles Darwin Online

rocks, but no danger of any description outside it. The hill of Mexillones is 2,650 feet high, has the appearance of a cone with the top cut off, and stands conspicuously above the surrounding heights. This in clear weather is undoubtedly the best of the two marks; but as the tops of hills on the coast of Peru are frequently covered with heavy clouds, the bluff is the surer mark, for it cannot be mistaken; as, besides its chalky appearance, it is the northern extreme of the peninsula, and the land falls back several miles to the eastward of it.

Round this head is the spacious bay of Mexillones, eight miles across—but of little use, as neither wood or water is to be obtained. The shore is steep-to; there is anchorage on the west side, two miles inside the bluff, a cable's length off a sandy spit, in seven fathoms sandy bottom: at the distance of three cables there is thirty fathoms.

From this bay the coast runs nearly north and south, without any thing worthy of remark, until you reach the Bay of Cobija, or La Mar. This lies N. 13° E. thirty-one miles from Leading Bluff, is the only port of the Bolivian Republic, and contains about fourteen hundred inhabitants. Vessels call occasionally to take in copper ore and cotton; but the trade is small (particularly in 1835, as the revolution in Peru had destroyed the little they had). Water is scarce, at least, that which is good: there are wells, but the water from them is very brackish, and will not keep in casks. Fresh meat may be procured at a high price; but fruit and vegetables, even for their own consumption, are brought from Valparaiso, a distance of seven hundred miles. They have a mud-built fort, of five or six guns, on the summit of the Point; the only fortification about the place.

If coming from the southward toward this bay: after having passed the Leading Bluff (which should always be made), it would be advisable to shape a course so as to close the land two or three leagues to windward of the port, and then coast along until two white-topped islets, off False Cobija Point, are seen; a mile and a quarter to the northward of them is the port. On the Cobija Point there is a white stone, which shews very plainly, in relief against the black rocks at the back of it: a white flag is usually hoisted at the fort, when a vessel appears in the offing—which is also a good guide. In going in there is no danger; the point is steep-to, and may be rounded at a

© The Complete Work of Charles Darwin Online

cable's length distant, and the anchorage is good in eight or nine fathoms, sand and broken shells. In the bay there are a number of straggling rocks, all well pointed out by kelp. It is high water at the full and change at 9 h. 54 m., and the tide rises four feet. Landing, at all times is indifferent, and at full and change, owing to the heavy swell, it requires some skill in winding through the narrow channel, formed by rocks on each side. Two miles north and east is Copper Cove, a convenient place for taking in the ore; there is anchorage in twelve fathoms, a short distance from the shore.

After leaving the north point of Cobija Bay, which has a number of straggling rocks a short distance off it, the coast takes a rather more easterly direction; generally shallow sand bays, with rocky points, and hills from two to three thousand feet high close to the coast, but no anchorage or place fit for shipping, until you reach Algodon Bay, twenty-eight miles from Cobija.

This bay is small, and the water deep; we anchored a quarter of a mile from the shore, in eleven fathoms, sand and broken shells, over a rocky bottom; its only use is as a stopping-place for water, should it be required. It may be obtained at the Gully of Mamilla (seven miles to the northward) from a spring, a mile and a half from the beach; the usual method of bringing it is in bladders made of seal-skin, holding seven or eight gallons each, with which most of the coasters are provided—the only vessels that profit by a knowledge of these places.

Algodon Bay may be distinguished by a gully leading down to it, and that of Mamilla to the northward, which has two paps on the heights, over the north side of it; there is also a white islet off Algodon Point.

N. 2° W., ten miles from this bay, is a projecting point, called in the Spanish chart San Francisco, but known more generally by the name of Paquiqui; on the north side of it, and near the extreme, is a large bed of guano, so much used on this coast for manure, that it may be said to be quite a trade. A brig of one hundred and seventy tons was loading with it for Islay at the time we passed; she was moored head and stern within a cable's length of the rocks, on which a considerable surf was breaking, and the guano was brought off in a balsa to a launch just outside the surf. There is better anchorage farther in the bay; but this is chosen for convenience.

© The Complete Work of Charles Darwin Online

N. 2° W., sixteen miles from Paquiqui, is Point Arena, a low, sandy point, with rocky outline: between the two is a small fishing village, near a remarkable hummock: anchorage may be obtained under Point Arena, in ten fathoms; fine sandy bottom.

N. 6° E., twelve miles from Point Arena, is the gully and river of Loa, which forms the boundary line between Bolivia and Peru. It is the principal river on this part of the coast; but its waters are extremely bad, in consequence of running over a bed of saltpetre, and the hills surrounding it containing a quantity of copper ore. It is said that the ashes of a volcano fall into it, which add greatly to its unwholesomeness; but bad as it is, the people residing on its banks have no other. At Chacansi, in the interior, where it divides, it is tolerably good. In the summer season it is about fifteen feet broad and a foot deep, and runs with considerable strength to within a quarter of a mile of the sea, where it spreads, and flows over, or filters through the beach; but does not make even a swatchway, or throw up any banks, ever so small. A chapel on the north bank, half a mile from the sea, is the only remains of a once populous village. People from the interior visit it occasionally for guano, which is in abundance.

There is good anchorage, but rather exposed to the sea-breeze, with the chapel bearing north, half a mile from the shore, in from eight to twelve fathoms, muddy bottom; and landing may be effected under Point Chileno; but the best anchorage near here is the Bay of Chipana, six miles N. 39° W. from the river, and a snug cove for landing, near the extreme of the point; but at the full and change, a heavy swell sets in, and I doubt a boat being able to land with goods at those times.

The best distinguishing mark for the Loa is the gully through which it runs, that may be easily known from its being in the deepest part of the bay, formed by Point Arena on the south and Point Lobo on the north; and the hills on the south side being nearly level, while those on the north are much higher and irregular.

For the Bay of Chipana—after making the land in the latitude of the Loa, a large white double patch is seen on the side of a hill near the beach, and another similar one, a little to the northward: on discovering these marks (which may be seen three or four leagues), a course should be shaped directly for the southern end, where lies the anchorage in seven fathoms, sand and broken shells, under a low,

© The Complete Work of Charles Darwin Online

level point. No danger need be feared in entering; as although the land is low, it may be approached within half a mile, in from six to ten fathoms. The anchorage inside the long kelp-covered reef might perhaps, be preferred; but the landing is not so good.

N. 27° W. of this bay, at the distance of eighteen miles, is Point Lobo, or Blanca, high and bold, on its extreme are several hillocks. Between these two is a small fishing village, called Chomache, under a point, which has a long reef off it, on the outer part of which a cluster of rocks shew themselves a few feet above water. The people of this village get their water from the Loa—a passage requiring, on a balsa, four days or more.

N. 21° W., fourteen miles off Point Lobo, is Point Pacache, a low rugged projecting point, with an islet a quarter of a mile off it, but quite clear outside this islet: half way between these two points is the Cone (Pabellon) of Pica, a remarkable hillock of guano appearing as if it had been covered with snow which had thawed at the top, leaving the lower half frozen, contrasting strongly with the surrounding hills, which are of a barren sun-burnt brown. This is also a place of resort for the guano vessels; they find pretty good anchorage close to the northward of the Pabellon.

East, a little southerly, a few miles in-shore of this, is a bell-shaped mountain, named Carrasco, 5,500 feet high: in clear weather it is a good mark for the neighbourhood of Iquique.

From Point Pacache to Point Grande, N. 8° W. twenty-eight miles, the coast is low and rocky, the termination of a long range of table land, called the heights of Oyarvide, or Barrancas, from its cliffy appearance: it has innumerable rocks and shoals off it, and should not be approached on any account nearer than a league, for the frequent calms and heavy swell peculiar to this coast render it unsafe for nearer approach.

Point Grande at the north end of the Barrancas, is a low cliffy point, with three white patches on its northern side; round this point is the Bay of Cheuranatta.

N. 3° W., eleven miles from Point Grande is the anchorage and town of Iquique; a miserable place that affords scarcely sufficient provisions for the consumption of its inhabitants, about five hundred souls; and no water nearer than Pisagua (a distance of nearly forty miles), from which place it is brought by boats built for the purpose, and is very dear. Yet, with these disadvantages, it is a place of con-

© The Complete Work of Charles Darwin Online

siderable trade, from the quantity of saltpetre, and the silver mines of Huantacayhua, in its neighbourhood: the latter are little worked, as the saltpetre is a surer profit, large cargoes of which are annually taken in English vessels. There are no imports; all the property belongs to merchants in Lima, where vessels are chartered, and have only to call here and take in their cargoes.

Vessels bound for this place should run in on the parallel of Point Grande, until the white patches on that point are discerned, when a course should be shaped for the northern of three large sand hills: stand boldly in on this course till the church steeple appears, when shortly after, the town and low island will be seen, under which is the anchorage; care must be taken in rounding this island to give it a good berth, a reef extending off it to the westward, to the distance of two cables' lengths.

The anchorage is good in eleven fathoms, with Point Piedras bearing N. 9° W.; W. extreme of the island, W. 32° S.; church steeple S. 15° E.

Vessels have attempted the passage between the island and the main by a mistake, and thereby got into danger, from which they have been extricated with difficulty: it is only fit for boats or very small vessels.

Landing is bad and the way hazardous, owing to the number of blind breakers with which it abounds; boats have been lost at the full and change of the moon, when the heavy swell sets in. Balsas are employed to bring cargoes to a launch at anchor outside the danger, as is the case in most of the ports on this coast.

N. 12° W., eighteen miles from Point Piedras (the north point of Iquique Bay, which has a cluster of rocks round it), is the small bay of Mexillones, appearing as a low black island with a white rock lying off it, and may be known by the Gully of Aurora a little to the southward, and a road apparently well trodden on the side of the hills, leading to the mines. And N. 20° W., thirty-three miles from Point Piedras, is Point Pichalo, a projecting ridge at right angles to the general trend of the coast, with a number of hummocks on it. Round to the northward of this point is the village and roadstead of Guano Pisagua; this, as well as Mexillones, is connected with Iquique in the saltpetre trade, and is resorted to by vessels for that article. In rounding the point, a sunken rock lies about half a cable's length off, and should be looked out for, as it is necessary to

© The Complete Work of Charles Darwin Online

hug the land close to ensure fetching the anchorage off the village at the beginning of the ridge; baffling winds are frequent, which may throw you near the shore, but do not signify, as the water is smooth and the shore steep-to. The best anchorage is with the extreme of Pisagua Point, N. 7° 30′ W.; and Pichalo Point, W. 19° S., two cables' length off the village, in eight fathoms, by which you will avoid a rock with four feet water on it, lying off the sandy cove at the distance of two cables.

North of this, at the distance of two miles and a half, is the gully and river of PISAGUA, the water of which supplies the neighbouring inhabitants; it is not, when at its greatest strength, more than ten feet across, and then does not overflow, but merely filters through the beach into the sea. Generally speaking, it is dry nine months in the year; wells are dug near it where water, such as it is, may always be found: but no vessel should trust to watering at this place, as, besides its unwholesomeness, the difficulty and expense attending it would be very great.

From this to Point Gordo the coast is in low broken cliffs, with a few scattered rocks off it, and ranges of high hills near. Point Gordo is a low jutting point, where a long line of cliff, several hundred feet high, commences; which continues, with only two breaks, to Arica.

These breaks or gullies, as they are called, are very remarkable, and are useful in making Arica from the southward. The first is the gully of Camarones, which lies seven miles north of Point Gordo, and is about a mile in width, running at right angles to the coast towards the mountains, with a stream of water running down it, and a quantity of brush-wood on its banks; it forms a slight sandy bay, scarcely sufficient to shelter a vessel from the heavy swell.

The Gully of Victor is the other; it lies N. 17° W., twenty-nine miles from that of Camarones, and fifteen miles from Arica; it is about three quarters of a mile in width, and from a high bold point, called Point Lobo, jutting out to the southward, forms a tolerably good anchorage for small vessels; it also runs toward the mountains in a similar manner to that of Camarones, and like it has a small stream running through, with verdure on its banks. Vessels bound to Arica should endeavour to make this gully or ravine, and when within three or four leagues of it they will see Arica Head, which appears as a steep bluff, with a round hill in shore, called Monte Gordo. Upon nearer approach the island Huano will be observed, joined to

© The Complete Work of Charles Darwin Online

the head by a reef of rocks. To the northward of this island, and round the head is the port and town of Arica, the sea-port of Tacna. Of late this place has been the seat of civil war from which it has severely suffered. It was in contemplation in the latter end of 1836 to make it the port of the Bolivian territory; should that take place, it would perhaps become next in importance to the harbour of Callao, the principal port in Peru: its present exports are bark, cotton, and wool; for which is received, in return, merchandize, chiefly British. Fresh provisions and vegetables, with all kinds of tropical fruit, may be had in abundance and upon reasonable terms; the water also is excellent, and may be obtained with little difficulty; as a mole is run out into the sea, which enables boats to lie quietly while loading and discharging: the only inconvenience is having to carry or roll it through the town. Fever and ague are said to be prevalent; this in all probability arises from the bad situation which has been chosen for the town, the high head to the southward excluding the benefit of the refreshing sea-breeze, which generally sets in about noon. In entering this place there is no danger whatever; the low island may be rounded at a cable's distance in seven or eight fathoms, and anchorage chosen where convenient.

Hence the coast takes a sudden turn to the westward, and as far as the river Juan de Dios, is a low sandy beach with regular soundings: from this river it gradually becomes more rocky, and increases in height till it reaches the Point and Morro Sama, known by some as the Devil's Headland. This is the highest and most conspicuous land near the sea, about this part of the coast, and appears from its boldness to project beyond the neighbouring coast line; on its western side is a cove formed by the point called Sama, where coasting vessels occasionally anchor for guano; there are three or four miserable looking huts, the residence of those who collect the guano; it would be quite impossible to land except in a balsa, and even then with difficulty. Should a vessel be drifted down here by baffling winds and heavy swell, which has been the case, she should endeavour to pass the head (as a number of rocks surround it); and about a mile to the westward anchorage may be obtained in fifteen fathoms.

N. 49° W., nine miles from Point Sama, is a low rocky point, called Tyki, and between the two, the small river Lucumbu, having low cliffs on each side of it; this, like most of the rivers on the coast, has not strength to make an outlet for itself, but is lost in the

© The Complete Work of Charles Darwin Online

shingle beach at the foot of the before-mentioned cliffs; regular soundings, which continue gradually increasing until you reach Point Coles, may be obtained at the distance of two miles, in from fifteen to twenty fathoms.

W. 21° N., at the distance of thirty-one miles from Point Sama, is Point Coles; the coast between is alternately sandy beach, with low cliff, and moderately high table land a short distance from the coast. I doubt if landing could be effected any where between Arica and Port Coles, as a high swell sets directly on this part and appears to break with redoubled violence.

Point Coles is very remarkable; it is a low, sandy spit, running out from an abrupt termination of a line of table land. Near its extreme is a cluster of small hummocks, the whole, at a distance, appearing as an island; off the point, to the south-west, is a cluster of rocks or islets, but no hidden danger exists, although there is generally a quantity of froth, under which a reef may be suspected. N. 13° E., five miles and a half from this point, is the village and roadstead of Ylo. This is a poor place, containing about three hundred inhabitants, under the local governor and captain of the port. But little trade is carried on, and that chiefly in guano: a mine of copper has been lately discovered, which may add to its importance. The inhabitants have to supply the necessaries of life by cultivation, and do not care to trouble themselves about luxuries. Water is scarce, and wood is brought from the interior, so that it is not on any account a suitable place for shipping. The best anchorage is off the village of Pacoche (a mile and a quarter south of the town), in twelve or thirteen fathoms, and the best landing is in Huano Creek: but bad, indeed, is the best, and great care must be taken lest the boat be swamped, or hurled with violence against the rocks.

In going into Ylo, the shore should not be approached nearer than half a mile (as many sharp rocks and blind breakers exist), until three small rocks, called 'the Brothers,' always visible inside the table end, bear east, when the village of Pacoche may be steered for, and anchorage taken abreast of it, as convenient.

English Creek affords the best landing, but boats are forbidden that cove, to prevent contraband trade being carried on.

From Ylo, the coast trends to the westward, with a cliffy outline, from two to four hundred feet in height, and with one or two

© The Complete Work of Charles Darwin Online

coves, useful only to small coasters, until you reach the VALLEY OF TAMBO, which is of considerable extent, and may be easily distinguished by its fertile appearance, contrasting strongly with the barren and desolate cliffs on either side: those on the east maintain their regularity for several miles, while on the west the regularity is broken, and from the near approach of the hills their aspect is bolder.

The next point of this valley is called Mexico, it is E. 18° S., twenty-one miles from Islay Point, and is exceedingly low, projecting considerably beyond the general trend of the coast; it is covered with brushwood to the water's edge, and at the distance of two miles in a southerly direction, soundings may be obtained in ten fathoms, muddy bottom; from that depth, in the same direction, it increases to twenty fathoms; but on each side of the bank there are fifty fathoms.

W. 18° N., twenty-one miles from Point Mexico, is Point Islay, and between the two, five miles from the latter, the cove of MOLLENDO, once the port of Arequipa; but of late years the bottom has been so much altered, that it is only capable of affording shelter to a boat or very small vessel; in consequence of which it has been thrown into disuse, and the bay of Islay now receives vessels that bring goods to the Arequipa market.

ISLAY, the port of Arequipa, formed by a few straggling islets off the point, extending to the north-west, is capable of containing twenty or five and twenty sail. The town is built on the west side of a gradually declining hill, sloping toward the anchorage, and is said to contain fifteen hundred inhabitants (chiefly employed by the merchants of Arequipa). As in all the sea-ports of Peru, a local governor and captain of the port are the Authorities; this is also the residence of a British vice-consul. Trade was in a more flourishing condition here, even during a civil war, than at any place we visited; there were generally four or five, and often double that number of vessels discharging or taking in cargoes. The principal exports were wool, bark, and specie, in exchange for which British merchandize was chiefly coveted.

Islay being much frequented by British merchant vessels, and differences of opinion having arisen as to the best method of making it, detailed and clear directions should be given. Vessels have frequently been in sight, to the westward of the port, yet from the strength of the current (half a knot, and at the full and change often

© The Complete Work of Charles Darwin Online

as much as one knot per hour) setting to the westward, have been prevented from anchoring for several days.

This, no doubt, has been partly owing to the hitherto inaccurate position assigned it, and from a proper reluctance to expose a vessel on an imperfectly known coast, to be baffled and drifted about by light and variable airs, in addition to a heavy swell continually rolling directly toward the shore.

With the following directions, it is to be hoped that more confidence will be acquired, and consequently less delay occasioned in sailing to the seaport of the second city of Peru.

Coming from the southward, the land abreast of Tambo should be made, and a certainty of that place ascertained, which (according to the state of the weather) may be seen from three to six leagues: the course should then be shaped toward a gap in the mountain to the westward, with a defined sharp-topped hill in the near range, a short distance from it. In this gap is the road leading to Arequipa, which winds along the foot of the before-named hill from Islay.

As the coast is approached, the foot of the hills will be seen to be covered with white ashes (said to have been thrown from the volcano of Arequipa), not found on any other part of the coast. This peculiarity commences a little westward of Tambo, and continues as far as Point Ornilius, and when within three leagues, the Point Islay and white islets forming the bay, will be plainly observed, and should be steered for.

Care must be taken in closing the point, as a rock, barely covered, lies a quarter of a mile to the southward. It is the custom to go to the westward of all the islands; but, with a commanding breeze, it would unquestionably be better to run between the third outer and next island,* which enables you to choose your berth at once; this can seldom be done by the other route, the wind heading as you enter, obliging you to anchor, and use warps. The best anchorage is just within Flat Rock Point, off the landing-place, in ten or twelve fathoms. A hawser is necessary to keep the bow to the swell, to prevent rolling heavily, even in the most sheltered part. Vessels from the eastward should close the land about Tambo, and observe the same directions.

If from the eastward the parallel of seventeen degrees five minutes

* His Majesty's ships Menai and Challenger passed in between these islands.

© The Complete Work of Charles Darwin Online

should be made, and run in on, this will be about a league to the southward of the point; and, if the longitude cannot be trusted, Point Ornelius, being the most remarkable land, and easily seen from that parallel, should be searched for in passing. It lies W. 28° N., fourteen miles from Point Islay—is about two hundred feet high—has the appearance of a fort, with two tier of guns, and is perfectly white; the adjacent coast to the west is dark, and forms a bay; and on the east are low black cliffs; with ashes on the top extending half-way up the hills. If the weather be clear, the valley of Quilca may be seen, which is the first green spot west of Tambo. Ornelius, however, must be searched for, and when abreast of it Point Islay will be seen, topping to the eastward, as two islands off a gradual declining point, the sharp hill before-named in the near range, will also be seen, if favourable weather; and shortly after the town will appear like black spots, in strong relief against the white ground, when a course may be shaped for the anchorage under the white islets, as before. Landing at ISLAY is far from good; a sort of mole, composed of a few planks, with a swinging ladder attached to it, enables you generally, with a little management, to get on shore in safety; but often at the full of the moon vessels are detained three days or more, without being able to land or take in cargo. Fresh provisions may be had on reasonable terms; but neither wood nor water can be depended on. There are no fortifications of any description.

The coast between Islay and Point Cornejo is an irregular black cliff, from fifty to two hundred feet high, bounded by scattered rocks to the distance of a cable's length; about two leagues from Islay is a cove, called Mollendito, the residence of a few fishermen: there is a similar cove a little to the eastward of Point Cornejo. Westward of that point the coast retires and forms a shallow bay, in which are three small coves—Aranta, La Guata, and Noratos; and W. 36° N., thirteen miles distant, is the valley and river of QUILCA, off which vessels occasionally anchor, under the Seal Rock lying to the south-east of Quilca Point. This anchorage is much exposed; but landing is good in the cove westward of the valley. Watering is sometimes attempted, by filling at the river and rafting off, but must always be attended with much difficulty and danger. The valley is about three-quarters of a mile in width, and differing from the others, which are level, runs down the side of a hill; and from the regu-

© The Complete Work of Charles Darwin Online

larity of the cliffs by which it is bounded, has the appearance of a work of art.

W. 6° N., at the distance of six leagues, is the valley of CAMANA; the coast between is nearly straight, with alternate sandy beach and low broken cliff, the termination of the barren hills immediately above. Camana is from two to three miles broad, near the sea; and apparently well cultivated: the village is situated about a mile from the sea; but is scarcely perceptible, being small, and surrounded by thick brushwood.

On approaching from the eastward, a remarkable cliff, resembling a fort, will be seen near the sea; this is an excellent guide till the valley becomes open. There is anchorage in ten or twelve fathoms, muddy bottom, due south about a mile; but landing would be dangerous.

W. 18° N., twenty-three miles, is the the valley of Ocoña, the next remarkable place; it is smaller and less conspicuous than the former; but similar in other respects. An islet lies at its southern extreme, and several rocks near the extreme of the cliff, on its eastern side.

W. 11° N., fourteen miles, is a projecting bluff point called PESCADORES, it has a cove on its east side surrounded by islets; and off the point, at the distance of three quarters of a mile in a southerly direction, lies a rock barely covered: to the westward of the point is a bay, but no anchorage; the coast then runs in nearly a direct line until you reach POINT ATICO, a rugged point, with a number of irregular broken hillocks on it, barely connected with the coast by a sandy isthmus. At a distance it appears like an island, the isthmus not being visible far off: there is tolerable anchorage in nineteen or twenty fathoms on its west side, and excellent landing in a snug cove at the inner extreme of the point. By keeping a cable's length off shore, no danger need be feared in running into this roadstead. The valley of the same name lies a league and a half to the eastward, where are about thirty houses, scattered among the trees, that grow to the height of some twenty feet. From this point the coast continues its westerly direction (low and broken cliff, with hills immediately above) until you reach Point Capa, where a bay commences that runs as far as Point Chala; in it there are several coves, but none that could be serviceable to shipping.

Point Chala bears from Point Atico W. 20° N. and distant sixteen

© The Complete Work of Charles Darwin Online

leagues and a half, is a high rocky point, the termination of the Morro, or hill of that name. This mount shows very prominently, and has several summits to it; on the east side is a valley that separates it from another lower hill, with two remarkable paps, and on the west it slopes suddenly to a sandy plain; the nearest range of hills to the westward are thrown in-shore considerably, making Morro Chala still more conspicuous.

W. 26° N., eighteen miles from Point Chala, is Point Chavini, which appears like a rock on the beach; between the two is a sandy beach, with little green hillocks and sand-hills; there are also two rivulets, running from the valleys of Atequipa and Lomas, that are seen in the distance.

Half a mile to the westward of Chavini is a small white islet, and a cluster of rocks level with the water's edge; hence to the roadstead of Lomas a sandy beach continues, with regular soundings off it, at two miles from the shore.

Point Lomas projects at right angles to the general trend of the coast, and, similar to Atico, is all but an island; it may easily be distinguished although low, by its marked difference (being black rock) from the adjacent coast.

This road is the port of Acari, affords good anchorage in from five to fifteen fathoms, and tolerable landing; it is the residence of a few fishermen, and used as a bathing place for the inhabitants of Acari, which, from the information obtained, is a populous town several leagues in-land. All supplies, even water, are brought here by those who visit it: the fishermen have a well of brackish water scarcely fit for use. Boats occasionally call here for otters, which are plentiful at particular seasons.

W. 21° N., twenty-three miles from Lomas Road, is the Harbour of San Juan; and eight miles further, that of San Nicolas. The former is exceedingly good, and fit for a vessel to undergo any repairs in, or heaving down, in case of necessity, without being inconvenienced by a swell; but all materials must be brought, as well as water and fuel, none of which are to be found there.

The shore is composed of irregular broken cliffs, and at the head of the bay is a sandy plain; still the harbour is good, indeed much better than any other on the south-west coast of Peru, and might be an excellent place to run for if in distress. It may be distinguished by Mount Acari, a remarkable sugar-loaf hill, almost perpendicu-

© The Complete Work of Charles Darwin Online

larly over the cliff on the north side of the bay; and three leagues to the eastward, a short distance from the coast, a high bluff head, the termination of a range of a table land. Between this bluff and the harbour the land is low and level, with few exceptions, and has a number of rocks lying off it to the distance of half a mile.

S.W. three-quarters of a mile from Steep Point (the southern point of the harbour) lies a small black rock, always visible, with a reef of rocks extending a quarter of a mile to the northward; and nearly two miles to the S.E., there is an islet that shows distinctly. A passage may exist between this reef and the point, but prudence would forbid its being attempted; the safest plan is to pass to the northward, giving it a berth of a cable's length; and not close the shore until well within the next point (a sunken rock lies off it), when you may haul your wind and work up to the anchorage at the head of the bay, and come to in any depth from five to fifteen fathoms, muddy bottom. In working up, the northern shore may be approached boldly; it is steep-to, and has no outlying dangers.

The harbour of San Nicolas lies N. 41° W. eight miles from San Juan, is quite as commodious and free from danger as the latter, but the landing is not so good.

Harmless Point may be rounded within a cable; there are a number of scattered rocks to the southward of it, but as they all appear, there is no danger to be feared. There are no inhabitants at either of these ports, so that vessels wanting any repairs may be sure of not being interrupted while so employed.

N. 59° W., eight and a half miles from Harmless Point, is Point Beware, high and cliffy, with a number of small rocks and blind breakers round, and some heights close above it; from this point the coast is alternately cliff and small sandy bays, till you reach Point Nasca, round which is what has been termed Port Caballos.

Point Nasca may be readily distinguished: it is a bluff head of a dark brown colour, 1,020 feet in height, with two sharp topped hummocks of a moderate height at the foot of it; the coast to the westward falls back to the distance of two miles, and is composed of white sand hills; in the depth of this bight is Caballos, a rocky shallow hole, that should only be known to be avoided; we lay at anchor in seven fathoms, as far in as it was thought prudent to go, for twenty four hours, without being able to effect a landing: the wind came round the head in heavy gusts, which, combined with the

© The Complete Work of Charles Darwin Online

long ground swell, made it doubtful if two anchors would hold us till our observations were concluded. The only traces we saw of there ever having been any inhabitants at this dreary place, was a pole sticking up on the top of a mound, near the head of the bay.

N. 64° W., thirteen leagues from Point Nasca is Point Santa Maria, and the rock called the Ynfiernillo. This point is low and rugged, surrounded by rocks and breakers. At the distance of a league and a half, inland, to the eastward, is a remarkable table topped hill, called the table of Doña Maria; this hill may be seen in clear weather at a considerable distance from seaward, and from its height and peculiar shape is a good mark for this part of the coast.

The Ynfiernillo Rock lies due west from the northern extreme of the point, at the distance of a mile; it is about fifty feet high, quite black, and in the form of a sugar loaf; no dangers exist near it: there are fifty-four fathoms at two miles distance. Between this rock and Point Caballos, the coast to a short distance west of the small River Yca is a sandy beach, with ranges of moderately high sand hills. From thence to the Ynfiernillo it is rocky, with grassy cliffs immediately over it, and some small white rocks lying off.

N. 31° W., ten and a half miles from Santa Maria, is Point Azua, a high bluff, with a low rocky point off it; between is a sandy beach, interrupted by rocky projections, and a small stream running from the hills.

N. 3° W., from Point Azua, and at the distance of twenty-one miles, is the southern entrance to the bay of the Yndependencia. This extensive bay which is fifteen miles in length in a N.W. and S.E. direction, and three miles and a half broad, has been till of late years, completely unknown or overlooked: no mention is made of it in the Spanish charts, and it was not till the year 1825 that the Hydrographer at Lima became aware of its existence, and then only by an accidental discovery. It has two entrances: the southern called Serrate, which takes its name from the master of the vessel by whom it was discovered, is formed by the Island of Santa Rosa on the north, and Point Quemada on the south: it is three quarters of a mile wide and free from danger. The northern entrance is named after the Dardo and Truxillano, two vessels that were conveying troops to Pisco: they ran in, mistaking it for that place, and were wrecked: many of the people on board perished. It is formed by Point Carretas on the north and the Island of Vieja on the south,

© The Complete Work of Charles Darwin Online

is five miles in width, and clear in all parts. It is bounded on the west by the Islands of Vieja and of Santa Rosa, and on the east by the main-land, which is moderately high, cliffy, and broken by a sandy beach, at the south end of which is a small fishing village called Tungo. The people of this village are residents of Yca, the principal town in the province, which is about twelve leagues distant; they come here occasionally to fish and remain a few days, bringing with them all their supplies, even to water, as that necessary of life is not to be obtained in the neighbourhood. There is anchorage in any part of this spacious bay; the bottom is quite regular, about twenty fathoms all over, excepting off the shingle spit on the north-east side of Vieja Island, where is a bank running off that spit to the northward, on which are five and six fathoms: this is decidedly the best place to anchor, for on the weather shore, near Quemado Point, it blows strong and in sudden gusts off the high land, and great difficulty would be found in landing; whereas, at the spit, you are not annoyed by the wind, and there is a snug cove, or basin, within it, where boats may land or lie in safety at any time.

Approaching this part of the coast from seaward, it may be distinguished by three clusters of hills, Quemado, Vieja Island, and Carretas; they are nearly of the same height, and at equal distances from one another. The S.W. sides of Morro Carretas and the Island of Vieja are steep dark cliff, but Morro Quemado slopes gradually to the water's edge, and is of a much lighter colour. At the southern extreme of Vieja Island, is a remarkable black lump of land, in the shape of a sugar loaf: off which lies the white level island of Santa Rosa, the S.W. side of which is studded with rocks and breakers, but there is no danger a mile from the shore.

N. 35° W., six leagues and a half from the north head, or Point Carretas, is the Boqueron, or southern entrance to the Bay of Pisco; between the two is a deep angular bay, with the Island of Zarate near its centre. The Boqueron is formed by the main land on the east, and the Island of San Gallan on the west; this island is two miles and one-third long in a north and south direction, and one mile in breadth: it is high, with a bold cliffy outline. There is a deep valley dividing the hills; which when seen from the south-west, gives it the appearance of a saddle; the south extreme terminating abruptly, while at its northern end it slopes more gradually and has

© The Complete Work of Charles Darwin Online

several peaks on it. Off this end are some detached rocks, the northern of which has the appearance of a nine-pin, and shews distinctly.

S. ¼ E., at the distance of a mile from its south extreme, lies the Pinero Rock, which is much in the way of vessels bound to Pisco from the southward; it is just level with the water's edge, and in fine weather can always be seen; but when it blows hard (which it sometimes does through this channel) and a weather tide is running, there is such a confused cross sea that the whole space is covered with foam, rendering it difficult to distinguish the rock; at such a time the shore should be kept well aboard on either side, and when in a line with the outer extreme of the island and the white rock off Point Huacas, you will be within the rock and may steer for Point Paracca; on rounding which you will open the Bay of Pisco.

This extensive bay, formed by the Peninsula of Paracca on the south, and the Ballista and Chincha Islands on the west, is the principal port of the province of Yca. The town of Pisco is built on the east side, about a mile from the sea; and is said to contain three thousand inhabitants, who derive considerable profit from a spirit they distil, known by the name of Pisco or Italia, great quantities of which are annually exported to different parts of the coast: sugar is also an article of trade, but the pisco is the staple commodity. Refreshment may be obtained on reasonable terms: wood is scarce: excellent water may be had at the head of Paraccas Bay, under the south cluster of trees, two miles from the fishing village of Paracca: the landing there is very good, and the wells are near the beach.

The best anchorage off the town is with the church open of the road, bearing E. 14° N., in four fathoms, muddy bottom, three-quarters of a mile from the shore. A heavy surf beats on the beach with rollers to the distance of a quarter of a mile off, rendering it dangerous to land in ship's boats; launches built for the purpose are used in loading and discharging vessels; but at times even these cannot stand it, and all communication is cut off for two or three days together.

There are four entrances to this capacious bay: that to the southward already named; between San Gallan and the Ballista Islands; between those and the Chincha Islands; and the great or northern entrance; all of which, from appearances, may be safely used; but,

© The Complete Work of Charles Darwin Online

between the islands, time would not allow a full examination, and, therefore, there may be dangers that were unseen by us.

In coming from the southward, after passing Point Paracca, a course may be shaped midway between Blanca Island and the church of Pisco, which will be seen distinctly: this will lead directly to the anchorage. A mile and a half round Point Paracca is a bay, off which a shoal patch extends, with four fathoms on it; the tail of this bank will be passed in standing towards the anchorage, the water then deepens suddenly, and when abreast of Blanca Island you will have twelve fathoms muddy bottom; from this depth it decreases gradually to the anchorage.

In coming from the northward it is all plain sailing; after passing the Chincha Islands stand in boldly to the anchorage; the water shoals quicker on this side Blanca Island, but there is no danger whatever. Vessels having to ballast here, should work up and anchor under Shingle Point; they can lie close to the shore, and boats may load with expedition.

In coming from seaward this part of the coast may easily be known by the Island of San Gallan, and the high Peninsula of Paracca at the back of it, which make like large islands, the land on each side being considerably lower and falling back to the eastward, so as not to be visible at a moderate distance. As the shore is approached the Chincha and Ballista Islands will be seen; which will confirm the position, there being no other islands lying off the coast about this parallel.

From Pisco the coast runs in a northerly direction, a low sandy beach with regular soundings off it, till you reach the River Chincha; from thence commences a clay cliffy coast, which continues as far as the River Canete. From this river to Point Frayle is a beautiful and fertile valley, in the middle of which is situated the town of Cerro Azul. This valley produces rum, sugar, and chancaca, a sort of treacle, for which it is resorted to by coasters. The anchorage is W.N.W. from the bluff that forms the cove, three-quarters of a mile distant, in seven fathoms; nearer the shore the water is shoal, which causes a long swell; the landing place is on the northern side of the point, on a stony beach, where a heavy surf is constantly breaking.

N. 39° W., fifteen miles from Cerro Azul, lies the Island of Asia. a round, white island, about a mile in circumference, with some rocks

© The Complete Work of Charles Darwin Online

extending from it to the shore. Between the two is a bay, but scarcely affording anchorage. The coast line is partly a rocky and partly a sandy beach; in-shore are hills about fourteen hundred feet in height, inclining gradually toward the coast.

N. 41° W., twenty miles from Asia Island, is CHILCA POINT; it is about three hundred feet in its highest part, has several rises on it, and terminates in a steep cliff, with a small flat rock close off it. The valley of Chilca lies a league to the southward of the point, and the harbour of the same name half a league to the northward. This is a snug cove, but very confined; anchorage is good in any part of it, and landing tolerable; there is a small village at the head of the bay, but no information could be obtained from the inhabitants about Chilca, for they deserted their huts on our arrival.

From Chilca the coast forms a bend to about the Valley of Lierin, off which are the PACHACAMAC ISLANDS. The northern is the largest, half a mile in length, and about a cable's length broad; the next but one to it is the most remarkable, being quite like a sugar-loaf, perfectly rounded at the top: the others are mere rocks, and not visible at any distance. At the northern end of these islands lies a small reef, even with the water's edge: the group run nearly parallel to the coast, in a N.W. and S.E. direction, and are about a league in extent. There is no danger on their outer side, but towards the shore the water is shoal, which causes a long swell, that at times must break. Between these islands and the Morro Solar is a sandy beach, with moderately high land a short distance from the sea. The Morro Solar is a remarkable cluster of hills, situated on a sandy plain; when seen from the southward it has the appearance of an island in the shape of a quoin, sloping to the westward, and falling abruptly on its in-shore side; facing the sea it terminates in a steep cliff, and has a sandy bay on each side of it.

Off the point of the southern sand bay is an islet with some rocks lying about it, and off the point of the northern sand bay is a reef of rocks of about a cable's length; round this reef, on the north side of the Morro, is the town and road of Chorillos. The town of Chorillos, built on the cliff, at the foot of one of the slopes of the Morro Solar, is used chiefly as a bathing-place for the inhabitants of Lima, and during a revolution its road is filled with the shipping from Callao; though it is an exceedingly bad place for them: the bottom is a hard sand, with patches of hard stony clay

© The Complete Work of Charles Darwin Online

mixed together, called tosca; and the heavy swell that sets round the point causing almost a roller, brings a vessel up to her anchor and throws her back again with a sudden jerk, each of which makes her drag, or endangers snapping the cable.

Vessels having to anchor here ought not to shut the southern point the Morro in with the next point to the northward: by keeping this mark open they will be in eight or nine fathoms, and not have so much swell as there is further in. The landing is very bad; canoes built purposely and dexterously managed are the usual means of communication: no doubt there are times when a ship's boat may land without danger, but very seldom probably without the crew being thoroughly drenched. From Chorillos the coast runs in a steady sweep with cliffs of less height, till it reaches the Point of Callao, which is a shingle spit, stretching out toward the Island of San Lorenzo, and with it forms the extensive and commodious Bay of Callao.

The Island of San Lorenzo, which is 1050 feet at its highest part, is four miles and a half long, in a N.W. and S.E. direction, and one mile broad. Off its S.E. end lies a small but bold-looking island, called Fronton, and to the S.W. are the Palominas rocks: its northern end, or Cape San Lorenzo, is clear, and round it is the usual passage to the anchorage at Callao. In rounding this Cape do not close the land nearer than half a mile, for within that distance there are light baffling airs caused by the eddy wind round the island; by getting among which you would be more delayed than if you gave the island a good berth, and should have to make an additional tack to fetch the anchorage.

This is the usual route; but there is another which, with common precaution, may be used to great advantage, by vessels coming from the southward. This is the Boqueron, formed by the Island of San Lorenzo and Callao Point. After making San Lorenzo and Fronton, steer so as to keep the south extreme of the latter about a point open on the bow port; and keep on this course until Callao Castle is seen, which has two martello towers on it, and is situated on the inner part of the shingle spit, that forms the point: then steer for it till Horadada Island (with a hole through it) comes on with the middle of the southern sandy bay of the Morro Solar, and with the inner declivity of the hill on Solar Point bearing S. 66° E.: with these marks on, and steering N. 66° W., for the furthest point of

© The Complete Work of Charles Darwin Online

Lorenzo you can see, you will be clear of all danger; and when the west martello tower in the castle comes on with the northern part of Callao spit, bearing N. 49° E., you may haul gradually round, till the same tower is seen to the northward of the breakers on a shoal lying off the spit; when a direct course may be shaped for the anchorage. There is no regular tide in this passage, but generally a little setting directly through, sometimes to the N.W. and at others the contrary; should the stream be adverse, and it fall calm while in the channel, there is good anchorage in eight or nine fathoms, with the leading marks on.

Callao is well known as the sea-port of Lima, which is seven miles inland, situated five hundred feet above the level of the sea, and at the foot of a range of mountains: when seen from the anchorage on a fine day, it has an imposing appearance.

Trade was in a flourishing condition in 1836, and when the government becomes settled, this may be the first commercial port on the west coast of South America.

Supplies of all sorts may be obtained for shipping; fresh provisions as well as vegetables, with an abundance of fruit: watering is also extremely convenient, a well-constructed mole being run out into the sea, at which boats can lie and fill from the pipes projecting from its side; wood is the scarcest article, and very dear, so that vessels likely to remain at this port should husband their fuel accordingly.

From Callao, the coast is a sandy beach, running in a northerly direction until you reach Point Vernal; it there becomes higher and cliffy, which character continues as far as Point Mulatas, round which is the little bay of Ancon.

To the west and south-west of Ancon lie the Pescador Islands, the outer and largest of which bears N. 31° W. from Callao Castle, and at the distance of eighteen miles. There is no danger among these islands; they are steep-to, with from twenty to thirty fathoms near them.

N. 33° W. from Point Mulatas, twelve miles distant, is the Bay of Chancay and river of that name; this bay may be known by the bluff head that forms the point, and has three hills on it, in an easterly direction; it is a confined place, and fit only for small coasters. From Chancay, the coast runs in a more westerly direction, as far as Point Salinas, a shingle beach, with a few broken, cliffy points; the

© The Complete Work of Charles Darwin Online

hills are near the coast, and from four hundred to five hundred feet high.

The point or head of Salinas is five miles in length, in a north and south direction; off its southern extreme is a reef of rocks, a quarter of a mile from the shore; and at its northern part, called Las Bajas, is an islet at a cable's distance; between these points are two coves fit only for boats; there is a remarkable round hill, called Salinas, at a short distance from the coast, and further in shore, is a level, sandy plain; at the south side of this plain is a number of salinas, or salt-ponds, from which the headland takes its name. These ponds are visited occasionally by people from Huacho.

Off the south part of Salinas, in a south-west direction, lie the Huara Islands, the largest of which is called Mazorque. It is two hundred feet in height, three-quarters of a mile long, and quite white; sealers occasionally frequent this island; there is landing on its north side.

The next in size is called Pelado; it lies S. 49° W. six miles and a half from Mazorque, is about one hundred and fifty feet high, and apparently quite round; between these two islands a safe passage exists, and may be used without fear in working up to Callao. Between Mazorque and Salinas are several smaller islands, all of which, from their appearance, may be approached without danger; but as no advantage could be gained, it would not be prudent to risk going between them. Vessels, in working up, sometimes go between the inner one and the point; but what they gain by so doing does not appear, for when the current sets to the southward, it runs equally as strong between Mazorque and Pelado as it does nearer the shore.

Round the northern point of Salinas Head is the bay of that name, of large dimensions, and affording anchorage. From this bay the coast is moderately high and cliffy, without any break, until you reach the Bay of Huacho. This bay lies round a bluff head, is small; but the anchorage is good in five fathoms, just within the two rocks that run off the northern part of the head. The town is built about a mile from the coast, in the midst of a fertile plain, and in coming from seaward has a pleasant appearance; it is not a place of much trade, but whale-ships find it useful for watering and refreshing their crews. Fresh provisions, vegetables, and fruit, are abundant and on reasonable terms; wood is also plentiful, and a stream of fresh water

© The Complete Work of Charles Darwin Online

runs down the side of the cliff into the sea. Landing is tolerably good: rafting seems to be the best method of watering.

In coming from seaward, the best distinguishing marks for this place, are the BEAGLE MOUNTAINS, three in number, in the near range, each of which has two separate peaks on it; these lie directly over the bay, and on closing the land, the round hill on Salinas Point and the Island of San Martin to the northward, will be seen; about midway between them is the Bay of Huacho, under a light brown cliff, the top of which is covered with brushwood: to the southward the coast is a dark, rocky cliff.

N. 29° W., three miles and two-thirds from Huacho, are the Head and BAY OF CARQUIN, scarcely as large as Huacho, and apparently shoal and useless to shipping; off the Head, which is a steep cliff, with a sharp-topped hill on it, are some rocks above water, and an islet about three-quarters of a mile distant. N. 31° W. three miles from this islet is the island of San Martin, and round to the northward of the point abreast of it, is the Bay of Bequeta.

This is no place for a vessel, being full of rocks and breakers, and having nothing to induce one to go there. From this bay the coast is moderately high, with sandy outline, until you reach Point Atahuanqui. This is a steep point, with two mounds on it, and is partly white on its south side: there is a small bay on its north side, fit only for boats. Between this point and the south part of Point Thomas the coast forms a sandy bay, low and shrubby; with the town of Supé about a mile from the sea.

Point Thomas is similar in appearance to Atahuanqui, without the white on the south side. To the northward of this Point is a snug little bay, capable of containing four or five sail; it is called the Bay of Supé, and is the port of that place and Barranca.

There is a fishing village at the south part of it, which is used by the inhabitants of Barranca during the bathing-season. Hitherto it had been a forbidden port by the government: in consequence of which it is little known, and has had few opportunities of exchanging its produce for the goods of other countries. When we were there, little information could be gained as to the size of the neighbouring towns, and number of inhabitants they contain; but from their appearance we thought they might be of considerable extent. These places produce chiefly sugar and corn, cargoes of which are taken in the various little vessels that trade along the coast. Refreshments may

© The Complete Work of Charles Darwin Online

be obtained ; but water is scarce, the greater part of which is brought from Supé, for the use of the inhabitants of the village.

The best anchorage is in four fathoms, with Point Thomas shut in by the inner point, about a cable's length from the rocks running off that point, and rather more than a quarter of a mile from the village. There is good anchorage further out, in six or seven fathoms, but little sheltered from the swell. In entering, there is no danger ; Point Thomas is bold, with regular soundings, from ten to fifteen fathoms three-quarters of a mile off it. Off Inner Point there are a few rocks to a short distance ; but there is no necessity for hugging the shore so close, as you can always fetch the anchorage, by keeping at a moderate distance in standing in.

To distinguish this port, the best guide at a distance is the Bell Mountain, the highest and most remarkable mountain in the second range ; it bears from the anchorage E. 39° N. ; may be distinguished by its shape like a bell, and has three distinct rises on its summit—the highest at the north end ; on that side it shews very distinctly, there being no other hills near it for a considerable distance. On approaching the coast, the island of San Martin to the southward, and Mount Darwin and Cerro Horca (a small round hill on the beach, with a steep, cliffy side to it, facing the sea, with apparently an islet off it), will be seen, nearly four leagues to the northward. The harbour itself has a white rock at its north extreme, and cannot be mistaken, for there is no other like it near this part of the coast.

From Supé the coast is a clay cliff, about a hundred feet in height, to the distance of a league and a half ; it then becomes low and covered with brushwood, until you reach Cerro Horca already mentioned ; here it again becomes hilly near the sea, with alternate rocky points and small sandy bays, which continue to the distance of six leagues ; where is the bay called Gramadel.

This is a wild-looking place, with a heavy swell rolling in ; it is visited occasionally for the hair seal, with which it abounds : there is anchorage in six or seven fathoms, sandy bottom, with the bluff that forms the bay bearing S.S.E. about half a mile from the shore ; but landing is scarcely practicable.

The coast maintains its rocky character, with deep water off it, as far as the Buffadero, a high, steep cliff, with a hill having two paps on it, a little in-shore. From this bluff is a rocky cliff, from two hundred to three hundred feet high, and more level country, as far as Point Leganto, round which is the Port of Guarmey.

© The Complete Work of Charles Darwin Online

This is a tolerable harbour, with good anchorage any where in from three and a half to ten fathoms, over a fine sandy bottom.

Fire-wood is the principal commodity, for which it is the best and cheapest place on the whole coast. Vessels of considerable burthen touch here for that article, which they carry up to Callao, and derive great profit from its sale. There are also some saltpetre works, established by a Frenchman, but little business is done in that line. The town lies in a north-easterly direction, about two miles from the anchorage, but is hid by the surrounding trees, which grow to the height of thirty feet. It has only one street, and cannot contain more than five or six hundred inhabitants. At the anchorage there is a small house, used to transact business, but no other building, which is unusual, as at most of these places there is a small village near the sea. Large stacks of wood are piled up on the beach, ready for embarking.

Fresh provisions, vegetables, and fruit, are plentiful and moderate; but water is not to be depended on. It is true, there is a river, and for several months after March there is a plentiful supply; but in the summer season there is sometimes great drought. At the time we were there, a whale-ship put in to supply her wants, and had to remain several days, waiting for the water to come down from the mountains.

Legarto Head is a steep cliff, with the land falling immediately inside it and rising again to about the same height. In sailing in, after having passed the head, a small, white islet will be seen in the middle of the bay; steer for it, that you may not border on the southern shore, for there are many straggling rocks running off the points; and when sufficiently far to the northward to shape a mid-channel course between the white islet and the point opposite it, to the southward, do so, and it will lead to the anchorage. In standing in, in this direction, the water shoals gradually to the beach; but the southern shore must on no account be approached nearer than a quarter of a mile.

The best anchorage is in four fathoms, with Harbour Islet bearing N. 26° W., and the ruins of a fort on a hill in-shore E. 5° N. about a quarter of a mile from the landing-place on the beach. This landing-place does not seem to be so good a one as a steep rock on the outer side of the bluff, where the sand beach commences; but probably it is the most convenient for loading boats.

The rise and fall of tide is irregular, and the time of high water

© The Complete Work of Charles Darwin Online

uncertain; but, generally speaking, three feet may be considered about the extent to which it ranges. The sea breeze sets in so strongly occasionally, that it is difficult for boats to pull against it; this is particularly the case under the high land, whence it comes in sudden gusts and squalls.

In coming from seaward, the best way to make this port is to stand in on a parallel of 10° 06′, and when within a few leagues of the coast, a sharp-peaked hill, with a large white mark on it, will be seen standing alone a little north of the port: the break in the hills through which the river runs, is high and cliffy on each side. The land is also much lower to the northward of Legarto Head; and there is a large white islet at the north end of Guarmey Bay.

N. 34° W., seven miles and a half from the white islet at the north extreme of Guarmey Bay, is Point Culebras, a level projecting point, similar in appearance to Legarto Head, as seen from the northward; the coast between is a mass of broken cliffs and innumerable detached rocks, with moderately high land near the coast.

On the north side of Point Culebras, there is anchorage off the valley of that name. From this point the coast is rocky, with small sandy bays, and some rocks lying off it about three quarters of a mile; there is also a white cliffy islet, five miles to the northward of Culebras; whence the coast takes a bend inwards, forming a bay, and then runs out towards the Colina Redonda; a point with two hummocks on it, and as seen from the southward, appearing like an island. On the north side of this point is the Caleta (only fit for boats); and immediately over it, the Cerro Mongon.

The Cerro Mongon is the highest and most conspicuous object on this part of the coast; when seen from the westward it has the appearance of being round, with rather a sharp summit; but from the southward, it shows as a long hill with a peak at each end. It is said there is a lake of fresh water on its summit, and that its valleys abound with deer; but the truth of this cannot be vouched for, as our examination did not extend so far.

From Mongon there is a range of hills running parallel to the coast (which is high and rocky, with some white islets lying off it) as far as Casma, where they terminate in a steep rocky bluff, that forms the southern head of the port of that name.

The Bay of Casma is a snug anchorage, something in the form of a horse-shoe; at its entrance it is a mile and three quarters in a

© The Complete Work of Charles Darwin Online

N.W. and S.E. direction, and a mile and a half deep from the outer part of the cheek, with regular soundings from fifteen to ten, and three fathoms near the beach.

The best anchorage is with the inner part of the south cheek, bearing about S.S.E. a quarter of a mile off shore, in seven fathoms water; by not going farther in you escape, in a great measure, the sudden gusts of wind that at times come down the valley with great violence. Captain Ferguson, of H.M.S. Mersey, mentions a rock with nine feet water on it, on the south side, half a mile from the shore, that sometimes breaks: we saw nothing of it while we were there, but doubtless it exists.

This place seemed quite deserted; the only things that indicated its ever having been visited, were a few stacks of wood piled up on the beach.

The best distinguishing mark for Casma, is the sandy beach in the bay, with the sand hills in-shore of it contrasting strongly with the hard dark rocks, of which the heads at the entrance are formed: there is also a small black islet lying a little to the westward of it.

From Casma the coast takes rather a more westerly direction, but continues bold and rocky.

N. 44° W., five leagues from Casma, is the Harbour of Samanco, or Huambacho; midway between them is a bay, almost hidden by two islands that lie across the entrance: this bay is four miles long and two miles deep; but as the Bay of Samanco is so near at hand, it was not examined by us as to its capabilities.

The Bay of Samanco is the most extensive on the coast to the northward of Callao; it is two leagues in length, in a N.W. and S.E. direction, and a league and a half wide: at its entrance it is two miles wide, formed by Point Samanco on the south, and Seal Island on the north, and has regular soundings all over it.

At the S.E. corner, in a sandy bay, is a small village (the residence of some fishermen), situated at the termination of the River Nepeña. This river, like most on the coast, has not sufficient strength to force a passage for itself through the beach, but terminates in a lagoon within a few yards of the sea.

The town of Huambacho is the nearest place to this bay; it lies about a league distant, at the east extreme of the valley. Nepeña, which is the principal town, lies to the north-east about five leagues off. There is very little trade at this place; small coasting vessels

© The Complete Work of Charles Darwin Online

from Payta sometimes call here with a mixed cargo, and they get in exchange sugar and a little grain,

Refreshment may be obtained from the neighbouring towns, but wood is scarce. The water of the river is brackish and unfit for use; but there are wells on the left bank, a short distance from the huts. When taken on board, this water is not good; but, contrary to the general rule, after it has been some time confined on board, it becomes wholesome and pleasant tasted.

When at a distance, the best mark to distinguish this bay, is Mount Division, a hill with three sharp peaks, situated on the peninsula between Samanco and the Bay of Ferrol. There is also a bell-shaped hill on the south side of the bay that shows very distinctly.

Mount Tortuga, a short distance inland to the N.N.E., will also be seen: it is higher, and similar in appearance to the Bell Mount. The south entrance point is a steep bluff, with some rocks lying off it to a cable's length; on opening the bay, Leading Bluff will be seen, a large lump of rock on the sandy beach at the N.E. side, that looks like an island. In going in, give Samanco Head a berth in passing; you may then stand in as close as convenient to the weather shore, and anchor off the village in four, five, or six fathoms, sandy bottom: when rounding the inner points, take care of your small spars; for the wind comes off the Bell Mount in sudden and variable puffs.

N. 43° W., three leagues from Samanco, is the entrance to the Bay of Ferrol, nearly equal in size to Samanco, and separated from it by a low sandy isthmus; it is an excellent place for a vessel to careen, being entirely free from the swell that sets into most of the ports. On its N.E. side is the Indian village of Chimbote, where, we were told, refreshment of any kind might be had, but no water. The entrance is clear; but there is a reef of rocks off Blanca Island, half a mile to the northward, which must be avoided.

N. 40° W., two leagues from the entrance of Ferrol, is Santa Island: about a mile and a half in length; lying N.N.E. and S.S.W., and of a very white colour; just without it are two sharp-pointed rocks, twenty feet above the sea. Two miles N.N.E. from the island is Santa Head, on the north side of which is the harbour of that name. This, although small, is a tolerable harbour; the best anchorage is in four or five fathoms, with the extreme of the head bearing S.W. Fresh provisions and vegetables may be obtained on moderate terms. It is also a tolerable place for watering.

© The Complete Work of Charles Darwin Online

The town lies west from the anchorage, about two miles distant; and the mouth of the river is a mile and a half along the beach. This is the largest and most rapid river on the coast of Peru: from Santa Head it is seen to wind its way down the valley, with several islets interrupting its course; but at its termination it branches off and becomes shallow, with only sufficient strength to make a narrow outlet for itself, through the sandy beach that forms the coast line: a heavy and dangerous surf lies off it; so that no boat could approach with any degree of safety.

This part of the coast may be known by the wide spreading valley down which the river runs, bounded on each side by ranges of sharp-topped hills; and as you approach, Santa Island will be plainly seen; with the Head of the same name; there is also a small but remarkable white island, called Corcovado, to the N.W. of the harbour. There is no danger in entering; the soundings are regular for some distance outside; and you may anchor any where between the islands in a moderate depth of water, but of course exposed to the swell.

N. 35° W., five leagues from Santa, lie the Chao Islands, one mile and three quarters off the point and hill of that name. The largest is a mile in circumference, about one hundred and twenty feet high, and, like most of these islands, quite white; there are regular soundings from ten to twenty fathoms, at the distance of a mile off shore.

Between Santa and Chao the coast is a low sandy beach, which continues and forms a shallow bay, as far as the hill of Guañape, with moderately high land a few miles in-shore.

The hill of Guañape is about three hundred feet high; rather sharp at its summit, and when seen from the southward, appears like an island; on the north side of it is a small cove, with tolerable landing just inside the rock that lies off the point.

S. 8° W. from this point, between six and seven miles from the coast, lie the Guanape Islands, with a safe passage between them and the shore; they may be said to be two, with some islets and rocks lying about them; the southern is the highest and most conspicuous.

From the hill of Guañape the coast continues a sandy beach, with regular soundings; and ranges of high sharp-topped hills, about two leagues from the sea, until you near the little hill of Carretas, which is on the beach, and has Morro Garita de Mocha overlooking it. Here commences the valley of Chimu, about the middle of which

© The Complete Work of Charles Darwin Online

is situated the city of Truxillo, and at the northern extreme, the village and road of HUANCHACO. This is a bad place for shipping, and seems to have been badly chosen: the north side of the hill of Carretas is a much better place for landing and embarking goods; and might be farther improved by sinking some small craft laden with stones, plenty of which the hill would afford.

The road of Huanchaco is on the north side of a few rocks that run out from a cliffy projection; sheltering the land in a slight degree, but affording no protection to shipping. The village is under the cliff, and not distinguishable till to the northward of the point; but the church, which is on the rising ground, shows very distinctly, and is a good guide when near the coast.

The usual anchorage is with the church and a tree that stands in the village in one, bearing about east, a mile and a quarter from the shore, in seven fathoms dark sand and mud. Vessels often have to weigh or slip and stand off, owing to the heavy swell that sets in: it is also customary to sight your anchor once in the twenty-four hours, to prevent its being imbedded so firmly as to require much time to weigh it when required.

Landing cannot be effected in ship's boats; there are launches constructed for the purpose, manned by Indians of the village, who are skilful in the management of them: they come off on your arrival, and will land you safely, for which they charge six dollars, equal to one pound four shillings sterling: it is to be remembered that no more is charged for a cargo of goods; their having to risk the surf being that for which you pay.

Fresh provisions may be had from Truxillo, but watering is out of the question. The city is said to contain 4,000 inhabitants. Rice is the principal production of the valley; for that article and specie it is that vessels call here.

If bound for this road, you should stand in on a parallel of 8°, (which is a mile to windward), and you will see Mount Campana, a bell-shaped mount, standing alone, about two leagues to the northward: and Huanchaco Peak, which is very sharp, and the first hill in the range on the north side of the valley. Shortly after the church will come in sight, and the shipping in the road.

The coast is cliffy for a few miles to the northward of Huanchaco; the low sandy soil with bushes on it then commences, with regular soundings off it, and continues as far as Malabrigo Road. This bay

© The Complete Work of Charles Darwin Online

although bad, is considerably preferable to Huanchaco; it is formed by a cluster of hills, projecting beyond the general trend of the coast, which at a distance appear like an island; there is a fishing village at the S.E. side, but no trade is carried on. The town of Paysan lies some leagues to the S.E., and, by the account they gave of it at Malabrigo, must be of considerable extent.

The best anchorage here is with the village bearing about E.S.E., three-quarters of a mile from the shore, in four fathoms sandy bottom: landing is bad, but the fishermen have what they call 'caballitos,' bunches of reed fastened together, turned up at the bow like a balsa of Chile, but much higher. These are so light that they are thrown on the top of the surf to the beach, when they jump off and carry them on their shoulders to the huts. It seems that each different bay or road has its peculiarly-constructed vessel, adapted to the surf which it has to go through. The small island of Macabi, lies S. by E. two leagues from Malabrigo, with a safe channel of ten fathoms between it and the main land.

N. 35° W., six leagues and a half from Malabrigo, is the road of Pacasmayo; between the two the coast is low and cliffy, with a sandy beach at the foot of the cliff, and soundings of nine and ten fathoms two miles off shore. Pacasmayo is a sufficiently good roadstead, under a projecting sandy point, with a flat running off it to the distance of a quarter of a mile. The best anchorage is with the point bearing about S. by E., and the village east; you will there have five fathoms, sand and mud: there is no danger in standing in; the soundings are regular, shoaling gradually towards the shore. Landing is difficult: launches are used as at Huanchaco. The principal export is rice, which is brought from the town of San Pedro de Yoco, two leagues inland. Fresh provisions may also be obtained from the same place; wood and water may be had at the village on the beach, which is principally inhabited by Indians, employed by the merchants of San Pedro.

To distinguish this road from seaward, the best guide is to stand in on a parallel of 7° 25′ to 30′, and when within six leagues, the hill of Malabrigo will be seen, which appears like an island sloping gradually on each side; and a little to the northward, Arcana Hill, rugged with sharp peaks. As you approach, the low yellow cliffs will appear (those north of the road the highest), on the summit of which, on the north side of the point, is a dark square building that

© The Complete Work of Charles Darwin Online

shews very distinctly. The best mark for the anchorage is the shipping, when any are there. From this road the coast continues low, with broken cliff, until you reach Point Eten, which is a double hill (the southern one the highest), with a steep cliff facing the sea. The north side of this cliff is white, and shews conspicuously.

N. 43° W., a little more than four leagues, is the road of LAMBAYEQUE, the worst anchorage on the coast of Peru. There is a small village on the rising ground, with a church that shews white towards the sea; off which vessels anchor in five fathoms, a mile and a quarter from the shore. The bottom is a hard sand, and bad holding ground, it is always necessary to have two anchors ready, for the heavy swell that sets on this beach renders it almost impossible to bring up with one, particularly after the sea breeze sets in.

Rice is the chief commodity for which vessels touch here: the only method of discharging or taking in a cargo (or in fact landing at all), is by means of the balsa. This is a raft of nine logs of the cabbage palm, secured together by lashings, with a platform raised about two feet, on which the goods are placed. They have a large lug sail which is used in landing, the wind being along the shore enables them to run through the surf and on the beach with ease and safety; and it seldom happens that any damage is sustained by this peculiar mode of proceeding. Supplies of fresh provisions, fruit, and vegetables may be obtained, but neither wood nor water.

The coast continues low and sandy, similar in appearance to that of Lambayeque, to the distance of twenty-five leagues: an extensive range of table-land of considerable height, with broken rocky points, then commences, and continues to Point Aguja or the Needle. Fifteen leagues from Lambayeque in an E.S.E. direction, lies a small group of islands called LOBOS DE AFUERA. These islands are a league in length north and south, and a mile and a half broad; are about a hundred feet high, of a mixed brown and white colour, and may be seen several leagues off; they are quite barren, affording neither wood nor water. There is a cove on the north side formed by the two principal islands, but with deep water and rocky bottom; within this cove are several nooks, in which a small vessel might careen, without being interrupted by the swell.

These islands are resorted to by fishermen from Lambayeque on their balsas; they carry all their necessaries with them, and remain

© The Complete Work of Charles Darwin Online

about a month salting fish, which fetch a high price at Lambayeque. There is no danger round these islands, at the distance of a mile; regular soundings will be found between them and the shore, from fifty fathoms abreast of the islands.

N. 26° W., ten leagues from Lobos de Afuera, lies the Island of Lobos de Tierra, nearly two leagues in length, north and south, and little more than two miles wide; when seen from seaward it has a similar appearance to the former islands, and many rocks and blind breakers lie round it, particularly on the west side. There is tolerable anchorage on the N.E. side, in eleven or twelve fathoms, sand and broken shells. A safe passage is said to exist between this island and the main, which is distant ten miles, but as no advantage could be gained by going between, it was not thoroughly examined by us.

Point Aguja is long and level, terminating in a steep bluff 150 feet high, and has a finger rock a short distance off it, with several detached rocks round the point.

Three miles and a half N.N.E. of this is Point Nonura, and five miles farther in the same direction is Point Pisura, the south point of the Bay of Sechura; between Aguja and Point Pisura are two small bays, where anchorage may be obtained, if required. The land about this part is much higher, and has deeper water off it, than on either side, and may be readily known by its regularity and table-top. The bay of Sechura is twelve leagues in length, formed by the little Lobos Island of Payta and Point Pisura, and is six leagues deep; on the S.E. side the coast shows low sand hills, but as you go northward it becomes cliffy and considerably higher.

Near the centre of the bay is the entrance to the River Piura, and the town of Sechura situated on the banks of it. This town is inhabited chiefly by Indians, who carry on a considerable trade in salt, which they take to Payta on their balsas, and sell to the shipping. The river is small, but of sufficient size to admit the balsas when laden. There is anchorage any where off the town, in from twelve to five fathoms, coarse sand; in the latter depth you will be better than a mile from the shore. This place may easily be distinguished by the church, which has two high steeples on it, and shows conspicuously above the surrounding sand hills; one of these steeples has a considerable inclination to the northward, which at a distance gives it more the appearance of a cocoa-nut tree than a stone building.

© The Complete Work of Charles Darwin Online

From Lobos Island Point the coast is cliffy, about 120 feet high, and continues so as far as Payta Point, which is three leagues distant; between these two, a mile and a half from the coast, is a cluster of hills called the saddle of Payta; accurately described by Captain Basil Hall. The SILLA or SADDLE OF PAYTA is sufficiently remarkable, it is high and peaked, forming three clusters of peaks joined together at the base, the middle being the highest; the two northern ones are of a dark brown colour; the southern is the lowest, and of a lighter brown. These peaks rise out of a level plain, and are an excellent guide to vessels bound for the Port of Payta from the southward.

A few leagues to the northward, as already mentioned, is PAYTA POINT, round which is the port of that name. This is without exception the best harbour on the coast, and considerable trade is carried on. Vessels of all nations touch here for cargoes, principally cotton, bark, hides, and drugs, in return for which they bring the manufactures of their several countries. In the year 1835 upwards of forty thousand tons of shipping anchored in this port. Communication with Europe (viâ Panama) is more expeditious than at any of the other ports.

The town is built on the slope and at the foot of the hill, on the south-east side of the bay; at a distance it is scarcely visible, the houses being of the same colour with the surrounding cliff. It is said to contain 5,000 inhabitants, and is the sea port of the province of Piura, the population of which is estimated at 75,000 souls.

The City of SAN MIGUEL DE PIURA is situated on the banks of the River Piura, in an easterly direction from Payta, between nine and ten leagues distant. Fresh provisions may be had at Payta on reasonable terms, but neither wood nor water, except at a high price, the latter being brought from Colan (a distance of four miles) for the inhabitants of the place. When we were there hopes were entertained of a supply of water from the west side of the bay; an American having commenced boring with an apparatus proper for the purpose.

There is no danger in entering this excellent harbour: after rounding the point which has a signal station on it, you will open False Bay: this must be passed, as the true bay is round Inner Point. That point ought not to be hugged closely, for there are some rocks to the distance of a cable's length, and the wind baffles off it.

© The Complete Work of Charles Darwin Online

After rounding Inner Point you may anchor where convenient, in quiet still water, with from four to seven fathoms, over a muddy bottom. The landing place is at the mole about the centre of the town.

N. 41°. W., nine leagues and a half from the town of Payta, is Point Parina, a bluff, about eighty feet high, with a reef to the distance of half a mile on its west side; between this point and Payta the coast is low and sandy, with table land of a moderate height, a short distance from the beach; and the mountain of Amatape five leagues in the interior.

After rounding Point Pariña (which is the western extreme of South America), the coast trends abruptly to the northward, and becomes higher and more cliffy, until you reach Point Talara. This is a double point, the southern part of which is cliffy; about eighty feet high, with a small black rock lying off it; the northern part is much lower, and has few breakers near. On the north side of this point is a shallow bay, in the depth of which the high cliffy coast again commences, and runs in a line towards Cape Blanco.

Cape Blanco is high and bold (apparently the corner of a long range of table-land), sloping gradually toward the sea; near the extreme of the cape there are two sharp-topped hillocks; and midway between them and the commencement of the table land, is another rise with a sharp top. There are some rocks that shew themselves about a quarter of a mile off, but no danger exists without that distance. From Cape Blanco the general trend of the coast is more easterly, in nearly a direct line to Point Malpelo, which is twenty-one leagues distant.

N. 34° E., seven leagues and a half from the former is Point Sal, a brown cliff, one hundred and twenty feet high; along the coast is a sandy beach, with high cliff as far as the valley of Mancora, where it is low with brush wood near the sea; the hills being at a distance inland.

Northward of Point Sal the coast is cliffy, to about midway between it and Point Picos; it then becomes lower, and similar to Mancora.

Point Picos is a sloping bluff, with a sandy beach outside it, and another point, exactly similar, a little to the northward: at the back of it is a cluster of hills with sharp peaks, hence arises, probably, the name given by the Spaniards to this point. From Point Picos the coast is a sandy beach, with a mixture of hill and cliff of a

© The Complete Work of Charles Darwin Online

light brown colour and well wooded. There are several small bays between it and Point Malpelo, which bears N. 41° E., seven and a half leagues distant.

Point Malpelo, the southern point of the entrance of Guayaquil River, may be readily known by the marked difference between it and the coast to the southward: it is very low and covered with bushes to its extreme; a short distance in-shore, is a clump of bushes higher and more conspicuous than the rest, which shews plainly on approaching. At the extremity of the point is the River Tumbes off which a reef extends, to the distance of a quarter of a mile. This place is much frequented by whalers, for fresh-water, which is found about a mile from the entrance, where they fill their boats from alongside; great care is necessary in crossing the bar, as a heavy and dangerous surf beats on it, rendering it at all times difficult to cross.

The entrance to the river may be distinguished by a hut on the port hand going in, which is perceived immediately you round the point. About two leagues up the river stood the old town of Tumbes, now scarcely more than a few huts, barely sufficient to supply the whalers with fruit and vegetables. This is the boundary line, between Peru and the State of the Equator. You may anchor any where off the point in six or seven fathoms.

Winds.

The prevailing winds on the coast of Peru blow from S.S.E. to S.W.; seldom stronger than a fresh breeze, and often in particular parts scarcely sufficient to enable shipping to make their passages from one port to another. This is especially the case on the south and south-western coast, between Cobija and Callao.

Sometimes during the summer, for three or four successive days, there is not a breath of wind; the sky is beautifully clear, with a nearly vertical sun.

On the days that the sea-breeze sets in, it generally commences about ten in the morning; then light and variable, but gradually increasing till one or two in the afternoon. From that time, a steady breeze prevails till near sunset, when it begins to die away; and soon after the sun is down there is a calm. About eight or nine

© The Complete Work of Charles Darwin Online

in the evening light winds come off the land, and continue till sunrise; when it again becomes calm until the sea-breeze sets in as before.

During winter (from April to August) light northerly winds may be frequently expected, accompanied by thick fogs, or dark lowering weather; but this seldom occurs in the summer months, although even then the tops of hills are frequently enveloped in mist.

To the northward of Callao, the winds are more to be depended on; the sea-breeze sets in with greater regularity, and fresher than on the southern parts; and near the limit of the Peruvian territory (about Payta and off Cape Blanco), a double-reefed topsail breeze is not uncommon.

It is to be remarked, and may be laid down as a general rule, that although such moderate winds blow on the coast of Peru, yet sudden and heavy gusts come over high land after the sea-breeze sets in, which, from the smallness of the ports, may be attended with some inconvenience, if precautions are not taken in shortening sail previous to entering them.

The only difference between winter and summer, as far as regards the winds, is the frequency of light northerly airs during the former months; but in the state of the weather, the difference is far greater than one would imagine in so low a latitude. In the summer the weather is delightfully fine, with the thermometer (Fahrenheit's) seldom below 70°, and often as high as 80°, in a vessel's cabin; but during winter the air is raw and damp, with thick fogs and a cloudy overcast sky. Cloth clothing is then necessary for the security of health; whereas in summer the lighter you are clad, the more conducive to comfort and health.

The general set of the CURRENT on the coast of Peru is along the shore to the northward, from half a knot to one knot an hour; but occasionally it sets to the southward, with equal or even greater strength.

The period at which these southerly sets take place cannot be ascertained with any degree of certainty. Neither seasons, the state of the moon, nor other causes common on almost every coast, seem to have an influence here. The oldest navigators, and men accustomed to the coasting trade, can assign no reason for these changes—they only know that they do take place, and endeavour to profit by them accordingly.

© The Complete Work of Charles Darwin Online

During our stay on the coast, we frequently experienced these southerly sets, immediately preceding and during northerly winds; but as this was not always the case, no general rule can be laid down, although it certainly appears a natural inference to draw. We also remarked, that at times the current was setting to the southward, when a fresh wind was, and for days previous, had been blowing from that quarter. And as no inequalities or irregularities in the coast line could have occasioned this, it only served to heighten our curiosity, without affording any clue to discover how the peculiarity was caused.

On Passages.

With regard to making passages on this coast—little difficulty is found in going northward; a fair offing is all that is requisite to ensure your making a certain port in a given number of days; but in working to windward, some degree of skill, and constant attention are necessary.

Much difference of opinion exists as to whether the in-shore or off-shore route should be preferred; but from the experience we had ourselves, and from information gained from those who were said to understand the coast, we were led to suppose the following the best line to follow.

On leaving Guayaquil or Payta, if bound to Callao, work close in-shore to about the island of Lobos de Afuera. All agree in this. Endeavour always to be in with the land soon after the sun has set, that advantage may be taken of the land wind, which begins about that time; this will frequently enable a ship to make her way nearly along shore throughout the night, and place her in a good situation for the first of the sea-breeze.

After having passed the before-named islands, it would be advisable to work up on their meridian, until you approach the latitude of Callao; then stand in, and if it is not fetched, work up along shore, as above directed.

Some people have attempted to make this passage, by standing off for several days, hoping to fetch in on the other tack, but have invariably found it a fruitless effort, owing to the northerly set that is experienced on approaching the equator.

If from Callao and bound to Valparaiso, there is no question but

© The Complete Work of Charles Darwin Online

that by running off with a full sail the passage will be made in much less time than by working in-shore, for you run quite through the trade-wind, and fall in with the westerly winds which are always found beyond the trades. But for the intermediate ports (excepting Coquimbo) the case is different, as they lie considerably within the trade-wind, and must be worked for by that alone.* It may, however, be recommended to work along shore as before stated, to about the island of San Gallan. Whence the coast trends more to the eastward, so that a long leg and a short one may be made (with the land just in sight) as far as Arica, or to any of the ports between Pisco and that place.

From Arica, the coast being nearly north and south, vessels bound to the southward should make an offing of about fifteen or twenty leagues (to ensure keeping the sea-breeze), and work up on that meridian till in the parallel of the place to which they are bound. On no account is it advisable to make a long stretch off; for as you approach the limit of the trade-wind it gradually hauls to the eastward, and great difficulty will be found in even fetching the port from which you started.

The average passage in a well-conditioned merchant-vessel from Guayaquil to Callao is from fifteen to twenty days; and from Callao to Valparaiso about three weeks; fast-sailing schooners have made these passages in much less time; and there is an instance of two men-of-war, in company, having gone from Callao to Valparaiso, remained there two days, and re-anchored at Callao on the twenty-first day. But these are rare occurrences, and only to be done under most favourable circumstances, such as taking a "norther" soon after leaving Callao.

N.B. These remarks and notices, relating to Peru, are the work of Mr. Usborne. Those referring to Northern Chile are by Lieut. Sulivan. Mr. Stokes and I have added a few words.

* A dull sailer might do better by running through the trade, making easting with westerly winds, and then steering northward along the coast, than by attempting to work to windward against a trade-wind, which varies but a few points.

Al Sñr. Comandante de la barca de S.M.B. Beagle, Dª. R. FITZ ROY.

Buenos Ayres, Nov. 8 de 1832.
Año 22 de la Libertad, y 17 de la Yndependencia.

El Ministro de Relaciones Esteriores que subscribe ha recibido con la mayor satisfaccion la Carta del Puerto de Bahia Blanca, que se ha servido remitirle el Sñr. Fitz Roy, Comandante de la Barca Beagle de S.M.B.

El Ministro agradece al Sñr. Fitz Roy este presente que considera de mucha importancia, y en su consecuencia tiene el placer de incluirle las ordenes que por el Ministerio de la Guerra se libran à los Comandantes politicos y militares de los Puertos de la Republica, para que no le pongan impedimento en sus operaciones facultativas sobre la Costa y si le faciliten los auxilios que puedan serle precisos para este desempeño.

Dios guarde muchos Años al Sñr. Comᵉ. Dⁿ. Roberto Fitz Roy.

MANUEL V. E. MAZA.

No. 43.

SIR, Lima, 21st June 1836.

We, the undersigned British merchants, residing in this capital, have just learned with much satisfaction from his Majesty's Consul-General, Mr. Wilson, that the survey of the sea-coast from Cape Horn to Guayaquil has been completed. This important work executed by you and under your orders, will, doubtless, prove of great value to British commerce in the Pacific; and we should be wanting in gratitude if we did not avail ourselves of the earliest opportunity of returning you our sincere thanks, not only for the skill and zeal you displayed in this arduous undertaking, but for the pecuniary sacrifices you made to insure its complete and speedy accomplishment. To Mr. Usborne we also feel much indebted, for the energy and perseverance manifested by him in the fulfilment of his duty, under circumstances not a little embarrassing and difficult; and we hope that his conduct, being made known in the proper quarter, will meet the reward it deserves. That you may long live to serve your

Description of a Quadrant, the power of which is increased by means of an additional Horizon Glass.

Let C A B, in the figure, represent a common quadrant, having the angle A C B equal to forty-five degrees: let C be the index-glass; C A the zero line, or the plane of the glass produced; D the horizon-glass, and E the sight-vane.

Suppose C and D to be parallel, and that a ray coming from an object H, is reflected from C, along the line C D, and from D along the line D E to the eye.

A ray of light from h may be supposed to come from H, if the two, H h, are more than half a mile from the instrument, and the object H will be seen directly, as well as by reflection, in the line D E.

The angle D C E being equal to the angle D E C, D C is equal to D E. With the centre D describe the circle C E F. Place a glass at F, similar to that at D, but making an angle with C B, which will reflect a ray passing along C F, in the line F E, to E.

C F E is an angle at the circumference of a circle, and therefore half C D E, at the centre; and equal to D E F, or forty-five degrees.

An object at H being reflected from F along the line F E, will appear in contact with an object at K, which we may here suppose to be the horizon of the sea. But, by looking through the glass F, and bringing an object into contact with the horizon, which is really forty-five degrees above it, the index of the quadrant will be at zero; and by looking through F, and bringing an object into contact with K, or the horizon, which is really one hundred and thirty-five degrees from it, the index of the quadrant will be at ninety degrees.

The principle being thus shown, it is unnecessary to go farther in this place; either in explaining how it applies equally well to a quintant or sextant, or in describing Mr. Worthington's ingenious method of taking advantage of it, in the sextants he has lately made with power to measure 160°.

In adjusting or verifying the adjustment of the additional glass, I found that by measuring the angular distance of two fixed stars more than forty degrees apart—first carefully by the ordinary method, and then using the extra or additional glass—it was practicable to ascertain its exact error: the only difficulty I had foreseen in the efficient use of this auxiliary.

I may add, that the telescope moves parallel to the plane of the instrument, and that there are two sets of numbers referring to one graduation.

No. 45.

On Clouds.

Clouds may be divided into four classes, called—

Cirrus, Stratus, Nimbus, Cumulus.

Cirrus is the first light cloud that forms in the sky after fine clear weather. It is very light and delicate in its appearance; and generally curling or waving, like feathers, hair, or horses' tails. It may also be called the 'Curl Cloud.'

Stratus is the shapeless smoke-like cloud that is most common, and of all sizes: sometimes it is small, and at a distance, like spots of inky or dirty water; its edges appearing faint or ill-defined; sometimes it rises in fog-banks from water, or land; sometimes it overspreads and hides the sky. Rain does not fall from it. Its exact

© The Complete Work of Charles Darwin Online

resemblance cannot be traced upon paper, because the edges are so ill-defined. It may also be called the 'Flat Cloud.'

Nimbus is the heavy-looking, soft, shapeless cloud, from which rain is falling. Whatever shape a cloud may have retained previous to rain falling from it—at the moment of its change from vapour to water, it softens in appearance, and becomes the 'Nimbus,' or 'Rain Cloud.'

Cumulus is the hard-edged cloud, or cloud with well-defined edges; whose resemblance can be accurately traced on paper. This cloud is not, generally speaking, so large as the Stratus or Nimbus, aud appears to be a compact mass of either the former or latter, or of both. It may also be called the 'Heap Cloud.'

These four classifications of clouds will not, however, suffice to describe exactly the appearance of the sky at all times. More minute distinctions are required, for which the following may be used:—

Cirro-stratus—signifying a mixture of Cirrus and Stratus.

Cirro-cumulus—Cirrus and Cumulus.

Cumulo-stratus—signifying a mixture of Cumulus and Stratus.

Which terms may be rendered more explanatory of the precise kind of cloud, by using the augmentative termination onus, or the diminutive, itus. Thus:—Cirronus, Cirritus; Cirrono-stratus; Cirrito-stratus; Cirrono-cumulus, Cirrito-cumulus; Stratonus, Stratitus; Cumulonus, Cumulitus; Cumulono-stratus, Cumulito-stratus. Should these be found insufficient to convey distinct ideas of every variety of clouds, the second word may be augmented or diminished, thus: Cirrono-stratitus, &c.

These terms may be abbreviated for common use by writing only the first letters of each word; allowing one letter to represent the diminutive, two letters the ordinary, or middle degree, and three letters the augmentative. As Cirrus and Cumulus begin with the same letter, it will be necessary to make a distinction between them by taking two, three, and four letters, respectively, of Cumulus: thus, C., Ci., Cir.; S., St., Str.; N., Ni, Nim.: Cu., Cum., Cumu. Suppose it were desired to express Cumulito-stratoni, C.-Str. would be sufficient, &c.

Winds.

Much notice has lately been taken of the theory respecting storms, suggested by Colonel Capper in 1801, discussed by Mr. Redfield in 1831, and carried out in much detail by Colonel Reid. I have neither ability, nor at present space, to make more than a few brief remarks on this subject.

Are not storms exceptions to the general winds, or atmospheric currents; not the causes of them?* Variable winds are almost continual, except during short intervals of calm; but hurricanes, or even ordinary storms, are rare. May not opposing or passing currents cause eddies, or whirls, on an immense scale in the air, not only horizontal, but inclined to the horizon, or vertical?

In laying a ship to, during a storm, there are other points to consider besides the veering of the wind; such as the direction of the sea, with or against a current, &c. I cannot agree with Colonel Reid, in his remarks (page 425) about the "problem to be solved," or in his "Rule for laying ships to in hurricanes."

I never myself witnessed a storm that blew from more than fifteen points of the compass, either successively, or by sudden changes.

In most, if not all of the storms to which I can bear any testimony, currents of air arriving from different directions appeared to succeed each other, or combine together. One usually brought 'the dirt,' to use a sailor's phrase, and another cleared it away, after driving much of it back again, often with redoubled fury. One of these currents was warm and moist—another cold and dry, comparatively speaking. While one lasted, the barometer fell, or was stationary; with another it rose. At all places I have visited, or of which I have obtained notices on the subject, the barometer stands high with easterly, and comparatively low with westerly winds, on an average. Northerly winds in the northern hemisphere affect the barometer, like southerly winds in the southern hemisphere.

No. 47.

Tides.

At the end of the year 1833, I received from Mr. Whewell a copy of a work for which seamen in general are deeply indebted to him. It

* Reid's Law of Storms, p. 120, &c.

© The Complete Work of Charles Darwin Online

bore the unpretending title of an "Essay towards a first approximation to a Map of Cotidal Lines;" but however lightly the author might esteem it, there can be no doubt that it tended to remove a cloud which hung over numerous difficulties; and to enable us not only to take a general view of them, but to see how we should direct our course in order to attain some knowledge of their intricacies.

In 1831 Mr. Lubbock called the attention of mathematicians, as well as of practical seamen, to the subject of Tides: but it was Mr. Whewell who aroused general interest; and, assisted by the Admiralty, engaged the co-operation of observers in all quarters of the globe.

At the first perusal of Mr. Whewell's essay, I was particularly struck by the following passages: "But in the meantime no one appears to have attempted to trace the nature of the connexion among the tides of the different parts of the world. We are, perhaps, not even yet able to answer decisively the inquiry which Bacon suggests to the philosophers of his time, whether the high water extends across the Atlantic so as to affect, contemporaneously, the shores of America and Africa? or, whether it is high on one side of this ocean when it is low on the other? at any rate, such observations have not been extended and generalized." * Also: †

"If the time of high water at Plymouth be five, and at the Eddystone eight (as formerly stated), the water must be falling for three hours on the shore, while it is rising at the same time at ten or twelve miles distance; and this through a height of several feet. We can hardly imagine that any elevation in one of the situations, should not be transferred to the other in a much shorter time than this.

"There is, in fact, no doubt that most, or all the statements of such discrepancies, are founded in a mistake arising from the comparison of two different phenomena; namely, the time of high-water, and the time of the change from the flow to the ebb current. In some cases the one, and in some the other of these times, has been observed as the time of the tide; and in this manner have arisen such anomalies as have been mentioned." And again: ‡

"The persuasion that, in waters affected by tides, the water rises while it runs one way, and falls while it runs the opposite way, though wholly erroneous, is very general."

These, and other valuable remarks, showed me what indistinct or erroneous ideas I had entertained; and that many other seamen had

* Philosophical Transactions, 1833, p. 148. † Ibid. 157. ‡ Ibid.

© The Complete Work of Charles Darwin Online

been similarly perplexed, I could have little doubt, having often talked to experienced practical men on the subject. Probably the expressions 'tide and half-tide,' 'tide and quarter-tide,' &c., conveyed more distinct ideas to their minds, than to mine: for to me they were unsatisfactory, and although quite aware of their meaning, I never liked them. From 1833, I and my companions on board the Beagle paid more attention to the subject, and made observations in the manner suggested by Mr. Whewell, as often as our other avocations allowed. It was, however, impossible to take interest in the subject, and discover difficulties, facts irreconcileable to theory, without trying to think how to account for them—unqualified even as I knew myself to be for such a task.* Perhaps I was encouraged to meditate by Mr. Whewell's concluding paragraph; † and, separated from assistance, I tried to reason my way out of the dilemma, by the help of such few data as I could dwell upon with certainty.

* Among the points which I could not establish in my own mind, by appeal to facts, were—"the tides of the Atlantic are, at least in their main features, of a derivative kind, and are propagated from south to north." (p. 164.) "That the tide-wave travels from the Cape of Good Hope to the bottom of the Gulf of Guinea, in something less than four hours." (p. 167.) "That the tide-wave travels along this coast (American) from north to south, employing about twelve hours in its motion from Acapulco to the Strait of Magalhaens." (p. 194.) "From the comparative narrowness of the passage to the north (of Australia), it is almost certain that these tides must come from the southern side of the continent." (p. 200.) "The derivative tide which enters such oceans (North and South Pacific) from the south-east, is diffused over so wide a space, that its amount is also greatly reduced." (p. 217.) &c.

† "I cannot conclude this memoir without again expressing my entire conviction of its very imperfect character. I should regret its publication, if I supposed it likely that any intelligent person could consider it otherwise than as an attempt to combine such information as we have, and to point out the want and the use of more. I shall neither be surprised nor mortified, if the lines which I have drawn shall turn out to be, in many instances, widely erroneous: I offer them only as the simplest mode which I can now discover of grouping the facts which we possess. The lines which occupy the Atlantic, and those which are near the coasts of Europe, appear to have the greatest degree of probability. The tides on the coasts of New Zealand and New Holland, have also a consistency which makes them very probable. The Indian Ocean is less certain; though it is not easy to see how the course of the lines can be very widely different

© The Complete Work of Charles Darwin Online

Some of the facts which seem to stand most in opposition to the theory that deduces tides in the northern Atlantic from the movement of a tide-wave originated in the great southern ocean are:—the comparative narrowness of the space between Africa and America; with the certainty that the sea is neither uniformly nor excessively deep in that space,* and the trifling rise of tide; not only upon either nearest shore (where it does not exceed four or five feet at the utmost), but at Ascension Island, where the highest rise is not two feet.† Secondly, the absence of any regular tide about the wide estuary of the river Plata, the situation and shape of which seems so well disposed for receiving an immense tide.‡ Thirdly, the flood-tide moving towards the west and south along the coast of Brazil,

rent from that which we have taken. The course of these lines in the Pacific appears to be altogether problematical; and though those which are drawn in the neighbourhood of the west coast of America connect most of the best observations, they can hardly be considered as more than conjecture: in the middle of the Pacific I have not even ventured to conjecture. It only remains to add, that I shall be most glad to profit by every opportunity of improving this map, and will endeavour to employ for this purpose any information with which I may be supplied."—pp. 234-5.

* Besides the 'Roccas', Fernando de Noronha, and St. Paul rocks, various accounts have been received, from time to time, of shoals near the equator, between the meridians of fifteen and twenty-four degrees west. There can be no doubt, from the descriptions, that many alarms have been caused in that neighbourhood by earthquakes; which are, to my apprehension, indications of no very great depth of water. In 1761, a small sandy island was said to have been seen by Captain Bouvet, of Le Vaillant. This, if seen, has probably sunk down since. Krusenstern saw a volcanic eruption thereabouts in 1806. In 1816, Captain Proudfoot, in the ship Triton, from Calcutta to Gibraltar, passed over a bank, in latitude 0° 32′ S. and longitude 17° 46′ W. It appeared to extend in an east and west direction three miles, and in a north and south direction one mile. They sounded in twenty-three fathoms, brown sand; but saw no appearance of breakers.

† At St. Helena it is not three feet: while at Tristan d'Acunha there is a rise of eight or nine feet under ordinary circumstances.

‡ I have passed months in that river without being able to detect any periodical rise of water, which I could attribute to tide; though it is said, that when the weather is very settled, some indications of a tide may be perceived.

© The Complete Work of Charles Darwin Online

from near Pernambuco to the vicinity of the river Plata; and lastly, the almost uniformity of the time of high water along that extent of the coast of Africa which reaches from near the Cape of Good Hope to the neighbourhood of the Congo.

Against the supposition that a tide-wave travels along the west coast of America, from north to south, are the facts—that the flood-tide impinges upon Chilóe and the adjacent outer coast, from the southward of west; that it is high water at Cape Pillar and at Chilóe, including the intermediate coast, almost at one time;* that from Valdivia to the Bay of Mexillones (differing eighteen degrees in latitude), there is not an hour's difference in the time of high-water; that from Arica to Payta the times vary gradually as the coast trends westward; that from Panama to California, the times also change gradually as the coast trends westward; and that from forty to sixty north, high water takes place at one time.

Having thus stated a few of the difficulties to be encountered by a theory which supposes such important tide-waves to move in the direction of a meridian, rather than in that of a parallel, I will venture to bring forward the results of much anxious meditation on the subject, trusting that they will be received by the reader—not as assertions—not as conclusions to which assent is asked without a reason for acquiescence being given—but as the very fallible opinion of one individual, who is anxious to contribute a mite, however small, towards the information of those for whom this work is more particularly written—namely, seafaring men; and who, if his ideas are fallacious, will rejoice at their refutation by the voice of truth.

Resting in confidence upon the Newtonian theory—which assigns as the primary causes of tides the attractions of the moon and sun—I will make a few remarks, and then state some facts from which to reason.

Some persons seem to view the tidal phenomena more in connection with what would have happened had the globe been covered with water, than with reference to what actually happens, now that the oceans are nearly separated by tracts of land. They appear to consider that the effects of the moon's attraction (leaving the sun's out of the question at present, as it is similar though smaller) are felt only in vertical lines; and they do not allow for the lateral action of

* Within about half an hour; an irregularity easily accounted for, and to which any one place is subject.

© The Complete Work of Charles Darwin Online

the moon upon a body of water, by which any portion is attracted towards her before she is vertically over it, as well as after she has passed to the westward of the meridian of that portion.

But little attention appears to have been paid to a consideration of the momentum acquired by any great body of water moved from the position it would occupy if undisturbed, and to the consequences of that momentum, when the water returns from a temporary displacement. And there seems to be a difficulty in altogether reconciling the statement that "tides are diminished by diffusion,* with the manner in which the great tides of the Northern Atlantic are supposed to be caused—a supposition which is mainly dependent upon the principle of "forced vibrations or oscillations."†

In consequence of similar ideas, excited by the facts previously mentioned, the following questions were inserted in the Geographical Journal for 1836:—

"It may appear presumption in a plain sailor attempting to offer an idea or two on the difficult subject of 'Tides;' yet, with the utmost deference to those who are competent to reason upon the subject, I will venture to ask whether the supposition of Atlantic tides being principally caused by a great tide-wave coming from the Southern Ocean, is not a little difficult to reconcile with the facts that there is very little tide upon the coasts of Brazil, Ascension, and Guinea, and that in the mouth of the great river Plata there is little or no tide?

"Can each ocean have its own tides, though affecting, and being affected by the neighbouring waters?

"Can the mass of an ocean have a tendency to move westward as well as upward, after and towards the moon as she passes? If so, after the moon has passed, will not the mass of that ocean have an easterly inclination to regain that equilibrium (with respect to the earth alone) from which the moon disturbed it (sun's action not here considered)?

"In regaining its equilibrium, would not its own momentum carry it too far eastward; and would not the moon's action be again approaching?

"Can one part of an ocean have a westward tendency, while another part, which is wider or narrower, from east to west, has an eastward

* Whewell's Essay, p. 217.

† Herschel's Astronomy, Cab. Cyc. p. 334.

movement? If so, many difficulties would vanish; among them those which were first mentioned, and those perplexing anomalies on the south coast of New Holland."—(Jour. R. Geog. Soc. vol. vi. part II. p. 336.)

It might have been concluded that these questions had scarcely been noticed, as I heard nothing on the subject, had I not lately read the following remarks in a work published in 1837. Whether their author ever saw the questions, I do not know; but as his observations bear strongly upon the subject, and are those of an eminent mathematician, I quote them verbatim:—

"Suppose several high, narrow strips of land were now to encircle the globe, passing through the opposite poles, and dividing the earth's surface into several great, unequal oceans; a separate tide would be raised in each. When the tidal wave had reached the farthest shore of one of them, conceive the causes that produced it to cease; then the wave thus raised would recede to the opposite shore, and continue to oscillate until destroyed by the friction of its bed. But if instead of ceasing to act, the causes which produced the tide were to re-appear at the opposite shore of the ocean, at the very moment when the reflected tide had returned to the place of its origin, then the second tide would act in augmentation of the first; and if this continued, tides of great height might be produced for ages. The result might be, that the narrow ridge dividing the adjacent oceans would be broken through, and the tidal wave traverse a broader tract than in the former ocean. Let us imagine the new ocean to be just so much broader than the old, that the reflected tide would return to the origin of the tidal movement half a tide later than before; then instead of those two super-imposed tides, we should have a tide arising from the subtraction of one from the other. The alterations of the height of the tides on shores so circumstanced might be very small, and this might again continue for ages, thus causing beaches to be raised at very different elevations, without any real alteration in the level, either of the sea or land."—(Babbage's Ninth Bridgewater Treatise, pp. 248, 249.)

Additional data, and leisure to reflect upon them, have tended to confirm the view taken previously to asking those questions in the Geographical Journal; but before stating this view more explicitly, it is necessary to lay facts before my readers, from which they may judge for themselves.

© The Complete Work of Charles Darwin Online

In the greatest expanse of ocean, that which meets with only partial interruption to free tidal movements—the zone, if it may be so called, near fifty-five degrees of south latitude—there is high water at opposite sides, and low water at opposite sides of the globe nearly at the same time.

At the eastern part of the Falkland Islands, exposed to the tide of this zone, it is high water, or full sea, at about nine o'clock on the day of new, or full moon, by Greenwich time ;* and on the southern shore of Van Diemen's Land it is high-water at about ten. This is not a point exactly opposite, it is true, but it is the nearest so at which we have yet observed.

At each of these places the tide rises six hours and falls six hours, alternately ; therefore when it is low water at one, it is also low water at the other. There is no intermediate place in this zone, rather distant from these points, at which I know of a tide observation deserving confidence ; but those above-mentioned are certain, and corroborate the Newtonian theory in a satisfactory manner.

This is, however, the only zone of ocean, which is at all able to follow the law which would govern its undulations if the globe were covered with water. In other zones (taking about ten degrees in latitude as a zone) it is high water, generally speaking, at one side of an ocean near the time that it is low on the other.

In oceans about ninety degrees wide, this happens very nearly ; but as the width diminishes, so do the times of high water at each side approach ; and as the width increases beyond ninety degrees, as in the case of zones of the Pacific, the times of high water still approach (in consequence of the tendency to high water at opposite points), and farther confirm the Newtonian theory.

For examples (on the day of full moon) :—In the Pacific, at Port Henry, in 50° S. it is high water at 5h. at which time it is near low water at Auckland Island, where the time of high tide is 12h. 30m. In this case, the interval between one high water, and the other on the opposite side of the ocean, is 7h. 30m. or 4.30 ; and the width of that ocean is nearly eight hours (measured in time.)

At Valdivia, in lat. 40° S. it is high water at 3h. 30m. and at New Zealand, on that parallel, at 9h. 50m. The space of ocean between is seven hours nearly : the differences are 6.20 and 5.40.

* To which all the times are here reduced for easy comparison.

© The Complete Work of Charles Darwin Online

In 30° S. at Coquimbo, it is high water at 2h. and at Norfolk Island it is high at about 9h. The intermediate space of ocean is nearly eight hours wide.*

In 20° S., at Iquique, it is high water at 1h. 30m., and at New Caledonia, in the same parallel, it is high water at 9h. 15m. The space between is about eight hours wide : the least difference 4.15.

Near 10°, or 12°, at Callao, it is high water at about ten; but as on this parallel a multitude of islands spread across half the Pacific, no comparison of times can be trusted.

On the equator—at the Galapagos Islands—it is high water at 8h. 20m.; and at New Ireland it is high water at 3h. 00m.—a difference of seven hours nearly. The ocean is here eight hours wide; but at New Ireland there is only one tide in twenty-four hours—an anomaly to be considered presently.

The parallel of 10° N. is similar to that of the equator—however, we may as well examine it. At the little Isle of Cocos, and at Nicoya, on the main, it is high water at about 8h.; and at the Philippine Islands, in the same latitude, at 4h.; the difference, eight hours, is not far from the meridian distance, which is about ten hours; but the Philippines also feel the effects of causes which influence the tides at New Ireland, and, generally, those of the Indian Archipelago.

In 20° N. at San Blas, it is high water at 3h; and at Loo-choo, the nearest known point of comparison at the other side of the ocean, at 10h. The difference, 7 hours, is about an hour less than the meridian distance. In 30° N. on the Coast of California, it is high water at 4h., and at Nangasaky, in Japan, in lat. 32° 44′, at 11.12. The difference, 7.12, is nearly half an hour less than the meridian distance. In 40° N. it is high water at about 8h. on the American coast, but for the opposite shore I have no data. In 50° N. it is high water on Vancouver Island at 9h., and at the south extreme of Kamschatka it is said to be high water at about 6h.; the difference, 9 or 3 hours, is anomalous—made so probably by a derivative tide.

Having examined the Pacific, let us proceed in a similar manner with the Atlantic, and the Indian Ocean :—

In 40° S. off Blanco Bay, the time of high water is 9h.; the same as at the Falklands.

At Amsterdam Island, one authority says 6h., another 12h, for the

* A derivative tide (p. 289) may act here.

© The Complete Work of Charles Darwin Online

time of high water. Both cannot be right: but thinking the latter correct, I have preferred it. In Bass Strait it is high water at about ten. Between the two extremes there are thirteen hours, and between the times of tide there are eleven, or thirteen hours. At Amsterdam Island, high water is taken as two hours after that of Bass Strait, but the difference of meridians is about four hours. The difference between the high water of Amsterdam, and Blanco Bay, is nine hours, and their difference of meridians is about nine hours.

In 30° S. it is high water on the African coast at two, and on the American coast at six. There are about four hours difference of meridian between them in that parallel.

In 20° S. it is high water at 3h. on the African shore, and 6h. on the Brazilian; the meridian distance is about three hours and three quarters.

In 10° S. at 3h. 15m. on the east side and 7h. on the west: the distance is about three hours and a quarter.

On the equator we have 4h. 30m. at the eastern limit, and nearly 8h. at the western; the distance being about three hours and a half.

In 10° N. 7h. and 10h. the distance being three hours.

In 20° N. at Cape Blanco, at about 1h.; and on the north coast of San Domingo, nearly at 11h. The interval is about 3.40: but there are interfering derivative tides, probably, as well as local peculiarities, among the West-India Islands.

In 30° N. about 4h. on the east and 1h. 30m. on the west. The distance is nearly five hours. This seems anomalous.

In 40° N. 3h. on the coast of Spain, and at about 1h. on the coast of America. This is another anomaly: but easy of explanation.

In 50° N. it is high water at 4h. 36m., in the mouth of the channel; and at 10h. 45m. on the coast of Newfoundland. Their meridian distance is about 3.20.

On the west coasts of Ireland and Scotland, from 5h. to 6h. is the hour of high water; on the coast of Labrador, it is from 10h. to 11h., in the same parallels. The meridian distances are from three to four hours: but as we approach the parallel of 60° N. the North Sea and Davis Strait open, which probably affect the tide between Ireland and Labrador.

The Indian Ocean appears to have high water on all sides at once, though not in the central parts at the same time. Thus, it is high water at the north-west extremity of Australia; on the coast of

Java; on that of Sumatra; at Ceylon; at the Laccadiva Islands; at the Seychelles; on the coast of Madagascar; and at Amsterdam Island, at twelve: but at the Chagos Islands and Mauritius it is high water at about nine, and at the Keeling Isles about eleven. Here, then, it would seem that there is cause for much perplexity.

Having now stated the principal facts which occur to my mind, I will mention the conclusions drawn from them, and then attempt to explain the anomalies.

Let E G (fig. 1.) represent a section of our globe, of which A B C D is supposed to be land, and E F G H water. Let H M show the direction in which the moon's attraction would operate. The effect of her attraction, according to Newton's demonstration, would be to raise the water at F by positive attraction of the water, and at H by attracting the earth more than the water:—let the dotted line represent the consequent figure of the ocean.

In fig. 2, let the ocean be supposed 90° or six hours wide; let the moon act in the direction M F; and let the dotted line represent the altered position of the water when moved out of its natural position (with respect to the earth) by the moon's attraction.

Again, in fig. 3, suppose the moon acting in the line M K, and the dotted line representing the figure taken in that case by the ocean.

It will occur to the reader that but little water can rise at F and H (fig. 1), at F (fig. 2), or at K (fig. 3), unless water falls or sinks, at E and G (fig. 1), G (fig. 2), F and G (fig. 3), because water is but slightly compressible, except under extraordinary pressure, and because it is incapable of being stretched; therefore, if at any place the sea is raised above its natural level, the excess must be supplied by a sinking taking place elsewhere. There cannot be a void space left under the sea between the water and its bed; and there is no lateral movement of the particles at the surface only of the ocean sufficient to cause high tides on either shore:—therefore the conclusion may be drawn, that the whole mass librates or oscillates.

By librating I mean such a movement as that which a large jelly would have, if its upper part were pushed on one side, and then allowed to vibrate while the base remained fixed: and by oscillating I mean a movement like that of water in a basin, after the basin is gently tilted and let down again: and that such a motion would be

© The Complete Work of Charles Darwin Online

imperceptible, except by its effects, there can be little doubt after reflecting how small a lateral movement of an ocean would cause immense commotion at its boundary, in consequence of the slight elasticity of water, when free to move.

Now let the moon be supposed to move from M in fig. 2 to M in fig. 3. The highest point of the water would then be transferred from F to K, during which transfer the water must fall at F and rise at G: and so of other points. In this manner when the moon causes a tide by her direct attraction, a wave or swelling, whose crest is above the natural level of the sea, moves westward, until it is stopped by a barrier of land. But when it recedes from that barrier, how is the excess of the wave above the height of the sea (when uninfluenced by the moon) transferred to the other side of the same ocean? There is no return wave: if there were, islands intermediate would have an ebb, and a flood tide, every six hours; four floods in twenty-four hours; but they have, on the contrary, six hour tides, alternate ebb and flow, twice in twenty-four hours, like those of the shores of continents, though generally smaller in amount. Water cannot rise in one place unless it falls in another —it does fall on one side of an ocean, while it rises on the other —how then is the fluid transferred? There is only one way— which is by the mass oscillating. In the former case when the moon passed over, it was a libratory movement, in this latter it is an oscillation.

If it is shown, as I believe, that the ocean oscillates, we see that there are two principal causes of tides—one the direct raising of water by the moon: and the other, oscillation excited by that temporary derangement of the natural level of the sea.

From the preceding facts and deductions combined with the commonly received laws of fluids and gravitation, the following conclusions may be drawn:—

1. Every large body of water is affected by the attraction of the moon, and sun, and has tides caused by their action.

2. Bodies of water are not only raised, or accumulated, vertically, by the attraction of the moon and sun; but they are also drawn laterally by them.

3. When a large body of water is prevented from continuing a horizontal movement, it rises until whatever momentum it had acquired ceases; and then it sinks gradually.

© The Complete Work of Charles Darwin Online

4. The momentum acquired by a body of water in thus sinking back to the position it should occupy, with reference to the earth's attraction only, carries it beyond that position to one from which it has a tendency to recoil again—and so to keep up an oscillation until brought to rest by the friction of its bed. (Attraction of the moon and sun not considered.)

5. The recurring influences of the moon and sun are checks on these oscillations, and prevent their taking place more than once between each separate raising of the water in consequence of their attractions.

6. Different zones (or widths measured by latitude) of an ocean, may move differently, each having waves and oscillations at times differing from those of an adjoining zone, in consequence of one having more or less longitude, depth, or freedom from obstacles than another.

7. Original waves and oscillations combine with, and modify one another, according to their relative magnitude, momentum, and direction.

8. The natural tendency of tide-waves, and oceanic librations, is from east to west; and of oscillations, from west to east, and east to west also: but derivative waves or oscillations move in various directions according to primary impulse, and local configuration of the bed of an ocean.

Conformably to these conclusions, I will now try to explain a few of the more remarkable anomalies of tides, in various parts of the world: taking it for granted that the reader is acquainted with existing works on the subject, especially those of Mr. Whewell,* and the brief but comprehensive and explanatory view taken by Sir J. Herschel in his treatise on astronomy.†

I mentioned that between Callao and the western shores of the Pacific, in the parallel of about 12° south, no comparison of times can be trusted? Why not? may be asked. Four or five hours west of Callao, there is a multitude of islands which checks the libration of the ocean. Another tide wave forms westward of them, on a small scale, and it is by this second tide, altered by derivative tides

* Published in the Philosophical Transactions.

† Cabinet Cyclopædia. A Treatise on Astronomy, chap. xi., pp. 334, 5, 6, 7, 8, 9.

© The Complete Work of Charles Darwin Online

from each side, that the western portion of this zone is affected. Otaheite is thus at the edge, or limit, of four tides—one east, another west, a third to the north, and a fourth to the south, and as these tides are moving with different impulses, and at different times, it is not at all surprising that they should almost neutralize each other at Otaheite. As we go west or east of that island, we find the tides augmenting gradually in height. At the Friendly Islands they rise five feet, and at the Gambier Islands three feet.

Respecting the twelve hour tide at New Ireland, and at other places in the Indian archipelago—appeal to facts, so far as we can trace the tides at present, tends to confirm the explanation of Sir Isaac Newton, which consisted in supposing that such tides are compounded of two tides, which arrive by different paths, one six hours later than the other. "When the moon is in the equator, the morning and evening tides of each component tide are equal, and the tides obliterate each other by interference, which takes place about the equinoxes. At other periods the higher tides of each component daily pair, are compounded into a tide which takes place at the intermediate time, that is, once a day; and this time will be after noon or before, according to the time of year."—Whewell, in Phil. Trans. 1833, p. 224.

At New Ireland, the time of high water is about 3; but at New Caledonia it is 9. Again, at the north-west coast of Australia, it is 12; and at the eastern approach to Torres Strait, 10: at the Philippine Islands it is 4; and at Loo Choo, 10. Now here are various times of tide, and different impulses, crowded together into a comparatively small space, sufficient to perplex any theorist of the present day. Owing to local configurations, and a variety of incidental circumstances, we find every kind of tide in this region, in a space sixty degrees square. Although tidal impulses, waves, and resulting currents are checked and altered by the broken land of the Indian archipelago, they cannot be suddenly destroyed, or prevented from influencing each other, while communications, more or less open, exist in so many directions.

At the Sandwich Islands there is said to be very little tide. As it is high water in 40° N., on the American coast, at 8; at which time it is also high water at the Galapagos, it appears that the two zones of the ocean—one about the equator, and the other near 40° N. —have high water, in the meridian of the Sandwich Islands, at two

© The Complete Work of Charles Darwin Online

very different times; and that the high water of the northern zone will have passed that meridian about three hours before the equatorial wave. Impulses derived from them might succeed one another at an intermediate point, such as the Sandwich Islands. Besides which, there is the tide of their own zone to be considered; in consequence of which alone it might be high water at about 6: thus these islands are so situated as to receive at least three tides—one primary and two derivative—whose respective times of high water are 1, 6, and 10, a succession which may well be supposed to neutralise any ebb, and maintain the water thereabout above its natural level, independent of tide.

About the Strait of Magalhaens, and along the eastern coast of Patagonia, there are very high tides; apparently complicated, but perhaps less so than is usually believed.

A powerful tide arrives at the Falklands, and at the east end of Staten Land, at about 9; which is opposed by another powerful tide arriving from the west. The union of these two accumulates the water between Tierra del Fuego and the Falklands, and on the east coast of Patagonia.

Within the Strait of Magalhaens, westward of the Second Narrow, it is high water at about 4.40, and the tide rises six feet: but eastward of the First Narrow it is high at 1.30, and the tide rises forty feet.

Now, as in one case the sea only rises three feet, and in the other twenty, above its mean level, every one would expect to find a rush of water through the Narrows, from the high sea to the low, and such is the fact. From ten to four the water runs westward with great velocity, and from four till ten it rushes eastward. During the first interval, from ten to four, the eastern body of water, between Tierra del Fuego and the Falklands, is above the mean level; and during the latter interval, from four till ten, it is below the mean level—that which it would have if there were no tides.

From 50° S. to near Blanco Bay in 40° S. the tide-wave certainly travels along the coast to the north; but this is a derivative from the meeting of tides above-mentioned, combined with the primary tides on the coast traversed. In this way principally may we account for a high tide in one place on this coast, and a low one on another (similarly situated, though differing in latitude); and, again, a high tide at another place. During the twenty-four hours that the deri-

© The Complete Work of Charles Darwin Online

vative wave occupies in moving from Cape Virgins to the Colorado, it alternately augments or diminishes two floods and two ebbs of the great ocean. Perhaps, indeed, it reaches farther and affects the water about the Plata.

The extraordinary 'races' about the Peninsula of San José, and the apparent absence of currents about the straight coast extending eastward from Blanco Bay, may be attributed to conflicting tidal impulses.

Why there should be no tide in the River Plata, situated and shaped as it is, seems extraordinary; but as it is high water at 6h. on the coast of Brazil, and at 9h. about Blanco Bay; and as a derivative wave from this neighbourhood must move eastward and northward, there is a filling up, from the southward, as an ebbing takes place in consequence of a regular six-hour tide; and vice versâ.

Tristan d'Acunha has a considerable rise of tide, about eight feet, though Ascension and St. Helena have only about two feet. The former place is affected by a great southern tide; the two latter are influenced by the comparatively small tide which traverses the space between Africa and Brazil.

In the West Indies there are varieties of tides, caused by primary and derivative impulses, exceedingly modified by local circumstances: none however are large, while some are as small as those of Otaheite—scarcely a foot at the utmost. There are places also in that archipelago where there is only one tide in twenty-four hours. In considering the West-India tides, those of the east coast of North America, and the exceedingly high ones of Fundy Bay, the gulf stream ought not to be overlooked, as it may affect the tides on the coasts it traverses even more than those on the Patagonian coast are altered by the current driven along it from near Tierra del Fuego.

I may here remark that Mr. Whewell was misled by inaccurate data respecting several times of high water, of material consequence to his cotidal lines. At the Western Islands he had $1\frac{1}{2}$ and $2\frac{1}{4}$, where there ought to have been $4\frac{1}{4}$, according to Mendoza Rios' tables, confirmed by the Beagle's observations; at Madeira he used $1\frac{1}{2}$, the time of the stream changing, instead of 4, the time of high water; at the Cape Verde Islands he took the time of low tide, instead of that of high water; his 5h. line is near Ascension, where the time of high water is 6.20; and his 2h. line is close to St. Helena, where the time is about five. The deficiency of data is so great, owing to mistaking

© The Complete Work of Charles Darwin Online

the turn of stream for the time of high water, and registering or calculating observations erroneously, that little dependence can be placed in at least one-third of those hitherto recorded. On this account chiefly, though partly to simplify the question, I have not hoped to be much nearer the mark than half an hour in this discussion, discarding fractions as much as possible, and attempting only to avoid errors of material consequence.

Looking at the Atlantic, as represented on a globe, we see that Newfoundland and the adjacent coasts are so placed as to receive tidal impulses from the Arctic Sea, North Atlantic Ocean, the tropical part of the North Atlantic and the gulf stream: besides which, no doubt, a derivative from the equatorial zone is felt there.

It is high water at the east side of the Atlantic, from the Canary Islands to Scotland, within an hour or two of the same time, on the salient points of the coast, namely, at about 4h.; and if the opposite coast were straight, like that of Chile, and uninfluenced by derivative tides or by currents, we might expect that it would be high water there at about 7h., allowing that the tide-wave moved as it is found to do generally. But it is high water at about 1h., from 30° to 40,° the times increasing northward from 40° N. to the Bay of Fundy, and also increasing southward from 50° N. to that bay, where, as every sailor knows, the tides rise higher than in any other part of the world. This sequence of times, each ending in about 43° N., the adjacent gulf stream, (an immense river in the ocean), and an accumulation of water in that corner higher than is known any where else, show that we cannot there expect to find data for tidal rules. In that quarter is evidently a marked exception, caused by the conflux of at least two primary tides, two derivatives, and a powerful current, aided by the peculiar configuration of the land.

In the Mediterranean it is supposed by many persons that there is no ebb and flow; but Captain Smyth, who surveyed so much of its shores, informs me that he found a tide, small certainly and apparently not governed by the moon, but regular. I have myself noticed a small rise and fall there; and the current, caused by tide, in the Faro of Messina, is well known.

As the moon passes over the Indian Ocean, the natural effect of her attraction must be to accumulate the waters, and draw the wave so caused after her, as in other places: but while that ocean is obey-

© The Complete Work of Charles Darwin Online

ing her power, and the wave is travelling toward the west, another wave is approaching from the Pacific—a wave which has been retarded in its passage—and its crest passes through the Indian archipelago, while the water would otherwise be falling at the western part of Torres Strait. At the same time, a derivative* wave moving northward along the west Australian coast, combines with the Pacific wave to raise a high tide about the north-west coast of Australia, where, if it were not for these auxiliaries, there would be low water at that time. Six hours afterwards, one body has ebbed toward the Pacific—the other southward, toward the then comparatively low ocean, south of Australia, and what—if Torres Straits were blocked up; and the water prevented from falling away toward the south—would be a high tide, is, in fact, low water. The tides in the two northern bays are derivatives, and move northward.

High water taking place at one time—within an hour—all along the east coast of Africa, shows that the rise of sea, or tide-wave, there moves westward or eastward, and the times of high water at the islands are farther confirmations; for the wave is at Chagos and at the Mauritius three or four hours before it is high water on the African coast. The Keeling time shows that there the water rises longer, in consequence of that part of the ocean being affected by the advancing swell of the Pacific.

The only remaining particular case which I now recollect is that of the south coast of Australia—from King George Sound to Spencer Gulf—a large space of sea, in which there is very little rise of tide—and even that little very irregular.

As the high water moves westward from the meridians of that great bay, a tide moves southward from the Indian archipelago, where it is high water just as it should be low in the bay mentioned: hence there is a filling, or flowing, from one wave, while another is retreating. In this wide expanse, affected by derivative tides from three adjoining oceans, we cannot but expect irregularities; either very high tides, caused by combination—or little or no tide, in consequence of mutual destruction—one tide ebbing from, while another is flowing toward the same place.

Throughout these remarks I have intentionally omitted to say much of the sun's action, because, though very inferior, it is simi-

* Derived from a great southern wave passing westward.

© The Complete Work of Charles Darwin Online

lar to that of the moon. Perhaps the Otaheite tide may be purely solar; this, however, is not at all certain.

It appears to me probable, that many important currents are caused by the tidal libration or oscillation of the sea. As the earth turns only one way, the moon is continually pulling, as it were, in one direction, and to this cause, I think, most of the greater currents may be traced. Wind, evaporation, and the variable weight of the atmosphere may each have a share in moving the waters horizontally; but there are many facts which lead to a conclusion that the moon and sun are principal agents in causing currents.*

Having alluded to the effect of atmospheric pressure on the ocean, I will take this opportunity of mentioning that the chief cause of water rising on the shore before hurricanes, or gales of wind, may be the lightened pressure on the surface of the sea, indicated by the mercury being low in a barometer. This is very remarkable at the Mauritius and in the river Plata, at both which places the water rises unusually before a storm, while at the same time the mercury falls. As the column rises, so the water falls again. I have instanced those places as being well known, and affected very little by tide: but the fact has been observed by me in many places during the Beagle's voyage, and I have besides collected the testimony of others respecting it.

These causes may materially affect the height of tides and the strength of currents. In the wide but shallow Plata, the depth of water and nature of current varies in extraordinary accordance with the barometer.

Another cause of the water rising before a high wind, or storm, as well as of a ground swell, of rollers, or of that disturbed tumultuous heaving of the sea, sometimes observed while there is little or no wind at the place, may be the action of wind on a remote part of that sea; an action, or pressure, which is rapidly transmitted, through a fluid but slightly elastic, to regions at a distance.

I have collected many instances of rollers, or a heavy swell, or a confused ground swell being felt at places, where not only there was no wind at the time, but to which the wind that caused the move-

* A continued stream may be produced by a succession of impulses, as a rotatory system of waves may "be kept in constant circulation by impulses received from the adjacent tides."—See Whewell in Phil. Trans. 1836, p. 299.

© The Complete Work of Charles Darwin Online

ments of water never reached. That they were caused by wind I proved by the logs of ships, which were in the respective gales at the time their effects on the sea were thus felt at a great distance. The places to which I particularly allude are the Cape Verde Islands, Ascension, St. Helena, Tristan d'Acunha, Cape Frio, Tierra del Fuego, Chiloe, the coast of Chile, the Galapagos Islands, Otaheite, the Keeling Islands, Mauritius, and the Cape of Good Hope.

Waves, or rollers, caused by earthquakes, or volcanic eruptions, are, of course, unconnected with wind or atmospheric pressure.

But in accounting for currents, as occasioned in some if not many instances by tidal pressure, or a succession of tidal impulses, we must not overlook the well known power of wind in giving horizontal motion to water, as well as in elevating or depressing it.

Wind blowing almost always in one direction is known to communicate a movement to waters, and it is remarkable that the general movements of the North Pacific as well as the North Atlantic are from west by the north to east, or, as a sailor would say, 'with the sun;' while in the southern oceans, Pacific, Atlantic, and Indian, they are generally 'against the sun,' or from west to east by the south—both corresponding to the general turn of the winds in the respective hemispheres. The Chile current after coasting Peru, preserves a temperature of about 60° up to the Galapagos, and there it meets a warm stream out of the Gulf of Panama, at a temperature of about 80°. The two unite together and turn westward along the equatorial zone. There is a remarkable exception on the east coast of Patagonia, where the current sets northward, owing, probably to tides.

I cannot end this imperfect attempt to sketch out some of the movements of ocean, without reminding young readers to whom the subject may not be so familiar as it is to others, that there may be circulations of water in a vertical direction, or in a plane inclined to the horizon, as well as horizontally: and that bodies of water differing in temperature, as well as in chemical composition, do not hastily blend together. Their reluctance to mix is observable at sea, when we sail out of one current, or body of water, into another—differing perhaps in temperature, chemical composition, and colour. At the meeting, or edge, of such bodies there is usually a well defined line, often considerable ripplings, which indicate some degree of mutual horizontal pressure—as of separate masses.

© The Complete Work of Charles Darwin Online

At the mouths of large rivers it sometimes happens that salt water is actually running up the river, underneath a stream of fresh water which still continues to run down. This I have witnessed in the river Santa Cruz. Of course intermixture takes place gradually, though by slow degrees.

The height of waves may be here mentioned, with reference to rollers or other undulations of water however caused. Large waves are seldom seen except where the sea is deep and extensive. The highest I have ever witnessed myself were not less than sixty feet in height, reckoning from the hollow between, perpendicularly to the level of two adjacent waves: but from twenty to thirty feet is a common height in the open ocean during a storm.

I am quite aware of, and have long been amused by the assertion of some persons, whose good fortune it has been not to witness really large waves—that the sea never rises above twelve or fifteen feet—or, that no wave exceeds thirty feet in height, reckoning in a vertical line from the level of the hollow to that of the crest.

In H. M. S. Thetis, during an unusually heavy gale of wind in the Atlantic, not far from the Bay of Biscay, while between two waves, her storm try-sails were totally becalmed, the crest of each wave being above the level of the centre of her main-yard, when she was upright between the two seas. Her main-yard was sixty feet from the water-line. I was standing near her taffrail, holding by a rope. I never saw such seas before, and have never seen any equal to them since, either off Cape Horn or the Cape of Good Hope.

Calculations of tides, applicable to the method of following out Newton's general principles, adopted by Mr. Whewell and most persons whose opinions on this subject all men respect—are equally applicable to the view here taken. In either case the time of high water, and rise of tide on a certain day, is ascertained at a given place experimentally: and as the causes of that tide are the moon and the sun; changes in their position with respect to the earth will operate changes in the tides, which, as to time and quantity, will depend upon the above data, and the positions of earth, moon, and sun.

The variation of tide is what we have to deal with in ordinary calculation, not the original movement.

No. 48.

Previous to sailing from England in 1831, the Beagle was fitted with the permanent lightning conductors invented by Mr. Wm. Snow Harris, F.R.S.

During the five years occupied in her voyage she was frequently exposed to lightning, but never received the slightest damage, although supposed to have been struck by it on at least two occasions, when—at the instant of a vivid flash of lightning, accompanied by a crashing peal of thunder—a hissing sound was heard on the masts; and a strange, though very slightly tremulous, motion in the ship indicated that something unusual had happened.

The Beagle's masts so fitted, answered well during the five years' voyage above-mentioned, and are still in use on board the same vessel, on foreign service.

Even in such small spars as her royal masts and flying jib-boom, the plates of copper held their places firmly, and increased rather than diminished their strength.

No objection which appears to me valid, has yet been raised against them; and were I allowed to choose between having masts so fitted and the contrary, I should not have the slightest hesitation in deciding on those with Mr. Harris's conductors.

Whether they might be farther improved, as to position and other details, is for their ingenious inventor to consider and determine. He has already devoted so many years of valuable time and attention to the very important subject of defending ships against the stroke of electricity; and has succeeded so well for the benefit of others—at great inconvenience and expense to himself—that it is earnestly to be hoped that the Government, on behalf of this great maritime country, will, at the least, indemnify him for time employed and private funds expended in a public service of so useful and necessary a character.

MEMORANDUM OF SOME OF THE FRESH PROVISIONS, PROCURED FOR THE BEAGLE'S CREW, BETWEEN 1831 AND 1835.

Many other animals and birds were shot at various places (besides those enumerated in this list), by which every one on board

© The Complete Work of Charles Darwin Online

profited in turn. Fish were caught frequently, either with nets or lines, sometimes with both; so that, except in long passages, the crew of the Beagle were seldom many weeks without a supply of fresh and wholesome food; while the provisions carried on board were always of the best quality that could be procured.

Number and Weight of the Animals killed with two Rifles only.

No. 52.

In pp. 228-9 of vol. ii, it is stated, "In 1501-2 Americus Vespucius, then employed by the King of Portugal, sailed six hundred leagues south, and one hundred and fifty leagues west, from Cape San Agostinho (lat. 8° 20′ S.) along the coast of a country then named Terra Sanctæ Crucis. His account of longitude may be very erroneous, but how could his latitude have erred thirteen degrees in this his southernmost voyage?"

Since those pages were printed, I have obtained a perfect copy of the four voyages of Americus Vespucius, written in Latin; and I now hasten to correct any erroneous impression which might arise out of my having asserted that Vespucius "could not have explored farther south than the right bank of La Plata."

By the subjoined extracts from the third voyage of Vespucius, it appears that he sailed to about fifty-two degrees of south latitude; and near that latitude discovered land:—which I have no doubt whatever was Georgia.

These extracts are not only verbally but literally copied from the original: every passage which can throw even the slightest light upon dates, times, courses, distances or positions, is here given; the portions of the narrative which are omitted relate solely to what Vespucius saw on the land. According to his narrative, he went to the Canaries, thence to the coast of Africa near Cape Verde; from which place he sailed to the coast of Brazil, near, but to the westward of Cape St. Roque; thence he worked to windward against the current, till he reached Cape San Agostinho; and from that point he coasted to about the River Grande, in thirty-two south. From this port, whether the River Grande or a place near it, Vespucius steered to the south-east (per Seroccum) five hundred leagues; found the south pole elevated fifty-two degrees, the night fifteen hours long, the cold excessive, a high sea, a succession of tempestuous weather, and land precisely like Georgia, but not at all resembling any part of the Falklands. Georgia lies somewhat farther south than the latitude mentioned (being in 54°—55°); but we should take into consideration the instruments used at sea in 1502; the all but utter ignorance of southern stars; and the succession of bad weather encountered by Vespucius about the time of his seeing land near 52° S.

© The Complete Work of Charles Darwin Online

From this latitude he sailed thirteen hundred leagues towards the north and north-east, and arrived at Sierra Leone; whence he went to the Azores and to Lisbon.

The internal evidence contained in the narrative of this voyage affords satisfactory proof of its authenticity. Whether the design of Vespucius was to seek for southern land, or endeavour to sail to 'Cathay' by the shortest line (the arc of a great circle), does not appear: but as we know he was skilled in mathematics and of an enterprising character, such a conjecture as the latter may be not totally improbable.

Navigatio tertia Americi Vesputii.

"Igitur ab hoc Lisbonæ portu cum tribus conservantiæ navibus die Maii decima MDI abeuntes, cursum nostrum versus magnæ Canariæ insulas arripuimus, secundum quas et ad earum prospectum instanter enavigantes, idem navigium nostrum collateraliter secundùm Aphricam occidentem versus sequuti fuimus."

No. 53.

BAROMETRIC OBSERVATIONS IN THE RIVER SANTA CRUZ.

Before leaving the Beagle, to explore part of the river, two mountain barometers, afterwards carried in the boats, were suspended on shore, close to the sea, and compared with a barometer on board the ship, the cistern of which instrument was at the level of the sea.

© The Complete Work of Charles Darwin Online

After returning from exploring part of the river, both mountain barometers were again similarly compared, and the difference between the best instrument and that fixed on board was found to be the same as before, namely, 0,19 inch. At sunrise on the 5th of May, at the westernmost station reached by the boats, the mountain barometer which was preferred showed 29,81 (β'); the thermometers, attached, and detached, 44° Fahrenheit; and the cistern of the instrument was one foot above the level of the river. At the same time (allowing the difference of longitude) the barometer on board the Beagle showed 30,07 (β); while the attached thermometer showed 44°, and the detached 43°.

The rise of tide that morning at the ship was twenty-one feet, and it was high water at thirty minutes past seven, A.M.

By Baily's rule—*

$B = 0{,}00000$ (subtract 0,19 from 29,81)

$\log.\ \beta' = 1{,}47159$

$1{,}47159$

$\log.\ \beta = 1{,}47813$

$D = 0{,}00654$ - - - $\log = \overline{7}{,}81558$

$c = \overline{9}{,}99980$

$A = 4{,}79207$

$405 = 2{,}60745$

$+\ 7$

412 feet.

Half-tide 10,5 feet.

$-\ 2{,}5$

8

$-\ 1$

7

Hence the western station appears to be about four hundred and twelve feet above the level of the eastern—that of the Beagle:—but other pairs of observations were made during the previous and following days (May 4th and 6th) of which the results, similarly deduced, were 464, 501, 527, 487, 497, 434, and 436;—each considerably above 400 feet: and as that part of the river (the western station) is about two hundred miles from the sea, the fall, on an average, cannot be less than two feet in each mile.

No. 54.

A FEW NAUTICAL REMARKS.

Without extending this work to an unwieldy size, it would be impossible to give particular descriptions of, or sailing directions for, half the anchorages surveyed by the Beagle and her consorts. I can here only allude to some which are least easy of access; and for details concerning the rest, I must ask the reader to refer to Captain King's Sailing Directions, published by the Admiralty in 1832; and, hereafter, to a similar work, which I am compiling.

In approaching or entering any port between the southern coast of Brazil and Tierra del Fuego,* both leads and charts must be closely attended to, tides and currents must be well considered, and the colour, as well as rippling of the water, narrowly watched. Generally speaking, much of this extent of coast is comparatively shallow, and beset with insidious dangers in the shape of banks and currents. Where rocks occur they are less to be feared, because their position is, in most cases,† pointed out by kelp.‡ Some of the banks are particularly dangerous, being exceedingly steep-sided and hard. Where there is a strong stream or great rise of tide, or where both are found, the risk of approaching such banks is proportionably increased.

Of the River Plata I have spoken briefly in Chapter IV., and of Blanco Bay there is a slight description in Chapter V. of the second volume.

Before entering Port Belgrano (within Blanco Bay), or any similar port, such as False Bay, Green Bay, Brightman Inlet, Union Bay, &c. I should advise anchoring, and ascertaining the ship's position exactly, sending a boat to find the middle of the principal entrance, and there dropping a buoy with a good anchor. If the weather is at all hazy, no marks on the distant low land will be made out by a stranger, until he has had time to take a few angles, look round from the masthead, and examine the chart leisurely. These things cannot be so well done while the ship is sailing fast; she may, however, be brought to for a time.

* Except at the Falklands.

† That in the entrance of Port Desire is a notable exception to the general rule

‡ Seaweed growing in rocky places.

© The Complete Work of Charles Darwin Online

The Falkland Islands, Tierra del Fuego,* the west part of Patagonia, the shores of the Chonos Archipelago, and Chiloe,† those of Chile and Peru, and the Galapagos Islands, have bold coasts, with deep water near them;—in such places the lead is of less importance. Most lurking dangers are buoyed by kelp; but where they are not so distinguished, the lead would hardly warn the seaman of them, because rocks usually rise so abruptly. A careful and experienced eye at the masthead, another perhaps on the fore-yard or at the jib-boom end, a manageable quantity of sail, under which the vessel may be instantly brought to the wind or hove in stays, and a good estimation of distances by the commanding officer will be of more consequence in frequenting these coasts, than either lead or directions. San Carlos and the Narrow of Chacao are remarkable exceptions. Both banks and rocks are there to be guarded against—by chart, eye, and lead, however, rather than by lengthy directions, which sometimes perplex more than they assist. Of these a particular plan is given in the map which accompanies the first volume of this work.

Remarks upon the winds, weather, and climate of each of the southern portions of the South American coast have already been given in various pages of this work; but I will add some more, referring particularly to the outer coast of Tierra del Fuego, previous to saying a few words on the passage round Cape Horn.

Some Observations upon the Appearance and Character of the Sea Coast of Tierra del Fuego; a brief Description of the Anchorages; and a few Remarks upon the Seasons, Wind, and Weather.

From Cape Pillar to Cape Horn the coast of Tierra del Fuego is very irregular and much broken; being, in fact, composed of an immense number of islands. It is generally high, bold, and free from shoals or banks; but there are many rocks nearly level with the surface of the water, distant two and even three miles from the nearest shore, which make it very unsafe for a vessel to approach nearer than five miles, excepting in daylight and clear weather. The coast varies in height from eight to fifteen hundred feet above the sea.

* Except the northernmost and the eastern shores.

† Except San Carlos de Chiloe.

© The Complete Work of Charles Darwin Online

Farther inshore are ranges of mountains always covered with snow, whose height is from two to four thousand feet, and in a few instances about six or seven thousand.

With daylight and clear weather a vessel may close the shore without risk, because the water is invariably deep, and no rock is found, which is not so marked by sea-weed (or kelp as it is generally called), that by a good look-out at the mast-head, its situation is as clearly seen as if it were buoyed. By avoiding kelp you are sure of having sufficient water for the largest ships on any part of this coast. At the same time, it must be remembered that kelp grows in some places from a depth of thirty fathoms, and that on many parts of this coast you may pass through thick beds of sea-weed without having less than six fathoms water; still it is always a sign of danger, and until the spot where it grows has been carefully sounded, it is not safe to pass over it with a ship. As an instance;—after sounding a large bed of this weed in one of the Beagle's boats, and thinking it might be passed safely, a rock was found, not more than four feet in diameter, having only one fathom water over it.

Viewing the coast at a distance, it appears high, rugged, covered with snow, and continuous, as if there were no islands. When near you see many inlets which intersect the land in every direction, and open into large gulfs or sounds, behind the seaward islands: and you then lose sight of the higher land, which is covered with snow throughout the year, and find the heights close to the sea thickly wooded towards the east, though barren on their western sides, owing to the prevailing winds. These heights are seldom covered with snow, because the sea winds and the rain melt it soon after it falls.

Opposite to the eastern valleys, where the land is covered with wood, and water is seen falling down the ravines, good anchorage is generally found. But these valleys are exposed to tremendous squalls which come from the heights. The best of all anchorages on this coast is where you find good ground on the western side of high land, and are protected from the sea by low islands. It never blows near so hard against high land as from it; but the sea on the weather side is of course very formidable, unless stopped, as I mentioned, by islets.

Where the land is chiefly composed of sandstone or slate, anchorages abound; where of granite, it is difficult to strike soundings.

The difference between the granite and slate or sandstone hills, can be distinguished by the former being very barren and rugged,

© The Complete Work of Charles Darwin Online

and of a grey or white appearance; whereas the latter are generally covered with vegetation, are dark-coloured, and have smoother outlines. The slate hills shew some sharp peaks, except which, the only bare places are those exposed to wind or sea.

Soundings extend about thirty miles from the coast. Between ten and twenty miles from the land, the depth of water varies from sixty to two hundred fathoms; the bottom almost every where being white or speckled sand. From ten to five miles distant, the average depth is fifty fathoms; it varies in general from thirty to one hundred, but in some places there is no ground with two hundred fathoms of line. Less than five miles from the shore the soundings are very irregular indeed, generally less than forty fathoms, though in some places deepening suddenly to one hundred or more; while in others a rock rises nearly to, or above the surface of the water.

After carrying fifty, forty, thirty, or twenty fathoms, towards an inlet, which you are desirous of entering, you will perhaps find the water deepen to sixty or one hundred fathoms as soon as you enter the opening: and in the large sounds, behind the seaward islands, the water is often considerably deeper than on the outside.

There is a bank of soundings along the whole coast, extending from twenty to thirty miles from it, which appears to have been formed by the continued action of the sea upon the shore, wearing it away, and forming a bank with its remains.

Between the islands, where there is no swell or surf worth notice, the water is deep, and the bottom very irregular.

A small ship may run among the islands in many places, and find good anchorage; but she will enter a labyrinth, from which her retreat may be difficult, and in thick weather very dangerous.

Fogs are extremely rare on this coast; but thick, rainy weather, and strong winds prevail. The sun shews himself but little; the sky, even in fine weather, being generally overcast and cloudy. A clear day is a rare occurrence.

Gales of wind succeed each other at short intervals, and last several days. At times the weather is comparatively fine and settled for perhaps a fortnight, but those periods of quiet are few.

Westerly winds prevail during the greater part of the year. The easterly wind blows occasionally in the winter months, and at times very hard, but it seldom blows in summer.

Winds from the eastern quarter invariably rise light, with fine

© The Complete Work of Charles Darwin Online

weather; they increase gradually, the weather changes, and at times they end in a determined heavy gale. More frequently they rise to the strength of a treble-reefed topsail breeze, then die away gradually, or shift to another quarter.

From the north the wind always begins to blow moderately, but with thicker weather and more clouds than when from the eastward: it is generally accompanied by small rain. Increasing in strength, it draws to the westward gradually, and blows hard from between north and north-west, with heavy clouds, thick weather, and much rain.

When the fury of the north-wester is expended, which varies from twelve to fifty hours, or even while it is blowing hard, the wind sometimes shifts suddenly into the south-west quarter, blowing harder than before. This wind soon drives away the clouds, and in a few hours causes clear weather, though perhaps with heavy squalls passing occasionally.

In the south-west quarter the wind (generally speaking) hangs several days, blowing strong, but moderating towards the end, and admitting two or three days of fine weather.

Northerly winds then usually begin again, during the summer months; but all manner of shifts and changes are experienced, from north to south by the west, during that season; which would hardly deserve the name of summer, were not the days so much longer, and the weather a little warmer. Rain and wind prevail during the long, much more than in the short days.

It should be remembered that bad weather never comes on suddenly from the eastward, neither does a south-west or southerly gale shift suddenly to the northward. South-west and southerly winds rise suddenly as well as violently, and must be well considered in choosing anchorages, or preparing for shifts of wind at sea.

The most usual weather in these regions is a fresh wind between north-west and south-west, with a cloudy overcast sky.

Much difference of opinion has prevailed as to the utility of a barometer in these latitudes. I may remark, that during some years' careful trial of a barometer and sympiesometer (Adie's), I found their indications of the utmost value. Their variations did not of course correspond to those of middle latitudes, but they corresponded to those of high northern latitudes in a remarkable manner, (changing south for north, east and west remaining the same).

Gales of wind from the southward, and squalls from the south-

© The Complete Work of Charles Darwin Online

west, are preceded, and therefore foretold, by heavy banks of large white clouds rising in those quarters, having hard edges, and appearing very rounded and solid.

Winds from the northward and north-westward are preceded and accompanied by low scud clouds, with a thickly overcast sky, in which other clouds appear to be at a great height. The sun shews dimly through them, and has a reddish appearance. For some hours, or a day before a gale from the north, or west, it is not possible to take an altitude of the sun, although he is visible; the haziness of the atmosphere in the upper regions causing his limbs to be quite indistinct. Sometimes, but very rarely, with the wind light between N.N.W. and N.N.E. there are a few days of beautiful weather: but they are sure to be succeeded by gales from the southward, with much rain.

It may be useful to say a few words regarding the seasons in the neighbourhood of Cape Horn, as much question has arisen respecting the propriety of making a passage round the Cape in winter rather than in summer.

The equinoctial months are the worst in the year, generally speaking, as in most parts of the world. Heavy gales prevail about those times, though not perhaps exactly at the equinoxes. In August, September, and October, there is usually very bad weather; strong winds, snow, hail, and cold, then prevail.

December, January, and February, are the warmest months; the days are long, and there is some fine weather; but westerly winds, at times very strong gales, with much rain, prevail throughout this season, which carries with it less of summer than in almost any part of the globe.

March, as I said, is stormy, and perhaps the worst month in the year, with respect to violent winds, though not so rainy as the summer months.

In April, May, and June, the finest weather is experienced; and though the days are short, it is more like summer than any other time of the year. Easterly winds are frequent, with fine, clear, settled weather. But bad weather occurs during these months, though not so often as at other times. During this period there is some chance of obtaining a few successive and corresponding observations. To try to rate chronometers by equal altitudes would be a fruitless waste of time at other seasons.

© The Complete Work of Charles Darwin Online

June and July are much alike, but easterly gales blow more during July. The days being so short, and the weather cold, make these two months very unpleasant, though they are, perhaps, the best for making a speedy passage to the westward, as the wind is then prevalent from the eastern quarter.

I should say that December and January are the best for making a passage from the Pacific to the Atlantic Ocean, though that passage is so short and easily made, that it hardly requires a choice of time. For going to the westward, I should prefer April, May, or June, and should wait for a wind.

Lightning and thunder are seldom known: violent squalls come from the south or south-west, giving warning of their approach by masses of clouds. They are rendered more formidable by snow and hail of a large size.

There is a continual current setting along the south-west coast of Tierra del Fuego, from the north-west towards the south-east, as far as the Diego Ramirez Islands. From their vicinity the current takes a more easterly direction, setting round Cape Horn towards Staten Island, or off to seaward to the E.S.E.

Much has been said of the strength of this current; some persons supposing that it is a serious obstacle in passing to the westward of Cape Horn, while others almost deny its existence.

We found it run at the average rate of a mile an hour. Its strength is greater during west,—less or insensible during easterly winds. It is strongest near the land, particularly near the projecting capes or detached islands.

This current sets rather from the land, which diminishes the danger of approaching the south-west parts of the coast: but there is, in fact, much less risk in approaching this coast than is generally supposed. Being high and bold, without sandbanks or shoals, its position accurately determined, and a bank of soundings extending twenty or thirty miles from the shore, it need not be much feared. Rocks, it is true, abound near the land, but they are very near to the shore, and out of a ship's way.

A line from point to point along the coast (beginning from the outermost Apostle), will clear all danger, excepting the Tower Rocks, which are steep to, and high above water.

The preceding notices were written by me in 1830, and I have not found it necessary to alter them materially. Taken in connection with

© The Complete Work of Charles Darwin Online

Capt. King's, Chapt. 24, in Vol. 1, and the following brief remarks, I hope they may prove useful to a stranger to the passage round Cape Horn: but he will doubtless avail himself also of what has been written on this subject by other persons, especially Weddell.

In going westward, Captain King recommends keeping near the eastern coast of Patagonia, and "after passing Staten Island, if the wind be westerly, the ship should be kept upon the starboard tack, unless it veer to the southward of S.S.W. until she reaches the latitude of 60° S."—(vol. i. pp. 464-5.) I do not think keeping near the eastern coast of Patagonia of importance to a large or strong vessel; smoother water is found near that coast, it is true, but currents set to the northward alongshore more strongly than in the open sea. Icebergs, however, are never found in sight of that land, though they have been met farther eastward, to the north of forty degrees south latitude. Instead of going into sixty, south latitude, I should prefer working to windward, near the shore of Tierra del Fuego;—through Nassau Bay; where anchorages are numerous, and easy of access.

In Orange Bay, or farther south, a ship may await a favourable time for making a long stretch to the westward: if foiled in one effort, she may return, or seek for anchorage under Noir Island, in Euston Bay, or elsewhere, until a better opportunity occurs. To make westing ought to be the principal object, in my humble opinion, till the meridian of about 82° is reached.* Icebergs are not found near the land of Tierra del Fuego, but they are frequently met with at a distance from it.

By adopting this plan of passing through Nassau Bay, or near Cape Horn, much labour and damage may be avoided, because a ship may lie quietly at anchor during the worst weather, and be ready to profit by any advantageous change.

* Eighty degrees will be far enough west for a fast-sailing ship; but eighty-five degrees will not be too westerly for a dull sailer.

No. 55.

REMARKS on the Chronometrical Observations made during the Surveying Voyages of H. M. Ships Adventure and Beagle, between the years 1826 and 1836.

Before I proceed to notice the chronometrical observations made during the Beagle's latter voyages, from 1831 to 1836, it appears to me necessary to give a copy of Captain King's Report of those made under his direction between 1826 and 1830.

Copy of a Report of the Chronometrical Observations made during a Voyage for the purpose of surveying the southern extremity of America, in H.M. Ships Adventure and Beagle, between the years 1826 and 1830, under the orders of Captain P. P. King, by direction of the Right Honourable the Lords Commissioners of the Admiralty.

Among the important objects to which my attention was directed by the Lord Commissioners of the Admiralty, upon my appointment to the command of the Expedition for the survey of the southern part of South America, was that of measuring the differences of certain meridians in the north and south Atlantic Oceans by means of chronometers; and for this purpose I was supplied from the Royal Observatory at Greenwich with nine chronometers; eight of which, at the suggestion of the Astronomer Royal, were suspended in gimbals, and divided into two boxes; and the ninth, an eight-day box-watch, was fitted in the usual manner. The whole were fixed in a chest that was firmly secured to the deck as low down as possible, and as near to the middle part of the ship as could be managed, in order to diminish the effect of the ship's motion, and to counteract that of the ship's local attraction, which, whatever it might have been, always remained the same, as the chronometers were never moved from their positions.

These nine chronometers were made by Mr. French. Their description and number were as follows:—

Eight-day box chronometer,	No.	3233	designated	Z
Two-day	.....	3296	.....	A
Two-day	.....	3295	.....	B
Two-day	.....	3271	.....	C
Two-day	.....	3227	.....	D

in one box.

© The Complete Work of Charles Darwin Online

One-day box chronometer,	No. 3290	designated	E		
One-day	.....	3291	.....	F	in
One-day	.....	3292	.....	G	one box.
One-day	.....	3293	.....	H	

Z had been going at the Observatory for many months, and had preserved a very regular rate, but all the others were quite new, and had scarcely settled to a steady rate when I received them.

In addition to the above I was furnished with a pocket chronometer, No. 553, by Mr. Murray. This watch had been at the Observatory for several months, and had performed remarkably well: and before I sailed Messrs. Parkinson and Frodsham intrusted to my care for trial a pocket chronometer, No. 1048, that was only completed in time to be sent to me two days before the Expedition sailed from Plymouth. Mr. French also lent me a pocket-watch to use for observing with, in order that the rest might not be unnecessarily moved.

In the Beagle were three excellent box chronometers. Two by Messrs. Parkinson and Frodsham, Nos. 254 and 228, which had been used in the Polar Voyages; and the third, No. 134, made by Mr. M'Cabe.

The means, therefore, that were placed at my command to effect this most interesting object were tolerably ample: and the result will prove how admirably these machines are adapted to measure such differences when a great number are employed; because the irregularities and errors of individual watches are compensated for by employing the mean of the whole.

In the observations for the determination of time, a sextant by Troughton, No. 1140, and an artificial horizon, were the instruments used: and the mode, whenever it could be adopted, was that of corresponding altitudes. Occasionally, however, absolute altitudes were used, but only in those places where the latitude was correctly ascertained;—and in some instances the chronometers were rated by a transit instrument.

The chronometers were always compared with the 'journeyman' watch before and after the observations, and when corresponding altitudes were observed all the watches were compared at noon. Their rates were carefully observed before sailing from one port, as well as after the arrival at another; and in calculating the acceleration or retardation of their rate of going, the correction was obtained by interpolation, upon the supposition of their having changed gradually. Whenever it appeared, by comparing the watches with each other,

© The Complete Work of Charles Darwin Online

that any one had suddenly varied from its rate, its result was omitted in the determination.

The method of interpolating for the alteration of the rates which I have adopted, is one that was successfully employed by Captain Flinders in his survey of New Holland; and one that I have been for many years in the habit of using with most satisfactory results. In cases where chronometers alter their rates suddenly, the rule cannot be applied; but, in general, the alterations are caused by changes of temperature; and as these changes are gradual, so the rates alter in the same progressive manner.

The correction has, therefore, been obtained by an arithmetical progression; in which the first term, the number of terms, and the common difference, are given to find the sum of the terms.

The difference between the two rates divided by the number of days that have intervened, called the daily variation of rate, is the first term F; as well as the common difference D: the interval between the determination of the errors of the watches, in mean time, of the place left and arrived at, is the number of terms N: and the sum of the terms is the correction required, S. The formula, when reduced to its simplest form, is $F\,(N+1)\,\frac{N}{2}=S$.

The places which I was instructed to visit for the purpose of measuring their respective meridional differences were Madeira, Santa Cruz in the island of Teneriffe, the north-east end of San Antonio, and Port Praya in the island of St. Jago, in the North Atlantic; and the island of Trinidada, Rio de Janeiro, and Monte Video, in the South Atlantic Ocean.

After the chronometers had been carefully rated at the Observatory, they were embarked on board H.M.S. Adventure, on the 23rd April, 1826; but as the ship was detained at Deptford and Northfleet until the 4th May, an opportunity was offered of ascertaining what change had been produced by the alteration of the place; and it turned out to be by no means inconsiderable. Five of the watches had accelerated, and the remaining four had retarded rates. It would be difficult to assign any other reason for this change than the effect of the ship's local attraction.

With this newly found rate we sailed for Plymouth; and, after five days' passage, arrived in the Sound; and, on the 9th May, obtained a set of corresponding altitudes upon the Breakwater, upon a stone marked $\frac{430}{1}$; which, by the Ordnance map, is $0'\,31''{\cdot}5$ in longi-

© The Complete Work of Charles Darwin Online

tude to the eastward of the flag-staff of Drake's Island; 10″ 2 to the westward of Plymouth old church, and 0′ 25″·1 to the westward of the new church. The longitude, therefore, of the station, by the Ordnance survey, would be 4° 7′ 41″·7, but by applying a proportion of the error detected by Dr. Tiarks, in his chronometrical observations between Greenwich and Falmouth, viz., 4″·09 or 1′ 11″·3, the corrected longitude of the station will be 4° 8′ 43″. Our chronometers made it 0′ 40″·2 to the eastward of the corrected longitude, and 0′ 19″·6 to the westward of the original determination by the Ordnance survey.

The Breakwater being the point from whence all my differences are measured, I have considered its longitude west of Greenwich to be as above stated, namely, 4° 8′ 43″.

It now remains to record the results, the details of which are given in another form.*

Madeira.—The observations were made at Mr. Veitch's garden-house, that being the spot used by Dr. Tiarks with ten chronometers. The difference between it and the Breakwater is 12°45′45″ west: the longitude will therefore be .....16° 54′ 28″ W. which is 0′17″·4 to the eastward of Dr. Tiarks's determination.

Teneriffe (Fort San Pedro)—by eleven chronometers is 0° 40′ 6″ to the eastward of Madeira, and will therefore be ...16°14′ 22″ W.

St. Jago (landing place at Port Praya)—by ten chronometers it was found to be 7° 15′ 55″ west of Teneriffe, and therefore.....23° 30′ 17″

Rio de Janeiro (Villegagnon Island)—by fourteen chronometers the difference was found between it and Port Praya to be 19° 34′ 46″ which will make its longitude.....43° 05′ 03″

St. Antonio (Terrafal Bay at the south-west end).—In consequence of unfavourable weather we were unable to land at the north-east end, and, therefore, made our observations at Terrafal Bay; the longitude of which was found by eleven chronometers to be 9° 05′ 39″ to the westward of Teneriffe which makes it .....25° 20′ 01″

Trinidada.—On account of the south-east trade being scant, we were prevented from making this island.

Monte Video (Rat Island).—The difference of longitude between this place and Rio de Janeiro was measured, on various occasions,

* These details are lodged in the Hydrographical Office. R. F.

© The Complete Work of Charles Darwin Online

between the years 1826 and 1830; and in the whole 62 different results were obtained, the mean of which makes it 13° 4′ 27″ west of Villegagnon Island, or.....56° 9′ 30″

Gorriti (well at the north-east end) is 1 15′ 51″, by twenty-four chronometrical results, to the eastward of Rat Island, Monte Video, or.....54° 53′ 38″

Cape St. Mary is.....54° 5′ 58″

Buenos Ayres (Cathedral).—By three chronometers is 2° 8′ 24″ west of Rat Island, Monte Video, or.....58° 17′ 53″

Port Famine (Observatory at the west side of the bay).—The meridional difference between this place and Rat Island at Monte Video was also found on the several occasions of the ships passing to and fro. In all, 54 chronometrical results were obtained, the mean of which makes the Observatory 14° 44′ 31″ to the westward, or.....70° 54′ 01″

Port Desire (Ruins of the Spanish colony).—Fifteen chronometrical results make it 9° 42′ 15″ to the west of Rat Island, Monte Video, or..... 65° 51′ 45′′

Sea Bear Bay (Sandy beach on the south side of the bay)—is 7′44″ east of Port Desire, and therefore .....65° 44′ 01″

St. Martin Cove, near Cape Horn (the head of the cove).—Twelve chronometers made its longitude 11° 19′ 33″ west of Rat Island, Monte Video, or.....67° 29′ 03″

Valparaiso (Cerro Alegre).—This place was found by seven chronometers to be 4° 3′ 48″ to the westward of St. Martin Cove, or 71° 32′ 51″ west of Greenwich, but between it and Port Famine the difference being by ten chronometers 0° 41′ 8″ or 71° 35′ 9″ west, the mean has been taken, viz.....71° 34′ 12″

Juan Fernandez (Cumberland Bay, the fort).—This place was found by nine chronometers to be 7° 11′ 52″ west of Valparaiso, which makes it .....78° 46′ 04″

Talcahuano Bay (Fort Galvez).—By eleven chronometers the difference between it and Valparaiso is...1° 28′ 53″ or 73° 03′ 05″

San Carlos de Chilóe (Sandy Point).—The point which is opposite to the town is, by twenty chronometrical results, 2° 16′ 13″ west of Valparaiso, or.....73° 50′ 25″

The above are the principal chronometrical determinations that were made: the following are dependant on them:—

© The Complete Work of Charles Darwin Online

Santos (the Arsenal).—By twelve chronometers this place is 3° 11′ 31″ west of Rio de Janeiro, or .....46° 16′ 33″

St. Catherine (Flag Staff of S^{ta}. Cruz D'Anhatomirim) is, by fifteen chronometrical results, 5° 24′ 38″ to the west of Rio de Janeiro, or..... .....48° 29′ 41″

Port Sta. Elena (the spot marked "Observatory" on the plan).—Eleven chronometers made it 10° 23′ 46″ west of the Island of Gorriti, or.....65° 17′ 25″

Cape Virgins (extremity of the cliff).—By ten chronometers is 13° 24′ 8″ to the west of Gorriti, or 68° 17′ 46″ west of Greenwich; but by comparing it with Port Famine, from which ten chronometers make it 2° 36′ 0″ to the eastward, the result is 68° 18′ 01″; the mean of the two determinations makes it..... 68° 17′ 53″

Port Gallant (Wigwam Point).—By twenty-one chronometers is 1° 2′ 55″ west of Port Famine, or.....71° 56′ 57″

Harbour of Mercy (Observation Islet) at the western end of the Strait of Magalhaens is 3° 40′ 55″ west of Port Famine, or 74° 34′ 56″ west of Greenwich. By the survey, however, it is laid down in.....74° 35′ 31″

During the voyage various astronomical observations were made for the longitude, the summary of which is as follows:

Period.	Place.	Between the ☾ and	No. of Series.		Longitude by Observation.	Longitude by Chronometer.
			On each side.	In all.		
Sept. 1826	Rio de Janeiro	☉	8	16	43° 8′ 18″	43° 5′ 3″
Oct. 1828	Gorriti*.....	☉	9	18	54 53 40	54 53 38
Nov. 1829	Chiloé	☉	8	16	73 48 42	73 50 25
Jan. 1830	Valparaiso....	☉	16	32	71 35 10	71 34 12

* The longitude of Gorriti by Captain Stokes's lunars was 54° 57′ W; that of Monte Video (Rat Island) 56° 14′; of Port Famine old observatory (at the west side of the bay) 70° 57′; and of Villegagnon Island, at Rio de Janeiro, 43° 9′ W. (each to the nearest minute only).

Captain Stokes was an excellent observer, and used one of Troughton's best repeating reflecting circles. His lunar observations, which were very

© The Complete Work of Charles Darwin Online

By referring these several observations to Port Famine by chronometrical differences, its longitude by observation will be 70° 54′ 11″ which is nearly identical with that produced by the chronometric chain from Plymouth, viz. 70° 54′ 01″ west. The last has, therefore, been taken for its longitude, and all the meridians of the coast, surveyed by the expedition under my command, depend upon that determination. PHILLIP PARKER KING.

After having perused Captain King's Report of the chronometrical observations made under his direction, I would ask the reader to turn to Dr. Tiarks's Report on Captain Foster's chronometrical observations in H.M.S. Chanticleer, published in the Appendix* to a "Narrative of a Voyage to the Southern Atlantic Ocean, in the years 1828, 29, 30, performed in H.M.S. Chanticleer, under the command of the late Captain Henry Foster, F.R.S.—By W. H. B. Webster, surgeon of the sloop."

It will also be useful to refer to a work on "Chronometers and Longitudes," by Captain Owen; and to the "Pilote du Brésil," by the Baron Roussin; as well as other works, before forming an opi-

very numerous, were chiefly computed by Lieutenant Skyring. During the years 1826 and 1827 Captain King considered the longitude of Villegagnon to be about 43° 9′, but afterwards he thought 43° 5′ more correct.

There is a striking accordance between the results of Captain Stokes's numerous lunar observations, and the late measurements by the Beagle's chronometers.

I was informed by Lieutenant Skyring, and by Mr. John L. Stokes, that the longitude of Villegagnon, by the Beagle's chronometers only, in 1826, was 43° 9′ (to the nearest minute).

In 1829, Mr. L. Stokes, a good observer even at that time, took many sets of lunar observations at San Carlos, in Chiloe; the mean result of which gave 73° 56′ for the longitude of Point Arena.

Now, these results are so close to those lately obtained in the Beagle—being within a mile in each case—that I should hesitate to give them without all their data, did I not know that the officers employed on board the Adventure and Beagle were aware of these determinations, and often discussed them, before the year 1836. Captain King and Lieutenant Stokes are more particularly acquainted with them.

ROBERT FITZROY.

These chronometers being embarked, and permanently fixed, more than a month previous to the Beagle's departure from England, sufficient time elapsed to ascertain their rates satisfactorily.

Suspended in gimbals, as usual, within a wooden box, each was placed in sawdust, divided and retained by partitions, upon one of two wide shelves. The sawdust was about three inches thick below, as well as at the sides of each box, and formed a bed for it which

* The 12 hour mark of each chronometer was invariably kept in one direction with respect to the ship.

† Never used after Feb. 1835. ‡ Never used after Sept. 1835.

© The Complete Work of Charles Darwin Online

rose rather above the centre of gravity of the box and watch; so that they could not be displaced unless the ship were upset. The shelves, on which the sawdust and boxes were thus secured, were between decks, low down, and as near the vessel's centre of motion as could be contrived. Placed in this manner, neither the running of men upon deck, nor firing guns,* nor the running out of chain-cables, caused the slightest vibration in the chronometers, as I often proved by scattering powder upon their glasses and watching it with a magnifying glass, while the vessel herself was vibrating to some jar or shock.

All the watches were in one small cabin, into which no person entered, except to compare or wind them, and in which nothing else was kept. The greater number were never moved from their first places, after being secured there in 1831, until finally landed at Greenwich in 1836.

During eight years' observation of the movements of chronometers, I have become gradually convinced that the ordinary motions of a ship, such as pitching and rolling moderately, do not affect tolerably good timekeepers, which are fixed in one place, and defended from vibration as well as concussion. Frequently employing chronometers in boats, and in very small vessels, has strengthened my conviction that temperature is the chief, if not the only cause (generally speaking) of marked changes of rate. The balances of but few watches are so well compensated as to be proof against a long continuance of higher or lower temperature. It often happens that the air in port, or near the land, is at a temperature very different from that over the open sea—in the vicinity; and hence the difference sometimes found between harbour and sea rates. The changes so frequently noticed to take place in the rates of chronometers moved from the shore to the ship, and the reverse, are well known to be caused partly by change of temperature and partly by change of situation.† In the Beagle we never found the watches go better than when their boxes were bedded in saw-dust, and they themselves were moving freely in good gimbals.

Suspending chronometers, as on board the Chanticleer, not only alters their rate, but makes them go less regularly; and when fixed

* The Beagle's guns were long six and long nine pounders, of brass: they were only fired from the foremost ports.

† This may be connected with magnetism.

© The Complete Work of Charles Darwin Online

to a solid substance, as on board the Adventure, they feel the vibrations caused by people running on the decks, by shocks, or by a chain cable running out. Cushions, hair, wool, or any such substance, is preferable to a solid bed; but, perhaps, there is nothing better than coarse dry saw-dust.

Some chronometrical measurements have erred, and caused much perplexity, in the following manner. The chronometers were rated in air whose average temperature was—let us suppose, for example, 70. They were then carried through air either considerably hotter, or considerably colder, and again rated in a temperature nearly equal to that specified. The rates were not found to differ much, and it was supposed that the chronometers had been going extremely well; though, in truth, the rates of most of the watches had differed extremely (from those found in port) during the voyage; but they had returned nearly to the old rates upon reaching nearly equal temperature. And this has happened, more or less, to every ship carrying chronometers across the Equator; especially when going to Rio de Janeiro with the sun to the northward of the Line.

How far, or in what manner, magnetism, or electrical influence, may affect chronometers, is hitherto unknown: but there is sufficient reason for suspecting considerable effects, under certain conditions, from one or both of these causes.

The Beagle's chronometers were all wound daily, at nine (except the eight-day watches, which were wound every Sunday morning), and compared at noon. Whatever other comparisons might be made, for equal or corresponding altitudes, sights for time, &c., the noon comparison was regularly made and forthwith examined, in order that any change might be at once detected. Whether at sea, or in harbour, this same method was punctually and accurately executed by one person only, under the inspection of Mr. Stokes and myself. This person, Mr. G. J. Stebbing, of Portsmouth—who was engaged for the purpose, as well as to keep our instruments in repair, take care of our collection of books,* assist in magnetic, and other observations, and write for me—was of invaluable assistance; and, I may well say, contributed largely to whatever was obtained by the Beagle's voyage.

In pages 74 and 75 of the second volume, I have mentioned a few

* Our books, which were not a few, considering the small size of the vessel, were collected in one cabin, under Mr. Stebbing's charge, and lent to the officers, without reserve, under certain regulations.

© The Complete Work of Charles Darwin Online

reasons for preferring to give undivided attention to an unbroken series of chronometrical observations, rather than allot any portion of time to independent astronomical observations; which, to be really valuable, required what I could not command, namely—time; a well-placed and good transit instrument; skill in its use; and habits of observing, which are neither readily nor easily acquired. Besides which, there is always a degree of uncertainty involving the deductions from observations of any celestial phenomena, at a great distance from well-known observatories; even when the observer and his means are unexceptionable. The causes of this uncertainty are familiar to many, but, as these pages may meet the eye of a reader who is not aware of them, I will mention that the figure of the earth is not yet quite accurately known, that parallax and refraction cannot be allowed for with absolute certainty, that levels and plumb-lines are not everywhere exactly at right angles to, or coincident with, a line drawn from them to the earth's centre; and that tables, however excellent, are not perfect.

That able and indefatigable astronomer, Mr. Fallows, was a long time at the Cape of Good Hope before he could determine its longitude; and, after all his exertions, his successors have adopted a result differing from it half a mile.* There is reason to doubt whether Paramatta Observatory is well determined in longitude. To fix that of St. Helena, and that of the Mauritius, occupied much time and talent, aided by excellent instruments in well-built observatories. A great deal of time and pains, and ability, have been employed at Madras; yet, as far as chronometers can tell, there is a great discordance between the hitherto published longitudes of Madras, the Mauritius, and Paramatta, when viewed in connection with their respective meridian distances; such, at least, as have yet been measured.

Even on the coast of the Baltic, what differences were found by Lieutenant-General Schubert, in 1833, between the received positions of various observatories, and those which he deduced from the results of fifty-six chronometers;—placed at his disposal, with a steam-boat, by the Emperor of Russia.†

But, to return from this digression:—In the Beagle's measure-

* Mr. Fallows considered the longitude of the Cape observatory to be 1h. 13m. 53s. E. Mr. Henderson 1h. 13m. 55s. E.

† Journal of the Royal Geographical Society. Vol. VI. Part II. 1836, pp. 413-6.

© The Complete Work of Charles Darwin Online

ments of meridian distances, time was invariably obtained by series of equal, or corresponding altitudes of the sun; observed by one and the same person with the same sextant, and the same artificial horizon, placed in the same manner, both before and after noon.

A very good pocket chronometer, carried by hand, in a box, was always used for taking time. In every instance, it was compared with the standard chronometers (the two supposed to be the best) immediately before the morning observation, and again immediately afterwards. It was also compared at noon, and before, as well as after the afternoon, observations. This watch* was so well constructed, that the intervals shown by it between morning and afternoon observations always agreed with those shown by the standards, (allowing for their respective rates).

Generally speaking, seven altitudes of one limb of the sun were taken, and then the same seven altitudes of the other limb, for one set of sights, or observations. Three such sets were usually taken, at short intervals, and the mean result used, unless any marked difference occurred, in which case the result of each separate pair of equal altitudes (morning and afternoon) was computed, and the erroneous ones were rejected. Those were considered erroneous which differed much from the majority. Generally, however, there was the closest agreement between the results of single pairs of sights, as well as between those of entire sets.

When clouds intervened the series was unavoidably irregular, but the pairs of equal altitudes were always numerous. In a very few instances the chronometers were rated by the results of absolute or independent altitudes, taken with every precaution at similar times of day with the same instruments, and by the same observer. In such cases the rates were obtained by comparing together the times obtained by morning observations, or those deduced from afternoon sights; not by morning and afternoon, or afternoon and morning observations. But the time, considered to be correct, was invariably deduced from equal altitudes, by the method of Professor Inman. At Paramatta, at the Cape of Good Hope, and under the walls of the Royal Observatory at Greenwich, we had opportunities of trying whether there was any difference between our time, thus obtained, and that of the respective astronomers; and I feel gratified in being able

* K. Parkinson and Frodsham. No. 1041

© The Complete Work of Charles Darwin Online

to state, that in no one instance did it differ a quarter of a second from theirs; indeed the figures would bear me out in saying, that it did not differ even a tenth of a second! These facts are well known to Lieut. Stokes, Lieut. Sulivan, and Mr. Usborne.

The sextant used throughout the voyage for this purpose, and this alone, was a particularly good one, made expressly for me by Worthington and Allan. Its index error never varied, nor was it ever the least out of adjustment. Between morning and afternoon observations it was more than usually guarded, and on no account handled, or exposed to a change of temperature.

Latitudes were obtained by other sextants, and by circles. I was always anxious to get many results, not only by one observer, or instrument, but by several observers, and different instruments. It sometimes happened that there were six observers seated on the ground, with as many different instruments and horizons, taking the sun's circum-meridian altitudes, or observing stars at night. Where so many were working against one another, errors were soon detected, either in observation or in computing. I have already mentioned that Dr. Inman's method of calculation was followed; but it remains to be shown what mode of interpolation was adopted when, as was usually the case, most of the watches were found to be going at rates different from those ascertained at the preceding place of rating.

With very few exceptions, the method used by Dr. Tiarks* was practised; and, in the excepted cases, that used by Flinders, Owen, Foster, King, and others, was employed. The following are the principal results upon which all others obtained during the Beagle's last voyage (1831-6) depend. Want of room alone prevents my giving the minutest details upon which they depend; it would be of little use to give computations without comparisons, or comparisons without rates, or rates without the calculations and observations on which they depend; or any part of these without the whole, which constitutes a mass of figures filling several thick folio books. All these, however, will be deposited at the Hydrographical Office, so that any one who will take the trouble may, after obtaining the Hydrographer's permission, examine them to the fullest extent.

Our first station was at the Devonport Baths, exactly in the meri-

dian of the centre of Government House. By the published survey of Plymouth and Devonport,* the Government-House at Devonport is 0° 1′ 48″ west of Plymouth old church, the longitude of which is given by Captain King in the preceding copy of his report.

This longitude, however, differs slightly from that obtained by the Beagle's chronometers carried from Devonport to Greenwich ; and as the longitude of Falmouth, by her chronometers, agrees with that determined by Dr. Tiarks, I have used in the construction of the table of positions (pp. 65-85) the result obtained directly by these chronometers, because so confirmed.

PRINCIPAL RESULTS of the Beagle's chronometrical measurements between 1831 and 1836; forming a connected chain of meridian distances around the globe, the first that has ever been completed, or even attempted, by means of chronometers alone.

While looking over the preceding results, enquiry may be made for those of the other chronometers: I should, therefore, mention that the others were useless. Some of the watches stopped; others altered their rates suddenly; and in one case (R) a mainspring broke when the chronometer had been going admirably, till that moment. Four chronometers were left with Mr. Usborne, on the coast of Peru, and in consequence of these diminutions of our original number, there were but eleven watches in tolerably effective condition during the last two principal links of the chain, namely, from Port Praya to the Azores, and from the Azores to Devonport.

Five years is a long time for chronometers to preserve their capability of going steadily, under various changes of climate, without being examined, and perhaps cleaned or fresh oiled, by an experienced chronometer maker.

© The Complete Work of Charles Darwin Online

Having given the principal results—those forming links of the chain of meridian distances carried round the globe—I have to mention that all others of a similar nature, obtained by the Beagle's officers, are based upon them, and that in no one instance do any of the longitudes given in the accompanying tables depend upon absolute or independent astronomical observations.

It ought to be clearly stated, however, that the sum of all the parts which form the chain amounts to more than twenty-four hours, therefore error must exist somewhere; but what has principally caused the error, or where it may be said to exist, I am unable to determine. The whole chain exceeds twenty-four hours, by about thirty-three seconds of time.

It appears very singular, that the more the various links of this chain are examined and compared with other authorities, the more reason there seems to be for believing them correct, at least to within a very small fraction of time; and even allowing that each link were one or two seconds of time wrong, it does not appear probable that all the errors would lie in one direction, unless some hitherto undetected cause affects chronometers when carried westward, which might affect them differently when carried eastward.

It would ill become me to speak of any value which may be attached to these chronometrical measures; even erroneous as they undoubtedly are in some part, if not to a certain degree almost every where. I can only lay the honestly-obtained results before persons who are interested in such matters, and request that they may be compared with those of the best authorities.

Callao, Sydney, and the Cape of Good Hope, are three remote points which might be selected rather than others, because generally supposed to be well determined. If the Beagle's position of Callao be proved incorrect, then must Humboldt's (calculated by Oltmanns), adopted by Daussy,* be also incorrect; and if her position of Sydney (reckoning eastward from Greenwich) be materially wrong, then must the best authorities for the longitude of that place be also in error, for they differ from the Beagle only about eight or ten seconds, which is but a minor part of thirty-three seconds.

The only idea I can dwell on, with respect to the cause of this error of thirty-three seconds, is, that chronometers may be affected by

* Connaissance des Tems.—1836.

© The Complete Work of Charles Darwin Online

magnetic action in consequence of a ship's head being for a considerable time towards the east, or west: yet this is but a conjecture. In the measures between Bahia and Rio de Janeiro, and in those between Rio de Janeiro and Cape Horn, there is no evidence of any permanent cause of error; but the greater part of those measurements were made with the ship's head usually near the meridian.

Were I to select three measurements which I thought less trustworthy than others—I should decide on that from the Galapagos to Otaheite, from Otaheite to New Zealand, and from Hobart Town to King George Sound; but I do not think that either one of these can be five seconds of time in error, according to regular computation, without supposing some unknown cause of error to exist. If each of the three were five seconds wrong, and each error lay in the same direction, still there would only be fifteen seconds out of thirty-two accounted for. Such a supposition as this, however, that each of these three measurements is five seconds, or thereabouts, in error (referring only to error caused by known means) appears to be extremely improbable, I would almost say impossible.

It will naturally occur to the reader, that as error, undetected as to locality, exists, arbitrary correction must be made in order to reduce 24h. 0m. 33s. to 24h.

Otaheite has been selected as a point at which such a correction might be made with the least degree of inconvenience: to that place the longitudes in the accompanying tables are given as measured westward by Cape Horn, and eastward from Greenwich by the Cape of Good Hope; and there, as the two portions of the chain overlap, a mean has been taken between the resulting longitudes.

I will now recapitulate the principal measurements, and confront them with various other determinations. Limited space prevents my quoting many; but I trust that enough will be given to show that some weight may be attached to at least a proportion of the results obtained by the Beagle's officers.

Fernando de Noronha to Bahia	0	24	23,6		—	
Port Praya to Bahia*	1	00	03,5	2	34	03,8
Bahia to Rio de Janeiro	0	18	31,4	2	52	35,2
Rio de Janeiro to Monte Video	0	52	17,6	3	44	52,8

Other Determinations.

Plymouth (or the Government House at Devonport) taken from the Ordnance Survey and Dr. Tiarks	0	16	41,4			
Captain W. F. W. Owen placed Port Praya in	1	34	04,8			
Dr. Tiarks's longitude of Madeira and Capt. P. P. King's meridian distance thence to the same spot in Port Praya placed it in	1	34	02,9			
Beagle—Plymouth to Port Praya	1	17	20,7			
Beagle—Port Praya to Plymouth	1	17	19,4			
Beagle—Port Praya to Bahia	1	00	03,0			
Beagle—Bahia to Port Praya	1	00	04,1			
Beagle—Bahia to Rio de Janeiro	0	18	31,6			
Beagle—Rio de Janeiro to Bahia	0	18	31,4			
Beagle—Bahia to Rio de Janeiro	0	18	31,5			
Captain Foster—Rio de Janeiro to Monte Video	0	52	19,0			
Captain King—Rio de Janeiro to Monte Video	0	52	17,8			
M. Barral—Rio de Janeiro to Monte Video	0	52	17,4			
Beagle in 1830—Monte Video to Rio de Janeiro	0	52	18,0			

The longitude of Rio de Janeiro given in this table is very near the latest determinations of the French, and almost identical with that which is stated, in the Ephemerides of Coimbra, to have been deduced from upwards of three thousand observations.

Note.—When more than one measurement is stated between the same two places, it is to be understood that the observations were taken at, or have been reduced to the same points.

* Using the mean of the measurements, outward and homeward.

Beagle's Chain of Meridian Distances and Resulting Longitudes in the Pacific Ocean, between Cape Horn and Otaheite.

1834—1835.

	H.	M.	S.	H.	M.	S.
Port Famine to San Carlos, Chiloe	0	11	53,5*	4	55	45,0
San Carlos to Valparaiso	0	08	59,2	4	46	45,8
Valparaiso to Callao	0	22	09,0	5	08	54,8
Callao to Chatham Island in the Galapagos	0	49	32,8	5	58	27,6
Chatham Island to Charles Island	0	03	39,5	6	02	07,1
Charles Island to Otaheite	3	56	12,3	9	58	19,4

Other Determinations.

Beagle 1830—Port Famine to Cape Horn, by true bearing of Sarmiento from Doris Peak	0	14	46,5
Beagle 1829-30—Cape Horn to San Carlos	0	26	39,9
Beagle 1829—Port Famine to San Carlos	0	11	54,0
Beagle 1829—San Carlos to Valparaiso	0	09	00,2
Malaspina and Espinosa had an observatory at San Carlos, whose longitude they considered	4	55	47,5
Their meridian distance † thence to Valparaiso was	0	08	59,8
Malaspina's and Espinosa's observations, calculated by Professor Oltmanns, give for Valparaiso	4	46	47,7
And for Callao Castle	5	08	57,1

Repeated examination of the successive differences of longitude given in these pages, and the data on which they rest, leads me to think that the alterations spoken of by Captain King, in page 493 of Volume I., were unnecessary.

By an unexceptionable true-bearing of Mount Sarmiento, from Doris Peak, I was enabled to connect the longitude of the outer coast with that of Port Famine in a most satisfactory manner.

M. Lartigue, in the French frigate Clorinde (see Connaissance des Tems, for 1836), made the meridian distance between Callao and Valparaiso almost identical with that of Espinosa and Malaspina, as well as the above stated result of the Beagle's measurement.

* oh. 11m. 59,4s. − 5,9s. =oh. 11m. 53,5s.

† In Malaspina's expedition there were at least four chronometers, made by Arnold, besides others.

OTHER DETERMINATIONS.

Captain Owen—Simon's Bay to Mauritius	2	36	23,2	
Captain Lloyd—Mauritius Observatory	3	50	08	
Captain Flinders—Mauritius	3	50	00	
Flinders (by lunars) made the difference of meridians between King George Sound and Sydney	2	13	15,3	
Beagle's measurement gives	2	13	21,1	

Captain Cook and Mr. Wales placed Otaheite (Point Venus) in 149° 35′—but subsequently Mr. Wales considered 149° 30′ more correct.

In Cook's first voyage the longitude of Otaheite was made 149° 32′ 30″; in the second, Mr. Wales made it 149° 34′ 50″; and in the third voyage, Cook and his officers made it 149° 37′ 32″ w. (at Point Venus).

I was informed that M. Duperrey, in the Coquille, made the longitude of the Bay of Islands 174° 01′ 00″ E. Our observations were made at the same point, and, if such is the case, his result agrees with that of the Beagle, taken westward from Greenwich.

The measurements made in 1829-30, here given, may be compared with the charts or other documents deposited in the Hydrographical Office in 1831.

© The Complete Work of Charles Darwin Online

Having thus endeavoured to give a view of the Beagle's principal measurements of meridian distances, with some of the collateral determinations which are at present within my reach, I willingly refrain from their discussion.

It is for those who have access to more extended information, and who are not personally interested in the question, by having assisted in making any of these measures themselves, to discuss and assign values to them.

For this reason, an intention which I entertained of attempting to make some enquiry into the grounds on which the longitudes of Jamaica, the Havannah, Chagres, Panama, &c. are by some persons considered to be well determined, has been relinquished.

I will conclude by remarking, that if so small a vessel as the Beagle, with so few chronometers going well, latterly, could attain, during a tedious and indirect voyage of five years, to within thirty-three seconds of the truth—a much nearer approach to exactness may be anticipated from measurements made in far less time, with a greater number of chronometers.

PREFACE.

I HAVE stated in the preface to the Zoology of the Voyage of the Beagle, that it was in consequence of a wish expressed by Captain FitzRoy, of having some scientific person on board, accompanied by an offer from him, of giving up part of his own accommodations, that I volunteered my services, which received, through the kindness of the hydrographer, Captain Beaufort, the sanction of the Lords of the Admiralty. As I feel that the opportunities, which I enjoyed of studying the Natural History of the different countries we visited, have been wholly due to Captain FitzRoy, I hope I may here be permitted to express my gratitude to him; and to add that, during the five years we were together, I received from him the most cordial friendship and steady assistance. Both to Captain FitzRoy and to all the Officers of the Beagle,*

* I must likewise take this opportunity of returning my sincere thanks to Mr. Bynoe, the surgeon of the Beagle, for his very kind attention to me when I was ill at Valparaiso.

© The Complete Work of Charles Darwin Online

I shall ever feel most thankful for the undeviating kindness with which I was treated, during our long voyage.

The present volume contains in the form of a journal, a sketch of those observations in Geology and Natural History, which I thought would possess some general interest. As it was originally intended to have preceded any more detailed account, and as its publication has been unavoidably delayed, the briefness and imperfection of several parts, I hope, will be excused. I have given a list of those errata (partly caused by my absence from town when some of the sheets were in the press) which affect the sense; and have added an Appendix, containing some additional facts (especially on the theory of the transportation of erratic blocks) which I have accidentally met with during the past year. I hope shortly to publish my geological observations; the first Part of which will be on the Volcanic Islands of the Atlantic and Pacific Oceans, and on Coral Formations; and the second Part will treat of South America. Several numbers of the Zoology of the Voyage of the Beagle, due to the disinterested zeal of several of our first naturalists, have already appeared. These works could not have been undertaken, had it not been for the liberality of the Lords Commissioners of Her Majesty's Treasury, who, through the representation of the Right Honourable the Chancellor of the Exchequer, have been pleased to grant a sum of one

© The Complete Work of Charles Darwin Online

thousand pounds towards defraying part of the expenses of publication. I have repeated in this volume my account of the habits of some of the birds and quadrupeds of South America, as I thought such observations might interest those readers who would not, probably, consult the larger work. But I trust that naturalists will remember, that mere sketches are here given on several subjects, which will hereafter be more fully entered on, or have already been so:—for instance, the notices of the strange fossil quadrupeds of the eastern plains of South America are exceedingly imperfect, whilst an admirable account of them by Mr. Owen now forms the first part of the Zoology of the Voyage of the Beagle.

I shall have the pleasure of acknowledging the great assistance I have received from several naturalists, in the course of this and the succeeding works; but I must be here allowed to return my most sincere thanks to the Reverend Professor Henslow, who, when I was an under-graduate at Cambridge, was one chief means of giving me a taste for Natural History, —who, during my absence, took charge of the collections I sent home, and by his correspondence directed my endeavours,—and who, since my return, has constantly rendered me every assistance which the kindest friend could offer.

CONTENTS.

CHAPTER I.

Porto Praya—Ribeira Grande—Dry and clear atmosphere—Effect of lava on a calcareous beach—Habits of Aplysia and Octopus—St. Paul's rocks non-volcanic—Incrustations and stalactites of phosphate of lime—Insects first colonists—Fernando Noronha—Bahia—Extent of granite—Burnished rocks—Habits of Diodon—Pelagic confervæ, infusoria—Causes of discoloured sea 1

CHAPTER II.

Rio de Janeiro—Excursion north of Cape Frio—Great evaporation—Slavery—Botofogo Bay—Terrestrial Planariæ—Clouds on Corcovado—Heavy rain—Musical Hyla—Lampyris and its larvæ—Elater, springing powers of—Blue haze—Noise of butterfly—Entomology—Ants—Wasp-killing spider—Parasitical spider—Artifices of Epeira—Gregarious spider—Spider with imperfect web. 21

CHAPTER III.

Monte Video—Maldonado—Excursion to R. Polanco—Lazo and Bolas—Partridges—Geology—Absence of trees—Cervus campestris—River hog—Tucutuco—Molothrus, cuckoo-like habits of—Tyrant-flycatcher—Mocking-bird—Carrion hawks—Tubes formed by lightning—House struck 44

CHAPTER IV.

Rio Negro—Estancias attacked by Indians—Salt lakes, geological position of—Flamingoes—R. Negro to Colorado—Sacred tree—Patagonian hare—Indian families—General Rosas—Proceed to Bahia Blanca—Sand dunes—Negro lieutenant—Bahia Blanca—Ground incrusted with Glauber salt—Punta Alta—Zorillo 74

CHAPTER V.

Bahia Blánca—Geology—Extinct quadrupeds, four Edentata, horse, Ctenomys—Recent extinction of—Longevity of species—Large animals do not require luxuriant vegetation—Southern Africa—Siberian fossils—Catalogue of extinct quadrupeds of South America—Two species of Ostrich, habits of—Tinochorus—Oven-bird—Armadilloes—Venomous snake, toad, lizard—Hybernation of animals—Habits of sea-pen—Indian wars and massacres—Arrow-head, antiquarian relic. . 95

© The Complete Work of Charles Darwin Online

CHAPTER VI.

Set out for Buenos Ayres—Rio Sauce—Sierra Ventana—Transportal of pebbles—Third posta—Driving horses—Bolas—Partridges and foxes—Features of country—Long-legged plover—Teru-tero—Hailstorm—Natural enclosures in Sierra Tapalguen—Flesh of puma—Meat diet—Guardia del Monte—Effects of cattle on the vegetation—Cardoon—Buenos Ayres—Corral where animals are slaughtered . . 124

CHAPTER VII.

Excursion to St. Fe—Thistle beds—Habits and range of Bizcacha—Little owl—Saline streams—Level plains—Mastodon—St. Fe—Change in landscape—Geology—Tooth of extinct horse—Range of fossil quadrupeds—Pampas full of remains—Effects of great droughts—Droughts periodical—Parana—Habits of Jaguar—Scissor-beak—Kingfisher, parrot, and scissor-tail—Revolution—Buenos Ayres—State of government 142

CHAPTER VIII.

Monte Video—Excursion to Colonia del Sacramiento—Horses, swimming—Value of an Estancia—Cattle, how counted—Geology—Great thistle-beds—Rio Negro—Perforated pebbles—Shepherd dogs—Horses broken in, Gauchos riding, feats with lazo—Toxodon—Armadillo-like gigantic covering—Great tail—Return to Monte Video—Character of inhabitants 167

CHAPTER IX.

Rio Plata—Flocks of butterflies—Beetles alive in the sea—Aeronaut spiders—Pelagic animals—Phosphorescence of sea—Port Desire—Spanish settlements—Zoology—Guanaco—Excursion to head of harbour—Indian grave—Port St. Julian—Geology of Patagonia, successive terraces, transport of pebbles—Fossil gigantic llama—Types of organization constant—Change in zoology of America—Causes of extinction 185

CHAPTER X.

Santa Cruz—Expedition up river—Indians—Character of Patagonia—Basaltic platform—Immense streams of lava—Non-transport of blocks by river—Excavation of valley—Condor, range and habits—Cordillera—Erratic boulders of great size—Indian relics—Return to the ship 213

CHAPTER XI.

Tierra del Fuego, first arrival—Good Success Bay—Interview with savages—Scenery of the forests—Sir J. Banks's hill—Cape Horn—Wigwam Cove—Miserable condition of savages—Beagle channel—Fuegians—Ponsonby Sound—Equality of condition among the natives—Bifurcation of the Beagle channel—Glaciers—Return to ship . 227

© The Complete Work of Charles Darwin Online

CHAPTER XII.

Falkland Islands—Excursion round island—Aspect—Cattle, horses, rabbit, wolf-like fox—Fire made of bones—Art in making fire—Manner of hunting wild cattle—Geology, fossil shells—Valleys filled with great fragments, scenes of violence—Penguin—Geese—Eggs of doris—Zoophytes, coralline phosphorescent—Compound animals . 245

CHAPTER XIII.

Strait of Magellan—Port Famine—Geology—Deep water in channels—Erratic boulders—Climate—Limit of fruit trees—Mean temperature—Luxuriant forests—Rigour of antarctic islands—Contrast with the north—Snow-line, great flexure of—Glaciers—Icebergs transport fragments of rock—Glaciers in low latitude—Absence of erratic blocks in intertropical regions—Glaciers and tropical vegetation—Comparison with northern hemisphere—Siberian animals in ice—Embedded in cold mud—Edible fungus—Zoology—Fucus giganteus—Leave Tierra del Fuego 263

CHAPTER XIV.

Valparaiso—Excursion to base of Andes—Structure of land—Ascend Bell of Quillota—Shattered masses of greenstone—Immense valleys—Mines—State of miners—Santiago—Hot baths of Cauquenes—Gold mines—Grinding mills—Perforated stones—Habits of puma—El turco and tapacolo—Humming-birds 308

CHAPTER XV.

Chiloe—General aspect—Boat excursion—Native Indians—Castro—Large leaves of Gunnera scabra—Tame fox—Ascend San Pedro—Chonos Archipelago—Peninsula of Tres Montes—Granitic range—Lowe's Harbour—Wild potato—Forest—Formation of peat—Myopotamus, otter and mice—Cheucau and barking-bird—Furnarius—Singular character of ornithology—Petrels 333

CHAPTER XVI.

San Carlos, Chiloe—Osorno in eruption—Ride to Castro and Cucao—Impenetrable forests—Valdivia—Apple-trees—Ride to Llanos—Indians—Earthquake—Concepcion—Great earthquake—Effects of wave—Rocks fissured—Appearance of the former towns—Water in the bay black and boiling—Direction of vibration—Stones displaced—Cause of great waves—Permanent elevation of land—Great lake of fluid rock beneath crust of the globe—Connexion of volcanic phenomena—Slow elevation of mountain chains, cause of earthquakes . . . 356

© The Complete Work of Charles Darwin Online

CHAPTER XVII.

Valparaiso—Passage of Andes by Portillo pass—Sagacity of mules—Mountain torrents—Mines, how discovered—Marine alluvium in valleys—Effect of snow on surface—Geology, fossil shells, double range, two periods of elevation—Red snow—Winds on the crest—Snow thawing in pinnacles—Dry and clear atmosphere—Electricity—Pampas—Zoology of opposite sides of Andes—Uniformity of Patagonia—Locusts—Great bugs—Mendoza—Uspallata—Silicified trees in vertical position—Indian ruins—Change of climate—Earthquake arching bed of river—Cumbre—Valparaiso. 382

CHAPTER XVIII.

Bell mountain—Miners—Great loads carried by the Apires—Coquimbo—Earthquake—Geology—Terraces—Excursion up valley—Road to Guasco—Desert country—Valley of Copiapó—Rain and earthquakes, Meteorolites—Hydrophobia—Copiapó—Excursion to Cordillera—Dry valley—Cold gales of wind—Noises from a hill—Iquique, complete desert—Salt alluvium—Nitrate of soda—Lima—Unhealthy country—Ruins of Callao, overthrown by earthquake—Elevated shells on island of San Lorenzo—Plain with embedded fragments of pottery . 416

CHAPTER XIX.

Galapagos Islands volcanic—Number of craters—Leafless bushes—Colony at Charles Island—James Island—Salt-lake in crater—Character of vegetation—Ornithology, curious finches—Great tortoises, habits of, paths to the wells—Marine lizard feeds on sea-weed—Terrestrial species, burrowing habits, herbivorous—Importance of reptiles in the Archipelago—Few and minute insects—American type of organization—Species confined to certain islands—Tameness of birds—Falkland Islands—Fear of man an acquired instinct. 453

CHAPTER XX.

Tahiti—Aspect of—Vegetation on the slope of the mountains—View of Eimeo—Excursion in the interior—Profound ravines—Succession of waterfalls—Number of wild useful plants—Temperance of inhabitants—Their moral state—Parliament convened—New Zealand—Bay of islands—Hippahs—Absence of all government—Excursion to Waimate—Missionary establishment—English weeds now run wild—Waiomio—Funeral service—Sail from New Zealand 479

CHAPTER XXI.

Sydney—Prosperity of—Excursion to Bathurst—Aspect of woods—Party of Natives—Gradual extinction of aborigines—Blue Mountains—Weatherboard—View of a grand gulf-like valley—Sheep farm—Lion-ant—Bathurst, general civility of lower orders—State of society—Van

© The Complete Work of Charles Darwin Online

Diemen's Land—Hobart Town—Aborigines all banished—Mount Wellington—King George's Sound—Cheerless aspect of country—Bald Head, calcareous casts like branches of trees—Party of natives—Leave Australia 515

CHAPTER XXII.

Keeling Island—Singular appearance of—Scanty Flora—Transport of seeds—Birds and insects—Ebbing and flowing springs—Coral formations resisting power of ocean—Fields of dead coral—Stones transported by roots of trees—Great crab—Stinging corals—Structure of lagoon islands—Encircling and Barrier reefs—General proofs of subsidence in the Pacific—Theory of lagoon islands caused by subsidence of the land—Pacific and Indian oceans divided into alternate areas of elevation and subsidence—Points of eruption lie within the areas of elevation. 539

CHAPTER XXIII.

Mauritius, beautiful appearance of—Hindoos—Cape of Good Hope—St. Helena—Geology—History of changes in vegetation, probable cause of extinction of land-shells—Ascension—Green Hill—Curious incrustations of calcareous matter on tidal rocks—Bahia—Brazil—Splendour of tropical scenery—Pernambuco—Singular reef—Azores—Supposed crater—Hints to collectors—Retrospect of the most impressive parts of the voyage 570

OF

CHARLES DARWIN, M.A.,

NATURALIST TO THE BEAGLE.

CHAPTER I.

Porto Praya—Ribeira Grande—Dry and clear atmosphere—Effect of lava on calcareous beach—Habits of Aplysia and Octopus—St. Paul's rock non-volcanic—Incrustations and stalactites of phosphate of lime—Insects first colonists—Fernando Noronha—Bahia—Extent of granite—Burnished rocks—Habits of Diodon—Pelagic confervæ, infusoria—Causes of discoloured sea.

ST. JAGO—CAPE DE VERD ISLANDS.

JAN. 16TH, 1832.—The neighbourhood of Porto Praya, viewed from the sea, wears a desolate aspect. The volcanic fire of past ages, and the scorching heat of a tropical sun, have in most places rendered the soil sterile and unfit for vegetation. The country rises in successive steps of table land, interspersed with some truncate conical hills, and the horizon is bounded by an irregular chain of more lofty mountains. The scene, as beheld through the hazy atmosphere of this climate, is one of great interest; if, indeed, a person, fresh from the sea, and who has just walked, for the first time, in a grove of cocoa-nut trees, can be a judge of any thing but his own happiness. The island would generally be considered as very uninteresting; but to any one accustomed only to an English landscape, the novel

BALFOUR LIBRARY CAMBRIDGE

© The Complete Work of Charles Darwin Online

prospect of an utterly sterile land possesses a grandeur which more vegetation might spoil. A single green leaf can scarcely be discovered over wide tracts of the lava plains; yet flocks of goats, together with a few cows, contrive to exist. It rains very seldom, but during a short portion of the year heavy torrents fall, and immediately afterwards a light vegetation springs out of every crevice. This soon withers; and upon such naturally-formed hay the animals live. At the present time it has not rained for an entire year. The broad, flat-bottomed, valleys, many of which serve during a few days only in the season as a water-course, are clothed with thickets of leafless bushes. Few living creatures inhabit these valleys. The commonest bird is a kingfisher (*Dacelo jagoensis*), which tamely sits on the branches of the castor-oil plant, and thence darts on the grasshoppers and lizards. It is brightly coloured, but not so beautiful as the European species: in its flight, manners, and place of habitation, which is generally in the driest valleys, there is also a wide difference.

One day, two of the officers and myself rode to Ribeira Grande, a village a few miles to the eastward of Porto Praya. Until we reached the valley of St. Martin, the country presented its usual dull brown appearance; but there, a very small rill of water produces a most refreshing margin of luxuriant vegetation. In the course of an hour we arrived at Ribeira Grande, and were surprised at the sight of a large ruined fort and cathedral. The little town, before its harbour was filled up, was the principal place in the island: it now presents a melancholy, but very picturesque appearance. Having procured a black Padre for a guide, and a Spaniard, who had served in the Peninsular war, as an interpreter, we visited a collection of buildings, of which an ancient church formed the principal part. It is here the governors and captain-generals of the islands have been buried. Some of the tombstones recorded dates of the sixteenth century.*

* The Cape de Verd Islands were discovered in 1449.

© The Complete Work of Charles Darwin Online

The heraldic ornaments were the only things in this retired place that reminded us of Europe. The church or chapel formed one side of a quadrangle, in the middle of which a large clump of bananas were growing. On another side was a hospital, containing about a dozen miserable-looking inmates.

We returned to the "Vênda" to eat our dinners. A considerable number of men, women, and children, all as black as jet, were collected to watch us. Our companions were extremely merry; and every thing we said or did was followed by their hearty laughter. Before leaving the town we visited the cathedral. It does not appear so rich as the smaller church, but boasts of a little organ, which sent forth most singularly inharmonious cries. We presented the black priest with a few shillings, and the Spaniard, patting him on the head, said, with much candour, he thought his colour made no great difference. We then returned, as fast as the ponies would go, to Porto Praya.

Another day we rode to the village of St. Domingo, situated near the centre of the island. On a small plain which we crossed, a few stunted acacias were growing; their tops, by the action of the steady trade-wind, were bent in a singular manner—some of them even at a right angle to the trunk. The direction of the branches was exactly N.E. by N., and S.W. by S. These natural vanes must indicate the prevailing direction of the force of the trade wind. The travelling had made so little impression on the barren soil, that we here missed our track, and took that to Fuentes. This we did not find out till we arrived there; and we were afterwards very glad of our mistake. Fuentes is a pretty village, with a small stream; and every thing appeared to prosper well, excepting, indeed, that which ought to do so most—its inhabitants. The black children, completely naked, and looking very wretched, were carrying bundles of firewood half as big as their own bodies.

Near Fuentes we saw a large flock of guinea-fowl—probably fifty or sixty in number. They were extremely wary,

© The Complete Work of Charles Darwin Online

and could not be approached. They avoided us, like partridges on a rainy day in September, running with their heads cocked up; and if pursued, they readily took to the wing.

The scenery of St. Domingo possesses a beauty totally unexpected, from the prevalent gloomy character of the rest of the island. The village is situated at the bottom of a valley, bounded by lofty and jagged walls of stratified lava. The black rocks afford a most striking contrast with the bright green vegetation, which follows the banks of a little stream of clear water. It happened to be a grand feast-day, and the village was full of people. On our return we overtook a party of about twenty young black girls, dressed in most excellent taste; their black skins and snow-white linen being set off by their coloured turbans and large shawls. As soon as we approached near, they suddenly all turned round, and covering the path with their shawls, sung with great energy a wild song, beating time with their hands upon their legs. We threw them some vintéms, which were received with screams of laughter, and we left them redoubling the noise of their song.

It has already been remarked, that the atmosphere is generally very hazy; this appears chiefly due to an impalpable dust, which is constantly falling, even on vessels far out at sea. The dust is of a brown colour, and under the blowpipe easily fuses into a black enamel. It is produced, as I believe, from the wear and tear of volcanic rocks, and must come from the coast of Africa. One morning the view was singularly clear; the distant mountains being projected with the sharpest outline, on a heavy bank of dark blue clouds. Judging from the appearance, and from similar cases in England, I supposed that the air was saturated with moisture. The fact, however, turned out quite the contrary. The hygrometer gave a difference of 29.6 degrees, between the temperature of the air, and the point at which dew was precipitated. This difference was nearly double that which I had observed on the previous mornings.

© The Complete Work of Charles Darwin Online

This unusual degree of atmospheric dryness was accompanied by continual flashes of lightning. Is it not an uncommon case, thus to find a remarkable degree of aerial transparency with such a state of weather?

The geology of this island is the most interesting part of its natural history. On entering the harbour, a perfectly horizontal white band, in the face of the sea cliff, may be seen running for some miles along the coast, and at the height of about forty-five feet above the water. Upon examination, this white stratum is found to consist of calcareous matter, with numerous shells embedded, such as now exist on the neighbouring coast. It rests on ancient volcanic rocks, and has been covered by a stream of basalt, which must have entered the sea, when the white shelly bed was lying at the bottom. It is interesting to trace the changes, produced by the heat of the overlying lava, on the friable mass. For a thickness of several inches it is converted, in some parts, into a firm stone, as hard as the best freestone; and the earthy matter, originally mingled with the calcareous, has been separated into little spots, thus leaving the limestone white and pure. In other parts a highly crystalline marble has been formed, and so perfect are the crystals of carbonate of lime, that they can easily be measured by the reflecting goniometer. The change is even more extraordinary, where the lime has been caught up by the scoriaceous fragments of the lower surface of the stream; for it is there converted into groups of beautifully radiated fibres resembling arragonite. The beds of lava rise in successive gently-sloping plains, towards the interior, whence the deluges of melted stone originally proceeded. Within historical times, no signs of volcanic activity have, I believe, been manifested in any part of St. Jago. This state of quiescence is, probably, owing to the neighbouring island of Fogo being frequently in eruption. Even the form of a crater can but rarely be discovered on the summits of any of the red cindery hills; yet the more recent streams can be distinguished on the coast, forming a line of cliffs of less height, but stretching out in advance of those belonging to an older

© The Complete Work of Charles Darwin Online

series: the height of the cliff thus affording a rude measure of the age.

During our stay, I observed the habits of some marine animals. A large Aplysia is very common. This sea-slug is about five inches long; and is of a dirty yellowish colour, veined with purple. At the anterior extremity, it has two pair of feelers; the upper ones of which resemble in shape the ears of a quadruped. On each side of the lower surface, or foot, there is a broad membrane, which appears sometimes to act as a ventilator, in causing a current of water to flow over the dorsal branchiæ. It feeds on delicate sea-weeds, which grow among the stones in muddy and shallow water; and I found in its stomach several small pebbles, as in the gizzards of birds. This slug, when disturbed, emits a very fine purplish-red fluid, which stains the water for the space of a foot around. Besides this means of defence, an acrid secretion, which is spread over its body, causes a sharp, stinging sensation, similar to that produced by the Physalia, or Portuguese man-of-war.

I was much interested, on several occasions, by watching the habits of an Octopus or cuttle-fish. Although common in the pools of water left by the retiring tide, these animals were not easily caught. By means of their long arms and suckers, they could drag their bodies into very narrow crevices; and when thus fixed, it required great force to remove them. At other times they darted tail first, with the rapidity of an arrow, from one side of the pool to the other, at the same instant discolouring the water with a dark chestnut-brown ink. These animals also escape detection by a very extraordinary, chameleon-like, power of changing their colour. They appear to vary the tints, according to the nature of the ground over which they pass: when in deep water, their general shade was brownish purple, but when placed on the land, or in shallow water, this dark tint changed into one of a yellowish green. The colour, examined more carefully, was a French gray, with numerous minute spots of bright yellow: the former of these varied in intensity; the latter

© The Complete Work of Charles Darwin Online

entirely disappeared and appeared again by turns. These changes were effected in such a manner, that clouds, varying in tint between a hyacinth red and a chestnut brown,* were continually passing over the body. Any part being subjected to a slight shock of galvanism, became almost black: a similar effect, but in a less degree, was produced by scratching the skin with a needle. These clouds, or blushes, as they may be called, when examined under a glass, are described as being produced by the alternate expansions and contractions of minute vesicles, containing variously-coloured fluids.†

This cuttle-fish displayed its chameleon-like power both during the act of swimming and whilst remaining stationary at the bottom. I was much amused by the various arts to escape detection used by one individual, which seemed fully aware that I was watching it. Remaining for a time motionless, it would then stealthily advance an inch or two, like a cat after a mouse; sometimes changing its colour: it thus proceeded, till having gained a deeper part, it darted away, leaving a dusky train of ink to hide the hole into which it had crawled.

While looking for marine animals, with my head about two feet above the rocky shore, I was more than once saluted by a jet of water, accompanied by a slight grating noise. At first I did not know what it was, but afterwards I found out that it was the cuttle-fish, which, though concealed in a hole, thus often led me to its discovery. That it possesses the power of ejecting water there is no doubt, and it appeared to me certain that it could, moreover, take good aim by directing the tube or siphon on the under side of its body. From the difficulty which these animals have in carrying their heads, they cannot crawl with ease when placed on the ground. I observed that one which I kept in the cabin was slightly phosphorescent in the dark.

St. Paul's Rocks.—In crossing the Atlantic we hove to,

* So named according to Pat. Symes's nomenclature.

† See Encyclo. of Anat. and Physiol., article *Cephalopoda*.

© The Complete Work of Charles Darwin Online

during the morning of February 16th, close to the island of St. Paul. This cluster of rocks is situated in 0° 58′ north latitude, and 29° 15′ west longitude. It is 540 miles distant from the coast of America, and 350 from the island of Fernando Noronha. The highest point is only fifty feet above the level of the sea, and the entire circumference is under three-quarters of a mile. This small point rises abruptly out of the depths of the ocean. Its mineralogical constitution is not simple; in some parts, the rock is of a cherty, in others, of a felspathic nature; and in the latter case it contains thin veins of serpentine, mingled with calcareous matter.

The circumstance of these rocks not being of volcanic origin is of interest, because, with very few exceptions, the islands situated in the midst of the great oceans are thus constituted. As the highest pinnacles of the great mountain ranges probably once existed as islands distant from any continent, we are led to expect that they would frequently consist of volcanic rocks. It becomes, therefore, a curious point to speculate on the changes which many of the present islands would undergo, during the lapse of the countless ages, which would be required to elevate them into snow-clad summits. If we take the case of Ascension, or St. Helena, both of which have long existed in an extinct condition, we may feel assured, before so vast a period could elapse, during the whole of which the surface would be exposed to constant wear and tear, that the mere nucleus or core of the island would remain; perhaps, every fragment of cellular rock having been decomposed, a mass of some compact stone, as phonolite or greenstone, would crown our new Chimborazo.

The rocks of St. Paul appear from a distance of a brilliantly white colour. This is partly owing to the dung of a vast multitude of seafowl, and partly to a coating of a glossy white substance, which is intimately united to the surface of the rocks. This, when examined with a lens, is found to consist of numerous exceedingly thin layers, its total thickness being about the tenth of an inch. The surface is smooth

© The Complete Work of Charles Darwin Online

and glossy, and has a pearly lustre; it is considerably harder than calcareous spar, although it can be scratched by a knife: under the blowpipe it decrepitates, slightly blackens, and emits a fetid odour. It consists of phosphate of lime, mingled with some impurities; and its origin without doubt is due to the action of the rain or spray on the bird's dung. I may here mention, that I found in some hollows in the lava rocks of Ascension considerable masses of the substance called *guano*, which on the west coast of the intertropical parts of South America occurs in great beds, some yards thick, on the islets frequented by seafowl. According to the analysis of Fourcroy and Vauquelin, it consists of the urates, phosphates, and oxalates of lime, ammonia, and potash, together with some other salts, and some fatty and earthy matter. I believe there is no doubt of its being the richest manure which has ever been discovered. At Ascension, close to the *guano*, stalactitic or botryoidal masses of impure phosphate of lime adhered to the basalt. The basal part of these had an earthy texture, but the extremities were smooth and glossy, and sufficiently hard to scratch common glass. These stalactites appeared to have shrunk, perhaps from the removal of some soluble matter, in the act of consolidation; and hence they had an irregular form. Similar stalactitic masses,* though I am not aware that they have ever been noticed, are, I believe, by no means of uncommon occurrence.

We only observed two kinds of birds—the booby and the noddy. The former is a species of gannet, and the latter a tern. Both are of a tame and stupid disposition, and are so unaccustomed to visiters, that I could have killed any number of them with my geological hammer. The booby lays her eggs on the bare rock; but the tern makes a very simple nest

* I may mention that I was shown, at Ascension, some very fine stalactites, composed of sulphate of lime, which had been taken out of a cavern. From their external appearance they would generally be mistaken for the ordinary calcareous kind. It was interesting to observe, in a fractured specimen, the double cleavage intersecting with its even planes, the irregular layers of successive deposition.

© The Complete Work of Charles Darwin Online

with sea-weed. By the side of many of these nests a small flying-fish was placed; which, I suppose, had been brought by the male bird for its partner. It was amusing to watch how quickly a large and active crab (*Graspus*), which inhabits the crevices of the rock, stole the fish from the side of the nest, as soon as we had disturbed the birds. Not a single plant, not even a lichen, grows on this island; yet it is inhabited by several insects and spiders. The following list completes, I believe, the terrestrial fauna: a species of Feronia and an acarus, which must have come here as parasites on the birds; a small brown moth, belonging to a genus that feeds on feathers; a staphylinus (*Quedius*) and a woodlouse from beneath the dung; and lastly, numerous spiders, which I suppose prey on these small attendants on, and scavengers of the waterfowl. The often-repeated description of the first colonists of the coral islets in the South Sea, is not, probably, quite correct: I fear it destroys the poetry of the story to find, that these little vile insects should thus take possession before the cocoa-nut tree and other noble plants have appeared.

The smallest rock in the tropical seas, by giving a foundation, for the growth of innumerable kinds of sea-weed and compound animals, supports likewise a large number of fish. The sharks and the seamen in the boats maintained a constant struggle, who should secure the greater share of the prey caught by the lines. I have heard, that a rock near the Bermudas, lying many miles out at sea, and covered by a considerable depth of water, was first discovered by the circumstance of fish having been observed in the neighbourhood.

Fernando Noronha, Feb. 20th.—As far as I was enabled to observe, during the few hours we staid at this place, the constitution of the island is volcanic, but probably not of a recent date. The most remarkable feature is a conical hill, about one thousand feet high, the upper part of which is exceedingly steep, and on one side overhangs its base. The rock is phonolite, and is divided into irregular

© The Complete Work of Charles Darwin Online

columns. From the first impression, on viewing one of these isolated masses, one is inclined to believe, that the whole has been suddenly pushed up in a semi-fluid state. At St. Helena, however, I ascertained that some pinnacles, of a nearly similar figure and constitution, had been formed by the injection of melted rock among the yielding strata; which thus formed the model for these gigantic obelisks. The whole island is covered with wood; but from the dryness of the climate there is no appearance of luxuriance. At some elevation great masses of the columnar rock, shaded by laurels, and ornamented by a tree covered by fine pink flowers like those of a foxglove, but without a single leaf, gave a pleasing effect to the nearer parts of the scenery.

Bahia, or San Salvador. Brazil, Feb. 29th.—The day has past delightfully. Delight itself, however, is a weak term to express the feelings of a naturalist who, for the first time, has been wandering by himself in a Brazilian forest. Among the multitude of striking objects, the general luxuuriance of the vegetation bears away the victory. The elegance of the grasses, the novelty of the parasitical plants, the beauty of the flowers, the glossy green of the foliage, all tend to this end. A most paradoxical mixture of sound and silence pervades the shady parts of the wood. The noise from the insects is so loud, that it may be heard even in a vessel anchored several hundred yards from the shore; yet within the recesses of the forest a universal silence appears to reign. To a person fond of natural history, such a day as this, brings with it a deeper pleasure than he ever can hope again to experience. After wandering about for some hours, I returned to the landing-place; but, before reaching it, I was overtaken by a tropical storm. I tried to find shelter under a tree which was so thick, that it would never have been penetrated by common English rain; but here, in a couple of minutes, a little torrent flowed down the trunk. It is to this violence of the rain we must attribute the verdure at the bottom of the thickest woods: if the showers were like those of a colder clime, the greater part would be

© The Complete Work of Charles Darwin Online

absorbed or evaporated before it reached the ground. I will not at present attempt to describe the gaudy scenery of this noble bay, because, in our homeward voyage, we called here a second time, and I shall then have occasion to remark on it.

The geology of the surrounding country possesses little interest. Throughout the coast of Brazil, and certainly for a considerable space inland, from the Rio Plata to Cape St. Roque, lat. 5° S., a distance of more than 2000 geographical miles, wherever solid rock occurs, it belongs to a granitic formation. The circumstance of this enormous area being thus constituted of materials, which almost every geologist believes to have been crystallized by the action of heat under pressure, gives rise to many curious reflections. Was this effect produced beneath the depths of a profound ocean? or did a covering of strata formerly extend over it, which has since been removed? Can we believe that any power, acting for a time short of infinity, could have denuded the granite over so many thousand square leagues?

On a point not far from the city, where a rivulet entered the sea, I observed a fact connected with a subject discussed by Humboldt.* At the cataracts of the great rivers Orinoco, Nile, and Congo, the syenitic rocks are coated by a black substance, appearing as if they had been polished with plumbago. The layer is of extreme thinness; and on analysis by Berzelius it was found to consist of the oxides of manganese and iron. In the Orinoco it occurs on the rocks periodically washed by the floods, and in those parts alone, where the stream is rapid; or, as the Indians say, "the rocks are black, where the waters are white." The coating is here of a rich brown instead of a black colour, and seems to be composed of ferrugineous matter alone. Hand specimens fail to give a just idea of these brown, burnished, stones which glitter in the sun's rays.

* Pers. Narr., vol. v., pt. i., p. 18.

© The Complete Work of Charles Darwin Online

They occur only within the limits of tidal action; and as the rivulet slowly trickles down, the surf must supply the polishing power of the cataracts in the great rivers. In the same manner, the rise and fall of the tide probably answers to the periodical inundations; and thus the same causes are present under apparently very different circumstances. The real origin, however, of these coatings of metallic oxides, which seem as if cemented to the rocks, is not understood; and no reason, I believe, can be assigned for their thickness remaining constant.

One day I was amused by watching the habits of a Diodon, which was caught swimming near the shore. This fish is well known to possess the singular power of distending itself into a nearly spherical form. After having been taken out of water for a short time, and then again immersed in it, a considerable quantity both of water and air was absorbed by the mouth, and perhaps likewise by the branchial apertures. This process is effected by two methods; the air is swallowed, and is then forced into the cavity of the body, its return being prevented by a muscular contraction which is externally visible; but the water, I observed, entered in a stream through the mouth, which was wide open and motionless: this latter action must, therefore, depend on suction. The skin about the abdomen is much looser than that of the back; hence, during the inflation, the lower surface becomes far more distended than the upper; and the fish, in consequence, floats with its back downwards. Cuvier doubts whether the Diodon, in this position, is able to swim; but not only can it thus move forward in a straight line, but likewise it can turn round to either side. This latter movement is effected solely by the aid of the pectoral fins; the tail being collapsed, and not used. From the body being buoyed up with so much air, the branchial openings were out of water; but a stream drawn in by the mouth, constantly flowed through them.

The fish, having remained in this distended state for a

© The Complete Work of Charles Darwin Online

short time, generally expelled the air and water with considerable force from the branchial apertures and mouth. It could emit, at will, a certain portion of the water; and it appears, therefore, probable, that this fluid is taken in partly for the sake of regulating its specific gravity. This diodon possessed several means of defence. It could give a severe bite, and could eject water from its mouth to some distance, at the same time it made a curious noise by the movement of its jaws. By the inflation of its body, the papillæ, with which the skin is covered, became erect and pointed. But the most curious circumstance was, that it emitted from the skin of its belly, when handled, a most beautiful carmine red and fibrous secretion, which stained ivory and paper in so permanent a manner, that the tint is retained with all its brightness to the present day. I am quite ignorant of the nature and use of this secretion.

March 18th.—We sailed from Bahia. A few days afterwards, when not far distant from the Abrolhos islets, my attention was called to a discoloured appearance in the sea. The whole surface of the water, as it appeared under a weak lens, seemed as if covered by chopped bits of hay, with their ends jagged. One of the larger particles measured .03 of an inch in length, and .009 in breadth. Examined more carefully, each is seen to consist of from twenty to sixty cylindrical filaments, which have perfectly rounded extremities, and are divided at regular intervals by transverse septa, containing a brownish-green flocculent matter. The filaments must be enveloped in some viscid fluid, for the bundles adhered together without actual contact. I do not know to what family these bodies properly belong, but they have a close general resemblance in structure with the confervæ which grow in every ditch. These simple vegetables, thus constituted for floating in the open ocean, must in certain places exist in countless numbers. The ship passed through several bands of them, one of which was about ten yards wide, and, judging from the mud-like colour of the

© The Complete Work of Charles Darwin Online

water, at least two and a half miles long. In almost every long voyage some account is given of these confervæ. They appear especially common in the sea near Australia. Off Cape Leeuwin, I found some very similar to those above described; they differed chiefly in the bundles being rather smaller, and being composed of fewer filaments. Captain Cook, in his third voyage, remarks, that the sailors gave to this appearance the name of sea-sawdust.

I may here mention that during two days preceding our arrival at the Keeling Islands in the Indian Ocean, I saw in many parts masses of flocculent matter, of a brownish-green colour, floating in the sea. They varied in size, from half to to three or four inches square; and were quite irregular in figure. In an opake vessel they could barely be distinguished, but in a glass one they were clearly visible. Under the microscope the flocculent matter was seen to consist of two kinds of confervæ, between which I am quite ignorant whether there exists any connexion. Minute cylindrical bodies, conical at each extremity, are involved in vast numbers, in a mass of fine threads. These threads have a diameter of about $\frac{2}{3000}$ of an inch; they possess an internal lining, and are divided at irregular and very wide intervals by transverse septa. Their length is so great, that I could never with certainty ascertain the form of the uninjured extremity; they are all curvilinear, and resemble in mass a handful of hair, coiled up and squeezed together. In the midst of these threads, and probably connected by some viscid fluid, the other kind, or the cylindrical transparent bodies, float in great numbers. These have their two extremities terminated by cones, produced into the finest points: their diameter is tolerably constant between .006 and .008 of an inch; but their length varies considerably from .04 to .06, and even sometimes to .08. Near one extremity of the cylindrical part, a green septum, formed of granular matter, and thickest in the middle, may generally be seen. This, I believe, is the bottom of a most delicate, colourless sack, composed of a pulpy substance, which lines the exterior case, but does

© The Complete Work of Charles Darwin Online

not extend within the extreme conical points. In some, small but perfect spheres of brownish granular matter supplied the place of the septa; and I observed the curious process by which they were produced. The pulpy matter of the internal coating suddenly grouped itself into lines, some of which assumed a form radiating from a common centre; it then continued, with an irregular and rapid movement, to contract itself, so that, in the course of a second, the whole was united into a perfect little sphere, which occupied the position of the septum at one end of the now quite hollow case. The appearance was as if an elastic membrane, for instance a thin Indian-rubber ball, had been distended with air, and then burst, in which case the edges would instantly shrink up and contract towards a point. The formation of the granular sphere was hastened by any accidental injury. I may add, that frequently a pair of these bodies were attached to each other, as represented in the accompanying rude drawing, cone beside

cone, at that end where the septum occurs. When floating uninjured in the sea, the formation of the spherical gemmules perhaps only takes place, when two of the plants (or rather animals, according to Bory St. Vincent) thus become attached, and married to each other. Nevertheless, I certainly witnessed this curious process in several individuals, when separate, and where there was no apparent cause of disturbance. In any case it does not seem probable, from the fixed structure of the septum, that the whole of the granular matter is transferred from one to the other body, as with the true Conjugatæ.

I will here add a few other observations connected with the discoloration of the sea from organic causes. On the coast of Chile, a few leagues north of Concepcion, the Beagle one day passed through great bands of muddy water; and

© The Complete Work of Charles Darwin Online

PHILOSOPHICAL LIBRARY
19 JUN 1901
CAMBRIDGE

again, a degree south of Valparaiso, the same appearance was still more extensive. Although we were nearly fifty miles from the coast, I at first attributed this circumstance to real streams of muddy water brought down by the river Maypo. Mr. Sulivan, however, having drawn up some in a glass, thought he distinguished, by the aid of a lens, moving points. The water was slightly stained as if by red dust; and after leaving it for some time quiet, a cloud collected at the bottom. With a lens, of one-fourth of an inch focal distance, small hyaline points could be seen darting about with great rapidity, and frequently exploding. Examined with a much higher power, their shape was found to be oval, and contracted by a ring round the middle, from which line curved little setæ proceeded on all sides; and these were the organs of motion. One end of the body was narrower and more pointed than the other. According to the arrangement of Bory St. Vincent, they are animalcula, belonging to the family of Trichodes: it was, however, very difficult to examine them with care, for almost the instant motion ceased, even while crossing the field of vision, their bodies burst. Sometimes both ends burst at once, sometimes only one, and a quantity of coarse brownish granular matter was ejected, which cohered very slightly. The ring with the setæ sometimes retained its irritability for a little while after the contents of the body had been emptied, and continued a riggling, uneven motion. The animal an instant before bursting expanded to half again its natural size; and the explosion took place about fifteen seconds after the rapid progressive motion had ceased: in a few cases it was preceded for a short interval by a rotatory movement on the longer axis. About two minutes after any number were isolated in a drop of water, they thus perished. The animals move with the narrow apex forwards, by the aid of their vibratory ciliæ, and generally by rapid starts. They are exceedingly minute, and quite invisible to the naked eye, only covering a space equal to the square of the thousandth of an inch. Their numbers were infinite; for the smallest

DARWIN LIBRARY
CAMBRIDGE

© The Complete Work of Charles Darwin Online

drop of water which I could remove contained very many. In one day we passed through two spaces of water thus stained, one of which alone must have extended over several square miles. What incalculable numbers of these microscopical animals! The colour of the water, as seen at some distance, was like that of a river which has flowed through a red clay district; but under the shade of the vessel's side, it was quite as dark as chocolate. The line where the red and blue water joined was distinctly defined. The weather for some days previously had been calm, and the ocean abounded, to an unusual degree, with living creatures. In Ulloa's voyage an account is given of crossing, in nearly the same latitude, some discoloured water, which was mistaken for a shoal: no soundings were obtained, and I have no doubt, from the description, that this little animalcule was the cause of the alarm.*

In the sea around Tierra del Fuego, and at no great distance from the land, I have seen narrow lines of water of a bright red colour, from the number of crustacea, which somewhat resemble in form large prawns. The sealers call them whale-food. Whether whales feed on them I do not know; but terns, cormorants, and immense herds of great unwieldly seals, on some parts of the coast, derive their chief sustenance from these swimming crabs. Seamen invariably attribute the discoloration of the water to spawn; but I found this to be the case only on one occasion. At the distance of several leagues from the Archipelago of the Galapagos, the ship sailed through three strips of a dark yel-

* M. Lesson (Voyage de la Coquille, vol. i., p. 255) mentions red water off Lima, apparently produced by the same cause. Peron, the distinguished naturalist, in the "Voyage Aux Terres Australes," gives no less than twelve references to voyagers who have alluded to the discoloured waters of the sea (vol. ii., p. 239). It was his intention to have written an essay on the subject. To the references given by Peron may be added, Humboldt's Pers. Narr., vol. vi., p. 804; Flinder's Voyage, vol. i., p. 92; Labillardiere, vol. i., p. 287; Ulloa's Voyage; Voyage of the Astrolabe and of the Coquille; Captain King's Survey of Australia, &c.

© The Complete Work of Charles Darwin Online

lowish, or mud-like, water; these strips were some miles long, but only a few yards wide, and they were separated from the surrounding surface by a sinuous yet distinct margin. The colour was caused by little gelatinous balls, about the fifth of an inch in diameter, in which numerous minute spherical ovules were embedded: they were of two distinct kinds, one being of a reddish colour and of a different shape from the other. I cannot form a conjecture as to what two kinds of animals these belonged. Captain Colnett remarks, that this appearance is very common among the Galapagos Islands, and that the direction of the bands indicates that of the currents; in the described case, however, the line was caused by the wind. The only other appearance which I have to notice, is a thin oily coat on the surface which displays iridescent colours. I saw a considerable tract of the ocean thus covered on the coast of Brazil; the seamen attributed it to the putrefying carcass of some whale, which probably was floating at no great distance. I do not here mention the minute gelatinous particles which are frequently dispersed throughout the water, for they are not sufficiently abundant to create any change of colour.

There are two circumstances in the above accounts which appear very remarkable: first, how do the various bodies which form the bands with defined edges keep together? In the case of the prawn-like crabs, their movements were as coinstantaneous as in a regiment of soldiers; but this cannot happen from any thing like voluntary action with the ovules, or the confervæ, nor is it probable among the infusoria. Secondly, what causes the length and narrowness of the bands? The appearance so much resembles that which may be seen in every torrent, where the stream uncoils into long streaks, the froth collected in the eddies, that I must attribute the effect to a similar action either of the currents of the air, or sea. Under this supposition we must believe that the various organized bodies are produced in certain favourable places, and are thence removed by the set of either wind or water. I confess,

© The Complete Work of Charles Darwin Online

however, there is a very great difficulty in imagining any one spot to be the birthplace of the millions of millions of animalcula and confervæ: for whence come the germs at such points?—the parent bodies having been distributed by the winds and waves over the immense ocean. But on no other hypothesis can I understand their linear grouping. I may add that Scoresby remarks, that green water abounding with pelagic animals, is invariably found in a certain part of the Arctic Sea.

CHAPTER II.

Rio de Janeiro—Excursion north of Cape Frio—Great evaporation—Slavery—Botofogo Bay—Terrestrial Planariæ—Clouds on Corcovado—Heavy rain—Musical Hyla—Lampyris and its larvæ—Elater, springing powers—Blue haze—Noise of butterfly—Entomology—Ants—Wasp-killing spider—Parasitical spider—Artifices of Epeira—Gregarious spider—Spider with imperfect web.

RIO DE JANEIRO.

April 4th to July 5th, 1832.—A few days after our arrival I became acquainted with an Englishman who was going to visit his estate situated, rather more than a hundred miles from the capital, to the northward of Cape Frio. As I was quite unused to travelling, I gladly accepted his kind offer of allowing me to accompany him.

April 8th.—Our party amounted to seven. The first stage was very interesting. The day was powerfully hot, and as we passed through the woods, every thing was motionless, excepting the large and brilliant butterflies, which lazily fluttered about. The view seen when crossing the hills behind Praia Grande was most beautiful; the colours were intense, and the prevailing tint a dark blue; the sky and the calm waters of the bay vied with each other in splendour. After passing through some cultivated country, we entered a forest, which in the grandeur of all its parts could not be exceeded. We arrived by midday at Ithacaia; this small village is situated on a plain, and round the central house are the huts of the negroes. These, from their regular form and position, reminded me of the drawings of the Hottentot habitations in Southern Africa. As the moon rose early, we determined to start the same evening for our sleeping-place at the Lagoa Marica. As it was growing

© The Complete Work of Charles Darwin Online

dark we passed under one of the massive, bare, and steep hills of granite which are so common in this country. This spot is notorious from having been, for a long time, the residence of some runaway slaves, who, by cultivating a little ground near the top, contrived to eke out a subsistence. At length they were discovered, and a party of soldiers being sent, the whole were seized with the exception of one old woman, who sooner than again be led into slavery, dashed herself to pieces from the summit of the mountain. In a Roman matron this would have been called the noble love of freedom: in a poor negress it is mere brutal obstinacy. We continued riding for some hours. For the few last miles the road was intricate, and it passed through a desert waste of marshes and lagoons. The scene by the dimmed light of the moon was most desolate. A few fireflies flitted by us; and the solitary snipe, as it rose, uttered its plaintive cry. The distant and sullen roar of the sea scarcely broke the stillness of the night.

April 9th.—We left our miserable sleeping-place before sunrise. The road passed through a narrow sandy plain, lying between the sea and the interior salt lagoons. The number of beautiful fishing birds, such as egrets and cranes, and the succulent plants assuming most fantastical forms, gave to the scene an interest which it would not otherwise have possessed. The few stunted trees were loaded with parasitical plants, among which the beauty and delicious fragrance of some of the orchideæ were most to be admired. As the sun rose, the day became extremely hot, and the reflection of the light and heat from the white sand was very distressing. We dined at Mandetiba; the thermometer in the shade being 84°. The beautiful view of the distant wooded hills, reflected in the perfectly calm water of an extensive lagoon, quite refreshed us. As the vênda* here was a very good one, and I have the pleasant, but rare remembrance, of an excellent dinner, I will be grateful and presently describe

* Vênda, the Portuguese name for an inn.

© The Complete Work of Charles Darwin Online

it, as the type of its class. These houses are often large, and are built of thick upright posts, with boughs interwoven, and afterwards plastered. They seldom have floors, and never glazed windows; but are generally pretty well roofed. Universally the front part is open, forming a kind of verandah, in which tables and benches are placed. The bed-rooms join on each side, and here the passenger may sleep as comfortably as he can, on a wooden platform, covered by a thin straw mat. The vênda stands in a courtyard, where the horses are fed. On first arriving, it was our custom to unsaddle the horses and give them their Indian corn; then, with a low bow, to ask the senhôr to do us the favour to give us something to eat. "Any thing you choose, sir," was his usual answer. For the few first times, vainly I thanked Providence for having guided us to so good a man. The conversation proceeding, the case universally became deplorable. "Any fish can you do us the favour of giving?"—"Oh! no, sir."—"Any soup?"—"No, sir."—"Any bread?"—"Oh! no, sir."—"Any dried meat?"—"Oh! no, sir." If we were lucky, by waiting a couple of hours, we obtained fowls, rice, and farinha. It not unfrequently happened, that we were obliged to kill, with stones, the poultry for our own supper. When thoroughly exhausted by fatigue and hunger, we timorously hinted that we should be glad of our meal, the pompous, and (though true) most unsatisfactory answer was, "It will be ready when it is ready." If we had dared to remonstrate any further, we should have been told to proceed on our journey, as being too impertinent. The hosts are most ungracious and disagreeable in their manners; their houses and their persons are often filthily dirty; the want of the accommodation of forks, knives, and spoons is common; and I am sure no cottage or hovel in England could be found in a state so utterly destitute of every comfort. At Campos Novos, however, we fared sumptuously; having rice and fowls, biscuit, wine, and spirits, for dinner; coffee in the evening, and fish with coffee for breakfast. All this, with good food for the

© The Complete Work of Charles Darwin Online

horses, only cost 2*s.* 6*d.* per head. Yet the host of this vênda, being asked if he knew any thing of a whip which one of the party had lost, gruffly answered, "How should I know? why did you not take care of it?—I suppose the dogs have eat it."

Leaving Mandetiba, we continued to pass through an intricate wilderness of lakes; in some of which were fresh, in others salt water shells. Of the former kind I found a Limnæa in great numbers in a lake, into which, the inhabitants assured me, the sea annually, and sometimes oftener, entered, and made the water quite salt. I have no doubt many interesting facts, in relation to marine and fresh water animals, might be observed in this chain of lagoons, which skirt the coast of Brazil. M. Gay* has stated that he found in the neighbourhood of Rio, shells of the marine genera solen and mytilus, and fresh water ampullariæ, living together in brackish water. I also frequently observed in the lagoon near the Botanic Garden, where the water is only a little less salt than in the sea, a species of hydrophilus, very similar to a species common in the ditches of England: in the same lake the only shell belonged to a genus generally found in estuaries.

Leaving the coast for a time, we again entered the forest. The trees were very lofty, and remarkable, compared to those of Europe, from the whiteness of their trunks. I see by my note-book, "wonderful and beautiful, flowering parasites," invariably struck me as the most novel object in these grand scenes. Travelling onwards we passed through tracts of pasturage, much injured by the enormous conical ants' nests, which were nearly twelve feet high. They gave to the plain exactly the appearance of the mud volcanoes at Jorullo, as figured by Humboldt. We arrived at Engenhodo after it was dark, having been ten hours on horseback. I never ceased, during the whole journey, to be surprised at the amount of labour which the horses were capable of enduring;

* Annales des Sciences Naturelles for 1833.

© The Complete Work of Charles Darwin Online

they appeared also to recover from any injury much sooner than those of our English breed. The Vampire bat is often the cause of much trouble, by biting the horses on their withers. The injury is generally not so much owing to the loss of blood, as to the inflammation which the pressure of the saddle afterwards produces. The whole circumstance has lately been doubted in England; I was therefore fortunate in being present when one* was actually caught on a horse's back. We were bivouacking late one evening near Coquimbo, in Chile, when my servant, noticing that one of the horses was very restive, went to see what was the matter, and fancying he could distinguish something, suddenly put his hand on the beast's withers, and secured the vampire. In the morning, the spot, where the bite had been inflicted, was easily distinguished from being slightly swollen and bloody. The third day afterwards we rode the horse, without any ill effects.

April 13th.—After three days' travelling we arrived at Socêgo, the estate of Senhôr Manuel Figuireda, a relation of one of our party. The house was simple, and, though like a barn in form, was well suited to the climate. In the sitting-room gilded chairs and sofas were oddly contrasted with the whitewashed walls, thatched roof, and windows without glass. The house, together with the granaries, the stables, and workshops for the blacks, who had been taught various trades, formed a rude kind of quadrangle; in the centre of which a large pile of coffee was drying. These buildings stand on a little hill, overlooking the cultivated ground, and surrounded on every side by a wall of dark green luxuriant forest. The chief produce of this part of the country is coffee. Each tree is supposed to yield annually, on an average, two pounds; but some give as much as eight. Mandioca or cassada is likewise cultivated in great quantity. Every part of this plant is useful: the leaves and stalks are

* This bat belongs to the genus Edostoma of D'Orbigny, but is a new species.

© The Complete Work of Charles Darwin Online

eaten by the horses, and the roots are ground into a pulp, which, when pressed dry and baked, forms the farinha, the principal article of sustenance in the Brazils. It is a curious, though well-known fact, that the expressed juice of this most nutritious plant is highly poisonous. A few years ago a cow died at this Fazênda, in consequence of having drunk some of it. Senhôr Figuireda told me that he had planted, the year before, one bag of feijaô or beans, and three of rice; the former of which produced eighty, and the latter three hundred and twenty fold. The pasturage supports a fine stock of cattle, and the woods are so full of game, that a deer had been killed on each of the three previous days. This profusion of food showed itself at dinner, where, if the tables did not groan, the guests surely did: for each person is expected to eat of every dish. One day, having, as I thought, nicely calculated so that nothing should go away untasted, to my utter dismay a roast turkey and a pig appeared in all their substantial reality. During the meals, it was the employment of a man to drive out of the room sundry old hounds, and dozens of little black children, which crawled in together, at every opportunity. As long as the idea of slavery could be banished, there was something exceedingly fascinating in this simple and patriarchal style of living: it was such a perfect retirement and independence of the rest of the world. As soon as any stranger is seen arriving, a large bell is set tolling, and generally some small cannon are fired. The event is thus announced to the rocks and woods, but to nothing else. One morning I walked out an hour before daylight to admire the solemn stillness of the scene; at last, the silence was broken by the morning hymn, raised on high by the whole body of the blacks; and in this manner, their daily work is generally begun. On such fazendas as these, I have no doubt the slaves pass happy and contented lives. On Saturday and Sunday they work for themselves, and in this fertile climate the labour of two days is sufficient to support a man and his family for the whole week.

April 14th.—Leaving Socêgo, we rode to another estate on the Rio Macâe, which was the last patch of cultivated ground in that direction. The estate was two and a half miles long, and the owner had forgotten how many broad. Only a very small piece had been cleared, yet almost every acre was capable of yielding all the various rich productions of a tropical land. Considering the enormous area of Brazil, the proportion of cultivated ground can scarcely be considered as any thing, compared to that which is left in the state of nature: at some future age, how vast a population it will support! During the second day's journey we found the road so shut up, that it was necessary that a man should go ahead with a sword to cut away the creepers. The forest abounded with beautiful objects; among which the tree ferns, though not large, were, from their bright green foliage, and the elegant curvature of their fronds, most worthy of admiration. In the evening it rained very heavily, and although the thermometer stood at 65°, I felt very cold. As soon as the rain ceased, it was curious to observe the extraordinary evaporation which commenced over the whole extent of the forest. At the height of a hundred feet the hills were buried in a dense white vapour, which rose like columns of smoke from the most thickly-wooded parts, and especially from the valleys. I observed this phenomenon on several occasions: I suppose it is owing to the large surface of foliage, previously heated by the sun's rays.

While staying at this estate, I was very nearly being an eyewitness to one of those atrocious acts, which can only take place in a slave country. Owing to a quarrel and a lawsuit, the owner was on the point of taking all the women and children from the men, and selling them separately at the public auction at Rio. Interest, and not any feeling of compassion, prevented this act. Indeed, I do not believe the inhumanity of separating thirty families, who had lived together for many years, even occurred to the person. Yet I will pledge myself, that in humanity and good feeling, he

© The Complete Work of Charles Darwin Online

was superior to the common run of men. It may be said there exists no limit to the blindness of interest and selfish habit. I may mention one very trifling anecdote, which at the time struck me more forcibly than any story of cruelty. I was crossing a ferry with a negro, who was uncommonly stupid. In endeavouring to make him understand, I talked loud, and made signs, in doing which I passed my hand near his face. He, I suppose, thought I was in a passion, and was going to strike him; for instantly, with a frightened look and half-shut eyes, he dropped his hands. I shall never forget my feelings of surprise, disgust, and shame, at seeing a great powerful man afraid even to ward off a blow, directed, as he thought, at his face. This man had been trained to a degradation lower than the slavery of the most helpless animal.

April 18th.—In returning we spent two days at Socêgo, and I employed them in collecting insects in the forest. The greater number of trees, although so lofty, are not more than three or four feet in circumference. There are, of course, a few of much greater dimension. Senhor Manuel, was then making a canoe seventy feet in length from a solid trunk, which had originally been 110 feet long, and of great thickness. The contrast of palm-trees, growing amidst the common branching kinds, never fails to give the scene an intertropical character. Here the woods were ornamented by the Cabbage Palm—one of the most beautiful of its family. With a stem so narrow that it might be clasped with the two hands, it waves its elegant head at the height of forty or fifty feet above the ground. The woody creepers, themselves covered by other creepers, were of great thickness: some which I measured were two feet in circumference. Many of the older trees presented a very curious appearance from the tresses of a liana depending from their boughs, and resembling bundles of hay. If the eye was turned from the world of foliage above, to the ground beneath, it was attracted by the extreme elegance of the leaves of the ferns

© The Complete Work of Charles Darwin Online

and mimosæ. The latter, in some parts, covered the surface with a brushwood only a few inches high. In walking across these thick beds, a broad track was marked by the change of shade, produced by the drooping of their sensitive petioles. It is easy to specify the individual objects of admiration in these grand scenes; but it is not possible to give an adequate idea of the higher feelings of wonder, astonishment, and devotion, which fill and elevate the mind.

April 19th.—Leaving Socêgo, during the two first days, we retraced our steps. It was very wearisome work, as the road generally ran across a glaring hot sandy plain, not far from the coast. I noticed that each time the horse put its foot on the fine siliceous sand, a gentle chirping noise was produced. On the third day we took a different line, and passed through the gay little village of Madre de Deos. This is one of the principal lines of road in Brazil; yet it was in so bad a state, that no wheel vehicle, excepting the clumsy bullock-waggon, could pass along. In our whole journey we did not cross a single bridge built of stone; and those made of logs of wood were frequently so much out of repair, that it was necessary to go on one side to avoid them. All distances are inaccurately known. The road is often marked by crosses, in the place of milestones, to signify where human blood has been spilled. On the evening of the 23d we arrived at Rio, having finished our pleasant little excursion.

During the remainder of my stay at Rio, I resided in a cottage at Botofogo Bay. It was impossible to wish for any thing more delightful than thus to spend some weeks in so magnificent a country. In England any person fond of natural history enjoys in his walks a great advantage, by always having something to attract his attention; but in these fertile climates, teeming with life, the attractions are so numerous, that he is scarcely able to walk at all.

The few observations which I was enabled to make were almost exclusively confined to the invertebrate animals. The

© The Complete Work of Charles Darwin Online

existence of a division of the genus Planaria, which inhabits the dry land, interested me much. These animals are of so simple a structure, that Cuvier has arranged them with the intestinal worms, though never found within the bodies of other animals. Numerous species inhabit both salt and fresh water; but those to which I allude were found beneath logs of rotten wood, even in the drier parts of the forest. In general form they resemble little slugs, but are very much narrower in proportion. I met with one specimen no less than five inches long. The lower surface, by which they crawl, is flat, the upper being convex: in this latter respect the terrestrial species all differ from the depressed forms of the aquatic. Their structure is very simple. Near the middle of the under surface, there are two small transverse slits, from the anterior one of which a funnel-shaped organ, or cup, can be protruded. This seems to act as the mouth. It is soft, highly irritable, and capable of various movements; when drawn within the body it is generally folded up like the bud of a plant. From the central position of the orifice, the animal has its mouth in the middle of what would commonly be called its stomach! For some time after the rest of the animal has become dead from the effects of salt water, or other cause, this organ still retains its vitality. The body is soft and parenchymatous; in the central part a transparent space, with lateral ramifications, appears to act as a system of circulation. Minute, black, eye-like specks are scattered round the margin of the crawling surface, and more abundantly close to the anterior extremity, which is constantly used as a feeler. In a marine species, I extracted from the central parts of the body vast numbers of little spherical eggs; they were .006 of an inch in diameter, and contained a central opake mass or yolk.

The terrestrial Planariæ, of which I have found no less than eight species, occur from within the tropic to lat. 47° south, and are common to South America, New Zealand, Van Diemen's Land, and Mauritius. Some of the species

© The Complete Work of Charles Darwin Online

are longitudinally striped with several bands of gay colours. At first sight there is a remarkable false analogy between these animals and snails, although so widely separated from each other in all essential points of organization. I suppose these Planariæ feed on rotten wood, for they are always found crawling on the under surface of old decayed trees; and some small specimens being kept with no other food, rapidly increased in size. Although gaily-coloured little animals, they dislike, and are very sensitive to the light. Some specimens which I obtained at Van Diemen's Land, I kept alive for nearly two months. Having cut one of them transversely into two nearly equal parts, in the course of a fortnight both had the shape of perfect animals. I had, however, so divided the body, that one of the halves contained both the inferior orifices, and the other, in consequence, none. In the course of twenty-five days from the operation, the more perfect half could not have been distinguished from any other specimen. The other had increased much in size; and towards its posterior end, a clear space was formed in the parenchymatous mass, in which a rudimentary cup-shaped organ could clearly be distinguished; on the under surface, however, no corresponding slit was yet open. If the increased heat of the weather, as we approached the equator, had not destroyed all the individuals, there can be no doubt that this last step would have completed its structure. Although so well-known an experiment, it was interesting to watch the gradual production of every essential organ, out of the simple extremity of another animal. It is extremely difficult to preserve these Planariæ; immediately the cessation of life allows the ordinary laws of change to act, their entire bodies become soft and fluid, with a rapidity which I have never seen equalled. A method of preservation that I found answered pretty well, was to dry the whole animal rapidly on a thin plate of mica, for the body thus becomes transparent, and allows the internal structure to be seen.

I first visited the forest in which these Planariæ were

© The Complete Work of Charles Darwin Online

found, in company with an old Portuguese priest who took me out to hunt with him. The sport consisted in turning into the cover a few dogs, and then patiently waiting to fire at any animal which might appear. We were accompanied by the son of a neighbouring farmer—a good specimen of a wild Brazilian youth. He was dressed in a tattered old shirt and trousers, and had his head uncovered: he carried an old-fashioned gun and a large knife. The habit of carrying the knife is universal; and in traversing a thick wood it is almost necessary, on account of the creeping plants. The frequent occurrence of murder may be partly attributed to this habit. The Brazilians are so dexterous with the knife, that they can throw it to some distance with precision, and with sufficient force to cause a fatal wound. I have seen a number of little boys practising this art as a game of play, and from their skill in hitting an upright stick, they promised well for more earnest attempts. My companion, the day before, had shot two large bearded monkeys. These animals have prehensile tails, the extremity of which, even after death, can support the whole weight of the body. One of them thus remained fast to a branch, and it was necessary to cut down a large tree to procure it. This was soon effected, and down came tree and monkey with an awful crash. Our day's sport, besides the monkey, was confined to sundry small green parrots and a few toucans. I profited, however, by my acquaintance with the Portuguese padre, for on another occasion he gave me a fine specimen of the Yaguarundi cat.

Every one has heard of the beauty of the scenery near Botofogo. The house in which I lived was seated close beneath the well-known mountain of the Corcovado. It has been remarked, with much truth, that abruptly conical hills are characteristic of the formation which Humboldt designates as gneiss-granite. Nothing can be more striking than the effect of these huge rounded masses of naked rock rising out of the most luxuriant vegetation.

I was often interested by watching the clouds, which,

© The Complete Work of Charles Darwin Online

rolling in from seaward, formed a bank just beneath the highest point of the Corcovado. This mountain, like most others, when thus partly veiled, appeared to rise to a far prouder elevation than its real height of 2300 feet. Mr. Daniell has observed, in his meteorological essays, that a cloud sometimes appears fixed on a mountain summit, while the wind continues to blow over it. The same phenomenon here presented a slightly different appearance. In this case the cloud was clearly seen to curl over, and rapidly pass by the summit, and yet was neither diminished nor increased in size. The sun was setting, and a gentle southerly breeze, striking against the southern side of the rock, mingled its current with the colder air above; and the vapour was thus condensed: but as the light wreaths of cloud passed over the ridge, and came within the influence of the warmer atmosphere of the northern sloping bank, they were immediately redissolved.

The climate, during the months of May and June, or the beginning of winter, was delightful. The mean temperature, from observations taken at nine o'clock, both morning and evening, was only 72°. It often rained heavily, but the drying southerly winds soon again rendered the walks pleasant. One morning, in the course of six hours, 1.6 inches of rain fell. As this storm passed over the forests, which surround the Corcovado, the sound produced by the drops pattering on the countless multitude of leaves, was very remarkable; it could be heard at the distance of a quarter of a mile, and was like the rushing of a great body of water. After the hotter days, it was delicious to sit quietly in the garden and watch the evening pass into night. Nature, in these climes, chooses her vocalists from more humble performers than in Europe. A small frog, of the genus Hyla,* sits on a blade of glass about an inch above the surface of the

* I had some difficulty in catching a specimen of this frog. The genus Hyla has its toes terminated by small suckers; and I found this animal could crawl up a pane of glass, when placed absolutely perpendicular.

© The Complete Work of Charles Darwin Online

water, and sends forth a pleasing chirp. When several were together they sung in harmony on different notes. Various cicadæ and crickets, at the same time, kept up a ceaseless shrill cry, but which, softened by the distance, was not unpleasant. Every evening after dark this great concert commenced; and often have I sat listening to it, until my attention has been drawn away by some curious passing insect.

At these times the fireflies are seen* flitting about from hedge to hedge. All that I caught belonged to the family of Lampyridæ, or glowworms, and the greater number were *Lampyris occidentalis*. I found that this insect emitted the most brilliant flashes when irritated: in the intervals the abdominal rings were obscured. The flash was almost coinstantaneous in the two rings, but it was first just perceptible in the anterior one. The shining matter was fluid and very adhesive: little spots, where the skin had been torn, continued bright with a slight scintillation, whilst the uninjured parts were obscured. When the insect was decapitated the rings remained uninterruptedly bright, but not so brilliant as before: local irritation with a needle always increased the vividness of the light. The rings in one instance retained their luminous property nearly twenty-four hours after the death of the insect. From these facts it would appear probable, that the animal has only the power of concealing or extinguishing the light for short intervals, and that at other times the display is involuntary. On the muddy and wet gravel-walks I found the larvæ of this lampyris in great numbers: they resembled in general form the female of the English glowworm. These larvæ possessed but feeble luminous powers; very differently from their parents, on the slightest touch they feigned death, and ceased to shine; nor did irritation excite any fresh display. I kept several of them alive for

* On a dark night the light could be seen at about two hundred paces distant. It is remarkable that in all the glowworms, shining elaters, and various marine animals, which I have observed (such as the crustacea, medusæ, nereidæ, a coralline of the genus Clytia, and Pyrosoma), the light has been of a well-marked green colour.

© The Complete Work of Charles Darwin Online

some time: their tails are very singular organs, for they act, by a well-fitted contrivance, as suckers, or organs of attachment, and likewise as reservoirs for saliva, or some such fluid. I repeatedly fed them on raw meat; and I invariably observed, that every now and then the extremity of the tail was applied to the mouth, and a drop of fluid exuded on the meat, which was then in the act of being consumed. The tail, notwithstanding so much practice, does not seem to be able to find its way to the mouth; at least the neck was always touched first, and apparently as a guide.

When we were at Bahia, an elater (*Pyrophorus luminosus*, Illig.) seemed the most common luminous insect. The light in this case was also rendered more brilliant by irritation. I amused myself one day by observing the springing powers of this insect, which have not,* as it appears to me, been properly described. The elater, when placed on its back and preparing to spring, moved its head and thorax backwards, so that the pectoral spine was drawn out, and rested on the edge of its sheath. The same backward movement being continued, the spine, by the full action of the muscles, was bent like a spring; and the insect at this moment rested on the extremity of its head and elytra. The effort being suddenly relaxed, the head and thorax flew up, and, in consequence, the base of the elytra struck the supporting surface with such force, that the insect by the reaction was jerked upwards to the height of one or two inches. The projecting points of the thorax, and the sheath of the spine, served to steady the whole body during the spring. In the descriptions which I have read, sufficient stress does not appear to have been laid on the elasticity of the spine: so sudden a spring could not be the result of simple muscular contraction, without the aid of some mechanical contrivance.

On several occasions I enjoyed some short but most pleasant excursions in the neighbouring country. One day

* Kirby's Entomology, vol. ii., p. 317.

© The Complete Work of Charles Darwin Online

I went to the Botanic Garden, where many plants, well known for their great utility, might be seen growing. The leaves of the camphor, pepper, cinnamon, and clove trees were delightfully aromatick; and the bread fruit, the jack, and the mango, vied with each other in the magnificence of their foliage. The landscape in the neighbourhood of Bahia almost takes its character from the two latter trees. Before seeing them, I had no idea that any trees could cast so black a shade on the ground. Both of them bear to the ever green vegetation of these climates, the same kind of relation which laurels and hollies in England do to the lighter green of the deciduous trees. It may be observed, that the houses within the tropics are surrounded by the most beautiful forms of vegetation, because many of them are at the same time most useful to man. Who can doubt that these qualities are united in the banana, the cocoa-nut, the many kinds of palm, the orange, and the bread-fruit tree?

During this day I was particularly struck with a remark of Humboldt's, who often alludes to "the thin vapour which, without changing the transparency of the air, renders its tints more harmonious, softens its effects," &c. This is an appearance which I have never observed in the temperate zones. The atmosphere, seen through a short space of half or three-quarters of a mile, was perfectly lucid, but at a greater distance all colours were blended into a most beautiful haze, of a pale French gray, mingled with a little blue. The condition of the atmosphere between the morning and about noon, when the effect was most evident, had undergone little change, excepting in its dryness. In the interval, the difference between the dew point and temperature had increased from 7°.5 to 17°.

On another occasion I started early and walked to the Gavia, or topsail mountain. The air was delightfully cool and fragrant; and the drops of dew still glittered on the leaves of the large liliaceous plants, which shaded the streamlets of clear water. Sitting down on a block of granite, it was delightful to watch the various insects and birds as they

© The Complete Work of Charles Darwin Online

flew past. The humming-birds seem particularly fond of such shady retired spots. Whenever I saw these little creatures buzzing round a flower, with their wings vibrating so rapidly as to be scarcely visible, I was reminded of the sphinx moths: their movements and habits are indeed, in many respects, very similar.

Following a pathway I entered a noble forest, and from a height of five or six hundred feet, one of those splendid views was presented, which are so common on every side of Rio. At this elevation the landscape has attained its most brilliant tint; and every form, every shade, so completely surpasses in magnificence all that the European has ever beheld in his own country, that he knows not how to express his feelings. The general effect frequently recalled to my mind the gayest scenery of the Opera-house or the great theatres. I never returned from these excursions empty-handed. This day I found a specimen of a curious fungus, called Hymenophallus. Most people know the English Phallus, which in autumn taints the air with its odious smell: this, however, as the entomologist is aware, is to some of our beetles a delightful fragrance. So was it here; for a Strongylus, attracted by the odour, alighted on the fungus as I carried it in my hand. We here see in two distant countries a similar relation between plants and insects of the same families, though the species of both are different. When man is the agent in introducing into a country a new species, this relation is often broken: as one instance of this I may mention, that the leaves of the cabbages and lettuces, which in England afford food to such a multitude of slugs and caterpillars, in the gardens near Rio are untouched.

During our stay in Brazil I made a large collection of insects. A few general observations on the comparative importance of the different orders, may be interesting to the English entomologist. The large and brilliantly-coloured Lepidoptera bespeak the zone they inhabit, far more plainly than any other race of animals. I allude only to the butterflies; for the moths, contrary to what might have been expected from the rankness of the vegetation, certainly appeared in much

© The Complete Work of Charles Darwin Online

fewer numbers than in our own temperate regions. I was much surprised at the habits of *Papilio feronia*. This butterfly is not uncommon, and generally frequents the orange-groves. Although a high flier, yet it very frequently alights on the trunks of trees. On these occasions its head is invariably placed downwards; and its wings are expanded in a horizontal plane, instead of being folded vertically, as is commonly the case. This is the only butterfly which I have ever seen that uses its legs for running. Not being aware of this fact, the insect, more than once, as I cautiously approached with my forceps, shuffled on one side just as the instrument was on the point of closing, and thus escaped. But a far more singular fact, is the power which this species possesses of making a noise.* Several times when a pair, probably male and female, were chasing each other in an irregular course, they passed within a few yards of me; and I distinctly heard a clicking noise, similar to that produced by a toothed wheel passing under a spring catch.† The noise was continued at short intervals, and could be distinguished at about twenty yards distance. I cannot form a conjecture how it is produced; but I am certain there is no error in the observation.

I was disappointed in the general aspect of the Coleoptera. The number of minute and obscurely-coloured beetles is exceedingly great.* The cabinets of Europe can, as yet, boast

* I find in Langsdorff's travels (in the years 1803-7, p. 74), it is said, that in the island of St. Catherine's, on the coast of Brazil, a butterfly called Februa Hoffmanseggi, makes a noise, when flying away, like a rattle.

† Mr. Waterhouse has had the kindness to examine this butterfly, but cannot discover any mechanism by which the noise is produced.

* I may mention, as a common instance of one day's (June 23d) collecting, when I was not attending particularly to the Coleoptera, that I caught sixty-eight species of that order. Among these, there were only two of the Carabidæ, four Brachelytra, fifteen Rhyncophora, and fourteen of the Chrysomelidæ. Thirty-seven species of Arachnidæ, which I brought home, will be sufficient to prove that I was not paying overmuch attention to the generally favoured order of Coleoptera.

© The Complete Work of Charles Darwin Online

only of the larger species from tropical climates. It is sufficient to disturb the composure of an entomologist's mind, to look forward to the future dimensions of a complete catalogue. The Carabidæ appear in extremely few numbers within the tropics. This is the more remarkable when compared to the opposed case of the carnivorous mammalia, an order which they certainly represent among insects. I was struck with this observation both on entering Brazil, and when I saw the elegant and active forms of the Harpalidæ reappearing on the temperate plains of La Plata. Do the very numerous Arachnidæ and rapacious Hymenoptera supply the place of these carnivorous beetles? The carrion-feeders and Brachelytra are very uncommon; on the other hand, the Rhyncophora and Chrysomelidæ, all of which depend on the vegetable world for subsistence, are present in astonishing numbers. I do not here refer to the number of different species, but to that of the individual insects; for on this it is that the most striking character in the entomology of different countries depends. The orders Orthoptera and Hemiptera are particularly numerous; as likewise is the stinging division of the Hymenoptera; the bees, perhaps, being excepted. A person, on first entering a tropical forest, is astonished at the labours of the ants: well-beaten paths branch off in every direction, on which an army of never-failing foragers may be seen, some going forth, and others returning, burdened with pieces of green leaf, often larger than their own bodies.

A small dark-coloured species sometimes migrates in countless numbers. One day, at Bahia, my attention was drawn by observing many spiders, cockroaches, and other insects, and some lizards, rushing in the greatest agitation across a bare piece of ground. A little way behind, every stalk and leaf was blackened by a small ant. The swarm having crossed the bare space, divided itself, and descended an old wall. By this means many insects were fairly enclosed; and the efforts, which the poor little creatures made to extricate themselves from such a death, were wonderful.

© The Complete Work of Charles Darwin Online

When the ants came to the road they changed their course, and in narrow files reascended the wall. Having placed a small stone, so as to intercept one of the lines, the whole body attacked it, and then immediately retired. Shortly afterwards another body came to the charge, and again having failed to make any impression, this line of march was entirely given up. By going an inch round, the file might have avoided the stone, and this doubtless would have happened, if it had been originally there: but having been attacked, the lion-hearted little warriors scorned the idea of yielding.

Certain wasp-like insects, which construct in the corners of the verandahs clay cells for their larvæ, are very numerous in the neighbourhood of Rio. These cells they stuff full of dead and dying spiders and caterpillars. I was much interested one day by watching a deadly contest between a Pepsis and a large spider of the genus Lycosa. The wasp made a sudden dash at its prey, and then flew away: the spider was evidently wounded, for trying to escape, it rolled down a little slope, but had still strength sufficient to crawl into a thick tuft of grass. The wasp soon returned, and seemed surprised at not immediately finding its victim. It then commenced as regular a hunt, as ever hound did after fox; making short semicircular casts, and all the time rapidly vibrating its wings and antennæ. The spider, though well concealed, was soon discovered; and the wasp, evidently still afraid of its adversary's jaws, after much manœuvring, inflicted two stings on the under side of its thorax. At last, carefully examining with its antennæ the now motionless spider, it proceeded to drag away the body. But I stopped both tyrant and prey.*

The number of spiders in proportion to other insects, is

* Don Felix Azara, vol. i., p. 175, mentioning a hymenopterous insect, probably of the same genus, says, he saw it dragging a dead spider through tall grass, in a straight line to its nest, which was one hundred and sixty-three paces distant. He adds that the wasp, in order to find the road, every now and then made "demi-tours d'environ trois palmes."

© The Complete Work of Charles Darwin Online

here as compared to England very much increased; perhaps more so, than with any other division of the articulate animals. The variety of species among the saltigrade, or jumping spiders, appears almost infinite. The genus, or rather family of Epeira, is here characterized by many singular forms; some species have pointed coriaceous shells, others enlarged and spiny tibiæ. Every path in the forest is barricaded with the strong yellow web of a species, belonging to the same division with the *Epeira clavipes* of Fabricius, which was formerly said by Sloane to make, in the West Indies, webs so strong as to catch birds. A small and pretty kind of spider, with very long anterior legs, and which appears to belong to an undescribed genus, lives as a parasite on almost every one of these webs. I suppose it is too insignificant to be noticed by the great Epeira, and is therefore allowed to prey on the minute insects, which adhering to the lines, would otherwise be wasted. When frightened, this little spider either feigns death by extending its front legs, or suddenly drops from the web. A large Epeira of the same division with *Epeira tuberculata* and *conica* (with fleshy prominences on its abdomen) is extremely common, especially in dry situations. Its web, which is generally placed among the great leaves of the common agave, is sometimes strengthened near the centre by a pair or even four zigzag ribbons, which connect two adjoining rays. When any large insect, as a grasshopper or wasp, is caught, the spider, by quickly giving it a revolving movement, and at the same time emitting a band of threads from its spinners, soon envelops its prey in a case like the cocoon of a silkworm. The spider now examines the powerless victim, and gives the fatal bite on the hinder part of its thorax; then retreating, it patiently waits till the poison has taken effect. The virulence of this poison may be judged of, from the fact that in half a minute I opened the mesh, and found a large wasp quite lifeless. This Epeira always stands with its head downwards near the centre of the web. When disturbed, it acts differently according to circumstances: if

© The Complete Work of Charles Darwin Online

there is a thicket below, it suddenly falls down. I may remark, that I have distinctly seen the thread from the spinners, lengthened by the will of the animal while yet stationary, as preparatory to its fall. If the ground is clear beneath, the Epeira seldom falls, but moves quickly through a central passage, from one to the other side. When still further disturbed, it practices a most curious manœuvre: standing in the middle, it violently jerks the web, which is attached to elastic twigs, till at last the whole acquires such a rapid vibratory movement, that even the outline of the spider's body becomes indistinct.

I will here just mention a gregarious Epeira found in great numbers near St. Fe Bajada, the capital of one of the provinces of La Plata. The spiders were of a large size, and of a black colour, with ruby marks on their backs. They were nearly all of one dimension, and therefore could not have been a few old individuals with their families. The webs were placed vertically, as is invariably the case with the genus Epeira: they were separated from each other by a space of about two feet, but were all attached to certain common lines, which were of great length, and extended to all parts of the community. In this manner the tops of some large bushes were encompassed by the united nets. Azara* has described a gregarious spider in Paraguay, which Walckenaer thinks must be a Theridion, but probably it is an Epeira, and perhaps even the same species as mine. I cannot, however, recollect seeing a central nest, as large as a hat, in which, during autumn when the spiders die, Azara says the eggs are deposited. These gregarious habits in so typical a genus as Epeira, present a singular case among insects, which are so bloodthirsty and solitary, that even the sexes attack each other.

In a lofty valley of the Cordillera, near Mendoza, I found another spider with a singularly-formed web. Strong lines radiated in a vertical plane from a common centre, where

the insect had its station; but only two of the rays were connected by a symmetrical mesh-work; so that the net, instead of being, as is generally the case, circular, consisted of a wedge-shaped segment. All the webs were similarly constructed.

CHAPTER III.

Monte Video—Maldonado—Excursion to R. Polanco—Lazo and Bolas—Partridges—Geology—Absence of trees—Cervus campestris—River hog—Tucutuco—Molothrus, cuckoo-like habits—Tyrant-flycatcher—Mocking-bird—Carrion hawks—Tubes formed by lightning—House struck.

MALDONADO.

JULY 5TH, 1832.—In the morning we got under way, and stood out of the splendid harbour of Rio de Janeiro. In our passage to the Plata, we saw nothing particular, excepting on one day a great shoal of porpoises, many hundreds in number. The whole sea was in places furrowed by them; and a most extraordinary spectacle was presented, as hundreds, proceeding together by jumps, in which their whole bodies were exposed, thus cut the water. When the ship was running nine knots, these animals could cross and recross the bows with the greatest ease, and then dash away right ahead. As soon as we entered the estuary of the Plata, the weather was very unsettled. One dark night we were surrounded by numerous seals and penguins, which made such strange noises, that the officer on watch reported he could hear the cattle bellowing on shore. On a second night we witnessed a splendid scene of natural fireworks; the mast-head and yard-arm ends shone with St. Elmo's light; and the form of the vane could almost be traced, as if it had been rubbed with phosphorus. The sea was so highly luminous, that the tracks of the penguins were marked by a fiery wake, and lastly, the darkness of the sky was momentarily illuminated by the most vivid lightning.

When within the mouth of the river, I was interested by observing how slowly the waters of the sea and river mixed. The latter, muddy and discoloured, from its less specific gravity, floated on the surface of the salt water. This was

© The Complete Work of Charles Darwin Online

curiously exhibited in the wake of the vessel, where a line of blue was seen mingling in little eddies, with the adjoining fluid.

JULY 26TH.—We anchored at Monte Video. The Beagle was employed in surveying the extreme southern and eastern coasts of America, south of the Plata, during the two succeeding years. To prevent useless repetitions, I will extract those parts of my journal which refer to the same districts, without always attending to the order in which we visited them.

MALDONADO is situated on the northern bank of the Plata, and not very far from the mouth of the estuary. It is a most quiet, forlorn, little town; built, as is universally the case in these countries, with the streets running at right angles to each other, and having in the middle a large plaza or square, which, from its size, renders the scantiness of the population more evident and more unsociable. It possesses scarcely any trade; the exports being confined to a few hides and living cattle. The inhabitants are chiefly landowners, together with a few shopkeepers and the necessary tradesmen, such as blacksmiths and carpenters, who do nearly all the business for a circuit of fifty miles round. The town is separated from the river by a band of sand-hillocks, about a mile broad: it is surrounded on all other sides, by an open slightly-undulating country, covered by one uniform layer of fine green turf, on which countless herds of cattle, sheep, and horses graze. There is very little land cultivated even close to the town. A few hedges, made of cacti and agave, mark out where some wheat or Indian corn has been planted. The features of the country are very similar along the whole northern bank of the Plata. The only difference is, that here the granitic hills are rather more boldly pronounced. The scenery is very uninteresting; there is scarcely a house, an enclosed piece of ground, or even a tree, to give it an air of cheerfulness. Yet, after being imprisoned for some time in a ship, there is a charm in the unconfined feeling of walking over boundless plains of turf. Moreover, if your view is

© The Complete Work of Charles Darwin Online

limited to a small space, many objects possess beauty. Some of the smaller birds are brilliantly coloured; and the bright green sward, browsed short by the cattle, is ornamented by dwarf flowers, among which a plant, looking like the daisy, claimed the place of an old friend. What would a florist say to whole tracts so thickly covered by the *Verbena melindres*, as, even at a distance, to appear of the most gaudy scarlet?

I staid ten weeks at Maldonado, in which time a nearly perfect collection of the animals, birds, and reptiles, was procured. Before making any observations respecting them, I will give an account of a little excursion I made as far as the river Polanco, which is about seventy miles distant, in a northerly direction. I may mention, as a proof how cheap every thing is in this country, that I paid only two dollars a day, or eight shillings, for two men, together with a troop of about a dozen riding-horses. My companions were well armed with pistols and sabres; a precaution which I thought rather unnecessary; but the first piece of news we heard was, that, the day before, a traveller from Monte Video had been found dead on the road, with his throat cut. This happened close to a cross, the record of a former murder.

On the first night we slept at a retired little country-house; and there I soon found out, that I possessed two or three articles, especially a pocket compass, which created unbounded astonishment. In every house I was asked to show the compass, and by its aid, together with a map, to point out the direction of various places. It excited the liveliest admiration that I, a perfect stranger, should know the road (for direction and road are synonymous in this open country) to places where I had never been. At one house a young woman, who was ill in bed, sent to entreat me to come and show her the compass. If their surprise was great, mine was greater, to find such ignorance among people who possessed their thousands of cattle, and "estancias" of great extent. It can only be accounted for by the circumstance that this retired part of the country is seldom visited by

© The Complete Work of Charles Darwin Online

foreigners. I was asked whether the earth or sun moved; whether it was hotter or colder to the north; where Spain was, and many other such questions. The greater number of the inhabitants had an indistinct idea that England, London, and North America, were different names for the same place; but the better informed well knew that London and North America were separate countries close together, and that England was a large town in London! I carried with me some promethean matches, which I ignited by biting; it was thought so wonderful that a man should strike fire with his teeth, that it was usual to collect the whole family to see it: I was once offered a dollar for a single one. Washing my face in the morning, caused much speculation at the village of Las Minas; a superior tradesman closely cross-questioned me about so singular a practice; and likewise why on board we wore our beards; for he had heard from my guide that we did so. He eyed me with much suspicion; perhaps he had heard of ablutions in the Mahomedan religion, and knowing me to be a heretick, probably he came to the conclusion that all hereticks were Turks. It is the general custom in this country to ask for a night's lodging at the first convenient house. The astonishment at the compass, and my other feats in jugglery, was to a certain degree advantageous, as with that, and the long stories my guides told of my breaking stones, knowing venemous from harmless snakes, collecting insects, &c., I repaid them for their hospitality. I am writing as if I had been among the inhabitants of central Africa: Banda Oriental would not be flattered by the comparison; but such were my feelings at the time.

The next day we rode to the village of Las Minas. The country was rather more hilly, but otherwise continued the same; an inhabitant of the Pampas no doubt would have considered it as truly Alpine. The country is so thinly inhabited, that during the whole day we scarcely met a single person. Las Minas is much smaller even than Maldonado. It is seated on a little plain, and is surrounded by low rocky

© The Complete Work of Charles Darwin Online

mountains. It is of the usual symmetrical form; and with its whitewashed church standing in the centre, had rather a pretty appearance. The outskirting houses rose out of the plain like isolated beings, without the accompaniment of gardens or courtyards. This is generally the case in the country, and all the houses have, in consequence, an uncomfortable aspect. At night we stopped at a pulperia, or drinking-shop. During the evening a great number of Gauchos came in to drink spirits and smoke cigars: their appearance is very striking; they are generally tall and handsome, but with a proud and dissolute expression of countenance. They frequently wear their moustaches, and long black hair curling down their backs. With their brightly-coloured garments, great spurs clanking about their heels, and knives stuck as daggers (and often so used) at their waists, they look a very different race of men from what might be expected from their name of Gauchos, or simple countrymen. Their politeness is excessive: they never drink their spirits without expecting you to taste it; but whilst making their exceedingly graceful bow, they seem quite as ready, if occasion offered, to cuty our throat.

On the third day we pursued rather an irregular course, as I was employed in examining some beds of marble. On the fine plains of turf we saw many ostriches (*Struthio Rhea*). Some of the flocks contained as many as twenty or thirty birds. These, when standing on any little eminence, and seen against the clear sky, presented a very noble appearance. I never met with such tame ostriches in any other part of the country: it was easy to gallop up within a short distance of them; but then, expanding their wings, they made all sail right before the wind, and soon left the horse astern.

At night we came to the house of Don Juan Fuentes, a rich landed proprietor, but not personally known to either of my companions. On approaching the house of a stranger, it is usual to follow several little pieces of etiquette: riding

© The Complete Work of Charles Darwin Online

up slowly to the door, the salutation of Ave Maria* is given, and until somebody comes out, and asks you to alight, it is not customary even to get off your horse. Having entered the house, some general conversation is kept up for a few minutes, till permission is asked to pass the night there. This is granted as a matter of course. The stranger then takes his meals with the family, and a room is assigned him, where with the horsecloths belonging to his recado (or saddle of the Pampas) he makes his bed. It is curious how similar circumstances produce such similar results in manners. At the Cape of Good Hope the same hospitality, and very nearly the same points of etiquette, are universally observed. The difference, however, between the character of the Spaniard and that of the Dutch boor is shown, by the former never asking his guest a single question beyond the strictest rule of politeness, whilst the honest Dutchman demands where he has been, where he is going, what is his business, and even how many brothers, sisters, or children he may happen to have.

Shortly after our arrival at Don Juan's, one of the large herds of cattle was driven in towards the house, and three beasts were picked out to be slaughtered for the supply of the establishment. These half-wild cattle are very active; and knowing full well the fatal lazo, they led the horses a long and laborious chase. After witnessing the rude wealth displayed in the number of cattle, men, and horses, Don Juan's miserable house was quite curious. The floor consisted of hardened mud, and the windows were without glass; the furniture of the sitting-room boasted only of a few of the roughest chairs and stools, with a couple of tables. The supper, although several strangers were present, consisted of two huge piles, one of roast beef, the other of boiled, with some pieces of pumpkin: besides this latter there was no other vegetable, and not even a morsel of bread. For drink-

* The formal answer of the owner of the place is, "sin pecado concebida"—(conceived without sin).

© The Complete Work of Charles Darwin Online

ing, a large earthenware jug of water served the whole party. Yet this man was the owner of several square miles of land, of which nearly every acre would produce corn, and, with a little trouble, all the common vegetables. The evening was spent in smoking, with a little impromptu singing, accompanied by the guitar. The signoritas all sat together in one corner of the room, and did not sup with the men.

So many works have been written about these countries, that it is almost superfluous to describe either the lazo or the bolas. The former consists of a very strong, but thin, well-plaited rope, made of raw hide. One end is attached to the broad surcingle, which fastens together the complicated gear of the recado, or saddle used in the Pampas; the other is terminated by a small ring of iron or brass, by which a noose can be formed. The Gaucho, when he is going to use the lazo, keeps a small coil in his bridle hand, and in the other holds the running noose, which is made very large, generally having a diameter of about eight feet. This he whirls round his head, and by the dexterous movement of his wrist keeps the noose open; then, throwing it, he causes it to fall on any particular spot he chooses. The lazo, when not used, is tied up in a small coil to the after part of the recado. The bolas, or balls, are of two kinds: the simplest, which is chiefly used for catching ostriches, consists of two round stones, covered with leather, and united by a thin plaited thong, about eight feet long. The other kind differs only, in having three balls united by the thongs to a common centre. The Gaucho holds the smallest of the three in his hand, and whirls the other two round and round his head; then, taking aim, sends them like chain shot revolving through the air. The balls no sooner strike any object, than, winding round it, they cross each other, and become firmly hitched. The size and weight of the balls varies, according to the purpose for which they are made: when of stone, although not so large as a big apple, yet they are sent with such force as sometimes to break the leg even of a horse. I have seen the balls made

© The Complete Work of Charles Darwin Online

of wood, and as large as a turnip, for the sake of catching these animals without injuring them. The balls are sometimes made of iron, and these can be hurled to the greatest distance. The main difficulty in using either lazo or bolas, is to ride so well, as to be able at full speed, and while suddenly turning about, to whirl them so steadily round the head, as to take aim: on foot any person would soon learn the art. One day, as I was amusing myself by galloping and whirling the balls round my head, by accident the free one struck a bush; and its revolving motion being thus destroyed, it immediately fell to the ground, and like magic caught one hind leg of my horse; the other ball was then jerked out of my hand, and the horse fairly secured. Luckily he was an old practised animal, and knew what it meant; otherwise he would probably have kicked till he had thrown himself down. The Gauchos roared with laughter; they cried they had seen every sort of animal caught, but had never before seen a man caught by himself.

During the two succeeding days, I reached the furthest point which I was anxious to examine. The country wore the same aspect, till at last the fine green turf became more wearisome than a dusty turnpike road. We every where saw great numbers of partridges (*Tinamus rufescens*). These birds do not go in coveys, nor do they conceal themselves like the English kind. It appears a very silly bird. A man on horseback by riding round and round in a circle, or rather in a spire, so as to approach closer each time, may knock on the head as many as he pleases. The more common method is to catch them with a running noose, or little lazo, made of the stem of an ostrich's feather, fastened to the end of a long stick. A boy on a quiet old horse will frequently thus catch thirty or forty in a day. The flesh of this bird, when cooked, is delicately white.

On our return to Maldonado, we followed rather a different line of road. Near Pan de Azucar, a landmark well known to all those who have sailed up the Plata, I stayed a day at the house of a most hospitable old Spaniard. Early

© The Complete Work of Charles Darwin Online

in the morning we ascended the Sierra de las Animas. By the aid of the rising sun the scenery was almost picturesque. To the westward the view extended over an immense level plain as far as the mount, at Monte Video, and to the eastward, over the mammillated country of Maldonado. On the summit of the mountain there were several small heaps of stones, which evidently had lain there for many years. My companion assured me that they were the work of the Indians in the old time. The heaps were similar, but on a much smaller scale, to those so commonly found on the mountains of Wales. The desire to signalize any event, on the highest point of the neighbouring land, seems an universal passion with mankind. At the present day, not a single Indian, either civilized or wild, exists in this part of the province; nor am I aware that the former inhabitants have left behind them any more permanent records, than these insignificant piles on the summit of the Sierra de las Animas.

The geological structure of the country is very simple. On the crest of every hill, granitic or ancient schistose rocks protrude; the intervening spaces being concealed by a great thickness of a red argillaceous earth. This at first sight would be mistaken for ordinary detritus; but on closer examination it is found to contain small concretionary balls of a friable limestone or marl, and to possess other peculiar characters. It extends over the whole province, and in some places is very remarkable, from containing the remains of several great extinct animals. This red earthy substance is part of the formation which composes those immense plains of Buenos Ayres, denominated the Pampas. For its origin, we must look to a period when the estuary of the Plata, occupying far wider limits, covered all the surrounding low countries with its brackish waters. Signs of the gradual elevation of the land can in many places be discovered on the shores of the river; and it is probable that the red earthy mass is, geologically speaking, of no very ancient date.

© The Complete Work of Charles Darwin Online

The general, and almost entire absence of trees in Banda Oriental is remarkable. Some of the rocky hills are partly covered by thickets, and on the banks of the larger streams, especially to the northward of the Las Minas, willow-trees are not uncommon. Near the Arroyo Tapes I heard of a wood of palms; and one of these trees, of considerable size, I saw near the Pan de Azucar, in lat. 35°. These, and the trees planted by the Spaniards, offer the only exceptions to the general scarcity of wood. Among the introduced kinds may be enumerated poplars, olives, peach, and other fruit-trees: the peaches succeed so well, that they afford the main supply of firewood to the city of Buenos Ayres. Extremely level countries, such as the Pampas, seldom appear favourable to the growth of trees. This may possibly be attributed either to the force of the winds, or the kind of drainage. In the nature of the land, however, around Maldonado, no such reason is apparent; the rocky mountains afford protected situations, enjoying various kinds of soil; streamlets of water are common at the bottoms of nearly every valley; and the clayey nature of the earth seems adapted to retain moisture. It has been inferred with much probability, that the presence of woodland is determined by the annual amount of moisture; yet in this province abundant and heavy rain falls during the winter; and the summer, though dry, is not so in any excessive degree.* We see nearly the whole of Australia covered by lofty trees, yet that country possesses a far more arid climate. Hence we must look to some other cause. The trees of Brazil cannot travel so far southward, on account of the colder climate; nor does there exist any other wooded country whence a migration could take place: we are therefore driven to the conclusion that herbaceous plants, instead of trees, were created to occupy that wide area, which within a period not very remote, has been raised above the waters of the sea.

* Azara says, "Je crois que la quantité annuelle des pluies est, dans toutes ces contrées, plus considérable qu'en Espagne."—Vol. i., p. 36.

© The Complete Work of Charles Darwin Online

Considering South America alone, we should be tempted to believe that trees could not possibly flourish, excepting in a very humid climate. The limit of the forest land certainly follows, in a most remarkable manner, that of the damp winds.* In the southern part of the continent, where the western gales, charged with moisture from the Pacific, prevail, every island on the broken west coast, from lat. 38° to the extreme point of Tierra del Fuego is densely covered by impenetrable forest. On the eastern side of the Cordillera, over the same extent of latitude, where a blue sky and a fine climate prove that the atmosphere has been drained of its moisture, the arid plains of Patagonia support a scanty vegetation. Within the limits of the constant south-east trade wind, the bulk of the eastern parts of the continent is ornamented by magnificent forests: the west coast, however, from lat. 4° south to lat. 32°, may be described as a desert. In this case, as before, all the vapour has been condensed by the snow-clad pinnacles of the Andes. In these two areas, determined by the prevalent winds, the forest and desert lands occupy reversed positions with respect to the great mountain axis. Between their limits a broad intermediate band, which is neither desert nor woodland, stretches across the entire continent. Central Chile and the Provinces of La Plata are included in this division. On the west coast, about four degrees south of the equator, where the trade wind loses its regularity, and heavy torrents of rain periodically fall, the desert coast of Peru assumes near Cape Blanco the character of luxuriance so celebrated at Guayaquil and on the shores of Panama.

After these facts, it will perhaps appear a sufficient answer to the question, to state that according to the South American type of vegetation, the climate of Banda Oriental is too dry for the growth of trees. But this reasoning, I apprehend, must not be extended to a general statement including other countries. The Falklands offer a more per-

* Maclaren, art. *America*, Encyc. Britan.

© The Complete Work of Charles Darwin Online

plexing case even than Maldonado. Situated under the same latitude with Tierra del Fuego, and only between two and three hundred miles distant from it, possessed of an entirely similar climate, with a geological formation almost identical, with favourable situations, and the same kind of peaty soil, yet these islands can scarcely boast of a plant deserving the title even of a bush; whilst in Tierra del Fuego, it is impossible to find an acre of land not covered by the densest forest. In this case, both the direction of the heavy gales of wind and of the currents of the sea are favourable to the transport of seeds. Canoes and other works of art, and trunks of trees, drifted from Tierra del Fuego, are frequently thrown on the shores of the Western Island. Hence perhaps it is that there are many plants common to the two countries: but with respect to trees, even some attempts which have been made to transplant them, have failed.

During our stay at Maldonado I paid particular attention to the mammalia and birds. Of the latter I procured, within the distance of a morning's walk, no less than eighty species, of which many were exceedingly beautiful—I think even more so than those of Brazil. The other orders were not neglected. Reptiles were numerous, and nine different kinds of snakes were taken. Of the indigenous mammalia, the only one now left of any size, which is common, is the *Cervus Campestris*. This deer is exceedingly abundant throughout the countries bordering the Plata. It is found in Northern Patagonia as far south as the Rio Negro (lat. 41°); but further southward none were seen by the officers employed in surveying the coast. It appears to prefer a hilly country; I saw very many small herds, containing from five to seven animals each, near the Sierra Ventana, and among the hills north of Maldonado. If a person crawling close along the ground, slowly advances towards a herd, the deer frequently, out of curiosity, approach to reconnoitre him. I have by this means killed, from one spot, three out of

© The Complete Work of Charles Darwin Online

the same herd. Although so tame and inquisitive, yet when approached on horseback, they are exceedingly wary. In this country nobody goes on foot, and the deer knows man as its enemy, only when he is mounted and armed with the bolas. At Bahia Blanca, a recent establishment in Northern Patagonia, I was surprised to find how little the deer cared for the noise of a gun: one day I fired ten times, from within eighty yards, at one animal; and it was much more startled at the ball cutting up the ground than at the report of the rifle. My powder being exhausted, I was obliged (to my shame as a sportsman be it spoken), to get up and halloo till the deer ran away.

The most curious fact with respect to this animal, is the overpoweringly strong and offensive odour which proceeds from the buck. It is quite indescribable: several times whilst skinning the specimen which is now mounted at the Zoological Museum, I was almost overcome by nausea. I tied up the skin in a silk pocket-handkerchief, and so carried it home: this handkerchief, after being well washed, I continually used, and it was, of course, as repeatedly washed; yet every time, for a space of one year and seven months, when first unfolded, I distinctly perceived the odour. This appears an astonishing instance of the permanence of some matter, which in its nature, nevertheless, must be most subtile and volatile. Frequently, when passing at the distance of half a mile to leeward of a herd, I have perceived the whole air tainted with the effluvium. I believe the smell from the buck is most powerful at the period when its horns are perfect, or free from the hairy skin. When in this state the meat is, of course, quite uneatable; but the Gauchos assert, that if buried for some time in fresh earth, the taint is removed. I have somewhere read that the islanders in the north of Scotland treat the rank carcasses of the fish-eating birds in the same manner.

The order Rodentia is here very numerous in species: of

© The Complete Work of Charles Darwin Online

mice alone I obtained no less than eight kinds.* The largest gnawing animal in the world, the *Hydrochærus Capybara* (the water-hog), is here also common. One which I shot at Monte Video weighed ninety-eight pounds: its length, from the end of the snout to the stump-like tail, was three feet two inches; and its girth, three feet eight. These great Rodents are generally called "carpinchos:" they occasionally frequent the islands in the mouth of the Plata, where the water is quite salt, but are far more abundant on the borders of fresh-water lakes and rivers. Near Maldonado three or four generally live together. In the daytime they either lie among the aquatic plants, or openly feed on the turf plain.† When viewed at a distance, from their manner of walking and colour, they resemble pigs: but when seated on their haunches, and attentively watching any object with one eye, they reassume the appearance of their congeners, the cavies. Both the front and side view of their head has quite a ludicrous aspect, from the great depth of their jaw. These animals, at Maldonado, were very tame; by cautiously walking, I approached within three yards of four old ones. This tameness may probably be accounted for, by the Jaguar having been banished for some years, and by the Gaucho not thinking it worth his while to hunt them. As I approached nearer and nearer they frequently made their peculiar noise, which is a low abrupt grunt; not having much actual sound,

* These have been named and described by Mr. Waterhouse at the meetings of the Zoological Society. I must be allowed to take this opportunity of returning my cordial thanks to Mr. Waterhouse, and to the other gentlemen attached to that Society, for their kind and most liberal assistance on all occasions.

† In the stomach and duodenum of a carpincho which I opened, I found a very large quantity of a thin yellowish fluid, in which scarcely a fibre could be distinguished. Mr. Owen informs me that a part of the œsophagus is so constructed, that nothing much larger than a crowquill can be passed down. Certainly the broad teeth and strong jaws of this animal are well fitted to grind into pulp the aquatic plants on which it feeds.

© The Complete Work of Charles Darwin Online

but rather arising from the sudden expulsion of air: the only noise I know at all like it, is the first hoarse bark of a large dog. Having watched the four from almost within arm's length (and they me) for several minutes, they rushed into the water at full gallop, with the greatest impetuosity, and emitted, at the same time, their bark. After diving a short distance they came again to the surface, but only just showed the upper part of their heads. When the female is swimming in the water and has young ones, they are said to sit on her back. These animals are easily killed in numbers; but their skins are of trifling value, and the meat is very indifferent. I have never heard of the carpincho being found south of the Plata; but as I see in a map that there is a Laguna del Carpincho high up the Rio Salado, I suppose such must have occurred. On the islands in the Rio Parana they are exceedingly abundant, and afford the ordinary prey to the Jaguar.

The Tucutuco (*Ctenomys Braziliensis*) is a curious small animal, which may be briefly described as a Rodent, with the habits of a mole. It is extremely abundant in some parts of the country,* but is difficult to be procured, and still more difficult to be seen, when at liberty. It lives almost entirely under ground, and prefers a sandy soil with a gentle inclination. The burrows are said not to be deep, but of great length. They are seldom open; the earth being thrown up at the mouth into hillocks, not quite so large as those made by the mole. Considerable tracts of country are so completely undermined by these animals, that horses, in passing over, sink above their fetlocks. The tucutucos appear, to a certain degree, to be gregarious. The man who procured the specimens for me had caught six together, and he said this was a common occurrence. They are nocturnal

* The wide plains north of the Rio Colorado are undermined by these animals; and near the Strait of Magellan, where Patagonia blends with Tierra del Fuego, the whole sandy country forms a great warren for the tucutuco.

© The Complete Work of Charles Darwin Online

in their habits; and their principal food is afforded by the roots of plants, which is the object of their extensive and superficial burrows. Azara says they are so difficult to be obtained, that he never saw more than one. He states that they lay up magazines of food within their burrows. This animal is universally known by a very peculiar noise, which it makes when beneath the ground. A person, the first time he hears it, is much surprised; for it is not easy to tell whence it comes, nor is it possible to guess what kind of creature utters it. The noise consists in a short, but not rough, nasal grunt, which is repeated about four times in quick succession; the first grunt is not so loud, but a little longer, and more distinct than the three following: the musical time of the whole is constant, as often as it is uttered.* The name Tucutuco is given in imitation of the sound. In all times of the day, where this animal is abundant, the noise may be heard, and sometimes directly beneath one's feet. When kept in a room, the tucutucos move both slowly and clumsily, which appears owing to the outward action of their hind legs; and they are likewise quite incapable of jumping even the smallest vertical height. Mr. Reid, who dissected a specimen which I brought home in spirits, informs me that the socket of the thigh-bone is not attached by a ligamentum teres; and this explains, in a satisfactory manner, the awkward movements of their hinder extremities. When eating, they rest on their hind legs and hold the piece in their fore paws; they appeared also to wish to drag it into some corner. They are very stupid in making any attempt to escape; when angry or

* At the R. Negro, in Northern Patagonia, there is an animal of the same habits, and probably a closely allied species, but which I never saw. Its noise is different from the Maldonado kind; it is repeated only twice instead of three or four times, and is more distinct and sonorous: when heard from a distance, it so closely resembles the sound made in cutting down a small tree with an axe, that I have sometimes remained in doubt concerning it.

© The Complete Work of Charles Darwin Online

frightened, they uttered the tucu-tuco. Of those I kept alive, several, even the first day, became quite tame, not attempting to bite or to run away; others were a little wilder.

The man who caught them asserted that very many are invariably found blind. A specimen which I preserved in spirits was in this state; Mr. Reid considers it to be the effect of inflammation in the nictitating membrane. When the animal was alive I placed my finger within half an inch of its head, and not the slightest notice was taken: it made its way, however, about the room nearly as well as the others. Considering the subterranean habits of the tucutuco, the blindness, though so frequent, cannot be a very serious evil; yet it appears strange that any animal should possess an organ constantly subject to injury. The mole, whose habits in nearly every respect, excepting in the kind of food, are so similar, has an extremely small and protected eye, which, although possessing a limited vision, at once seems adapted to its manner of life.

Birds of many kinds are extremely abundant on the undulating grassy plains around Maldonado. Several species, of the genus Cassicus, allied to our starlings in habits and structure, and of Tyrant-flycatchers, and a mocking-bird, from their numbers, give a character to the ornithology. Some of the Cassici are very beautiful, black and yellow being the prevailing colours; but *Oriolus ruber*, Gme., offers an exception, in having its head, shoulders, and thighs of the most splendid scarlet. This bird differs from its congeners in being solitary. It frequents marshes; and, seated on the summit of a low bush, with its mouth wide open, utters a plaintive agreeable cry, which can be heard at a long distance.

Another species,* of a purplish-black colour, with a metallic lustre, feeds on the plain in large flocks, mingled

* Le Troupiale commun of Azara (vol. iii., p. 169)—a second species of Molothrus.

© The Complete Work of Charles Darwin Online

with other birds. Several may often be seen standing on the back of a cow or horse. While perched on a hedge, and pluming themselves in the sun, they sometimes attempt to sing, or rather to hiss: the noise is very peculiar; it resembles that of bubbles of air passing rapidly from a small orifice under water, so as to produce an acute sound. Azara states that this bird, like the cuckoo, deposits its eggs in other birds' nests. I was several times told by the country people, that there was some bird with this habit; and my assistant in collecting, who is a very accurate person, found a nest of the sparrow* of the country, with one egg in it larger than the others, and of a different colour and shape. Mr. Swainson† has remarked that with the exception of the *Molothrus pecoris*, the cuckoos are the only birds which can be called truly parasitical; namely, such as "fasten themselves, as it were, on another living animal, whose animal heat brings their young into life, whose food they alone live upon, and whose death would cause theirs during the period of infancy." The *Molothrus pecoris* is a North-American bird, and is closely allied in general habits, even in such peculiarities as standing on the backs of cattle (as its name implies), and in appearance, with the species from the plains of La Plata; it only differs in being rather smaller and of a different colour, yet the two birds would be considered by every naturalist as distinct species. It is very interesting to see so close an agreement in structure, and in habits, between allied species coming from opposite parts of a great continent. It is also very remarkable, that the cuckoos and the molothri, although opposed to each other in almost every habit, should agree in the one strange one of their parasitical propagation. The molothrus, like our starling, is

* A Zonotrichia;—the *chingolo* of Azara. The egg is rather less than that of the missel-thrush; it is of a nearly globular form, but with one end rather smaller than the other. The ground colour is a pale pinkish-white, with irregular spots and blotches of a pinkish brown, and others less distinct of a grayish hue. The egg is now in the museum of the Zoological Society.

† Magazine of Zoology and Botany, vol. i., p. 217.

© The Complete Work of Charles Darwin Online

eminently sociable, and lives on the open plains without art or disguise:* the cuckoo, as every one knows, is a singularly shy bird; it frequents the most retired thickets, and feeds on fruit and caterpillars. In structure these birds are likewise widely removed from each other.

I will only mention two other birds, which are very common, and render themselves prominent from their habits. The *Saurophagus sulphureus* is typical of the great American tribe of Tyrant-flycatchers. In its structure it closely approaches the true shrikes, but in its habits may be compared to many birds. I have frequently observed it, hunting a field, hovering over one spot like a hawk, and then proceeding on to another. When thus seen suspended in the air, it might very readily at a short distance be mistaken for one of the Rapacious order; its stoop, however, is very inferior in force and rapidity. At other times the Saurophagus haunts the neighbourhood of water, and there, like a kingfisher, remaining stationary, it catches any small fish which may come near the margin. These birds are not unfrequently kept either in cages, or in courtyards with their wings cut. They soon become tame, and are very amusing from their cunning odd manners, which were described to me, as being similar to those of the common magpie. Their flight is undulatory, for the weight of the head and bill appear too great for the body. In the evening the Saurophagus takes its stand on a bush, often by the road-side, and continually repeats, without change, a shrill and rather agreeable cry, which somewhat resembles articulate words. The Spaniards say it is like the words, "Bien te veo" (I see you well), and accordingly have given it this name.

A mocking-bird, *Orpheus modulator*, called by the inhabitants Calandria, is remarkable, from possessing a song far superior to that of any other bird in the country: indeed, it is nearly the only bird in South America which I have observed to take its stand for the purpose of singing. The

* See Azara, vol. iii., p. 170.

© The Complete Work of Charles Darwin Online

song may be compared to that of the Sedge warbler, but is more powerful; some harsh notes and some very high ones, being mingled with a pleasant warbling. It is heard only during the spring. At other times its cry is harsh and far from harmonious. It frequents thickets and hedges, is very active, and whilst quickly hopping about, often expands its tail. Near Maldonado these birds were tame and bold; they constantly attended in numbers the country houses, to pick the meat which was hung up on the posts or walls: if any other small bird joined the feast, the Calandria directly chased it away. On the wide uninhabited plains of Patagonia another closely allied species, *O. Patagonica* of D'Orbigny, which frequents the valleys clothed with spiny bushes, is a wilder bird, and has a slightly different tone of voice. It appears to me a curious circumstance, as showing the fine shades of difference in habits, that, judging from this latter respect alone, when I first saw this second species, I thought it was different from the Maldonado kind. Having afterwards procured a specimen, and comparing the two without particular care, they appeared so very similar, that I changed my opinion; but now Mr. Gould* says that they are certainly distinct; a conclusion in conformity with the trifling difference of habit, of which, however, he was not aware.

I will conclude these few ornithological observations with an account of the various carrion-feeding hawks which frequent the extratropical parts of South America. The number, tameness, and disgusting habits of these birds, make them pre-eminently striking to any one accustomed only to the birds of Northern Europe. In this list may be included four species of the Caracara or Polyborus, the Turkey buzzard, the Gallinazo, and the Condor. The Caracaras are, from their structure, placed among the eagles: we shall soon see how ill they become so high a rank. In their habits they well supply the place of our carrion-crows, magpies, and ravens; a tribe of birds which is totally wanting in South

* Mr. Gould was not at the time aware that M. D'Orbigny had described them as different.

© The Complete Work of Charles Darwin Online

America. To begin with the *Polyborus Braziliensis:* this is a common bird, and has a wide geographical range; it is most numerous on the grassy savannahs of La Plata (where it goes by the name of Carrancha), and is far from unfrequent throughout the sterile plains of Patagonia. In the desert between the rivers Negro and Colorado, numbers constantly attended the line of road to devour the carcasses of the exhausted animals which chanced to perish from fatigue and thirst. Although thus common in these dry and open countries, and likewise on the arid shores of the Pacific, it is nevertheless found inhabiting the damp impervious forests of West Patagonia and Tierra del Fuego. The Carranchas, together with the *Polyborus Chimango,* constantly attend in numbers the estancias and slaughtering-houses. If an animal dies on the plain the Gallinazo commences the feast, and then the two Caracaras pick the bones clean. These birds, although thus commonly feeding together, are far from being friends. When the Carrancha is quietly seated on the branch of a tree, or on the ground, the Chimango often continues for a long time flying backwards and forwards, up and down, in a semicircle, trying each time, at the bottom of the curve, to strike its larger relative. The Carrancha takes little notice, except by bobbing its head. Although the Carranchas frequently assemble in numbers, they are not gregarious; for in desert places they may be seen solitary, or more commonly by pairs. Besides the carrion of large animals, these birds frequent the borders of streams and sea beaches, to pick up whatever the waters may cast on shore. In Tierra del Fuego, and on the west coast of Patagonia, they must exclusively live on such supplies.

The Carranchas are said to be very crafty, and to steal great numbers of eggs. They attempt also, together with the Chimango, to pick off the scabs from the sore backs of the horses and mules. The poor animal, on the one hand, with its ears down and its back arched; and, on the other, the hovering bird, eyeing, at the distance of a yard, the disgusting morsel, form a picture, which has been described by

© The Complete Work of Charles Darwin Online

Captain Head with his own peculiar spirit and accuracy. The Carranchas kill wounded animals; but Mr. Bynoe saw one seize in the air a live partridge, which escaped, and was for some time chased on the ground. I believe this circumstance is very unusual: at all events there is no doubt that the chief part of their sustenance is derived from carrion. A person will discover the *Necrophagous* habits of the Carrancha, by walking out on one of the desolate plains, and there lying down to sleep. When he awakes, he will see, on each surrounding hillock, one of these birds patiently watching him with an evil eye. It is a feature in the landscape of these countries, which will be recognised by every one who has wandered over them. If a party goes out hunting with dogs and horses, it will be accompanied, during the day, by several of these attendants. After feeding, the uncovered craw protrudes; at such times, and indeed generally, the Carrancha is an inactive, tame, and cowardly bird. Its flight is heavy and slow, like that of an English rook. It seldom soars; but I have twice seen one at a great height gliding through the air with much ease. It runs (in contradistinction to hopping), but not quite so quickly as some of its congeners. At times the Carrancha is noisy, but is not generally so: its cry is loud, very harsh and peculiar, and may be likened to the sound of the Spanish guttural *g*, followed by a rough double *r r*. Perhaps the Gauchos, from this cause, have called it Carrancha. Molina, who says it is called Tharu in Chile, states, that when uttering this cry, it elevates its head higher and higher, till at last, with its beak wide open, the crown almost touches the lower part of the back. This fact, which has been doubted, is quite true; I have seen them several times with their heads backwards in a completely inverted position. The Carrancha builds a large coarse nest, either in a low cliff, or in a bush or lofty tree. To these observations I may add, on the high authority of Azara, that the Carrancha feeds on worms, shells, slugs, grasshoppers, and frogs; that it destroys young lambs by tearing the umbilical cord; and that it pursues the Gallinazo,

© The Complete Work of Charles Darwin Online

till that bird is compelled to vomit up the carrion it may have recently gorged. Lastly, Azara states that several Carranchas, five or six together, will unite in chase of large birds, even such as herons. All these facts show that it is a bird of very versatile habits and considerable ingenuity.

The *Polyborus Chimango* is considerably smaller than the last species. It is common on both sides of the continent, but does not appear to extend so far northward as the last species. It is found in Chiloe, and on the coast of Patagonia, and I have seen it in Tierra del Fuego. We have already remarked that it feeds on carrion, in common with the Carrancha. It is generally the last bird which leaves the skeleton; and may often be seen within the ribs of a cow or horse, like a bird in a cage. The Chimango often frequents the sea-coast and the borders of lakes and swamps, where it picks up small fish. It is truly omnivorous, and will eat even bread, when thrown out of a house with other offal: I was also assured that they materially injure the potato crops in Chiloe, by stocking up the roots when first planted. In the same island I myself saw them by scores following the plough, and feeding on the worms and larvæ of insects. I do not believe they ever kill birds or animals. They are more active than the Carranchas, but their flight is heavy; I never saw one soar; they are very tame; are not gregarious; commonly perch on stone walls, and not upon trees; and frequently utter a gentle, shrill scream.

The third species of Polyborus* is remarkable from the confined localities which it frequents: we met with it only in one valley in Patagonia. The last species which we have to mention is the *Polyborus Novæ Zelandiæ*. This bird is exceedingly numerous over the whole of the Falkland Islands, which appear to be its metropolis. I was informed by the sealers, that they are found in the Diego Ramirez rocks and the Ildefonso isles, but never on the mainland of Tierra del Fuego. Nor do they occur on Georgia or the more southern

* A species allied to "Montanus" of D'Orbigny, but distinct.

© The Complete Work of Charles Darwin Online

islands. In many respects these hawks resemble in their habits the Carranchas. They live on the flesh of dead animals and on marine productions; and on the Ramirez rocks their whole sustenance must depend on the sea. They are extraordinarily tame and fearless, and haunt the neighbourhood of houses for offal. If a hunting party kills an animal, a number soon collect and patiently await, standing on the ground on all sides. After eating, their uncovered craws are largely protruded, giving them a disgusting appearance. They readily attack wounded birds: a cormorant in this state having taken to the shore, was immediately seized on by several, and its death hastened by their blows. The Beagle was at the Falklands only during the summer, but the officers of the Adventure, who were there in the winter, mention many extraordinary instances of the boldness and rapacity of these birds. They actually pounced on a dog that was lying fast asleep close by one of the party; and the sportsmen had difficulty in preventing the wounded geese from being seized before their eyes. It is said that several together (in this respect resembling the Carranchas) wait at the mouth of a rabbit-hole, and together seize on the animal when it comes out. They were constantly flying on board the vessel when in the harbour; and it was necessary to keep a good look out to prevent the leather being torn from the rigging, and the meat or game from the stern. These birds are very mischievous and inquisitive; they will pick up almost any thing from the ground; a large black glazed hat was carried nearly a mile, as was a pair of the heavy balls, used in catching cattle. Mr. Usborne experienced during the survey a more severe loss, in their stealing a small Kater's compass in a red morocco leather case, which was never recovered. These birds are, moreover, quarrelsome and very passionate; tearing up the grass with their bills from rage. They are not truly gregarious; do not soar; their flight is heavy and clumsy; on the ground they run with extreme quickness, very much like pheasants. They are noisy, uttering several harsh cries; one of which is like that of the English rook; hence the sealers

© The Complete Work of Charles Darwin Online

always so call them. It is a curious circumstance that, when crying out, they throw their heads upwards and backwards, after the same manner as the Carrancha. They build on the rocky cliffs of the sea-coast, but only in the small islets, and not in the two main islands. This is a singular precaution in so tame and fearless a bird. The sealers say that the flesh of these birds when cooked, is quite white, and very good eating.

We have now only to mention the turkey-buzzard (*Vultur aura*), and the Gallinazo. The former is found wherever the country is moderately damp, from Cape Horn to North America. Differently from the *Polyborus Braziliensis* and *Chimango*, it has found its way to the Falkland Islands. The turkey-buzzard is a solitary bird, or at most goes in pairs. It may at once be recognised from a long distance, by its lofty, soaring, and most elegant flight. It is well known to be a true carrion feeder. On the west coast of Patagonia, among the thickly-wooded islets and broken land, it lives exclusively on what the sea throws up, and on the carcasses of dead seals. Wherever these animals are congregated on the rocks, there the vultures may be seen. The Gallinazo (*Cathartes atratus*) has a different range from the last species, as it never occurs to the southward of lat. 41°. Azara states that there existed a tradition that these birds, at the time of the conquest, were not to be found near Monte Video, but that they subsequently followed the inhabitants from more northern districts. At the present day they are numerous in the valley of the Colorado, which is three hundred miles due south of Monte Video. It seems probable that this additional migration has happened since the time of Azara. The Gallinazo generally prefers a humid climate, or rather the neighbourhood of fresh water; hence it is extremely abundant in Brazil and La Plata, while it is never found on the desert and arid plains of Northern Patagonia, excepting near some stream. These birds frequent the whole Pampas to the foot of the Cordillera, but I never saw or heard of one in Chile: in Peru they are preserved as

© The Complete Work of Charles Darwin Online

scavengers. These vultures certainly may be called gregarious, for they seem to have pleasure in society, and are not solely brought together by the attraction of a common prey. On a fine day a flock may often be observed at a great height, each bird wheeling round and round without closing its wings, in the most graceful evolutions. This is clearly done for sport-sake, or perhaps is connected with their matrimonial alliances.

I have now mentioned all the carrion-feeders, excepting the condor, an account of which will be more appropriately introduced when we visit a country more congenial to its habits than the plains of La Plata.

In a broad band of sand-hillocks which separate the Laguna del Potrero from the shores of the Plata, at the distance of a few miles from Maldonado, I found a group of those vitrified, siliceous tubes, which are generally supposed to have been formed by lightning entering the loose sand. These tubes resemble in every particular those from Drigg, in Cumberland, described in the Geological Transactions.* The sand-hillocks of Maldonado, not being protected by vegetation, are constantly changing their position. From this cause the tubes projected above the surface; and numerous fragments lying near, showed that they had formerly been buried to a greater depth. Four sets entered the sand perpendicularly: by working with my hands I traced one of them two feet deep; and some fragments which evidently had belonged to the same tube, when added to the other part, measured five feet three inches. The diameter of the whole was nearly equal, and therefore we must suppose that originally it extended to a much greater depth. These dimensions are however small, compared to those of the tubes from Drigg, one of which was traced to a depth of not less than thirty feet.

The internal surface is completely vitrified, glossy, and smooth. A small fragment examined under the micro-

* Geolog. Transact., vol. ii., p. 528.

© The Complete Work of Charles Darwin Online

scope, appeared, from the number of minute entangled air or perhaps steam bubbles, like an assay fused before the blowpipe. The sand is entirely, or in greater part, siliceous; but some points are of a black colour, and from their glossy surface possess a metallic lustre. The thickness of the wall of the tube varies from a thirtieth to a twentieth of an inch, and occasionally even equals a tenth. On the outside, the grains of sand are rounded, and have a slightly glazed appearance: I could not distinguish any sign of crystallization. In a similar manner to that described in the Geological Transactions, the tubes are generally compressed, and have deep longitudinal furrows, so as closely to resemble a shrivelled vegetable stalk, or the bark of the elm or cork tree. Their circumference is about two inches, but in some fragments which are cylindrical and without any furrows, it is double, or four inches. The compression from the surrounding loose sand, acting while the tube was still softened from the effects of the intense heat, has evidently caused the creases or furrows. Judging from the uncompressed fragments, the measure or bore of the lightning (if such a term may be used), must have been about one inch and a quarter. At Paris, M. Hachette and M. Beaudant* succeeded in making tubes, in most respects similar to these fulgurites, by passing very strong shocks of galvanism through finely-powdered glass: when salt was added, so as to increase its fusibility, the tubes were larger in every dimension. They failed both with powdered felspar and quartz. One tube, formed with pounded glass, was very nearly an inch long, namely, .982, and had an internal diameter of .019. When we hear that the strongest battery in Paris was used, and that the effect on a substance of such easy fusibility as glass, was to form tubes so diminutive, we must feel greatly astonished at the power of a shock of lightning, which, striking the sand in several places, has formed a cylinder, in one instance of at least thirty feet long, and

* Annales de Chimie et de Physique, tom. xxxvii., p. 319.

© The Complete Work of Charles Darwin Online

having an internal bore, where not compressed, of full an inch and a half; and this in a material so extraordinarily refractory as quartz!

The tubes, as I have already remarked, enter the sand nearly in a vertical direction. One, however, which was less regular than the generality, had a deviation from a right line, which amounted, at the most considerable bend, to thirty-three degrees. From this same tube, two small branches, about a foot apart, were sent off; one pointed downwards, and the other upwards. This latter case is remarkable, as the electric fluid must have turned back at the acute angle of 26°, to the line of its main course. Besides the four tubes which I found vertical, and traced beneath the surface, there were several other groups of fragments, the original site of which without doubt was near. All occurred in a level area, sixty yards by twenty, of shifting sand, situated among some high sand-hillocks; and at the distance of about half a mile, from a chain of hills four or five hundred feet in height. The most remarkable circumstance, as it appears to me, in this case as well as in that of Drigg, and in one described by M. Ribbentrop in Germany, is the number of tubes found within such limited spaces. At Drigg, within an area of fifteen yards, three were observed, and the same number occurred in Germany. In the case which I have described, certainly more than four existed within the space of the sixty by twenty yards. As it does not appear probable that the tubes are produced by successive and distinct shocks, we must believe that the lightning, shortly before entering the ground, divides itself into separate branches.

The neighbourhood of the Rio Plata seems peculiarly subject to electric phenomena. In the year 1793,* one of the most destructive thunderstorms perhaps on record happened at Buenos Ayres: thirty-seven places within the city were struck by lightning, and nineteen people killed. From facts stated in several books of travels, I am inclined to suspect

* Azara's Voyage, vol. i., p. 36.

© The Complete Work of Charles Darwin Online

that thunderstorms are very common near the mouths of great rivers. Is it not possible that the mixture of large bodies of fresh water with the salt may disturb the electrical equilibrium? Even during our occasional visits to this part of South America, we heard of a ship, two churches, and a house, having been struck. Both the church and the house I saw shortly afterwards: the house belonged to Mr. Hood, the consul-general at Monte Video. Some of the effects were curious: the paper, for nearly a foot on each side of the line where the bell-wires had run, was blackened. The metal had been fused, and although the room was at least fifteen feet high, the globules dropping on the chairs and furniture, had drilled in them a chain of minute holes. A part of the wall was shattered as if by gunpowder, and the fragments had been blown off with force sufficient to dent the walls on the opposite side of the room. The frame of a looking-glass was blackened, and the gilding must have been volatilized, for a smelling-bottle, which stood on the chimney-piece, was coated with bright metallic particles, which adhered as firmly as if they had been enamelled.

CHAPTER IV.

Rio Negro—Estancias attacked by Indians—Salt lakes, geological position of—Flamingoes—R. Negro to Colorado—Sacred tree—Patagonian hare—Indian families—General Rosas—Proceed to Bahia Blanca—Sand dunes—Negro lieutenant—Bahia Blanca—Ground incrusted with Glauber salt—Punta Alta—Zorillo.

RIO NEGRO TO BAHIA BLANCA.

JULY 24TH, 1833.—The Beagle sailed from Maldonado, and on August the 3d she arrived off the mouth of the Rio Negro. This is the principal river on the whole line of coast between the Straits of Magellan and the Plata. It enters the sea about three hundred miles south of the estuary of the latter. About fifty years since, under the old Spanish government, a small colony was established here; and it is still the most southern position (lat. 41°) on this eastern coast of America which is inhabited by civilized man.

The country near the mouth of the river is wretched in the extreme: on the south side a long line of perpendicular cliffs commences, which exposes a section of the geological nature of the country. The strata are of sandstone, and one layer was remarkable, from being composed of a firmly-cemented conglomerate of pumice pebbles, which must have travelled more than four hundred miles, from the Andes. The surface is every where covered up by a thick bed of gravel, which extends far and wide over the open plain. Water is extremely scarce, and, where found, is almost invariably brackish. The vegetation is scanty; and although there are bushes of many kinds, all are armed with formidable thorns, which seem to warn the stranger not to enter on these inhospitable regions.

The settlement is situated eighteen miles up the river. The road follows the foot of the sloping cliff, which forms

© The Complete Work of Charles Darwin Online

the northern boundary of the great valley, in which the Rio Negro flows. On the way we passed the ruins of some fine "estancias," which a few years since were destroyed by the Indians. They withstood several attacks. A man present at one gave me a very lively description of what took place. The inhabitants had sufficient notice to drive all the cattle and horses into the "corral"* which surrounded the house, and likewise to mount some small cannon. The Indians were Araucanians from the south of Chile; several hundreds in number, and highly disciplined. They first appeared in two bodies on a neighbouring hill; having there dismounted, and taken off their fur mantles, they advanced naked to the charge. The only weapon of an Indian is a very long bamboo or chuzo, ornamented with ostrich feathers, and pointed by a sharp spear head. My informer seemed to remember with the greatest horror the quivering of these chuzos as they approached near. When close, the cacique Pincheira hailed the besieged to give up their arms, or he would cut all their throats. As this would probably have been the result of their entrance under any circumstances, the answer was given by a volley of musketry. The Indians, with great steadiness, came to the very fence of the corral: but to their surprise they found the posts fastened together by iron nails instead of leather thongs, and, of course, in vain attempted to cut them with their knives. This saved the lives of the Christians: many of the wounded Indians were carried away by their companions; and at last one of the under caciques being wounded, the bugle sounded a retreat. They retired to their horses, and seemed to hold a council of war. This was an awful pause for the Spaniards, as all their ammunition, with the exception of a few cartridges, was expended. In an instant the Indians mounted their horses, and galloped out of sight. Another attack was still more quickly repulsed. A cool Frenchman managed the gun; he

* The corral is an enclosure made of tall and strong stakes. Every estancia, or farming estate, has one attached to it.

© The Complete Work of Charles Darwin Online

stopped till the Indians approached close, and then raked their line with grape-shot: he thus laid thirty-nine of them on the ground; and, of course, such a blow immediately routed the whole party.

The town is indifferently called El Carmen or Patagones. It is built on the face of a cliff which fronts the river, and many of the houses are excavated even in the sandstone. The river is about two or three hundred yards wide, and is deep and rapid. The many islands, with their willow-trees, and the flat headlands, seen one behind the other on the northern boundary of the broad green valley, forms, by the aid of a bright sun, a view almost picturesque. The number of inhabitants does not exceed a few hundreds. These Spanish colonies do not, like our British ones, carry within themselves the elements of growth. Many Indians of pure blood reside here: the tribe of the Cacique Lucanee constantly have their Toldos* on the outskirts of the town. The local government partly supplies them with provisions, by giving them all the old, worn out horses, and they earn a little by making horse-rugs and other articles of riding gear. These Indians are considered civilized; but what their character may have gained by a lesser degree of ferocity, is almost counterbalanced by their entire immorality. Some of the younger men are, however, improving; they are willing to labour, and a short time since a party went on a sealing voyage, and behaved very well. They were now enjoying the fruits of their labour, by being dressed in very gay, clean clothes, and by being very idle. The taste they showed in their dress was admirable; if you could have turned one of these young Indians into a statue of bronze, his drapery would have been perfectly graceful.

One day I rode to a large salt lake, or Salina, which is distant fifteen miles from the town. During the winter it consists of a shallow lake of brine, which in summer is converted into a field of snow-white salt. The layer near the

* The hovels of the Indians are thus called.

© The Complete Work of Charles Darwin Online

margin is from four to five inches thick, but towards the centre its thickness increases. This lake was two and a half miles long, and one broad. Others occur in the neighbourhood many times larger, and with a floor of salt, two and three feet in thickness, even when under water during the winter. One of these brilliantly-white and level expanses, in the midst of the brown and desolate plain, offers an extraordinary spectacle. A large quantity of salt is annually drawn from the salina; and great piles, some hundred tons in weight, were lying ready for exportation. It is singular that the salt, although well crystallized, and appearing quite pure, does not answer so well for preserving meat as sea salt from the Cape de Verd Islands. Although the latter is necessarily much dearer, it is constantly imported and mixed with the salt procured from these salinas. A merchant at Buenos Ayres told me that he considered the Cape de Verd salt worth fifty per cent. more than that from the Rio Negro. The season for working the salinas forms the harvest of Patagones; for on it, the prosperity of the place depends. Nearly the whole population encamps on the banks of the river, and the people are employed in drawing out the salt in bullock-waggons.

The border of the lake is formed of mud: and in this numerous large crystals of gypsum, some of which are three inches long, lie embedded; whilst on the surface, others of sulphate of magnesia lie scattered about. The Gauchos call the former the "Padre del sal," and the latter the "Madre"; they state that these progenitive salts always occur on the borders of the salinas, when the water begins to evaporate. The mud is black, and has a fetid odour. I could not, at first, imagine the cause of this, but I afterwards perceived that the froth, which the wind drifted on shore was coloured green, as if by confervæ: I attempted to carry home some of this green matter, but from an accident failed. Parts of the lake seen from a short distance appeared of a reddish colour, and this, perhaps, was owing to some infusorial animalcula. The mud in many places was thrown up by numbers of

© The Complete Work of Charles Darwin Online

some kind of worm, or annelidous animal. How surprising it is that any creatures should be able to exist in a fluid, saturated with brine, and that they should be crawling among crystals of sulphate of soda and lime! And what becomes of these worms when, during a long summer, the surface at least is hardened into a solid layer of salt? Flamingoes* in considerable numbers inhabit this lake; they breed here, and their bodies are sometimes found by the workmen, preserved in the salt. I saw several wading about in search of food,—probably for the worms which burrow in the mud; and these latter, perhaps, feed on infusoria or confervæ. Thus we have a little world within itself, adapted to these little inland seas of brine.†

With respect to the geological position of the salinas, they occur either in the plains composed of shingle, and overlying various deposits, or within the grand calcareo-argillaceous formation of the Pampas. The only rule I can discover, is, that they do not occur where the substratum is granitic, as in Brazil and Banda Oriental. I know of their occasional existence over the immense territory extending from lat. 23°, near the Rio Vermejo, to 50° south. The climate may generally be considered as rather dry; at least, such is the case in Patagonia, where the salinas are most numerous. Those which I saw occurred in depressions,

* Throughout South America, the flamingo appears singularly attached to salt lakes. I saw instances of this throughout Patagonia, in the Cordillera of Northern Chile, and at the Galapagos Islands.

† In the Linnæan Transactions, vol. xi., p. 205, a minute crustaceous animal is described, under the name of *Cancer salinus*. It is said to occur in countless numbers in the brine pans at Lymington; but only in those in which the fluid has attained, from evaporation, considerable strength; namely, about a quarter of a pound of salt to a pint of water. This cancer is said, also, to inhabit the salt lakes of Siberia. Well may we affirm, that every part of the world is habitable! Whether lakes of brine, or those subterranean ones hidden beneath volcanic mountains—warm mineral springs; the wide expanse and depths of the ocean; the upper regions of the atmosphere; and even the surface of perpetual snow;—all support organic beings.

© The Complete Work of Charles Darwin Online

whence there was no exit; in a more humid climate the water flowing from the lake would soon have hollowed a channel in the soft strata, and thus converted the depression of the soil into an ordinary valley. There is reason to believe that the whole of these great plains have been raised above the level of the sea within a recent geological period. May we not then consider the salinas as the receptacles of the washings of the sedimentary strata? On this idea we understand their absence where the land is granitic. It is manifest that these great natural evaporating dishes can only occur where the amount of annual rain is small.*

To the northward of the Rio Negro, between it and the inhabited country near Buenos Ayres, the Spaniards have only one small settlement, recently established at Bahia Blanca. The distance in a straight line to the capital is very nearly five hundred British miles. The wandering tribes of horse Indians, which have always occupied the greater part of this country, having of late much harassed the outlying estancias, the government at Buenos Ayres equipped some time since an army under the command of General Rosas for the purpose of exterminating them. The troops were now encamped on the banks of the Colorado; a river lying about eighty miles to the northward of the Rio Negro. When General Rosas left Buenos Ayres, he struck in a direct line across the unexplored plains: and as the country was thus pretty well cleared of Indians, he left behind him, at wide

* Almost every circumstance here mentioned, occurs in the salt lakes near the borders of the Caspian. That country, like Patagonia, appears to have been recently elevated above the waters of the sea. Pallas states that the salt lakes occupy shallow depressions in the steppes; that the mud on the borders in every case is black and fetid; that beneath the crust of sea salt, sulphate of magnesia occurs, imperfectly crystallized; that the muddy sand is mixed with lentils of gypsum. We have before stated that these lakes are inhabited by small crustaceous animals; and flamingoes (Edin. New Philos. Jour., Jan. 1830) likewise frequent them. As these circumstances, apparently so trifling, occur in two distant continents, we may feel sure they are the necessary results of some common cause.—See *Pallas's Travels*, 1793 to 1794, p. 129—134.

© The Complete Work of Charles Darwin Online

intervals, a small party of soldiers, with a troop of horses (a *posta*), so as to be enabled to keep up a communication with the capital. As the Beagle intended to call at Bahia Blanca, I determined to proceed there by land; and ultimately I extended my plan so as to travel the whole way by the postas to Buenos Ayres.

August 11th.—Mr. Harris, an Englishman residing at Patagones, a guide, and five Gauchos, who were proceeding to the army on business, were my companions on the journey. The Colorado, as I have already said, is nearly eighty miles distant: and as we travelled slowly, we were two days and a half on the road. The whole line of country deserves scarcely a better name than that of a desert. Water is found only in two small wells: it is called fresh; but even at this time of the year, during the rainy season, it was quite brackish. In the summer this must be a distressing passage; for now it was sufficiently desolate. The valley of the Rio Negro, broad as it is, has merely been excavated out of the sandstone plain; for immediately above the bank on which the town stands, a level country commences, which is interrupted only by a few trifling valleys and depressions. Every where the landscape wears the same sterile aspect; a dry gravelly soil supports tufts of brown withered grass, and low scattered bushes, armed with thorns.

Shortly after passing the first spring we came in sight of a famous tree, which the Indians reverence as the altar of Walleechu. It is situated on a high part of the plain, and hence is a landmark visible at a great distance. As soon as a tribe of Indians come in sight of it, they offer their adorations by loud shouts. The tree itself is low, much branched, and thorny. Just above the root it has a diameter of about three feet. It stands by itself without any neighbour, and was indeed the first tree we saw; afterwards we met with a few others of the same kind, but they were far from common. Being winter the tree had no leaves, but in their place numberless threads, by which the various offerings, such as cigars, bread, meat, pieces of cloth, &c.,

© The Complete Work of Charles Darwin Online

had been suspended. Poor people not having any thing better, only pulled a thread out of their ponchos, and fastened it to the tree. The Indians, moreover, were accustomed to pour spirits and maté into a certain hole, and likewise to smoke upwards, thinking thus to afford all possible gratification to Walleechu. To complete the scene, the tree was surrounded by the bleached bones of the horses which had been slaughtered as sacrifices. All Indians of every age and sex, made their offerings; they then thought that their horses would not tire, and that they themselves should be prosperous. The Gaucho who told me this, said that in the time of peace he had witnessed this scene, and that he and others used to wait till the Indians had passed by, for the sake of stealing their offerings from Walleechu.

The Gauchos think that the Indians consider the tree as the god itself; but it seems far more probable that they regard it as the altar. The only cause which I can imagine for this choice, is its being a landmark in a dangerous passage. The Sierra de la Ventana is visible at an immense distance; and a Gaucho told me that he was once riding with an Indian a few miles to the north of the Rio Colorado, when the latter commenced making the same loud noise, which is usual at the first sight of the distant tree; putting his hand to his head, and then pointing it in the direction of the Sierra. Upon being asked the reason of this, the Indian said in broken Spanish, "First see the Sierra." This likewise would render it probable that the utility of a distant landmark is the first cause of its adoration. About two leagues beyond this curious tree we halted for the night: at this instant an unfortunate cow was spied by the lynx-eyed Gauchos. Off they set in chase, and in a few minutes she was dragged in by the lazo, and slaughtered. We here had the four necessaries of life "en el campo,"—pasture for the horses, water (only a muddy puddle), meat, and firewood. The Gauchos were in high spirits at finding all these luxuries; and we soon set to work at the poor cow. This was the first night which I had ever passed

© The Complete Work of Charles Darwin Online

under the open sky, with the gear of the recado for my bed. There is high enjoyment in the independence of the Gaucho life—to be able at any moment to pull up your horse, and say, "Here we will pass the night." The deathlike stillness of the plain, the dogs keeping watch, the gipsy-group of Gauchos making their beds round the fire, have left in my mind a strongly-marked picture of this first night, which will not soon be forgotten.

The next day the country continued similar to that above described. It is inhabited by few birds or animals. Occasionally a deer, or a Guanaco (wild Llama) may be seen; but the Agouti (*Cavia Patagonica*) is the commonest quadruped. This animal here represents our hares. It differs, however, from that genus in many essential respects; for instance, it has only three toes behind. It is also nearly twice the size, weighing from twenty to twenty-five pounds. The Agouti is a true friend to the desert; it is a common feature in the landscape to see two or three hopping quickly one after the other in a straight line across these wild plains. On the eastern side of America their northern limit is formed by the Sierra Tapalguen (lat. 37° 30′), where the plains rather suddenly become greener and more humid. The limit certainly depends on this change, for near Mendoza (lat. 33° 30′), which is much further north, but where the country is very sterile, I again met the Agouti. It is not evident by what circumstances their southern limit is governed; it occurs between Port Desire and St. Julian (about 48° 30′), where there is no change in the kind of land, and only a trifling and gradual one of temperature. It is a singular fact, that although the Agouti is not now found so far south as Port St. Julian, yet that Captain Wood, in his voyage in 1670, talks of them as being numerous there. What cause can have altered, in a wide, uninhabited, and rarely-visited country, the range of an animal like this? It appears, also, from the number shot in one day at Port Desire, that they must have been considerably more abundant there formerly than at present. Azara states that the Agouti never ex-

© The Complete Work of Charles Darwin Online

cavates its own burrow, but uses that of the Bizcacha. Wherever this animal is present, without doubt this is true; but on the sandy plains of Bahia Blanca, where the Bizcacha is not found, the Gauchos maintain that the Agouti is its own workman. The same thing occurs with the little owls of the Pampas (*Noctua cunicularia*), which have so often been described as standing like sentinels at the mouths of the burrows; for in Banda Oriental, owing to the absence of the Bizcacha, they are obliged to hollow out their own habitations. Azara also says that the Agouti, except when pressed by danger, does not enter its burrow: on this point I must again differ from that high authority. At Bahia Blanca I have repeatedly seen two or three of these animals sitting on their haunches by the mouths of their holes, which, as I passed by at a distance, they quietly entered. Daily in the neighbourhood of these spots the Agouti were abundant: but differently from most burrowing animals, it wanders, commonly two or three together, to miles or leagues from its home; nor do I know whether it returns at night. The Agouti feeds and roams about by day; is shy and watchful; does not squat, or so rarely that I never saw an instance of this; it cannot run very fast; and, therefore, is frequently caught by a couple of dogs, even of mixed breed. Its manner of running more resembles that of a rabbit than of a hare. The Agouti generally produces two young ones at a birth, which are brought forth within the burrow. The flesh, when cooked, is very white; it is, however, rather tasteless and dry.

The next morning, as we approached the Rio Colorado, the appearance of the country changed; we soon came on a plain covered with turf, which, from its flowers, tall clover, and little owls, resembled the Pampas. We passed also a muddy swamp of considerable extent, which in summer dries, and becomes incrusted with various salts; and hence is called a salitral. It was covered by low succulent plants, of the same kind with those growing on the sea-shore. The Colorado, at the pass where we crossed it, is only about

© The Complete Work of Charles Darwin Online

sixty yards wide; generally it must be nearly double that width. Its course is very tortuous, being marked by willow-trees and beds of reeds: in a direct line the distance to the mouth of the river is said to be nine leagues, but by water twenty-five. We were delayed crossing in the canoe by some immense troops of mares, which were swimming the river in order to follow a division of troops into the interior. A more ludicrous spectacle I never beheld, than the hundreds of heads, all directed one way, with pointed ears and distended nostrils, appearing just above the water like a great shoal of some amphibious animals. Mare's flesh is the only food which the soldiers have when on an expedition. This gives them a very great facility of movement; for the distance to which horses can be driven over these plains is quite surprising: I have been assured that an unloaded horse can travel a hundred miles a day for many days successively.

The encampment of General Rosas was close to the river. It consisted of a square formed by waggons, artillery, straw huts, &c. The soldiers were nearly all cavalry; and I should think such a villanous, banditti-like army, was never before collected together. The greater number of men were of a mixed breed, between Negro, Indian, and Spaniard. I know not the reason, but men of such origin seldom have a good expression of countenance. I called on the secretary to show my passport. He began to cross-question me in the most dignified and mysterious manner. By good luck I had a letter of recommendation from the government of Buenos Ayres* to the commandant of Patagones. This was taken to General Rosas, who sent me a very obliging message; and the secretary returned all smiles and graciousness. We took up our residence in the *rancho*, or hovel, of a curious old Spaniard, who had served with Napoleon in the expedition against Russia.

We staid two days at the Colorado; I had little to do, for

* I am bound to express, in the strongest terms, my obligation to the Government of Buenos Ayres for the obliging manner in which passports to all parts of the country were given me, as naturalist of the Beagle.

© The Complete Work of Charles Darwin Online

the surrounding country was a swamp, which in summer, (December) when the snow melts on the Cordillera, is overflowed by the river. My chief amusement was watching the Indian families as they came to buy little articles at the rancho, where we staid. It was supposed that General Rosas had about six hundred Indian allies. The men were a tall, fine race, yet it was afterwards easy to see in the Fuegian savage the same countenance rendered hideous by cold, want of food, and less civilization. Some authors, in defining the primary races of mankind, have separated these Indians into two classes; but I cannot think this is correct. Among the young women or chinas, some deserve to be called even beautiful. Their hair was coarse, but bright and black; and they wore it in two plaits hanging down to the waist. They had a high colour, and eyes that glistened with brilliancy; their legs, feet, and arms were small and elegantly formed; their ankles, and sometimes their waists, were ornamented by broad bracelets of blue beads. Nothing could be more interesting than some of the family groups. A mother with one or two daughters would often come to our rancho, mounted on the same horse. They ride like men, but with their knees tucked up much higher. This habit, perhaps, arises from their being accustomed, when travelling, to ride the loaded horses. The duty of the women is to load and unload the horses; to make the tents for the night; in short to be, like the wives of all savages, useful slaves. The men fight, hunt, take care of the horses, and make the riding gear. One of their chief indoor occupations is to knock two stones together till they become round. The bolas is a very important weapon to the Indian; for with it he catches his game, and also his horse which roams free over the plain. In fighting, his first attempt is to throw the horse of his adversary with the bolas, and when entangled by the fall to kill him with the chuzo. If the balls only catch the neck or body of an animal, they are often carried away and lost. As the making the stones round is the labour of two days, the manufacture of the balls is a very common employment.

© The Complete Work of Charles Darwin Online

Several of the men and women had their faces painted red, but I never saw the horizontal bands which are so common among the Fuegians. Their chief pride consists in having every thing made of silver; I have seen a cacique with his spurs, stirrups, handle of his knife, and bridle made of this metal: the head-stall and reins being of wire, were not thicker than whipcord; and to see a fiery steed, wheeling about under the command of so light a chain, gave to the horsemanship a remarkable character of elegance.

General Rosas intimated a wish to see me; a circumstance which I was afterwards very glad of. He is a man of an extraordinary character, and has a most predominant influence in the country, which it seems probable he will use to its prosperity and advancement. He is said to be the owner of seventy-four square leagues of land, and to have about three hundred thousand head of cattle. His estates are admirably managed, and are far more productive of corn than any others. He first gained his celebrity by his laws for his own estancias, and by disciplining several hundred men, so as to resist with success the attacks of the Indians. There are many stories current about the rigid manner in which his laws were enforced. One of these was, that no man, on penalty of being put into the stocks, should carry his knife on a Sunday: this day being the principal one for gambling and drinking, many quarrels arose, which from the general manner of fighting with the knife often proved fatal. One Sunday the Governor came in great form to pay the Estancia a visit, and General Rosas, in his hurry, walked out to receive him with his knife, as usual, stuck in his belt. The steward touched his arm, and reminded him of the law; upon which turning to the Governor, he said he was extremely sorry, but that he must go into the stocks, and that till let out, he possessed no power even in his own house. After a little time the steward was persuaded to open the stocks, and to let him out, but no sooner was this done, than he turned to the steward and said, "You now have broken the laws, so you must take my place in the stocks."

© The Complete Work of Charles Darwin Online

Such actions as these delighted the Gauchos, who all possess high notions of their own equality and dignity.

General Rosas is also a perfect horseman—an acomplishment of no small consequence in a country where an assembled army elected its general by the following trial: A troop of unbroken horses being driven into a corral, were let out through a gateway, above which was a cross-bar: it was agreed, whoever should drop from the bar on one of these wild animals, as it rushed out, and should be able without saddle or bridle, not only to ride it, but also to bring it back to the door of the corral, should be their general. The person who succeeded was accordingly elected; and doubtless made a fit general for such an army. This extraordinary feat has also been performed by Rosas.

By these means, and by conforming to the dress and habits of the Gauchos, he has obtained an unbounded popularity in the country, and in consequence a despotic power. I was assured by an English merchant, that a man who had murdered another, when arrested and questioned concerning his motive, answered, "He spoke disrespectfully of General Rosas, so I killed him." At the end of a week the murderer was at liberty. This doubtless was the act of the general's party, and not of the general himself.

In conversation he is enthusiastic, sensible, and very grave. His gravity is carried to a high pitch: I heard one of his mad buffoons (for he keeps two, like the barons of old) relate the following anecdote: "I wanted very much to hear a certain piece of music, so I went to the general two or three times to ask him; he said to me, 'Go about your business, for I am engaged.' I went a second time; he said, 'If you come again I will punish you.' A third time I asked, and he laughed. I rushed out of the tent, but it was too late; he ordered two soldiers to catch and stake me. I begged by all the Saints in heaven, he would let me off; but it would not do;—when the general laughs he spares neither mad man or sound." The poor flighty gentleman looked quite dolorous, at the very recollection of the staking. This

© The Complete Work of Charles Darwin Online

is a very severe punishment; four posts are driven into the ground, and the man is extended by his arms and legs horizontally, and there left to stretch for several hours. The idea is evidently taken from the usual method of drying hides. My interview passed away without a smile, and I obtained a passport and order for the government post-horses, and this he gave me in the most obliging and ready manner.

In the morning we started for Bahia Blanca, which we reached in two days. Leaving the regular encampment, we passed by the toldos of the Indians. These are round like ovens, and covered with hides; by the mouth of each a tapering chuzo was stuck in the ground. The toldos were divided into separate groups, which belonged to the different caciques' tribes, and the groups were again divided into smaller ones, according to the relationship of the owners. For several miles we travelled along the valley of the Colorado. The alluvial plains on the side appeared fertile, and it is supposed that they are well adapted to the growth of corn. Turning northward from the river, we soon entered on a country, differing from those plains that extend south of the river. The land still continued dry and sterile; but it supported many different kinds of plants, and the grass, though brown and withered, was more abundant, as the thorny bushes were less so. These latter in a short space entirely disappeared, and the plains were left without a thicket to cover their nakedness. This change in the vegetation marks the commencement of the grand calcareo-argillaceous deposit, which I have already noticed as forming the wide extent of the Pampas, and as covering the granitic rocks of Banda Oriental. From the Strait of Magellan to the Colorado, a distance of about eight hundred miles, the face of the country is every where composed of shingle: the pebbles are chiefly of porphyry, and probably owe their origin to the rocks of the Cordillera. North of the Colorado the bed thins out, and the pebbles become exceedingly small, and here the characteristic vegetation of Patagonia ceases.

© The Complete Work of Charles Darwin Online

Having ridden about twenty-five miles, we came to a broad belt of sand-dunes, which stretch, as far as the eye can reach, to the east and west. The sand-hillocks resting on the clay, allow small pools of water to collect, and thus afford, in this dry country, an invaluable supply of fresh water. The great advantage arising from depressions and elevations of the soil, is not often brought home to the mind. The two miserable springs in the long passage between the Rio Negro and Colorado were caused by trifling inequalities in the plain; without them not a drop of water would have been found. The belt of sand-dunes is about eight miles wide; at some former period, it probably formed the margin of a grand estuary, where the Colorado now flows. In this district, where absolute proofs of the recent elevation of the land occur, such speculations can hardly be neglected by any one, although merely considering the physical geography of the country. Having crossed the sandy tract, we arrived in the evening at one of the post-houses; and, as the fresh horses were grazing at a distance, we determined to pass the night there.

The house was situated at the base of a ridge, between one and two hundred feet high—a most remarkable feature in this country. This posta was commanded by a negro lieutenant, born in Africa: to his credit be it said, there was not a rancho between the Colorado and Buenos Ayres in nearly such neat order as his. He had a little room for strangers, and a small corral for the horses, all made of sticks and reeds; he had also dug a ditch round his house, as a defence in case of being attacked. This would, however, have been of little avail, if the Indians had come; but his chief comfort seemed to rest in the thought of selling his life dearly. A short time before, a body of Indians had travelled past in the night; if they had been aware of the posta, our black friend and his four soldiers, would assuredly have been slaughtered. I did not any where meet a more civil and obliging man, than this negro; it was therefore the more painful to see that he would not sit down and eat with us.

© The Complete Work of Charles Darwin Online

In the morning we sent for the horses very early, and started for another exhilarating gallop. We passed the Cabeza del Buey, an old name given to the head of a large marsh, which extends from Bahia Blanca. Here we changed horses, and passed through some leagues of swamps and saltpetre marshes. Changing horses for the last time, we again began wading through the mud. My animal fell, and I was well soused in black mire—a very disagreeable accident, when one does not possess a change of clothes. Some miles from the fort we met a man, who told us that a great gun had been fired, which is a signal that Indians are near. We immediately left the road, and followed the edge of a marsh, which when chased offers the best mode of escape. We were glad to arrive within the walls, when we found all the alarm was about nothing, for the Indians turned out to be friendly ones, who wished to join General Rosas.

Bahia Blanca scarcely deserves the name of a village. A few houses and the barracks for the troops are enclosed by a deep ditch and fortified wall. The settlement is only of recent standing (since 1828); and its growth has been one of trouble. The government of Buenos Ayres did not follow the wise example of the Spanish viceroys in purchasing the land from the Indians, as they did with the Rio Negro, but unjustly occupied it by force. Hence the need of the fortifications; hence the few houses and little cultivated land without the limits of the walls: even the cattle are not safe from the attacks of the Indians beyond the boundaries of the plain, on which the fortress stands.

The part of the harbour where the Beagle intended to anchor being distant twenty-five miles, I obtained from the Commandant a guide and horses, to take me to see whether she had arrived. Leaving the plain of green turf, which followed the course of the little brook, we soon entered on a wide level waste, consisting either of sand, saline marshes, or bare mud. Some parts were clothed by low thickets, and others with those succulent plants, which luxuriate only

© The Complete Work of Charles Darwin Online

where salt abounds. Bad as the country was, ostriches, deer, cavies, and armadilloes, were abundant. My guide told me, that two months before he had a most narrow escape of his life: he was out hunting, at no great distance from this part of the country, with two other men, when they were suddenly met by a party of Indians, who giving chase, soon overtook and killed his two friends. His own horse's legs were also caught by the bolas; but he jumped off, and with his knife cut them free: while doing this he was obliged to dodge round his horse, and received two severe wounds from their chuzos. Springing on the saddle, he managed, by a most wonderful exertion, just to keep ahead of the long spears of his pursuers, who followed him to within sight of the fort. From that time there was an order that no one should stray far from the settlement. I did not know of this when I started, and was surprised to observe how earnestly my guide watched a deer, which appeared to have been frightened from a distant quarter.

We found the Beagle had not arrived, and consequently set out on our return, but the horses soon tiring, we were obliged to bivouac on the plain. In the morning we had caught an armadillo, which, although a most excellent dish when roasted in its shell, did not make a very substantial breakfast and dinner for two hungry men. The ground at the place where we stopped for the night, was incrusted with a layer of Glauber salt, and hence, of course, was without water. Yet many of the smaller rodents managed to exist even here, and the tucutuco was making its odd little grunt beneath my head, during half the night. Our horses were very poor ones, and in the morning they were soon exhausted from not having had any thing to drink, so that we were obliged to walk. About noon the dogs killed a kid, which we roasted. I eat some of it, but it made me intolerably thirsty. This was the more distressing as the road, from some recent rain, was full of little puddles of clear water, yet not a drop was drinkable. I had scarcely

© The Complete Work of Charles Darwin Online

been twenty hours without water, and only part of the time under a hot sun, yet the thirst rendered me very weak. How people survive two or three days under such circumstances, I cannot imagine: at the same time, I must confess that my guide did not suffer at all, and was astonished that one day's deprivation should be so troublesome to me.

I have several times alluded to the surface of the ground being incrusted with salt. This phenomenon is quite different from that of the salinas, and much more extraordinary. In many parts of South America, wherever the climate is moderately dry, these incrustations occur; but I have nowhere seen them so abundant as near Bahia Blanca. The salt here consists of a large proportion of sulphate of soda mixed with a very little of the common muriate. As long as the ground remains moist in these salitrales (as the Spaniards improperly call them, mistaking this substance for saltpetre), nothing is to be seen but an extensive plain composed of a black, muddy soil, supporting scattered tufts of succulent plants. I was therefore much surprised, after a week's hot weather, when I first saw square miles of country, that I had previously ridden over in the former condition, white, as if from a slight fall of snow which the wind had heaped up into partial drifts. This latter appearance is chiefly due to the tendency which the salt has to crystallize, like hoar-frost, round the blades of grass, stumps of wood, or on the top of the broken ground, in lieu of the bottoms of the puddles of water. The salinas, as a general rule, occur in depressions on the more elevated plains; the salitrales, either on level tracts elevated a few feet above the level of the sea, and appearing as if lately inundated, or on alluvial land bordering rivers. In this latter case, although I am not absolutely certain, I have strong reasons for believing that the salt is often removed by the waters of the river, and is again reproduced. Several circumstances incline me to think that the black, muddy soil, generates the sulphate of soda. The whole phenomenon is well worthy the

© The Complete Work of Charles Darwin Online

attention of naturalists: what can be more singular than thus to see square miles of country thinly crusted over with Glauber salt? It may be asked whether plants do not decompose the muriate of soda? but whence comes the sulphuric acid? In Peru, nitrate of soda occurs in beds far thicker than these of the sulphate. Both cases are equally mysterious. I suspect that, as a general rule, the salts of soda are infinitely more common in South America than those of potash.

Two days afterwards, I again rode to the harbour, but to a nearer part of it. When not far from our destination, my companion, the same man as before, spied three people hunting on horseback. He immediately dismounted, and watching them intently, said, "They don't ride like Christians, and nobody can leave the fort." The three hunters joined company, and likewise dismounted from their horses. At last one mounted again and rode over the hill out of sight. My companion said, "We must now get on our horses: load your pistol;" and he looked to his own sword. I asked, "Are they Indians?"—"Quien sabe? (who knows?) if there are no more than three, it does not signify." It then struck me, that the one man had gone over the hill to fetch the rest of his tribe. I suggested this; but all the answer I could extort was, "Quien sabe?" His head and eye never for a minute ceased scanning slowly the distant horizon. I thought his uncommon coolness too good a joke, and asked him why he did not return home. I was startled when he answered, "We are returning, but in a line so as to pass near a swamp, into which we can gallop the horses as far as they can go, and then trust to our own legs; so that there is no danger." I did not feel quite so confident of this, and wanted to increase our pace. He said, "No, not until they do." When any little inequality concealed us, we galloped; but when in sight continued walking. At last we reached a valley, and turning to the left, galloped quickly to the foot of a hill, he gave me his horse to hold, made the dogs lie down, and then crawled on his hands and knees to reconnoitre. He re-

© The Complete Work of Charles Darwin Online

mained in this position for some time, and at last, bursting out in laughter, exclaimed, "Mugeres!" (women!) He knew them to be the wife and sister-in-law of the major's son, hunting for ostrich's eggs. I have described this man's conduct, because he acted under the full impression that they were Indians. As soon, however, as the absurd mistake was found out, he gave me a hundred reasons, why they could not have been Indians; but all these were forgotten at the time. We then rode on in peace and quietness to a low point called Punta Alta, whence we could see nearly the whole of the great harbour of Bahia Blanca.

The wide expanse of water is choked up by numerous great mud-banks, which the inhabitants call Cangrejales, or *crabberies*, from the number of small crabs. The mud is so soft, that it is impossible to walk over them, even for the shortest distance. Many of the banks have their surfaces covered with long rushes, the tops of which alone are visible at high water. On one occasion, when in a boat, we were so entangled by these shallows, that we could hardly find our way. Nothing was visible, but the flat beds of mud: the day was not very clear, and there was much refraction, or as the sailors expressed it, "things loomed high." The only object within our view, which was not level, was the horizon; rushes looked like bushes unsupported in the air, and water like mud-banks, and mud-banks like water.

We passed the night in Punta Alta, and I employed myself in searching for fossil bones; this point, being a perfect catacomb for monsters of extinct races. The evening was perfectly calm and clear; the extreme monotony of the view gave it an interest, even in the midst of mud-banks and gulls, sand-hillocks, and solitary vultures. In riding back in the morning, we came across a very fresh track of a Puma, but did not succeed in finding him. We saw also a couple of Zorillos, or skunks,—odious animals, which are far from uncommon. In general appearance the Zorillo resembles a polecat, but it is rather larger, and much thicker in proportion. Conscious of its power, it roams by day about

© The Complete Work of Charles Darwin Online

the open plain, and fears neither dog nor man. If a dog is urged to the attack, its courage is instantly checked by a few drops of the fetid oil, which brings on violent sickness and running at the nose. Whatever is once polluted by it, is for ever useless. Azara says the smell can be perceived at a league distant; more than once, when entering the harbour of Monte Video, the wind being off shore, we have perceived the odour on board the Beagle. Certain it is, that every animal most willingly makes room for the Zorillo.

CHAPTER V.

Bahia Blanca — Geology — Extinct quadrupeds, four Edentata, horse, ctenomys—Recent extinction—Longevity of species—Large animals do not require luxuriant vegetation—Southern Africa—Siberian fossils—Catalogue of extinct quadrupeds in South America—Two species of Ostrich, habits of—Tinochorus—Oven-bird—Armadilloes—Venomous snake, toad, lizard—Hybernation of animals—Habits of sea-pen—Indian wars and massacres—Arrow-head, antiquarian relic.

BAHIA BLANCA.

THE Beagle arrived on the 24th of August, and a week afterwards sailed for the Plata. With Captain Fitzroy's consent I was left behind, to travel by land to Buenos Ayres. I will here add some observations, which were made during this visit, and on a previous occasion, when the Beagle was employed in surveying the harbour. Not much can be made out respecting the geology. At the distance of some miles inland, an escarpment of a great argillaceo-calcareous formation of rock extends. The space near the coast consists of plains of hardened mud, and broad bands of sand-dunes, which present appearances, that can easily be accounted for by a rise of the land; and of this phenomenon,* although to a trifling amount, we have other proofs.

At Punta Alta, a low cliff, about twenty feet high, exposes a mass of partly consolidated shingle, irregularly interstratified with a reddish muddy clay, and containing numerous recent shells. We may believe a similar accumulation would now take place, on any point, where tides and waves were opposed. In the gravel a considerable number of bones were embedded. Mr. Owen, who has undertaken the description of these remains, has not yet examined them

* A few leagues further south, near the Bay of San Blas, M. D'Orbigny found great beds of recent shells elevated between 25 and 30 feet above the level of the sea.—Vol. ii., p. 43.

© The Complete Work of Charles Darwin Online

with care; but the following list may give some idea of their nature: 1st, a tolerably perfect head of a megatherium, and a fragment and teeth of two others; 2d, an animal of the order Edentata, as large as a pony, and with great scratching claws; 3d and 4th, two great Edentata related to the megatherium, and both fully as large as an ox or horse; 5th, another equally large animal, closely allied or perhaps identical with the Toxodon (hereafter to be described), which had very flat grinding teeth, somewhat resembling those of a rodent; 6th, a large piece of the tesselated covering like that of the armadillo, but of gigantic size; 7th, a tusk which in its prismatic form, and in the disposition of the enamel, closely resembles that of the African boar; it is probable that it belonged to the same animal with the singular flat grinders. Lastly, a tooth in the same state of decay with the others: its broken condition does not allow Mr. Owen, without further comparison, to come to any definite conclusion; but the part that is perfect, resembles in every respect the tooth of the common horse.* All these remains were found embedded in a beach which is covered at spring tides; and the space in which they were collected could not have exceeded one hundred and fifty yards square. It is a remarkable circumstance that so many different species should be found together; and it proves how numerous in kind the ancient inhabitants of this country must have been.

At the distance of about thirty miles, in another cliff of red earth, I found several fragments of bones. Among them were the teeth of a rodent, much narrower, but even larger than those of the *Hydrochœrus capybara;* the animal which has been mentioned as exceeding in dimensions every existing member of its order. There was

* With respect to the remains of the last animal, as some doubt may be entertained by others, respecting its origin; it must be remarked, that it was fairly embedded in the gravel with the other bones; and that its state of decay was equal. To this circumstance it may be added, that the surrounding country is without fresh water, and is uninhabited, and that the settlement, itself only of five years standing, is twenty-five miles distant.

© The Complete Work of Charles Darwin Online

also part of the head of a Ctenomys; the species being different from the Tucutuco, but with a close general resemblance.

The remains at Punta Alta were associated, as before remarked, with shells of existing species. These have not as yet been examined with scrupulous care, but it may be safely asserted, that they are most closely similar to the species now living in the same bay: it is also very remarkable, that not only the species, but the proportional numbers of each kind, are nearly the same with those now cast up on the pebble beaches. There are eleven marine species (some in an imperfect state), and one terrestrial. If I had not collected living specimens from the same bay, some of the fossils would have been thought extinct; for Mr. Sowerby, who was kind enough to look at my collection, had not previously seen them. We may feel certain that the bones have not been washed out of an older formation, and embedded in a more recent one, because the remains of one of the Edentata were lying in their proper relative position (and partly so in a second case); which could not have happened, without the carcass had been washed to the spot where the skeleton is now entombed.

We here have a strong confirmation of the remarkable law so often insisted on by Mr. Lyell, namely, that the "longevity of the species in the mammalia, is upon the whole inferior to that of the testacea."* When we proceed to the southern part of Patagonia, I shall have occasion to describe the case of an extinct camel, from which the same result may be deduced.

From the shells being littoral species (including one terrestrial), and from the character of the deposit, we may feel absolutely certain that the remains were embedded in a shallow sea, not far from the coast. From the position of the skeleton being undisturbed, and likewise from the fact that full-grown serpulæ were attached to some of the bones,

* Principles of Geology, vol. iv., p. 40.

© The Complete Work of Charles Darwin Online

we know that the mass could not have been accumulated on the beach itself. At the present time, part of the bed is daily washed by the tide, while another part has been raised a few feet above the level of the sea. Hence we may infer, that the elevation has here been trifling, since the period when the mammalia, now extinct, were living. This conclusion is in harmony with several other considerations (such as the recent character of the beds underlying the Pampas deposit), but which I have not space in this work to enter on.

From the general structure of the coast of this part of South America, we are compelled to believe, that the changes of level have all (at least of late) been in one direction, and that they have been very gradual. If, then, we look back to the period when these quadrupeds lived, the land probably stood at a level, less elevated only by a few fathoms than at present. Therefore, its general configuration since that epoch cannot have been greatly modified; a conclusion which certainly would be drawn from the close similarity in every respect, between the shells now living in the bay (as well as in the case of the one terrestrial species) with those which formerly lived there.

The surrounding country, as may have been gathered from this journal, is of a very desert character. Trees nowhere occur, and only a few bushes, which are chiefly confined to depressions among the sand-hillocks, or to the borders of the saline marshes. Here, then, is an apparent difficulty: we have the strongest evidence that there has occurred no great physical change to modify the features of the country, yet in former days, numerous large animals were supported on the plains now covered by a thin and scanty vegetation.

That large animals require a luxuriant vegetation, has been a general assumption, which has passed from one work to another. I do not hesitate, however, to say that it is completely false; and that it has vitiated the reasoning of geologists, on some points of great interest in the ancient history of the world. The prejudice has probably been derived

© The Complete Work of Charles Darwin Online

from India, and the Indian islands, where troops of elephants, noble forests, and impenetrable jungles, are associated together in every account. If, on the other hand, we refer to any work of travels through the southern parts of Africa, we shall find allusions in almost every page either to the desert character of the country, or to the numbers of large animals inhabiting it. The same thing is rendered evident by the many sketches which have been published of various parts of the interior. When the Beagle was at Cape Town, I rode a few leagues into the country, which at least was sufficient to render that which I had read more fully intelligible.

Dr. Andrew Smith, who, at the head of his adventurous party, has so lately succeeded in passing the Tropic of Capricorn, informs me that, taking into consideration the whole of the southern part of Africa, there can be no doubt of its being sterile country. On the southern and south-eastern coasts there are some fine forests, but with these exceptions, the traveller may pass, for days together, through open plains, covered by a poor and scanty vegetation. It is difficult to convey any accurate idea of degrees of comparative fertility; but it may be safely said, that the amount of vegetation supported at any one time* by Great Britain, exceeds, perhaps even tenfold, the quantity on an equal area, in the interior parts of Southern Africa. The fact that bullock-waggons can travel in any direction, excepting near the coast, without more than occasionally half an hour's delay, gives, perhaps, a more definite notion of its scantiness. Now if we look to the animals inhabiting these wide plains, we shall find their numbers extraordinarily great, and their bulk immense. We must enumerate the elephant, three species of rhinoceros, and as Dr. Smith is convinced two others also, the hippopotamus, giraffe, the bos caffer—as large as a full-grown bull, and the elan—but little less, two

* I mean by this to exclude the total amount, which may have been successively produced and consumed during a given period.

© The Complete Work of Charles Darwin Online

zebras, and the quaccha, two gnus, and several antelopes even larger than these latter animals. It may be supposed that although the species are numerous, the individuals of each kind are few. By the kindness of Dr. Smith, I am enabled to show that the case is very different. He informs me, that in lat. 24°, in one day's march with the bullock-waggons, he saw, without wandering to any great distance on either side, between one hundred and one hundred and fifty rhinoceroses, which belonged to three species. That the same day he saw several herds of giraffes, amounting together to nearly a hundred; and that, although no elephant was observed, yet they are found in this district. At the distance of a little more than one hour's march from their place of encampment on the previous night, his party actually killed at one spot eight hippopotamoses, and saw many more. In this same river there were likewise crocodiles. Of course it was a case quite extraordinary, to see so many great animals crowded together, but it evidently proves that they must exist in great numbers. Dr. Smith describes the country passed through that day, as "being thinly covered with grass, and bushes about four feet high, and still more thinly with mimosa-trees." The waggons were not prevented travelling in a nearly direct line.

Besides these large animals, every one the least acquainted with the natural history of the Cape, has read of the herds of antelopes, which can be compared only to flocks of migratory birds. The numbers indeed of the lion,* panther, and hyæna, and the multitude of birds of prey, plainly tell of the abundance of the smaller quadrupeds. As Dr. Smith remarked to me, the carnage each day in Southern Africa must indeed be terrific! I confess it is truly surprising, how such a number of animals can find support in a country producing so little food. The larger quadrupeds no doubt roam over wide extents in search of it; and their food chiefly con-

* Dr. Smith mentioned to me, that one evening seven lions were counted at one time walking on the plain, round the encampment.

© The Complete Work of Charles Darwin Online

sists of underwood, which probably contains much nutriment in a small bulk. Dr. Smith also informs me that the vegetation has a rapid growth; no sooner is a part consumed, than its place is supplied by a fresh stock. I apprehend, however, that our ideas respecting the quantity necessary for the support of large quadrupeds are exaggerated. It should have been remembered that the camel, an animal of no mean bulk, has always been considered as the emblem of the desert.

The belief that where large quadrupeds exist, the vegetation must necessarily be luxuriant, is the more remarkable, because the converse is far from true. Mr. Burchell observed to me that when entering Brazil, nothing struck him more forcibly than the splendour of the South American vegetation, contrasted with that of South Africa, together with the absence of all large quadrupeds. In his Travels,* he has suggested that the comparison of the respective weights (if there were sufficient data) of an equal number of the largest herbivorous quadrupeds of each country would be extremely curious. If we take on the one side the elephant,† hippopotamus, giraffe, bos caffer, elan, certainly three species of rhinoceros, and probably five; and on the

* Travels in the interior of South Africa, vol. ii., p. 207.

† The elephant which was killed at Exeter Change, was estimated (being partly weighed) at five tons and a half. The elephant actress, as I was informed, weighed one ton less; so that we may take five as the average of a full-grown elephant. I was told at the Surrey Gardens, that a hippopotamus which was sent to England cut up into pieces, was estimated at three tons and a half; we will call it three. From these premises we may give three tons and a half to each of the five rhinoceroses; perhaps a ton to the giraffe, and half to the bos caffer as well as the elan, (a large ox weighs from 1200 to 1500 pounds). This will give an average (from the above conjectures) of 2.7 of a ton for the ten largest herbivorous animals of Southern Africa. In South America, allowing 1200 pounds for the two tapirs together, 550 for the guanaco and vicuna, 500 for three deer, 300 for capybara, peccari, and a monkey, we shall have an average of 250 pounds, which I believe is overstating the result. The ratio will therefore be, as 6048 to 250, for the ten largest animals from the two countries.

© The Complete Work of Charles Darwin Online

other side, two tapirs, the guanaco, three deer, the vicuna, peccari, capybara (after which we must choose from the monkeys to complete the number), and then place these two groups alongside each other, it is not easy to conceive ranks more disproportionate. After the above facts, we are compelled to conclude, against anterior probability,* that among the mammalia there exists no close relation between the *bulk* of the species, and the *quantity* of the vegetation, in the countries they inhabit.

With regard to the number of large quadrupeds, there certainly exists no quarter of the globe which will bear comparison with Southern Africa. After the different statements which have been given, the extremely desert character of that region will not be disputed. In the European division of the world, we must look back to the tertiary epochs, to find a condition of things among the mammalia resembling that which is now found at the Cape of Good Hope. That tertiary epoch, which we are apt to consider as abounding to an astonishing degree with large animals, because we find the remains of many ages accumulated at certain spots, could boast of but few more of the large quadrupeds, than Southern Africa does at present. If we speculate on the condition of the vegetation during that epoch, we are at least bound so far to consider existing analogies, as not to urge as absolutely necessary a luxuriant vegetation, when we see a state of things so totally different in the region to which we refer.

We know† that the extreme regions of North America,

* If we suppose the case of the discovery of a skeleton of a Greenland whale in a fossil state, not a single cetaceous animal being known to exist, what naturalist would even conjecture on the possibility of a carcass so gigantic, being supported on the minute crustacea and mollusca, living in the frozen seas of the extreme North?

† See Zoological Remarks to Capt. Back's Expedition, by Dr. Richardson. He says, "The subsoil north of latitude 56° is perpetually frozen, the thaw on the coast not penetrating above three feet, and at Bear Lake, in latitude 64°, not more than twenty inches. The frozen substratum does not of itself destroy vegetation, for forests flourish on the surface, at a distance from the coast."

© The Complete Work of Charles Darwin Online

many degrees beyond the limit where the ground at the depth of a few feet remains perpetually congealed, are covered by forests of large and tall trees. In a like manner, in Siberia, we have woods of birch, fir, aspen, and larch, growing in a latitude* (64°), where the mean temperature of the air falls below the freezing point, and where the earth is so completely frozen, that the carcass of an animal embedded in it is perfectly preserved. With these facts we must grant, as far as *quantity alone* of vegetation is concerned, that the great quadrupeds of the later tertiary epochs might, in most parts of Northern Europe and Asia, have lived on the spots where their remains are now found. I do not here speak of the *kind* of vegetation necessary for their support; because, as there is evidence of physical changes, and as the animals have become extinct, so may we suppose that the species of plants have likewise been changed.

These remarks directly bear on the case of the Siberian animals preserved in ice. The firm conviction of the necessity of a vegetation, possessing a character of tropical luxuriance, to support such large animals, and the impossibility of reconciling this with the proximity of perpetual congelation, was one chief cause of the several theories of sudden revolutions of climate, and of overwhelming catastrophes, which were invented to account for their entombment. I am far from supposing that the climate has not changed since the period when those animals lived, which now lie buried in the ice. At present I only wish to show, that as far as *quantity* of food *alone* is concerned, the ancient rhinoceroses might have roamed over the *steppes* of central Siberia (the northern parts probably being under water) even in their present condition, as well as the living rhi-

* See Humboldt Fragmens Asiatiques, p. 386: Barton's Geography of Plants: and Malte Brun. In the latter work it is said, that the limit of the growth of trees in Siberia may be drawn under the parallel of 70°.

© The Complete Work of Charles Darwin Online

noceroses and elephants over the *Karros* of Southern Africa.

After our long digression, if we return to the case of the fossil animals at Bahia Blanca, there is a difficulty from our not knowing on what food the great Edentata probably lived. If on insects and larvæ, like their nearest representatives the armadilloes and anteaters, there is an end to all conjecture. But as vegetation is the first source of life in every part of the world, I think we may safely conclude that the country around Bahia Blanca, with a very little increase of fertility, would support large animals. The plains of the Rio Negro, thickly scattered over with thorny bushes, I do not doubt would supply sufficient food equally well with the *Karros* of Africa. As there is evidence of a physical change to a small amount, so may we allow it to be probable that the productiveness of the soil has decreased in an equally small degree. With this concession I apprehend every difficulty is removed. On the other hand, if we imagine a luxuriant vegetation to be necessary for the support of these animals, we become involved in a series of contradictions and improbabilities.

As the notices of the remains of several quadrupeds, which I discovered in South America, are scattered in different parts of this volume, I will here give a catalogue of them. After having enlarged on the diminutive size of the present races, it may be of interest to see that formerly a very different order of things prevailed. First, the megatherium, and the four or five other large edentata, already alluded to; 6th, an immense mastodon, which must have abounded over the whole country; 7th, the horse (I do not now refer to the broken tooth at Bahia Blanca, but to more certain evidence); 8th, the toxodon, an extraordinary animal as large as a hippopotamus; 9th, a fragment of the head of an animal larger than a horse, and of a very singular character; 10th, 11th, and 12th, parts of rodents—one of considerable size; lastly, a llama or *guanaco*, fully as large as the camel. All these animals coexisted during an epoch

© The Complete Work of Charles Darwin Online

which, geologically speaking is so recent, that it may be considered as only just gone by. These remains have been presented to the College of Surgeons, where they are now in the hands of those best qualified to appreciate whatever value they may possess.

I will now give an account of the habits of some of the more interesting birds, which are common on these wild plains; and first of the *Struthio Rhea*, or South American ostrich. This bird is well known to abound over the plains of Northern Patagonia, and the united provinces of La Plata. It has not crossed the Cordillera; but I have seen it within the first range of mountains on the Uspallata plain, elevated between six and seven thousand feet. The ordinary habits of the ostrich are familiar to every one. They feed on vegetable matter; such as roots and grass; but at Bahia Blanca, I have repeatedly seen three or four come down at low water to the extensive mud-banks which are then dry, for the sake, as the Gauchos say, of catching small fish. Although the ostrich in its habits is so shy, wary, and solitary, and although so fleet in its pace, it falls a prey, without much difficulty, to the Indian or Gaucho armed with the bolas. When several horsemen appear in a semicircle, it becomes confounded, and does not know which way to escape. They generally prefer running against the wind; yet at the first start they expand their wings, and like a vessel make all sail. On one fine hot day I saw several ostriches enter a bed of tall rushes, where they squatted concealed, till quite closely approached. It is not generally known that ostriches readily take to the water. Mr. King informs me that at the Bay of San Blas, and at Port Valdes in Patagonia, he saw these birds swimming several times from island to island. They ran into the water both when driven down to a point, and likewise of their own accord when not frightened: the distance crossed was about 200 yards. When swimming, very little of their bodies appear above water, and their necks are extended a little forward: their progress is slow. On two occasions, I saw some ostriches swimming across the Santa

© The Complete Work of Charles Darwin Online

Cruz river, where its course was about four hundred yards wide, and the stream rapid. Captain Sturt, when descending the Murrumbidgee, in Australia, saw two emus in the act of swimming.

The inhabitants who live in the country readily distinguish, even at a distance, the cock bird from the hen. The former is larger and darker-coloured,* and has a bigger head. The ostrich, I believe the cock, emits a singular deep-toned, hissing note. When first I heard it, standing in the midst of some sand-hillocks, I thought it was made by some wild beast, for it is a sound that one cannot tell whence it comes, or from how far distant. When we were at Bahia Blanca in the months of September and October, the eggs, in extraordinary numbers, were found all over the country. They either lie scattered single, in which case they are never hatched, and are called by the Spaniards, huachos; or they are collected together into a shallow excavation, which forms the nest. Out of the four nests which I saw, three contained twenty-two eggs each, and the fourth twenty-seven. In one day's hunting on horseback sixty-four eggs were found; forty-four of these were in two nests, and the remaining twenty scattered huachos. The Gauchos unanimously affirm, and there is no reason to doubt their statement, that the male bird alone hatches the eggs, and for some time afterwards accompanies the young. The cock when on the nest lies very close; I have myself almost ridden over one. It is asserted that at such times they are occasionally fierce, and even dangerous, and that they have been known to attack a man on horseback, trying to kick and leap on him. My informer pointed out to me an old man, whom he had seen much terrified by one chasing him. I observe in Burchell's travels in South Africa, that he remarks, "having killed a male ostrich, and the feathers being dirty, it was said by the Hottentots to be a nest bird." I understand that the

* A Gaucho assured me, that he had once seen a snow-white, or Albino variety, and that it was a most beautiful bird.

© The Complete Work of Charles Darwin Online

male emu, in the Zoological Garden, takes charge of the nest: this habit, therefore, is common to the family.

The Gauchos unanimously affirm that several females lay in one nest. I have been positively told, that four or five hen birds have been seen to go, in the middle of the day, one after the other, to the same nest. I may add, also, that it is believed in Africa, that two females lay in one nest.* Although this habit at first appears very strange, I think the cause may be explained in a simple manner. The number of eggs in the nest varies from twenty to forty, and even to fifty; and according to Azara to seventy or eighty. Now although it is most probable, from the number of eggs found in one district being so extraordinarily great, in proportion to that of the parent birds, and likewise from the state of the ovarium of the hen, that she may in the course of the season lay a large number, yet the time required must be very long. Azara states,† that a female in a state of domestication laid seventeen eggs, each at the interval of three days one from another. If the hen were obliged to hatch her own eggs, before the last was laid the first probably would be addled; but if each laid a few eggs at successive periods, in different nests, and several hens, as is stated to be the case, combined together, then the eggs in one collection would be nearly of the same age. If the number of eggs in one of these nests is, as I believe, not greater on an average than the number laid by one female in the season, then there must be as many nests as females, and each cock bird will have its fair share of the labour of incubation; and that during a period when the females could not sit, on account of not having finished laying. I have before mentioned the great numbers of huachos, or scattered eggs; so that in one day's hunting the third part were found in this state. It appears odd that so many should be wasted. Does it not arise from the difficulty of several females associating together, and persuading an old cock to undertake the office

* Burchell's Travels, vol. i., p. 280. † Azara, vol. iv., p. 173.

© The Complete Work of Charles Darwin Online

of incubation? It is evident that there must at first be some degree of association, between at least two females; otherwise the eggs would remain scattered over the wide plains, at distances far too great to allow of the male collecting them into one nest. Some have believed that the scattered eggs were deposited for the young birds to feed on. This can hardly be the case in America, because the huachos, although oftentimes found addled and putrid, are generally whole.

When at the Rio Negro, in Northern Patagonia, I repeatedly heard the Gauchos talking of a very rare bird which they called Avestruz Petise. They described it as being less than the common ostrich (which is there abundant), but with a very close general resemblance. They said its colour was dark and mottled, and that its legs were shorter, and feathered lower down than those of the common ostrich. It is more easily caught by the bolas than the other species. The few inhabitants who had seen both kinds, affirmed they could distinguish them apart from a long distance. The eggs of the small species appeared, however, more generally known; and it was remarked, with surprise, that they were very little less than those of the Rhea, but of a slightly different form, and with a tinge of pale blue. Some eggs, picked up on the plains of Patagonia, agree pretty well with this description, and I do not doubt are those of the Petise. This species occurs most rarely on the plains bordering the Rio Negro; but about a degree and a half further south they are tolerably abundant. One Gaucho, however, said he distinctly recollected having seen one, many years before, near the mouth of the Rio Colorado, which is to the north of the Rio Negro. They are said to prefer the plains near the sea. When at Port Desire, in Patagonia (lat. 48°), Mr. Martens shot an ostrich; and I looked at it, forgetting at the moment, in the most unaccountable manner, the whole subject of the Petises, and thought it was a two-third grown one of the common sort. The bird was cooked and eaten before my memory returned. Fortunately the head, neck, legs, wings, many of the larger feathers, and a large part of the skin, had

© The Complete Work of Charles Darwin Online

been preserved. From these a very nearly perfect specimen has been put together, and is now exhibited in the museum of the Zoological Society. Mr. Gould, who in describing this new species did me the honour of calling it after my name, states, that besides the smaller size and different colour of the plumage, the beak is of considerably less proportional dimensions than in the common Rhea; that the tarsi are covered with differently-shaped scales, and that they are feathered six inches beneath the knee. In this latter respect, and in the broader feathers of the wing, this bird perhaps shows more affinity to the gallinaceous family than any other of the Struthionidæ.

Among the Patagonian Indians in the Strait of Magellan, we found a half Indian, who had lived some years with the tribe, but had been born in the northern provinces. I asked him if he had ever heard of the Avestruz Petise? He answered by saying, "Why there are none others in these southern countries." He informed me that the number of eggs in the nest of the petise is considerably less than with the other kind, namely, not more than fifteen on an average; but he asserted that more than one female deposited them. At Santa Cruz we saw several of these birds. They were excessively wary: I think they could see a person approaching when he was so far off as not to distinguish the ostrich. In ascending the river few were seen; but in our quiet and rapid descent, many, in pairs and by fours or fives, were observed. It was remarked, and I think with truth, that this bird did not expand its wings, when first starting at full speed, after the manner of the northern kind. The fact of these ostriches swimming across the river has been mentioned. In conclusion, I may repeat that the *Struthio Rhea* inhabits the country of La Plata as far as a little south of the Rio Negro, in lat. 41°, and that the petise takes its place in Southern Patagonia; the part about the Rio Negro being neutral territory. Wallis saw ostriches at Batchelor's river (lat. 53° 54′), in the Strait of Magellan, which must be the extreme southern possible range of the petise. M. D'Or-

© The Complete Work of Charles Darwin Online

bigny, when at the Rio Negro, made great exertions to procure this bird, but never had the good fortune to succeed. He mentions it in his Travels,* and proposes (in case, I presume, of a specimen being obtained) to call it *Rhea pennata:* a fuller notice was given long before in Dobrizhoffer's Account of the Abipones† (A.D. 1749). He says, "You must know, moreover, that Emus differ in size and habits in different tracts of land; for those that inhabit the plains of Buenos Ayres and Tucuman are larger, and have black, white, and gray feathers; those near to the Strait of Magellan are smaller and more beautiful, for their white feathers are tipped with black at the extremity, and their black ones in like manner terminate in white."

A very singular little bird, lately described by St. Hilaire and Lesson under the name of *Tinochorus Eschscholtzii*, is here common. In its habits, general appearance, and structure, it nearly equally partakes of the character of a quail and a snipe. Yet these two birds are widely contrasted in the form of their beaks, wings, and legs. The Tinochorus is found in the whole of southern South America, wherever there are sterile plains, or open dry pasture-land. We saw it as far south as the inland plains of Patagonia at Santa Cruz, in lat. 50°. On the western side of the Cordillera near Concepcion, where the forest land changes into an open country, this bird is found: from that point throughout Chile, as far as Copiapó, it frequents the most desolate places, where scarcely another living creature can exist. They are found either in pairs or small flocks of five or six; but near the Sierra Ventana I saw as many as thirty or forty together. Upon being

* Vol. ii., p. 76.—When at the Rio Negro, we heard much of the indefatigable labours of this naturalist. M. D'Alcide D'Orbigny, during the years 1826 to 1833, traversed several large portions of South America, and has made a collection, and is now publishing the results on a scale of magnificence, which at once places him in the list of American travellers second only to Humboldt.

† Vol. i. (English translation), p. 314.

© The Complete Work of Charles Darwin Online

approached they squat close, and then are very difficult to be distinguished; so that they often rise quite unexpectedly. When feeding they walk rather slowly, with their legs wide apart. They dust themselves in roads and sandy places. They frequent particular spots, and may be found there day after day. When a pair are together, if one is shot the other seldom rises; for these birds, like partridges, only take wing in a flock. In all these respects, in the muscular gizzard adapted for vegetable food, in the arched beak and fleshy nostrils, short legs and form of foot, the Tinochorus has a close affinity with quails. But directly the bird is seen flying, one's opinion is changed; the long, pointed wings, so different from those in the gallinaceous order, the irregular manner of flight, and plaintive cry uttered at the moment of rising, recal the idea of a snipe. The sportsmen of the Beagle unanimously called it the shortbilled snipe. To this genus, or rather to that of the sandpiper, it approaches, as Mr. Gould informs me, in the shape of its wing, the length of the scapulars, the form of the tail, which closely resembles that of *Tringa hypoleucos*, and in the general colour of the plumage. The male bird, however, has a black mark on its breast, in the form of a yoke, which may be compared to the horseshoe on the breast of the English partridge. The nest is said to be placed on the borders of lakes, although the bird itself is an inhabitant of the parched desert.

The Tinochorus is closely related to some other South American birds. Two species of the genus Attagis, are in almost every respect ptarmigans in their habits; one in Tierra del Fuego, above the limits of forest land; the other just beneath the snow line on the Cordillera of Central Chile. A bird of another closely-allied genus, *Chionis alba*, which solitary species was long thought to form a family by itself, is an inhabitant of the antarctic regions; it feeds on sea-weed and shells on the tidal rocks. Although not web-footed, from some unaccountable taste it is frequently met with far out at sea. This small family of birds is one of

© The Complete Work of Charles Darwin Online

those which, from its varied relations, although at present offering only difficulties to the systematic naturalist, ultimately may assist in revealing the grand scheme, common to the present and past ages, on which organized beings have been created.

I may also briefly notice the genus Furnarius. It contains several species, all small birds, living on the ground, and inhabiting open, dry countries. In structure they cannot be compared to any European form. Ornithologists have generally included them among the creepers, although opposed to that family in every habit. The best known species is the common oven-bird of La Plata, the Casara or housemaker of the Spaniards, and *Furnarius rufus* of Viell. The nest, whence it takes its name, is placed in the most exposed situations, as on the top of a post, a bare rock, or on a cactus. It is composed of mud and bits of straw, and has strong thick walls: in shape it precisely resembles an oven, or depressed beehive. The opening is large and arched, and directly in front, within the nest, there is a partition, which reaches nearly to the roof, thus forming a passage or antechamber to the true nest.

Another and smaller species of Furnarius, something like a lark in appearance, resembles the oven-bird in many points, as in the general reddish tint of its plumage, a peculiar shrill reiterated cry, an odd manner of running by starts, &c. From its affinity, the Spaniards call it Casarita (or little housebuilder), although its nidification is quite different. The Casarita builds its nest at the bottom of a narrow cylindrical hole, which is said to extend horizontally to nearly six feet under ground. Several of the country people told me, that when boys they had attempted to dig out the nest, but had scarcely ever succeeded in getting to the end. The bird chooses any low bank of firm sandy soil by the side of a road or stream. Here (at Bahia Blanca) the walls are built of hardened mud; and I noticed that one, which enclosed a courtyard where I lodged, was penetrated by round holes in a score of places. On asking the owner

© The Complete Work of Charles Darwin Online

the cause of this, he bitterly complained of the little casarita, several of which I afterwards observed at work. It is rather curious, that although they were constantly flitting over the low wall, they must be quite incapable of gaining an idea of thickness even after the shortest circuitous route, for otherwise they would not have made so many vain attempts. I do not doubt that each bird, as often as it came to daylight on the opposite side, was greatly surprised at the marvellous fact.

I have already mentioned nearly all the mammalia common in this country. Of armadilloes three species occur, namely, the Dasypus minutus or *pichy*, the Villosus or *peludo*, and the *apar*. The first extends as far south as lat. 50°, which is about ten degrees further than any other kind. A fourth species, the *Mulita*, only extends as far south as the Sierra Tapalguen, lat. 37° 30′, which is north of Bahia Blanca. The four species have nearly similar habits; the *peludo*, however, is nocturnal, while the others wander by day over the open plains, feeding on beetles, larvæ, roots, and even small snakes. The *apar*, commonly called *mataco*, is remarkable by having only three moveable bands; the rest of its tesselated covering being nearly inflexible. It has the power of rolling itself into a perfect sphere, like one kind of English woodlouse. In this state it is safe from the attack of dogs; for the dog not being able to take the whole in its mouth, tries to bite one side, and the ball slips away. The smooth hard covering of the *mataco* offers a better defence than the sharp spines of the hedgehog. The *pichy* prefers a very dry soil, and the sand-dunes near the coast, where for many months it can never taste water, is its favourite resort. In the course of a day's ride, near Bahia Blanca, several were generally met with. The instant one was perceived, it was necessary in order to catch it, almost to tumble off one's horse; for if the soil was soft, the animal burrowed so quickly, that its hinder quarters had almost disappeared before one could alight. The *pichy* likewise often tries to escape notice, by squatting close to the ground. It appears almost

© The Complete Work of Charles Darwin Online

a pity to kill such nice little animals, for as a Gaucho said, while sharpening his knife on the back of one, "Son tan mansos" (they are so quiet).

Of reptiles there are many kinds: one snake (a Trigonocephalus, or more properly a Cophias), from the size of the poison channel in its fangs, must be very deadly. Cuvier, in opposition to some other naturalists, makes this a sub-genus of the rattlesnake, and intermediate between it and the viper. In confirmation of this opinion, I observed a fact, which appears to me very curious and instructive, as showing how every character, even though it may be in some degree independent of structure, has a tendency to vary by slow degrees. The extremity of the tail of this snake is terminated by a point, which is very slightly enlarged; and as the animal glided along, it constantly vibrated the last inch; and this part striking against the dry grass and brushwood, produced a rattling noise, which could be distinctly heard at the distance of six feet. As often as the animal was irritated or surprised, its tail was shaken; and the vibrations were extremely rapid. Even as long as the body retained its irritability, a tendency to this habitual movement was evident. This Trigonocephalus has, therefore, in some respects the structure of Vipera, with the habits of a Crotalus; the noise, however, being produced by a simpler device. The expression of this snake's face was hideous and fierce; the pupil consisted of a vertical slit in a mottled and coppery iris; the jaws were broad at the base, and the nose terminated in a triangular projection. I do not think I ever saw any thing more ugly, excepting, perhaps, in some of the vampire bats. I imagine this repulsive aspect originates from the features being placed in positions, with respect to each other, somewhat proportional to those of the human face; and thus we obtain a scale of beauty.

Amongst the Batrachian reptiles, I found only one little toad, which was most singular from its colour. If we imagine, first, that it had been steeped in the blackest ink, and then when dry, allowed to crawl over a board, freshly painted

© The Complete Work of Charles Darwin Online

with the brightest vermilion, so as to colour the soles of its feet and parts of its stomach, a good idea of its appearance will be gained. If it is an unnamed species, surely it ought to be called *diabolicus*, for it is a fit toad to preach in the ear of Eve. Instead of being nocturnal in its habits, as other toads are, and living in damp obscure recesses, it crawls during the heat of the day about the dry sand-hillocks and arid plains, where not a single drop of water can be found. It must necessarily depend on the dew for its moisture; and this probably is absorbed by the skin, for it is known, that these reptiles possess great powers of cutaneous absorption. At Maldonado, I found one in a situation nearly as dry as at Bahia Blanca, and thinking to give it a great treat, carried it to a pool of water; not only was the little animal unable to swim, but, I think, without help would soon have been drowned.

Of lizards there were many kinds, but only one remarkable, from its habits. It lives on the bare sand near the sea coast, and from its mottled colour, the brownish scales being speckled with white, yellowish red, and dirty blue, can hardly be distinguished from the surrounding surface. When frightened it attempts to avoid discovery by feigning death, with outstretched legs, depressed body, and closed eyes: if further molested, it buries itself with great quickness in the loose sand. This lizard, from its flattened body and short legs, cannot run quickly. It belongs to the genus Ophryessa.

I will here add a few remarks on the hybernation of animals in this part of South America. When we first arrived at Bahia Blanca, September 7th, 1832, we thought nature had granted scarcely a living creature to this sandy and dry country. By digging, however, in the ground, several insects, large spiders, and lizards were found in a half torpid state. On the 15th, a few animals began to appear, and by the 18th (three days from the equinox), every thing announced the commencement of spring. The plains were ornamented by the flowers of a pink wood sorrel, wild peas, œnotheræ, and geraniums; and the birds began to lay their

© The Complete Work of Charles Darwin Online

eggs. Numerous Lamellicorn and Heteromerous insects, the latter remarkable for their deeply sculptured bodies, were slowly crawling about; while the Saurian tribe, the constant inhabitants of a sandy soil, darted in every direction. During the first eleven days, whilst nature was dormant, the mean temperature taken from observations made every two hours on board the Beagle, was 51°; and in the middle of the day the thermometer seldom ranged above 55°. On the eleven succeeding days, in which all living things became so animated, the mean was 58°, and the range in the middle of the day between sixty and seventy. Here then an increase of seven degrees in mean temperature, but a greater one of extreme heat, was sufficient to awake the functions of life. At Monte Video, from which we had just before sailed, in the twenty-three days included between the 26th of July and the 19th of August, the mean temperature from 276 observations was 58°.4; the mean hottest day being 65°.5, and the coldest 46°. The lowest point to which the thermometer fell was 41°.5, and occasionally in the middle of the day it rose to 69° or 70°. Yet with this elevated temperature, almost every beetle, several genera of spiders, snails, and land shells, toads, and lizards were all lying torpid beneath stones. But we have seen that at Bahia Blanca, which is four degrees to the southward, and therefore with a climate only a very little colder, this same temperature with a rather less extreme heat, was sufficient to awake all orders of animated beings. This shows how nicely the required degree of stimulus is adapted to the general climate of the place, and how little it depends on absolute temperature. It is well known that within the tropics, the hybernation, or more properly estivation, of animals is governed by the times of drought. Near Rio de Janeiro, I was at first surprised to observe, that, a few days after some little depressions had been changed into pools of water by the rain, they were peopled by numerous full-grown shells and beetles. Humboldt has related the strange accident of a hovel having been erected over a spot, where a young crocodile lay buried in

© The Complete Work of Charles Darwin Online

the hardened mud. He adds "The Indians often find enormous boas; which they call Uji, or water serpents, in the same lethargic state. To reanimate them, they must be irritated or wetted with water."

I will only mention one other animal, a zoophyte allied to Virgularia,* a kind of sea-pen. It consists of a thin, straight, fleshy stem, with alternate rows of polypi on each side, and surrounding an elastic stony axis. It varies in length from eight inches to two feet. The stem at one extremity is truncate, but at the other is terminated by a vermiform fleshy appendage, which is separated into two compartments; and in these, small, yellow, spherical ova are contained. The stony axis which gives strength to the stem, may be traced at this extremity into a mere vessel filled with granular matter. This undeveloped portion is enclosed in a transparent, elastic, irritable bag, containing a fluid in which a very distinct circulation of particles could be seen. This bag floats in one of the compartments of the fleshy terminal appendage. At low water hundreds of these zoophytes might be seen, projecting like stubble, with the truncate end upwards, a few inches above the surface of the muddy sand. When touched or pulled, they drew themselves in, suddenly and with force, so as nearly or quite to disappear. By this action, the highly elastic axis must be bent at the lower extremity, where it is naturally slightly curved; and I imagine it is by this elasticity that the zoophyte is enabled to rise again through the mud. Each polypus, though closely united to its brethren, has a distinct mouth, body, and tentacula. Of these polypi, in a large specimen, there must be many thousands; yet we see that they act by one movement; that they have one central axis connected with a system of obscure circulation; and that the ova are produced in an organ distinct from the separate individuals. Well may one be allowed to ask, what is an individual? I will add only one other observation on this zoophyte. The cavities leading from the fleshy compartments of the extremity, were filled

* I believe *Virgularia Patagonica* of D'Orbigny.

© The Complete Work of Charles Darwin Online

with a yellow pulpy matter, which, examined under a microscope, presented an extraordinary appearance. The mass consisted of rounded, semi-transparent, irregular grains, aggregated together into particles of various sizes. All such particles, and the separate grains, possessed the power of rapid movement; generally revolving around different axes, but sometimes progressive. The movement was visible with a very weak power, but with the highest its cause could not be perceived. It was very different from the circulation of the fluid in the elastic bag, containing the thin extremity of the axis. On other occasions, when dissecting small marine animals beneath the microscope, I have seen particles of pulpy matter, some of large size, immediately they were disengaged, commence revolving. I have imagined, I know not with how much truth, that this granulo-pulpy matter was in process of being converted into ova. Certainly in this zoophyte such appeared to be the case.

During my stay at Bahia Blanca, while waiting for the Beagle, the place was in a constant state of excitement, from rumours of wars and victories, between the troops of Rosas and the wild Indians. One day an account came, that a small party forming one of the postas on the line to Buenos Ayres, had been found all murdered. The next day, three hundred men arrived from the Colorado, under the command of Commandant Miranda. A large portion of these men were Indians (*mansos*, or tame), belonging to the tribe of the Cacique Bernantio. They passed the night here; and it was impossible to conceive any thing more wild and savage than the scene of their bivouac. Some drank till they were intoxicated; others swallowed the steaming blood of the cattle slaughtered for their suppers, and then, being sick from drunkenness, they cast it up again, and were besmeared with filth and gore.

> Nam simul expletus dapibus, vinoque sepultus
> Cervicem inflexam posuit, jacuitque per antrum
> Immensus, saniem eructans, ac frusta cruenta
> Per somnum commixta mero.

© The Complete Work of Charles Darwin Online

In the morning they started for the scene of the murder, with orders to follow the "rastro," or track, even if it led them to Chile. We subsequently heard that the wild Indians had escaped into the great Pampas, and from some cause the track had been missed. One glance at the rastro tells these people a whole history. Supposing they examine the track of a thousand horses, they will soon guess by seeing how many have cantered the number of men; by the depth of the other impressions, whether any horses were loaded with cargoes; by the irregularity of the footsteps, how far tired; by the manner in which the food has been cooked, whether the pursued travelled in haste; by the general appearance, how long it has been since they passed. They consider a rastro of ten days or a fortnight, quite recent enough to be hunted out. We also heard that Miranda struck from the west end of the Sierra Ventana, in a direct line to the island of Cholechel, situated seventy leagues up the Rio Negro. This is a distance of between two and three hundred miles, through a country completely unknown. What other troops in the world are so independent? With the sun for their guide, mares' flesh for food, their saddle-cloths for beds,—as long as there is a little water, these men would penetrate to the land's end.

A few days afterwards I saw another troop of these banditti-like soldiers start on an expedition against a tribe of Indians at the small salinas, who had been betrayed by a prisoner cacique. The Spaniard who brought the orders for this expedition was a very intelligent man. He gave me an account of the last engagement at which he was present. Some Indians, who had been taken prisoners, gave information of a tribe living north of the Colorado. Two hundred soldiers were sent; and they first discovered the Indians by a cloud of dust from their horses' feet, as they chanced to be travelling. The country was mountainous and wild, and it must have been far in the interior, for the Cordillera was in sight. The Indians, men, women, and children, were about one hundred and ten in number, and they were nearly all

© The Complete Work of Charles Darwin Online

taken or killed, for the soldiers sabre every man. The Indians are now so terrified, that they offer no resistance in a body, but each flies, neglecting even his wife and children; but when overtaken, like wild animals, they fight against any number to the last moment. One dying Indian seized with his teeth the thumb of his adversary, and allowed his own eye to be forced out, sooner than relinquish his hold. Another, who was wounded, feigned death, keeping a knife ready to strike one more fatal blow. My informer said, when he was pursuing an Indian, the man cried out for mercy, at the same time that he was covertly loosing the bolas from his waist, meaning to whirl it round his head and so strike his pursuer. "I however struck him with my sabre to the ground, and then got off my horse, and cut his throat with my knife." This is a dark picture; but how much more shocking is the unquestionable fact, that all the women who appear above twenty years old, are massacred in cold blood. When I exclaimed that this appeared rather inhuman, he answered, "Why, what can be done? they breed so!"

Every one here is fully convinced that this is the most just war because it is against barbarians. Who would believe in this age, in a Christian civilized country, that such atrocities were committed? The children of the Indians are saved, to be sold or given away as servants, or rather slaves, for as long a time as the owners can deceive them; but I believe in this respect there is little to complain of.

In the battle four men ran away together. They were pursued, and one was killed, but the other three were taken alive. They turned out to be messengers or ambassadors from a large body of Indians, united in the common cause of defence, near the Cordillera. The tribe to which they had been sent was on the point of holding a grand council; the feast of mare's flesh was ready, and the dance prepared: in the morning the ambassadors were to have returned to the Cordillera. They were remarkably fine men, very fair, above six feet high, and all under thirty years of age. The three survivors of course possessed very valuable information; and

© The Complete Work of Charles Darwin Online

to extort this they were placed in a line. The two first being questioned, answered, "No se" (I do not know), and were one after the other shot. The third also said "No se;" adding, "Fire, I am a man, and can die!" Not one syllable would they breathe to injure the united cause of their country! The conduct of the cacique was very different: he saved his life by betraying the intended plan of warfare, and the point of union in the Andes. It was believed that there were already six or seven hundred Indians together, and that in summer their numbers would be doubled. Ambassadors were to have been sent to the Indians at the small salinas, near Bahia Blanca, whom I mentioned that a cacique, this same man, had betrayed. The communication, therefore, extends from the Cordillera to the east coast.

General Rosas's plan is to kill all stragglers, and having driven the remainder to a common point, in the summer, with the assistance of the Chilenos, to attack them in a body. This operation is to be repeated for three successive years. I imagine the summer is chosen as the time for the main attack, because the plains are then without water, and the Indians can only travel in particular directions. The escape of the Indians to the south of the Rio Negro, where in such a vast unknown country they would be safe, is prevented by a treaty with the Tehuelches to this effect;—that Rosas pays them so much to slaughter every Indian who passes to the south of the river, but if they fail in so doing, they themselves are to be exterminated. The war is waged chiefly against the Indians near the Cordillera; for many of the tribes on this eastern side are fighting with Rosas. The general, however, like Lord Chesterfield, thinking that his friends may in a future day become his enemies, always places them in the front ranks, so that their numbers may be thinned. Since leaving South America we have heard that this war of extermination completely failed.

Among the captive girls taken in the same engagement, there were two very pretty Spanish ones, who had been car-

© The Complete Work of Charles Darwin Online

ried away by the Indians when young, and could now only speak the Indian tongue. From their account, they must have come from Salta, a distance in a straight line of nearly one thousand miles. This gives one a grand idea of the immense territory over which the Indians roam: yet, great as it is, I think there will not, in another half-century, be a wild Indian northward of the Rio Negro. The warfare is too bloody to last; the Christians killing every Indian, and the Indians doing the same by the Christians. It is melancholy to trace how the Indians have given way before the Spanish invaders. Schirdel* says, that in 1535, when Buenos Ayres was founded, there were villages containing two and three thousand inhabitants. Even in Falconer's time (1750) the Indians made inroads as far as Lucan, Areco, and Arrecife, but now they are driven beyond the Salado. Not only have whole tribes been wholly exterminated, but the remaining Indians have become more barbarous: instead of living in large villages, and being employed in the arts of fishing, as well as of the chase, they now wander about the open plains, without home or fixed occupation.

I heard also some account of an engagement which took place, a few weeks previously to the one mentioned, at Cholechel. This is a very important station, on account of being a pass for horses; and it was, in consequence, for some time the head-quarters of a division of the army. When the troops first arrived there, they found a tribe of Indians, of whom they killed twenty or thirty. The cacique escaped in a manner which astonished every one. The chief Indians always have one or two picked horses, which they keep ready for any urgent occasion. On one of these, an old white horse, the cacique sprung, taking with him his little son. The horse had neither saddle nor bridle. To avoid the shots, the Indian rode in the peculiar method of his nation; namely, with an arm round the horse's neck, and one leg only on its back. Thus hanging on one side, he was

* Purchas's Collection of Voyages.

© The Complete Work of Charles Darwin Online

seen patting the horse's head, and talking to him. The pursuers urged every effort in the chase; the Commandant three times changed his horse, but all in vain. The old Indian father and his son escaped, and were free. What a fine picture one can form in one's mind,—the naked bronze-like figure of the old man with his little boy, riding like a Mazeppa on the white horse, thus leaving far behind him the host of his pursuers!

I saw one day a soldier striking fire with a piece of flint, which I immediately recognised as having been a part of the head of an arrow. He told me it was found near the island of Cholechel, and that they are frequently picked up there. It was between two and three inches long, and therefore twice as large as those now used in Tierra del Fuego: it was made of opake cream-coloured flint, but the point and barbs had been intentionally broken off. It is well known that no Pampas Indians now use bows and arrows. I believe a small tribe in Banda Oriental must be excepted; but they are widely separated from the Pampas Indians, and border close on those tribes that inhabit the forest, and live on foot. It appears, therefore, that these arrow-heads are antiquarian* relics of the Indians, before the great change in habits consequent on the introduction of the horse into South America.

* Azara has even doubted whether the Pampas Indians ever used bows.

CHAPTER VI.

Set out for Buenos Ayres—Rio Sauce—Sierra Ventana—Transportal of pebbles—Third posta—Driving horses—Bolas—Partridges and foxes—Features of country—Long-legged plover—Teru-tero—Hailstorm—Natural enclosures in Sierra Tapalguen—Flesh of puma—Meat diet—Guardia del Monte—Effects of cattle on the vegetation—Cardoon—Buenos Ayres—Corral where animals are slaughtered.

BAHIA BLANCA TO BUENOS AYRES.

SEPTEMBER 8TH.—Having with some difficulty hired a Gaucho to accompany me, on my ride to Buenos Ayres, we started early in the morning. The distance is about four hundred miles, and nearly the whole way through an uninhabited country. Ascending a few hundred feet from the basin of green turf on which Bahia Blanca stands, we entered on a wide desolate plain. It consists of a crumbling argillaceo-calcareous rock, which, from the dry nature of the climate, supports only scattered tufts of withered grass, without a single bush or tree to break the monotonous uniformity. The weather was fine, but the atmosphere remarkably hazy; I thought the appearance foreboded a gale, but the Gauchos said it was owing to the plain, at some great distance in the interior, being on fire. After a long gallop, having changed horses twice, we reached the Rio Sauce. It is a deep, rapid, little stream, but not above twenty-five feet wide. The second posta on the road to Buenos Ayres stands on its banks; a little above there is a pass for horses, where the water does not reach to the horse's belly; but from that point, in its course to the sea, it is quite impassable, and hence makes a most useful barrier against the Indians.

Insignificant as this stream is, the Jesuit Falconer, whose information is generally so very correct, figures it as a considerable river, rising at the foot of the Cordillera. With respect to its source, I do not doubt this is the case; for the

© The Complete Work of Charles Darwin Online

Gauchos assured me, that in the middle of the dry summer, this stream, at the same time with the Colorado, has periodical floods; which can only originate in the snow melting on the Andes. It is extremely improbable that a stream, so small as the Sauce then was, should traverse the entire width of the continent; and indeed, if it were the residue of a large river, its waters, as in other ascertained cases, would be saline. During the winter we must look to the springs round the Sierra Ventana as the source of its pure and limpid stream. I suspect the plains of Patagonia, like those of Australia, are traversed by many water-courses, which only perform their proper parts at certain periods. Probably this is the case with the water which flows into the head of Port Desire, and likewise with the Rio Chupat, on the banks of which masses of highly cellular scoriæ were found by the officers employed in the survey.

As it was early in the afternoon when we arrived, we took fresh horses, and a soldier for a guide, and started for the Sierra de la Ventana. This mountain is visible from the anchorage at Bahia Blanca; and Capt. FitzRoy calculates its height to be 3500 feet;—an altitude very remarkable on this eastern side of the continent. I am not aware that any foreigner, previous to my visit, had ascended this mountain; and indeed very few of the soldiers at Bahia Blanca knew any thing about it. Hence we heard of beds of coal, of gold and silver, of caves, and of forests, all of which inflamed my curiosity, only to disappoint it. The distance from the posta was about six leagues, over a level plain of the same character as before. The ride was, however, interesting, as the mountain began to show its true form. When we reached the foot of the main ridge, we had much difficulty in finding any water, and we thought we should have been obliged to have passed the night without any. At last we discovered some, by looking close to the mountain, for at the distance even of a few hundred yards, the streamlets were buried and entirely lost in the friable calcareous stone, and loose detritus. I do not think nature ever made a more solitary,

© The Complete Work of Charles Darwin Online

desolate pile of rock;—it well deserves its name of *Hurtado*, or separated. The mountain is steep, extremely rugged, and broken, and so entirely destitute of trees and even bushes, that we actually could not find a skewer to stretch out our meat over the fire made of thistle* stalks. The strange aspect of this mountain is contrasted by the sea-like plain, which not only abuts against its steep sides, but likewise separates the parallel ranges. The uniformity of the colouring gives, also, an extreme quietness to the view;—the whitish gray of the quartz rock, and the light brown of the withered grass of the plain, being unrelieved by any brighter tint. From custom, one expects to see in the neighbourhood of a lofty and bold mountain a broken country, strewed over with huge fragments. Here nature shows, that the last movement before the bed of the sea is changed into dry land, may sometimes be one of tranquillity. Under these circumstances, I was curious to observe how far from the parent rock any pebbles could be found. On the shores of Bahia Blanca, and near the settlement, there were some of quartz, which certainly must have come from this source: the distance is forty-five miles.

The dew, which in the early part of the night wetted the saddle-cloths, under which we slept, was in the morning frozen. From the sharpness of the cold, I supposed we were already at a considerable elevation, although, to the eye, the plain had appeared horizontal. In the morning (9th September) the guide told me to ascend the nearest ridge, which he thought would lead me to the four peaks that crown the summit. The climbing up such rough rocks was very fatiguing, the sides were so indented, that, what was gained in one five minutes, was often lost in the next. At last, when I reached the ridge, my disappointment was extreme in finding a precipitous valley as deep as the plain, which cut the chain transversely in two, and separated me from the four

* I call these thistle stalks for the want of a more correct name. I believe it is a species of Eryngium.

© The Complete Work of Charles Darwin Online

points. This valley is very narrow, but flatbottomed, and it forms a fine horse-pass for the Indians, as it connects the plains on the northern and southern sides of the range. Having descended, and while crossing it, I saw two horses grazing: I immediately hid myself in the long grass, and began to reconnoitre; but as I could see no signs of Indians, I proceeded cautiously on my second ascent. It was late in the day, and this part of the mountain, like the other, was steep and rugged. I was on the top of the second peak by two o'clock, but got there with extreme difficulty; every twenty yards I had the cramp in the upper part of both thighs, so that I was afraid I should not have been able to have descended. It was also necessary to return by another road, as it was out of the question to pass over the saddle-back. I was therefore obliged to give up the two higher peaks. Their altitude was but little greater, and every purpose of geology had been answered; so that the attempt was not worth the hazard of any further exertion. I presume the cause of the cramp was the great change in the kind of muscular action, from that of hard riding to that of still harder climbing. It is a lesson worth remembering, as in some cases it might cause much difficulty.

I have already said the mountain is composed of white quartz rock, and with it a little glossy clay-slate is associated. At the height of a few hundred feet above the plain, patches of conglomerate adhered in several places to the solid rock. They resembled in hardness, and in the nature of the cement, the masses which may be seen daily forming on some coasts. I do not doubt these pebbles were, in a similar manner, aggregated, at a period when the great calcareous formation was depositing beneath the surrounding sea. We may believe that the jagged and battered forms of the hard quartz yet show the effects of the waves of an open ocean.

I was, on the whole, disappointed with this ascent. Even the view was insignificant;—a plain like the sea, but without its beautiful colour and defined outline. The scene, however, was novel, and a little danger, like salt to meat, gives it

© The Complete Work of Charles Darwin Online

a relish. That the danger was very little was certain, for my two companions made a good fire—a thing which is never done when it is suspected that Indians are near. I reached the place of our bivouac by sunset, and drinking much maté, and smoking several cigaritos, soon made up my bed for the night. The wind was very strong and cold, but I never slept more comfortably.

September 10th.—In the morning, having fairly scudded before the gale, we arrived by the middle of the day at the Sauce posta. On the road we saw great numbers of deer, and near the mountain a guanaco. The plain, that abuts against the Sierra, is traversed by some curious gullies, of which one was about twenty feet wide, and at least thirty deep; we were obliged in consequence to make a considerable circuit, before we could find a pass. We staid the night at the posta, the conversation, as was generally the case, being about the Indians. The Sierra Ventana was formerly a great place of resort; and three or four years ago there was much fighting here. My guide had been present when many men were killed: the women escaped to the top of the ridge, and fought most desperately with big stones; many thus saving themselves.

September 11th.—Proceeded to the third posta in company with the lieutenant who commanded it. The distance is called fifteen leagues; but it is only guess-work and is generally overstated. The road was uninteresting, over a dry grassy plain; and on our left hand at a greater or less distance there were some low hills; a chain of which, we crossed close to the posta. Before our arrival, we met a large herd of cattle and horses, guarded by fifteen soldiers; but we were told many had been lost. It is very difficult to drive animals across the plains; for if in the night a lion, or even a fox, approaches, nothing can prevent the horses dispersing in every direction; and a storm will have the same effect. A short time since, an officer left Buenos Ayres with 500 horses, and when he arrived at the army he had under twenty.

Soon afterwards we perceived by the cloud of dust, that a

© The Complete Work of Charles Darwin Online

party of horsemen were coming towards us; when far distant my companions knew them to be Indians, by their long hair streaming behind their backs. The Indians generally have a fillet round their heads, but never any covering; and their black hair blowing across their swarthy faces, heightens to an uncommon degree, the wildness of their appearance. They turned out to be a party of Bernantio's friendly tribe, going to a salina for salt. The Indians eat much salt, their children sucking it like sugar. This habit is very different from that of the Spanish Gauchos, who, leading the same kind of life, eat scarcely any. The Indians gave us good-humoured nods as they passed at full gallop, driving before them a troop of horses, and followed by a train of lanky dogs.

SEPTEMBER 12TH and 13TH.—I staid at this posta two days, waiting for a troop of soldiers, which, General Rosas had the kindness to send to inform me, would shortly travel to Buenos Ayres; and he advised me to take the opportunity of such an escort. In the morning we rode to some neighbouring hills to view the country, and to examine the geology. After dinner the soldiers divided themselves into two parties for a trial of skill with the bolas. Two spears were stuck in the ground thirty-five yards apart, but they were struck and entangled only once in four or five times. The balls can be thrown fifty or sixty yards, but with little certainty. This, however, does not apply to a man on horseback; for when the speed of the horse is added to the force of the arm, it is said, that they can be whirled with effect to the distance of eighty yards.* In the middle of the day two men had ar-

* As a proof of the force with which the balls are hurled, I may mention an anecdote that happened at the Falkland Islands. At the time the Spaniards murdered some of their own countrymen, and all the Englishmen, a young Spaniard was running away, when a great tall Indian, by name Luciano, came at full gallop after him, shouting to him to stop, and saying that he only wanted to speak to him. Just as the Spaniard was on the point of reaching the boat, Luciano threw the balls: they struck him on the legs, with such a jerk, as to throw him down and to render him for some time insensible. The man, after Luciano had had his talk, was al-

© The Complete Work of Charles Darwin Online

rived, who brought a parcel from the next posta to be forwarded to the general; so that besides these two, our party consisted of myself and guide, the lieutenant and his four soldiers. The latter were strange beings; the first a fine young negro; the second half Indian and negro; and the two others nondescripts; namely, an old Chilian miner, the colour of mahogany, and another partly a mulatto; but two such mongrels, with such detestable expressions, I never saw before. At night, when they were sitting round the fire, and playing at cards, I retired to view such a Salvator Rosa scene. They were seated under a low cliff, so that I could look down upon them; around the party were lying dogs, arms, remnants of deer and ostriches; and their long spears were stuck in the turf. Further in the dark background, their horses were tied up, ready for any sudden danger. If the stillness of the desolate plain was broken by one of the dogs barking, a soldier, leaving the fire, would place his head close to the ground, and thus slowly scan the horizon. Even if the noisy teru-tero uttered its scream, there would be a pause in the conversation, and every head, for a moment a little inclined.

What a life of misery these men appear to us to lead! They were at least ten leagues from the Sauce posta, and since the murder committed by the Indians, twenty from another. The Indians are supposed to have made their attack in the middle of the night; for very early in the morning after the murder, they were luckily seen approaching this posta. The whole party, however, escaped, together with the troop of horses; each one taking a line for himself, and driving with him as many animals as he was able to manage.

The little hovel, built of thistle-stalks, in which they slept, neither kept out the wind or rain; indeed in the latter case the only effect the roof had, was to condense it into larger

lowed to escape. He told us that his legs were marked by great weals, where the thong had wound round, as if he had been flogged with a whip.

© The Complete Work of Charles Darwin Online

drops. They had nothing to eat excepting what they could catch, such as ostriches, deer, armadilloes, &c., and their only fuel was the dry stalks of a small plant, somewhat resembling an aloe. The sole luxury which these men enjoyed was smoking the little paper cigars, and sucking maté. I used to think the carrion vulture, man's constant attendant on these dreary plains, while seated on some little eminence, seemed by its very patience to say, "Ah! when the Indians come we shall have a feast."

In the morning we all sallied forth to hunt, and although we had not much success, there were some animated chases. Soon after starting the party separated, and so arranged their plans, that at a certain time of the day (in guessing which they show much skill) they should all meet from different points of the compass on a plain piece of ground, and thus drive together the wild animals. One day I went out hunting at Bahia Blanca, but the men there merely rode in a crescent, each being about a quarter of a mile apart from the other. A fine male ostrich being turned by the headmost riders, tried to escape on one side. The Gauchos pursued at a reckless pace, twisting their horses about with the most admirable command, and each man whirling the balls round his head. At length the foremost threw them, revolving through the air: in an instant the ostrich rolled over and over, its legs fairly lashed together by the thong.

The plains abound with three kinds of partridge,* two of which are as large as hen pheasants. Their destroyer, a small and pretty fox, was also singularly numerous; in the course of the day we could not have seen less than forty or fifty. They were generally near their earths, but the dogs killed one. When we returned to the posta, we found two of the party returned who had been hunting by themselves. They had killed a puma, and had found an ostrich's nest with twenty-seven eggs in it. Each of these is said to equal in

* Two species of Tinamus, and *Eudromia elegans* of D'Orbigny, which can only be called a partridge with regard to its habits.

© The Complete Work of Charles Darwin Online

weight eleven hens' eggs; so that we obtained from this one nest as much food as 297 hens' eggs would have yielded.

SEPTEMBER 14TH.—As the soldiers belonging to the next posta meant to return, and we should together make a party of five, and all armed, I determined not to wait* for the expected troops. After galloping some leagues, we came to a low swampy country, which extends for nearly eighty miles to the northward, as far as the Sierra Tapalguen. In some parts there were fine damp plains, covered with grass, while others had a soft, black, and peaty soil. There were also many extensive but shallow lakes, and large beds of reeds. The country on the whole resembled the better parts of the Cambridgeshire fens. At night we had some difficulty in finding, amidst the swamps, a dry place for our bivouac.

SEPTEMBER 15TH.—Rose very early in the morning, and shortly after passed the posta, where the Indians had murdered the five soldiers. The officer had eighteen chuzo wounds in his body. By the middle of the day, after a hard gallop, we reached the fifth posta: on account of some difficulty in procuring horses we staid there the night. As this point was the most exposed on the whole line, twenty-one soldiers were stationed there; at sunset they returned from hunting, bringing with them seven deer, three ostriches, and many armadilloes and partridges. When riding through the country, it is a common practice to set fire to the plain; and hence at night, as on this occasion, the horizon was illuminated in several places by brilliant conflagrations. This is done partly for the sake of puzzling any stray

* The lieutenant pressed me much to stop. As he had been very obliging—not only providing me with food, but lending me his private horses—I wanted to make him some remuneration. I asked my guide whether I might do so, but he told me certainly not; that the only answer I should receive, probably would be, "We have meat for the dogs in our country, and therefore do not grudge it to a Christian." It must not be supposed that the rank of lieutenant in such an army, would at all prevent the acceptance of payment: it was only the high sense of hospitality, which every traveller is bound to acknowledge as nearly universal throughout these provinces.

© The Complete Work of Charles Darwin Online

Indians, but chiefly for improving the pasture. In grassy plains unoccupied by the larger ruminating quadrupeds, it seems necessary to remove by fire the superfluous vegetation, so as to render serviceable the new year's growth.

The rancho at this place did not boast even of a roof, but merely consisted of a ring of thistle-stalks, to break the force of the wind. It was situated on the borders of an extensive but shallow lake, swarming with wild fowl, among which the black-necked swan was conspicuous.

The kind of plover, which appears is if mounted on stilts, (*Himantopus melanura*) is here common in flocks of considerable size. It has been wrongfully accused of inelegance; when wading about in shallow water, which is its favourite resort, its gait is far from awkward. These birds in a flock utter a noise, that singularly resembles the cry of a pack of small dogs in full chase: waking in the night, I have more than once been for a moment startled at the distant sound. The teru-tero (*Vanellus cayanensis*), is another bird, which often disturbs the stillness of the night. In appearance and habits it resembles in many respects our peewits; its wings, however, are armed with sharp spurs, like those on the legs of the common cock. As our peewit takes its name from the sound of its voice, so does the teru-tero. While riding over the grassy plains, one is constantly pursued by these birds, which appear to hate mankind, and I am sure deserve to be hated, for their never-ceasing, unvaried, harsh screams. To the sportsman they are most annoying, by telling every other bird and animal of his approach: to the traveller in the country, they may possibly, as Molina says, do good, by warning him of the midnight robber. During the breeding season, they attempt, like our peewits, by feigning to be wounded, to draw away from their nests dogs and other enemies. The eggs of this bird are esteemed a great delicacy.

September 16th.—To the seventh posta at the foot of the Sierra Tapalguen. The country was quite level, with a coarse herbage and a soft peaty soil. The hovel was there remarkably neat, the posts and rafters being made of about a

© The Complete Work of Charles Darwin Online

dozen dry thistle-stalks bound together with thongs of hide; and by the aid of these Ionic-like columns the roof and sides were thatched with reeds. We were here told a fact, which I would not have credited, if I had not had partly ocular proof of it; namely, that, during the previous night, hail as large as small apples, and extremely hard, had fallen with such violence, as to kill the greater number of the wild animals. One of the men had already found thirteen deer (*Cervus campestris*) lying dead, and I saw their *fresh* hides; another of the party, a few minutes after my arrival, brought in seven more. Now I well know, that one man without dogs, would hardly have killed seven deer in a week. The men believed they had seen about fifteen dead ostriches (part of one of which we had for dinner); and they said that several were running about evidently blind in one eye. Numbers of smaller birds, as ducks, hawks, and partridges, were killed. I saw one of the latter with a black mark on its back, as if it had been struck with a paving-stone. A fence of thistle-stalks round the hovel, was nearly broken down, and my informer putting his head out to see what was the matter, received a severe cut, and now wore a bandage. The storm was said to have been of limited extent: we certainly saw from our last night's bivouac a dense cloud and lightning in this direction. It is marvellous how such strong animals as deer could thus have been killed; but I have no doubt, from the evidence I have given, that the story is not in the least exaggerated. I am glad, however, to have its credibility supported by the Jesuit Drobrizhoffer,* who, speaking of a country much to the northward, says, hail fell of an enormous size and killed vast numbers of cattle: the Indians hence called the place *Lalegraicavalca*, meaning "The little white things."

Having finished our dinner of hail-stricken meat, we crossed the Sierra Tapalguen; a low range of hills, a few hundred feet in height, which commences at Cape Corrientes.

* History of the Abipones, vol. ii., p. 6.

© The Complete Work of Charles Darwin Online

The rock in this part is pure quartz; further eastward I understand it is granitic. The hills are of a remarkable form; they consist of flat patches of table-land, surrounded by low but perpendicular cliffs, like the outliers of a sedimentary deposit. The hill which I ascended was very small, not above a couple of hundred yards in diameter; but I saw others larger. One which goes by the name of the "Corral," is said to be two or three miles in diameter, and encompassed on all sides by perpendicular cliffs, between thirty and forty feet high, excepting at one spot, where the entrance lies. Falconer* gives a curious account of the Indians driving within it troops of wild horses, and then by guarding the entrance, keeping them secure. I have never heard of any other instance of table-land in a formation of quartz, and which, in the hill I examined, had neither cleavage or stratification. I was told that the rock of the "Corral" was white, and would strike fire.

We did not reach the posta on the Rio Tapalguen till after it was dark. At supper, from something which was said, I was suddenly struck with horror at thinking that I was eating one of the favourite dishes of the country, namely, a half-formed calf, long before its proper time of birth. It turned out to be Puma; the meat is very white, and remarkably like veal in taste. Dr. Shaw was laughed at for stating that, "the flesh of the lion is in great esteem, having no small affinity with veal, both in colour, taste, and flavour." Such certainly is the case with the Puma. The Gauchos differ in their opinion, whether the Jaguar is good eating, but are unanimous in saying that cat is excellent.

SEPTEMBER 17TH.—We followed the course of the Rio Tapalguen, through a very fertile country, to the ninth posta. Tapalguen itself, or the town of Tapalguen, if it may be so called, consists of a perfectly level plain, studded over as far as the eye can reach, with the toldos, or oven-

* Falconer's Patagonia, p. 70.

© The Complete Work of Charles Darwin Online

shaped huts of the Indians. The families of the friendly Indians, who were fighting on the side of Rosas, resided here. We met and passed many young Indian women, riding by two or three together on the same horse: they, as well as many of the young men, were strikingly handsome,—their fine ruddy complexions being the picture of health. Besides the toldos, there were three ranchos; one inhabited by the Commandant, and the two others by Spaniards with small shops.

We were here able to buy some biscuit. I had now been several days without tasting any thing besides meat: I did not at all dislike this new regimen; but I felt as if it would only have agreed with very hard exercise. I have heard that patients in England, when desired to confine themselves exclusively to an animal diet, even with the hope of life before their eyes, have hardly been able to endure it. Yet the Gaucho in the Pampas, for months together, touches nothing but beef. But they eat, I observe, a very large proportion of fat, which is of a less animalized nature; and they particularly dislike dry meat, such as that of the Agouti. It is, perhaps, from this regimen that the Gauchos, like other carnivorous animals, can abstain long from food. I was told that at Tandeel, some troops voluntarily pursued a party of Indians for three days, without eating or drinking.

We saw in the shops, many articles, such as horsecloths, belts, and garters, woven by the Indian women. The patterns were very pretty, and the colours brilliant; the workmanship of the garters was so good, that an English merchant at Buenos Ayres, maintained they must have been manufactured in England, till he found the tassels had been fastened by split sinew.

September 18th.—We had a very long ride this day. At the twelfth posta, which is seven leagues south of Rio Salado, we came to the first estancia with cattle and white women. Afterwards we had to ride for many miles through a country flooded with water above our horses' knees. By crossing the stirrups, and riding Arab-like with our legs bent up, we

© The Complete Work of Charles Darwin Online

contrived to keep tolerably dry. It was nearly dark when we arrived at the Salado; the stream was deep, and about forty yards wide; in summer, however, its bed becomes almost dry, and the little remaining water nearly as salt as that of the sea. We slept at one of the great estancias of General Rosas. It was fortified, and of such an extent, that arriving in the dark I thought it was a town and fortress. In the morning we saw immense herds of cattle, as well we might, the general here having seventy-four square leagues of land. Formerly nearly three hundred men were employed about this estate, and they defied all the attacks of the Indians.

SEPTEMBER 19TH.—Passed the Guardia del Monte. This is a nice scattered little town, with many gardens, full of peach and quince trees. The plain here looked like that around Buenos Ayres; the turf being short and bright green, with beds of clover and thistles, and with bizcacha holes. I was very much struck with the marked change in the aspect of the country after having crossed the Salado. From a coarse herbage we passed on to a carpet of fine green verdure. I at first attributed this to some change in the nature of the soil, but the inhabitants assured me that in this part, as well as in Banda Oriental, where there was as great a difference between the country around Monte Video and the thinly-inhabited savannahs of Colonia, that the whole was to be attributed to the manuring and grazing of the cattle. I am not botanist enough to say, whether the change is owing to the introduction of new species, to the altered growth of the same, or to a difference in their proportional numbers. Azara has also observed with astonishment this change: he is likewise much perplexed by the immediate appearance of plants not occurring in the neighbourhood, on the borders of any track that leads to a newly-constructed hovel. In another part he says,* "Ces chevaux (sauvages) ont la manie de préférer les chemins, et le bord des routes pour déposer leurs excrémens, dont on trouve des monceaux dans ces endroits." Does this not

* Azara's Voyage, vol. i., p. 373.

© The Complete Work of Charles Darwin Online

partly explain the circumstance? We thus have lines of richly-manured land serving as channels of communication across wide districts.

Near the Guardia we find the southern limit of two European plants, now become excessively common. The fennel in great profusion covers the ditch banks in the neighbourhood of Buenos Ayres, Monte Video, and other towns. But the cardoon (*Cynara cardunculus*)* has a far wider range: it occurs in these latitudes on both sides of the Cordillera, across the continent. I saw it in unfrequented spots in Chile, Entre Rios, and Banda Oriental. In the latter country alone, very many (probably several hundred) square miles are covered by one mass of these prickly plants, and are impenetrable by man or beast. Over the undulating plains, where these great beds occur, nothing else can live. Before their introduction, however, I apprehend the surface supported as in other parts a rank herbage. I doubt whether any case is on record, of an invasion on so grand a scale of one plant over the aborigines. As I have already said, I nowhere saw the cardoon south of the Salado; but it is probable that in proportion as that country becomes inhabited, the cardoon will extend its limits. The case is different with the giant thistle (with variegated leaves) of the Pampas, for I met with it in the valley of the Sauce. According to the principles so well laid down by Mr. Lyell,

* D'Orbigny (vol. i., p. 474), says that the cardoon and artichoke are both found wild. Dr. Hooker (Botanical Magazine, vol. lv., p. 2862), has described a variety of the Cynara from this part of South America under the name of *inermis*. He states that botanists are now generally agreed that the cardoon and the artichoke are varieties of one plant. I may add, that an intelligent farmer assured me, he had observed in a deserted garden, some artichokes changing into the common cardoon. Dr. Hooker believes that Head's vivid description of the thistle of the Pampas applies to the cardoon; but this is a mistake. Captain Head referred to the plant, which I have mentioned a few lines lower down, under the title of giant thistle. Whether it is a true thistle I do not know; but it is quite different from the cardoon, and more like a thistle properly so called.

© The Complete Work of Charles Darwin Online

few countries have undergone more remarkable changes, since the year 1535, when the first colonist of La Plata landed with seventy-two horses. The countless herds of horses, cattle, and sheep, not only have altered the whole aspect of the vegetation, but they have almost banished the guanaco, deer, and ostrich. Numberless other changes must likewise have taken place; the wild pig in some parts probably replaces the peccari; packs of wild dogs may be heard howling on the wooded banks of the less frequented streams; and the common cat, altered into a large and fierce animal, inhabits rocky hills. I have alluded to the invasion of the cardoon: in a like manner, the islands near the mouth of the Parana, are thickly clothed with peaches and orange-trees, springing from seeds carried there by the waters of the river.

While changing horses at the Guardia, several people questioned us much about the army,—I never saw any thing like the enthusiasm for Rosas, and for the success of the "most just of all wars, because against barbarians." This expression it must be confessed is very natural, for till lately, neither man, woman, nor horse, was safe from the attacks of the Indians. We had a long day's ride over the same rich green plain abounding with various flocks, and with here and there a solitary estancia, and its one *ombu* tree. In the evening it rained heavily: on arriving at a post-house, we were told by the owner that if we had not a regular passport we must pass on, for there were so many robbers he would trust no one. When he read, however, my passport, which began with "El Naturalista Don Carlos, &c." his respect and civility were as unbounded, as his suspicions had been before. What a naturalist may be, neither he nor his countrymen, I suspect, had any idea; but probably my title lost nothing of its value from that cause.

September 20th.—We arrived by the middle of the day at Buenos Ayres. The outskirts of the city looked quite pretty, with the agave hedges, and groves of olive, peach, and willow trees, all just throwing out their fresh green leaves. I rode to the house of Mr. Lumb, an English merchant, to

© The Complete Work of Charles Darwin Online

whose kindness and hospitality, during my stay in the country, I was greatly indebted.

The city of Buenos Ayres is large*; and I should think one of the most regular in the world. Every street is at right angles to the one it crosses, and the parallel ones being equidistant, the houses are collected into solid squares of equal dimensions, which are called quadras. On the other hand, the houses themselves are hollow squares; all the rooms opening into a neat little courtyard. They are generally only one story high, with flat roofs, which are fitted with seats, and are much frequented by the inhabitants in summer. In the centre of the town is the Plaza, where the public offices, fortress, cathedral, &c., stand. Here also, the old viceroys, before the revolution, had their palaces. The general assemblage of buildings possesses considerable architectural beauty, although none individually can boast of any.

The great *corral* where the animals are kept for slaughter to supply food to this beef-eating population, is one of the spectacles best worth seeing. The strength of the horse as compared to that of the bullock is quite astonishing: a man on horseback having thrown his lazo round the horns of a beast, can drag it any where he chooses. The animal having ploughed up the ground with outstretched legs, in vain efforts to resist the force, generally dashes at full speed to one side; but the horse immediately turning to receive the shock, stands so firmly, that the bullock is almost thrown down, and one would think, would certainly have its neck dislocated. The struggle is not, however, one of fair strength; the horse's girth being matched against the bullock's extended neck. In a similar manner a man can hold the wildest horse, if caught with the lazo, just behind the ears. When the bullock has been dragged to the spot where it is to be slaughtered, the *matador* with great caution cuts the hamstrings. Then is given the death bellow; a noise more

* Is said to contain 60,000 inhabitants. Monte Video, the second town of importance on the banks of the Plata, has 15,000.

© The Complete Work of Charles Darwin Online

expressive of fierce agony than any I know: I have often distinguished it from a long distance, and have always known that the struggle was then drawing to a close. The whole sight is horrible and revolting, the ground is almost made of bones; and the horses, and riders are drenched with gore.

CHAPTER VII.

Excursion to St. Fe—Thistle beds—Habits and range of Bizcacha—Little owl—Saline streams—Level plains—Mastodon—St. Fe—Change in landscape—Geology—Tooth of extinct horse—Range of fossil quadrupeds—Pampas full of remains—Effects of great droughts—Droughts periodical—Parana—Habits of Jaguar—Scissor-beak—Kingfisher, parrot, and scissor-tail—Revolution—Buenos Ayres—State of government.

BUENOS AYRES TO ST. FE.

SEPTEMBER 27TH.—In the evening I set out on an excursion to St. Fe, which is situated nearly three hundred English miles from Buenos Ayres, on the banks of the Parana. The roads in the neighbourhood of the city, after the rainy weather were extraordinarily bad. I should never have thought it possible for a bullock waggon to have crawled along: as it was, they scarcely went at the rate of a mile an hour, and a man was kept ahead, to survey the best line for making the attempt. The bullocks were terribly jaded: it is a great mistake to suppose that with improved roads, and an accelerated velocity of travelling, the sufferings of the animals increase in the same proportion. We passed a train of waggons and a troop of beasts on their road to Mendoza. The distance is about 580 geographical miles, and the journey is generally performed in fifty days. These waggons are very long, narrow, and thatched with reeds; they have only two wheels, the diameter of which in some cases is even ten feet. Each is drawn by six bullocks which are urged on by a goad at least twenty feet long: this is suspended from within the roof; for the wheel bullocks a smaller one is kept; and for the intermediate pair, a point projects at right angles from the middle of the long one. The whole apparatus looked like some implement of war.

SEPTEMBER 28TH.—We passed the small town of Luxan,

© The Complete Work of Charles Darwin Online

where there is a wooden bridge over the river—a most unusual convenience in this country. We passed also Areco. The plains appeared level, but were not so in fact; for in various places the horizon was distant. The estancias are here wide apart; for there is little good pasture, owing to the land being covered by beds either of an acrid clover, or of the great thistle. The latter, well known from the animated description given by Sir F. Head, were at this time of the year two-thirds grown; in some parts they were as high as the horse's back, but in others they had not yet sprung up, and the ground was bare and dusty as on a turnpike road. The clumps were of the most brilliant green, and they made a pleasing miniature-likeness of broken forest land. When the thistles are fully grown, the great beds are impenetrable, except by a few tracks, as intricate as those in a labyrinth. These are only known to the robbers, who at this season inhabit them, and sally forth at night to rob, and cut throats, with impunity. Upon asking at a house whether robbers were numerous, I was answered, "The thistles are not up yet;"—the meaning of which reply was not at first very obvious. There is little interest in passing over these tracts, for they are inhabited by few animals or birds, excepting the bizcacha and its friend the little owl.

The bizcacha* is well known to form a prominent feature in the zoology of the Pampas. It is found as far south as the Rio Negro, in lat. 41°, but not beyond. It cannot, like the agouti, subsist on the gravelly and desert plains of Patagonia, but prefers a clayey or sandy soil, which produces a different and more abundant vegetation. Near Mendoza, at the foot of the Cordillera, it occurs in close neighbourhood with the allied alpine species. It is a very curious circumstance in its geographical distribution, that it has never been seen, fortunately for the inhabitants, in Banda Oriental, to the eastward of the river Uruguay: yet in that province

* The bizcacha (*Calomys bizcacha*) somewhat resembles a large rabbit, but with bigger gnawing teeth and a long tail: it has, however, only three toes behind, like the agouti. During the last three or four years, the skins of these animals have been sent to England for the sake of the fur.

© The Complete Work of Charles Darwin Online

there are plains which appear admirably adapted to its habits. That river has formed an insuperable obstacle to its migration; although the broader barrier of the Parana has been passed, and the bizcacha is common in Entre Rios (the province between the two rivers), directly on the opposite shore of the Uruguay. Near Buenos Ayres these animals are exceedingly common. Their most favourite resort appears to be those parts of the plain, which during one half the year are covered with giant thistles, to the exclusion of other plants. The Gauchos affirm that it lives on roots; which, from the great strength of its gnawing teeth, and the kind of localities frequented by it, seems probable. As in the case of the rabbit, a few holes are commonly placed together. In the evening the bizcachas come out in numbers, and there quietly sit on their haunches. They are at such times very tame, and a man on horseback passing by, seems only to present an object for their grave contemplation. They do not wander far from their burrows. They run very awkwardly, and, when hurrying out of danger, from their elevated tails and short front legs much resemble great rats. Their flesh, when cooked, is very white and good, but it is seldom used.

The bizcacha has one very singular habit; namely, dragging every hard object to the mouth of its burrow. Around each group of holes many bones of cattle, stones, thistle-stalks, hard lumps of earth, dry dung, &c., are collected into a scattered heap, which frequently amounts to as much as a wheelbarrow would contain. I was credibly informed that a gentleman, when riding on a dark night, dropped his watch; he returned in the morning, and by searching the neighbourhood of every bizcacha hole on the line of road, as he expected, soon found it. This habit of picking up whatever may be lying on the ground any where near its habitation, must cost much trouble. For what purpose it is done I am quite unable to form even the most remote conjecture: it cannot be for defence, because the rubbish is chiefly placed above the mouth of the burrow, which enters the ground at a very small inclination. No doubt there must exist some good

© The Complete Work of Charles Darwin Online

reason; but the inhabitants of the country are quite ignorant respecting it.

The little owl (*Noctua cunicularia*), which has been so often mentioned, on the plains of Buenos Ayres exclusively inhabits the holes of the bizcacha; but in Banda Oriental it is its own workman. During the open day, but more especially in the evening, these birds may be seen in every direction standing frequently by pairs on the hillock near their burrows. If disturbed they either enter the hole, or, uttering a shrill harsh cry, move with a remarkably undulatory flight to a short distance, and then turning round, steadily gaze at their pursuer. Occasionally in the evening they may be heard hooting. I found in the stomachs of two which I opened the remains of mice, and I one day saw a small snake killed and carried away. It is said these latter animals are their common prey during the daytime. I may here mention, as showing on what various kinds of food owls subsist, that a species that was killed among the islets of the Chonos Archipelago, had its stomach full of good-sized crabs.

In the evening we crossed the Rio Arrecife, on a simple raft made of barrels lashed together, and slept at the post-house on the other side. I this day paid horse hire for thirty-one leagues; and although the sun was glaring hot I was but very little fatigued. When Captain Head talks of riding fifty leagues a day, I do not imagine the distance is equal to 150 English miles. At all events the thirty-one leagues was only 76 miles in a straight line, and in an open country I should think four additional miles for turnings would be a sufficient allowance.

29TH AND 30TH.—We continued to ride over plains of the same character. At San Nicholas I first saw the noble river of the Parana. At the foot of the cliff on which the town stands, some large vessels were at anchor. Before arriving at Rozario, we crossed the Saladillo, a stream of fine clear running water, but too saline to drink. Rozario is a large town built on a dead level plain, which forms

© The Complete Work of Charles Darwin Online

a cliff about sixty feet high over the Parana. The river here is very broad, with many islands, which are low and wooded, as is also the coast of the opposite shore. The view would resemble that of a great lake, if it were not for the linear-shaped islets, which alone give the idea of running water. The cliffs are the most picturesque part; sometimes they are absolutely perpendicular, and of a red colour; at other times in large broken masses, covered with cacti and mimosa-trees. The real grandeur, however, of an immense river like this, is derived from reflecting how important a means of communication and commerce, it forms between one nation and another; to what a distance it travels; and from how vast a territory it drains the great body of fresh water which flows past your feet.

For many leagues north and south of San Nicholas and Rozario, the country is really level. Scarcely any thing which travellers have written about its extreme flatness, can be considered as exaggeration. Yet I could never find a spot, where, by slowly turning round, objects were not seen at greater distances in some directions than in others; and this manifestly proves inequality in the plain. At sea, a person's eye being six feet above the surface of the water, his horizon is two miles and four-fifths distant. In like manner, the more level the plain, the more nearly does the horizon approach within these narrow limits: and this, in my opinion, entirely destroys that grandeur, which one would have imagined that a vast level plain would have possessed.

October 1st.—We started by moonlight and arrived at the Rio Tercero by sunrise. This river is also called the Saladillo, and it deserves the name, for the water is brackish.

I staid here the greater part of the day, searching for fossil bones. Falconer mentions having seen, in the bed of this river, great bones, and the case of a giant armadillo. By good fortune, I discovered a tooth embedded in a layer of rock marl, which was afterwards found exactly to fit the socket in the head of a strange animal, the Toxodon, which

© The Complete Work of Charles Darwin Online

will presently be mentioned. Hearing also of the remains of one of the old giants, which a man told me he had seen on the banks of the Parana, I procured a canoe, and proceeded to the place. Two groups of immense bones projected in bold relief from the perpendicular cliff. They were, however, so completely decayed, that I could only bring away small fragments of one of the great molar-teeth; but these were sufficient to show that the remains belonged to a species of Mastodon. The men who took me in the canoe, said they had long known of them, and had often wondered how they had got there: the necessity of a theory being felt, they came to the conclusion, that, like the bizcacha, the mastodon formerly was a burrowing animal! In the evening we rode another stage, and crossed the Monge, another brackish stream, bearing the dregs of the washings of the Pampas.

October 2d. — We passed through Corunda, which, from the luxuriance of its gardens, was one of the prettiest villages I saw. From this point to St. Fe the road is not very safe. The western side of the Parana further northward, ceases to be inhabited; and hence the Indians sometimes come down, and waylay travellers. The nature of the country also favours this, for instead of a grassy plain, there is an open woodland, composed of low prickly mimosas. We passed some houses that had been ransacked and since deserted; we saw also a spectacle, which my guides viewed with high satisfaction; it was the skeleton of an Indian with the dried skin hanging on the bones, suspended to the branch of a tree.

In the morning we arrived at St. Fe. I was surprised to observe how great a change of climate a difference of only three degrees of latitude between this place and Buenos Ayres had caused. This was evident from the dress and complexion of the men—from the increased size of the ombu-trees—the number of new cacti and other plants—and especially from the birds. In the course of an hour I remarked

© The Complete Work of Charles Darwin Online

half-a-dozen of the latter, which I had never seen at Buenos Ayres. Considering that there is no natural boundary between the two places, and that the character of the country is nearly similar, the difference was much greater than I should have expected.

October 3d and 4th.—I was confined to my bed by a headach for these two days. A goodnatured old woman, who attended me, wished me to try many odd remedies. A common practice is, to bind an orange-leaf, or a bit of black plaster, to each temple; and a still more general plan is, to split a bean into halves, moisten them, and place one on each temple, where they will easily adhere. It is not thought proper ever to remove the beans or plaster, but to allow them to drop off; and sometimes, if a man, with patches on his head, is asked, what is the matter? he will answer, "I had a headache the day before yesterday."

St. Fe is a quiet little town, and is kept clean, and in good order. The governor, Lopez, was a common soldier at the time of the revolution; but has now been seventeen years in power. This stability of government is owing to his tyrannical habits; for tyranny seems as yet better adapted to these countries, than republicanism. The governor's favourite occupation is hunting Indians: a short time since he slaughtered forty-eight, and sold the children at the rate of three or four pounds apiece.

October 5th.—We crossed the Parana to St. Fe Bajada, a town on the opposite shore. The passage took some hours, as the river here consisted of a labyrinth of small streams, separated by low wooded islands. I had a letter of introduction to an old Catalonian Spaniard, who treated me with the most uncommon hospitality. The Bajada is the capital of Entre Rios. In 1825 the town contained 6000 inhabitants, and the province 30,000; yet, few as they are, none have suffered more from bloody and desperate revolutions. They boast here of representatives, ministers, a standing army, and governors: so it is no wonder that they have

© The Complete Work of Charles Darwin Online

their revolutions. At some future day this must be one of the richest countries of La Plata. The soil is varied and productive, and its almost insular form gives it two grand lines of communication by the rivers Parana and Uruguay.

I was delayed here five days, and employed myself in examining the geology of the surrounding country, which was very interesting. We here see beds of sand, clay, and limestone, containing sea-shells and sharks' teeth, passing above into an indurated marl, and from that into the red clayey earth of the Pampas, with its calcareous concretions and the bones of terrestrial animals. This vertical section clearly tells us, of a large bay of pure salt-water, gradually encroached on, and at last becoming the bed of a muddy estuary, into which floating carcasses were swept. I found near the Bajada a large piece, nearly four feet across, of the giant armadillo-like case; also a molar tooth of a mastodon, and fragments of very many bones, the greater number of which were rotten, and as soft as clay.

A tooth which I discovered by one point projecting from the side of a bank, interested me much, for I at once perceived that it had belonged to a horse. Feeling much surprise at this, I carefully examined its geological position, and was compelled to come to the conclusion,* that a horse, which cannot from a comparison of the tooth alone, be distinguished from the existing species,† lived as a contemporary with the various great monsters that formerly inhabited South America. Mr. Owen and myself, at the College of Surgeons, compared this tooth with a fragment of another, probably belonging to the Toxodon, which was embedded at the dis-

* The broken tooth mentioned at Bahia Blanca must not be forgotten.

† As this horse existed at the same time with animals now extinct, it is not probable, that it is the same species with the recent kind, although from the similarity of the teeth it must have been closely allied. Cuvier, talking of the remains of the horse, found fossil under similar conditions in Europe, remarks, " It is not possible to say whether it was one of the species now existing or not, because the skeletons of these species are so like each other, that they cannot be distinguished by the mere comparison of isolated fragments."—*Theory of the Earth*, English translation, p. 285.

© The Complete Work of Charles Darwin Online

tance only of a few yards in the same earthy mass. No sensible difference in their state of decay could be perceived; they were both tender, and partially stained red. If the horse did not coexist with the Toxodon, the tooth must by some accident, not very easily understood, have been embedded within the last three centuries (the period of the introduction of the horse), with the remains of those animals, which ages since perished, when the Pampas was covered by the waters of the sea. Now, I may ask, will any one credit that two teeth of nearly equal size, buried in the same substance close together, after a period of so vast an inequality, could exist in the same condition of decay? We must conclude otherwise. Certainly it is a marvellous event in the history of animals, that a native kind should have disappeared* to be succeeded in after ages by the countless herds introduced with the Spanish colonist! But our surprise should be modified when it is already known, that the remains of the *Mastodon angustidens* (the tooth formerly alluded to as embedded near that of the horse, probably belonged to this species) have been found both in South America, and in the southern parts of Europe.

With regard to North America, Cuvier says† the *Elephas primigenius* "has left thousands of its carcasses from Spain to the shores of Siberia, and it has been found in the whole of North America." The fossil ox, in a like manner, he writes,‡ is buried "dans toute la partie boréale des deux continens, puisque on en a d'Allemagne, d'Italie, de Prussie, de la Sibérie occidentale et orientale, et de l'Amérique." I may here add that horses' bones, mingled with those of the mastodon, have several times been transmitted for sale from North America to England; but it has always been imagined, from the simple fact of their being horses' bones, that they had been accidentally mingled with the fossils. Among the

* I need not here state, that there is no kind of evidence to support the belief, that a horse existed in America previously to the age of Columbus.

† Theory of the Earth, p. 281 (English translation).

‡ Ossemens Fossiles, vol. iv., p. 147.

© The Complete Work of Charles Darwin Online

remains brought home by Captain Beechey from the west coast of the same continent, in the frozen region of 66° north, Dr. Buckland* has described the astragalus metacarpus, and metatarsus of the horse, which were associated with the remains of the *Elephas primigenius*, and of the fossil ox. Thus we have an elephant, an ox, and a horse (the species of the latter is only presumed to be identical), common to Europe and to North America.

Very few species of living quadrupeds,† which are altogether terrestrial in their habits, are common to the two continents, and these few are chiefly confined to the extreme frozen regions of the north. The separation, therefore, of the Asiatic and American zoological provinces appears formerly to have been less perfect than at present. The remains of the elephant and of the ox have been found on the banks of the Anadir (long. 175° E.), on the extreme part of Siberia, nearest the American coast: and the former remains, according to Chamisso, are common in the peninsula of Kamtschatka. On the opposite shores, likewise, of the narrow strait which divides these two great continents, we know, from the discoveries of Kotzebue and Beechey, that the remains of both animals occur abundantly: and as Dr. Buckland has shown they are associated with the bones of the horse, the teeth of which animal in Europe, according to Cuvier, accompany by thousands the remains of the pachydermata of the later periods. With these facts, we may safely look at this quarter, as the line of communication (now interrupted by the steady progress of geological change) by which the elephant, the ox, and the horse, entered America, and peopled its wide extent.‡

* See the admirable Appendix to Beechey's Voyage, p. 592 (quarto edition).

† See Dr. Richardson's very interesting Report on North American Zoology for the British Association of 1836.

‡ I do not here mean to fix on the more northern parts of the old world as the parent country of these two animals. I only want to point out the channel of communication—not the course of the stream—

© The Complete Work of Charles Darwin Online

The occurrence of the fossil horse and of *Mastodon angustidens* in South America, is a much more remarkable circumstance than that of the animals mentioned above in the northern half of the continent; for if we divide America, not by the Isthmus of Panama, but by the southern part of Mexico,* in lat. 20°, where the great table-land presents an obstacle to the migration of species, by affecting the climate, and by forming, with the exception of some valleys and of a fringe of low land on the coast, a broad barrier; we shall then have two zoological provinces strongly contrasted with each other. Some few species alone have passed the barrier, and may be considered as wanderers, such as the puma, opossum, kinkajou, and peccari. The mammalogy of South America is characterized by possessing several species of the genera of llama, cavy (and the allied animals), tapir, peccari, opossum, anteater, sloth, and armadillo. If North America had possessed species of these genera proper to it, the distinction of the two provinces could not have been drawn; but the presence of a few wanderers scarcely affects the case. North America, on the other hand, is characterized by its numerous rodents,† and by four genera of solid horned ruminants,‡ of which section the southern half does not possess a single species.

whether from west to east, or the reverse. Perhaps, when we recollect how extraordinarily the Pachydermata abounded during the Tertiary epochs in the Old World, and that the representatives of these animals now only exist in that quarter, it may seem most probable that the migration took place from Asia to America.

* This is the division followed by Lichtenstein, Swainson, and Richardson. The section from Vera Cruz to Acapulco, given by Humboldt in the Atlas to Polit. Essay on Kingdom of N. Spain, will show how immense a barrier the Mexican table-land forms.

† Dr. Richardson (Report to Brit. Assoc., p. 157), talking of the identification of a Mexican animal with the *Synetheres prehensilis*, says, "We do not know with what propriety, but, if correct, it is, if not a solitary instance, at least very nearly so, of a rodent animal being common to North and South America."

‡ *Dicranocerus furcifer, Capra Americana, Ovis montana, Bos Americana,* and *Moschatus*.—Report to Brit. Assoc., p. 159.

© The Complete Work of Charles Darwin Online

This distinction of the two zoological provinces does not appear always to have existed. At the present day the order of Edentata is much more strongly developed in South America, than in any other part of the world: and concluding from the fossil remains, which were discovered at Bahia Blanca, such must have been the case during a former epoch. In America, north of Mexico, not one of this order is now found: yet, as is well known, the gigantic megalonyx, considered by Cuvier as a species of Megatherium, has been found only in that country; and as it appears from recent observations,* the Megatherium Cuvierii itself likewise occurs there. Mr. Owen showed me the tibia of some large animal, which Sir Philip Egerton had purchased out of a collection of the remains of the mastodon brought from North America. Mr. Owen says it certainly belongs to one of the Edentata, and it so closely resembles a bone which I found embedded, together with fragments of the great armadillo-like covering, in Banda Oriental, that it probably forms a species of the same genus. Lastly, among the fossils brought home by Captain Beechey from the N.W. coast, there was a cervical vertebra, which, when compared by Mr. Pentland† with the skeletons at Paris, was found to resemble that of the sloth and anteater more than that of any other animal, although having some points of essential difference.

Of the Pachydermata four or five species are now found in America; but, as in the case of the Edentata, none are peculiar to the continent north of Mexico; and one alone seems to exist there as a wanderer. Yet the account of the multitude of bones of the mastodon and elephant, which have been discovered in the salt-licks of North America, is familiar to every one. The remains of the *Mastodon giganteum* have been found nowhere else; but those of the *Elephas primigenius* are common to a large part of the

* Ed. New Phil. Journal. July, 1828, p. 327. From a paper by Mr. Cooper in the Lyceum of Natural History of New York.

† See Dr. Buckland. Appendix to Beechey's Voyage, p. 597.

© The Complete Work of Charles Darwin Online

terrestrial globe.* This elephant must have existed in Mexico; and Cuvier,† judging from a fragment of a tusk, thinks it even extended to the neighbourhood of Quito in South America. In the latter country three species of Mastodon have been discovered. One of these, *M. angustidens*, is common to Europe. It is singular that its remains, as yet, have never been brought from North America; nevertheless, considering that it was a contemporary of the extinct animals above mentioned, it seems highly probable that it arrived by the same line of communication on the N.W. coast. As its remains have frequently been found at a great elevation in the Cordillera, perhaps its habits led it to follow that chain of mountains from north to south.

After these facts, it is only in conformity with what we might almost have expected, that the horse, belonging to the same order of Pachydermata, should formerly have inhabited both North and South America. It is interesting thus to discover an epoch anterior to the division, as far at least as two important orders among the mammalia are concerned, of the continent into two separate zoological provinces. The geologist who believes in considerable oscillations of level in the crust of the globe within recent periods, will not fear to speculate either on the elevation of the Mexican platform, as a cause of the distinction, or on the submergence of land in the West Indian seas,—a circumstance which is perhaps indicated by the zoology of those islands.‡

* I may observe that at the present day both species of elephants have wide ranges. The African one is found from the Senegal to the Cape of Good Hope, a distance of about 3000 miles. The Asiatic kind formerly had an equal range, namely, from the banks of the Indus to the East Indian Isles. The hippopotamus is believed to have reached from the Cape to Egypt.

† Ossemens Fossiles, vol. i., p. 158. Cuvier says he cannot decide positively, not having seen a molar tooth.

‡ Dr. Richardson (Report for 1836, to Brit. Assoc., p. 157) says, "the spotted cavy (*cælogenys*), and perhaps a species of *cavia*, and one *dasyprocta*, extend from South America to the West Indies and Mexico." Cuvier says the Kinkajou is found in the larger Antilles, but others

© The Complete Work of Charles Darwin Online

The number of bones embedded in the grand estuary deposit of the Pampas must he very great; I myself heard of, and saw many groups. The names of such places as "the stream of the animal," "the hill of the giant," tell the same story. At other times I heard of the marvellous property of certain rivers, which had the power of changing small bones into large; or as some maintained, the bones themselves grew. As far as I am aware, not one of these animals, as was formerly supposed, perished in the marshes, or muddy river-beds of the present land, but their bones have been exposed by the streams intersecting the deposit in which their remains were formerly buried. We may therefore conclude that the whole area of the Pampas is one wide sepulchre for these extinct quadrupeds.

While travelling through the country, I received several vivid descriptions of the effect of a great drought; and the account of this may throw some light on the cases, where vast numbers of animals of all kinds, have been embedded together. The period included between the years 1827 and 1830 is called the "gran seco" or the great drought. During this time, so little rain fell, that the vegetation, even to the thistles, failed; the brooks were dried up, and the whole country assumed the appearance of a dusty high-road. This was especially the case in the northern part of the province of Buenos Ayres, and the southern part of St. Fe. Very great numbers of birds, wild animals, cattle, and horses, perished from the want of food and water. A man told me, that the deer* used to come into his courtyard to the well,

affirm that this is an error: according to M. Gervais, the *Didelphis crancrivora* inhabits the Antilles. A tooth of the Mastodon has been brought from Bahama (Ed. New Phil. Journal, July, 1826, p. 395). We cannot, however, from this conclude, that the Mastodon formerly inhabited those islands, for the carcass might have been floated there. Some mammalia certainly are peculiar to the Archipelago.

* In Capt. Owen's Surveying Voyage (vol. ii., p. 274) there is a curious account of the effects of a drought on the elephants, at Benguela (west coast of Africa). "A number of these animals had sometime since entered the

© The Complete Work of Charles Darwin Online

which he had been obliged to dig to supply his own family with water; and that the partridges had hardly strength to fly away when pursued. The lowest estimation of the loss of cattle in the province of Buenos Ayres alone, was taken at one million head. A proprietor at San Pedro had previously to these years 20,000 cattle; at the end not one remained. San Pedro is situated in the middle of the finest country; and even now again abounds with animals; yet, during the latter part of the "gran seco," live cattle were brought in vessels for the consumption of the inhabitants. The animals roamed from their estancias, and wandering far to the southward, were mingled together in such multitudes, that a government commission was sent from Buenos Ayres to settle the disputes of the owners. Sir Woodbine Parish informed me of another and very curious source of dispute; the ground being so long dry, such quantities of dust were blown about, that in this open country the landmarks became obliterated, and people could not tell the limits of their estates.

I was informed by an eyewitness, that the cattle in herds of thousands rushed into the Parana,* and being exhausted by hunger they were unable to crawl up the muddy banks, and thus were drowned. The arm which runs by San Pedro was so full of putrid carcasses, that the master of a vessel told me, that the smell rendered it quite impossible to pass that way. Without doubt several hundred thousand animals thus perished in the river. Their bodies when putrid floated down the stream, and many in all probability were deposited

town, in a body, to possess themselves of the wells, not being able to procure any water in the country. The inhabitants mustered, when a desperate conflict ensued, which terminated in the ultimate discomfiture of the invaders, but not until they had killed one man, and wounded several others." The town is said to have a population of nearly three thousand!

* Azara talks of the fury of the wild horses rushing into the marshes during a dry season: "et les premiers arrivés sont foulés, et écrasés par ceux, qui les suivent. Il m'est arrivé plus d'une fois de trouver plus de mille cadavres de chevaux sauvages morts de cette façon."—Vol. i., p. 374.

© The Complete Work of Charles Darwin Online

in the estuary of the Plata. All the small rivers became highly saline, and this caused the death of vast numbers in particular spots; for when an animal drinks of such water it does not recover. I noticed, but probably it was the effect of a gradual increase, rather than of any one period, that the smaller streams in the Pampas were paved with a breccia of bones.* Subsequently to this unusual drought a very rainy season commenced, which caused great floods. Hence it is almost certain, that some thousands of these skeletons were buried by the deposits of the very next year. What would be the opinion of a geologist, viewing such an enormous collection of bones, of all kinds of animals and of all ages, thus embedded in one thick earthy mass? Would he not attribute it to a flood having swept over the surface of the land, rather than to the common order of things?

These droughts to a certain degree seem to be periodical; I was told the dates of several others, and the intervals were about fifteen years. A tendency to periodical droughts is, I believe, common in most dry climates :† such certainly is the case in Australia. Captain Sturt says they return after every ten and twelve years, and are then followed by excessive rains, which gradually become less and less, till another drought is the consequence. The year 1826 and the two following were singularly dry in Australia, and the latter were the first of the "gran seco." I mention this, because

* In the neighbourhood of the great towns on the shores of the Plata, the number of bones strewed over the ground is truly astonishing. Since our return I have been informed, that ships have been freighted to this country with a cargo of bones. That cattle should be fattened on turnips manured with the bones of animals that lived in the southern hemisphere, is a curious fact in the commerce of the world In the East Indies the luxurious drink wine cooled with North-American ice, which in its journey has twice crossed the equator!

† Perhaps in every country, but the effect is more marked where the mean annual quantity of rain is small. I have seen the trunk of an old tree in England, in which the successive rings showed a tendency to periodical increase and diminution of size; about every tenth ring being small. See Mr. Babbage's Ninth Bridgewater Treatise. Note M.

© The Complete Work of Charles Darwin Online

General Beatson in his account of the island of St. Helena, has remarked that variations in climate sometimes appear to be the effect of the operation of some very general cause. He says (page 43), "The severe drought felt here in 1791 and 1792, was far more calamitous in India. Doctor Anderson states, in a letter to Colonel Kyd, dated the 9th of August, 1792, that, owing to a failure of rain, during the above two years, one half of the inhabitants in the northern provinces had perished by famine; and the remainder were so feeble and weak, that on the report of rice coming from the Malabar coast, 5000 poor people left Rajamundy, and very few of them reached the sea-side, although the distance is only 50 miles. It appears by Mr. Bryan Edwards's History of the West Indies, that the seasons 1791-2 were unusually dry at the island of Montserrat." Barrow* in the latter part of 1792, when at the Cape de Verd islands says, "In fact a drought of three years' continuance, and consequent famine for almost the same period, had nearly desolated the island."

October 12th.—I had intended to have pushed my excursion further, but not being quite well, I was compelled to return by a balandra, or one-masted vessel of about a hundred tons burden, which was bound to Buenos Ayres. As the weather was not fair, we moored early in the day to a branch of a tree on one of the islands. The Parana is full of islands, which undergo a constant round of decay and renovation. In the memory of the master several large ones had disappeared, and others again had been formed and protected by vegetation. They are composed of muddy sand, without even the smallest pebble, and were then about four feet above the level of the river; but during the periodical floods they are inundated. They all present one character; numerous willows and a few other trees are bound together by a great variety of creeping plants, thus forming a thick jungle. These thickets afford a retreat for carpinchos and jaguars.

* Voyage to Cochin China, p. 67.

© The Complete Work of Charles Darwin Online

The fear of the latter animal, quite destroyed all pleasure in scrambling through the woods. This evening I had not proceeded a hundred yards, before finding indubitable signs of the recent presence of the tiger, I was obliged to come back. On every island there are tracks; and as on the former excursion "el rastro de los Indios" had been the subject of conversation, so in this was "el rastro del tigre."

The wooded banks of the great rivers appear to be the favourite haunt of the jaguar; but south of the Plata, I was told, they frequented the reeds bordering lakes: wherever they are, they seem to require water. The jaguar has been killed on the banks of the Rio Negro, in lat. 41°; and Falconer states that the lake Nahuel-huapi, takes its name from the Indian word for tiger: the latitude of this lake is about 42°; which corresponds to the situation of the Pyrenees in the northern hemisphere. These animals are particularly abundant on the isles of the Parana; their common prey is the carpincho, so that it is generally said, where the carpinchos are plentiful there is little danger of the jaguar. Falconer states, that near the mouth of the Plata, on the southern side, the jaguars are numerous, and that they chiefly live on fish; this account I have heard repeated. On the Parana they have killed many wood-cutters, and have even entered vessels at night. There is a man now living in the Bajada, who, coming up from below when it was dark, was seized on the deck; he escaped, however, with the loss of the use of one arm. When the floods drive these animals from the islands they are most dangerous. I was told, that a few years since, a very large one found its way into a church at St. Fe: two padres entering one after the other were killed, and a third, who came to see what was the matter, escaped with difficulty. The beast was destroyed by being shot from a corner of the building which was unroofed. They commit also at these times great ravages among the cattle and horses. It is said they kill their prey by breaking the vertebræ of the neck. If driven from the carcass they seldom return to it. The Gauchos say that the jaguar, when

© The Complete Work of Charles Darwin Online

wandering about at night, is much tormented by the foxes yelping as they follow him. This is a curious coincidence with the fact which is generally affirmed of the jackals accompanying, in a similarly officious manner, the East Indian tiger. The jaguar is a noisy animal, roaring much by night, and especially before bad weather.

One day, when hunting on the banks of the Uruguay, I was shown certain trees, to which these animals are said constantly to recur, for the purpose of sharpening their claws. I saw three well-known trees; in front the bark was worn smooth, and on each side there were deep scratches, or rather grooves, extending in an oblique line, nearly a yard in length. The scars were of different ages. A common method of ascertaining whether a jaguar is in the neighbourhood, is to examine these trees. I imagine this habit of the jaguar is exactly similar to one, which may any day be seen in the common cat, as with outstretched legs and exserted claws it scrapes the leg of a chair. Some such habit must be also common to the puma, for on the bare hard soil of Patagonia I have frequently seen scores so deep, that no other animal could have made them. The object of this practice is, I should think, to blunt rather than to sharpen (as the Gauchos say), the points of their claws, which are so seldom used. The jaguar is killed, without much difficulty, by the aid of dogs baying and driving him up a tree, where he is despatched with bullets.
