PROCEEDINGS

OF

THE FIRST EXPEDITION,

1826—1830,

UNDER THE COMMAND OF

CAPTAIN P. PARKER KING,

R.N., F.R.S.

© The Complete Work of Charles Darwin Online

© The Complete Work of Charles Darwin Online

TO

THE RIGHT HONOURABLE

THE EARL OF MINTO, G.C.B.,

FIRST LORD COMMISSIONER

OF THE

ADMIRALTY.

MY LORD:

I have the honour of dedicating to your lordship, as Head of the Naval Service, this narrative of the Surveying Voyages of the Adventure and Beagle, between the years 1826 and 1836.

Originated by the Board of Admiralty, over which Viscount Melville presided, these voyages have been carried on, since 1830, under his lordship's successors in office.

Captain King has authorized me to lay the results of the Expedition which he commanded, from 1826 to 1830, before your lordship, united to those of the Beagle's subsequent voyages.

I have the honour to be,

MY LORD,

Your lordship's obedient servant,

ROBERT FITZ-ROY.

PREFACE.

In this Work, the result of nine years' voyaging, partly on coasts little known, an attempt has been made to combine giving general information with the paramount object—that of fulfilling a duty to the Admiralty, for the benefit of Seamen.

Details, purely technical, have been avoided in the narrative more than I could have wished; but some are added in the Appendix to each volume: and in a nautical memoir, drawn up for the Admiralty, those which are here omitted will be found.

There are a few words used frequently in the following pages, which may not at first sight be familiar to every reader, therefore I need hardly apologize for saying that, although the great Portuguese navigator's name was Magalhaens—it is generally pronounced as if written Magellan:—that the natives of Tierra del Fuego are commonly called Fuegians;—and that Chiloé is thus accented for reasons given in page 384 of the second volume.

In the absence of Captain King, who has entrusted to me the care of publishing his share of this work, I may have overlooked errors which he would have detected. Being hurried, and unwell, while attending to the printing of his volume, I was not able to do it justice.

© The Complete Work of Charles Darwin Online

It may be a subject of regret, that no paper on the Botany of Tierra del Fuego is appended to the first volume. Captain King took great pains in forming and preserving a botanical collection, aided by a person embarked solely for that purpose. He placed this collection in the British Museum, and was led to expect that a first-rate botanist would have examined and described it; but he has been disappointed.

In conclusion, I beg to remind the reader, that the work is unavoidably of a rambling and very mixed character; that some parts may be wholly uninteresting to most readers, though, perhaps, not devoid of interest to all; and that its publication arises solely from a sense of duty.

ROBERT FITZ-ROY.

London, March 1839.

INTRODUCTION.

In 1825, the Lords Commissioners of the Admiralty directed two ships to be prepared for a Survey of the Southern Coasts of South America; and in May, of the following year, the Adventure and the Beagle were lying in Plymouth Sound, ready to carry the orders of their Lordships into execution.

These vessels were well provided with every necessary, and every comfort, which the liberality and kindness of the Admiralty, Navy Board, and officers of the Dock-yards, could cause to be furnished.

On board the Adventure, a roomy ship, of 330 tons burthen, without guns,* lightly though strongly rigged, and very strongly built, were—

Phillip Parker King, Commander and Surveyor, Senior Officer of the Expedition.

J. Cooke ..... Lieutenant.
B. Ainsworth ..... Master.
J. Tarn ..... Surgeon.

* Excepting one for signals.

© The Complete Work of Charles Darwin Online

G. Rowlett ..... Purser.
R. H. Sholl..... Mate.
J. C. Wickham..... Mate.
J. F. Brand ..... Mate.
T. Graves..... Mate and Assistant Surveyor.
G. Harrison ..... Mate.
E. Williams..... Second Master.
J. Park ..... Assistant Surgeon.
W. W. Wilson ..... Midshipman.
A. Millar..... Master's Assistant.
A. Mellersh ..... Volunteer 1st Class.
J. Russell ..... Volunteer 2d Class.
G. Hodgskin ..... Clerk.
J. Anderson ..... Botanical Collector.

Gunner——Boatswain——and Carpenter.

Serjeant and fourteen Marines; and about forty Seamen and Boys.

In the Beagle, a well-built little vessel, of 235 tons, rigged as a barque, and carrying six guns, were—

Pringle Stokes ..... Commander and Surveyor.
E. Hawes ..... Lieutenant.
W. G. Skyring ..... Lieut. and Assist. Surveyor.
S. S. Flinn ..... Master.
E. Bowen ..... Surgeon.
J. Atrill ..... Purser.
J. Kirke ..... Mate.
B. Bynoe ..... Assistant Surgeon.
J. L. Stokes ..... Midshipman.
R. F. Lunie ..... Volunteer 1st Class.
W. Jones ..... Volunteer 2d Class.
J. Macdouall ..... Clerk.

Carpenter.

Serjeant and nine Marines; and about forty Seamen and Boys.

© The Complete Work of Charles Darwin Online

In the course of the voyage, several changes occurred among the officers, which it may be well to mention here.

In September, 1826, Lieutenant Hawes invalided: and was succeeded by Mr. R. H. Sholl, the senior mate in the Expedition.

In February, 1827, Mr. Ainsworth was unfortunately drowned; and, in his place, Mr. Williams acted, until superseded by Mr. S. S. Flinn, of the Beagle.

Lieutenant Cooke invalided in June, 1827; and was succeeded by Mr. J. C. Wickham.

In the same month Mr. Graves received information of his promotion to the rank of Lieutenant.

Between May and December, 1827, Mr. Bowen and Mr. Atrill invalided; besides Messrs. Lunie, Jones, and Macdouall: Mr. W. Mogg joined the Beagle, as acting Purser; and Mr. D. Braily, as volunteer of the second class.

Mr. Bynoe acted as Surgeon of the Beagle, after Mr. Bowen left, until December, 1828.

In August, 1828, Captain Stokes's lamented vacancy was temporarily filled by Lieutenant Skyring; whose place was taken by Mr. Brand.

Mr. Flinn was then removed to the Adventure; and Mr. A. Millar put into his place.

© The Complete Work of Charles Darwin Online

In December, 1828, the Commander-in-chief of the Station (Sir Robert Waller Otway) superseded the temporary arrangements of Captain King, and appointed a commander, lieutenant, master, and surgeon to the Beagle. Mr. Brand then invalided, and the lists of officers stood thus—

Adventure (1828-30).

PHILLIP PARKER KING, Commander and Surveyor, Senior Officer of the Expedition.

T. GRAVES..... Lieut. and Assist. Surveyor.
J. C. WICKHAM ..... Lieutenant.
S. S. FLINN ..... Master.
J. TARN ..... Surgeon.
G. ROWLETT ..... Purser.
G. HARRISON ..... Mate.
W. W. WILSON..... Mate.
E. WILLIAMS..... Second Master.
J. PARK ..... Assistant Surgeon.
A. MELLERSH ..... Midshipman.
A. MILLAR .... Master's Assistant.
J. RUSSELL ..... Volunteer 2d Class.
G. HODGSKIN ..... Clerk.
J. ANDERSON ..... Botanical Collector.

Gunner——Boatswain——and Carpenter.

Serjeant and fourteen Marines: and about fifty* Seamen and Boys.

Beagle (1828-30).

ROBERT FITZ-ROY ... Commander and Surveyor.
W. G. SKYRING ..... Lieut. and Assist. Surveyor.
J. KEMPE ..... Lieutenant.
M. MURRAY ..... Master.

* Twelve additional seamen having been ordered, by the Admiralty, for the Adelaide schooner.

© The Complete Work of Charles Darwin Online

J. Wilson ..... Surgeon.
W. Mogg ..... (Acting) Purser.
J. Kirke ..... Mate.
B. Bynoe ..... Assistant Surgeon.
J. L. Stokes ..... Midshipman.
J. May ..... Carpenter.
D. Braily ..... Volunteer 2d Class.
J. Megget ..... Clerk.

Serjeant and nine Marines: and about forty Seamen and Boys.

In June, 1829, Lieutenant Mitchell joined the Adventure; and in February, 1830, Mr. A. Millar died very suddenly:—and very much regretted.

The following Instructions were given to the Senior Officer of the Expedition.

"By the Commissioners for executing the Office of Lord High Admiral of the United Kingdom of Great Britain and Ireland, &c.

"Whereas we think fit that an accurate Survey should be made of the Southern Coasts of the Peninsula of South America, from the southern entrance of the River Plata, round to Chilóe; and of Tierra del Fuego; and whereas we have been induced to repose confidence in you, from your conduct of the Surveys in New Holland; we have placed you in the command of His Majesty's Surveying Vessel the Adventure; and we have directed Captain Stokes, of His Majesty's Surveying Vessel the Beagle, to follow your orders.

"Both these vessels are provided with all the

© The Complete Work of Charles Darwin Online

means which are necessary for the complete execution of the object above-mentioned, and for the health and comfort of their Ships' Companies. You are also furnished with all the information, we at present possess, of the ports which you are to survey; and nine Government Chronometers have been embarked in the Adventure, and three in the Beagle, for the better determination of the Longitudes.

"You are therefore hereby required and directed, as soon as both vessels shall be in all respects ready, to put to sea with them; and on your way to your ulterior destination, you are to make, or call at, the following places, successively; namely; Madeira: Teneriffe: the northern point of St. Antonio, and the anchorage at St. Jago; both in the Cape Verd Islands: the Island of Trinidad, in the Southern Atlantic: and Rio de Janeiro: for the purpose of ascertaining the differences of the longitudes of those several places.

"At Rio de Janeiro, you will receive any supplies you may require; and make with the Commander-in-chief, on that Station, such arrangements as may tend to facilitate your receiving further supplies, in the course of your Expedition.

"After which, you are to proceed to the entrance of the River Plata, to ascertain the longitudes of the Cape Santa Maria, and Monte Video: you are then to proceed to survey the Coasts, Islands, and Straits; from Cape St. Antonio, at the south side

© The Complete Work of Charles Darwin Online

of the River Plata, to Chilóe; on the west coast of America; in such manner and order, as the state of the season, the information you may have received, or other circumstances, may induce you to adopt.

"You are to continue on this service until it shall be completed; taking every opportunity to communicate to our Secretary, and the Commander-in-Chief, your proceedings: and also, whenever you may be able to form any judgment of it, where the Commander-in-Chief, or our Secretary, may be able to communicate with you.

"In addition to any arrangements made with the Admiral, for recruiting your stores, and provisions; you are, of course, at liberty to take all other means, which may be within your reach, for that essential purpose.

"You are to avail yourself of every opportunity of collecting and preserving Specimens of such objects of Natural History as may be new, rare, or interesting; and you are to instruct Captain Stokes, and all the other Officers, to use their best diligence in increasing the Collections in each ship: the whole of which must be understood to belong to the Public.

"In the event of any irreparable accident happening to either of the two vessels, you are to cause the officers and crew of the disabled vessel to be

© The Complete Work of Charles Darwin Online

removed into the other, and with her, singly, to proceed in prosecution of the service, or return to England, according as circumstances shall appear to require; understanding that the officers and crews of both vessels are hereby authorized, and required, to continue to perform their duties, according to their respective ranks and stations, on board either vessel to which they may be so removed. Should, unfortunately, your own vessel be the one disabled, you are in that case to take the command of the Beagle: and, in the event of any fatal accident happening to yourself; Captain Stokes is hereby authorized to take the command of the Expedition; either on board the Adventure, or Beagle, as he may prefer; placing the officer of the Expedition who may then be next in seniority to him, in command of the second vessel: also, in the event of your inability, by sickness or otherwise, at any period of this service, to continue to carry the Instructions into execution, you are to transfer them to Captain Stokes, or to the surviving officer then next in command to you, who is hereby required to execute them, in the best manner he can, for the attainment of the object in view.

"When you shall have completed the service, or shall, from any cause, be induced to give it up; you will return to Spithead with all convenient expedition; and report your arrival, and proceedings, to our Secretary, for our information.

© The Complete Work of Charles Darwin Online

"Whilst on the South American Station, you are to consider yourself under the command of the Admiral of that Station; to whom we have expressed our desire that he should not interfere with these orders, except under peculiar necessity.

"Given under our hands the 16th of May 1826.

(Signed) "MELVILLE.
"G. COCKBURN.

"To Phillip P. King, Esq., Commander of His Majesty's Surveying Vessel Adventure, at Plymouth.

"By command of their Lordships.

(Signed) "J. W. CROKER."

On the 22d of May, 1826, the Adventure and Beagle sailed from Plymouth; and, in their way to Rio de Janeiro, called successively at Madeira, Teneriffe, and St. Jago.

Unfavourable weather prevented a boat being sent ashore at the northern part of San Antonio; but observations were made in Terrafal Bay, on the south-west side of the island: and, after crossing the Equator, the Trade-wind hung so much to the southward, that Trinidad could not be approached without a sacrifice of time, which, it was considered, might be prejudicial to more important objects of the Expedition.

Both ships anchored at Rio de Janeiro on the

© The Complete Work of Charles Darwin Online

10th of August, and remained there until the 2d of October, when they sailed to the River Plata.

In Maldonado,* their anchors were dropped on the 13th of the same month; and, till the 12th of November, each vessel was employed on the north side of the river, between Cape St. Mary and Monte Video.

* On the north side of the river Plata.

SURVEYING VOYAGES

OF THE

ADVENTURE AND THE BEAGLE,

1826—1830.

CHAPTER I.

Departure from Monte Video—Port Santa Elena—Geological remarks—Cape Fairweather—Non-existence of Chalk—Natural History—Approach to Cape Virgins, and the Strait of Magalhaens (or Magellan).

We sailed from Monte Video on the 19th of November 1826; and, in company with the Beagle, quitted the river Plata.

According to my Instructions, the Survey was to commence at Cape San Antonio, the southern limit of the entrance of the Plata; but, for the following urgent reasons, I decided to begin with the southern coasts of Patagonia, and Tierra del Fuego, including the Straits of Magalhaens.* In the first place, they presented a field of great interest and novelty; and secondly, the climate of the higher southern latitudes being so severe and tempestuous, it appeared important to encounter its rigours while the ships were in good condition—while the crews were healthy—and while the charms of a new and difficult enterprize had full force.

* Commonly called Magellan. See p. 11.

© The Complete Work of Charles Darwin Online

Our course was therefore southerly, and in latitude 45° south, a few leagues northward of Port Santa Elena, we first saw the coast of Patagonia. I intended to visit that port; and, on the 28th, anchored, and landed there.

Seamen should remember that a knowledge of the tide is of especial consequence in and near Port Santa Elena. During a calm we were carried by it towards reefs which line the shore, and were obliged to anchor until a breeze sprung up.

The coast along which we had passed, from Point Lobos to the north-east point of Port Santa Elena, appeared to be dry and bare of vegetation. There were no trees; the land seemed to be one long extent of undulating plain, beyond which were high, flat-topped hills of a rocky, precipitous character. The shore was fronted by rocky reefs extending two or three miles from high-water mark, which, as the tide fell, were left dry, and in many places were covered with seals.

As soon as we had secured the ships, Captain Stokes accompanied me on shore to select a place for our observations. We found the spot which the Spanish astronomers of Malaspina's Voyage (in 1798) used for their observatory, the most convenient for our purpose. It is near a very steep shingle (stony) beach at the back of a conspicuous red-coloured, rocky projection which terminates a small bay, on the western side, at the head of the port. The remains of a wreck, which proved to be that of an American whaler, the Decatur of New York, were found upon the extremity of the same point; she had been driven on shore from her anchors during a gale.

The sight of the wreck, and the steepness of the shingle beach just described, evidently caused by the frequent action of a heavy sea, did not produce a favourable opinion of the safety of the port: but as it was not the season for easterly gales, to which only the anchorage is exposed, and as appearances indicated a westerly wind, we did not anticipate danger.

While we were returning on board, the wind blew so strongly that we had much difficulty in reaching the ships, and the boats were no sooner hoisted up, and every thing

© The Complete Work of Charles Darwin Online

made snug, than it blew a hard gale from the S.W. The water however, from the wind being off the land, was perfectly smooth, and the ships rode securely through the night: but the following morning the gale increased, and veered to the southward, which threw a heavy sea into the port, placing us, to say the least, in a very uneasy situation. Happily it ceased at sunset. In consequence of the unfavourable state of the weather, no attempt was made to land in order to observe an eclipse of the sun; to make which observation was one reason for visiting this port.

The day after the gale, while I was employed in making some astronomical observations, a party roamed about in quest of game: but with little success, as they killed only a few wild ducks. The fire which they made for cooking communicated to the dry stubbly grass, and in a few minutes the whole country was in a blaze. The flames continued to spread during our stay, and, in a few days, more than fifteen miles along the coast, and seven or eight miles into the interior were overrun by the fire. The smoke very much impeded our observations, for at times it quite obscured the sun.

The geological structure of this part of the country, and a considerable portion of the coast to the north and south, consists of a fine-grained porphyritic clay slate. The summits of the hills near the coast are generally of a rounded form, and are paved, as it were, with small, rounded, siliceous pebbles, imbedded in the soil, and in no instance lying loose or in heaps; but those of the interior are flat-topped, and uniform in height, for many miles in extent. The valleys and lower elevations, notwithstanding the poverty and parched state of the soil, were partially covered with grass and shrubby plants, which afford sustenance to numerous herds of guanacoes. Many of these animals were observed feeding near the beach when we were working into the bay, but they took the alarm, so that upon landing we only saw them at a considerable distance. In none of our excursions could we find any water that had not a brackish taste. Several wells have been dug in the valleys, both near the sea and at a considerable distance from it, by the

© The Complete Work of Charles Darwin Online

crews of sealing vessels; but, except in the rainy season, they all contain saltish water. This observation is applicable to nearly the whole extent of the porphyritic country. Oyster-shells, three or four inches in diameter, were found, scattered over the hills, to the height of three or four hundred feet above the sea. Sir John Narborough, in 1652, found oyster-shells at Port San Julian; but, from a great many which have been lately collected there, we know that they are of a species different from that found at Port Santa Elena. Both are fossils.

No recent specimen of the genus *Ostrea* was found by us on any part of the Patagonian coast. Narborough, in noticing those at Port San Julian, says, " They are the biggest oyster-shells that I ever saw, some six, some seven inches broad, yet not one oyster to be found in the harbour: whence I conclude they were here when the world was formed."

The short period of our visit did not enable us to add much to natural history. Of quadrupeds we saw guanacoes, foxes, cavies, and the armadillo; but no traces of the puma (*Felis concolor*), or South American lion, although it is to be met with in the interior.

I mentioned that a herd of guanacoes was feeding near the shore when we arrived. Every exertion was made to obtain some of the animals; but, either from their shyness, or our ignorance of the mode of entrapping them, we tried in vain, until the arrival of a small sealing-vessel, which had hastened to our assistance, upon seeing the fires we had accidentally made, but which her crew thought were intended for signals of distress. They shot two, and sent some of the meat on board the Adventure. The next day, Mr. Tarn succeeded in shooting one, a female, which, when skinned and cleaned, weighed 168 lbs. Narborough mentions having killed one at Port San Julian, that weighed, " cleaned in his quarters, 268 lbs." The watchful and wary character of this animal is very remarkable. Whenever a herd is feeding, one is posted, like a sentinel, on a height; and, at the approach of danger, gives instant alarm by a loud neigh, when away they all go, at a hand-gallop, to the next eminence, where they quietly resume their feeding,

© The Complete Work of Charles Darwin Online

until again warned of the approach of danger by their vigilant 'look-out.'

Another peculiarity of the guanaco is, the habit of resorting to particular spots for natural purposes. This is mentioned in the 'Dictionnaire d'Histoire Naturelle,' in the 'Encyclopédie Méthodique,' as well as other works.

In one place we found the bones of thirty-one guanacoes collected within a space of thirty yards, perhaps the result of an encampment of Indians, as evident traces of them were observed; among which were a human jaw-bone, and a piece of agate ingeniously chipped into the shape of a spear-head.

The fox, which we did not take, appeared to be small, and similar to a new species afterwards found by us in the Strait of Magalhaens.

The cavia* (or, as it is called by Narborough, Byron, and Wood, the hare, an animal from which it differs both in appearance and habits, as well as flavour), makes a good dish; and so does the armadillo, which our people called the shell-pig.† This little animal is found abundantly about the low land, and lives in burrows underground; several were taken by the seamen, and, when cooked in their shells, were savoury and wholesome.

Teal were abundant upon the marshy grounds. A few partridges, doves, and snipes, a rail, and some hawks were shot. The few sea-birds that were observed consisted of two species of gulls, a grebe and a penguin (*Aptenodytes Magellanica*).

We found two species of snakes and several kinds of lizards. Fish were scarce, as were also insects; of the last, our collec-

* *Dasyprocta patachonica:* it is the *Patagonian cavy* of Dr. Shaw, and Pennant's Quadr., tab. 39, and the *lièvre pampa* of D'Azara. M. Desmarest thinks that if the teeth were examined it would form a new genus, for which he proposes the name of *Dolichotis* (Ency. Meth. Mamm. p. 359). At present he has, from its external character, placed it amongst the genus *Dasyprocta* (agouti). The only one that was taken was not preserved, which prevented me from ascertaining the fact.

† *Dasypus minutus*, Desm. *Tatou pichiy*, or *tatou septième* of D'Azara, &c. &c. It has seven bands.

© The Complete Work of Charles Darwin Online

tions consisted only of a few species of *Coleoptera*, two or three *Lepidoptera*, and two *Hymenoptera*.

Among the sea-shells, the most abundant was the *Patella deaurata*, Lamk.; this, with three other species of Patella, one *Chiton*, three species of *Mytilus*, three of *Murex*, one of *Crepidula*, and a *Venus*, were all that we collected.

About the country, near the sea-shore, there is a small tree, whose stem and roots are highly esteemed for fuel by the crews of sealing-vessels which frequent this coast. They call it 'piccolo.' The leaf was described to me as having a prickle upon it, and the flower as of a yellow colour. A species of berberis also is found, which when ripe may afford a very palatable fruit.

Our short visit gave us no flattering opinion of the fertility of the country near this port. Of the interior we were ignorant; but, from the absence of Indians and the scarcity of fresh water, it is probably very bare of pasturage. Falkner, the Jesuit missionary, says these parts were used by the Tehuelhet tribes for burying-places: we saw, however, no graves, nor any traces of bodies, excepting the jaw-bone abovementioned; but subsequently, at Sea Bear Bay, we found many places on the summits of the hills which had evidently been used for such a purpose, although then containing no remains of bodies. This corresponds with Falkner's account, that after a period of twelve months the sepulchres are formally visited by the tribe, when the bones of their relatives and friends are collected and carried to certain places, where the skeletons are arranged in order, and tricked out with all the finery and ornaments they can collect.

The ships sailed from Port Santa Elena on the 5th December, and proceeded to the southward, coasting the shore as far as Cape Two Bays.

Our object being to proceed with all expedition to the Strait of Magalhaens, the examination of this part of the coast was reserved for a future opportunity. On the 13th, we had reached within fifty miles of Cape Virgins, the headland at the entrance of the strait, but it was directly in the wind's eye

© The Complete Work of Charles Darwin Online

of us. The wind veering to S.S.W., we made about a west course. At day-light the land was in sight, terminating in a point to the S.W., so exactly like the description of Cape Virgins and the view of it in Anson's voyage, that without considering our place on the chart, or calculating the previous twenty-four hours' run, it was taken for the Cape itself, and, no one suspecting a mistake, thought of verifying the ship's position. The point, however, proved to be Cape Fairweather. It was not a little singular, that the same mistake should have been made on board the Beagle, where the error was not discovered for three days.*

From the appearance of the weather I was anxious to approach the land in order to anchor, as there seemed to be every likelihood of a gale; and we were not deceived, for at three o'clock, being within seven miles of the Cape, a strong wind sprung up from the S.W., and the anchor was dropped. Towards evening it blew so hard, that both ships dragged their anchors for a considerable distance.

On the charts of this part of the coast the shore is described to be formed of "chalk hills, like the coast of Kent." To geologists, therefore, especially, as they were not disposed to believe that such was the fact, this was a question of some interest. From our anchorage the appearance of the land favoured our belief of the existence of chalk. The outline was very level and steep; precipitous cliffs of whitish colour, stratified horizontally, with their upper part occasionally worn into hollows, strongly resembled the chalk cliffs of the English coasts.

The gale prevented our landing for three days, when (19th) a few minutes sufficed to discover that the cliffs were composed

* A similar error was made by one of the ships of the fleet under Loyasa in the year 1525. The Nodales also, in their description of the coast, mention the similarity of appearance in the two capes, Virgins and Fairweather. "Y venido de mar en fuera à buscar la tierra facilmente podian hacer de Rio de Gallegos el Cabo de Virgenes," (and in making the land Cape Virgins may easily be mistaken for the river Gallegos). —Viage de los Nodales, p. 53.

© The Complete Work of Charles Darwin Online

of soft clay, varying in colour and consistence, and disposed in strata running horizontally for many miles without interruption, excepting where water-courses had worn them away. Some of the strata were very fine clay, unmixed with any other substance, whilst others were plentifully strewed with round siliceous gravel,* without any vestige of organic remains. The sea beach, from high-water mark to the base of the cliffs, is formed by shingle, with scattered masses of indurated clay of a green colour.† Between the high and low tide marks there is a smooth beach of the same green clay as the masses above-mentioned, which appears to have been hardened by the action of the surf to the consistence of stone. Generally this beach extends for about one hundred yards farther into the sea, and is succeeded by a soft green mud, over which the water gradually deepens. The outer edge of the clay forms a ledge, extending parallel with the coast, upon the whole length of which the sea breaks, and over it a boat can with difficulty pass at low water.

The very few shells we found were dead. Strewed about the beach were numbers of fish, some of which had been thrown on shore by the last tide, and were scarcely stiff. They principally belonged to the genus *Ophidium*; the largest that we saw measured four feet seven inches in length, and weighed twenty-four pounds. Many caught alongside the ship were, in truth, coarse and insipid; yet our people, who fed heartily upon them, called them ling, and thought them palatable. The hook, however, furnished us with a very wholesome and well-flavoured species of cod (*Gadus*). Attached to the first we found two parasitical animals; one was a *Cymothoa*, the other a species of *Lernæa*, which had so

* Some of the specimens of the clay strata consist, according to Dr. Fitton, who has kindly examined my collection, of a white marl not unlike certain varieties of the lower chalk; and of a clay having many of the properties of fuller's earth. The pebbles on the beach consist of quartz, red jasper, hornstone, and flinty slate, but do not contain any stone resembling chalk flint.

† Dr. Fitton considers these masses of clay to bear a resemblance to the upper green sand of England.

© The Complete Work of Charles Darwin Online

securely attached itself under the skin, as not to be removed without cutting off a piece of the flesh with it. An undescribed species of *Muræna* was also taken.

Whilst we were on shore, the Beagle moved eight or nine miles nearer to the Cape, where Captain Stokes landed to fix positions of remarkable land. One peaked hill, from the circumstance of his seeing a large animal near it, he called Tiger Mount. Mr. Bowen shot a guanaco; and being at a distance in shore, unable to procure assistance, he skinned and quartered it with his pocket-knife, and carried it upon his shoulders to the boat.

Next morning the ships weighed, and proceeded towards Cape Virgins.

When a-breast of Cape Fairweather, the opening of the river Gallegos was very distinctly seen; but the examination of it was deferred to a future opportunity. Passing onward, the water shoaled to four fathoms, until we had passed extensive banks, which front the river.

Our approach to the entrance of the Strait, although attended with anxiety, caused sensations of interest and pleasure not easily to be described. Though dangers were experienced by some navigators who had passed it, the comparative facility with which others had effected the passage showed that, at times, the difficulties were easily surmounted, and we were willing to suppose that in the former case there might have been some little exaggeration.

The most complete, and, probably, the only good account of the navigation of the Strait of Magalhaens is contained in the narrative of Don Antonio de Cordova, who commanded the Spanish frigate Santa Maria de la Cabeza, on a voyage expressly for the purpose of exploring the strait. It was published under the title of 'Ultimo Viage al Estrecho de Magallanes.' That voyage was, however, concluded with only the examination of the eastern part, and a subsequent expedition was made, under the command of the same officer, the account of which was appended to the Cabeza's voyage; so that Cordova's expedition still retained the appellation of 'Ultimo

© The Complete Work of Charles Darwin Online

Viage, &c.' It is written in a plain and simple style, gives a most correct account of every thing seen, and should therefore be in the possession of every person who attempts the navigation of the strait.

Cordova's account of the climate is very uninviting. Speaking of the rigours of the summer months (January, February, and March), he says, "Seldom was the sky clear, and short were the intervals in which we experienced the sun's warmth: no day passed by without some rain having fallen, and the most usual state of the weather was that of constant rain."*

The accounts of Wallis and Carteret are still more gloomy. The former concludes that part of his narrative with the following dismal and disheartening description: "Thus we quitted a dreary and inhospitable region, where we were in almost continual danger of shipwreck for near four months, having entered the strait on the 17th of December, and quitted it on the 11th of April 1767: a region where, in the midst of summer, the weather was cold, gloomy, and tempestuous, where the prospects had more the appearance of a chaos than of nature; and where for the most part the valleys were without herbage and the hills without wood."

These records of Cordova and Wallis made me feel not a little apprehensive for the health of the crew, which could not be expected to escape uninjured through the rigours of such a climate. Nor were the narratives of Byron or Bougainville calculated to lessen my anxiety. In an account, however, of a voyage to the strait by M. A. Duclos Guyot, the following paragraph tended considerably to relieve my mind upon the subject:—"At length, on Saturday the 23d of March, we sailed out of that famous Strait, so much dreaded, after having experienced that there, as well as in other places, it was very fine, and very warm, and that for three-fourths of the time the sea was perfectly calm."

In every view of the case, our proximity to the principal scene of action occasioned sensations of a peculiar nature, in which, however, those that were most agreeable and hopeful

* Ultimo Viage al Estrecho de Magallanes, part ii. p. 298.

© The Complete Work of Charles Darwin Online

preponderated. The officers and crews of both ships were healthy, and elated with the prospect before them; our vessels were in every respect strong and sea-worthy; and we were possessed of every comfort and resource necessary for encountering much greater difficulties than we had any reason to anticipate.

There has existed much difference of opinion as to the correct mode of spelling the name of the celebrated navigator who discovered this Strait. The French and English usually write it Magellan, and the Spaniards Magallanes; but by the Portuguese (and he was a native of Portugal) it is universally written Magalhaens. Admiral Burney and Mr. Dalrymple spell it Magalhanes, which mode I have elsewhere adopted, but I have since convinced myself of the propriety of following the Portuguese orthography for a name which, to this day, is very common both in Portugal and Brazil.

© The Complete Work of Charles Darwin Online

CHAPTER II.

Enter the Straits of Magalhaens (or Magellan), and anchor off Cape Possession — First Narrow—Gregory Bay — Patagonian Indians— Second Narrow — Elizabeth Island — Freshwater Bay — Fuegian Indians—Arrival at Port Famine.

A CONTRARY tide and light winds detained us at anchor near Cape Virgins until four o'clock in the afternoon, when, with the turn of the tide, a light air carried us past Dungeness Point, aptly named by Wallis from its resemblance to that in the English Channel. A great number of seals were huddled together upon the bank, above the wash of the tide, whilst others were sporting about in the surf. Cape Possession was in sight, and with the wind and tide in our favour we proceeded until ten o'clock, when the anchor was dropped. At daylight we found ourselves six miles to the eastward of the cape. The anchor was then weighed, and was again dropped at three miles from the cape until the afternoon, when we made another attempt; but lost ground, and anchored a third time. Before night a fourth attempt was made, but the tide prevented our making any advance, and we again anchored.

Mount Aymond* and "his four sons," or (according to the old quaint nomenclature) the Asses' Ears, had been in sight all day, as well as a small hummock of land on the S.W. horizon, which afterwards proved to be the peaked hillock upon Cape Orange, at the south side of the entrance to the First Narrow.

At this anchorage the tide fell thirty feet, but the strength of the current, compared with the rate at which we afterwards found it to run, was inconsiderable Here we first experienced

* A hill on the north shore of Possession Bay, having near it, to the westward, four rocky summits, which, from a particular point of view, bear a strong resemblance to the cropped ears of a horse or ass. These are described less briefly in the Sailing Directions.

© The Complete Work of Charles Darwin Online

the peculiar tides of which former navigators have written. During the first half of the flood* or westward tide, the depth decreased, and then, after a short interval, increased until three hours after the stream of tide had begun to run to the eastward.

The following morning (21st) we gained a little ground. Our glasses were directed to the shore in search of inhabitants, for it was hereabouts that Byron, and Wallis, and some of the Spanish navigators held communication with the Patagonian Indians; but we saw none. Masses of large sea-weed,† drifting with the tide, floated past the ship. A description of this remarkable plant, although it has often been given before, may not be irrelevant here. It is rooted upon rocks or stones at the bottom of the sea, and rises to the surface, even from great depths. We have found it firmly fixed to the ground more than twenty fathoms under water, yet trailing along the surface for forty or fifty feet. When firmly rooted it shows the set of the tide or current. It has also the advantage of indicating rocky ground: for wherever there are rocks under water, their situation is, as it were, buoyed by a mass of sea-weed‡ on the surface of the sea, of larger extent than that of the danger below. In many instances perhaps it causes unnecessary alarm, since it often grows in deep water; but it should not be entered without its vicinity having been sounded, especially if seen in masses, with the extremities of the stems trailing along the surface. If there be no tide, or if the wind and tide are the same way, the plant lies smoothly upon the water, but if the wind be against the tide, the leaves curl up and are visible at a distance, giving a rough, rippling appearance to the surface of the water.

During the last two days the dredge had furnished us with a few specimens of *Infundibulum* of Sowerby (*Patella trochi-formis*, Lin.), and some dead shells (*Murex Magellanicus*) were brought up by the sounding-lead.

We made another attempt next morning, but again lost

* Flowing into the strait from the east towards the west.

† Fucus giganteus.

‡ Usually called by seamen 'kelp.'

© The Complete Work of Charles Darwin Online

ground, and the anchor was dropped for the eighth time. The threatening appearances of the clouds, and a considerable fall of the barometer indicating bad weather, Captain Stokes agreed with me in thinking it advisable to await the spring-tides to pass the First Narrow: the ships were therefore made snug for the expected gale, which soon came on, and we remained several days wind-bound, with top-masts struck, in a rapid tide-way, whose stream sometimes ran seven knots. On the 28th, with some appearance of improving weather, we made an attempt to pass through the Narrow. The wind blowing strong, directly against us, and strengthening as we advanced, caused a hollow sea, that repeatedly broke over us. The tide set us through the Narrow very rapidly, but the gale was so violent that we could not show more sail than was absolutely necessary to keep the ship under command. Wearing every ten minutes, as we approached either shore, lost us a great deal of ground, and as the anchorage we left was at a considerable distance from the entrance of the Narrows, the tide was not sufficient to carry us through. At slack water the wind fell, and as the weather became fine, I was induced to search for anchorage near the south shore. The sight of kelp, however, fringing the coast, warned me off, and we were obliged to return to an anchorage in Possession Bay. The Beagle had already anchored in a very favourable berth; but the tide was too strong to permit us to reach the place she occupied, and our anchor was dropped a mile astern of her, in nineteen fathoms. The tide was then running five, and soon afterwards six miles an hour. Had the western tide set with equal strength, we should have succeeded in passing the Narrow. Our failure, however, answered the good purpose of making us more acquainted with the extent of a bank that lines the northern side of Possession Bay, and with the time of the turn of tide in the Narrow; which on this day (new moon) took place within a few minutes of noon.

As we passed Cape Orange, some Indians were observed lighting a fire under the lee of the hill to attract our notice; but we were too busily engaged to pay much attention to

© The Complete Work of Charles Darwin Online

their movements. Guanacoes also were seen feeding near the beach, which was the first intimation we had of the existence of that animal southward of the Strait of Magalhaens.

When day broke (29th) it was discovered that the ship had drifted considerably during the night. The anchor was weighed, and with a favourable tide we reached an anchorage a mile in advance of the Beagle. We had shoaled rather suddenly to eight fathoms, upon which the anchor was immediately dropped, and on veering cable the depth was eleven fathoms. We had anchored on the edge of a bank, which soon afterwards, by the tide falling, was left dry within one hundred yards of the ship. Finding ourselves so near a shoal, preparations were made to prevent the ship from touching it. An anchor was dropped under foot, and others were got ready to lay out, for the depth alongside had decreased from eleven to seven fathoms, and was still falling. Fortunately we had brought up to leeward of the bank, and suffered no inconvenience; the flood made, and as soon as possible the ship was shifted to another position, about half a mile to the S. E., in a situation very favourable for our next attempt to pass the Narrow. This night the tide fell thirty-six feet, and the stream ran six knots.

The ensuing morning we made another attempt to get through the Narrow, and, from having anchored so close to its entrance, by which the full benefit of the strength, as well as the whole duration of the tide was obtained, we succeeded in clearing it in two hours, although the distance was more than twenty miles, and the wind directly against us, the sea, as before, breaking repeatedly over the ship.

After emerging from the Narrow we had to pass through a heavy 'race' before we 'reached' out of the influence of the stream that runs between the First and Second Narrow, but the tide lasted long enough to carry us to a quiet anchorage. In the evening we weighed again, and reached Gregory Bay, where the Beagle joined us the next morning.

Since entering the Strait, we had not had any communication

© The Complete Work of Charles Darwin Online

with the Beagle on account of the weather, and the strength of the tide; this opportunity was therefore taken to supply her with water, of which she had only enough left for two days.

The greater part of this day was spent on shore, examining the country and making observations. Large smokes* were noticed to the westward. The shore was strewed with traces of men and horses, and other animals. Foxes and ostriches were seen; and bones of guanacoes were lying about the ground.

The country in the vicinity of this anchorage seemed open, low, and covered with good pasturage. It extends five or six miles, with a gradual ascent, to the base of a range of flat-topped land, whose summit is about fifteen hundred feet above the level of the sea. Not a tree was seen; a few bushes† alone interrupted the uniformity of the view. The grass appeared to have been cropped by horses or guanacoes, and was much interspersed with cranberry plants, bearing a ripe and juicy, though very insipid fruit.

Next day the wind was too strong and adverse to permit us to proceed. In the early part of the morning an American sealing vessel, returning from the Madre de Dios Archipelago on her way to the Falkland Islands, anchored near us. Mr. Cutler, her master, came on board the Adventure, passed the day and night with us, and gave me much useful information respecting the nature of the navigation, and anchorages in the Strait. He told me there was an Englishman in his vessel who was a pilot for the strait, and willing to join the ship. I gladly accepted the offer of his services.

In the evening an Indian was observed on horseback riding to and fro upon the beach, but the weather prevented my sending a boat until the next morning, when Lieutenant Cooke went on shore to communicate with him and other Indians who appeared, soon after dawn, upon the beach. On landing, he was received by them without the least distrust. They were eight or ten in number, consisting of an old man and his wife, three young men, and the rest children, all mounted on

* Columns of smoke rising from large fires. † Berberis.

PHILOSOPHICAL LIBRARY
CAMBRIDGE

good horses. The woman, who appeared to be about fifty years of age, was seated astride upon a pile of skins, hung round with joints of fresh guanaco meat and dried horse-flesh. They were all wrapped in mantles, made chiefly of the skins of guanacoes, sewed together with the sinews of the same animal. These mantles were large enough to cover the whole body. Some were made of skins of the 'zorillo,' or skunk, an animal like a pole-cat, but ten times more offensive; and others, of skins of the puma.

The tallest of the Indians, excepting the old man, who did not dismount, was rather less than six feet in height. All were robust in appearance, and with respect to the head, length of body, and breadth of shoulders, of gigantic size; therefore, when on horseback, or seated in a boat, they appeared to be tall, as well as large men. In proportion to the parts above-mentioned, their extremities were very small and short, so that when standing they seemed but of a moderate size, and their want of proportion was concealed by the mantle, which enveloped the body entirely, the head and feet being the only parts exposed.

When Mr. Cooke landed, he presented some medals * to the oldest man, and the woman; and suspended them round their necks. A friendly feeling being established, the natives dismounted, and even permitted our men to ride their horses, without evincing the least displeasure, at the free advantage taken of their good-nature. Mr. Cooke rode to the heights, whence he had a distinct view of the Second Narrow, and Elizabeth Island, whither, he explained to the Indians who accompanied him, we were going.

Mr. Cooke returned to the ship with three natives, whom he had induced to go with us to Elizabeth Island; the others were to meet them, and provide us with guanaco meat, to which arrangement the elders of the family had, after

* Previous to the expedition quitting England, I had provided myself with medals, to give away to the Indians with whom we might communicate, bearing on one side the figure of Britannia, and on the reverse "George IV." "Adventure and Beagle," and "1826."

BALFOUR LIBRARY

much persuasion, assented. At first they objected to their companions embarking with us, unless we left hostages for their safety; but as this was refused, they did not press the point, and the three young men embarked. They went on board singing; in high glee.

While the ship was getting under way, I went ashore to a larger number of Indians who were waiting on the beach. When my boat landed they were mounted, and collected in one place. I was surprised to hear the woman accost me in Spanish, of which, however, she knew but a few words. Having presented medals to each of the party, they dismounted (excepting the elders), and in a few minutes became quite familiar. By this time Captain Stokes had landed, with several of his officers, who increased our party to nearly double the number of theirs: notwithstanding which they evinced neither fear nor uneasiness. The woman, whose name was Maria, wished to be very communicative; she told me that the man was her husband, and that she had five children. One of the young men, whom we afterwards found to be a son of Maria, who was a principal person of the tribe, was mounted upon a very fine horse, well groomed, and equipped with a bridle and saddle that would have done credit to a respectable horseman of Buenos Ayres or Monte Video. The young man wore heavy brass spurs, like those of the Guachos of Buenos Ayres. The juvenile and feminine appearance of this youth made us think he was Maria's daughter, nor was it until a subsequent visit that our mistake was discovered. The absence of whiskers and beard gives all the younger men a very effeminate look, and many cannot be distinguished, in appearance, from the women, but by the mode in which they wrap their mantles around them, and by their hair, which is turned up and confined by a fillet of worsted yarn. The women cross their mantle over the breast like a shawl, and fasten it together with two iron pins or skewers, round which are twisted strings of beads and other ornaments. They also wear their hair divided, and gathered into long tresses or tails, which hang one before each ear; and those who have short hair, wear false tails made of horse-hair. Under

© The Complete Work of Charles Darwin Online

their mantle the women wear a sort of petticoat, and the men a triangular piece of hide instead of breeches. Both sexes sit astride, but the women upon a heap of skins and mantles, when riding. The saddles and stirrups used by the men are similar to those of Buenos Ayres. The bits, also, are generally of steel; but those who cannot procure steel bits have a sort of snaffle, of wood, which must, of course, be frequently renewed. Both sexes wear boots, made of the skins of horses' hind legs, of which the parts about the hock joints serve for the heels. For spurs, they use pieces of wood, pointed with iron, projecting backwards two or three inches on each side of the heel, connected behind by a broad strap of hide, and fastened under the foot and over the instep by another strap.

The only weapons which we observed with these people were the 'bolas,' or balls, precisely similar to those used by the Pampas Indians; but they are fitter for hunting than for offence or defence. Some are furnished with three balls, but in general there are only two. These balls are made of small bags or purses of hide, moistened, filled with iron pyrites, or some other heavy substance, and then dried. They are about the size of a hen's egg, and attached to the extremities of a thong, three or four yards in length. To use them, one ball is held in the hand, and the other swung several times around the head until both are thrown at the object, which they rarely miss. They wind round it violently, and if it be an animal, throw it down. The bolas, with three balls, similarly connected together, are thrown in the same manner.

As more time could not be spared we went on board, reminding the natives, on leaving them, of their promise to bring us some guanaco meat. Aided by the tide, the ships worked to windward through the Second Narrow, and reached an anchorage out of the strength of tide, but in an exposed situation. The wind having been very strong and against the tide, the ship had much motion, which made our Patagonian passengers very sick, and heartily sorry for trusting themselves afloat. One of them, with tears in his eyes, begged to be landed, but was soon convinced of the difficulty of compliance,

© The Complete Work of Charles Darwin Online

and satisfied with our promise of sending him ashore on the morrow.

After we anchored, the wind increased to a gale, in which the ship pitched so violently as to injure our windlass. Its construction was bad originally, and the violent jerks received in Possession Bay had done it much damage. While veering cable, the support at one end gave way, and the axle of the barrel was forced out of the socket, by which some of the pawls were injured. Fortunately, dangerous consequences were prevented, and a temporary repair was soon applied.

The Beagle, by her better sailing, had reached a more advanced situation, close to the N.E. end of Elizabeth Island, but had anchored disadvantageously in deep water, and in the strength of the tide. Next morning we made an attempt to pass round Elizabeth Island, but found the breeze so strong that we were forced to return, and were fortunate enough to find good anchorage northward of the island, out of the tide.

The Patagonians, during the day, showed much uneasiness at being kept on board so much longer than they expected; but as they seemed to understand the cause of their detention, and as their sickness ceased when we reached smooth water, they gradually recovered their good-humour, and became very communicative. As well as we could understand their pronunciation, their names were 'Coigh,' 'Coichi,' and 'Aighen.' The country behind Cape Negro they called 'Chilpéyo;' the land of Tierra del Fuego, 'Oschērri;' Elizabeth Island, 'Tŭrrĕtterr;' the island of Santa Magdalena, 'Shrēe-ket-tup;' and Cape Negro, 'Oērkrĕckur.' The Indians of Tierra del Fuego, with whom they are not on friendly terms, are designated by them 'Săpāllĭŏs.' This name was applied to them in a contemptuous tone.

Aighen's features were remarkably different from those of his companions. Instead of a flat nose, his was aquiline and prominent, and his countenance was full of expression. He proved to be good-tempered, and easily pleased; and whenever a shade of melancholy began to appear, our assurance of

© The Complete Work of Charles Darwin Online

landing him on the morrow restored his good-humour, which was shown by singing and laughing.

The dimensions of Coichi's head were as follows :—

From the top of the fore part of the head to the eyes			4 inches.
Do	do	to the tip of the nose	6
Do	do	to the mouth	7
Do	do	to the chin	9
Width of the head across the temples			7½
Breadth of the shoulders			18½

The head was long and flat, at the top; the forehead broad and high, but covered with hair to within an inch and a half of the eyebrow, which had scarcely any hair. The eyes were small, the nose was short, the mouth wide, and the lips thick. Neck short, and shoulders very broad. The arms were short, and wanting in muscle, as were also the thighs and legs. The body was long and large, and the breast broad and expanded. His height was nearly six feet.

The next day we rounded Elizabeth Island, and reached Cape Negro, where we landed the Indians, after making them several useful presents, and sending some trifles by Aighen to Maria, who, with her tribe, had lighted large fires about the country behind Peckett's Harbour, to invite us to land. Our passengers frequently pointed to them, telling us that they were made by Maria, who had brought plenty of guanaco meat for us.

Our anxiety to reach Port Famine prevented delay, and, as soon as the boat returned, we proceeded along the coast towards Freshwater Bay, which we reached early enough in the afternoon to admit of a short visit to the shore.

From Cape Negro the country assumed a very different character. Instead of a low coast and open treeless shore, we saw steep hills, covered with lofty trees, and thick underwood. The distant mountains of Tierra del Fuego, covered with snow, were visible to the southward, some at a distance of sixty or seventy miles.

We had now passed all the difficulties of the entrance, and had reached a quiet and secure anchorage.

© The Complete Work of Charles Darwin Online

The following day was calm, and so warm, that we thought if Wallis and Cordova were correct in describing the weather they met with, Duclos Guyot was equally entitled to credit; and we began to hope we had anticipated worse weather than we should experience. But this was an unusually fine day, and many weeks elapsed, afterwards, without its equal. The temperature of the air, in the shade on the beach, was 67½°, on the sand 87½°; and that of the water 55°. Other observations were made, as well as a plan of the bay, of which there is a description in the Sailing Directions.

Here we first noticed the character of the vegetation in the Strait, as so different from that of Cape Gregory and other parts of the Patagonian coast, which is mainly attributable to the change of soil; the northern part being a very poor clay, whilst here a schistose sub-soil is covered by a mixture of alluvium, deposited by mountain streams; and decomposed vegetable matter, which, from the thickness of the forests, is in great quantity.

Two specimens of beech (*Fagus betuloides* and *antarctica*), the former an evergreen,—and the winter's bark (*Wintera aromatica*), are the only trees of large size that we found here; but the underwood is very thick, and composed of a great variety of plants, of which *Arbutus rigida*, two or three species of *Berberis*, and a wild currant (*Ribes antarctica*, Bankes and Solander MSS.), at this time in flower, and forming long clustering bunches of young fruit, were the most remarkable. The berberis produces a berry of acidulous taste, that promised to be useful to us. A species of wild celery, also, which grows abundantly near the sea-shore, was valuable as an antiscorbutic. The trees in the immediate vicinity of the shore are small, but the beach was strewed with trunks of large trees, which seemed to have been drifted there by gales and high tides. A river falls into the bay, by a very narrow channel, near its south end; but it is small, and so blocked up by trees as not to be navigable even for the smallest boat: indeed, it is merely a mountain torrent, varying in size according to the state of the weather.

© The Complete Work of Charles Darwin Online

Tracks of foxes were numerous about the beach, and the footsteps of a large quadruped, probably a puma, were observed. Some teal and wild ducks were shot; and several geese were seen, but, being very wary, they escaped.

Upon Point St. Mary we noticed, for the first time, three or four huts or wigwams made by the Fuegian Indians, which had been deserted. They were not old, and merely required a slight covering of branches or skins to make them habitable. These wigwams are thus constucted: long slender branches, pointed at the end, are stuck into the ground in a circular or oval figure; their extremities are bent over, so as to form a rounded roof, and secured with ligatures of rush; leaving two apertures, one towards the sea, and the other towards the woods. The fire is made in the middle, and half fills the hut with smoke. There were no Indians in the bay when we arrived, but, on the following evening, Lieutenant Sholl, in walking towards the south end of the bay, suddenly found himself close to a party which had just arrived in two canoes from the southward. Approaching them, he found there were nine individuals—three men, and the remainder women and children. One of the women was very old, and so infirm as to require to be lifted out of the canoe and carried to the fire. They seemed to have no weapons of any consequence; but, from our subsequent knowledge of their habits, and disposition, the probability is they had spears, bows, and arrows concealed close at hand. The only implement found amongst them was a sort of hatchet or knife, made of a crooked piece of wood, with part of an iron hoop tied to the end. The men were very slightly clothed, having only the back protected by a seal's skin; but the females wore large guanaco mantles, like those of the Patagonian Indians, whom our pilot told us they occasionally met for the purpose of barter. Some of the party were devouring seal's flesh, and drinking the oil extracted from its blubber, which they carried in bladders. The meat they were eating was probably part of a sea lion (*Phoca jubata*); for Mr. Sholl found amongst them a portion of the neck of one of those animals, which is

© The Complete Work of Charles Darwin Online

remarkable for the long hair, "like a lion's mane," growing upon it. They appeared to be a most miserable, squalid race, very inferior, in every respect, to the Patagonians. They did not evince the least uneasiness at Mr. Sholl's presence, or at our ships being close to them; neither did they interfere with him, but remained squatting round their fire while he staid near. This seeming indifference, and total want of curiosity, gave us no favourable opinion of their character as intellectual beings; indeed, they appeared to be very little removed from brutes; but our subsequent knowledge of them has convinced us that they are not usually deficient in intellect. This party was perhaps stupified by the unusual size of our ships, for the vessels which frequent this Strait are seldom one hundred tons in burthen.

We proceeded next morning at an early hour. The Indians were already paddling across the bay in a northerly direction. Upon coming abreast of them, a thick smoke was perceived to rise suddenly from their canoes; they had probably fed the fire, which they always carry in the middle of their canoe, with green boughs and leaves, for the purpose of attracting our attention, and inviting us to communicate with them.

It was remarked that the country begins to be covered with trees at Cape Negro; but they are stunted, compared with those at Freshwater Bay. Near this place, also, the country assumes a more verdant aspect, becoming also higher, and more varied in appearance. In the neighbourhood of Rocky Point some conspicuous portions of land were noticed, which, from the regularity of their shape, and the quantity as well as size of the trees growing at the edges, bore the appearance of having been once cleared ground; and our pilot Robinson (possessing a most inventive imagination) informed us that they were fields, formerly cleared and cultivated by the Spaniards, and that ruins of buildings had been lately discovered near them. For some time his story obtained credit, but it proved to be altogether void of foundation. These apparently cleared tracts were afterwards found to be occasioned by unusual poverty of soil, and by being overrun with thick

© The Complete Work of Charles Darwin Online

spongy moss, the vivid green colour of which produces, from a distance, an appearance of most luxuriant pasture land. Sir John Narborough noticed, and thus describes them: "The wood shows in many places as if there were plantations: for there were several clear places in the woods, and grass growing like fenced fields in England, the woods being so even by the sides of it."*

The wind, after leaving Freshwater Bay, increased, with strong squalls from the S.W., at times blowing so hard as to lay the ship almost on her broadside. It was, however, so much in our favour, that we reached the entrance of Port Famine early, and after some little detention from baffling winds, which always render the approach to that bay somewhat difficult, the ships anchored in the harbour.

CHAPTER III.

Prepare the Beagle, and our decked boat (the Hope) for surveying the Strait—Beagle sails westward, and the Hope towards the south-east—Sarmiento's voyage—and description of the colony formed by him at Port Famine—Steamer-duck—Large trees—Parroquets—Mount Tarn—Barometrical observations — Geological character — Report of the Hope's cruize.

In almost every account published of the Strait of Magalhaens, so much notice has been taken of Port Famine, that I had long considered it a suitable place for our purposes; and upon examination I found it offered so many advantages, that I did not hesitate to make it our head-quarters. As soon, therefore, as the ship was moored, tents were pitched, our decked-boat was hoisted out and hauled on shore, to be coppered and equipped for the survey;—and Captain Stokes received orders to prepare the Beagle for examining the western part of the Strait; previous to which she required to be partially refitted, and supplied with fuel and water.

For several days after our arrival, we had much rain and strong south-westerly wind, with thick clouds, which concealed the high land to the southward; allowing us only now and then a partial glimpse. One evening (11th) the air was unusually clear, and many of the mountains in that direction were distinctly defined. We had assembled to take leave of our friends in the Beagle, and were watching the gradual appearance of snow-capped mountains which had previously been concealed, when, bursting upon our view, as if by magic, a lofty mountain appeared towering among them; whose snowy mantle, strongly contrasted with the dark and threatening aspect of the sky, much enhanced the grandeur of the scene.

This mountain was the "Snowy Volcano" (*Volcan Nevado*) of Sarmiento, with whose striking appearance that celebrated navigator seems to have been particularly impressed, so minute

and excellent is his description. It is also mentioned in the account of Cordova's voyage.* The peculiar shape of its summit as seen from the north would suggest the probability of its being a volcano, but we never observed any indication of its activity. Its volcanic form is perhaps accidental, for, seen from the westward, its summit no longer resembles a crater. From the geological character of the surrounding rocks its formation would seem to be of slate. It is in a range of mountains rising generally two or three thousand feet above the sea; but at the N.E. end of the range are some, at least four thousand feet high. The height of the "Snowy Volcano," or as we have called it, Mount Sarmiento,† was found, by trigonometrical measurement, to be six thousand eight hundred feet‡ above the level

* Ultimo Viage, p. 120.

† From an attentive perusal of the voyage of Magalhaens, I have lately been led to think that this is the mountain which Magalhaens called Roldan's Bell. Sarmiento has, however, assigned that name to a mountain at the back of his Bay of Campana, which will be noticed in it's proper place. The name of Mount Sarmiento was too long, and too well established with us, or I should have restored the name bestowed upon it by Magalhaens. Herrera, in his Descripcion de las Indias Occidentales, cap. xxiii, notices the "Campana de Roldan" as a great mountain in the midst of the entrance of a channel; they gave it this name (Campana de Roldan) because one of Magalhaens's companions, named Roldan, an artillery officer, went to examine it. "Y la Campana de Roldan una Peña grande en medio al principio de un canal: dieron le este nombre porque la fué a reconocer uno de los compañeros de Magallanes llamado Roldan que era artillero."

of the sea. It is the highest land that I have seen in Tierra del Fuego; and to us, indeed, it was an object of considerable interest, because its appearance and disappearance were seldom failing weather guides. In our Meteorological Diary, a column was ruled for the insertion of its appearances.*

This clear state of the atmosphere was followed by a heavy fall of rain, with northerly and easterly winds, which did not, however, last long.

In the vicinity of our tents erected on the low land, on the S.W. side of the bay, were several ponds of water, perfectly fit for immediate use; but, perhaps, too much impregnated with vegetable matter to keep good for any length of time. Captain Stokes, therefore, filled his tanks from the river; but as that water did not keep well, it was probably taken into the boat too near the sea. This, however, was unavoidable, except by risking the boats among a great number of sunken trees in the bed of the river.

The Beagle sailed on the 15th, to survey the western entrance of the Strait, with orders to return to Port Famine by the end of March.

Our decked boat, the Hope, being ready, the command of her was given to Mr. Wickham, who was in every way qualified for the trust. We were, however, much mortified by finding that she leaked so considerably as to oblige us to unload, and again haul her on shore. When ready for sea, she sailed under the direction of my assistant-surveyor, Mr. Graves, to examine the St. Sebastian channel and the deep opening to the S.E. of Cape Valentyn. Her crew consisted of seven men, besides Mr. Wickham, and Mr. Rowlett, the purser.

Having despatched the Beagle and the Hope, I was at leisure to carry on the survey of the coast in the neighbourhood of Port Famine, and to make a plan of the port itself. The

* At a subsequent visit, embracing a period of 190 days, it was only seen on twenty-five, and during seven days only was it constantly visible. On the remaining eighteen, portions only were seen, and those but for a few hours at a time.

© The Complete Work of Charles Darwin Online

Transit, and Altitude circle, were set up; but from the very unfavourable state of the weather, and the interference of other occupations, I was only enabled to procure a series of zenith distances of the sun, and stars, for the latitude.

Port Famine, a name well known to all who have interested themselves about the Strait of Magalhaens, was selected by Sarmiento as the most convenient place for the site of an establishment formed, at his suggestion, by Philip II. King of Spain.

The voyage of Sir Francis Drake through the Strait into the Pacific, and his successes against the Spanish colonies and trade on the western side of the continent of America, induced the Viceroy of Lima to send an Expedition to pursue the "Corsair," with orders to fight and take him, dead or alive.* This Expedition, commanded by Pedro Sarmiento de Gamboa, who had already been engaged twice with Drake, consisted of two ships, containing in all two hundred armed men, sailors and soldiers; a force which was considered sufficient to ensure the capture.†

The Strait of Magalhaens being the most likely place to meet with Drake, Sarmiento was ordered to proceed through it, and take the opportunity of exploring its coasts.

All this he performed in a manner highly creditable, as well for the excellent description handed down in his unpretending journal, as for the enterprising zeal, and steady perseverance, shown among difficulties of no trifling nature. To his accounts of various places there will be frequent occasion to refer. Our object, at present, is to give a short account of the Colony.

Sarmiento sailed from Peru (1583), and entered the Strait from the Pacific. After experiencing many serious difficulties, and escaping imminent dangers, in the western part of the Strait, where the climate is so rigorous and the country so desolate, it was not surprising that he should become enraptured with the verdant, and picturesque appearance of the shores to the eastward of Cape Froward, and with the open country in

* Sarmiento's Voyage, p. 25. † Id. l. c.

© The Complete Work of Charles Darwin Online

the neighbourhood, and to the northward of Cape Virgins.* After much opposition from the Duke of Alva† and other powerful people, he succeeded in convincing the King of the expediency of fortifying the shores of the First Narrow, and forming several establishments within the Strait, to prevent the passage of strange ships, to the prejudice of the King's colonies in Chile and Peru; for at that time the passage round Cape Horn was not known. Accordingly, an Expedition was prepared, consisting of twenty-three vessels, under the joint command of Diego Florez de Valdez and Sarmiento; the former being appointed Captain-general of the fleet, and of the coast of Brazil; and the latter, Captain-general of the Strait of Magalhaens, and Governor of all the Establishments that should be formed within it.

Of the twenty-three ships which sailed from Spain, five only reached the entrance of the Strait; and these, after experiencing many difficulties from bad weather and foul winds, returned to Rio de Janeiro to refit, where Sarmiento met four vessels which had been sent from Spain to his succour. His colleague and General in chief, Florez, who had deserted the Expedition, did all in his power to impede Sarmiento, to the latest moment of his stay at the Brazils. At last, however, five ships, commanded by Ribera, and manned by five hundred and thirty men,‡ sailed; and, without encountering further loss or detention, arrived off the Strait in December (1584), and soon after reached an anchorage, between the First and Second Narrows.

Ribera would go no further; but landed about three hundred men, under Sarmiento. A city was marked out, and named Jesus,§ in a valley well provided with water. The

* See Burney, ii. p. 45, for a fuller account; also id. 71.

† Who made a remark on the occasion, which became proverbial, "that if a ship carried out only anchors and cables, sufficient for her security against the storms in that part of the world, she would go well laden." Burney Coll. vol. ii. 45.

§ The situation of "Jesus" must have been about half-way between the First and Second Narrow, near the point named in the chart N. S. de Valle,

© The Complete Work of Charles Darwin Online

ships were blown away to sea, leaving the colonists very destitute; fortunately, however, they were enabled to return, but were four times, afterwards, obliged to put to sea, from stress of weather. On the last return, one of the ships, La Trinidad, was run on shore. The ardour of Ribera being damped by repeated misfortunes, he returned to Spain, without the knowledge or consent of Sarmiento, leaving, for the use of the colony, only one ship, the Maria.

While unloading the Trinidad, the Spaniards were attacked by Indians, whom they dispersed.

Sarmiento, after making the necessary arrangements at Jesus, set out by land with one hundred men, to go to Point St. Anna,* the ship Maria being ordered to follow. On the journey, the sufferings of the party were very great, as well from the fatiguing nature of the march, as from their being harassed by the natives, with whom they had an engagement, in which one was killed, and ten men were wounded. A mutiny among his people then broke out, which was quelled by assistance from the ship. At last they reached their destination, and founded, with the usual solemnities, the city of King Philip (or San Felipe).

At the latter end of March, while preparing habitations, the winter set in so suddenly, that for fifteen days it did not cease to snow. Sarmiento, then, after quelling a mutiny which had broken out afresh among the soldiers, embarked with thirty men to visit the first encampment at Jesus, and to superintend the erection of forts in the Narrow; but upon reaching the anchorage, a gale of wind forced him to sea, and, lasting twenty days, obliged him (with his people blinded and frost-bitten) to bear up for Rio de Janeiro.

Here his ship was stranded; upon which he chartered a vessel to convey flour to the Strait, and went himself to Pernambuco, to procure large boats for carrying supplies to his

Valle, where some peaked elevations, dividing vallies near the coast line, are conspicuous. The Beagle anchored there, and found plenty of fresh water.

* Close to Port Famine.

© The Complete Work of Charles Darwin Online

colony, and assisting in the recovery of his stranded ship; she had, however, drifted off, and sunk near Bahia; and all his boats were destroyed. Still Sarmiento persevered in his zealous efforts to succour his friends in the Strait; and succeeded in procuring a vessel of fifty or sixty tons, which, loaded with arms and whatever he considered useful, sailed, and reached Rio de Janeiro a month after the departure of the first vessel (January 1585). He followed, but in the latitude of 39° met with a furious gale, which drove him back to Rio de Janeiro, where the vessel that had preceded him had returned in distress.

Disappointed in his attempts to carry succour to the colony, he determined to go to Spain; but on his voyage thither, to complete the catalogue of his misfortunes, his ship was captured by three English vessels, and taken to England, after which the ill-fated colony in the Strait was neglected, if not entirely forgotten.

Two months after Sarmiento's departure from the Strait of Magalhaens, in the month of August, the middle of the winter of that region, the party belonging to the first establishment at Jesus set off by land, and joined that at San Felipe, with the unwelcome tidings of their deserted state. But as the provisions at San Felipe were insufficient to support all the people, Andres de Viedma, who, after Sarmiento's departure, had assumed the command, detached two hundred soldiers, under the command of Juan Iniguez, back to Jesus, for the purpose of communicating with any ship that might make her appearance, and awaiting the expected return of Sarmiento; but the winter and following summer passed by without any relief.

In this unhappy state, the colonists were obliged to think only of providing for their safety, and built two boats; in which fifty people embarked, besides Viedma, Suarez, a Franciscan friar named Antonio, and five Spanish women. They had not proceeded farther than Point Santa Brigida,*

* From Sarmiento's description of the coast, Point Santa Brigida is the outward point of Nassau Island.(*a*) See Sarmiento's Voyage, p. 220.

(*a*) By Nassau Island is meant the land forming the south shore of the Second Narrow.—R. F.

© The Complete Work of Charles Darwin Online

when one of the boats struck upon a reef, and was lost, but the people were saved. The loss of this boat caused them to give up every hope of saving themselves in that way; and Viedma, with Suarez, the friar, and twenty soldiers, returned in the remaining boat to San Felipe, leaving the rest of the party, consisting of thirty men and five women, to support themselves through the approaching winter as they could. After that season had passed, Viedma sent to collect the wanderers; but fifteen men, and three women only, could be found; the rest having died of hunger and disease. The survivors then determined upon going to the first establishment at Jesus; on their way to which they passed by the skeletons of the two hundred who had been first detached. Travelling onwards, they observed three ships entering the strait, which anchored at a distance to the southward.

During the night, Viedma and his companions kept up large fires, supposing that the ships belonged to their own nation. Next morning a boat was despatched from them; and three of Viedma's party obtained permission to go and reconnoitre her. Having approached near enough, a signal was made; upon which, the people in the boat pulled towards the beach, and said they were from England, bound to Peru, and that if the Spaniards wanted a passage, they had better embark. After some hesitation, arising from the fear of trusting themselves in the power of heretics, they consented; and one was permitted to get in, but the other two were left on the beach. In the boat was the enterprizing Cavendish* himself, who, on hearing the particulars of their story, sent the other two soldiers to Viedma, offering to take him and the residue of his people on board. Cavendish returned to his ship; but, without further delay, sailed on to the Isla dos Patos (Santa Magdalena Island), where he leisurely salted down six casks of penguins; and then proceeded to San Felipe, for wood and water; he remained there four days (during which time he destroyed the houses of the Spaniards, and embarked six guns); and thence continued his voyage. The person saved

* Formerly spelled 'Candish.'

© The Complete Work of Charles Darwin Online

by Cavendish, whose name was Tomé Hernandez, afterwards escaped from him at Quintero, near Valparaiso; and, proceeding to Peru, gave an account of the fate of this cruelly neglected colony.

This was the first, and perhaps will be the last, attempt made to occupy a country, offering no encouragement for a human being; a region, where the soil is swampy, cold, and unfit for cultivation, and whose climate is thoroughly cheerless.

The name, San Felipe, ceased with the colony; for Cavendish called it Port Famine, in allusion to the fate of the colonists, all of whom, except the man he took away, and one saved two years afterwards (in 1589), by Andrew Mericke,* perished from hunger and its attendant diseases; and by this appellation the bay has since been universally known. To commemorate the ill-fated town, a very thickly-wooded mountain at the bottom of the bay, which forms a conspicuous and picturesque object, has been named by us Mount San Felipe.

At this port, Sarmiento, on his first voyage through the Strait, communicated with a large party of Indians, in consequence of which he called it Bahia de la Gente; and the river, which now bears the name of Sedger, he named San Juan. Of this river Sarmiento took formal possession, as well as of the whole Strait, for the 'Mui Poderoso y mui Católico Señor Phelipe Segundo,' &c. &c. It was also here that, in consequence of the miraculous preservation of his vessel on many

* "Near to Port Famine they took on board a Spaniard, who was the only one then remaining alive of the garrison left in the Strait by Sarmiento. The account given by this man, as reported by Magoths, is, that he had lived in those parts six years, and was one of the four hundred men sent thither by the King of Spain in the year 1582, to fortify and inhabit there, to hinder the passage of all strangers that way into the South Sea. But that town (San Felipe) and the other Spanish colony being destroyed by famine, he said he had lived in a house, by himself, a long time, and relieved himself with his caliver(*b*) until our coming thither." Burney, ii. p. 96. This man died on the voyage to Europe Id. p. 97.

(*b*) A kind of gun —R. F.

occasions, he attempted to change the name of the strait to Estrecho de la Madre de Dios; but it had been too long called Magalhaens, for even the influence of Sarmiento, backed by the power of Philip, to persuade the world to countenance so great an injustice.

> " Magallanes, Señor, fué el primer hombre
> Que abriendo este camino le dió nombre."
>
> Ercilla Araucana, Cant. I. oct. 8.

During an excursion with Mr. Tarn to Eagle Bay,* beyond Cape San Isidro, we found many wigwams. They were then novelties to us, and we were ignorant of their being such certain indications of very sheltered places, as subsequent experience has shown them to be. We often used them, after they had been well cleaned out: a boat's sail, thrown over the hemispherical roof, was a sufficient protection from rain;—and from wind they are always well defended by their situation. Here we saw, for the first time, that most remarkable bird the Steamer-duck. Before steam-boats were in general use, this bird was denominated, from its swiftness in skimming over the surface of the water, the 'race-horse,' a name which occurs frequently in Cook's, Byron's, and other voyages. It is a gigantic duck, the largest I have met with. It has the lobated hind-toe, legs placed far backwards, and other characteristics of the oceanic ducks.† The principal peculiarity of this bird is, the shortness and remarkably small size of the wings, which, not having sufficient power to raise the body, serve only to propel it along, rather than through the water, and are used like the paddles of a steam-vessel. Aided by these and its strong, broad-webbed feet, it moves with astonishing velocity.

* So named by Bougainville.

† It belongs to the group which M. Temminck has lately named *Hylobates*, without attending to the name long since conferred upon it by Dr. Fleming. I designated it *Oidemia Patachonica*, from its large dimensions, in my communication upon the Ornithology of the Straits. Zoological Journal, vol. iv. p. 100. On my return to England, I found that M. de Freycinet had figured this bird, in the account of his last voyage in l'Uranie, where it is described by Messrs. Quoy and Gaimard under the name of *Micropterus brachypterus*.

© The Complete Work of Charles Darwin Online

It would not be an exaggeration to state its speed at from twelve to fifteen miles an hour. The peculiar form of the wing, and the short rigid feathers which cover it, together with the power this bird possesses of remaining a considerable length of time under water, constitute it a striking link between the genera *Anas* and *Aptenodytes*. It has been noticed by many former navigators. The largest we found measured forty inches, from the extremity of the bill, to that of the tail, and weighed thirteen pounds; but Captain Cook mentions, in his second voyage, that the weight of one was twenty-nine pounds.* It is very difficult to kill them, on account of their wariness and thick coat of feathers, which is impenetrable by any thing smaller than swan shot. The flavour of their flesh is so strong and fishy, that at first we killed them solely for specimens. Five or six months, however, on salt provisions, taught many to think such food palatable, and the seamen never lost an opportunity of eating them. I have preferred these ducks to salt-beef, but more as a preventive against scurvy, than from liking their taste.

I am averse to altering names, particularly in natural history, without very good reason, but in this case I do think the name of 'steamer' much more appropriate, and descriptive of the swift paddling motion of these birds, than that of 'race-horse.' I believe, too, the name of 'steamer' is now generally given to it by those who have visited these regions.

Many shells† were taken from the bottom by means of a fizgig which Mr. Tarn found in one of the wigwams: it was a

* Cook's Second Voyage, 4to. p. 570.

† On the shores of Eagle Bay we procured a large collection of shells, among which were *Margarita violacea* (Nob. in Zool. Journ. v. 346, No. 53), a beautiful *Modiola* (*M. trapesina*, Lam.ᵏ), a new *Pecten* (P. vitreus Nob. in Zool. Jour. v. 337, No. 17), and a delicate transparent-shelled *Patella*, answering the description of *P. cymbularia*. These four species were found attached to floating leaves of the kelp (*Fucus giganteus*), and afford food to the steamer-duck. We also collected good specimens of *Murex Magellanicus*, Lam.ᵏ, of *Fissurella picta*, Lam.ᵏ, and a great number of the common patella of the Strait, which forms a considerable article of food for the Natives.

© The Complete Work of Charles Darwin Online

rough pole, eight or ten feet long, split crosswise at one end, and opened so as to form four prongs, kept apart by two small pieces of wood. Although rudely made, it was excellently adapted for a shell-gatherer, and is used by the Indians for collecting sea-eggs, which are found in the Strait of very large size, and are doubtless, to them, a great delicacy.

During our excursion we ascertained the best place to ascend the snowy mountain, since named 'Tarn;' and the surgeon, whose name it bears, set off with a party of officers to make the attempt, in which he succeeded, and obtained such an extensive view as induced me to decide upon ascending it, a few days afterwards, to procure bearings from the summit, and for the purpose of measuring its height with a barometer.

In the meantime I visited the Sedger river (Sarmiento's 'Rio de San Juan de Posesion'), and found some difficulty in entering it, because of several banks which are dry at low water. Between them, however, the stream keeps a small channel open, by which we effected our purpose. Every gale of wind causes the banks to shift, and between the times of our first, and last, visit to Port Famine, the river's mouth underwent many changes. The bed of the river is so full of fallen trees, that we could not go, with the boat, more than three miles and a half above the entrance; there it was about fifteen yards wide, bounded on each side by thickly wooded banks, of moderate height. The trees on these banks are large, chiefly the two species of Beech before-mentioned, and Winter's-bark; there are besides many shrubs, and an impenetrable underwood of Arbutus, Berberis, and currant bushes. The largest Beech-tree that we saw could not have been more than thirty or forty inches in diameter, which was insignificant compared with those noticed by Commodore Byron. In describing his excursion up this river, he mentions "trees that would supply the British navy with the best masts in the world."* "Some of them are of a great height, and more than eight feet in diameter, which is proportionably more than eight yards in circum-

* Byron's Voyage round the World, 4to. p. 38.

© The Complete Work of Charles Darwin Online

ference."* The Commodore may have been pleased by the appearance of these trees, but must have fancied their quality and dimensions such as he describes. The largest are generally rotten at the heart, and all are more or less defective. Their wood is heavy, and far too brittle for masts: we could not use it even for boat-hook staves. It makes, however, tolerable plank for boat-building, and, when seasoned, might be used in ships. For common purposes, such as houses, or fences, it is very serviceable.

We wandered about to examine the country; but, excepting the track of some quadruped, whose foot was small and cloven, rather like a pig's, we saw nothing new. The traces of foxes were numerous every where. We found no fish of any description in the river. Geese and wild ducks were numerous, whose young were at this time scarcely fledged, and an easy prey. We also observed here, for the first time, the parroquet, which Bougainville described to be common in the Strait. He carried specimens home with him; but some naturalists of those days decided that there must have been a mistake, because, as they averred, parroquets did not exist in so high a latitude. Bougainville, however, made no mistake, for the species† is very abundant in the neighbourhood of Port Famine, and has been seen by us in all parts of the Strait. It feeds principally upon the seeds of the Winter's-bark. The existence of this bird in Tierra del Fuego is also mentioned by Cook and Narborough.*

* I. c.

† *Psittacus smaragdinus*, Gmel. I have no doubt that the bird we saw is the same as Bougainville procured, and from which a description has been given in the Ency. Méth., art. Ornith. 139; although a material error is made, for they are not *splendidé viridis*, nor is the *uropygium* red; in other points, however, the description is correct. See Buffon's Hist. Nat. des Oiseaux, vi. 262. Pl. enl. n. 85, Perruche des Terres Magellaniques.

* Bougainville says, "we have likewise perceived some perrokeets: the latter are not afraid of the cold." To which the English translator, T. R. Forster, who is incredulous of the correctness of Bougainville's assertion, appends the following note: "Perruches, probably sea-parrots, or

© The Complete Work of Charles Darwin Online

All accounts of Port Famine informed us of its abounding in fish, but as yet we had taken none excepting with hook and line, although the seine had been frequently shot. At last, however, in the first week of February, we had a successful haul of mullet and smelts, many of the former weighing eight pounds, and the latter measuring fifteen inches in length. After this we were often very fortunate, and on one occasion caught, at one haul of the seine, sixteen hundred-weight of smelts, some weighing two pounds, and measuring twenty inches in length. A few days previously we had a draught of mullet, which served the crews of both Adventure and Beagle for three days. Geese, wild ducks and teal, snipe, and now and then woodcocks, were to be found by taking a short walk; there were, however, no quadrupeds fit for food which we could take. Foxes and wild cats were occasionally seen, and a foot-mark of some large animal of the feline race, probably a puma, was once observed upon the beach. We found many traces of horses, which showed that the Patagonian Indians sometimes come thus far south. Had we been so fortunate as to meet them here, we might have procured, perhaps, a regular supply of guanaco meat.

On the 9th of February, as the weather seemed favourable for ascending Mount Tarn,* Lieutenant Cooke, the Surgeon, and Anderson, the botanical collector, set off in advance to select a convenient place for passing the night, carrying with them a tent and provisions. I followed later in the day, and, while the boat's crew were arranging their loads, made some observations with a barometer on the beach.

Our way led through thick underwood, and then, with a gradual ascent, among fallen trees, covered with so thick a coating of moss, that at every step we sunk up to the knees

or auks." Buffon also doubted the fact, and the author of Histoire Naturelle, art. Oiseaux, tom. ii. p. 322, suggests the possibility of a specimen having been obtained in some other part of the world, and put, by mistake, amongst those collected in the Strait.

* So named because Mr. Tarn, the surgeon of the Adventure, was the first person who reached its summit.

© The Complete Work of Charles Darwin Online

before firm footing could be found. It was very laborious work, and the ground being saturated, and each tree dripping with moisture, we were soon wet through. We proceeded along the same sort of road up a steep ascent; some one of the party constantly falling into deep holes covered by moss, or stumbling over fallen trunks of trees. As I carried a barometer I was obliged to proceed with caution, and succeeded in emerging from this jungle without accident. After about three quarters of an hour spent in this way, we reached an open space, where we rested, and I set up the barometer. Here we found a cypress of very stunted growth.

Our road hence was rather more varied: always steep, but sometimes free from impediment. Here and there we observed the boggy soil was faced with a small plant (*Chamitis sp.*) of a harsh character, growing so thick and close as to form large tufts, over which we walked as on hard ground. We struggled through several thickets of stunted beech-trees, with a thick jungle of Berberis underneath, whose strong and sharp thorns penetrated our clothes at every step; and began to find the fatigue very oppressive: some of my boat's crew suffered much, being unused to such exercise. At last we approached the place where Mr. Cooke and his party had established themselves, and upon hailing, were invigorated by a cheer in reply. We reached the bivouac in a very way-worn condition, and found, to our great comfort, the tent pitched, and a good fire burning.*

The ground was so exceedingly wet, that although we slept upon branches, forming a layer at least a foot thick, we found ourselves, in the night, lying as if in a morass, and suffering from cold, even with a large fire blazing at our feet. At day-light next morning, just as we were starting, a boat was seen sailing round Cape San Isidro, which, by the aid of a telescope, I made out to be the Hope.

We resumed the ascent, and passed over, rather than through, thickets of the crumply-leaved beech, which, from

* The height of this place, as shown by the barometer, on the ascent, was 941 feet, and, on the descent, 973 feet.

© The Complete Work of Charles Darwin Online

their exposure to the prevailing winds, rose no higher than twelve or fourteen inches from the ground, with widely-spreading branches, so closely interwoven, as to form a platform that bore our weight in walking. We next traversed an extent of table-land,* much intersected by ponds of water. Mr. Tarn shot two plovers of a new species (*Charadrius rubecola*, Zool. Jour. vol. iv. p. 96), and a snipe. We then ascended three or four hundred feet, and crossed a deep ravine. The bottom of the ravine was clay-slate in a decomposing state, but the surface of the ground was strewed with pebbles of granite. Another plain, with many ponds, succeeded; the intervening spaces being covered with tufts of chamitis, and studded here and there with small clusters of dwarf beech; but the ground was so hard, and firm, that we proceeded rapidly, without fatigue, until we attained the height of 1,800 feet, when the ascent became very steep. Near the summit lay a large mass of snow, rapidly melting away. We reached the highest pinnacle of the mount at seven o'clock (having left our resting-place at four), and immediately set up the instruments. I was obliged to avail myself of Mr. Tarn's assistance to hold the barometer, whilst two of my boat's crew held the legs of the theodolite-stand, for the wind was blowing very strongly, and the edge of a precipice was close to us, perpendicular for many hundred feet, and thence downwards so steep, that any body going over would fall at least a thousand feet. The theodolite-stand was unavoidably placed within a very few inches of the edge, and I took a round of angles, suffering, however, intense pain from the piercing coldness of the wind, which, heated as we were by the ascent, was much felt, though the temperature was not lower than 39°. I was lightly clothed, and should have fared badly, had not one of the party lent me his Flushing jacket, while he descended under the lee of the mountain-top to make a fire. The barometer stood at 26, 618, the temperature of the air being 40°, and of

* On this table-land the barometer stood at 27,767. Temperature of the air 46°,5, and of the mercury 47°,5, which gave the elevation 1,327 feet.

© The Complete Work of Charles Darwin Online

the mercury 43°.* Unfortunately the day was very cloudy, and many squalls of sleet and rain, which obscured the hills, passed whilst I was taking bearings. To the N.E., towards the supposed Sebastian Channel, the horizon was too hazy to allow much view. A deep inlet was seen in that direction; but whether the land closed round, or whether a channel was at the bottom, we could not distinguish. A considerable body of water was observed to the southward of Cape St. Valentyn, behind Lomas Bay, but its extent was screened from our view by the intervention of the Lomas hills. It appeared to be a channel, the opposite or eastern side of it being formed by the high ranges previously seen from Point St. Mary. Cordova's Ports San Antonio and Valdez were distinctly made out; but, to the southward, every thing was enveloped in mist.

The bearings and observations, which occupied me nearly two hours, being completed, we all adjourned to a sheltered cleft in the rock close to our station, where we soon recovered the use of our fingers.†

* The result of the barometric observation for the height of Mount Tarn is as follows:

Height by one barometer	ascent 2,567·7 / descent 2,625·4	mean 2,596·5 feet.	
Do. two do.	ascent 2,619·3 / descent 2,596·7	—	2,608·0
			2,602·2

By angular measurement from Observation Cove, Port Famine, with theodolite, allowing $\frac{1}{13}$ of the intercepted arc for terrestrial refraction, the height is 2,850 feet.

Another observation, with the sextant, made it 2,855 feet. The mean 2,852 I consider more correct, from the difficulty of obtaining a correct reading of the barometer on the summit.

† By Daniell's hygrometer, used in this sheltered spot, I found the temperature of the air to be 48°; dew point 41°: but upon exposing the instrument to the wind, the air was 39½°, and the dew point 36°: the difference in the former being 7°; and the latter 3½°; from which the following results are obtained:

	air.	dew pt.	diff.	exp.	dryness.	weight of a cubic foot of air.
In the ravine	48	41	7	292	776	3·323
Exposed to wind	39½	36	3½	248	898	2·871
Difference	8½	5	3½	44	122	0·452

The

© The Complete Work of Charles Darwin Online

Having accomplished our object, we began the descent. In a comparatively mild and agreeable spot, I again set up the theodolite and barometer, while some of the party employed themselves in fruitless attempts to kindle a fire. The height, by the barometer, proved to be 1,845 feet above the sea; and the bearings from this station were much better than those I had taken from the exposed summit.

We reached our tent at noon, having been absent seven hours. At three we reached the beach, where the barometer stood at 29,312 (air 61.°3,* and mercury 62,°5).

Excepting near the sea, where clay-slate (very similar to that of Point St. Anna, but with an opposite dip) showed itself, the side of the hill is clothed with trees and underwood, and no rock is visible until one arrives at the ravine. Around the summit of Mount Tarn the ground is bare, but so covered with small decomposed fragments, that the solid rock only appears occasionally: it is very hard, and breaks with a conchoidal fracture: some of the specimens which we detached bore indistinct impressions of organic remains. We also found, projecting from the rock in which they were embedded, nodules, or small rounded masses of stone, in an advanced state of decomposition, mouldering away in laminar forms somewhat resembling the inner leaves of a cabbage. Several were brought away carefully, but before we arrived on board they had crumbled to pieces: the nucleus was quite hard, but was surrounded by concentric laminæ, more brittle the nearer they approached to the outer surface. It seemed as if the face of the summit

The above being the difference in the short space of three feet apart; the instrument, in the first case, being just under the lee of the rocky summit of the mountain, and in the last, above it, exposed to the wind.

* The air was so dry this afternoon that I failed to procure a deposit of dew upon Daniell's hygrometer, although the internal temperature was lowered from 61° to 37°. One of Jones's portable hygrometers was also tried, and the temperature was lowered to 31°½ without a deposit; so that, the difference being more than thirty degrees, the expansive force of the air must have been less than 212, the dryness, on the thermometric scale, less than 367, and the weight of vapour, in a cubic foot of air, less than 2,355 grains.

© The Complete Work of Charles Darwin Online

above-mentioned was covered with the decomposing fragments of these nodules.

The highest parts of the Mount form a ridge extending S. E. and N.W., being a succession of strata of slaty rock, dipping to the eastward, at an angle of 15° or 20° from the horizon. The strata are very narrow, and separated from each other by a vein of quartz, much of which is in a crystallized state. We reached the ship about seven o'clock, and found that the Hope and her party had done well. Her cruize proved interesting, with regard to the geography of the Strait, and a summary of it is subjoined.

Mr. Graves's orders were to survey the Sebastian Channel; but in the event of his seeing any thing more interesting to the S.E., he was allowed to defer that service to another opportunity. The Hope crossed the Strait, and anchored in a small bay, formed between the two projecting points of Cape Valentyn, where some few defects in the vessel were remedied, and a good round of angles obtained from the summit of the Cape, whence there was a fine view. The country was low, undulating, and destitute of trees. From a station about two miles overland, to the eastward, a large body of water was observed to the southward, forming a channel, or deep sound, and it was determined to follow up its examination, rather than risk the crew in the deep bay that was supposed to communicate with the San Sebastian Channel, on board a vessel whose capabilities were unknown. Several fire-places and remains of wigwams were seen; the latter were, however, very different, both in shape and material, from those at Port Famine, for the country being destitute of trees, they were built of driftwood, piled up in a conical form.

Passing round Cape Valentyn, the Hope hauled to the southward, keeping the land on board. At night she anchored in Philip Gidley Cove, at the bottom of Willes Bay, where she was weather-bound until the 29th of January. The shores of Willes Bay are thickly clothed with wood, growing to the water's edge, except at the S.W. side. The great abundance of muscles and limpets attracts the Indians, whose wigwams

© The Complete Work of Charles Darwin Online

were found standing, and from the green appearance of the branches with which they were formed, seemed to have been lately erected. After leaving Willes Bay, the Hope visited Fox Bay, and Sir Edward Owen's Sound, which, it was thought, would lead into Lomas Bay, opposite to Port Famine; but, after running ten miles up, they got into shoal water, and as there was no current, or stream of tide, they landed, and found that a mile and a half farther on, the sound was terminated by low land. Another day, while proceeding along the south side of Brenton Sound, the smoke of Indians' fires was noticed near the beach. As this was the first time the Natives of this part had been seen, the course was shaped towards them, until the Hope anchored. Three Indians then approached, holding up the skins of some animal, and inviting them to land. The small boat was hoisted out, and Messrs. Wickham and Rowlett, with Robinson the pilot, went on shore. The Fuegians presented a fox skin to each of the party, who in return gave them some trifles. After a short interview the boat left them, and no further communication was held that night. The following morning a canoe came off to the vessel, containing three young men, two women, and three children, the youngest not more than four months old. They were no sooner alongside than the men went on board, and commenced an active traffic with all the valuables they possessed; and for a few buttons, a glass bottle, or an empty preserved-meat canister, many of their goods were bartered. They had several fox-skins with them, but no other kind of peltry, except their clothing, obtained from the seal or guanaco: and though many of them wore a penguin skin suspended from their girdle, some were without even that covering. This canoe was followed by another, containing an old man, sixty or seventy years of age, with a grey beard; an elderly woman, and two children. Before they came alongside they put their dogs on shore.

Although the visit from these Indians did not last very long, they had time enough to pilfer. One of the young men, who was seen going into a canoe, excited, by his manner, a suspi-

© The Complete Work of Charles Darwin Online

cion of his having stolen something, and a tin pot was found concealed under his mantle. As there was every probability of their soon separating, and Mr. Graves feared that punishment would cause a rupture, he only turned him out of the vessel: the rest soon followed him, and landed. Having made a fire, the men squatted round it; while the women were despatched to collect shell-fish.

As soon as the Natives had finished their meal, they embarked, and proceeded eastward. Next day they again visited the Hope, but in consequence, perhaps, of the occurrence the day before, did not venture alongside, until invited by the words, 'ho-say, ho-say,' which mean, 'come, come.' In a few minutes confidence was restored, and they began to barter. The trade was opened by one of the women making a peace-offering of a shell necklace, in return for which, red caps and medals were given to each of the women and children. The Hope went thence to Soapsuds Cove, where the crew washed their clothes, and replaced a broken spar.

In a S.E. direction from this cove there appeared to be a considerable channel leading to the S.E., and to the southward was a deep sound, towards which they were proceeding the next morning; but having advanced about two miles, the land of Cape Expectation trended suddenly round to the eastward, and a long narrow channel presented itself, which seemed likely to communicate with the Strait, to the southward of Port San Antonio. They proceeded through this channel, which takes a very straight course, and gradually narrows from Port Waterfall, where it is two miles and a half wide, to Passage Cove, where it is scarcely three quarters of a mile; and there they anchored.

Between Port Waterfall and Passage Cove, a party of Natives was seen; but, being probably the same who were met at Indian Cove, no attention was paid to their hallooings and fires of invitation.* The Hope came into the Strait, eastward of an opening then called Magdalen Sound; her passage

* Fires made to attract attention, and invite strangers to land.

© The Complete Work of Charles Darwin Online

must therefore have been through Sarmiento's 'San Gabriel' Channel.

At night, when between Cape Froward and Port San Antonio, a heavy squall from S.W. carried the little vessel rapidly towards Cape San Isidro, and, at daylight the next morning, she was in the position observed by us, while ascending Mount Tarn.

CHAPTER IV.

Deer seen — Hope sails again — Eagle Bay — Gabriel Channel — 'Williwaws' — Port Waterfall — Natives — Admiralty Sound — Gabriel Channel — Magdalen Channel — Hope returns to Port Famine — San Antonio — Lomas Bay — Loss of boat — Master and two seamen drowned.

From Mr. Graves's report of the appearance of the channel to the S.E. of Dawson Island, I decided to proceed there as soon as the Hope was ready, for she required some alteration, and repairs.

A deer having been seen on Point St. Anna, Mr. Tarn landed, very early in the morning, eager for the prize, but could only get an ineffectual shot. At another time a few deer were seen by our party, near the river; but instead of returning with the information, they fired their guns, loaded with small shot only, which served but to scare them away. As the animal was new to us, and we had evidence of its being equally new to Science, I was anxious to procure a specimen, but never afterwards had an opportunity. Here Sarmiento saw the only deer which he mentions in his journal.

The morning of the 16th seeming more favourable, I set out in the Hope. The heights were covered with snow which had fallen the preceding night, the thermometer had been at freezing point, and much ice had formed; but the appearance of the weather deceived us: we had scarcely left the ship, when it began to rain, and by the time we reached Cape San Isidro the wind had freshened to a gale, which obliged me to anchor in Eagle Bay.

Having landed, a tent was pitched, and a blazing fire made to dry our clothes. In the evening the gale blew with great

© The Complete Work of Charles Darwin Online

violence from S.W., and the Hope, at her anchor, sheered about by the squalls, was occasionally laid over so as to dip her gunwale under water.

The following day (17th), although the rain had ceased, the wind was still strong. Towards evening it fell, and early on the 18th we left Eagle Bay with a fresh breeze from E.N.E., and passed close to Port San Antonio; but were then delayed by calms and squalls. At noon a westerly wind sprung up, and we proceeded down the Gabriel Channel, with the wind aft, and the tide in our favour. Port Waterfall sheltered us for the night.

The apparently artificial formation of this channel is very striking. It seems to have been formerly a valley between two ridges of the range, in the direction of the strata (of which there are frequent instances, such as the valley in the Lomas Range, opposite Cape San Isidro, the valley of Valdez Bay, and one immediately to the north of the channel itself, besides many others), and that at some remote period the sea had forced its way through, effecting a communication between the Strait and the waters behind Dawson Island: as if one of those great 'northern waves,' of which we once heard so much, had rolled down the wide reach of the Strait (the parallelism of whose shores is also remarkable) from the north-west, towards Cape Froward; and finding itself opposed by the Lomas Range, had forced a passage through the valley until stopped by the mountains at Fitton Bay. Having imagined such a wave in motion, the reader may fancy it uniting with another northern roller from Cape San Valentyn, attacking the hills and carrying all before it, until Mount Hope, at the bottom of Admiralty Sound, arrested its course. I have already noticed the remarkably straight direction in which this curious channel trends. At both extremities the width may be from two to three miles; but the shores gradually approach each other midway, and the coast on each side rises abruptly to the height of fifteen hundred feet. The south shore, sheltered from the prevailing and strongest winds, is thickly covered with trees and luxuriant underwood, which, being chiefly evergreen, improve

© The Complete Work of Charles Darwin Online

the scenery greatly, particularly in the winter season: the north shore is also well wooded for about two-thirds up; but the summit is barren and the outline very much serrated, as is usual in slate formations.

On the north shore we noticed some extraordinary effects of the whirlwinds which so frequently occur in Tierra del Fuego. The crews of sealing vessels call them 'williwaws,' or 'hurricane-squalls,' and they are most violent. The south-west gales, which blow upon the coast with extreme fury, are pent up and impeded in passing over the high lands; when, increasing in power, they rush violently over the edges of precipices, expand, as it were, and descending perpendicularly, destroy every thing moveable. The surface of the water, when struck by these gusts, is so agitated, as to be covered with foam, which is taken up by them, and flies before their fury until dispersed in vapour. Ships at anchor under high land are sometimes suddenly thrown over on their beam-ends, and the next moment recover their equilibrium, as if nothing had occurred. Again a squall strikes them, perhaps on the other side, and over they heel before its rage: the cable becomes strained, and checks the ship with a jerk, that causes her to start a-head through the water, until again stopped by the cable, or driven astern by another gust of wind.

At all these anchorages, under high land, there are some parts more exposed than others; and by watching for those places which are least troubled by these squalls, a more secure, or rather a more quiet, spot may be selected. I do not consider ships so anchored to be in danger if their ground tackle be good; but every thing that offers a stiff resistance must suffer from the fury of these blasts. In many parts of this country trees are torn up by the roots, or rent asunder by the wind; and in the Gabriel Channel the 'williwaws' bursting over the mountainous ridge, which forms the south side of the channel, descend, and striking against the base of the opposite shore, rush up the steep, and carry all before them. I know of nothing to which I can better compare the bared track left by one of these squalls than to a bad broad road. After

© The Complete Work of Charles Darwin Online

having made such an opening, the wind frequently sweeping through prevents the growth of vegetation. Confused masses of up-rooted trees lie at the lower ends of these bared tracks, and show plainly what power has been exerted.

The southern shore of the channel is formed by the base of that range of hills, which extends, from the eastern side of the Magdalen Channel, towards the E.S.E. It is the highest part of Tierra del Fuego, and on it are several remarkable mountains, besides Sarmiento, towering over all.

Close to the east end of the Gabriel Channel is Mount Buckland, a tall obelisk-like hill, terminating in a sharp needle-point, and lifting its head above a chaotic mass of 'reliquiæ diluvianæ,' covered with perpetual snow, by the melting of which an enormous glacier on the leeward, or north-eastern side, has been gradually formed. This icy domain is twelve or fourteen miles long, and extends from near the end of the channel to Port Waterfall, feeding, in the intermediate space, many magnificent cascades, which, for number andheight, are not perhaps to be exceeded in an equal space of any part of the world. Within an extent of nine or ten miles, there are upwards of a hundred and fifty waterfalls, dashing into the channel from a height of fifteen hundred, or two thousand feet. The course of many is concealed, at first, by intervening trees, and, when half-way down the descent, they burst upon the view, leaping, as it were, out of the wood. Some unite as they fall, and together are precipitated into the sea, in a cloud of foam; so varied, indeed, are the forms of these cascades, and so great their contrast with the dark foliage of the trees, which thickly cover the sides of the mountain, that it is impossible adequately to describe the scene. I have met with nothing exceeding the picturesque grandeur of this part of the Strait.

There are several coves on the south shore, but opposite to them there is no shelter until you reach a deep bay in which are several islets; and where, I think, there is a communication with Brenton Sound, but we did not enter it.

Port Waterfall may easily be known by a large flat-topped bare rock, lying across the summit of the eastern head, and

© The Complete Work of Charles Darwin Online

by a magnificent cascade formed by the union of two torrents.

All the plants of the Strait grow here: a sweet-scented Callixene (*C. marginata*, Lam^k.) filled the air with its odour; and a beautiful flower we had not previously seen, was found by Mr. Graves: it was pendulous, tubular, about two inches long (Class. Hexand. Monog. Cal. 2. Pet. 3. pointed), and of a rich carnation colour.

The trees are small and stunted; they are of the usual species, Beech and Winter's-bark. Here we first noticed a large fern,* having a stem two or three feet long, and five or six inches in diameter, very similar to the Zamia of New Holland. We saw very few birds, and no quadrupeds. Among the former was a king-fisher, which at the time was new to us; but it is distributed over a large tract of South America, and I have since seen a specimen said to have been shot at Rio de Janeiro.

Fitton Harbour is a deep inlet, surrounded on all sides by precipitous land, rising to the height of three, or four thousand feet, and terminated by peaks, of most fantastic shape, covered with ice and snow.

Between Fitton Harbour and Cape Rowlett are high mountains, two of which, more conspicuous than the rest, we called 'Mount Sherrard,' and 'Curious Peak.'

Card Point proved to be clay-slate, and I think the projection of Cape Rowlett, and the mountains, are also of this rock.

While crossing over towards Cape Rowlett, (the south head of a deep sound, trending to the S.E., which it was my intention to examine), we were met by three canoes, containing, together, about twenty-four people, and ten or twelve dogs. Mr. Wickham recognised them to be the same party who had visited the Hope on her last cruize; the thief, however, was not amongst them, fearing probably he might be known.

These natives conducted themselves very quietly, and, except one of the women, who wished to keep a tin-pot in which some

water had been given her, made no attempt to pilfer. One of the party, who seemed more than half an idiot, spit in my face; but as it was not apparently done angrily, and he was reproved by his companions, his uncourteous conduct was forgiven.

If possessed of any furs, they had left them, perhaps concealed, near their wigwams: only a few arrows, a necklace of shells, and a fillet for the head, made of ostrich feathers, were obtained by barter. Their canoes were paddled by the women, occasionally helped by the men. One or two of the former were young, and well-featured, but the rest were hideous; and all were filthy and most disagreeable, from the quantity of seal-oil and blubber, with which they had covered their bodies. After we had obtained, by barter, all the articles they had to dispose of, I presented them with red caps and medals, of which they were very proud: the latter they requested might have a hole drilled through them, that they might be suspended by a string round their necks. Their astonishment was much excited, and they were pleased by hearing a watch tick; but I believe I had very nearly, though unintentionally, given great offence, by cutting off a lock of hair, from the head of one of the men. Assuming a grave look, he very carefully wrapped the hair up, and handed it to a woman in the canoe, who, as carefully, stowed it away in a basket, in which she kept her beads and paint: the man then turned round, requesting me, very seriously, to put away the scissors, and my compliance restored him to good-humour.

The features of these people bore a great resemblance to those of the Patagonian Indians, but in person they were considerably shorter and smaller. The elderly people of both sexes had hideous figures; the children, however, and young men, were well-formed; particularly one of the boys, whom they called 'Yāl-lă-bă,' which, I believe, meant a youth, or a young warrior. The word 'Shērrōo' was used to denote a canoe, or vessel.

They were ill-clothed, with mantles made of guanaco, or otter skins, but not so neatly as those of the Patagonians.

© The Complete Work of Charles Darwin Online

Their bodies were smeared over with a mixture of earth, charcoal, or red-ocre, and seal-oil; which, combined with the filth of their persons, produced a most offensive smell. Some were partially painted with a white argillaceous earth; others were blackened with charcoal; one of the men was daubed all over with a white pigment. Their hair was bound by a fillet of plaited twine, made perhaps with strips of bark, and a few of them had it turned up; but to none did it appear to be an object of attention, except one of the young women, who repeatedly combed and arranged her's with the well-toothed jaw of a porpoise.

During a remarkably calm night, we were frequently startled by the loud blowing of whales, between us and the shore. We had noticed several of those monsters on the previous day, but had never heard them blow in so still a place.

At dawn, a light air carried us towards some broken land to the S.E. of Cape Rowlett, between the eastern trend of which, and the projecting point of an island, we found a secure and land-locked harbour, with two entrances, one to the north and the other to the south of High Islet. The south side of the port, which I called Port Cooke,* is a narrow strip of land, forming the head of a deep inlet or sound, called† Brook Harbour. It seemed to extend to the base of the high mountainous range, and to be separated only by a narrow isthmus from Fitton Harbour.

We had scarcely been at anchor half an hour when the same party of Fuegians was seen arriving. The men hastened to us in their canoes, as soon as the women had landed, to cover or thatch the wigwams, which they found standing, and to light fires.

We afterwards went ashore, and, sitting down near them, commenced a brisk trade for arrows, skins, necklaces, and other commodities. The furs which covered their backs they parted with, for a few beads, and went quite naked the whole evening.

Among them was a young man, who appeared to be treated

* After the lieutenant of the Adventure.

† At Mr. Tarn's request.

© The Complete Work of Charles Darwin Online

with some deference by the others; he was one of the best-looking of the party; and there was a good-natured smile on his countenance during our communication, while the rest frequently manifested displeasure, even about trifles. He was, at least, the master of one of the two families; his wigwam contained his wife, and two children, his, or his wife's father, and mother, as well as the idiot, and his wife, who, from her appearance, must have been a Patagonian, or else a woman of unusual size among these people. The old woman was very inquisitive, and the man, in a long speech, described to her all the wonders I had shown him, applying to me, from time to time, to point out to her the articles he was trying to describe.

Their dexterity with the sling is extraordinary; and, I should think, when used as a weapon of offence, it must be very formidable. Upon asking the same man to show us its use, he picked up a pebble, about the size of a pigeon's egg, and placed it in the sling; then intimating that he was going to strike a canoe, he turned his back to the mark, and threw the stone in an opposite direction, against the trunk of a tree, whence it rebounded over his head, and fell close to the canoe.

I have seen them strike a cap, placed upon the stump of a tree, fifty or sixty yards off, with a stone from a sling. In using the bow and arrow, also, with which they kill birds, they are very dexterous. The spear is principally for striking porpoises and seals, but is also used in war; and from the nature of the barb, must be an efficient weapon. For close quarters, they use clubs, stones held in the hand, and short wooden daggers, pointed with very sharp-edged quartz, pitch-stone, or flint.

The next morning, seeing us underweigh, they came alongside and tried to induce us to anchor again. The young man, of whom I have spoken, was very importunate, and at last offered us his wife, as a bribe, who used all her fancied allurements to second his proposal.

So highly did they esteem beads and buttons, that a few of each would have purchased the canoe, the wife, and children,

© The Complete Work of Charles Darwin Online

their dogs, and all the furniture. Seeing us proceed to the southward, with the apparent intention of sailing down the inlet, they motioned to us to go to the north, repeatedly calling out 'Sherroo, sherroo,' and pointing to the northward; which we thought intimated that there was no passage in the direction we were taking.

At noon, I landed to observe the latitude, and take bearings down the Sound to the S.E., at the bottom of which was a hill, standing by itself, as it were, in mid-channel. The view certainly excited hopes of its being a channel; and as we had begun to calculate upon reaching Nassau Bay in a few days, we named this hill, Mount Hope.

The point on which we landed was at the foot of a high snow-capped hill, called by us Mount Seymour; whence, had not the Indians been near, I should have taken bearings.

We sailed south-eastward, close to the south shore, until the evening; when from the summit of some hills, about three hundred feet above the sea, we had a view down the Sound, which almost convinced us it would prove to be a channel. The rock at this place differed from any we had seen in the Strait. The mountains are high, and evidently of clay-slate; but the point, near which we anchored, is a mass of hard, and very quartzose sand-stone, much resembling the old red sand-stone formation of Europe, and precisely like the rock of Goulburn Island, on the north coast of New Holland.*

The following morning (23d), we proceeded towards Mount Hope, while running down to which some squalls passed over, clouding the south shore, and as we passed Parry Harbour it bore so much the appearance of a channel, that we stood into it; but the clouds clearing away soon exposed the bottom to our view, where there seemed to be two arms or inlets. In the south-eastern arm, the shores were covered with thick ice (like the bottom of Ainsworth Harbour, to the west of Parry Harbour, where an immense glacier slopes down to the water's edge). The south-west arm appeared to be well sheltered, and if it affords a moderate depth of water, would be an excellent harbour.

* King's 'Australia,' vol. i. p. 70; also vol. ii. pp. 573, 582, and 613.

© The Complete Work of Charles Darwin Online

After satisfying ourselves that there was no channel here, we bore up on our original course; but, before long, found ourselves within two miles of the bottom of the Sound; which is shallow, and appears to receive two rivers. The great quantity of ice water, which mingles here with the sea, changed its colour to so pale a blue, that we thought ourselves in fresh water.

Mount Hope proved to be an isolated mass of hills, lying like the rest N.W. and S.E., having low land to the southward, over which nothing was visible except one hill, thirty or forty miles distant, covered with snow, to which the rays of the sun gave the appearance of a sheet of gold. Finding ourselves embayed, we hastened out of the scrape, and, after beating for some hours, anchored in Parry Harbour.

Our entrance into a little cove in Parry Harbour disturbed a quantity of ducks, steamers, shags, and geese. Their numbers showed that Indians had not lately visited it.

Next day we reached Ainsworth Harbour, which is of the same character as Parry Harbour, and affords perfect security for small vessels: by dint of sweeping, we reached a secure anchorage in a cove at the south-east corner.

The bottom of the port is formed, as I before said, by an immense glacier, from which, during the night, large masses broke off and fell into the sea with a loud crash,* thus explaining the nocturnal noises we had often heard at Port Famine, and which at the time were thought to arise from the eruption of volcanoes. Such were also, probably, the sounds heard by the Spanish officers during their exploration of the Straits, whilst in the port of Santa Monica, where they had taken refuge from a violent gale of wind.†

* At high tide the sea-water undermines, by thawing, large masses of ice, which, when the tide falls, want support, and, consequently, break off, bringing after them huge fragments of the glacier, and falling into the still basin with a noise like thunder.

† "En los dias 24, y 25, oimos un ruido sordo, y de corta duracion, que, por el pronto, nos pareció trueno; pero habiendo reflexîonado, nos inclinamos à creer que fué efecto de alguna explosion subterranea, formado

© The Complete Work of Charles Darwin Online

The harbour was full of fragments of ice, the succeeding morning, drifting into the Sound, where the sea-water, being at a higher temperature than the air, rapidly melted them.

Since our departure from Port Waterfall, the weather had been mild, clear, and settled; but as it wanted only three days of the change of the moon, at which period, as well as at the full, it always blew a gale, I wished to reach a place of security in the Gabriel Channel or Magdalen Sound.

Near the islands of Ainsworth Harbour, three canoes passed us, steering across the Sound, each with a seal-skin fixed up in the bow for a sail; and we recognised in them the party left at Port Cooke, among whom was the Indian who had been detected in stealing a tin pot. They did not come along-side; but as we went by, pointed to the north, apparently urging us to go in that direction.

We had noticed several wigwams at Parry and Ainsworth Harbours, which shows that they are much frequented by Indians, perhaps on their way to the open low country east of Mount Hope, where numerous herds of guanacoes may be found.

Porpoises and seal were not scarce in this inlet, and in the entrance there were many whales. The presence of seal and whales made me think it probable there was a channel; but I believe every person with me was satisfied of its being a sound, terminating under Mount Hope. Since my later experience of the deceptive character of some passages in Tierra del Fuego (the Barbara Channel, for example), I have felt less certain that there may not be a communication with the low land, behind Mount Hope, round its northern base. The improbability was, however, so great,—from the bottom of the sound

formado en el seno de alguna de las montañas inmediatas, en que parece haber algunos minerales, y aun volcanes, que están del todo ó casi apagados, moviéndonos a hacer este juicio, el haberse encontrado, en la cima de una de ellas, porcion de materia compuesta de tierra y metal, que en su peso, color, y demas caracteres, tenia impreso el sello del fuego activo en que habia tomado aquel estado, pues era una perfecta imagèn de las escorias del hierro que se ven en nuestras ferrerías.—*Apendice al Viage de Cordova al Magallanes*, p. 65.

© The Complete Work of Charles Darwin Online

being shoal,—from the very slight tide-stream,—and from the information of the Natives; who evidently intended to tell us we could not get out to sea,—that we did not consider it worth while to make another examination.

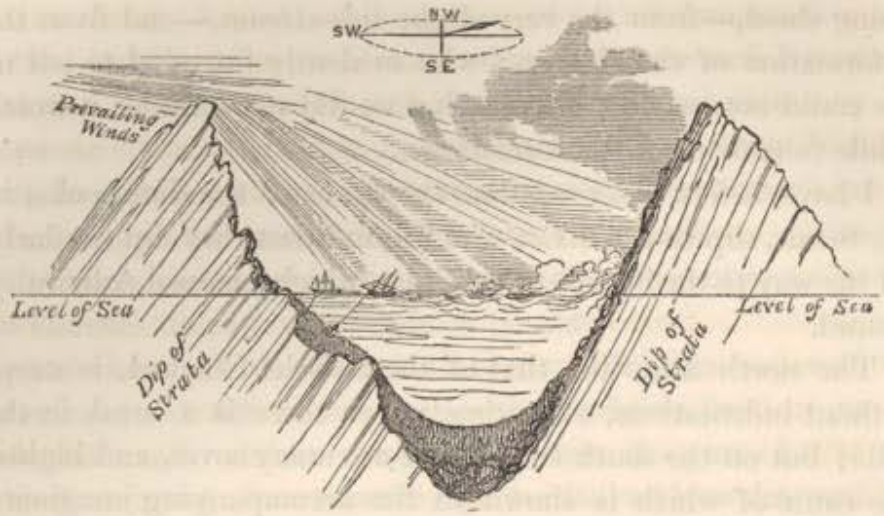
I have before observed that the strata of the slate rocks, in the Strait, dip to the S.E.; and I found that they dip similarly all the way to the bottom of this inlet, which I named Admiralty Sound.

The north side, like that of the Gabriel Channel, is steep, without indentations, excepting where there is a break in the hills; but on the south shore there are many coves, and bights, the cause of which is shown in the accompanying imaginary section of the Gabriel Channel. The same cause operates on the outline of the north shore of the reach of Cape Froward, westward as far as Cape Holland, where the rock assumes a still more primitive form. Its general character, however, is micaceous slate, with broad veins of quartz; the latter being particularly conspicuous at Port Gallant.

The following slight sketch, intended to represent an imaginary section of such an opening as the Gabriel Channel, may also serve to give a general idea of many Fuegian anchorages;—of deep water passages existing between the almost innumerable islands of Tierra del Fuego;—and of the effects of those sudden, and violent gusts of wind,—so frequent and dangerous,—commonly called hurricane-squalls,* or williwaws.

* No canvas could withstand some of these squalls, which carry spray, leaves, and dirt before them, in a dense cloud, reaching from the water to the height of a ship's lower yards, or even lower mast-heads. Happily their duration is so short, that the cable of a vessel, at anchor, is scarcely strained to the utmost, before the furious blast is over. Persons who have been some time in Tierra del Fuego, but fortunate enough not to have experienced the extreme violence of such squalls, may incline to think their force exaggerated in this description: but it ought to be considered, that their utmost fury is only felt during unusually heavy gales, and in particular situations; so that a ship might pass through the Strait of Magalhaens many times, without encountering one such blast as has occasionally been witnessed there.—R.F.

© The Complete Work of Charles Darwin Online



The rock, of course, decomposes equally on both sides; but on that exposed to the south wind, it breaks off in flakes parallel to the direction of the strata, and therefore does not make the course of the beach more irregular; while on the other side it moulders away transversely to the direction of the dip, leaving holes, in which water lodges, and hastens decomposition by entering deeply into the interstices. Water, air, and frost decompose the rock, and form a soil, which, if not too much exposed to the wind, is soon occupied by vegetation.

The rugged faces of the cliffs, on the southern shore, caused by the rock decomposing across the grain, collect sand and mud; and hence it happens that anchorages are frequently found on one side, whilst, on the other, the anchor will not hold, from the steepness of the ground; there being nothing upon the smooth declivity to retain mud and sand before it gets to the bottom; which, in most cases known to me, lies far beyond the reach of the anchor.

After a tedious and difficult passage through the Gabriel Channel, we anchored in a snug harbour within the entrance of Magdalen Channel, on the west side, under a peaked hill called by Sarmiento 'El Vernal,'—in our plan, the 'Sugar-loaf.' The entrance is about a quarter of a mile wide; but after a few hundred yards the harbour opens, extending in for nearly a mile. It is of easy depth; seven fathoms in the entrance, and four, five, and six fathoms within; so that it is

© The Complete Work of Charles Darwin Online

very convenient for a small vessel: to us, indeed, it was a most welcome discovery. The land rises, around this cove, to the height of two or three thousand feet. It is covered with Beech, and Winter's-bark, and near the water is adorned with large groves of Fuchsia, Berberis, and the common shrubs of Port Famine, growing so thickly as to form an almost impenetrable jungle; but, notwithstanding the picturesque character of its scenery, the towering height of the hills, which exclude the sun's rays for the whole day, during the greater portion of the year, renders it a gloomy and melancholy spot.*

We found a family of Fuegians in the inner harbour. Three canoes were hauled up on the beach, but their owners were not at first visible. At last, after our repeatedly calling out 'Ho-say, ho-say,' they appeared, and, rather reluctantly, invited us, by signs, to land. There seemed to be fourteen or fifteen people, and seven or eight dogs. Mr. Wickham and Mr. Tarn went on shore to these natives, who exhibited some timidity, until a hideous old woman began to chatter, and soon made them understand that the young men (Lā-ā-pas) were absent on a hunting excursion, but were every moment expected to return. There were only three men with the women and children. To inspire them with confidence in our good intentions, Mr. Wickham gave each man a red cap, and some other trifles. One of them complained of being sick, but I rather imagine his illness was feigned, and the others did not at all seem to like our visit. By degrees their fears subsided, and, restraint being laid aside, an active trade began; in which several otter skins, shell-necklaces, spears, and other trifles, were obtained from them in exchange for beads, buttons, medals, &c. The otters are caught by the help of dogs, on which account, principally, the latter are so valuable.

These people were slightly clothed with skins of the seal and otter, but some had pieces of guanaco mantles over their shoulders, whence we supposed that they were either of the same tribe, or at peace, with the Indians of Admiralty Sound:

* "sub rupe cavatâ
Arboribus clausam circum atque horrentibus umbris."

© The Complete Work of Charles Darwin Online

unless, indeed, they trade with the Patagonian Indians; but such is the poverty of the Fuegians, they can scarcely possess any thing of value sufficient to exchange with the goods of their northern neighbours, unless it be iron pyrites, which I think is not found in the open country inhabited by the Patagonian Indians, and, from the facility with which it yields sparks of fire, must be an object of importance.

We were not a little amused by the surprise which these natives showed at the things in our possession, and by the effect produced in their countenances when they saw any thing extraordinary: the expression was not that of joy or surprise, but a sort of vacant, stupified, stare at each other. They must have been very suspicious of our intentions, or very much excited by what they had seen during the day, as throughout the night an incessant chattering of voices was heard on shore, interrupted only by the barking of their dogs.

Looking down the Magdalen Inlet, we saw two openings, which, while the hills were enveloped in mist, had the appearance of being channels. We proceeded for some distance into the more westerly of the two, but found that it was merely a sound, terminated by high land. The boat was then steered under a steep mass of black mountainous land,* the summit of which is divided into three peaks, which Sarmiento called 'El Pan de Azucar de los Boquerones' (the Sugar-loaf of the Openings). We ran southward, fifteen miles down this sound, and reached the Labyrinth Islands; but finding there no suitable anchorage, resumed our course towards the bottom of what we thought another sound, terminated by mountains. At noon, the furthest point, on the west shore, which we called Cape Turn, was within three miles of us, and we should soon have discovered the continuation of the channel (as it has since been proved); but a breeze set in from the S.W., and in a short time it blew so strong as to oblige us to turn back. 'Williwaws' and baffling eddy winds kept us seven hours under Mount Boqueron. These squalls were at first alarming, but by taking in all sail, before they passed, we sustained no injury. At sun-

* Mount Boqueron.

© The Complete Work of Charles Darwin Online

set we were abreast of Hope Harbour, in which we purposed taking shelter from the gale. Our late neighbours, the Indians, had lighted a fire at the entrance to invite our return; but wind and tide were against us, and as we knew of no port to leeward, our only resource was to run out of the sound. Furious squalls carried us into the true, or steady, wind, which we found very strong; and as Port San Antonio was on the lee-bow, we had to carry such a press of sail, that our excellent boat had nearly half the lee side of her deck under water. By daylight we got into smooth water, and, with less wind and better weather, steered for Port Famine. The smoother water enabled us to light a fire and cook a meal, not an unimportant affair, as we had eaten nothing since six o'clock on the preceding morning.

In our absence Mr. Graves had surveyed Lomas Bay, and, after his return, Mr. Ainsworth had crossed the Strait with the gig and cutter to survey Port San Antonio. They were victualled for five days; the gig was manned by my own boat's crew, and the cutter by volunteers: but although they had not come back, we felt no anxiety about their safety, being assured that Mr. Ainsworth would not run the risk of crossing the Strait during bad weather. The tempestuous state of the two following days, however, made us uneasy, and on the third morning, when the wind moderated much, we looked out anxiously for their arrival. In the evening the cutter returned; but, alas! with the melancholy information of the loss of Mr. Ainsworth, and two seamen, drowned by the upsetting of the gig. One of the latter was my excellent coxswain, John Corkhill. The remainder of the gig's crew were only rescued from drowning by the strenuous exertions of those in the cutter.

Mr. Ainsworth, anxious to return to the ship, thought too little of the difficulty and danger of crossing the Strait during unsettled weather. He set out from Port San Antonio under sail, and, while sheltered by the land, did very well; but as soon as they got into the offing, both wind and sea increased so much that the gig was in great danger, although under only a small close-reefed sail.

© The Complete Work of Charles Darwin Online

The people in the cutter were anxiously watching her labouring movements, when she disappeared! They hastened to the spot—saved three men; but the other two had gone down. Poor Ainsworth was still clinging to the gig's gunwale when his shipmates eagerly approached; but letting go his hold from extreme exhaustion, and being heavily clothed, he sunk from their sight to rise no more.

He had been cheering the drowning crew, and trying to save his companions, till the moment his grasp relaxed. Just before Ainsworth himself let go, Mr. Hodgskin lost his hold, exclaiming, "Ainsworth, save me!" when, exhausted as he was, with one hand he rescued his friend, and, directly afterwards, his strength failing, sunk.

This addition of three people to the already loaded cutter, made her cargo more than was safe, therefore Mr. Williams, who commanded her, very prudently bore up for the first convenient landing-place, and happily succeeded in reaching the only part of the beach, between Lomas Bay and Cape Valentyn, where a boat could land.

The following morning, the weather being more favourable, they crossed under sail to Freshwater Bay, and thence pulled to Port Famine.

This melancholy disaster was much felt by every one. Ainsworth was a deserving officer, and highly esteemed. Corkhill was captain of the forecastle, and had served in the Polar voyages under Sir Edward Parry. On the Sunday following, the colours were hoisted half-mast high, and the funeral service was read after morning prayers: for although to recover the bodies was impossible, their watery grave was before our eyes; and the performance of this last sad duty was a melancholy satisfaction.

> "Ours are the tears, tho' few, sincerely shed,
> When ocean shrouds and sepulchres our dead."

A tablet was subsequently erected, on Point St. Anna, to record this fatal accident.

CHAPTER V.

Lieutenant Sholl arrives—Beagle returns—Loss of the Saxe Cobourg sealer—Captain Stokes goes to Fury Harbour to save her crew—Beagle's proceedings—Bougainville's memorial—Cordova's memorial—Beagle's danger—Difficulties—Captain Stokes's boat-cruize—Passages—Natives—Dangerous service—Western entrance of the Strait of Magalhaens—Hope's cruize—Prepare to return to Monte Video.

The Beagle's time of absence had expired on the 1st of April, and our anxiety, more excited by our recent loss, was becoming painful. I detained the Hope from going upon a service for which she was prepared, in case she might be required to search for our consort: but on the 6th a strange whale-boat was descried pulling towards us from the southward, in which we soon distinguished Lieut. Sholl. His appearance, under such circumstances, of course raised fears for the Beagle's safety; but, on approaching, his gratifying shout, "all's well!" at once removed anxiety.

Mr. Sholl informed me, that the Beagle had picked up a boat, belonging to the schooner 'Prince of Saxe Cobourg,' wrecked in Fury Harbour, at the south entrance of the Barbara Channel; and that she had put into Port Gallant, whence Captain Stokes had gone with the boats to assist the Sealers, leaving Lieut. Skyring on board.

The safety of the Beagle being established, I despatched Mr. Graves, in the Hope, to examine some openings between the Magdalen Channel and the Dos Hermanos of Bougainville.

Several days earlier than I expected, the Beagle made her appearance, and Captain Stokes soon gave me the agreeable intelligence of having succeeded in saving the Prince of Saxe Cobourg's crew. Favoured by the weather, though delayed by his guide having forgotten the way, Captain Stokes reached Fury Harbour in two days, and embarked the master and

© The Complete Work of Charles Darwin Online

crew of the wrecked vessel, with all their personal property, and the greater part of the seal-skins which they had cured. He reached Port Gallant again on the fourth day; sailed immediately in the Beagle, and two days afterwards anchored in Port Famine.

The Prince of Saxe Cobourg, belonging to Mr. Weddel (whose voyage towards the South Pole is so well known), and commanded by Mr. Matthew Brisbane, who accompanied Weddel on that occasion, sailed from England in the summer of 1826, on a sealing voyage. At South Shetland she encountered a continuance of bad weather, was beset by a large body of ice for several days, and received so much damage as to oblige her to run for the Fuegian coast, and anchor in Fury Harbour, at the entrance of the Barbara Channel. There (December 16th, 1826) she was driven on shore by the furious strength of the williwaws, and wrecked. The crew were, however, enabled to save most of the provisions and stores, as well as their three boats. Having made tents, and established themselves on shore, they remained in anxious expectation of the arrival of some vessel which might relieve them; day after day however passed, without succour.

Two boats were despatched to look for any sealing vessel that might be in the vicinity, but after fifteen days' absence they returned unsuccessful. In this interval one of the crew, who had long been sickly, died; and another, in carelessly discharging a musket, exploded twenty pounds of gunpowder, by which he was very much burned. Three of the people being mutinous, were punished by being sent, each to a different island, with only a week's provisions.

Soon afterwards another boat was sent away, which reached Hope Harbour, but found no vessel there. Seven of the people then obtained permission from the master (who kept up a very proper state of discipline), to take the largest whale-boat, and go towards the River Negro. Previous to their departure they drew up articles of agreement for their general conduct, a breach of which was to be punished by the offender being left upon the coast, wherever they might happen to

© The Complete Work of Charles Darwin Online

be. The boat eventually arrived safely at the place of her destination, and the crew entered as volunteers on board of the Buenos Ayrean squadron, at that time engaged in the war with Brazil.

Again a boat was despatched, directed to go westward through the Strait in search of vessels. She had only reached as far as Playa Parda, when the Beagle fell in with her (March 3d, 1827). While passing through the small channels, before entering the Strait, she met several canoes, with Indians, who endeavoured to stop her, and shot arrows at the crew; but, happily, without doing any mischief.

After the last boat's departure, Mr. Brisbane began to build a small vessel, and, while so employed, was visited by a party of natives, who conducted themselves very peaceably, and went away. Their visit, however, gave the shipwrecked people, now much reduced in number,* reason to apprehend the return of a larger body, who might try to possess themselves of the property which was lying about on the shore; they therefore buried a great deal, and took means to preserve the rest by making preparations to repel attack. When Captain Stokes appeared with his two boats, the Sealers flew to their arms, calling out "the Indians, the Indians!" but in a very few minutes excess of joy succeeded to their sudden alarm.

Captain Stokes found the vessel lying on the rocks, bilged, and an utter wreck. The master and crew were extremely anxious to get away, he therefore embarked them, with as much of the property as could be carried, and succeeded (after another night in the boats, and a long pull of eighty miles,) in conveying them safely to the Beagle.

The following is an abstract of Captain Stokes's journal of his cruise to the western entrance of the Strait.

The Beagle sailed from Port Famine on the 15th of January, to explore the Strait westward of Cape Froward, and to fix particularly the positions of Cape Pillar, the rock called West-

* Including the master, there were on board, when cast away, twenty-two persons.

© The Complete Work of Charles Darwin Online

minster Hall, and the Islands of Direction, at the western entrance of the Strait.

For the first night Captain Stokes anchored in San Nicolas Bay, and in the evening examined a harbour* behind Nassau Island, which Bougainville, in the year 1765, visited for the purpose of procuring wood for the French settlement at the Falkland Islands.

On the second night, after a day nearly calm, the Beagle was anchored in a cove to the eastward of Cape Froward, and the next day (17th) passed round the Cape, carrying a heavy press of sail against a dead foul wind. Captain Stokes's account of this day's beat to windward will give the reader an idea of the sort of navigation.

"Our little bay had screened us so completely from the wind, that though, when (at five A.M.) we weighed, the breeze was so light as scarcely to enable us, with all sail set, to clear its entrance; no sooner were we outside, than we were obliged to treble reef the topsails. We continued to beat to windward under a heavy press of sail; our object being to double Cape Froward, and secure, if possible, an anchorage ere nightfall under Cape Holland, six leagues further to the westward. At first we made 'boards' right across the Straits to within a third of a mile of each shore, gaining, however, but little. We then tried whether, by confining our tacks to either coast, we could discover a tide by which we might profit; and for that purpose I began with the north shore, for though we were there more exposed to violent squalls which came down the valleys, I thought it advisable to avoid the indraught of various channels intersecting the Fuegian coast; but having made several boards without any perceptible advantage, we tried the south shore, with such success that I was induced to keep on that side during the remainder of the day.

"And here let me remark, that in consequence of the westerly winds which blow through the western parts of the Straits of Magalhaens, with almost the constancy (as regards

* Bougainville Harbour, better known to Sealers by the name of 'Jack's Harbour.'

© The Complete Work of Charles Darwin Online

direction, not force) of a trade-wind; a current setting to the eastward, commonly at the rate of a knot and three quarters an hour, will be found in mid-channel. The tides exert scarcely any influence, except near either shore; and sometimes appear to set, up one side of the Straits, and down the other: the weather tide is generally shown by a rippling. (*c*)

"Heavy squalls off Cape Froward repeatedly obliged us to clew all up. By day their approach is announced, in time for the necessary precautions, by their curling up and covering with foam the surface of the water, and driving the spray in clouds before them.

"At last we doubled Cape Froward. This Cape (called by the Spaniards El Morro de Santa Agueda), the southernmost point of all America, is a bold promontory, composed of dark coloured slaty rock; its outer face is nearly perpendicular, and whether coming from the eastward or westward, it 'makes' as a high round-topped bluff hill ('Morro').

"Bougainville observes, that 'Cape Froward has always been much dreaded by navigators.'† To double it, and gain an anchorage under Cape Holland, certainly cost the Beagle as tough a sixteen hours' beat as I have ever witnessed: we made thirty-one tacks, which, with the squalls, kept us constantly on the alert, and scarcely allowed the crew to have the ropes out of their hands throughout the day. But what there is to inspire a navigator with 'dread' I cannot tell, for the coast on both sides is perfectly clear, and a vessel may work from shore to shore."

From Cape Holland, the Beagle proceeded to Port Gallant, and during her stay there, Mr. Bowen ascended the Mountain de la Cruz. Upon the summit he found some remains of a glass bottle, and a roll of papers, which proved to be the memorials stated to have been left by Don Antonio de Cordova,

(*c*) While the 'current' runs eastward for many days in mid-channel, or along one shore, it often happens that the 'stream of tide' either sets in a contrary direction, along each side of the Strait, or that it follows only the shore opposite to that washed by the 'current.'—R. F.

† "Voyage autour du Monde." 1767.

and a copy of a document that had previously been deposited there by M. de Bougainville. With these papers was found a Spanish two-rial piece of Carlos III., which had been bent to admit of its being put into the bottle. It was with considerable difficulty that any of the writing could be decyphered, for the papers, having been doubled up, were torn, and the words defaced at the foldings, and edges.

Bougainville's memorial was in Latin. Cordova's, besides a document in Latin, was accompanied by an account of his voyage, written in four languages, Spanish, French, Italian, and English. The legible part of the former was as follows :—

together with a list of the officers of both vessels, and enclosing a memorial of Cordova's former voyage in the Santa Maria de la Cabeza. The originals are placed in the British Museum; but before we finally left the Strait, copies were made on vellum, and deposited on the same spot.

The Beagle left Port Gallant* with a fair wind, which carried her to Swallow Harbour.

The next stopping place was Marian's Cove, a very snug anchorage on the north shore, a few miles beyond Playa Parda. Proceeding thence to the westward, with the wind 'in their teeth,' and such bad weather, that they could only see the land of either coast at intervals, and failing in an attempt to find anchorage under Cape Upright, the Beagle was kept under weigh during a squally dark night.

In that very place, Commodore Byron, with the Dolphin and Tamar, passed the anxious night, which he thus describes:—

"Our situation was now very alarming; the storm increased every minute, the weather was extremely thick, and the rain seemed to threaten another deluge; we had a long dark night before us, we were in a narrow channel, and surrounded on

* One of the feathered tribe, which a naturalist would not expect to find here, a 'humming bird,' was shot near the beach by a young midshipman.—Stokes MS.

© The Complete Work of Charles Darwin Online

every side by rocks and breakers."* The Beagle was under similar circumstances, but the land being known to be high and bold, her danger was not considered so imminent.

Eastward of Cape Upright the water was smooth; but between it and Cape Providence a heavy breaking sea was caused by the deep swell of the Pacific. Captain Stokes found an anchorage the next night in a bay under Cape Tamar; and the following evening very nearly reached another under Cape Phillip; but the darkness of a rainy night, and strong squalls, prevented their attempting to anchor in an unknown place, and the only resource was to bear up for shelter under Cape Tamar, where the previous night had been passed. Even this was a dangerous attempt; they could hardly discern any part of the high land, and when before the wind could not avoid the ship's going much too fast. While running about eight knots, a violent shock—a lift forward—heel over—and downward plunge—electrified every one; but before they could look round, she was scudding along, as before, having fairly leaped over the rock.

It was afterwards found that a great part of the gripe and false keel were knocked away. Captain Stokes's account of this day's beat will give an idea of the difficulties which the Beagle's crew encountered, in working out of the Strait.

January 31st. "The hands were turned up at daylight "up anchor;" but the heavy squalls that came off the high land of the harbour, rendered it too hazardous to weigh, until a temporary lull enabled us to make sail, and re-commence beating to the westward against a dead foul wind, much rain, hard squalls, and a turbulent cross sea.

"The squalls became more frequent and more violent after noon; but they gave, in daylight, sufficient warning, being preceded by dark clouds gradually expanding upwards, until their upper line attained the altitude of about fifty degrees: then came heavy rain, and perhaps hail; immediately after followed the squall in all its fury, and generally lasted fifteen or twenty minutes.

* Hawkesworth's Coll. of Voyages, vol. i. p. 76.

© The Complete Work of Charles Darwin Online

"In working to windward we frequently extended our 'boards' to the south shore (not without risk considering the state of the weather), with the hope of making out Tuesday Bay, or some anchorage thereabout; but the coast was covered with so thick a mist, that not a single point, mentioned by preceding navigators, could be recognised.

"About seven in the evening we were assailed by a squall, which burst upon the ship with fury far surpassing all that preceded it; had not sail been shortened in time, not a stick would have been left standing, or she must have capsized. As it was, the squall hove her so much over on her broadside, that the boat which was hanging at the starboard quarter was washed away. I then stood over to the north shore, to look for anchorage under the lee of a cape, about three leagues to the north-west of Cape Tamar. On closing it, the weather became so thick that at times we could scarcely see two ships' lengths a-head.

"These circumstances were not in favour of exploring unknown bays, and to think of passing such a night as was in prospect, under sail in the Straits, would have been a desperate risk; I was obliged therefore to yield the hard-gained advantage of this day's beat, and run for the anchorage whence we had started in the morning.

"It was nearly dark ere we reached it; and in entering, desirous to keep well up to windward, in order to gain the best anchorage, I went too close to the outer islet, and the ship struck violently on a rocky ledge. However, she did not hang a moment, and was soon anchored in safety."

Finding so much danger and difficulty, in proceeding with the ship, without first knowing where to run for anchorages, Captain Stokes left her in Tamar Bay, under the charge of Lieutenant Skyring; and, accompanied by Mr. Flinn, set out in the cutter, with a week's provisions, to examine the south coast.

In a very arduous and dangerous cruize he discovered several well-sheltered anchorages, but experienced a "constant heavy gale from W.N.W., with thick weather and incessant drenching rain."

© The Complete Work of Charles Darwin Online

Captain Stokes says, " Our discomfort in an open boat was very great, since we were all constantly wet to the skin. In trying to double the various headlands, we were repeatedly obliged (after hours of ineffectual struggle against sea and wind) to desist from useless labour, and take refuge in the nearest cove which lay to leeward."

From the Harbour of Mercy, Captain Stokes attempted to cross the Strait, on his return to the Beagle; but the sea ran too high, and obliged him to defer his daring purpose until the weather was more favourable.

During his absence, Lieutenant Skyring surveyed Tamar Bay and its vicinity.

Again the Beagle weighed, and tried hard to make some progress to the westward, but was obliged a third time to return to Tamar Bay. After another delay she just reached Sholl Bay, under Cape Phillip, and remained there one day, to make a plan of the anchorage, and take observations to fix its position.

The Beagle reached the Harbour of Mercy (Separation Harbour of Wallis and Carteret),* after a thirty days' passage from Port Famine, on the 15th, having visited several anchorages on the south shore in her way. But tedious and harassing as her progress had been, the accounts of Byron, Wallis, Carteret, and Bougainville show that they found more difficulty, and took more time, in their passages from Port Famine to the western entrance of the Strait. Byron, in 1764, was forty-two days; Wallis, in 1766, eighty-two; Carteret, in the same year, eighty-four; and Bougainville, in 1768, forty days, in going that short distance.

Five days were passed at this place, during which they communicated with a few natives, of whom Captain Stokes remarks; " As might be expected from the unkindly climate in which they dwell, the personal appearance of these Indians does not

* It was here that Commodore Wallis and Captain Carteret separated, the Dolphin going round the world; the Swallow returning to England. Sarmiento's name of Puerto de la Misericordia, or ' Harbour of Mercy,' being of prior date, ought doubtless to be retained.

exhibit, either in male or female, any indications of activity or strength. Their average height is five feet five inches; their habit of body is spare; the limbs are badly turned, and deficient in muscle; the hair of their head is black, straight, and coarse; their beards, whiskers, and eyebrows, naturally exceedingly scanty, are carefully plucked out; their forehead is low; the nose rather prominent, with dilated nostrils; their eyes are dark, and of a moderate size; the mouth is large, and the under-lip thick; their teeth are small and regular, but of bad colour. They are of a dirty copper colour; their countenance is dull, and devoid of expression. For protection against the rigours of these inclement regions, their clothing is miserably suited; being only the skin of a seal, or sea-otter, thrown over the shoulders, with the hairy side outward.

"The two upper corners of this skin are tied together across the breast with a strip of sinew or skin, and a similar thong secures it round the waist; the skirts are brought forward so as to be a partial covering. Their comb is a portion of the jaw of a porpoise, and they anoint their hair with seal or whale blubber; for removing the beard and eyebrows they employ a very primitive kind of tweezers, namely, two muscle shells. They daub their bodies with a red earth, like the ruddle used in England for marking sheep. The women, and children, wear necklaces, formed of small shells, neatly attached by a plaiting of the fine fibres of seal's intestines.

"The tracts they inhabit are altogether destitute of four-footed animals; they have not domesticated the geese or ducks which abound here; of tillage they are utterly ignorant; and the only vegetable productions they eat are a few wild berries and a kind of sea-weed. Their principal food consists of muscles, limpets, and sea-eggs, and, as often as possible, seal, sea-otter, porpoise, and whale: we often found in their deserted dwellings bones of these animals, which had undergone the action of fire.

"Former voyagers have noticed the avidity with which they swallowed the most offensive offal, such as decaying seal-skins,

© The Complete Work of Charles Darwin Online

rancid seal, and whale blubber, &c. When on board my ship, they ate or drank greedily whatever was offered to them, salt-beef, salt-pork, preserved meat, pudding, pea-soup, tea, coffee, wine, or brandy—nothing came amiss. One little instance, however, happened, which showed what they preferred. As they were going ashore, a lump of the tallow used for arming the lead was given to them, and received with particular delight. It was scrupulously divided, and placed in the little baskets which they form of rushes, to be reserved for eating last, as the richest treat.

"To their dwellings have been given, in various books of voyages, the names of huts, wigwams, &c.; but, with reference to their structure, I think old Sir John Narborough's term for them will convey the best idea to an English reader; he calls them 'arbours.' They are formed of about a couple of dozen branches, pointed at the larger ends, and stuck into the ground round a circular or elliptical space, about ten feet by six; the upper ends are brought together, and secured by tyers of grass, over which is thrown a thatching of grass and seal-skins, a hole being left at the side as a door, and another at the top as a vent for the smoke. A fire is kept burning within, over which the natives are constantly cowering; hence, when seen abroad, instead of appearing to be hardy savages, inured to wet and cold, you see wretched creatures shivering at every breeze. I never met people so sensible of cold as these Fuegian Indians.

"The nature of their domestic ties we had no opportunity of discovering; their manner towards their children is affectionate and caressing. I often witnessed the tenderness with which they tried to quiet the alarms our presence at first occasioned, and the pleasure which they showed when we bestowed upon the little ones any trifling trinkets. It appeared that they allow their children to possess property, and consult their little whims and wishes, with respect to its disposal; for lying in a boat, alongside one of the canoes, bargaining for various articles, spears, arrows, baskets, &c., I took a fancy to a dog lying near one of the women, and offered a price for it; one of my seamen, supposing the bargain concluded, laid

© The Complete Work of Charles Darwin Online

hands on the dog, at which the woman set up a dismal yell; so bidding him desist, I increased my offers. She declined to part with it, but would give two others. At last, my offers became so considerable, that she called a little boy out of the thick jungle (into which he had fled at our approach), who was the owner of the dog. The goods were shown to him, and all his party urged him to sell it, but the little urchin would not consent. He offered to let me have his necklace, and what he received in exchange was put away in his own little basket.

"These people never evinced any thankfulness for our presents. Whatever was offered they 'clutched at,' doubtful of getting it, although held out to them; and when in their own hand, it was instantly stowed away, as if they feared it would be recalled.

"I sometimes tried to discover whether they preferred any particular colour, and for that purpose held out three strings of beads, black, white, and red; they clutched at all three, in their usual manner, without showing any preference.

"Their pronunciation is exceedingly harsh and guttural; not more than two words, whose signification was at all ascertained, could be made out, 'sherroo,' a ship, boat, or canoe, and 'peteet,' a child. They have a wonderful aptitude for imitating the sounds of strange languages: let a sentence, of even a dozen words, be distinctly pronounced, and they will repeat it with the utmost precision.

"Their only articles of traffic, besides such implements and weapons as they use, are seal and otter skins; and I should say that the quantity of peltry to be procured from them would be insignificant towards completing the cargo of a sealing vessel."

During the next few days the Beagle was employed in the most exposed, the least known, and the most dangerous part of the Strait. Fortunately, she was favoured by weather, and effected her purpose without injury or loss; but I never reflect upon this piece of service without an inward tribute of admiration to the daring, skill, and seamanship of Captain Stokes, Lieutenant Skyring, and Mr. Flinn.

© The Complete Work of Charles Darwin Online

In his journal Captain Stokes says:

"Incessant rain and thick clouds prevented my completing, until this day (19th), the observations necessary for making an island, just outside the Harbour of Mercy, the southern end of my base, for the trigonometrical connection of the coasts and islands near the western entrance of this weather-beaten Strait.

"On the 20th, I weighed and beat to windward, intending to search for anchorage on the north shore, where I might land and fix the northern end of our base line. In the evening we anchored in an archipelago of islands, the real danger of whose vicinity was much increased to the eye by rocks, scattered in every direction, and high breakers, occasioned doubtless by reefs under water. We observed that most of the larger islands have small banks of sand at their eastern sides, on which anchorage may be found; but for ordinary purposes of navigation, this cluster of islands* need only be pointed out to be avoided. The number and contiguity of the rocks, below as well as above water, render it a most hazardous place for any square-rigged vessel: nothing but the particular duty on which I was ordered would have induced me to venture among them. Fore-and-aft vessels might work with far less risk; and as the rocks are frequented by vast numbers of fur seal, a season or two might be profitably passed here by a sealing vessel so rigged.

"This morning (21st) I landed on one of the larger islands, with Lieutenant Skyring, and having ascended an eminence (Observation Mount) with the necessary instruments, fixed its position, and made it the northern end of our base.

"It was a beautiful, and clear day; the Isles of Direction (or Evangelists), as well as every point of importance on the adjacent coast, were seen distinctly during several hours.

"My next object was to fix the position of Cape Victory, and ascertain whether anchorage could be found in its neighbourhood. Accordingly, we weighed early next morning (22d,) and after extricating ourselves from this labyrinth (not without much difficulty and danger), we beat to the westward. Violent squalls, a heavy sea, and thick weather, which came on about

* Called the Scilly Isles.

© The Complete Work of Charles Darwin Online

noon, obliged me to choose the least evil, and run for the Harbour of Mercy.

"On the 23d, we went out again, and beat towards the Isles of Direction, off which we passed a night under sail.

"The morning of the 24th was very fine, and the wind moderate. Leaving the Beagle to sound about the Isles of Direction, I set out in my boat, with two days' provisions, towards Cape Victory. As we rowed along these rocky shores, threading the mazes of the labyrinth of islets which fringe them, we saw vast numbers of black whales, and the rocks were quite covered with fur seal and brant geese.

"After pulling, in earnest, for six hours, we landed upon Cape Victory, the north-western limit of the Strait of Magalhaens, and there, with a sextant, artificial horizon, and chronometer, ascertained the position of this remarkable promontory. From an eminence, eight hundred feet above the sea, we had a commanding view of the adjacent coasts, as well as of the vast Pacific, which enabled us to rectify former material errors. Late in the evening we were fortunate enough to get safely on board again, which, considering the usual weather here and the heavy sea, was unexpected success. This night was passed under sail in the Pacific, and next morning we commenced our return to Port Famine.

"When within four or five miles of Cape Pillar, and to the westward of it, a current was found to set southward, at about two knots an hour. As we neared the Cape the wind fell, and the Beagle was set rapidly towards those dangerous rocks, called the Apostles. Fortunately, a commanding breeze sprung up, and we extricated ourselves from the difficulty. While passing Cape Pillar, I landed in a cove near it, and determined its position. By sunset we had arrived near the Harbour of Mercy; and being becalmed, towed the ship in, with her boats, until an anchor was dropped at the proper place.

"On the 26th, we went to Tuesday Bay, and on the 27th crossed the Strait, and anchored under Cape Parker. I have rarely witnessed such a high, cross, and irregular sea as we this day passed through, near the strange mass of rock, called by

© The Complete Work of Charles Darwin Online

Narborough, 'Westminster Hall.' The coast about our unsafe anchorage was as barren and dismal-looking as any part of this country, which, as the old navigator above-mentioned said, is 'so desolate land to behold.'

"Next day (March 1st) we ran down to Cape Upright, and there remained until the 3d, collecting the required data for our survey.

"While standing towards the bay called Playa Parda (on the 3d), a boat under sail was seen making towards us from the southern coast. I fired several guns, to show our position, before we became shut in by the land, and soon after anchoring a whale-boat came alongside, with the second mate and five men belonging to the sealing-vessel Prince of Saxe Cobourg.

"Anxious not to lose a moment in hastening to the relief of our shipwrecked countrymen, I ran down next day to Port Gallant, and thence proceeded with two ten-oared boats (on the 5th) through the Barbara Channel, and the following evening reached Fury Harbour."

Having already given a short account of the Saxe Cobourg's loss, and the rescue of her crew by Captain Stokes, I will not repeat the story by extracting more from his journal.

Mr. Graves returned from his cruize in the Hope on the 17th, after suffering much from stormy weather and incessant rain; but having made a survey of the openings in the land to the west of Magdalen Channel as far as the Sugar Loaf Point, at the west head of Lyell Sound, which he found to be deep inlets, affording no anchorages of value to navigation.

The time having arrived for our return to Monte Video, preparations were made for sailing, and in the mean time I went to the northward, in the Hope, to survey the coast between Port Famine and Elizabeth Island, including Shoal Haven.

At the bottom of Shoal Haven we were stopped by the water shoaling to five feet, so that we were obliged to haul out till we could anchor in more than two fathoms. During the night the wind shifted to N.E., and blew right in, obliging us to weigh, and work under the S.W. end of Elizabeth Island into a bay close to that shore. From the summit of the S.W.

© The Complete Work of Charles Darwin Online

point I afterwards took angles, among which the most important gave Mount Sarmiento bearing S. 1½° W. (true). Its distance must have been (by recent observations) ninety-four miles.

Elizabeth Island is a long, low strip of land, lying parallel to the shores of the Strait, which here take a N.N.E. direction. Compared with the land to the southward it is very low, no part being more than two or three hundred feet high. It is composed of narrow ranges of hills, extending in ridges in the direction of its length, over which are strewed boulders of the various rocks, which have been noticed before as forming the shingle beaches of Point St. Mary and Point St. Anna; two kinds of rock, greenstone and hornblende, being the most common. The vallies which divide the hilly ridges were well clothed with grass, and in many places were seen hollows, that had contained fresh water, but now were entirely dried up. These spots were marked by a white crust, apparently caused by the saline quality of the soil.

Geese and wild ducks, and the red-bill (*Hæmatopus*), seem to be the only inhabitants of this island. The Indians sometimes visit it, for at the S.W. end we found remains of wigwams and shell-fish. Perhaps it is a place whence they communicate with the Patagonian natives, or they may in the season frequent it for eggs.

We anchored in Laredo Bay, and visited a lake about a mile from the beach, distinguished on the chart by the name of Duck Lagoon: it is very extensive, and covered with large flights of gulls, ducks, and widgeons. We shot one widgeon, which was a most beautiful bird, and of a species we had not before seen.*

Here the country begins to be clothed with the deciduous leaved Beech tree (*Fagus Antarctica*), which is stunted in growth, but very convenient for fuel. Though the hardiest tree of this region, it is never found of large size, the larger trees being the evergreen Beech (*Fagus betuloides*). We also met with several small plants common to Cape Gregory. One

* 'Anas Rafflesii,' Zool. Journ., vol. iv., and Tab. Supp., xxix.

© The Complete Work of Charles Darwin Online

may consider Cape Negro to be the boundary of two countries, as entirely different from each other in geological structure and appearance, as they are in climate, to which last difference may be attributed the dissimilarity of their botanical productions.

Hence we returned to Port Famine. In our absence, a boat from the Beagle had crossed the Strait to Lomas Bay, where a party of natives had kindled fires of invitation.

The weather, since the sun crossed the equator, had been unusually fine; and, with the exception of one day's heavy rain, the sky was so clear (the wind being moderate from the N.E.) that all the heights were exposed to our view, and amongst them Mount Sarmiento stood pre-eminent.

Our preparations for sailing being nearly completed, the Hope was unrigged and hoisted in, and our temporary settlement on shore abandoned. It consisted of a marquée and a large bell tent. In the former was Mr. Harrison (mate), who had charge of the party, and of the meteorological instruments: the bell tent held the crew. Near them were the observatory, a sawpit, and a cooking place, where a cheerful fire was always blazing. The carpenter's shop, cooper's bench, and armourer's forge had each its place, as well as a rope-walk, close to which our rigging was refitted, and the sails were repaired. After working-hours the shore party roamed about the woods with guns, or at low water picked up shell fish,* by which they usually procured a fresh meal twice, but always once, a week. Meanwhile the ship was kept carefully clean and in order. The officers not immediately employed in active duty made excursions with their guns; and although the immediate vicinity of our tents was pretty well thinned of game, yet a walk of a few miles was always rewarded by ample sport. When opportunities offered, some of the men were permitted to amuse themselves on shore with their guns, for which many had provided themselves with powder and shot. Every Sunday, after divine service, which was performed as regularly as possible under our circumstances, such of the ship's company as desired per-

* Of these a species of mactra (*M. edulis Nob.*) was most abundant.

© The Complete Work of Charles Darwin Online

mission to land obtained it. On one occasion, however, we had nearly suffered for this indulgence, which was conducive to the men's health, and seldom abused: for one of them having made a fire at a little distance from the tents, the flames spread, and the exertions of all hands, for three hours, only just prevented it from communicating to the tents. On another occasion, two men set out on a shooting excursion, intending to cross the river Sedger, against doing which there had been no particular orders, as such a proceeding was scarcely contemplated. Having reached the bank near its mouth, and searched for a fordable place unsuccessfully, they launched a log of wood, and sitting astride, without providing themselves with a pole or paddle, pushed off from the shore, supposing it would go across; but, on reaching the middle of the stream, it was soon carried, by the current, out of the river, into the bay. One man, Gilly, seeing that the log was still floating away with the ebb tide, plunged in, and just reached the shore south of the river, in a very exhausted state; the other, Rix, unable to swim, kept his place, and was carried out to sea on a voyage that might have been fatal, had he not been seen from the ship, and saved by a boat.

Before leaving Port Famine we hauled one of our boats ashore, and left her (as we thought) securely hidden among the trees.

Being now ready to sail, and only waiting for wind, the officers of both ships, twenty-seven in number, dined together on shore.

CHAPTER VI.

Trees—Leave Port Famine—Patagonians—Gregory Bay—Bysante—Maria—Falkner's account of the Natives—Indians seen on the borders of the Otway Water, in 1829—Maria visits the Adventure—Religious Ceremony—Patagonian Encampment—Tomb of a Child—Women's employment—Children—Gratitude of a Native—Size of Patagonians—Former accounts of their gigantic height—Character—Articles for barter—Fuegians living with Patagonians—Ships sail—Arrive at Monte Video and Rio de Janeiro.

While detained by northerly winds, the carpenter and a party of people were employed in the woods selecting and cutting down trees to be ready for our next visit. After felling thirteen trees, from twenty-four to thirty-six inches in diameter, eight were found to be rotten at the heart; but by afterwards taking the precaution of boring the trees with an augur, while standing, much trouble was saved, and fifteen sound sticks of considerable diameter were cut down. We found one tree, an evergreen beech, too large for any of our saws: it measured twenty-one feet in girth at the base, and from the height of six feet to twenty it was seventeen feet in circumference; above this height, three large arms (each from thirty to forty inches in diameter), branched off from the trunk. It is, perhaps, the very tree described by Byron in his account of this place. We only once saw it equalled in size, and that was by a prostrate trunk, very much decayed.

In this interval of fine weather and northerly wind, we had the thermometer as high as 58°, and the barometer ranging between 29.80 and 30.00; but for two days before the wind shifted, the alteration was predicted by a gradual descent of the mercurial column, and a considerable increase of cold. On the 7th May, as there was some appearance of a change, we got under weigh; but were hardly outside the port, when a northerly wind again set in, and prevented our going farther than Fresh-

© The Complete Work of Charles Darwin Online

water Bay, where we passed the night. At last, on the 8th, accompanied by the Beagle, we proceeded on our course with a strong south-westerly breeze, which carried us quickly up to Cape Negro, when it blew so hard that I anchored off Laredo Bay. At this anchorage we certainly felt the air much colder and sharper than at Port Famine, arising from our being in a more exposed situation, and from the approach of winter, as well as from the severe south-west gale which was blowing.

After the gale had abated, we proceeded with fair weather and a light breeze to the Second Narrow, when the wind fell; but the tide being in our favour, we passed rapidly through. On a hill near us we observed three or four Patagonian Indians standing together, and their horses feeding close to them. A fire was soon kindled, to attract our notice, to which signal we replied by showing our colours; and had we not already communicated with these people, we should certainly have thought them giants, for they "loomed very large" as they stood on the summit of the hill. This optical deception must doubtless have been caused by mirage: the haze has always been observed to be very great during fine weather and a hot day, arising from rapid evaporation of the moisture so abundantly deposited, on the surface of the ground, in all parts of the Strait.

As soon as the Patagonians found they were noticed, they mounted and rode along the shore abreast of us, being joined by other parties, until the whole number could not have been less than forty. Several foals and dogs were with them. Having anchored in Gregory Bay, where I intended remaining for two days to communicate with them, I sent up a rocket, burnt a blue-light, and despatched Lieutenant Cooke on shore to ask for a large supply of guanaco meat, for which we would pay in knives and beads. The boat returned on board immediately, bringing off four natives, three men and 'Maria.' This rather remarkable woman must have been, judging by her appearance, about forty years old: she is said to have been born at Assuncion, in Paraguay, but I think the place of her birth was nearer Buenos Ayres. She spoke broken, but intel-

© The Complete Work of Charles Darwin Online

ligible, Spanish, and stated herself to be sister of Bysante, the cacique of a tribe near the Santa Cruz River, who is an important personage, on account of his size (which Maria described to be immense), and his riches. In speaking of him, she said he was *very* rich; he had many mantles, and also many hides ("*muy* rico, tiene muchas mantas y tambien muchos cueros"). One of Maria's companions, a brother of Bysante, was the tallest and largest man of this tribe; and though he only measured six feet in height, his body was large enough for a much taller man. He was in great affliction: his daughter had died only two days before our arrival; but, notwithstanding his sad story, which soon found him friends, it was not long before he became quite intoxicated, and began to sing and roar on the subject of his misfortunes, with a sound more like the bellowing of a bull than the voice of a human being. Upon applying to Maria, who was not quite so tipsy as her brother, to prevent him from making such hideous noises, she laughed and said, "Oh, never mind, he's drunk; poor fellow, his daughter is dead" (Es boracho, povrecito, muriò su hija); and then, assuming a serious tone, she looked towards the sky, and muttered in her own language a sort of prayer or invocation to their chief demon, or ruling spirit, whom Pigafetta, the companion and historian of Magalhaens, called *Setebos*, which Admiral Burney supposes to have been the original of one of Shakspeare's names in the "Tempest"—

> "——— his art is of such power
> He would controul my dam's god Setebos."*

Maria's dress was similar to that of other females of the tribe; but she wore ear-rings, made of medals stamped with a figure of the Virgin Mary, which, with the brass-pin that secured her mantle across her breast, were given to her by one Lewis, who had passed by in an American sealing-vessel, and who, we understood from her, had made them "Christians." The Jesuit Falkner, who lived among them for many years, has written a long and, apparently, a very authentic account

* Burney, i. 35 and 37.

© The Complete Work of Charles Darwin Online

of the inhabitants of the countries south of the River Plata, and he describes those who inhabit the borders of the Strait and sea-coast to be, "Yacana-cunnees, which signifies foot-people, for they have no horses in their country; to the north they border on the Sehuau-cunnees, to the west on the Key-yus, or Key-yuhues, from whom they are divided by a ridge of mountains; to the east they are bounded by the ocean; and to the south by the islands of Tierra del Fuego, or the South Sea. These Indians live near the sea on both sides of the Strait, and often make war with one another. They make use of light floats, like those of Chilóe, in order to pass the Straits, and are sometimes attacked by the Huilliches and other Tehuelhets, who carry them away for slaves, as they have nothing to lose but their liberty and their lives. They subsist chiefly on fish, which they catch either by diving, or striking them with their darts. They are very nimble afoot, and catch guanacoes and ostriches with their bowls. Their stature is much the same as that of the other Tehuelhets, rarely exceeding seven feet, and oftentimes not six feet. They are an innocent, harmless people." *

To the north of this race, Falkner describes "the Sehuau-cunnees, the most southern Indians who travel on horseback; Sehuau signifies in the Tehuel dialect a species of black rabbit, about the size of a field rat; and as their country abounds in these animals, their name may be derived from thence: cunnee signifying 'people.'"

With the exception of their mode of killing the guanaco by bowls, or balls, the description of the Key-yus would apply better to the Fuegian Indians; and if so, they have been driven across the Strait, and confined to the Fuegian shores by the Sehuau-cunnees, who must be no other than Maria's tribe. The Key-yus, who are described to inhabit the northern shore of the Strait, between Peckett's Harbour and Madre de Dios, are probably the tribe found about the south-western islands, and now called Alikhoolip; whilst the eastern Fuegians, or Yacana-cunnees, who have also been turned off the conti-

* Falkner's Patagonia, pp. 110, 111.

© The Complete Work of Charles Darwin Online

nent by their powerful neighbours, are now called Tekeenikas. Our knowledge of the names of these two tribes, Alikhoolip and Tekeenika, results from Captain Fitz-Roy's subsequent examination of the outer coast of Tierra del Fuego in the Beagle (1830). A Cacique, belonging to the nation of the Key-yus, told Falkner that he had been in a house made of wood, that travelled on the water. A party of the Indians, in four canoes, were met on the borders of the Otway Water by Captain Fitz-Roy in 1829, whose arms, implements, and every thing they had, were precisely like the Fuegian Indians, excepting that they had a quiver made from the skin of a deer, and were in form a superior race, being both stronger and stouter.

For want of better information upon the subject, we must be content to separate the natives into Patagonians and Fuegians. The sealing vessels' crews distinguish them as Horse Indians, and Canoe Indians.

These people have had considerable communication with the sealers who frequent this neighbourhood, bartering their guanaco skins and meat, their mantles, and furs, for beads, knives, brass ornaments, and other articles; but they are equally anxious to get sugar, flour, and, more than all, "aqua ardiente," or spirits. Upon the arrival of a boat from any vessel, Maria, with as many as she can persuade the boat's crew to take, goes on board, and, if permitted, passes the night. As soon as our boat landed, Maria and her friends took their seats as if it had been sent purposely for them. Not expecting such a visit, I had given no order to the contrary, and the novelty of such companions overcame the scruples of the officer, who was sent on shore to communicate with them. Their noisy behaviour becoming disagreeable, they were soon conducted from below to the deck, where they passed the night. Maria slept with her head on the windlass; and was so intoxicated, that the noise and concussion produced by veering eighty fathoms of cable round it did not awake her. The following morning, whilst I was at breakfast, she very unceremoniously introduced herself, with one of her companions, and

© The Complete Work of Charles Darwin Online

seating herself at table, asked for tea and bread, and made a hearty meal. I took the precaution of having all the knives, and articles that I thought likely to be stolen, removed from the table; but neither then, nor at any time, did I detect Maria in trying to steal, although her companions never lost an opportunity of pilfering.

After breakfast the Indians were landed, and as many of the officers as could be spared went on shore, and passed the whole day with the tribe, during which a very active trade was carried on. There were about one hundred and twenty Indians collected together, with horses and dogs. It is probable that, with the exception of five or six individuals left to take care of the encampment, and such as were absent on hunting excursions, the whole of the tribe was mustered on the beach, each family in a separate knot, with all their riches displayed to the best advantage for sale.

I accompanied Maria to the shore. On landing, she conducted me to the place where her family were seated round their property. They consisted of Manuel, her husband, and three children, the eldest being known by the appellation of Capitan Chico, or "little chief." A skin being spread out for me to sit on, the family and the greater part of the tribe collected around. Maria then presented me with several mantles and skins, for which I gave in return a sword, remnants of red baize, knives, scissors, looking-glasses, and beads: of the latter I afterwards distributed bunches to all the children, a present which caused evident satisfaction to the mothers, many of whom also obtained a share. The receivers were selected by Maria, who directed me to the youngest children first, then to the elder ones, and lastly to the girls and women. It was curious and amusing, to witness the order with which this scene was conducted, and the remarkable patience of the children, who, with the greatest anxiety to possess their trinkets, neither opened their lips, nor held out a hand, until she pointed to them in succession.

Having told Maria that I had more things to dispose of for guanaco meat she dismissed the tribe from around me, and,

© The Complete Work of Charles Darwin Online

saying she was going for meat (carne), mounted her horse, and rode off at a brisk pace. Upon her departure a most active trade commenced: at first, a mantle was purchased for a string of beads; but as the demand increased, so the Indians increased their price, till it rose to a knife, then to tobacco, then to a sword, at last nothing would satisfy them but 'aqua ardiente,' for which they asked repeatedly, saying "bueno es boracho—bueno es—bueno es boracho;"*—but I would not permit spirits to be brought on shore.

At Maria's return with a very small quantity of guanaco meat, her husband told her that I had been very inquisitive about a red baize bundle, which he told me contained "Cristo," upon which she said to me "Quiere mirar mi Cristo" (do you wish to see my Christ), and then, upon my nodding assent, called around her a number of the tribe, who immediately obeyed her summons. Many of the women, however, remained to take care of their valuables. A ceremony then took place. Maria, who, by the lead she took in the proceedings, appeared to be high priestess† as well as cacique of the tribe, began by pulverising some whitish earth in the hollow of her hand, and then taking a mouthful of water, spit from time to time upon it, until she had formed a sort of pigment, which she distributed to the rest, reserving only sufficient to mark her face, eyelids, arms, and hair with the figure of the cross. The manner in which this was done was peculiar. After rubbing the paint in her left hand smooth with the palm of the right, she scored marks across the paint, and again others at right angles, leaving the impression of as many crosses, which she

* It is good to be drunk, it is pleasant to be drunk.

† Two Portuguese seamen, however, who had resided some months with them, having been left behind by a sealing vessel, and taken off by us at a subsequent period of the voyage at their own request, informed us that Maria is not the leader of religious ceremonies. Each family possesses its own household god, a small wooden image, about three inches in length, the rough imitation of a man's head and shoulders, which they consider as the representative of a superior being, attributing to it all the good or evil that happens to them.

© The Complete Work of Charles Darwin Online

stamped upon different parts of her body, rubbing the paint, and marking the crosses afresh, after every stamp was made.

The men, after having marked themselves in a similar manner (to do which some stripped to the waist and covered all their body with impressions), proceeded to do the same to the boys, who were not permitted to perform this part of the ceremony themselves. Manuel, Maria's husband, who seemed to be her chief assistant on the occasion, then took from the folds of the sacred wrapper an awl, and with it pierced either the arms or ears of all the party; each of whom presented in turn, pinched up between the finger and thumb, that portion of flesh which was to be perforated. The object evidently was to lose blood, and those from whom the blood flowed freely showed marks of satisfaction, while some whose wounds bled but little underwent the operation a second time.

When Manuel had finished, he gave the awl to Maria, who pierced his arm, and then, with great solemnity and care, muttering and talking to herself in Spanish (not two words of which could I catch, although I knelt down close to her and listened with the greatest attention), she removed two or three wrappers, and exposed to our view a small figure, carved in wood, representing a dead person, stretched out. After exposing the image, to which all paid the greatest attention, and contemplating it for some moments in silence, Maria began to descant upon the virtues of her Christ, telling us it had a good heart ('buen corazon'), and that it was very fond of tobacco. "Mucho quiere mi Cristo tabaco, da me mas," (my Christ loves tobacco very much, give me some). Such an appeal, on such an occasion, I could not refuse; and after agreeing with her in praise of the figure, I said I would send on board for some. Having gained her point, she began to talk to herself for some minutes, during which she looked up, after repeating the words "muy bueno es mi Cristo, muy bueno corazon tiene," and slowly and solemnly packed up the figure, depositing it in the place whence it had been taken. This ceremony ended, the traffic, which had been suspended, recommenced with redoubled activity.

© The Complete Work of Charles Darwin Online

According to my promise, I sent on board for some tobacco, and my servant brought a larger quantity than I thought necessary for the occasion, which he injudiciously exposed to view. Maria, having seen the treasure, made up her mind to have the whole, and upon my selecting three or four pounds of it, and presenting them to her, looked very much disappointed, and grumbled forth her discontent: I taxed her with greediness, and spoke rather sharply, which had a good effect, for she went away and returned with a guanaco mantle, which she presented to me.

During this day's barter we procured guanaco meat, sufficient for two days' supply of all hands, for a few pounds of tobacco. It had been killed in the morning, and was brought on horseback cut up into large pieces, for each of which we had to bargain. Directly an animal is killed, it is skinned and cut up, or torn asunder, for the convenience of carrying. The operation is done in haste, and therefore the meat looks bad; but it is well tasted, excellent food, and although never fat, yields abundance of gravy, which compensates for its leanness. It improves very much by keeping, and proved to be valuable and wholesome meat.

Captain Stokes, and several of the officers, upon our first reaching the beach, had obtained horses, and rode to their 'toldos,' or principal encampment. On their return, I learned that, at a short distance from the dwellings, they had seen the tomb of the child who had lately died. As soon, therefore, as Maria returned, I procured a horse from her, and, accompanied by her husband and brother, the father of the deceased, and herself, visited these toldos, situated in a valley extending north and south between two ridges of hills, through which ran a stream, falling into the Strait within the Second Narrow, about a mile to the westward of Cape Gregory.

We found eight or ten huts arranged in a row; the sides and backs were covered with skins, but the fronts, which faced the east, were open; even these, however, were very much screened from wind by the ridge of hills eastward of the plain. Near them the ground was rather bare, but a little

© The Complete Work of Charles Darwin Online

farther back there was a luxuriant growth of grass, affording rich and plentiful pasture for the horses, among which we observed several mares in foal, and colts feeding and frisking by the side of their dams: the scene was lively and pleasing, and, for the moment, reminded me of distant climes, and days gone by.

The 'toldos' are all alike. In form they are rectangular, about ten or twelve feet long, ten deep, seven feet high in front, and six feet in the rear. The frame of the building is formed by poles stuck in the ground, having forked tops to hold cross pieces, on which are laid poles for rafters, to support the covering, which is made of skins of animals sewn together so as to be almost impervious to rain or wind. The posts and rafters, which are not easily procured, are carried from place to place in all their travelling excursions. Having reached their bivouac, and marked out a place with due regard to shelter from the wind, they dig holes with an iron bar or piece of pointed hard wood, to receive the posts; and all the frame and cover being ready, it takes but a short time to erect a dwelling. Their goods and furniture are placed on horseback under the charge of the females, who are mounted aloft upon them. The men carry nothing but the lasso and bolas, to be ready for the capture of animals, or for defence.

Maria's toldo was nearly in the middle, and next to it was her brother's. All the huts seemed well stored with skins and provisions, the former being rolled up and placed at the back, and the latter suspended from the supporters of the roof; the greater part was in that state well known in South America by the name of charque (jerked beef); but this was principally horse-flesh, which these people esteem superior to other food. The fresh meat was almost all guanaco. The only vessels they use for carrying water are bladders, and sufficiently disagreeable substitutes for drinking utensils they make: the Fuegian basket, although sometimes dirty, is less offensive.

About two hundred yards from the village the tomb was erected, to which, while Maria was arranging her skins and

© The Complete Work of Charles Darwin Online

mantles for sale, the father of the deceased conducted me and a few other officers.

It was a conical pile of dried twigs and branches of bushes, about ten feet high and twenty-five in circumference at the base, the whole bound round with thongs of hide, and the top covered with a piece of red cloth, ornamented with brass studs, and surmounted by two poles, bearing red flags and a string of bells, which, moved by the wind, kept up a continual tinkling.

A ditch, about two feet wide and one foot deep, was dug round the tomb, except at the entrance, which had been filled up with bushes. In front of this entrance stood the stuffed skins of two horses, recently killed, each placed upon four poles for legs. The horses' heads were ornamented with brass studs, similar to those on the top of the tomb; and on the outer margin of the ditch were six poles, each carrying two flags, one over the other.

The father, who wept much when he visited the tomb, with the party of officers who first went with him, although now evidently distressed, entered into, what we supposed to be, a long account of the illness of his child, and explained to us that her death was caused by a bad cough. No watch was kept over the tomb; but it was in sight of, and not very far from their toldos, so that the approach of any one could immediately be known. They evidently placed extreme confidence in us, and therefore it would have been as unjust as impolitic to attempt an examination of its contents, or to ascertain what had been done with the body.

The Patagonian women are treated far more kindly by their husbands than the Fuegian; who are little better than slaves, subject to be beaten, and obliged to perform all the laborious offices of the family. The Patagonian females sit at home, grinding paint, drying and stretching skins, making and painting mantles. In travelling, however, they have the baggage and provisions in their charge, and, of course, their children. These women probably have employments of a more laborious nature than what we saw; but they cannot be compared with

those of the Fuegians, who, excepting in the fight and chace, do every thing. They paddle the canoes, dive for shells and sea-eggs, build their wigwams, and keep up the fire; and if they neglect any of these duties, or incur the displeasure of their husbands in any way, they are struck or kicked most severely. Byron, in his narrative of the loss of the Wager, describes the brutal conduct of one of these Indians, who actually killed his child for a most trifling offence. The Patagonians are devotedly attached to their offspring. In infancy they are carried behind the saddle of the mother, within a sort of cradle, in which they are securely fixed. The cradle is made of wicker-work, about four feet long and one foot wide, roofed over with twigs like the frame of a tilted waggon. The child is swaddled up in skins, with the fur inwards or outwards according to the weather. At night, or when it rains, the cradle is covered with a skin that effectually keeps out the cold or rain. Seeing one of these cradles near a woman, I began to make a sketch of it, upon which the mother called the father, who watched me most attentively, and held the cradle in the position which I considered most advantageous for my sketch. The completion of the drawing gave them both great pleasure, and during the afternoon the father reminded me repeatedly of having painted his child ("pintado su hijo.")

One circumstance deserves to be noticed, as a proof of their good feeling towards us. It will be recollected that three Indians, of the party with whom we first communicated, accompanied us as far as Cape Negro, where they landed. Upon our arrival on this occasion, I was met, on landing, by one of them, who asked for my son, to whom they had taken a great fancy; upon my saying he was on board, the native presented me with a bunch of nine ostrich feathers, and then gave a similar present to every one in the boat. He still carried a large quantity under his arm, tied up in bunches, containing nine feathers in each; and soon afterwards, when a boat from the Beagle landed with Captain Stokes and others, he went to meet them; but finding strangers, he withdrew without making them any present.

© The Complete Work of Charles Darwin Online

In the evening my son landed, when the same Indian came down to meet him, appeared delighted to see him, and presented him with a bunch of feathers, of the same size as those which he had distributed in the morning. At this, our second visit, there were about fifty Patagonian men assembled, not one of whom looked more than fifty-five years of age. They were generally between five feet ten and six feet in height: one man only exceeded six feet—whose dimensions, measured by Captain Stokes, were as follows:—

	ft.	in.
Height	6	1¾
Round the chest.....	4	1½
Do. loins	3	4¾

I had before remarked the disproportionate largeness of head, and length of body of these people, as compared with the diminutive size of their extremities; and, on this visit, my opinion was further confirmed, for such appeared to be the general character of the whole tribe; and to this, perhaps, may be attributed the mistakes of some former navigators. Magalhaens, or rather Pigafetta, was the first who described the inhabitants of the southern extremity of America as giants. He met some at Port San Julian, of whom one is described to be "so tall, that our heads scarcely came up to his waist, and his voice was like that of a bull." Herrera,* however, gives a less extravagant account of them: he says, "the least of the men was larger and taller than the stoutest man of Castile;" and Maxim. Transylvanus says they were "in height ten palms or spans; or seven feet six inches."

In Loyasa's voyage (1526), Herrera mentions an interview with the natives, who came in two canoes, "the sides of which were formed of the ribs of whales." The people in them were of large size "some called them giants; but there is so little conformity between the accounts given concerning them, that I shall be silent on the subject."†

As Loyasa's voyage was undertaken immediately after the return of Magalhaens' expedition, it is probable that, from the

* Burney, i. p. 33. † Ibid. p. 135.

© The Complete Work of Charles Darwin Online

impressions received from Pigafetta's narrative, many thought the Indians whom they met must be giants, whilst others, not finding them so large as they expected, spoke more cautiously on the subject; but the people seen by them must have been Fuegians, and not those whom we now recognise by the name of Patagonians.

Sir Francis Drake's fleet put into Port San Julian, where they found natives 'of large stature;' and the author of the 'World Encompassed,' in which the above voyage is detailed, speaking of their size and height, supposes the name given them to have been *Pentagones*, to denote a stature of "five cubits, viz. seven feet and a half," and remarks that it described the full height, if not somewhat more, of the tallest of them.* They spoke of the Indians whom they met within the Strait as small in stature.†

The next navigator who passed through the Strait was Sarmiento; whose narrative says little in proof of the very superior size of the Patagonians. He merely calls them "Gente Grande,"‡ and "los Gigantes;" but this might have originated from the account of Magalhaens' voyage. He particularises but one Indian, whom they made prisoner, and only says "his limbs are of large size:" ("Es crecido de miembros.") This man was a native of the land near Cape Monmouth, and, therefore, a Fuegian. Sarmiento was afterwards in the neighbourhood of Gregory Bay, and had an encounter with the Indians, in which he and others were wounded; but he does not speak of them as being unusually tall.

After the establishment, called 'Jesus,' was formed by Sarmiento, in the very spot where 'giants' had been seen, no people of large stature are mentioned, in the account of the colony; but Tomé Hernandez, when examined before the Vice-Roy of Peru, stated, "that the Indians of the plains, who are giants, communicate with the natives of Tierra del Fuego, who are like them.§

(which is contained in Purchas), is not considered credible. He describes the Patagonians to be fifteen or sixteen spans in height; and that of these cannibals, there came to them at one time above a thousand! The Indians at Port Famine, in the same narrative, are mentioned as a kind of strange cannibals, short of body, not above five or six spans high, very strong, and thick made.*

The natives, who were so inhumanly murdered by Oliver Van Noort, on the Island of Santa Marta (near Elizabeth Island), were described to be nearly of the same stature as the common people in Holland, and were remarked to be broad and high-chested. Some captives were taken on board, and one, a boy, informed the crew that there was a tribe living farther in-land, named 'Tiremenen,' and their territory 'Coin;' that they were "great people, like giants, being from ten to twelve feet high, and that they came to make war against the other tribes,† whom they reproached for being eaters of ostriches!"‡

Spilbergen (1615) says he "saw a man of extraordinary stature, who kept on the higher grounds to observe the ships; and on an island, near the entrance of the Strait, were found the dead bodies of two natives, wrapped in the skins of penguins, and very lightly covered with earth; one of them was of the common human stature, the other, the journal says, was two feet and a half longer.§ The gigantic appearance of the man on the hills may perhaps be explained by the optical deception we ourselves experienced.

Le Maire and Schouten, whose accounts of the graves of the Patagonians agree precisely with what we noticed at Sea Bear Bay, of the body being laid on the ground covered with

a heap of stones, describe the skeletons as measuring ten or eleven feet in length, "the skulls of which we could put on our heads in the manner of helmets!"

The Nodales did not see any people on the northern side of the Strait; those with whom they communicated were natives of Tierra del Fuego, of whose form no particular notice is taken.

Sir John Narborough saw Indians at Port San Julian, and describes them as "people of a middling stature: well-shaped. * * * Mr. Wood was taller than any of them." He also had an interview with nineteen natives upon Elizabeth Island, but they were Fuegians.

In the year 1741, Patagonian Indians were seen by Bulkley and his companions. They were mounted on horses, or mules, which is the first notice we have of their possessing those animals.

Duclos de Guyot, in the year 1766, had an interview with seven Patagonian Indians, who were mounted on horses equipped with saddles, bridles, and stirrups. The shortest of the men measured five feet eleven inches and a quarter English. The others were considerably taller. Their chief or leader they called 'Capitan.'

Bougainville, in 1767, landed amongst the Patagonians. Of their size he remarks: "They have a fine shape; among those whom we saw, not one was below five feet ten inches and a quarter (English), nor above six feet two inches and a half in height. Their gigantic appearance arises from their prodigiously broad shoulders, the size of their heads, and the thickness of all their limbs. They are robust and well fed: their nerves are braced and their muscles strong, and sufficiently hard, &c." This is an excellent account; but how different is that of Commodore Byron, who says, "One of them, who afterwards appeared to be chief, came towards me; he was of gigantic stature, and seemed to realise the tales of monsters in a human shape: he had the skin of some wild beast thrown over his shoulders, as a Scotch Highlander wears his plaid, and was painted so as to make the most hideous appearance I

© The Complete Work of Charles Darwin Online

ever beheld: round one eye was a large circle of white, a circle of black surrounded the other, and the rest of his body was streaked with paint of different colours. I did not measure him; but if I may judge of his height by the proportion of his stature to my own, it could not be less than seven feet. When this frightful colossus came up, we muttered somewhat to each other as a salutation, &c."* After this he mentions a woman "of most enormous size;" and again, when Mr. Cumming, the lieutenant, joined him, the commodore says, "Before the song was finished, Mr. Cumming came up with the tobacco, and I could not but smile at the astonishment which I saw expressed in his countenance upon perceiving himself, though six feet two inches high, become at once a pigmy among giants, for these people may, indeed, more properly be called giants than tall men: of the few among us who are full six feet high, scarcely any are broad and muscular, in proportion to their stature, but look rather like men of the common bulk grown up accidentally to an unusual height; and a man who should measure only six feet two inches, and equally exceed a stout well-set man of the common stature in breadth and muscle, would strike us rather as being of a gigantic race, than as an individual accidentally anomalous; our sensations, therefore, upon seeing five hundred people, the shortest of whom were at least four inches taller, and bulky in proportion, may be easily imagined."†

This account was published only seven years after the voyage, and the exaggeration, if any, might have been exposed by numbers. There can be no doubt, that among five hundred persons several were of a large size; but that all were four inches taller than six feet must have been a mistake. The commodore says, that he "caused them all to be seated," and in that position, from the length of their bodies, they would certainly appear to be of very large stature.‡

‡ See a letter from Mr. Charles Clarke, an officer on board the Dolphin, to Mr. Maly, M.D., secretary of the Royal Society, dated Nov. 3, 1766, read before the Royal Society on 12th April 1767, and published in the

© The Complete Work of Charles Darwin Online

Shortly afterwards, Wallis, in the neighbourhood of Cape Virgins, communicated with the same people, and as the story of the Patagonian giants had been spread abroad, and was very much discredited, he carried two measuring rods with him; and says, in his narrative, "We went round and measured those that appeared to be the tallest. One was six feet seven inches high, several more were six feet five, and six feet six inches; but the stature of the greatest part of them was from five feet ten to six feet."

In the voyage of the Santa Maria de la Cabeza,* 1786, it is related that the height of one or two Patagonians, with whom the officers had an interview, was six feet eleven inches and a half (of Burgos), which is equal to six feet four inches and a half (English). This man wore a sword, on which was engraved "Por el Rey Carlos III.," and spoke a few words in Spanish, proofs of his having had communication with some of the Spanish settlements. It does not, however, appear from the account that there were many others, if any, of that height.

Of all the above accounts, I think those by Bougainville and Wallis the most accurate. It is true, that of the number we saw, none measured more than six feet two inches; but it is possible that the preceding generation may have been a larger race of people, for none that we saw could have been alive at the time of Wallis's or Byron's voyage. The oldest certainly were the tallest; but, without discrediting the accounts of Byron, or any other of the modern voyagers, I think it probable that, by a different mode of life, or a mixture by marriage with the southern or Fuegian tribes, which we know has taken place, they have degenerated into a smaller race, and have lost all right to the title of giants; yet their bulky,

the fifty-seventh volume of the Phil. Trans., part i. p. 75, in which an exaggerated account is given of this meeting. The men are described to be eight feet high, and the women seven and a half to eight feet. "They are prodigious stout, and as well and proportionably made as ever I saw people in my life." This communication was probably intended to corroborate the commodore's account.

* Ultimo Viage, p. 21.

© The Complete Work of Charles Darwin Online

muscular forms, and length of body, in some measure bear out the above accounts; for had the present generation proportionate limbs, they might, without any exaggeration, justify the account of Commodore Byron. The Jesuit Missionary Falkner,* who, from an intercourse of forty years with the Indians of South America, must be considered as one of the best authorities, says, speaking of a Patagonian named Cangapol, "This chief, who was called by the Spaniards the Cacique Bravo,† was tall and well-proportioned; he must have been seven feet and some inches in height, because on tiptoe I could not reach the top of his head: I was very well acquainted with him, and went some journeys in his company: I do not recollect ever to have seen an Indian that was above an inch or two taller than Cangapol. His brother Sausimian was but about six feet high. The Patagonians or Puelches are a large-bodied people; but I never heard of that gigantic race which others have mentioned, though I have seen persons of all the different tribes of the Southern Indians."

This is an account in 1746, only twenty years before that of Bougainville. Taking all the evidence together, it may be considered, that the medium height of the males of these southern tribes is about five feet eleven inches. The women are not so tall, but are in proportion broader and stouter: they are generally plain-featured. The head is long, broad and flat, and the forehead low, with the hair growing within an inch of the eyebrows, which are bare. The eyes are often placed obliquely, and have but little expression, the nose is generally rather flat, and turned up; but we noticed several with that feature

* Falkner, according to Dean Funes, was originally engaged in the slave trade at Buenos Ayres; but afterwards became a Jesuit, and studied in the college at Cordova, where, to an eminent knowledge of medicine, he added that of theology. He is the author of a description of Patagonia, published in London after the expulsion of the Jesuits.—(*Ensayo de la Historia Civil del Paraguay, Buenos Ayres, y Tucuman, por el Doctor Don Gregorio Funes, iii. p.* 23, *note. Published at Buenos Ayres.* 8*vo.* 1817.)

† See Dean Funes's account of Buenos Ayres, and of the Indian tribes, vol. ii. 394.

straight, and sometimes aquiline: the mouth is wide, with prominent lips, and the chin is rather large; the jaws are broad, and give the face a square appearance; the neck is short and thick; the shoulders are broad; the chest is broad, and very full; but the arm, particularly the fore-arm, is small, as are also the foot and leg; the body long, large and fat, but not corpulent. Such was the appearance of those who came under my observation.

As to their character, the Patagonians are friendly, without that disposition to quarrel, after the novelty of first acquaintance has worn off, which is so common among savages in general. This probably arises from interested motives, certainly not from fear, unless it be the fear of being avoided instead of visited by the ships which pass by, and from which they procure many useful articles, and many temporary gratifications.

Swords, long knives, tobacco, Paraguay tea, bits, saddles, guns, lead for balls, red cloth, beads (particularly of a sky-blue colour), flour, sugar, and spirits, are much desired in exchange for their peltry and guanaco meat; but they have no idea beyond that of satisfying the wants of the moment.

After a few pounds of tobacco had been distributed amongst them, although they are very fond of smoking, it became quite a drug, and it was necessary to produce something new to excite their attention. From Maria's influence, and the reference so constantly made to her, it would seem that she was considered as cacique of the tribe; but her apparent superiority may arise from her connexion with Bysante, of whom they all spoke as 'El Cacique Grande,' or from the attention paid to her by ships with whom they communicate.

The people of this tribe seemed to live together harmoniously; no bickerings or jealous feelings were observed, and certainly none were expressed by any one of our bulky friends on witnessing another receiving a valuable present, or a good exchange for his property.

At sunset our people were ordered to embark, upon which the price of Patagonian goods immediately fell, at least, a thousand per cent., though many held back in expectation of

the next day. Maria put into the boat, after my refusal to let her go on board to pass the night, two bags, and asked me to send her flour and sugar. She was most importunate for aqua ardiente, which, however, I refused. Her constant cry was "It is very good to be drunk; I like drinking very much; rum is very good.—Give me some?" ('Muy bueno es boracho, mucho mi gusta, mucho mi gusta de beber, muy bueno es aqua ardiente.—Da me no mas?')

Among them was a Fuegian Indian; but it did not appear clearly whether he was living with them permanently, or only on a visit. Some of us thought we understood the account of one of the Patagonians, who seemed to be the most interested about him, to be, that a master of a sealer had left him amongst them. We knew him instantly by his squalid and comparatively diminutive appearance, and were confirmed in our ideas by his recognition of the words 'Hosay' and Sherroo.' The Patagonian name for a ship is 'Carro grande,' and for a boat 'Carro chico,' a mixture of their own and the Spanish language. All that I could understand of his history was, that he was Cacique of some Indian tribes at a distance: he was evidently a great favourite, and although Maria spoke generally with much contempt of the Fuegian Indians, she had patronised this stranger, for he lived in her toldo, and shared all the presents that were made to her.

The following morning it rained hard, and blew so fresh a gale, from the westward, that it would have been dangerous to send a boat on shore: and I was obliged to weigh without landing the things which I had promised. After we were under weigh, the weather cleared partially, when we observed Maria on the beach, mounted on her white horse, with others watching our departure, and when it was evident that we were really gone, she rode slowly back to her toldo, no doubt considerably vexed. I was very sorry to treat them in this way, for their conduct towards us had been open and friendly. All I could hope to do, to make amends, was to give something of value at my return.

We steered across the Bay of St. Philip, accompanied by

the Beagle,* left the Strait of Magalhaens with a fair wind, and, after a favourable passage, reached Monte Video on the 24th April 1827.

From Monte Video we went to Rio de Janeiro, to procure stores, and prepare for another voyage to the Strait. On our arrival I received the Commander-in-chief's leave to apply to the Lord High Admiral for permission to employ a tender, to facilitate the surveys of the sounds and deep channels, in the neighbourhood of the Strait, and the inner sounds on the west coast; for which, neither the Adventure, nor the Beagle, were adapted; and I thought it best to delay our departure until an answer to my application was received.

* We left Gregory Bay in the morning, and passed Cape Virgins in the evening of the same day.

CHAPTER VII.

Leave Rio de Janeiro—Santos—St. Catherine's—Monte Video—Purchase the Adelaide schooner, for a Tender to the Adventure—Leave Monte Video—Beagle goes to Port Desire—Shoals off Cape Blanco—Bellaco Rock—Cape Virgins—Possession Bay—First Narrow—Race—Gregory Bay—View—Tomb—Traffic with Natives—Cordial meeting—Maria goes on board—Natives intoxicated—Laredo Bay—Port Famine.

We were ready to resume our voyage early in September (1827); but not having received any communication by the packet, from the Admiralty, relative to the purchase of a tender, I determined to await the arrival of the next, early in October. I was again disappointed, and very reluctantly left Rio de Janeiro, on the 16th, for Monte Video; but that I might still benefit by the orders which were sure to be in the following packet, I determined upon calling at Santos, and St. Catherine's, for chronometrical observations; leaving the Beagle to wait for letters conveying the decision of his Royal Highness the Lord High Admiral.

We reached Santos on the 18th, and staid there until the 28th. In this interval I paid a short visit to St. Paul's, for the purpose of making barometrical observations.* At St. Cathe-

* On our passage from Santos to St. Catherine's, in latitude 28° south, we caught a 'dolphin' (*Coryphena*), the maw of which I found filled with shells, of *Argonauta tuberculosa*, and all containing the '*Octopus Ocythöe*' that has been always found as its inhabitant. Most of the specimens were crushed by the narrow passage into the stomach, but the smaller ones were quite perfect, and had been so recently swallowed that I was enabled to preserve several of various sizes containing the animal. To some of them was attached a nidus of eggs, which was deposited between the animal and the spire. The shells varied in size from two-thirds of an inch to two and a half inches in length; each contained an octopus, the bulk and shape of which was so completely adapted to that of the shell,

rine's we remained eight days, and during the interval necessary for ascertaining the rates of the chronometers, I obtained magnetic observations.

After a tedious voyage of nineteen days from St. Catherine's, I arrived at Monte Video, and there received intelligence that the long-wished permission from the Lord High Admiral, to procure a tender, had been obtained. I accordingly purchased a schooner, which I named the Adelaide, and appointed Lieutenant Graves to the command. Five months' additional provisions for both vessels were purchased, and put into her; and on the 23d December, after running up the river to complete our water, we sailed out by the southern entrance, passing to the westward of the Archimedes' Shoal, and proceeded without farther detention to the southward.

On the 1st of January (in latitude 43° 17′ and long. 61° 9′), I was informed that we were close to a rock. Upon going on deck, I saw the object; but in a very short time I perceived it was a dead whale, upon whose half-putrid body large flocks of birds were feeding. Many on board were, however, sceptical, until, on passing to leeward, the strong odour testified the fact. Its appearance certainly was very like the summit of a dark brown rock, covered with weeds and barnacles, and the myriads of birds which surrounded it added to the deception. It could, however, be distinguished by its buoyancy; for the water did not break over it, as of course it would have done had it been a fixed body. Such is probably the origin of half the 'vigias' that are found on the charts. Whales, when struck by the fishers, frequently escape and perish; the carcass then floats on the surface of the sea, until decomposed or eaten by birds and fishes. A small vessel striking against such a mass, would probably be severely injured; and at night, the

shell, that it seemed as if the shell increased with the animal's growth. When so many learned naturalists have differed so materially as to the character of the inhabitants of the argonauta, it would be presumption in me to express even an opinion; I therefore merely mention the fact, and state that in no one specimen did there appear to be any connexion between the animal and the shell.

© The Complete Work of Charles Darwin Online

body, from its buoyancy and the sea not breaking against it, would not be readily seen.

On the 4th, being about one hundred miles to the N.E. of Cape Blanco, I communicated with Captain Stokes, and gave him directions to proceed to Port Desire for chronometrical observations, and then follow me immediately to Cape Fairweather or Cape Virgins. We had light winds during the night, so that the Beagle made very little progress. In the afternoon, Cape Blanco, a long level-topped ridge, came in sight, of which good views are given in Lord Anson's voyage. We steered towards the land, and at six o'clock were in eighteen fathoms, the rocky hill at the extremity of the Cape bearing S. 10° E. thirteen miles; at seven o'clock, the same hill was six miles and a half off, bearing S. 3° E., when we observed a line of rippling water, extending from east to as far as we could see on the south horizon. The depth was seventeen fathoms, but as we proceeded it gradually decreased to twelve and ten, and soon afterwards to seven fathoms, when the Beagle was observed to be firing guns; but whether they were intended to warn us of danger, or as signals of her own distress, we could not determine, and I hauled to the wind to cross where the ripple appeared least violent. In passing through it we had not less than seven fathoms, and then it deepened to twelve and fifteen fathoms. We had now leisure to attend to the Beagle, and soon saw that her signals were only to warn us, for she had resumed her course under a press of sail.

After steering four miles to the S.E., we again found ourselves in the midst of ripplings, in which the water shoaled to six fathoms. It being then dark, and not knowing how to proceed, we shortened sail and brought to the wind, in order that if the ship struck it might be with less force; but happily we passed on without any further decrease of soundings. In going through the ripple, the Adelaide, though deeply laden, behaved well.

Commodore Byron passed over these shoals, which he describes as lying at a greater distance from the shore: it was to avoid them that we passed so near the land.

© The Complete Work of Charles Darwin Online

During the following evening there was a very heavy dew, the never-failing prognostic of a northerly wind; the horizon, also, was very hazy, and the water perfectly smooth. We were not more than ten miles off shore, yet the land was completely distorted in appearance by mirage.

Next morning we were very close to the position assigned to the Bellaco, or St. Estevan's Shoal, the existence of which has been very much doubted. It was discovered by the Nodales, and in the diary of their voyage is thus described: "At five o'clock, or later in the evening, we discovered a rock a-wash ('una baxa que lababa la mar en ella') about five leagues from the shore, more or less. It is a very deceitful rock ('Es muy bellaco baxo'), because it is under water, over which, in fine weather and smooth water, the sea breaks. We sounded near it, and found twenty-six fathoms stony bottom. Its latitude is 48½°, according to our noon observation, and the course and distance we have since run."*

The late Don Felipe Bauza, one of the companions of Malespina, informed me, that on the voyage of the Descubierta and Atrevida, their boats were sent to look for it, but were unsuccessful.

At noon we were in lat. 48° 40′ S., long. 66° 6′, depth forty-two fathoms, but without any signs of the Bellaco. Sailing on, the coast was seen in the neighbourhood of Beachy Head (so named from its resemblance to the well-known promontory). Afterwards, Cape Fairweather came in sight, and on the 10th Cape Virgins, which we passed in the evening, and, half an hour afterwards, rounding Dungeness, we again entered the Strait of Magalhaens; and anchored near the northern shore.

In Possession Bay we were detained several days, although repeated attempts to pass the First Narrow were anxiously made.

One evening, clouds gathered, and the weather assumed such a threatening appearance, that I expected to be obliged to run to sea; but to our surprise, when the cloudy mass seemed on

* Nodales, p. 48.

© The Complete Work of Charles Darwin Online

the point of bursting over us with a deluge of rain, it suddenly vanished, and was succeeded by a beautifully clear and fine night. This favourable appearance gave us hopes of being able to make good our entrance on the following day; but a fresh gale set in, and kept us at our anchorage.

Early on the 14th we made another fruitless attempt to pass the First Narrow. As the Adelaide sailed under our stern, Lieutenant Graves informed me that he had lost an anchor, and had only one left, to which he had bent his chain-cable; and that she had shipped so much water in attempting to beat through, that he was on the point of asking permission to bear up when we ourselves gave up the attempt. It blew too hard to give any assistance to the Adelaide, but next morning, when the weather was more moderate, I seized an opportunity of sending our two kedge anchors; and in the afternoon we supplied her with some water and other necessaries, so that she was comparatively well off, and my anxiety on her account much relieved.

Fires on the Fuegian side had been kept up since our arrival, but we could not distinguish any inhabitants; on the Patagonian shores we saw a great number of guanacoes feeding quietly, a proof of there being no Indians near them.

On the 16th, the weather appearing favourable, our anchor was weighed, and, with the Adelaide, we soon entered the sluice of the Narrow, proceeding rapidly, though the wind blew hard against us. The tide carried us to an anchorage, about four miles beyond the western entrance, and it was slack water when the anchor was dropped; but, no sooner had the stream turned, than we found ourselves in the midst of a 'race,' and during the whole tide, the water broke furiously over the ship. At slack water we got underweigh, but the Adelaide not being able (from the strength of the tide), to purchase her anchor, was obliged to slip the cable: it was fortunate that we had supplied her with our kedges, or she would then have been without an anchor. The night was tempestuous, and although we reached a much quieter birth, the Adelaide drifted considerably; had she remained at the morning's anchorage,

© The Complete Work of Charles Darwin Online

in order to save her anchor and cable, we should probably never have seen her again.

The succeeding morning, after a hard beat to windward, both vessels anchored in Gregory Bay. No Indians were in the neighbourhood, or we should have seen their fires. In the afternoon the wind moderated, and as there was every appearance of fine weather, I remained to survey the coast.

On the summit of the land, about half a mile northward of the extremity of the Cape, while Lieutenant Graves and I were taking bearings, and making observations, two guanacoes came up and stood neighing at us; the observation, however, was of consequence, and as they were not disturbed, they remained watching us for some minutes before they took alarm and fled.

Lieutenant Wickham and Mr. Tarn made an excursion to the summit of the Table Land, previously described as extending from the low land behind the Second Narrow to the N.E., in the direction of Mount Aymond, and were amply repaid for a fatiguing walk, with the thermometer at 81°, by a magnificent view: Cape Possession to the eastward, and to the south the mountains near Mount Tarn, eighty miles distant, were plainly distinguished. The view to the westward, stretching over a large extent of grassy plains, was bounded by lofty ranges of snow-capped mountains; but to the north it was intercepted by another summit of the mountain upon which they stood. The country they passed over was covered with short grass, through which a mass of granite occasionally protruded. Neither trees nor shrubs were observed, excepting a few herbaceous plants, and the berberis; a goose, some ducks, snipe, and plovers were shot; and guanacoes were seen at a distance, but no ostriches, nor did they meet any Indians. Large fires were, however, kindled on both shores of the Strait, in answer to the fire which they made for cooking. In consequence of those on the Patagonian coast appearing so close to us, we expected a visit from the natives before night, but none made their appearance.

Next morning, Mr. Graves accompanied me in a boat to a

© The Complete Work of Charles Darwin Online

station three miles within the Second Narrow on the north side, and in our way we found the geological structure of the cliffs to be of a decomposed clay-slate, arranged in strata, much distorted by the violent action of the water, and dispersed in vertical and inclined directions in very thin laminæ.

These cliffs are about one hundred feet high, the soil a sandy alluvium, of a sterile character, scantily covered with a wiry, stunted grass, and here and there a berberis bush, loaded with ripe fruit, which, from the poverty of the soil, was tasteless and dry; the ground was also, in many parts, over-run to a considerable extent with an insipid cranberry, scarcely worth the trouble of gathering.

We struck across the country, with the view of examining the place where the Indians were residing at our last visit, and the tomb which had then been erected. Grass had grown up, and effaced the traces of feet; but the tomb had suffered no farther alteration than the weather might have effected. We found that the place had been recently visited by the natives, for within a few yards of the entrance were strewed the ashes of a large fire, containing vestiges of the former decorations of the tomb, and the end of one of the flag-staffs, with the unburnt corner of one of the banners. Amongst the ashes, also, we found calcined bones; but whether they were human or not, we could not ascertain.

The discovery of the bones impressed us with the idea that the body had been burnt, and determined me to examine the tomb. The bushes that filled up the entrance appeared to be placed exactly as when we first saw them, and indeed the whole pile seemed to have remained quite undisturbed; but there was no appearance of the brass ornaments, or of the effigies of the horses.

Having effected an opening in the bushes, we found an inner covering, made of horse-skins. Having cut two holes opposite each other, for the admission of light, we saw nothing but two parallel rows of stones, three in each row, probably intended as a bier for the body or a covering for the grave; but the ground around and between them bore no appearance

© The Complete Work of Charles Darwin Online

of having been disturbed for burial.* As we hourly expected the Indians would arrive (the place being in the direct line of their journey to the ships), and were unwilling to let them know we had disturbed the sanctuaries of their dead, we restored the former appearance of the tomb; and it was fortunate we did so, for three women on horseback, carrying their children in cradles, with a quantity of skins, provisions, and other merchandise, evidently the harbingers of the tribe, made their appearance, and immediately began to erect their tents.

When we next went on shore we found several Indians arrived, and divided into three groups, with mantles, ostrich-feathers, skins, and joints of guanaco meat displayed for sale.

As the meat appeared fresh, it is probable that, on seeing us, the women were despatched to place the toldos, while the men set out to provide guanaco meat, for they knew our partiality for this excellent food. When we landed, an active barter began.

From the haste and avidity shown in offering their goods, and closing the bargains, it seemed as if they were anxious to monopolize our articles of barter before the rest of their party, or tribe arrived. One old man attempted to cheat; but my interdiction of all farther traffic with him brought him to a sense of his error, and I then made him a present of some tobacco and allowed him to trade, which he afterwards did, with cheerfulness and honesty.

One of the party was the Fuegian chief, whom I previously noticed, as a squalid, meagre-looking man; but he was now enlarged to Patagonian dimensions, by his improved diet and more cheerful mode of life. The appearance of bad weather obliged us to suspend the barter and get on board. After we had reached the ship, successive parties of the tribe arrived,

* Falkner says, in his account of the burial ceremonies of the southern Patagonians—that, after a certain interval, the bodies are taken out of the tomb, and skeletons are made of them by the women—the flesh and entrails having been burnt. It is possible that in this case the body had been so treated, and that the fire near it was for the purpose of burning the flesh, and perhaps with it all the flags and ornaments of the tomb.

© The Complete Work of Charles Darwin Online

and formed the encampment. Among them, mounted on her white horse, was Maria, who, duly escorted, paraded on the beach to challenge our recognition. In the centre of the encampment, a large flag suspended from a pole was a signal to us, and showed the position of her toldo.

The next morning being fine, we landed near the encampment, and were most cordially received. Maria was particularly attentive, and embraced me closely, while her companions chaunted in chorus a song of delight at our arrival.

When we reached her toldo, a mat was spread out for me to sit on. Maria and her family placed themselves in front of me, while the rest sat round. Almost the first question was an inquiry for my son Philip, whom they called Felipe,* and two or three skins were given to me for him. They then asked for our pilot on the former voyage, and were much disappointed to find he had left the ship. After a short conversation I returned the two bags (which I had so unwillingly carried away at our last visit), having filled them with flour and sugar, and then proceeded to deliver our presents. As each article was delivered into her hands, she repeated, in Spanish, "I'll pay for this;" but upon a bit for her horse being presented, a general burst of admiration followed, and it was handed round the tents, whilst each individual, as it passed on, looked, I thought, anxious to be its possessor.

Maria then began to consider what adequate requital she could possibly make me. The result was, a present of two mantles, one new, of guanaco skin, and the other well worn, of zorillo skin, besides two or three skins of the puma. She then produced a piece of paper, carefully wrapped up in canvas, containing a letter, or memorandum, left by Mr. Low, master of the Uxbridge sealer, addressed to any shipmaster passing through the Strait, apprising him "of the friendly disposition of the Indians, and impressing him with the necessity of treating them well, and not deceiving them; for they had good memories, and would seriously resent it."

The advice, no doubt, was good; but I think the fear of

* He was a great favourite with them.

© The Complete Work of Charles Darwin Online

forfeiting advantages and comforts to be derived from traffic would induce them to restrain their resentment.

I brought no spirits; for which, after a short time, Maria asked, complaining that she was very ill, and had sore eyes, and for some time past had nothing but water to drink, and wood to smoke. Her illness was evidently assumed, but her eyes seemed highly inflamed; and no wonder, for the upper part of her face was smeared over with an ochrous red pigment, even to the very edge of her eyelids: indeed, the whole tribe had ornamented themselves similarly, in compliment, I suppose, to our visit.

As I prepared to return on board, Maria's importunity induced me to allow her to accompany me; upon which she began to muster up all her empty bags, old mantles, and skins, and, attended by her husband, her brother-in-law, his wife and daughter, got into the boat. While going on board, the spray washed the painted countenances of our visitors, much to their regret.

Upon reaching the ship, I ordered them to be regaled with meat and biscuit, of which they partook very sparingly, but took care to put what remained into their bags. Some spirits and water, too, which I thought would be soon dispatched, and which had been plentifully diluted to prevent their being made tipsy, they emptied into bottles to take on shore "for the evening," when, as Maria said, they would be "very drunk."

Among various things shown to amuse them was a musical snuff-box, which I had procured for the express purpose of exciting their astonishment; but I was surprised to find, that a penny-whistle produced a ten-fold greater effect upon their senses. This indifference to musical sounds I should not have suspected, because they frequently sing, though certainly in a monotonous manner.

As soon as their repast was concluded, the party, except Maria and the girls, commenced bartering their mantles and skins, and, by the time their stock was expended, they had amassed a large quantity of biscuit, and a bundle of various

© The Complete Work of Charles Darwin Online

trifles, some of which they had attempted to get by pilfering. They made themselves so contented, that it was not without much difficulty we could persuade them to go on shore. Maria had made her mind up to pass the night on board, and so anxious were they all to remain, that it was only by giving Maria two bottles of spirits (which had been well diluted) that they were induced to get into the boat, and accompany me ashore. Being a lee-tide, and low water, the boat grounded at a considerable distance from the beach; seeing this, some of the Indians rode into the water, and taking us up behind them, conveyed us to the encampment, my place being behind Maria, the smell of whose zorillo-skin mantle was hardly bearable; but it was necessary to conceal our dislike of our companions as much as possible, for they are very sensitive, and easily offended.

While waiting for the tide, we witnessed a drunken scene at Maria's toldo. Fifteen persons, seated around her, shared the spirits she had obtained on board, until all were intoxicated. Some were screaming, others laughing, some stupified, and some bellowing. The uproar drew all the other Indians round the tent, who tendered their assistance to compose their friends, and we returned to the ship. When we visited them the next day, they were quite recovered, and gave us some guanaco meat, which had been brought in that morning. On communicating my intention of proceeding on the voyage, Maria wished to know when we should finish our "seal-killing," and come back. I told her "in five moons," upon which she endeavoured to persuade me to return in four, because she would then have plenty of skins to barter.

I wrote a few lines to Captain Stokes, who, I expected, would arrive in a day or two, communicating my desire that he should follow, as soon as possible, to Port Famine, and committed the letter to Maria's care, who promised to deliver it to him; then, taking leave of her and her companions, I embarked, and proceeded through the Second Narrow to an anchorage off Cape Negro.

Our visit to Gregory Bay, and communication with the

© The Complete Work of Charles Darwin Online

Indians, furnished us with many additions to our zoological collection; among them was a tiger-cat, which seemed, from the description, to be the *Felis pajaros* of the Encyclopédie Méthodique (the "Chat de Pampa" of D'Azara). Maria gave me a very large bezoar stone, that was taken from the stomach of a guanaco. It is used medicinally by the Indians, as a remedy for bowel complaints.*

Whilst we were at the anchorage before Cape Negro, Mr. Tarn and Mr. Wickham visited the lake at the back of Laredo Bay, and saw two swans, which, from the colour of their plumage, seemed to be the black-necked swan of the River Plata and of the Falkland Islands† (Dom Pernettey, ii. p. 148). They brought on board with them a new species of duck, which is described in the proceedings of the Zoological Society as *Anas specularis* (Nob.), and a small burrowing animal, of the rat tribe, that, from the character of its teeth, is probably of a genus not hitherto noted: it approaches nearest to F. Cuvier's *Helamys*.

We next anchored in Port Famine, where the tents, &c. were replaced in their former positions, the ship was unrigged and secured for the winter, and all hands set to work, preparing the Adelaide for service.

* The medicinal property of this intestinal concretion is well known wherever the animal is found. Marcgrave, in his "Tractatus topographicus et meteorologicus Brasiliæ," folio, p. 36, says:—"Hæc animalia (guanacoes) generant lapides Bezoares in sinu quodam ventriculi, qui maximi æstimantur contra venena et febres malignos ad roborandum et refocillandum cor, aliosque affectus. Materia è qua generantur sunt herbæ insignis virtutis, quibus vescuntur naturæ instinctu ad sanitatem tuendum, aut morbos et venena superandum. Hi lapides inveniuntur in adultioribus hisce animalibus atque interdum tam grandes, ut unum in Italiam attulerim qui pendet uncias duas supra triginta."—Mr. Thompson, on Intestinal Concretions. See his Syn. of Chemistry, iv. 576.

CHAPTER VIII.

Find that the Cutter had been burned—Anxiety for the Beagle—Uxbridge Sealer—Beagle arrives—Her cruize—Bellaco Rock—San Julian—Santa Cruz—Gallegos—Adeona—Death of Lieutenant Sholl—Adelaide Sails—Supposed Channel of San Sebastian—Useless Bay—Natives—Port San Antonio—Humming-birds—Fuegians—Beagle sailed—Sarmiento—Roldan—Pond—Whales—Structure—Scenery—Port Gallant.

Port Famine bore evident marks of having been visited in our absence by the Indians, for a large fire, apparently recent, had over-run the grass, and burned the trees upon Point Santa Anna, particularly in that part where our boat had been so carefully concealed. Eager to know whether she had escaped the fire, I lost no time in hastening to the spot, directly after the Adventure anchored, and found, as our fears had anticipated, that she had been completely destroyed, scarcely a vestige of her wood remaining, and most of the iron-work having been carried away; for which, doubtless, the Indians had set her on fire.

The sheds for the cooper and armourer, which had been erected with some pains, were also entirely consumed, and every thing portable had been carried away. Those things which were of no use to them were either broken or burnt; but some of our station poles on Point Santa Anna were left uninjured; as well as the tablet erected to the memory of Mr. Ainsworth and the boat's crew; which was singular, because it was secured by iron hoops—of great value, in their eyes.

From the fresh traces of horses in the neighbourhood, we at first suspected the conflagration to have been caused by the Patagonians; but we soon found we owed our loss to the Fuegians, for in two new wigwams were strewed some remains of our boat.

The last winter appeared to have been milder than that preceding it, for last January, Mount Sarmiento and the hills to

© The Complete Work of Charles Darwin Online

the southward, over Fitton Bay, were so covered with snow, that not a particle of the rock could be seen; but this year many bare spots were visible. Every thing else, however, indicated a bad season, and the berberis bushes and arbutus shrubs had scarcely any show of fruit; which was rather a disappointment, as the berries of the former plant proved an agreeable addition to our food last year. However, there was no scarcity of birds, and with the seine we procured plenty of fish.

The Beagle's long and unexpected absence caused us much uneasiness, and some apprehension for her safety. Her visit to Port Desire ought not to have occupied more than three days, and her superior sailing should have enabled Captain Stokes to rejoin us in the entrance of the Strait. People were sent daily to look out for her, and every succeeding day increased our anxiety.

A long succession of blowing and rainy weather much impeded our progress with the Adelaide; but the Hope was hoisted out, and prepared for service.

Before daylight on the 14th I was informed that the Beagle was seen in the offing. Blue lights were burnt, and lanterns immediately shown to guide her to the anchorage; but our disappointment was great when the stranger proved to be Mr. W. Low's schooner, the Uxbridge. He had been sealing since November in the neighbourhood of Noir Island, near the outer entrance of the Barbara Channel, and was on his way to Cape Gregory to meet his elder brother, who had been collecting sea-elephant oil at South Shetland. The Uxbridge had entered the Strait from the Pacific, by the Magdalen 'Channel,' which last year we thought a Sound, and had attempted to explore in the Hope, but had been deceived by the abrupt change in the direction of the Channel at Cape Turn.

At last (on the 28th), after the Beagle's absence had been protracted to more than a month beyond the time intended, we were relieved from painful anxiety, and much rejoiced, by Mr. Tarn's telling us he had just seen her, and in two hours afterwards she arrived.

Captain Stokes, to my great surprise, told me that he had

© The Complete Work of Charles Darwin Online

been examining the whole coast between Port Desire and Cape Virgins, and for the last ten days had been detained in the Gallegos River by heavy gales of wind. He had sounded round, and fixed the position of the Bellaco Rock, or St. Estevan's Shoal, the existence of which had been so long doubted. He had also visited and partially surveyed, the harbours of Port San Julian and Santa Cruz, besides Coy Bay, and had made almost a complete survey of the River Gallegos, which he found to be a large and rapid river, whose entrance forms a spacious port: instead of being blocked up by a mound of shingle four or five feet above the level of the sea, and having so small a stream as to escape the notice of Mr. Weddell as he walked along the beach.* Cape Fairweather is so remarkable, and so correctly placed upon the chart, that Mr. Weddell, in his search for the river, must have very much deceived himself. I should think he must have mistaken the ravine described upon my former visit, since that is the only part which answers his description: it could not be Coy Bay, because that opening, although of minor importance, has a broad boat communication with the sea.

Captain Stokes described the tide at the anchorage, within the mouth of the Gallegos, as running at the rate of five knots, and rising forty-six feet. From Mr. Weddell's account, he was on the point of passing by without examining it; but the weather being fine, he determined to go in his boat and ascertain the truth of that description. It was soon evident that the river was large, and, returning to his ship, he lost no time in anchoring her within the entrance, where she rode out a heavy gale from S.W.

The Beagle left the Gallegos on the 23d, and reached Port Famine on the 28th, a very short passage, since she remained for a night and the greater part of a day at Gregory Bay, to communicate with the natives. When approaching the First Narrow, Captain Stokes observed a brig, apparently at anchor, under Cape Orange, and supposing her either to have found a good anchorage, or to be in distress, steered towards her.

* Weddell's Voyage.

© The Complete Work of Charles Darwin Online

Before he had reached within two miles of her, the Beagle touched the ground, but was extricated from the danger most fortunately, because it was nearly high water; and had she remained a-ground during the tide, the consequences might have been serious—at least, she could not have been got off without lightening her considerably. The brig proved to be the Adeona (Mr. Low's vessel), on her way to meet the Uxbridge. In attempting to enter the narrow, she grounded on the shoals, and had been left dry. The following tide again floated her, and she was on the point of getting underweigh, when the Beagle hove in sight. Captain Stokes finding that the Adeona had received no damage, proceeded to Gregory Bay.

By the Beagle's arrival we were informed of the death of Lieutenant Robert H. Sholl, after an illness of ten days. His remains were interred at Port San Julian, where a tablet was erected to his memory.

This excellent young man's death was sincerely regretted by all his friends, and by none more than by me. He was appointed to the expedition, as a midshipman, solely on account of his high character.

During our voyage from England, he made himself conspicuously useful in saving the cargo of a vessel, which was stranded in Port Praya; and on our arrival at Rio de Janeiro, the Commander-in-chief appointed him to a vacant lieutenantcy on board the Beagle: an appointment which, up to the period of his lamented death, he filled zealously and most creditably.*

On the 1st of March we were surprised by the appearance of three Europeans, walking round Point St. Anna. A boat

* I cannot avoid noticing here the considerate conduct of the Commander-in-chief (Sir George Eyre) with respect to this appointment. By the tenor of my instructions the Adventure and Beagle were placed under the Admiral's orders; and the vacancy, had he wished to exercise his prerogative, might have been filled by one of his own followers. It was, however, given, at my request, to Mr. Sholl, as being more conversant with the duties of this peculiar service than any of the midshipmen of the flag-ship. The Admiral's conduct, on this occasion, calls for my warmest thanks.

© The Complete Work of Charles Darwin Online

was sent for them, and we found they were deserters from the Uxbridge, who had come to volunteer for our ships.

The following day the Adeona and Uxbridge arrived, on their way to Port San Antonio, to boil their oil; but I recommended Bougainville, or (as the sealers call it) Jack's Harbour, as more convenient for their purpose, and more secure from storms, as well as from troublesome visits of the natives.

Upon my offering to restore the three deserters to the Uxbridge, Mr. Low requested me to keep them, and another, also, who was anxious to join the Adventure, to which I consented, as the Adelaide wanted men.

A few days after Mr. Low's departure, he returned in a whale-boat to ask assistance in repairing the Uxbridge's rudder. By our help it was soon made serviceable, and she was enabled to prosecute her voyage, which could not otherwise have been continued.

The Adelaide being ready for sea: her first service was to be an examination of the St. Sebastian Channel, which, from its delineation on the old charts, would seem to penetrate through the large eastern island of Tierra del Fuego. In the voyage of the Nodales (in the year 1618), an opening on the eastern coast, supposed to be the mouth of a channel, communicating with the Strait of Magalhaens, was discovered. After describing the coast to the south of Cape Espiritu Santo, the journal of that voyage states: "We found, in the channel of St. Sebastian, twenty fathoms clear ground. The north shore is a beach of white sand, five leagues in extent, stretching out from the high land that terminates at Cape Espiritu Santo, and giving the coast here the appearance of a deep bay; but, on a nearer approach, a projecting tract of low shore is observed. The south extremity of this low beach is a sandy point, round which the channel trends; the mouth is a league and a half wide. The south shore is higher than the land to the northward, and in the middle of the bay the depth is from fifteen to twenty fathoms clear ground, and a good bottom; but from mid-channel to the south shore the bottom is stony, and the water, of little depth, there being only six and seven fathoms. From

© The Complete Work of Charles Darwin Online

hence the channel shows itself, and continues, as far as we could see, of the same breadth. It seemed to be a large sea. The latitude was observed to be 53° 16′." *

From the above account, and from the chart that accompanies it, in which this inlet is made to communicate with the Strait of Magalhaens by the opening round Cape Monmouth, our knowledge of the supposed St. Sebastian Channel was derived. That there is a deep bay, in the latitude of 53° 16′, not only appears from the account of the Nodales, who were within the heads, although it seems they did not proceed beyond the stony ground on the south side of the entrance; but also from the accounts of vessels who have lately seen it; and of one ship-master who was deterred from entering, by the formidable notice on our charts of its being "only navigable for small vessels," whence he conjectured that the tides would be very strong, and the channel occasionally narrow, as well as and shoal.

Sarmiento, Narborough, Byron, Wallis, Bougainville, and Cordova, have severally noticed an opening, which corresponds to this supposed channel, namely, that between Capes Monmouth and Valentyn; but the object of those voyagers having been to make the passage through the known Strait, to explore this opening was, in all probability, considered a waste of time; yet, that such a channel was supposed to exist, we must conclude from the conspicuous figure it makes in the charts of Tierra del Fuego.

Had there been a knowledge of its affording any communication with the sea, surely Sarmiento and Narborough, as well as the Nodales, who navigated the Strait from west to east, would have been induced to attempt to pass through; and avoid the dangers, as well as difficulties, of the channels to the northward.

Anxious to set the question at rest, I gave Captain Stokes orders to proceed to survey the western coasts, between the Strait of Magalhaens and latitude 47° south, or as much of

* Relacion del Viage, &c. que hicieron los Capitanes B. G. de Nodales y Gonzalo de Nodales, p. 59.

© The Complete Work of Charles Darwin Online

those dangerous and exposed shores as he could examine, with the means at his disposal, and sailed myself, in the Adelaide, to explore the supposed St. Sebastian Channel. Every discretionary power was given to Captain Stokes to act as he pleased, for the benefit of the service; but he had strict orders to return to Port Famine by the 24th of July, when I hoped to move the Adventure to some other part of the Strait, and to recommence operations with the earliest days of spring, if the winter should be unfit for our work.

Having crossed over to the southward of Point Boqueron, we proceeded, on the 13th of March, to the N.E. (in which direction the opening trended), at no great distance from the northern shore; behind which the country seemed to rise gradually to the summit of a long ridge of table-land, terminating near the First Narrow, and appearing like that in the neighbourhood of Cape Gregory. It was inhabited; for here and there we observed the smoke of fires, perhaps intended as invitations for us to land.

The south side of the opening seemed (after forming a small bay under Nose Peak) to extend in a direction parallel to the northern coast of the bay, for three or four leagues, when it dipped beneath the horizon. Neither shore had any opening or indenture in its coast line, of sufficient size to shelter even a boat; so that a vessel caught here, with a south-westerly gale, would have little chance of escape; unless a channel should exist, of which, from the stillness of the water and the total absence of tide, we had very little hope. The soundings were variable between twenty and thirty fathoms, and the bottom seemed to be of shells, probably covering a substratum of clay or sand. As we stood on, a small rocky lump came in sight, which appeared to be the termination of the northern shore, and again we flattered ourselves with the expectation of finding a passage; but in less than half an hour afterwards, the bay was distinctly seen to be closed by low land, and the rocky lump proved to be an isolated mass of rock, about two miles inland. As every person on board was then satisfied of the non-existence of any channel, we put about to return, and

© The Complete Work of Charles Darwin Online

by bearings of Mount Tarn, crossed by angles from Mount Graves, Nose Peak, and Point Boqueron, our position, and the extent of this bay, were determined. As it affords neither anchorage nor shelter, nor any other advantage for the navigator, we have named it Useless Bay. It was too much exposed to the prevailing winds to allow of our landing to examine the country, and its productions, or to communicate with the Indians; and as there was not much likelihood of finding anything of novel character, we lost no time in retreating from so exposed a place. Abreast of Point Boqueron the patent log gave for our run twenty-six miles, precisely the same distance which it had given in the morning; so that from five o'clock in the morning until ten, and from ten o'clock until four in the afternoon, we had not experienced the least tide, which of itself is a fact confirmatory of the non-existence of a channel.

From the fires of the natives in this part having been noticed at a distance from the beach, it would seem that they derive their subsistence from hunting rather than fishing; and as there are guanacoes on the south shore of the First Narrow, it is probable the people's habits resemble those of the Patagonians, rather than the Fuegians; but as they have no horses, the chase of so shy and swift an animal as the guanaco must be fatiguing and very precarious.*

Sarmiento is the only person on record who has communicated with the natives in the neighbourhood of Cape Monmouth. He calls them in his narrative a large race (Gente grande). There it was that he was attacked by the Indians, whom he repulsed, and one of whom he made prisoner.

We remained a night in Port Famine, and again set out in the Adelaide to survey some of the western parts of the Strait.

* Falkner describes the Indians who inhabit the eastern islands of Tierra del Fuego, to be 'Yacana-cunnees,' and as he designates those who inhabit the Patagonian shore of the Strait by the same name, it might be inferred that they are of the same race; but however closely connected they may have been formerly, they certainly are not so now, for Maria (the Patagonian) spoke very contemptuously of them, and disclaimed their alliance; calling them 'zapallios,' which means slaves.

© The Complete Work of Charles Darwin Online

Bad weather forced us into Port San Antonio; of which Cordova gives so favourable an account, that we were surprised to find it small and inconvenient, even for the Adelaide.

He describes the port to be a mile and a half long, and three quarters of a mile broad: we found the length a mile and a quarter, and the mean breadth scarcely a quarter of a mile. It possesses no one advantage that is not common to almost every other harbour and cove in the Strait; and for a ship, or square-rigged vessel of any kind, it is both difficult to enter, and dangerous to leave. Besides the local disadvantages of Port San Antonio, the weather in it is seldom fair, even when the day is fine elsewhere. It lies at the base of the Lomas Range, which rises almost perpendicularly to the height of three thousand feet, fronting the great western channel of the Strait, whence it receives upon its cold surface the western winds, and is covered by the vapour, which is condensed from them, while in all other parts the sun may be shining brightly.

This port is formed by a channel, a quarter of a mile wide, separating two islands from the shore. The best anchorage is off a picturesque little bay on the south island, which is thickly wooded to the water's edge with the holly leaved berberis,* fuchsia, and veronica, growing to the height of twenty feet; over-topped and sheltered by large beech, and Winter's-bark trees, rooted under a thick mossy carpet, through which a narrow Indian path winds between arbutus and currant bushes, and round prostrate stems of dead trees, leading to the seaward side of the island. Upon the beach, just within the bushes, and sheltered by a large and wide-spreading fuchsia bush, in full flower, stood two Indian wigwams, which, apparently, had not been inhabited since the visit of poor Ainsworth. He had occupied these very wigwams for two days, having covered them over with the boat's sail; and remains of the ropeyarns that tied it down were still there: a melancholy memento.

In no part of the Strait did we find the vegetation so luxuriant as in this little cove. Some of the Winter's-bark and currant trees had shoots more than five feet long, and many of the

© The Complete Work of Charles Darwin Online

Winter's-bark trees were two feet in diameter. The veronica (I believe *V. decussata*) grows in the sheltered parts to the height of twenty feet, with a stem six inches in diameter. It was found too on the windward side of the island in abundance, and of large size, rooted in the very wash of the sea-beach, and exposed to the full force of the cold winds and hail-storms, which rush down the wide western reach of the Strait.

The fuchsia also grows to a large size; but it is a more delicate plant than the veronica, and thrives only in sheltered places. Many were observed six inches in diameter; the stems of the two last plants were used by us, during our stay, for fuel.

The day after our arrival, the gale subsided, and the weather became very fine indeed. The stillness of the air may be imagined, when the chirping of humming-birds, and buzzing of large bees, were heard at a considerable distance. A humming-bird had been seen at Port Gallant last year, and was brought to me by Captain Stokes, since which none had been noticed. Here, however, we saw, and procured several; but of only one species.* It is the same as that found on the western coast, as high as Lima; so that it has a range of 41° of latitude, the southern limit being 53½°, if not farther south.

The islets, at the north part of the port, were well stocked with geese and other birds, which supplied our people with fresh meals. The steamer duck we found difficult to shoot, from its excessive wariness, and power of remaining, for a great length of time, under water.

Our fine weather lasted but a few hours, and (no unusual occurrence in these regions) was succeeded by a week's rain and wind, during which we were confined to the small space

* The specimen that was found at Port Gallant was sent by me to Mr. Vigors, who considering it, although well known to ornithologists, as never having yet been named, describes it in the Zoological Journal (vol. iii. p. 432, Aug. 1827), as Mellisuga Kingii. Shortly afterwards M. Lesson published it in his Manuel d'Ornithologie (vol. ii. p. 80.), as *Ornismya sephaniodes*, as a discovery belonging to La Coquille's voyage, in the illustrations of which it is figured at plate 31. I rather think, however, that it is Molina's *Trochilus galeritus*.—(Molina, i. 275.).

© The Complete Work of Charles Darwin Online

of the Adelaide; and for some days had three anchors down, owing to the violent squalls. Farenheit's thermometer ranged between thirty-six and forty-six degrees, and we had several snow storms, but the snow did not lie on the low grounds.

On the 28th the gale began to subside, and there was a change for the better; but we were again disappointed, and not until the 31st could we effect our departure from this dreary and confined little place.

The day before we sailed, three canoes, containing in all sixteen persons, of whom six only were men, came alongside.

For about an hour they had hesitated to approach; but when once near us, very little invitation was necessary to induce them to come on board. One was clothed in a duck shirt, which was recognised by one of our people, who had joined us from the Uxbridge, as having been given to them a few weeks before, when that vessel passed through Magdalen Channel: another wore a red flannel shirt, and in the canoe we observed an European boarding-pike, painted green, and a part of the iron-work of the cutter, burned at Port Famine during our absence; also some relics of the boat in which Mr. Ainsworth was drowned, which last they had doubtless found thrown up on the beach. Upon our inquiring how they became possessed of the iron-work, they pointed towards Port Famine; and I have no doubt they were concerned in the fire; but as we could not explain to them the mischief they had occasioned, it was thought better not to notice the affair, and the articles were returned to them. They could have had no idea of our being the owners of the boat, or they would have concealed all that belonged to her.

They conducted themselves very quietly during their stay on board, with the exception of one, who tried to pick my pocket of a handkerchief; the offender was ordered out of the vessel, and there was no further attempt to pilfer. They wished to go below; but this was not permitted, because the odour of their oily persons was scarcely tolerable, even in the open air. As to food, tallow-candles, biscuit, beef, plumb-pudding, were

© The Complete Work of Charles Darwin Online

equally liked, and swallowed most voraciously. One of them was discovered taking the tallow out of the end of the deep sea lead and eating it, although mixed with sand and dirt.

Before sunset their canoes were despatched on shore to prepare the wigwams, during which operation three of the men remained on board; and as soon as the preparations were made they called for a canoe and went on shore. We obtained several spears, baskets, necklaces, bows and arrows from them in barter; but they seemed to have very few skins. Perhaps those they possessed were hidden in the bushes, because they had no wish to part with them.

One woman was covered with a guanaco mantle; another merely wore a seal-skin over her back and shoulders, which, while she crouched in the canoe, was sufficient to cover her person. One had a black stripe down the nose, but she was the only female among them who was so painted.

Next morning the Indians visited us with a fresh assortment of bows and arrows, in the manufacture of which they had evidently passed the night, for every one was quite new; the bows were of green wood, and the arrows not even pointed. They found, however, a ready sale. One of the party was a man who had been turned out of our vessel the preceding evening, for picking my pocket; but he was daubed over with a whitish pigment to deceive us, and would probably have escaped detection, but for the unusual ugliness of his person, which was not so easily disguised. He was much disconcerted by our recognition; and our refusal to barter with him made him angry and sullen.

The women had daubed their faces all over with bright red ochre; to add to their beauty, no doubt.

We sailed out of the port by the northern passage, and standing across the Strait, anchored in San Nicolas Bay. Mr. Graves went to Bougainville Harbour, to communicate with the Adeona, and take letters from me to Lieutenant Wickham. He brought back an account of all being well at Port Famine, and of the Beagle having sailed on the 17th.

When we left Port Famine my intention was to examine

© The Complete Work of Charles Darwin Online

the Magdalen Channel; but, upon leaving San Nicolas Bay (1st April), the weather was so favourable for our proceeding to the westward, that I changed my mind and steered round Cape Froward in order to get to Port Gallant, whence, with a westerly wind, we might more easily survey the coast in returning. An easterly breeze carried us near Cape Holland, into Wood's Bay, where we anchored, and obtained a bearing of Mount Sarmiento, which, being clear of clouds, was a conspicuous, and even splendid object; for the sun's setting rays, shining upon the projecting snowy ridges on its western side, gave it the appearance of a mass of streaky gold. It had been in sight the whole day, as well as the preceding evening, when its bearings were taken from the islet in San Nicolas Bay.

The next day was so calm that we only reached an anchorage in Bradley Cove, on the west side of Bell Bay, of which a plan was made; an extensive set of bearings was also taken on the west point of the bay, evidently that called by Sarmiento Tinquichisgua.* The conspicuous mountain at the back of the bay, on its south-eastern side, is particularly noticed by him, and, according to his opinion, is the "Campana de Roldan" of Magalhaens.† Between Bradley Cove and Point Tinquichisgua are two coves, over which a high double-peaked mountain forms a conspicuous object upon rounding Cape Froward; and they were named in compliment to Mr. Pond, the late Astronomer Royal.

While at Point Tinquichisgua we were discovered by some natives to the westward, who immediately got into their canoes, and paddled towards us; but, as we had no arms in the boat, I did not think it prudent to await their arrival; and therefore, after taking the requisite angles, embarked and returned to the Adelaide, examining the inlets under Mount Pond on our way. Nothing more was seen of the Indians until the following morning, when, as we sailed out of the bay, they made their appearance, but we did not communicate

* Sarmiento, p. 213.

† Este monte es el que llaman las Relaciones antiguas la Campana de Roldan.—Sarmiento.

© The Complete Work of Charles Darwin Online

with them. They were as vociferous as usual, and pointed to the shore, inviting us to land. One of them, who stood up in the canoe while we passed, was ornamented about the hair and body with white feathers.

This part of the Strait teems with whales, seals, and porpoises. While we were in Bradley Cove, a remarkable appearance of the water spouted by whales was observed; it hung in the air like a bright silvery mist, and was visible to the naked eye, at the distance of four miles, for one minute and thirty-five seconds before it disappeared.

A glance at the chart of this part of the Strait will show the difference of geological structure in the opposite coasts. The north shore, from Cape Froward to Port Gallant, forms a straight line, with scarcely a projection or bight; but on the opposite side there is a succession of inlets, surrounded by precipitous mountains, which are separated by ravines. The northern shore is of slate; but the other is principally of greenstone, and its mountains, instead of running up into sharp peaks, and narrow serrated ridges, are generally round-topped. The vegetation on both sides is almost equally abundant, but the trees on the south shore are much smaller. The smooth-leaved beech (*Fagus betuloides*) and Winter's-bark are the principal trees; but here and there a small tree was observed, like a cypress, which does not grow to the eastward, excepting on the sides of Mount Tarn, where it only reaches the height of three or four feet.

The scenery of this part of the Strait, instead of being as Cordova describes it, "horrible," is at this season exceedingly striking and picturesque. The highest mountains certainly are bare of vegetation; but their sharp peaks and snow-covered summits afford a pleasing contrast to the lower hills, thickly clothed with trees quite to the water's side, which is bordered by masses of bare rock, studded with ferns and moss, and backed by the rich dark-green foliage of the berberis and arbutus shrubs, with here and there a beech-tree, just beginning to assume its autumnal tints.

In working into the narrow entrance of Port Gallant, the

© The Complete Work of Charles Darwin Online

schooner grounded upon a bank that extends off the mouth of the river; but the water being perfectly smooth, no damage was caused. As a secure cove, Port Gallant is the best in the Strait of Magalhaens; from the stillness of its waters, it is a perfect wet dock, and from its position it is invaluable. There are many coves as safe and convenient when once entered; but the prevailing steepness of the shores, as well as the great depth of water, are obstacles of serious importance. Here, however, is an exception: the bottom is even and the depth moderate; besides, Fortescue Bay, close by, is an excellent roadstead or stopping-place, to await an opportunity of entering.

For repairing a ship, Port Famine is more convenient, on account of the quantity and size of well-seasoned timber lying about the beach, and also from the open character of the country. At Port Gallant the trees are much stunted, and unfit for present use, while the shore, as is the case around almost every cove to the westward of Cape Froward, is covered with shrubs and brushwood, quite to the high-water mark; so that there is no possibility of walking easily to any distance from the sea-side. A shingle, or sandy beach, twenty or thirty yards in length, occasionally intervenes, but is scarcely preferable to a vessel's deck, for a walk.

CHAPTER IX.

Detention in Port San Antonio—Humming-birds in snow showers—Fuegians—Geological remarks—Canoes—Carving—Birds—Fish—Shag Narrows—Glaciers—Avalanches—Natives—Climate—Winter setting in—Adelaide loses a boat—Floods—Lightning—Scurvy—Adelaide's survey—Bougainville Harbour—Indians cross the Strait, and visit Port Famine—Sealing vessels sail—Scurvy increases—Adelaide sent for guanaco meat—Return of the Beagle—Captain Stokes very ill—Adelaide brings meat from the Patagonians—Death of Captain Stokes.

Our stay at this port was prolonged beyond my intention by thick snowy weather and hard gales, which cut off our communication with the shore; for notwithstanding we were in so sheltered a place, and the vessel had three anchors down, we did not consider her quite secure against the violent squalls. We had been fortunate in procuring observations, and took advantage of our detention to lay down the operations of the preceding days on paper. Muscles were found in great abundance on the mud flats. There are three varieties, one of which has a bitter, disagreeable taste, but the others are exceedingly good and wholesome. One of the latter is of large size (*Mytilus Magellanicus* of the Ency. Méth.) The other is of a more globose form than the bitter sort, and has a very obtuse hinge and margin. The bitter kind contains pearls, which are valueless, because small, and of a bad colour.

At first there were plenty of sea-birds* in the cove, which took refuge at the head of the bay; till after two days, they deserted us altogether. There appeared to be an abundance of fish; but as we had not provided ourselves with a seine, and they

* Here we obtained a second species of the Steamer-duck, which is described in the Proceedings of the Zoological Society of London, as '*Micropterus Patachonicus*, Nob.' It differs from the *M. brachypterus* not only in colour but in size, being a smaller bird, and having the power of raising its body, in flight, out of the water. We called it the 'Flying Steamer.'

© The Complete Work of Charles Darwin Online

would not take bait, we were confined for refreshments principally to shell-fish.

No traces of quadrupeds, excepting an Indian dog, were noticed. Here Wallis's people saw a large cloven-footed animal, which they described to be as "big as a jack-ass." It was probably a deer, one or two of which had occasionally appeared at Port Famine.(*e*)

It has been mentioned that we found many humming-birds at Port San Antonio, which we attributed to the sheltered situation of the place, and the luxuriant growth of fuchsias and other plants, upon the sweets of whose flowers they feed. Here, however, one of the same species was seen sporting about in a most exposed place and during the falling of a snow shower, a proof of the hardy character of this little bird, which, if it does migrate upon the approach of winter to a warmer clime, lingers, at least, as long as it possibly can. This was the middle of April, the winter had, in fact, already commenced, and all the mountains around us were clothed with snow, while the ground was also coated with the same dazzling covering. Mr. Graves intended to ascend the Mountain de la Cruz; but a heavy fall of snow prevented the attempt, and we lost the opportunity of obtaining a round of angles from that elevation, which would have materially assisted our operations. We should also have obtained a bird's-eye view of the Barbara Channel and the Sounds on the opposite side of the Strait, whose extent and nature we did not know; for Cordova's notice of San Simon's Bay, and a deep inlet which exists to the westward of it, is very unsatisfactory.

There were no signs of a recent visit from the Fuegians, though at the entrance of the cove we found three or four wigwams in good repair; whence it seems probable, that the place is one of their frequent haunts. When the Beagle came here last year, some station staves were left standing; but, before her return, every one had been removed; and when Captain Stokes went down the Barbara Channel, to the relief

(*e*) Or the animal called by Molina 'Huemul.'—R. F.

© The Complete Work of Charles Darwin Online

of the Saxe Cobourg's crew, those staves were seen in the possession of the Indians.

A fine morning (11th) induced us to leave this quiet anchorage, to examine the openings of the south shore; and in the afternoon, the anchor was dropped in a convenient place, on the west side of the western inlet, named by us Warrington Cove. While crossing the bay from Point Elvira, the north extremity of Cayetano Island, several 'smokes' were observed on the low land, at the bottom of the inlet; and after we anchored two canoes visited us, containing six men, four women, and two or three children. They approached very cautiously, and could not be induced to come alongside. At last the men landed, and invited us to communicate with them. I therefore went on shore with two or three officers, and remained with them half an hour, during which they gradually lost the distrust they had at first evinced; but each man still carried a number of pebbles in the corner of his wrapper, ready to repel any attack we might make upon them; from the knowledge we have since obtained of their character, I think it probable that they had lately committed some act of aggression on a sealing-vessel, and were afraid of retaliation. Our conduct tended to assure them of our friendship; and, shortly after we left the shore, they came alongside in their canoes, and were very familiar, eagerly bartering their necklaces and baskets. In their way to us they had probably landed their more valuable goods, such as otter and seal-skins, as well as their weapons and dogs, without which they never go far.

The natives of this part are considered by the sealers to be the most mischievously inclined of any in the Strait, or Tierra del Fuego. The appearance of our visitors was certainly against them; but they did not commit themselves during our two or three days' communication, by any act which could make us complain, or cause suspicion of their honesty and friendship. We, however, kept too good a look-out, to enable them to take advantage of our seeming good-nature.

Among bushes behind the high beach were three wigwams, but the Indians had no intention of remaining with us for the

© The Complete Work of Charles Darwin Online

night. They went away, to our great satisfaction, at an early hour, and returned to the bottom of the sound, where a large party of their countrymen was assembled. Their departure enabled us to look round, in the vicinity of our anchorage, and examine its productions, which differed in no way from those of other parts of the coast. Its geological structure is, however, different: the rocks are greenstone, or granite, without slate. Mount Maxwell, rising immediately over the cove, is the termination of a rocky mountain range, whose summits are crowned with snow. The verdant sides of the hill, interspersed at intervals with large masses of bare rock, produced, from a distance, rather a pleasing effect; but, upon examination, the verdure was found to consist principally of moss, or a stunted vegetation, covering a soft and swampy soil. The upper portions of the mount are so precipitous as not to be easily reached; and, indeed, many parts rise with a perpendicular ascent for more than a hundred feet. On the south side of Mount Maxwell is Smyth Inlet, which contains anchorage on the north shore, particularly one in Earle Cove; but in the centre the water is deep, and on that account, it is not an inviting place for a ship. During Mr. Graves's absence in Smyth Harbour, I examined the coast as far as Cape Edgeworth, where I obtained an extensive set of bearings. The afternoon was particularly favourable for the purpose, the snow-capped mountains of the north shore were perfectly distinct; and among them was a very high one, shaped like a Highland target, the peak of the mountain answering to the central spike of the shield. We never afterwards saw it, nor could I, on this occasion, fix its position better, than by estimating its distance. The rock is chiefly greenstone, accompanied by considerable masses of granite. A little islet, off Dighton Cove, is composed of granite, of a lamelliform structure. Mr. Graves brought me a specimen of lamelliform granite attached to a mass of greenstone.

The Indians visited us every day, their number being generally from twelve to sixteen, of which five or six only were men, the rest were women, and children of all ages. One of the latter could not have been more than three weeks old; yet the

© The Complete Work of Charles Darwin Online

mother, apparently about sixteen years of age, was always occupied in the laborious employment of paddling the canoes. The child was secured in the mother's lap, with its head on her bosom, by a mantle, which was drawn tightly round both mother and child. Their canoes were similar to those of the eastern parts of the Strait, about ten feet long, holding four or five grown persons and two or three children, besides their dogs, implements, and weapons: they are formed of bark, and kept in shape by wooden cross supports secured to the gunwale, which is lined by a long, slender pole. They are divided into three compartments, the foremost occupying about one-third of the length, contains the spears, placed ready for immediate use; in the second are the grown persons, with the fire-place between them, the men sitting between the fire-place and the spears, to be ready to use them upon the approach of seals or porpoises; on the opposite side of the fire-place are seated the women who paddle the canoe, in which the men sometimes assist, when great expedition is necessary. Behind the women, in the third division, are the elder children and the dogs, the younger children being generally stowed away in the women's laps, for the sake of mutual warmth. The fire is made upon a layer of clay, several inches thick, at the bottom of the canoe; and above the fire, across the gunwales, are laid several pieces of half-burnt wood, for fuel.

During our communications with these visitors they conducted themselves peaceably, and made no attempt to pilfer, although there was some little roguery displayed by them in barter. One of the men having parted with all his disposable property, tendered one of his daughters, a fine girl of fourteen or fifteen years of age, for some mere trifle, and, being refused, became very pressing and importunate to close the bargain for the price that was jestingly offered; nor was it without difficulty that he was convinced we were not in earnest. They were as poor as the rest of their countrymen, very badly clothed, and possessing few skins to barter. Two of them exchanged their otter skin mantles for cotton shirts, which they continued to wear without complaining of cold.

© The Complete Work of Charles Darwin Online

As their visits lasted all day they always brought their food, consisting of the blubber of seals and porpoises. The method used by them in cutting it up is nearly similar to that adopted by the Esquimaux Indians, as described by Sir Edward Parry in his second voyage, and also resembles the process of the natives of King George's Sound, which I have described in the account of my survey of Australia (vol. ii. p. 140): a piece of blubber being held in the left hand, a corner of it is taken between the teeth, and it is then cut by a knife, held underhanded, into strips backward and forward, without passing the instrument entirely through: so that when the operation is finished the piece draws out into a long band, about an inch thick, formed by the connected strips. The whole affair from first to last is most offensive to the sight; and the countenance of the carver is beyond description, for his eyes being directed to the blubber, squint shockingly, and give his ugly face a hideous appearance. The strip of blubber is next divided among the party, each of whom proceeds to extract its oily juices by drawing it through his teeth and sucking it, after which it is warmed in the fire to facilitate its division into small pieces, which are swallowed or bolted without mastication. Morsels of this dainty food were given not only to the elder children, but even to infants at the breast.

On the 14th, while preparing to weigh, the Indians came on board and helped to heave in the cable, but without rendering us much real assistance. When the sails were loosed, the women in the canoes began to chatter and scream for fear we should carry off their friends, and their alarm was no sooner given than the deck was cleared of our visitors, who seemed to be quite as much frightened for their safety as the women were. In a few minutes afterwards we were proceeding to the southward, and first tried to anchor in a bay on the south side of Smyth Harbour, but finding the depth too great, I sent Lieut. Graves to sound behind an islet where there were indications of a place of shelter, but he returned unsuccessful. During his absence I went to a very narrow passage, which he had discovered, leading to a large channel or sound; but finding it

© The Complete Work of Charles Darwin Online

intricate, I deferred trying to enter with the vessel until a more favourable opportunity should offer, and we returned to the place south of Warrington Cove, called Dighton Bay, where we anchored off a sandy beach in twenty fathoms, and secured the vessel by laying the kedge on the shore. This sandy beach was the first we had found in the eastern part of the Strait. The sand is quartzose, of a white colour, and being a novelty, rendered the place interesting. A stream, supplied by the ravines of Mount Maxwell, runs over the beach into the sea, and from it an abundant supply of excellent water may be obtained without difficulty.

We observed no quadrupeds; but, of the feathered tribe, we found woodpeckers, kingfishers, and woodcocks, and in the sheltered nooks several humming-birds were darting about the flowery underwood of berberis, fuchsia, and arbutus. In the tide-way, at the narrow passage, the sea teemed with fish; over which hovered corvorants and other sea-fowl, preying upon the small fry that were trying to elude their voracious enemies, the porpoises and seals, thousands of which were seen sporting about as we proceeded on our way. Whales were also numerous in the vicinity, probably because of an abundance of the small red shrimp, which constitutes their principal food.

I went again to examine the passage, and the tide being against us, we were obliged to pull close to the western shore to benefit by the partial eddies, otherwise we could not have proceeded until the turn of the tide.

These narrows, named 'Shag' Narrows, from the quantity of birds there so called by seamen, are not a hundred yards wide. The south end is fronted by an island, from whose summit, about four hundred feet high, I hoped to obtain a good view southward, and after passing the narrows we landed and reached the summit. While looking around at the view, and preparing the theodolite, a woodcock started up from the long grass and walked away so leisurely, that Mr. Tarn nearly succeeded in striking it with a stick. This bird afforded us a name for the station, which we found to be at the northern side of a large basin, ten miles wide, and six long, terminated at

© The Complete Work of Charles Darwin Online

its south end by a channel leading to the open sea, but crowded with islands and rocks. A deep inlet or chasm in the land, at the N.W. corner of this basin, was filled with masses of floating ice, broken from an enormous glacier.

After obtaining all the bearings and embarking, we pulled three miles to the westward, and took a round of angles at Point Cairncross, the south-west point of Field's Bay, and again another set at the south head of Icy Sound, near Dinner Cove, where we found a very convenient anchorage for small vessels. Through Icy Sound we found some difficulty in penetrating, as the channel was much obstructed by ice.

Three miles within this sound the rocky shore became more precipitous, and at two miles farther, where the width across was not more than one hundred and fifty yards, the rocks rise perpendicularly on each side to the height of seven or eight hundred feet. Beyond this remarkable part the channel opens out to a basin about half a mile in diameter, bounded by a sloping glacier, from which immense masses of ice broke off frequently, and falling with a noise like the discharge of a ship's broadside, threw up the foaming water with terrific violence.

As we entered the basin, we were startled by a sudden roar, occasioned by the fall of one of these avalanches, followed by echoes which reverberated round the basin and among the mountains. We remained for half an hour afterwards waiting for another fall, but were not gratified. Several were heard at a distance, probably high up the sides of the glacier. The examination of Icy Sound occupied us until dark, when we returned to the schooner.

During our absence, Indians had again visited the Adelaide, the greater number of whom were strangers. We had also seen a party in a canoe close to Mount Woodcock, who were striking seal, and too intent upon their object to pay much attention to any thing else.

On the 16th, the term of our absence having expired, we left Dighton Bay on our return: at night we anchored in St. Nicholas Bay, and the day after arrived at Port Famine.

© The Complete Work of Charles Darwin Online

Natives had discovered and visited the ship while I was away, but Lieut. Wickham did not encourage them to remain; and two or three attempts to pilfer being detected, they were treated with very little ceremony; so finding their company was not desired, they went across the Strait to Lomas Bay, where for several days afterwards the smoke of their fires was seen. They were the same Indians whom we had met at Port San Antonio.

That these Indians should be received so coolly, may seem to have been impolitic on our side, when it is considered that our smaller vessels and boats might be met with, and their crews ill-treated by way of retaliation. It was, however, time that they should know our superiority; for, of late, several very treacherous attacks had been made by them on sealing vessels, and this party was the most forward and insolent we had seen. One of them was teazing several of the men to box, an accomplishment he had probably learnt from the crews of sealing vessels; among others, he fixed upon the serjeant of marines, who very unceremoniously pushed him over the side, and made him return to his canoe, which he resented by pushing off from the ship's side, and throwing a stone at the serjeant, who was standing at the gangway. As it missed him, and did no harm, no notice was taken of his mischief. We afterwards heard that the same party had visited Bougainville Harbour, where the Adeona was at anchor; but as Mr. Low neither gave them encouragement to remain, nor permitted them to go on board his brig, they very soon went away.

The difference between the climates of the western and eastern portions of the Strait was very striking. To the westward the country, being principally clothed with evergreens, such as the smooth-leaved beech, and Winter's-bark, with an underwood of arbutus and berberis, seems to possess a constant verdure, nor until the snow covers all, does it assume any thing like the appearance of winter. To the eastward, evergreens are less common, their place being occupied by the beech (*Fagus Antarctica*), whose leaves fall very early. Snow had also begun to cover the lower grounds, giving signs of winter. April termi-

© The Complete Work of Charles Darwin Online

nated with finer weather than we had experienced for some weeks, but May set in with north-easterly winds and much rain, succeeded by a heavy fall of snow.

"Tristis hyems montes niveo velamine vestit."

As yet the thermometer had not been very low. On one or two occasions it had fallen during the night to 28°, but generally it ranged between 45° and 38°.

The Adelaide was again despatched on the 30th April, to carry on an examination of the openings on each side of Cayetano Island; but she returned on the 21st of May, with the disagreeable intelligence of having had her only serviceable boat stolen by the Indians. This was a serious loss, not only on account of so much time being thrown away, but also because we had no other boat to substitute for her. To prevent delay, I sent to Mr. Low, at Bougainville Harbour, requesting that he would sell one of his boats; but he was himself so badly off, from similar losses, that he could only assist us by lending one for a few weeks, and as it was the only boat he possessed, it could not be spared to go far from his vessel. I, therefore, despatched Mr. Graves, in the Adelaide, to Bougainville Harbour, to employ himself in examining the coast thence to Cape Froward, and in the mean time began to build a whale-boat, to be ready for the Adelaide's use as soon as winter had passed over; for, from Mr. Graves's report of the state of the climate to the westward, very little could be done during the winter months.

The following is Lieut. Graves's account of the loss of his boat:—Upon leaving Port Famine he proceeded at once to Port Gallant, and surveyed Cordes Bay; after which he crossed the Strait to St. Simon's Bay, and anchored in Millar Cove, on its western side, immediately to the north of Port Langara, from which it is only separated by a narrow neck of land. The Adelaide remained there at anchor while Mr. Graves visited the different parts of the bay. Her presence had attracted a large party of Indians, who, occupying several wigwams near the entrance of the cove, paid daily visits to

© The Complete Work of Charles Darwin Online

our people, and were apparently very familiar and well-disposed.

But they had cast a longing eye on the whale-boat, which, when equipped for service, contained many things very useful to them, and they laid a plan to carry her off, which succeeded. One evening she was prepared for going away at an early hour the following day, and, to save time, every thing that might be required was placed in her, and she was made fast for the night. Two or three Indians were then on board, and observing what was done, laid their plan, and at sunset took their leave as usual. The night was pitchy dark, and at nine o'clock the boat was missed from alongside. The alarm was given, and instant search made at the wigwams of the Indians, who had all decamped, without leaving the least trace of themselves or the boat. The 'painter,' or rope by which she had been fastened to the vessel, had been cut through with some sharp instrument, most probably a knife, which our people had sharpened for them on the grindstone that very day.

Every possible search was made next morning, but without success; the boat that was left was one which could not be used with any advantage, and Mr. Graves returned to Port Famine. Vexatious as the accident was, I could not blame him for what had occurred, for no one had suspicions of such conduct from the Indians, who, on all other occasions, had kept at a distance from us after night-fall. The boat was properly secured alongside, and the night was so cold that no person would have thought the Indians would expose themselves to such a temperature (28°); for they must have swum alongside to cut her adrift, and then must have towed her away very gradually, to prevent the theft being discovered, for there were two persons walking the deck at the time.

Mr. Tarn, who accompanied Mr. Graves on this occasion, brought me a very fine sea-eagle (*Polyborus Novæ Zealandiæ*), and some other birds, and a specimen from a shrub which we had not before observed, a species of *Desfontanea*.

In order to prevent a similar loss in future, the Adelaide

© The Complete Work of Charles Darwin Online

was forthwith fitted with cranks outside, for hoisting up her boats when in harbour.

Winter advanced rapidly; the ground was constantly covered with snow, from one to two feet deep, and every night more fell. In the early part of June we had a gale of wind from the N.W., which flooded the low ground upon which our tents stood; but fortunately the large tent had been accidentally placed on a higher part, and escaped. This flood filled, and, of course, spoiled the water in all the ponds about the tents; and we had afterwards to procure our supplies from a considerable distance.

On the 8th of June much lightning was observed to the northward, and repeated rumbling noises were heard, which continued for long periods; one lasted distinctly for the space of twenty minutes. At first, they were thought to be eruptions of some distant volcano; but, from the frequent lightning, they were probably echoes of thunder, reverberating through the deep ravines that intersect the rocky ridges of the Cordillera, from which we were distant at least one hundred and fifty miles.

A succession of bad weather followed, during which the barometer fluctuated rapidly. On the 14th, the mercury fell to 28. 17. inches, after which it gradually rose, with fine settled weather, until it reached 30. 50., when bad weather again set in. The people at the tents experienced another inundation. Had the water risen six inches more, it would have carried every thing away; and as the wind was blowing dead upon the shore, while a heavy surf was beating upon the beach, we could have rendered them very little assistance from the ship.

The severity of the weather brought a most disagreeable accompaniment. Scurvy appeared, and increased; while the accidental death of a seaman, occasioned by falling down a hatchway, followed by the decease of two others, and also of Mr. Low, of the Adeona, whose body was brought to me for burial, tended to create a despondency amongst the crew that I could in no way check. The monotony of their occupations, the chilling and gloomy appearance of the country, and the severity of the climate, all tended to increase the number of the

© The Complete Work of Charles Darwin Online

sick, as well as the unfavourable symptoms of their disease. The Beagle's term of absence was, however, drawing to a close, and I caused a rumour to be spread, that upon her appearance we should quit Port Famine. To give a semblance of reality to this report, the topmasts were ordered to be fidded, and the ship otherwise prepared for sea, which had a manifest effect upon the scorbutic, of whom several were in a bad stage of that horrid disease, and many others were just attacked. We found ourselves now, too, thrown on our own resources for fresh food: scarcely a fish was taken with the hook, and the seine, although frequently shot, never caught anything. Of birds, only a few hawks and small finches were procured, which were all reserved for the sick, the greater number of whom lived on shore, at the tents, where they might walk about, and amuse themselves as they pleased.

The Adelaide returned from Bougainville Harbour on the 18th of June, having succeeded in the object for which she was sent. The extremity of Cape Froward, a bluff head, over which is a round-topped hill (precisely the French 'Morre') is what Sarmiento called the Morro de Santa Agueda. Any name given by this excellent old navigator is too classical and valuable to be omitted; therefore, while the extremity itself may retain the modern appellation of Cape Froward, the mountain by which it is formed may still be allowed to keep his distinction. Behind it, the land rises to a higher ridge, the edge of which is remarkably serrated, and probably of a slaty character.

The specimens procured from the Cape were clay-slate, much intermixed with iron pyrites, and crossed by small veins of white quartz. Of the anchorages examined by Mr. Graves, Bougainville Harbour, better known to sealers by the name of Jack's Cove, or Harbour, is the most sheltered.

It is surrounded on all sides by high precipitous hills, thickly clothed with trees. The depth is moderate, and the water so beautifully clear, that the anchors, and even shells and stones, were distinctly seen upon the bottom. It was here that Bougainville procured wood for the use of the settlement

© The Complete Work of Charles Darwin Online

at the Falkland Islands. Captain Stokes says of this place: "After seeing the abundant supplies of timber which Freshwater Bay and Port Famine afford, I had shared in the surprise which Byron expresses, that any one should have come so far up the Strait to get it; but on examining the spot, I found that a happier selection could not have been made. It is a little cove, just round the eastern point of the Bay of San Nicolas, about a hundred yards wide and three times as long. Here, moored to the shore, a ship may lie in eight fathoms, perfectly sheltered from any wind, the water as smooth as in a wet-dock. Shapely trees, of all dimensions, are growing within a few yards of the shore; and the wood, when felled, may be hoisted on board from the beach, by tackles from the yard-arms. Here, too, with very little trouble, a supply of water may be got from the many streams that make their way through the underwood which skirts the cove. As we pulled up this sequestered nook, the unusual sound of our oars and voices put to flight multitudes of birds, and the surface of the water was broken by the jumping of fine fish. Some very eatable geese were shot. Our stay was too short to admit of hauling the seine; but my boat's crew contrived to half-fill the boat with excellent muscles and limpets, which are found here in great plenty."

The geological character of the coast between Cape St. Isidro and San Nicolas Bay is clay-slate; near the beach, however, this rock is not visible, since it is there covered with a kind of breccia of rounded pebbles, in an indurated sandy rock, of green colour. The pebbles are principally of slate; but some were found to be of granite and other quartzose rock, perhaps greenstone.

One of the headlands, called by M. Bougainville Cape Remarquable, was examined by Mr. Graves for fossil shells, of which the French navigator speaks. Half the rock was beaten to pieces, without detecting anything like organic remains. Living shells were in the greatest abundance about the base of the Cape, but that is the case every where. The species generally found are limpets and muscles, but with little variety and no novelty.

© The Complete Work of Charles Darwin Online

On the 21st of June, after a heavy north-east gale, we had an unusually fine day. The hills at the bottom of Magdalen Channel were more distinct than we had ever noticed them, and Mount Sarmiento was particularly clear; indeed its outline was so sharply defined, that the distance did not appear to be more than ten miles. This extraordinary transparency of the air was at first considered a presage of wet weather; yet the clear and sharp appearance of the distant land was unlike that which usually precedes a fall of rain. The long series of rainy weather we had experienced made us look for a good result from such an unusual atmosphere, and we were not deceived. The following day our hopes were still further confirmed by seeing three Indian canoes, coming across the Strait, towards us, from Lomas Bay, which they would not have attempted had they not been sure of its continuing fine; for their canoes are ill adapted to encounter the short cross sea found during bad weather in mid-channel of the Strait.

Although the presence of the natives did not in general please me, because it naturally put a stop to all work; yet, on this occasion it was agreeable, as it tended in some measure to enliven the monotonous manner in which we passed our days.

Upon reaching the bay, the Indians did not approach the ship, but paddled into the coves under Point Santa Anna, where our boat was employed watering. Mr. Graves went to them, to prevent mischief, and found they were the same party who had before visited us. When our boats returned, they paddled over to the wigwam at the head of the port, about a quarter of a mile beyond our tents, and began to repair it, and by sunset were housed and sheltered for the night. We had, however, so lately experienced their treacherous disposition, that no confidence was placed in appearances. Sentinels were posted at the tents, to give the alarm, should any of them approach; and at eight o'clock a volley of musketry was fired, by way of intimidation, and to impress them with the idea that we kept a watch upon their movements, and were prepared.

While the wigwams were repairing, a few of the Indians visited our tents; but were not allowed to pass within a rope

© The Complete Work of Charles Darwin Online

that, by my orders, was stretched around our property, a restriction which they did not attempt to evade. At sunset all were told to go away, and they immediately, as well as cheerfully, complied.

The next morning, and indeed throughout the whole day, the neighbourhood of the wigwams exhibited the appearance of a fair. I visited them, and found that they had not only repaired an old wigwam, but erected another. Both together contained the whole party, consisting of twenty-six individuals, among whom were an old man, and two old women. They had brought over a collection of baskets, bows and arrows, stone heads of knives, &c. to sell to our people, who had always shown eagerness to possess these curiosities. The knife-heads were made generally of pitch-stone; but the greater number were of broken glass bottles, which they had collected when they visited us last year. A few strings of beads purchased all their riches; after which they sold their dogs, and Mr. Graves procured one of them for a knife and a string of beads. It was a remarkably fine animal, and showed great reluctance to be handled by our people, several of whom were bitten in their attempts to take him to the boat.

At night one of the canoes was despatched to collect shell-fish, probably sea-eggs, from the reef of Rocky Bay. The following morning all their goods were embarked, and then they paddled their canoes to the beach, near the tents, where some of their men landed. They had nothing to offer in exchange for several things which tempted them, and were beginning to grow troublesome. One of them, the individual who threw a stone at the sergeant, persisting to pass the boundary that was marked upon the ground, which no one of them had before presumed to do, was pushed back by the sentinel; upon which he ran to his canoe and took out several spears, doubtless intending to try to force a passage; but the appearance of two or three muskets brought him to his senses, and the spears were returned to the canoe; after which he became familiar, and apparently friendly. This affair, however, was soon followed by their departure, which gave me much satis-

© The Complete Work of Charles Darwin Online

faction. They went southward, landing for the night in Voces Bay, and the following day went to the Adeona, in Bougainville Harbour, where they remained some days.

The day after the Indians left us, a boat came from the Adeona, to acquaint us that, in a day or two, she and her companions, the Uxbridge and Mercury, intended to leave the Strait for the Falkland Islands; upon which I prepared letters for England, and a report of my proceedings for the Secretary of the Admiralty. The ships passed by on the 30th, and took my letters.

This last month (June) set in with snow or rain, which continued until the 11th, when the weather assumed a very threatening appearance. On the 14th the barometer fell to 29. 27, and the wind blew a hard gale from N.E.; but in the afternoon it veered round to S.W., and the mercury rose rapidly. A gale from S.W. followed, and then to the end of the month we had a series of moderate weather, but much snow. The mean temperature for June was 32°,97 the range being between 19°,2 and 48°,7.

July commenced with an unusually low temperature and a high barometer; the former, on the 4th was 12°,2, and the latter, at the same time, at 30,5 inches, having risen since the 14th of June 1.82 of an inch. After this we had a few mild and fine days, but paid dearly for them; a northerly gale set in, bringing with it unwholesome damp weather, in which the temperature rose to between 35° and 42°, and melted much of the snow that had covered the ground, quite to the water's edge, during the last two months. Our sick-list, particularly of cases of scurvy, increased so much, during this damp, trying weather, that I determined upon sending the Adelaide to the northward, to procure a supply of fresh meat from the Patagonians; and, at the same time, to survey that part of the Strait lying between Cape Negro and the Second Narrow.

Lieutenants Graves and Wickham, and Mr. Tarn, went upon this service, the latter being most anxious to procure some change of diet for the sick under his care, for some of whom he was much alarmed. The appearance and severity of this dis-

© The Complete Work of Charles Darwin Online

ease, although every precaution had been used, and subsequent attention paid to their diet, are not easy to account for: fresh provisions, bread baked on board, pickles, cranberries, large quantities of wild celery, preserved meats and soups, had been abundantly supplied; the decks were kept well-aired, dry, and warm, but all to no purpose; these precautions, perhaps, checked the disease for a time; but did not prevent it, as had been fully expected.

The Adelaide sailed on the 16th of July, with every prospect of fine weather. The same evening, an American sealing schooner anchored near us, on her way to Staten Land. She had entered the Straits by Cutler and Smyth Channels, and in forty-eight hours arrived at Port Famine. After obtaining some trifling assistance from our forge, she sailed.

On the 25th, three new cases of scurvy appeared, one being the assistant-surgeon, which increased our sick-list to fourteen. Feeling the necessity of doing something, I ordered the hands to be turned up, 'Prepare ship for sea!' No sooner had the words escaped the boatswain's lips, than all was life, energy, and delight. The preliminary preparations were made, and every one looked forward with pleasure to the change, except myself. I had hoped to pass the twelve months at Port Famine, with the intention of completing a meteorological journal, for which this place afforded peculiar advantages. My plan was, on the Beagle's return, to despatch her and the schooner along the West Coast, and join them in the Adventure at Chilóe.

As our departure was now supposed to depend on the Beagle's arrival, every eye was on the stretch to watch for her, and every morning some one of our party ascended the heights, to look out. On the 27th she was seen, beating up from the southward; but as the wind was contrary, she did not anchor in the bay until the evening. Her return was greeted with three most hearty cheers; but on passing under our stern, Lieutenant Skyring informed me that Captain Stokes was confined to his cabin by illness, and could not wait on me. I therefore went to the Beagle, and found Captain Stokes looking very ill, and in low spirits. He expressed himself much distressed by the hard-

© The Complete Work of Charles Darwin Online

ships the officers and crew under him had suffered; and I was alarmed at the desponding tone of his conversation. He told me that the Beagle had been up the western coast as high as Cape Tres Montes, in latitude 47°, had surveyed the Gulf of Peñas and other portions of the coast, particularly Port Henry, at Cape Three Points, the entrance of the Gulf of Trinidad, and Port Santa Barbara, at the north end of Campana Island.

During the survey of the Gulf of Peñas they had experienced very severe weather, both stormy and wet, during which the Beagle's crew were incessantly employed, and had consequently suffered greatly. Captain Stokes seemed not to have spared himself. He appeared much gratified by my visiting him, and before we parted he was for a time restored to his usual energy, detailing the circumstances of the voyage, and conversing upon the plan of our future operations with considerable animation.

The return of the Beagle cheered our ship's company, and on the 30th the Adelaide came back, with a large quantity of guanaco meat, which had been procured from the Patagonian Indians at Peckett's Harbour.

When the Adelaide anchored there, about thirty natives appeared on the shore. Mr. Tarn landed, and communicated our wants, saying that he would give tobacco and knives for as much guanaco meat as they could procure; with them was the Fuegian, who seemed to be a leading man, and to have become one of the most active of the party. He was the principal spokesman, and upon commencing the hunt he pointed to the snow upon the ground, and called it 'bueno' (good), because it would show the traces of the animals, and the direction they had taken. Mr. Wickham thus described to me the manner in which they hunted: Two men ascended a hill, placed themselves one at each end of its summit, and stood motionless for some time, on the look-out. As soon as guanacoes were seen, their position and movements were communicated, by signs, to the men in the valley, who were thus enabled to approach their game unawares. The guanacoes are taken with the bolas, which entangle their legs and throw them down. As soon as they are killed,

© The Complete Work of Charles Darwin Online

they are skinned and cut up. The first night seven hundred pounds of meat were brought, and two thousand and forty-six pounds were obtained in a few days.

This ample change of diet inspired me with the hope that our sick, at least those affected by scurvy, would recover, and that after another large supply, which we now knew how to obtain, we might be enabled to prosecute our voyage as was first intended. All hands were therefore allowed fresh meat for a week, and the residue was placed at the disposal of the surgeon, for the use of the sick, but all ineffectually; the list still increased, and Lieutenant Wickham, with a violent cold, and Mr. Rowlett, with scurvy, were added to it. The assistant-surgeon's became the worst case of scurvy on board; and our people, finding that the preparations for quitting the place were not going on, began to despond again. Captain Stokes was anxious to prepare his vessel for another cruize, being very averse to giving up our plans and returning to Monte Video, since he thought the crews, from utter disgust at the privations and hardships they had endured, would not be persuaded to go on another voyage; but that if they were to go to Chiloé or Valparaiso, to refresh, they might recover their strength and spirits, and be willing to renew the survey; which, however, he himself seemed to dread, for he never mentioned the subject without a shudder. He was evidently much excited, and suspicions arose in my mind that all was not quite right with him. I endeavoured to prevail on him to give his people a longer rest, but he was the more anxious to make preparations. On the 31st July he sent an application for provisions, and in the evening I received a note from him, which was written in his former usual flow of spirits. The officers, however, knew more of the diseased state of his mind than I did; and it was owing to a hint given to me, that I desired Mr. Tarn to communicate with Mr. Bynoe, and report to me whether Captain Stokes's health was sufficiently restored to enable him to commence another cruize. This was on the 1st of August. The provisions had been sent, in compliance with his application, and the surgeons were on board the Adventure,

© The Complete Work of Charles Darwin Online

considering upon their report, which was, as I afterwards found, very unfavourable, when a boat came from the Beagle, with the dreadful intelligence that Captain Stokes, in a momentary fit of despondency, had shot himself.

The surgeons instantly repaired on board, and finding him alive, had recourse to every means in their power, but without hope of saving his life. During the delirium that ensued, and lasted four days, his mind wandered to many of the circumstances, and hair-breadth escapes, of the Beagle's cruize. The following three days he recovered so much as to be able to see me frequently; and hopes were entertained by himself, but by no one else, that he would recover. He then became gradually worse, and after lingering in most intense pain, expired on the morning of the 12th.

Thus shockingly and prematurely perished an active, intelligent, and most energetic officer, in the prime of life. The severe hardships of the cruize, the dreadful weather experienced, and the dangerous situations in which they were so constantly exposed—caused, as I was afterwards informed, such intense anxiety in his excitable mind, that it became at times so disordered, as to cause the greatest apprehension for the consequences. On the return of the Beagle he got better; and the officers were so sanguine in hoping for his complete restoration to health, on account of his progressive recovery, that nothing which had transpired was communicated to me until after his decease.

His remains were interred at our burial-ground, with the honours due to his rank, and a tablet was subsequently erected to his memory.

CHAPTER X.

Account of the Beagle's cruize—Borja Bay—Cape Quod—Stuart Bay—Cape Notch—Remarks on weather, and errors of Chart—Evangelists—Santa Lucia—Madre de Dios—Gulf of Trinidad—Port Henry—Puma's track—Humming-birds—Very bad weather—Campana Island—Dangers—Gale—Wet—Sick—Santa Barbara—Wager's beam—Wigwams—Guaianeco Islands—Cape Tres Montes—St. Paul's—Port Otway—Hoppner Sound—Cape Raper.

THE following account of the Beagle's cruize is drawn up from Captain Stokes's unfinished journal, and from detached memoranda, which were found amongst his papers.

It will be recollected that, on my departure from Port Famine, in the Adelaide, in the month of March, to survey portions of the southern side of the Strait, I left instructions with Captain Stokes to proceed in the execution of his orders as soon as the Beagle was ready. The details of those orders it is unnecessary to repeat here, as they were performed to my entire satisfaction; it will be merely requisite, as briefly as possible, to follow him through a most arduous and distressing service. It is the sequel that embitters the record.

"On the 18th of March, I sailed from Port Famine, and next day reached Port Gallant.

"On the 23d, we anchored in the little cove called Borja Bay, which, though very confined, and rather difficult of access, suited our purpose extremely well. (See Sailing Directions). While there we measured the height of one of the principal hills in the neighbourhood, and found it 1,800 feet.

"Bad weather detained us until the 26th, when we passed Cape Quod, and reached Stuart Bay. Many places were left unexamined, because my object was to hasten westward before the year was farther advanced.

"(27th.) We left Stuart Bay, and continued our progress to the westward, with westerly winds, thick weather, and rain.

© The Complete Work of Charles Darwin Online

The shores of the Straits were seldom visible to us, from a thick mist with which they were clouded: it is, however, a bold coast on each side, otherwise the Strait would be utterly unnavigable in such weather. Near Cape Notch the mountains spire up into peaks of great height, singularly serrated, and connected by barren ridges. About their bases there are generally some green patches of jungle; but, upon the whole, nothing can be more sterile and repulsive than the view. This afternoon we passed Playa Parda, and in the evening anchored in Marian Cove.

"In the course of the next day the wind freshened to a strong and squally gale from the W.N.W., with much rain; the weather was so thick that we could scarcely make out the coast. In this kind of weather, the lower parts of the shore are screened from view by mist, and the upper ones are seen looming through it in lofty masses, in a manner which would lead a stranger to believe that the ship was completely environed with islands.

"In the evening we anchored in the little cove called Half Port Bay, and next morning resumed our daily struggle against wind, tide, and weather.

"We crossed the mouth of a deep sound on the north shore,* where no tide or current was remarked: the delineation of the coast about this point is particularly defective in the old charts; fortunately, however, for the navigator, he has here to deal with shores where the omission of a whole island, or even the addition of a few that do not exist, is of less consequence to his safety than the exact limit of one sand-bank in other parts of the world. This night we anchored in Upright Bay, which, though affording excellent shelter from the prevailing winds, is bad with a southerly one; as, from the steepness of the bottom requiring a vessel to anchor close to the shore, sufficient scope is not left for veering cable.

"Sheltered by the high land under which we were anchored,

* Afterwards examined by Capt. Fitz Roy. It was called Xaultegua by Sarmiento, who very correctly describes it.—(Sarmiento's Voyage, p. 208.)

© The Complete Work of Charles Darwin Online

with the exception of occasional gusts down the ravines and sounds, we had the wind light at W.S.W.; but the rapid travelling of the scud over-head showed that the usual weather prevailed. We weighed early next morning (30th), and by noon had reached so far to the westward that the easternmost of the round islands in Cape Tamar Bight bore north about two miles. By nightfall we were off Cape Cortado; but the weather seeming settled and the wind drawing to the southward, I resolved to keep under weigh, and try to get out to sea that night. Circumstances favoured us; the weather was fine, the moon remained unclouded, and the wind held at S.S.W. An hour after midnight Cape Pillar bore W.S.W., distant about two miles, and thence we shaped our course for the Evangelists, which we passed at the distance of a mile.

"The Evangelists, as they are called by the early Spanish voyagers, or as they were afterwards named (1670) by Sir John Narborough, the Isles of Direction,* are a group of four rocky islets, and some detached rocks and breakers, occupying altogether a space of three miles; they are exceedingly rugged and barren, and suited only to afford a resting-place for seals and oceanic birds. From the heavy sea prevalent there, and the raging surf that generally breaks around, landing on them can be rarely practicable; yet sealers effect it. The mate of a sealing vessel told me that he had landed on the largest in a whale-boat, and killed several thousand seals. The Evangelists are of sufficient height to be seen in clear weather from a ship's deck, at the distance of six or seven leagues, but the superior elevation of the coast on both sides will usually render it visible, before these islands can be observed.

"Immediately on rounding the Evangelists a cape was distinguished, appearing to terminate the northern coast line, which we made out to be 'Cape Isabel' of the Spanish charts. It is a steep, rocky promontory of great height, having at its base some detached columnar masses of rock, and at its summit a peak, and a serrated ridge; off it is a steep-sided island,

* Because they formed a capital leading mark for the Strait of Magalhaens.

© The Complete Work of Charles Darwin Online

which proved to be that (Beagle Island) of which Lieut. Skyring and I took the bearing last year, when we were on the summit of Cape Victory.

"Northward of Cape Victory the land forms a deep bight, of which Cape Santa Lucia is the north-eastern headland. The coast in the interval is exceedingly rugged and mountainous. Cape Santa Lucia may be distinguished by a portion of flat table-land, about one-third of the altitude of the mountain from which it proceeds, and terminating at its outer face with a perpendicular precipice.

"The coast between Capes Isabel and Santa Lucia is dangerous to approach nearer than ten miles, for there are within that distance many sunken rocks, on which the sea only occasionally breaks. Some of these breakers were seen to seaward of us, as we proceeded along the coast, at the distance of five or six miles. When off Santa Lucia, whales were very numerous around us.

"The general aspect of this portion of the coast is similar to that of the most dreary parts of the Magalhaenic regions: bare, rugged, rocky, and mountainous, intersected by inlets, and bordered by islets, rocks, and breakers.

"The information we possessed respecting the prevalent winds on this coast was very scanty; yet, since all we could procure represented them as prevailing from the northward and north-westward, I considered it advisable to take advantage of the present southerly wind to proceed to the northern part of the coast assigned for our survey, instead of stopping to explore the bight between Cape Isabel and Cape Santa Lucia.

"From the bearings at sunset,* we ran along the land with bright moonlight, sounding every hour; and at daylight were about ten miles from the Island of Madre de Dios.

"We closed the land and proceeded to the northward, keeping at a distance of about three miles off shore, sounding

* Beagle Island N. 71°. E., Cape Isabel N. 32°. E., a remarkable mountain in the bight between Cape Santa Lucia and Cape Isabel N. 11°. W. Cape Santa Lucia N. 33°. W.; distance off shore three leagues; and soundings fifty fathoms, sandy bottom.

© The Complete Work of Charles Darwin Online

between twenty-eight and thirty-three fathoms, sandy bottom. The weather was clear and fine, and we were enabled to make observations, and take the bearings and angles, necessary for laying down the coast satisfactorily.

"At noon we were in latitude 50° 12′ south, and in the meridian of Cape Tres Puntas, between which and a cape bearing from us N. 13° E. (magnetic), distant eight miles, there was evidently an inlet: this cape is marked on the chart as Cape William. The character of the land is the same with that which we had hitherto passed, bare, rugged, rocky mountains, with peaks, and sharply serrated ridges. From daylight to noon we had run twenty-one miles along the coast; in that interval only one inlet was seen, which was in the latitude of 50° 27′ south, agreeing well with the 'West Channel' of the Spanish chart. It was four miles wide at its mouth, and appeared to follow a winding course to the eastward. The land of Cape Tres Puntas curved in to the eastward, until it closed with Cape William; at dusk we were abreast of Cape William, and two leagues off shore, where we lay-to till daylight, as I wished to examine the inlet between it and Cape Tres Puntas, which subsequently proved to be Sarmiento's Gulf of Trinidad. The old navigator thus describes its discovery:

"'At daylight, 17th of March, 1579, in the name of the most holy Trinity, we saw land, bearing E.S.E., ten leagues distant, towards which we steered to explore it. At mid-day, being near the land, we observed the latitude 49½°, but Hernando Alonzo made it 49° 9′. In approaching the shore we saw a great bay and gulf, which trended deeply into the land towards some snowy mountains. To the south there was a high mountain, with three peaks, wherefore Pedro Sarmiento named the bay 'Golfo de la Sanctisima Trenidad.' The highest land of the three peaks was named 'Cabo de Tres Puntas ó montes.' This island is bare of vegetation, and at the water-side is low and rugged, and lined with breakers; on the summit are many white, grey, and black-coloured portions of ground, or rock. Six leagues to the north of Cape Tres Puntas is the opposite side of the gulf, where it forms a large high mountain, backed

© The Complete Work of Charles Darwin Online

to the north by low land, and fronted by many islands. This high mountain, which appears to be an island from the offing, was called 'Cabo Primero.' "*

"The following night was clear, and the wind moderate from S.E., but in the course of next morning it shifted to N.E., with squalls, rain, and thick weather; we worked into the inlet notwithstanding, and by noon had reached three miles within its S.W. head-land, Cape William, and were abreast of a bay, into which I sent a boat to look for anchorage. On her return we stood into it, and anchored in the excellent harbour, afterwards named Port Henry, where we remained from the 2d to the 5th of April, employed in making a correct survey of the harbour and its adjacencies, and determining the latitude and longitude.†

"The inner harbour, distinguished in the plan by the name of 'Aid Basin,' is perfectly land-locked, and sufficiently spacious to contain a numerous squadron of the largest ships in twenty fathoms water, over a mud bottom, and as completely sheltered from the effects of wind and sea as in wet-docks. At the south-west side of the basin is a fresh-water lake, which discharges itself by a small stream, whence casks might be conveniently filled by means of canvas hoses, and the shores around have wood for fuel in abundance; but, from the lofty surrounding mountains, some rising almost perpendicularly to an elevation of two thousand feet, the thick clouds with which this basin was generally overhung, and the dense exhalations that arose from it during the rare intervals of sunshine, together with the exceeding prevalence of heavy rain on this coast, this place must be disagreeable and unhealthy. Such objections do not apply to the outer harbour, for while its shores afford shelter, they do not obstruct a free circulation of air. It is sufficiently large to afford convenient and secure anchorage for five or six frigates.

"We hauled the seine with very poor success, as a few smelt only were taken; we had no better luck with our fishing-lines;

* (Sarmiento, p. 65.)

† The description of Port Henry is given in our Sailing Directions.

© The Complete Work of Charles Darwin Online

but the trial might have been more profitable at another season, judging from the number of seals we saw on the rocks off the Port, which live principally upon fish. Muscles, limpets, and sea-eggs abound here, and are good and wholesome of their kind. Birds are few in number, and of the species most common in these regions. No quadruped of any kind was seen; but the purser told me that he had observed, near the sandy beach, traces of a four-footed animal, resembling those of a tiger: he followed them to a cavern, and thence to the jungle. He also said that he had seen several humming-birds.

"With the exception of wild celery and the arbutus berry, I know not of any useful vegetable production that this place affords, unless the 'Winter's-bark tree' may be mentioned. Some coarse grass, fit perhaps for animals, may be there procured. The only signs of inhabitants were some wigwams on the western point, which seemed to have been long forsaken: in their construction they were precisely similar to those erected by the migratory tribes in the Straits of Magalhaens; and the shells of muscles, limpets, and sea-eggs, within and about them, showed that the former tenants of these hovels drew, like the Magalhaenic tribes, a principal part of their subsistence from shell-fish.

"Around the harbour are granite mountains, perfectly bare at their summits and north-western sides, but the lower parts are thickly covered in sheltered places and ravines, partly with trees, and partly with brushwood: among the trees growing here we observed, as usual, two kinds of beech, a tree like the cypress, but of small size, and the Winter's-bark. The underwood is composed of all the various shrubs we had met with in the Straits of Magalhaens; and this brushwood is so thickly spread over the lower parts of the shores of the harbour, that it is only by crawling over it that the distance of a few yards from the rocks can be gained; and being generally of insufficient strength to support a man's weight, it frequently gives way beneath him, and he is so completely buried, as to make it difficult for him to extricate himself.

"Scarcely any of the trees attain a size to render them fit

© The Complete Work of Charles Darwin Online

for any thing but firewood; of those we felled there was scarcely one that was not more or less rotten at the heart, a defect probably caused by the extreme humidity of the climate.

"During our stay, the master, accompanied by our boatswain's mate,*(f)* an experienced sealer, went to take seal on the rocks, and returned in a few hours with some of the inferior sort, called 'hair seal,' which were numerous; but the surf was in most places too heavy to allow them to land without much risk. The fry of the young seals we thought extremely good, not exceeded even by the finest lamb's fry.

"On the morning of the 5th we worked to the westward, to clear the land on each side of the inlet; and at sunset, Cape Tres Puntas bore N. b. W. ½ W., distant two leagues. The northerly breeze, which we had worked with since leaving Port Henry, increased rapidly to a hard gale, and by 8 P.M. we were reduced to the close-reefed main-topsail and reefed foresail. The gale continued with unabated violence during the 6th, 7th, and 8th, from the north, N.W., and S.W., with a confused mountainous sea. Our decks were constantly flooded, and we could rarely show more than the close-reefed main-topsail and reefed foresail. Only two accidents occurred: the little boat which we carried astern was washed away by a heavy sea that broke over us, while hoisting her in-board; and the marine barometer was broken by the violent motion of the vessel. At noon, on the 8th, Cape Corso bore from us, by account, S.E. (true), distant fifty-five miles. I had tried to gain a wide offing to get a less turbulent sea, and because not even an outline of the sea-coast of Campana Island was drawn in the chart. We had not, during these three days, a glimpse of the sun or of a star, for it blew a constant gale, accompanied by squalls, thick weather, and rain. According to the time of year, the season of winter had not arrived, but the weather seemed to say it was already come—

> Sullen and sad, with all it's rising train
> Of vapours, clouds, and storms.

(f) Thomas Sorrell, now boatswain of the Beagle (1837). He was boatswain of the Saxe Cobourg, when wrecked in Fury Harbour.—R. F.

© The Complete Work of Charles Darwin Online

"The wind abated at daylight on the 9th, and drew to the southward, and thence to the S.E. (the fair weather quarter of this coast). We bore up to make the land, and at about 10 A.M. the 'loom' of it was seen from the mast-head. At noon, high mountains were visible from the deck; our latitude, by observation, was 48° 51′, and our longitude, by chronometer, 00° 27′ west of Port Henry. No soundings were obtained with one hundred and ten fathoms of line. Hence we steered east (magnetic) towards a remarkable mountain, which, from our being nearly in the parallel of it at noon, has been marked in the chart as Parallel Peak. The coast we were upon was that of the Island 'Campana,' and, in its general appearance, did not differ from that of Madre de Dios. It was late before we got very close to the land; but, for a couple of leagues to the northward, and about a league to the southward of the parallel of our latitude at noon, we could distinguish rocks and breakers skirting the coast to a distance of two leagues from the shore.

"At dusk we hauled off for the night; but instead of being able to resume the examination of the coast next morning, we had to encounter another gale of wind from the N.W., which, before noon, reduced us to close-reefed main-topsail and reefed foresail. This gale suddenly subsided in the western quarter, which was singular; for those we have experienced generally commenced at north, thence drew round to the westward, from which point to S.W. they blew with the greatest fury, and hauling to the southward, usually abated to the eastward of south.

"During the afternoon, we again made the land near Parallel Peak, but could not close it. Next morning (11th), with fine weather, and a fresh breeze at S.W. b. W., we once more saw the land about Parallel Peak; and when distant from the shore about eight miles, steered N. b. E. along the coast. At noon our latitude was 48° 47′.

"Throughout our run along the coast this day, we skirted a number of rocky islets, rocks, and breakers, lying off shore at the distance of three or four miles. Some of the islets were elevated several feet above the surface of the sea; others were

© The Complete Work of Charles Darwin Online

a-wash, and there were breakers that showed themselves only occasionally. Along this line the surf beat very heavily, and, outside, a long rolling sea prevailed, in which the ship was very uneasy.

"This line of dangers is not altogether continuous; for there is an opening about two miles wide, abreast of Parallel Peak, to the southward of which is a bight, where possibly a harbour may exist; but, considering the prevalence of heavy westerly gales and thick weather, if there be one, few vessels would venture to run for it; and this line must, I should think, be considered as a barrier that they ought not pass. As seal are found on the rocks, vessels engaged in that trade might not, perhaps, be deterred by these dangers, but every other would give all this extent of coast a wide berth. We ran past the breakers at the distance of about a mile, having rocky soundings, from thirty to twenty-three fathoms.

"The termination of the coast line northward was a high, rugged island, with a small peak at the north end. The extremity of the main land was rather a high bluff cape, whence the coast extends southward, with craggy, mountainous peaks and ridges, as far as Parallel Peak. At sunset, the N.W. end of Campana bore north (magnetic), distant three leagues, and from the mast-head I could see very distinctly the belt of rocks and breakers extending uninterruptedly to the northward, as far as the end of Campana.

"We hauled off for the night, and had light variable airs, or calms, until 2 A.M. of the 12th, when a breeze from the northward sprung up, and freshened so rapidly, that by noon we were again reduced to a close-reefed main-topsail and foresail. The gale was accompanied, as usual, by incessant rain and thick weather, and a heavy confused sea kept our decks always flooded.

"The effect of this wet and miserable weather, of which we had had so much since leaving Port Famine, was too manifest by the state of the sick list, on which were now many patients with catarrhal, pulmonary, and rheumatic complaints. The gale continued undiminished until the morning of the 13th,

© The Complete Work of Charles Darwin Online

when, having moderated, we bore up and steered N.E. to close the land. At noon a good meridional altitude gave our latitude 48° 30′ south, and about the same time we saw the land bearing N.E. b. E., which we soon made out to be Parallel Peak. After allowing amply for heave of sea, and lee-way, we were considerably southward of our reckoning, which indicates a southerly current; but under such circumstances of wind and weather its exact direction, or strength, could not be ascertained.

"We proceeded along the land, taking angles and bearings for the survey, and at sunset the N.W. end of Campana bore from us north (magnetic), distant five leagues. Being now off the N.W. end of the island of Campana, which forms the south-western headland of the Gulf of Peñas, I considered that, before I proceeded to examine its inlets, I ought to look for the Harbour of Santa Barbara, which has been placed on the old charts in this neighbourhood. Accordingly we lay-to during the night, and at 4 A.M. bore up to close the land; at daylight the extremes of it were seen indistinctly through a very cloudy and hazy atmosphere, from N. 39° E. to S. 53° E. About noon the weather cleared off, and we got the meridian altitude of the sun, which gave our latitude 48° 09′ south.* We directed the course for the Dundee Rock, and when abreast of it, steered N.E. (compass) for an opening in the low part of the coast ahead, backed by very high mountains, which we found was the entrance of Port Santa Barbara. The coast to the southward was lined with rocky islets, rocks, and breakers, extending a league to seaward, and there were others to the northward. We were in a channel half a mile wide, through which we continued our course, sounding from fifteen to eleven fathoms, and in the evening anchored near the entrance of the harbour.

* The N.W. end of the Island de la Campana bearing N. 71°. 40′. E. Two distant hummocky islands (answering pretty well in position with the Guaianeco Islands of the Spanish charts) N. 53°. 30′. E., and N. 55°. 48′. E., and a remarkable rock, the 'Dundee' of Bulkeley and Cummings, about forty-five feet high, rising like a tower from the sea, distant off shore five miles, bearing east of us, distant one mile.

© The Complete Work of Charles Darwin Online

"As our present situation was completely exposed to westerly winds, I went to examine a deep bight in the southern shore, which proved to be a good harbour, perfectly sheltered from all winds, with a depth of three and a half fathoms over a fine sandy bottom. In the afternoon we weighed anchor and warped into a berth in the inner harbour, where we moored in three fathoms. I found lying, just above high-water mark, half buried in sand, the beam of a large vessel.* We immediately conjectured that it had formed part of the ill-fated Wager, one of Lord Anson's squadron (of whose loss the tale is so well told in the narratives of Byron and Bulkeley): the dimensions seemed to correspond with her size, and the conjecture was strengthened by the circumstance that one of the knees that attached it to the ship's side had been cut, which occurred in her case, when her decks were scuttled to get at the provisions; all the bolts were much corroded; but the wood, with the exception of the outside being worm-eaten, was perfectly sound. Our carpenter pronounced it to be English oak.

"The land about this harbour is similar to that about Port Henry. Its shores are rocky, with some patches of sandy beach, but every where covered with trees, or an impervious jungle, composed of dwarfish trees and shrubs. The land, in most places, rises abruptly from the shore to mountains, some of which attain an altitude of more than two thousand feet, and are quite bare at their summits and on their sides, except in sheltered ravines, where a thick growth of trees is found. These mountains, or at least their bases, where we could break off specimens, were of basalt, with large masses of quartz imbedded in it; but on some parts of the shores the rocks were of very coarse granite.

"As in the vicinity of Port Henry, the thickness of the jungle prevented our going far inland; the greatest distance was gained by Lieut. Skyring, who, with his wonted zeal to prosecute the survey, ascended some of the mountains for the

* Length twenty feet five inches and a half, sided twelve inches, and moulded eight inches and a half.

© The Complete Work of Charles Darwin Online

purpose of obtaining bearings of remote points: he remarked to me, 'that many miles were passed over in ascending even moderate heights; the land was very high and very irregular; the mountains seemed not to lie in any uniform direction, and the longest chain that was observed did not exceed five miles. The flat land between the heights was never two miles in extent: the ground was always swampy, and generally there were small lakes receiving the drainage of mountain-streams. Indeed the whole country appeared broken and unconnected.'

"Some of the mountains were ascertained to be 2,500 feet high, but the general height was about 2,000 feet. A large island, on the northern side of the harbour, is an excellent watering-place, at which casks may be conveniently filled in the boat. It is also an object of great natural beauty: the hill, which forms its western side, rises to seven or eight hundred feet, almost perpendicularly, and when viewed from its base in a boat, seems stupendous: it is clothed with trees, among which the light-green leaves of the Winter's-bark tree, and the red flowers of the Fuchsia, unite their tints with the darker foliage of other trees. This perpendicular part extends to the northward till it is met by the body of the mountain, which is arched into a spacious cavern, fifty yards wide and a hundred feet high, whose sides are clothed with a rich growth of shrubs; and before it a cascade descends down the steep face of the mountain.

"On the shore we found two Indian wigwams and the remains of a third; but they had evidently been long deserted, for the grass had grown up both around and within them to the height of more than a foot. These wigwams were exactly similar to those in the Strait of Magalhaens: one was larger than any I had met with, being eighteen feet in diameter. The only land birds I saw were two owls, which passed by us after dusk with a screeching noise.

"On the patches of sandy beach, in the inner harbour, we hauled the seine, but unsuccessfully; we expected to find fish plentiful here, from seeing many seals on the rocks outside, and from finding the water quite red with the spawn of cray-

© The Complete Work of Charles Darwin Online

fish. Muscles and limpets were pretty abundant, and the shells (*Concholepas Peruviana*) used by the Magalhaenic tribes as drinking cups, were found adhering to the rocks in great numbers.

"Nothing could be worse than the weather we had during nine days' stay here; the wind, in whatever quarter it stood, brought thick heavy clouds, which precipitated themselves in torrents, or in drizzling rain. We were well sheltered from the regular winds; but many troublesome eddies were caused by the surrounding heights, while the passing clouds showed that strong and squally north-west winds were prevalent.

"On the morning of the 24th, we put to sea with a southerly breeze. The extent of coast from the eastern part of Port Santa Barbara to the outer of the Guaianeco Islands presents several inlets running deep into the land; but it is completely bound by rocks and rocky islets, which, with its being generally a lee-shore, renders it extremely unsafe to approach. Observing an opening between some islets, of which we had taken the bearing at noon, we stood in to see whether it afforded anchorage; and approaching the extremity of the larger island, proceeded along it at the distance of only half a mile, when, after running two miles through a labyrinth of rocks and kelp, we were compelled to haul out, and in doing so scarcely weathered, by a ship's length, the outer islet. Deeming it useless to expend further time in the examination of this dangerous portion of the gulf, we proceeded towards Cape Tres Montes, its north-western headland.

"At sunset Cape Tres Montes bore N. 25° W., distant eighteen miles. In this point of view the cape makes very high and bold; to the eastward of it, land was seen uninterruptedly as far as the eye could reach. We stood in shore next morning, and were then at a loss to know, precisely, which was the cape. The highest mountain was the southern projection, and has been marked on the chart as Cape Tres Montes: but none of the heights, from any point in which we saw them, ever appeared as 'three mounts.' The land, though mountainous, seemed more wooded, and had a less

© The Complete Work of Charles Darwin Online

rugged outline than that we had been hitherto coasting, since leaving the Strait. We steered along the western coast of the land near Cape Tres Montes, and at noon, being three miles from the shore, observed, in latitude 46° 5. south, the cape, bearing N. 80° E. (mag.), distant seven miles. The northernmost cape in sight N. 26° W., distant ten miles, soundings ninety-seven fathoms. Shortly afterwards another cape opened at N. 37° W. (mag.).

"The parallel of forty-seven degrees, the limit assigned for our survey, being already passed, I did not venture to follow the coast further, although we were strongly tempted to do so by seeing it trend so differently from what is delineated on the old charts. An indentation in the coast presenting itself between mountainous projections on each side of low land (of which the northernmost was the cape set at noon), we hauled in to look for an anchorage; but it proved to be a mere unsheltered bight, at the bottom of which was a furious surf. We then stood to the southward, along the land of Cape Tres Montes, with the view of examining the north side of the Gulf of Peñas.

"The following morning was fine: Cape Tres Montes bore N.E., distant about three leagues. We lay off and on during the day, while the master went in the whale-boat, to examine a sandy bay (of which Cape Tres Montes was the easternmost point) for anchorage: he returned about sunset, and reported that it did afford anchorage; but was quite unsheltered from wind, and exposed to a great swell. The boat's crew had fallen in with a number of seals, and the quantity of young seal's fry they brought on board afforded a welcome regale to their messmates and themselves.

"At daylight (27th) we were four leagues from Cape Tres Montes, bearing N. 68° W. (magnetic) a remarkable peak, marked in the chart the 'Sugar Loaf,' N. 19° E., distant twenty-four miles, and our soundings were sixty-eight fathoms. This peak resembled in appearance, the Sugar Loaf at Rio de Janeiro: it rises from a cluster of high and thickly-wooded islands, forming apparently the eastern shore of an inlet, of which

© The Complete Work of Charles Darwin Online

the land of Cape Tres Montes is the western head. Further to the N.E. stands a lofty and remarkable mountain, marked in our chart as 'the Dome of Saint Paul's.' It is seen above the adjacent high land. The height of the Sugar Loaf is 1,836 feet, and that of the Dome of Saint Paul's, 2,284 feet.

"During the day we worked up towards the land, eastward of Cape Tres Montes, and at night succeeded in anchoring in a sandy bay, nine miles from the Cape, where our depth of water was twelve fathoms, at the distance of a cable and a half off shore. We lay at this anchorage until noon the following day, while Lieut. Skyring landed on some low rocks detached from the shore, where he was able to take some advantageous angles; and on his return we weighed and worked up the gulf, between the eastern land of Cape Tres Montes, and high, well wooded islands. The shores of the main land, as well as of the islands, are bold, and the channel between them has no dangers: the land is in all parts luxuriantly wooded. About a mile and a half to the northward of the sandy beach which we had left, lies another, more extensive; and a mile further, a considerable opening in the main land, about half a mile wide, presented itself, having at its mouth two small thickly-wooded islands, for which we steered, to ascertain whether there was a harbour. The water was deep at its mouth, from thirty-eight to thirty-four fathoms; but the comparative lowness of the shores at its S.W. end, and the appearance of two sandy beaches, induced us to expect a moderate depth within. As we advanced, a long white streak was observed on the water, and was reported from the mast-head as a shoal; but it was soon ascertained to be foam brought down by the tide, and we had the satisfaction of anchoring in sixteen fathoms over a sandy bottom, in a very excellent port, which we named Port Otway, as a tribute of respect to the Commander-in-chief of the South American Station, Rear Admiral Sir Robert Waller Otway, K.C.B."

* * * *

A deficiency here occurs in Captain Stokes's journal, which the Beagle's log barely remedies. From the 30th of April to

© The Complete Work of Charles Darwin Online

the 9th of May there was a succession of stormy weather, accompanied by almost incessant and heavy rain, which prevented the ship being moved; but proved, in one respect, advantageous, by affording a very seasonable cessation from work to the fatigued crew, and obliging Captain Stokes to take some little rest, which he so much required; but regretted allowing himself, and submitted to most reluctantly. He continues his journal on the 9th of May, stating that, "Among the advantages which this admirable port presents to shipping, a capital one seems to be the rich growth of stout and shapely timber, with which its shores, even down to the margin of the sea, are closely furnished, and from which a frigate of the largest size might obtain spars large enough to replace a topmast, topsail-yard, or even a lower-yard. In order to try what would be the quality of the timber, if, in case of emergency, it were used in an unseasoned state, I sent the carpenter and his crew to cut two spars for a topgallant-mast and yard. Those they brought on board were of beech-wood; the larger being thirteen inches in diameter, and thirty feet in length.

"On the 10th, the weather having improved, the Beagle was moved to the head of the inlet, to an anchorage in Hoppner Sound, and on the 11th I went with Lieut. Skyring to examine the opening, off which we were anchored.

"On each side of it we found coves, so perfectly sheltered, and with such inexhaustible supplies of fresh water and fuel, that we lamented their not being in a part of the world where such advantages could benefit navigation. The depth of water in mid-channel was generally forty fathoms; in the bights, or coves, it varied from sixteen to twenty-five fathoms, with always a sandy bottom. We saw a great many hair seals, shoals of pie-bald porpoises, and birds of the usual kinds in considerable numbers. On several points of the shores were parts of the skeletons of whales; but we no where saw a four-footed animal, or the slightest trace of a human habitation. The unusual fineness of the morning, the smoothness of the water, and the proximity of the adjacent lofty mountains, clothed almost to their summits by the fullest foliage, with every

© The Complete Work of Charles Darwin Online

leaf at rest, combined with the stillness around to give the scene a singular air of undisturbed repose. We reached the extremity of the inlet, which we found was about six miles from its mouth; and thinking that it was the inner shore of an isthmus, of no great width, curiosity prompted us to endeavour to see its outer shore: so we secured the boat, and accompanied by five of the boat's crew, with hatchets and knives to cut their way, and mark the trees to guide us on our way back, we plunged into the forest, which was scarcely pervious on account of its entangled growth, and the obstructions presented by trunks and branches of fallen trees.

"Our only guide was an occasional glimpse, from the top of a tree, of the ranges of mountains, by which we steered our course. However, two hours of this sort of work were rewarded by finding ourselves in sight of the great South Sea. It would be vain to attempt describing adequately the contrast to the late quiet scene exhibited by the view we had on emerging from this dark wood. The inlet where we left our boat resembled a calm and sequestered mountain lake, without a ripple on its waters: the shore on which we now stood was that of a horrid rock-bound coast, lashed by the awful surf of a boundless ocean, impelled by almost unceasing west winds

"Our view of the coast was limited on each side by rocky mountainous promontories: off the northernmost, which I called Cape Raper, were rocks and breakers, extending nearly a mile to seaward. Having taken the few bearings our situation enabled us to obtain, we retraced our steps to the boat, and by aid of the marks we had left on the trees, reached her in an hour and forty-three minutes.

"Some of the beech-trees of this wood were fifteen feet in circumference; but I noticed none differing in their kind from those already observed about Port Otway. A few wrens were the only living creatures we saw; not even an insect was found in our walk. In the beds of some of the streams intersecting the woods was a singularly sparkling sand, which had so much the appearance of gold, that some of our party carried

© The Complete Work of Charles Darwin Online

a bag-full on board to be tested. The shining substance proved to be, as I had supposed, the micaceous particles of disintegrated granite. It was not our good fortune to discover streams similar to those sung of by the poet,

"Whose foam is amber, and whose gravel gold."

CHAPTER XI.

Leave Port Otway—San Quintin's Sound—Gulf of Peñas—Kelly Harbour—St. Xavier Island—Death of Serjeant Lindsey—Port Xavier—Ygnacio Bay—Channel's mouth—Bad weather—Perilous situation—Lose the yawl—Sick list—Return to Port Otway—Thence to Port Famine—Gregory Bay—Natives—Guanaco meat—Skunk—Condors—Brazilians—Juanico—Captain Foster—Changes of officers.

The Beagle returned to Port Otway the following day, and in an interval of better weather obtained the observations necessary for ascertaining the latitude and longitude of the port, and for rating the chronometers.

Captain Stokes's journal continues on the 19th of May: "We left Port Otway, and as soon as we had cleared its entrance, steered E.N.E. across the gulf; leaving to the northward all that cluster of islands, distinguished in the chart as the 'Marine Islands,' and went to within a mile from the eastern shore. Thence we ran four miles and a half parallel with the direction of coast E.S.E. (mag.), at the mean distance of a mile off shore. The aspect of the eastern and western portions of this gulf is very different, and the comparison is much to the disadvantage of the eastern. Ranges of bare, rugged, rocky mountains now presented themselves, and where wood was seen, it was always stunted and distorted. A long swell rolled in upon the shore, and every thing seemed to indicate a stormy and inclement coast. There are a few bays and coves, in which is anchorage depth, with a pretty good bottom of dark coarse sand: but rock-weed in large patches, seen in some of them, denoted foul ground; and they are all more or less exposed, and extremely unsafe. As night advanced, the weather became rainy and thick; so having reached a bight which seemed less insecure than others that we passed, I hauled in, and at about seven P.M., guided only by the gradual decrease of our soundings, from

© The Complete Work of Charles Darwin Online

fourteen to eight fathoms, and the noise of the surf, came to an anchor.

"Next morning (20th) we found that we had anchored in a small bay, at about half a mile from a shingle beach, on which a furious surf was breaking so heavily as to prevent our landing any where. We were completely exposed to S.W. winds, with a heavy rolling sea; and the surf on all points cuts off communication with the shore. A breeze from the S.W. would have rendered it difficult to get out, and would have exposed us to imminent hazard. It is called on the chart Bad Bay. We left it eagerly, and proceeded to trace the coast to the E.S.E., until we were nearly abreast of a moderately high and thickly-wooded island, called Purcell Island. We passed to the northward of Purcell Island, leaving on the left a rock only a few feet above the surface of the sea, which lies about midway between that island and the main land. As we advanced to the eastward, a large and very remarkable field of ice was seen lying on the low part of the coast, which, at a distance, we took for a dense fog hanging over it, as nothing of the kind was observable in any other part. When nearly abreast of San Xavier Island, a deep sound was observed to the left, or north, which we concluded was the San Quintin Sound of the Spanish chart: it seemed to be about five miles in breadth, and following a westerly direction. We kept sight of the Sugar Loaf, and other points we had fixed, until more could be established, which enabled us to chart the coast as we went along. My next object was to trace the Sound of San Quintin to its termination, and at nightfall we succeeded in getting an anchorage at the entrance.

"On the 21st we proceeded up the sound, passing to the northward of Dead Tree Island. Our soundings, until abreast of it, were from sixteen to ten fathoms, on a mud bottom; it then shoaled to four fathoms, and after running about three miles in that depth, we came to an anchor at the distance of a mile from the north shore of the sound, in four fathoms.

"Exceedingly bad weather detained us at this anchorage. From the time of our arrival, on the evening of the 21st,

© The Complete Work of Charles Darwin Online

until midnight of the 22d, it rained in torrents, without the intermission of a single minute, the wind being strong and squally at W., W.N.W., and N.W.

"When the weather improved, on the 23d, we weighed, and made sail along the northern side of the sound, for the purpose of ascertaining whether it admitted of a passage to the northward. We kept within a mile of the shore, sounding from eight to fifteen fathoms, generally on a sandy bottom; and a run of seven miles brought us within three miles of the bottom of the inlet, the depth of water being four fathoms, on sand. The termination of this sound is continuous low land, with patches of sandy beach, over which, in the distance, among mountains of great height, we were again able to make out and take the bearing of that remarkable one, named the 'Dome of St. Paul's.' The shores of this inlet are thickly wooded; the land near them is, for the most part, low, but rises into mountains, or rather hills, from twelve to fifteen hundred feet in height, from which many streams of water descend. As soon as a ship has passed Dead Tree Island, she becomes land-locked; and as in all parts of the sound there is anchorage depth, with a muddy or sandy bottom, the advantages offered to shipping would be of great consequence in parts of the world more frequented than the Gulf of Peñas.

"Whales were numerous, and seals were seen in this inlet, now called the Gulf of San Estevan.

"Hence we went to Kelly Harbour, at the north-eastern side of the Gulf of Peñas, four miles N.E. of Xavier Island. The land around it is rocky and mountainous, but by no means bare of wood. Near the entrance it is low, as compared with the adjacent land; but in the interior are lofty snow-capped mountains.

"A large field of ice, lying on the low land near Kelly Harbour, was remarkable. There was none on the low grounds at the other (southern) side of the port, though it was almost the winter solstice at the time of our visit.

"Another day and night of incessant rain. In the morning of the 25th we had some showers of hail, and at daylight found

© The Complete Work of Charles Darwin Online

that a crust of ice, about the thickness of a dollar, had been formed in all parts of the harbour. The water at our anchorage being fresh at half-tide, was, no doubt, in favour of this rapid congelation. Lieutenant Skyring having completed the examination of the harbour, we left it and steered between St. Xavier Island and the mainland, through a fine bold channel, nearly four miles wide, with a depth of more than thirty fathoms. The land on both sides is closely wooded, and rises into high mountains. About dusk we stood into Port Xavier, a little bight, with a sandy beach, on the eastern side of the island; and, at a distance of two cables' length from the beach, anchored for the night in seventeen fathoms.

"(26th). This sandy beach extended about half a mile between the points of the bay, and, at fifty yards from the water, was bounded by thick woodland, which rose with a rapid ascent to the height of a thousand feet. The trees were like those in the neighbourhood of Port Otway, and were stout and well-grown. A tree, large enough for a frigate's topmast, might be selected close to the shore. The Winter's-bark tree attains here a greater size than I had before seen. One, which was felled by our wood-cutters, measured eighty-seven feet in length, and was three feet five inches in circumference. All the trees were in full foliage and verdure, though the season corresponded to the latter part of November in our northern latitudes. At the south end of the sandy beach was a stream of fresh water, several yards in width, and various waterfalls descended from the mountains. The shore to the southward was composed of fragments of granite, lying at the base of a lead-coloured clay cliff, at least three hundred feet in height. In this cliff the mountain-torrents had formed deep chasms, and strewed the beach with its débris, and with uprooted timber. The only living creatures seen were steamer-ducks, king-fishers, and turkey-buzzards.

"While on shore, I received a melancholy message, announcing the death of Serjeant Lindsey, of the Royal Marines. During the last few days he had suffered from inflammation of the bowels, which brought his existence to a close.

© The Complete Work of Charles Darwin Online

"The following day (27th) a grave was dug, and we discharged the last sad duties to our departed shipmate. A wooden cross was erected at the head of his grave, on which was an inscription to his memory: we also named the south point of the bay after him. About noon we left Port Xavier, and coasted the island, at the mean distance of a mile, examining it for anchorages, until, after a run of eight miles, we reached its south point. For the first four or five miles of that distance, the coast of the island consisted of a high steep cliff, having at its base a narrow beach, composed of various-sized masses of rock. In the interior there were heights, rising twelve or fourteen hundred feet, wooded nearly to the summits, with many streams of water descending from them; but for the remainder of the distance the coast was low, and the wood stunted and scanty. All along the shore rolled a heavy surf, that would have rendered any attempt to land exceedingly hazardous; there was no place fit for anchorage, except a small bight, near the extreme south point, into which we stood, and with some difficulty succeeded in anchoring at a cable's length from the shore. The bay proved to be that called by the Spanish missionary voyagers 'Ygnacio Bay.' Over the south point,—a narrow tongue of land, about five hundred yards across, with rocks and breakers stretching off shore, to the distance of two miles,—we took bearings and angles to various fixed points in the northern part of the gulf. The latitude, chronometric differences of longitude, and magnetic variation, were determined on shore at this southern point.

"Our observations being completed, we left this anchorage; and as it is little likely to be visited again, it will be enough to say that it is exceedingly dangerous. Nothing would have induced me to enter it, but the duty of examining the coast for anchorage, and the danger of remaining under sail close to an unexplored shore.

"Under an impression that the island of St. Xavier* was the

* Xavier's Island is certainly the Montrose Island of Byron's Narrative. The Wager was lost, as will be seen, more to the southward, on the Guaianeco Islands.

© The Complete Work of Charles Darwin Online

scene of the Wager's wreck, I wished to examine its western side; but a strong N.N.E. wind did not permit my doing so, without risking the loss of more time than could be spared for an object of mere curiosity. I steered, therefore, to the south-eastward for an inlet, which proved to be the Channel's Mouth of the Spanish charts, and reached it, after running seventeen miles from the south end of Xavier Island. We got no soundings with ninety fathoms of line, when at its entrance; but making no doubt that we should get anchorage within, we left, at the distance of half a mile, the islets of the northern point; passed between two others distant apart only one-fifth of a mile, and shortly after anchored in twenty fathoms, sheltered by an island to the westward, but with rocky islets around us in all directions, except the S.E., some of which were less than a cable's length from us.* Here we were detained until the 10th of June by the worst weather I ever experienced: we rode with three anchors down and the topmasts struck; and though we lay within a couple of hundred yards of the islands and rocks, and less than half a mile from the shores of the inlet, such a furious surf broke on them all, that it was but rarely a boat could land, even in the least exposed situations the inlet afforded. The evening of our arrival was fine, and we put up the observatory tent, on the island to the westward of us; but the weather was so bad, during the next day, that we could effect no landing to remove it, although we anticipated the result that followed, namely, its being washed away.

"In the short intervals of the horrible weather that prevailed, boats were sent to the northern shore of the inlet, for the purpose of procuring water and fuel; but though they sometimes succeeded, by dint of great perseverance, in landing through a raging surf, it was but seldom they could embark the small casks (barecas) which had been filled, or the wood they had cut.

"Upon this shore the master observed remains of some Indian wigwams, that seemed to have been long forsaken, and

* This group was afterwards called Hazard Isles.

© The Complete Work of Charles Darwin Online

he described them to be exactly like those we had hitherto met to the southward.

"This was the northernmost point at which we noticed traces of human beings.

"Finding the boats' crews suffer much from their unavoidable exposure during continually wet weather, I ordered some canvas to be given to each man for a frock and trowsers, to be painted at the first opportunity, as a protection against rain and spray.

"Nothing could be more dreary than the scene around us. The lofty, bleak, and barren heights that surround the inhospitable shores of this inlet, were covered, even low down their sides, with dense clouds, upon which the fierce squalls that assailed us beat, without causing any change: they seemed as immovable as the mountains where they rested.

"Around us, and some of them distant no more than two-thirds of a cable's length, were rocky islets, lashed by a tremendous surf; and, as if to complete the dreariness and utter desolation of the scene, even birds seemed to shun its neighbourhood. The weather was that in which (as Thompson emphatically says) 'the soul of man dies in him.'

"In the course of our service since we left England, we have often been compelled to take up anchorages, exposed to great risk and danger. But the Beagle's present situation I deemed by far the most perilous to which she had been exposed: her three anchors were down in twenty-three fathoms of water, on a bad bottom of sand, with patches of rock. The squalls were terrifically violent, and astern of her, distant only half a cable's length, were rocks and low rocky islets, upon which a furious surf raged.

"I might use Bulkeley's words in describing the weather in this neighbourhood, and nearly at this season: 'Showers of rain and hail, which beat with such violence against a man's face, that he can hardly withstand it.'

"On the 10th, the wind being moderate, and the weather better, preparations were made to quit this horrid place. We put to sea, with a moderate breeze from N. b. W., which

© The Complete Work of Charles Darwin Online

increased rapidly to a strong gale; and scarcely were we fairly freed from the channel, than we found ourselves in a heavy confused sea. Anxious to clear the entrance, I had not waited to hoist in the yawl, with which we had weighed one of our anchors, expecting to find smooth water as we went out; but the sea we met made it unsafe to tow her, and while hauling up to hoist her in, she was so badly stove by blows received from the violent motion of the ship, that we were obliged to cut her adrift. This was a heavy loss. She was a beautiful boat, twenty-eight feet in length,—pulled and sailed well, and was roomy, light, and buoyant; her loss was second only to that of the ship.

"We endeavoured to clear the Guaianeco Islands, by carrying a heavy press of sail, but soon after midnight were obliged to furl the reefed mainsail. Before daylight the wind shifted suddenly to W. b. N., taking us aback by a violent squall, with much vivid lightning and heavy rain. Our admirable little vessel paid off without sustaining any damage; but for a minute her situation was critical. At daylight, the land of Cape Tres Montes bore W. $\frac{1}{2}$ N. (magnetic), distant four leagues. The violence of the gale we had just had put it out of our power to clear the gulf; and, from the state to which we were reduced by the loss of our yawl, both gigs being in bad condition, and our cutter so much stove as to be useless, I considered that it would not be justifiable to attempt proceeding in a lone ship to an unknown and most stormy coast, without a single efficient boat; so I resolved to hasten to Port Otway, and put the boats into an effective state. We had baffling winds all day; but in the evening succeeded in reaching the harbour, and anchoring nearly in our old berth. On the 13th and 14th, we had a continued hard gale, with the usual accompaniment of heavy rain. The carpenters were, however, kept constantly at work to render the cutter effective. On the 15th, the state of the sick list caused me to require from the surgeon, his opinion as to the 'necessity of a temporary cessation of surveying operations.' Mr. Bynoe's reply stated 'that in consequence of great exposure to a long-continued succession of

© The Complete Work of Charles Darwin Online

incessant and heavy rain, accompanied by strong gales, the health of the ship's company had been seriously affected, particularly with pulmonic complaints, catarrhal, and rheumatic affections; and that, as a recurrence of them would probably prove fatal in many instances, a temporary cessation would be of the greatest advantage to the crew, by affording an opportunity of recruiting their health.'

"On receiving the above communication from the surgeon, I ordered the yards and topmasts to be struck, and the ship covered over with sails. Precaution was used to prevent the people from being subjected to frequent exposure, by not employing any of them in boats, except once a day in procuring muscles, and every thing was avoided that could in the least interfere with the recovery of their health: but this place is exceedingly ill adapted for the winter quarters of a ship's company, as the woods that surround it, down even to the water's edge, allow no space for exercise on shore, and there is neither game nor fish to be procured, except shell-fish; of which, fortunately (muscles and clams), we found an abundance, and they proved useful in removing symptoms of scurvy, besides affording a change of diet. The place being destitute of inhabitants, is without that source of recreation, which intercourse with any people, however uncivilized, would afford a ship's company after a laborious and disagreeable cruise in these dreary solitudes. Every port along this coast is alike ill suited for a winter's residence, and it was only our peculiar situation that induced me to determine on making a short stay at this place."

Here poor Captain Stokes's remarks and notes end. Those who have been exposed to one of such trials as his, upon an unknown lee shore, during the worst description of weather, will understand and appreciate some of those feelings which wrought too powerfully upon his excitable mind.

The Beagle remained quiet until the 29th of June, when the surgeon reported "the crew sufficiently healthy to perform their duties without any material injury to their constitutions."

© The Complete Work of Charles Darwin Online

Leaving Port Otway, she steered along the coast with, strange to say, easterly winds and fine weather, which enabled Lieut. Skyring to add much to the survey of the coast of Madre de Dios. Captain Stokes now began to show symptoms of a malady, that had evidently been brought on by the dreadful state of anxiety he had gone through during the survey of the Gulf of Peñas. He shut himself up in his cabin, becoming quite listless, and inattentive to what was going on; and after entering the Strait of Magalhaens, on his return to Port Famine, he delayed at several places without any apparent reason; conduct quite opposite to what his would naturally have been, had he then been of sound mind. At last, want of provisions obliged him to hasten to Port Famine; and the day on which he arrived every article of food was expended.

The fatal event, which had cast an additional gloom over every one, decided our quitting the Strait. Both ships were immediately prepared, and we sailed on the 16th August; but previously, I appointed Lieutenant Skyring to act as commander of the Beagle; Mr. Flinn to be master of the Adventure; and Mr. Millar, second master of the Adventure, to act as master of the Beagle. The day we sailed, Mr. Flinn was taken ill; and, Lieutenant Wickham being on the sick list, I was the only commissioned officer able to keep the deck. As the wind was from the N.W., we were obliged to beat to windward all night, and the next morning were off Sandy Point; but it blew so very strong from the westward, and the weather was so thick from snow-squalls, which passed in rapid succession, that we bore up, and anchored in Freshwater Bay, where the ships were detained by northerly winds until the 21st, when we proceeded; the wind, however, again opposing, we anchored about half a mile from the shore, in a bight, seven miles southward of Sandy Point. The following day we were underweigh early, and reached Gregory Bay. When off Elizabeth Island, I despatched the Beagle to Pecket's Harbour to recall the Adelaide, in which Lieutenant Graves had been sent to procure guanaco meat. The Beagle worked through, between Elizabeth Island and Cape Negro, and was seen by

© The Complete Work of Charles Darwin Online

us at anchor off Pecket's Harbour before we entered the Second Narrow.

Upon our anchoring under Cape Gregory, two or three Patagonians were seen on the beach, and before half an hour had elapsed others joined them. By sunset several toldos, or tents, were erected, and a large party had arrived. When the Adelaide first went to Pecket's Harbour, Mr. Tarn told the Indians that the Adventure would be at Gregory Bay in twenty-five days, and, accidentally, we arrived punctually to the time. The Patagonians must have been on their way to meet us, for they could not have travelled from Pecket's Harbour in the short space of time that we were in sight. To their great mortification, however, we held no communication with them that evening, and the next day the weather was so bad we could not even lower a boat. At noon the wind blew harder than I had ever witnessed; but since we were on good holding-ground, and the water was smooth, no danger was anticipated.

As the snow-squalls cleared off, we looked towards the Patagonians, with the full expectation of seeing their huts blown down:—to our astonishment, they had withstood the storm, although placed in a very exposed situation. We counted twelve or fourteen of them, and judging by our former experience of the number belonging to each, there must have been, at least, one hundred and fifty persons collected. During the gale they kept close; and it was only now and then that a solitary individual was observed to go from one toldo to another.

The weather having moderated, the Beagle and Adelaide joined us on the following day. They rode the gale out, without accident, off the entrance of Pecket's Harbour. The next morning being fine, we prepared to proceed; but previous to weighing I landed, and communicated with our old acquaintances. Maria was with them, and, if possible, dirtier, and more avaricious than ever. We collected the guanaco meat they had brought for us; distributed a few parting presents, and then returned on board.

The Adelaide brought sixteen hundred pounds of meat, which, with what was first obtained, amounted to four thousand

© The Complete Work of Charles Darwin Online

pounds weight; and cost altogether ten pounds of tobacco, forty biscuits, and six pocket-knives. At first a biscuit was considered equivalent to forty or fifty pounds of meat; but as the demand increased, the price rose four or five hundred per cent. With the Patagonians were two of Mr. Low's crew, who had left him. They were Portuguese, in a miserable state, and appeared to be thoroughly ashamed of being the companions of such a dirty set: they could not speak English, and could give us very little information. They had not then assumed the Indian garb, although, from the state of their clothes, they would very soon be obliged to adopt it.

At Pecket's Harbour a few words of the native language were collected, which are very different from those given by Falkner, in his description of the Patagonian natives: he says himself, that the language of the northern Indians differs materially from that of the 'Yacana Cunnees.'

During Lieutenant Graves's communication with the natives, at Pecket's Harbour, he obtained some interesting information respecting these Indians, which will be given in a subsequent part of the work.

The Adelaide brought me a few very gratifying additions to my zoological collection, among which was the Zorillo, or Skunk, of the Pampas; differing in no way whatever from the species found about the River Plata, in such numbers as to impregnate the air with their disagreeable odour for many miles around.

I have frequently found the scent of this offensive little animal distinctly perceptible when I was on board the Adventure, lying at anchor about two miles from Monte Video, with the wind blowing from the land.*

* D'Azara, in his Essai sur l'Histoire Naturelle des Quadrupèdes de Paraguay, gives the following account of this animal, which he calls Yagouaré. It burrows in the ground, eats insects, eggs, and birds, when it can surprise them, and moves about the plains and fields both by day and night in search of food; brushing the ground with its body, and carrying its tail horizontally. It regards not the presence of man or beast; unless an attempt be made to injure or take it, when it gathers up its body, bristles up the hairs of its tail, erecting it vertically; and in this

© The Complete Work of Charles Darwin Online

A very large condor was shot by one of the Adelaide's party, which measured, in length, four feet three inches and a half, and nine feet two inches between the extremities of the wings. It was presented to the British Museum. Many exaggerated accounts of this bird have been given by old voyagers; but the largest dimensions stated, of whose accuracy there exists no doubt, are those of one that was preserved in the Leverian Museum, which measured thirteen feet one inch, from wing to wing. This, however, must have been an old bird; for the one we killed is larger than the usual size of specimens which have been obtained. Molina states, in his account of this bird, vol. i. p. 298, that the largest he ever saw measured fourteen feet and some inches (Spanish measure), from the tip of one wing to that of the other. M. Humboldt also gives a detailed description.

"It is with the condor," says this celebrated voyager, "as with the Patagonian, and many other objects of natural history; the more they are examined, the more they diminish in size." They inhabit the highest mountains of the Andes, and only descend to the plains when pressed by hunger. Frequently, in troops, they attack cattle, deer, guanacoes, and even the puma, and always succeed in killing them; but their principal food is carrion, of which, in a country so abundantly stocked with quadrupeds, there is probably no want.

Our departure from the Strait was attended with beautiful weather; the moon was full, and the wind fair and moderate.

this position awaits the approach of its enemy, at whom it ejects its urine, which produces so unbearable a smell, that neither man, dog, nor tiger, will attempt to touch the animal.

The yagouaré moves very slowly, and cannot run. It produces two young ones, which are placed at the bottom of its burrow. The unconquered Indians of the Pampas make mantles with the furs of the fox, cavia, or other animals, and border them with the skins of the yagouaré, which are very soft and fine, and would be fit for being employed by the furrier were it not for the disagreeable odour which they impart to every thing they touch. The Indians eat the flesh of this animal, which they irritate until its only means of defence is unavailing, and it can be captured without offensive consequences.

© The Complete Work of Charles Darwin Online

Cape Virgins was passed soon after sunset, and we proceeded on our course with rapidity.

The timely supply of guanaco meat had certainly checked the scurvy, for we had no new cases added to the number of the sick, now amounting to twenty. The Beagle was not so sickly; but, during the last cruise, upwards of forty cases, principally pulmonic, had occurred, and several were not yet recovered. On the passage, a man fell overboard from the Beagle, at night, and was drowned.

In latitude 45° S. we were delayed three days, by northerly winds and damp foggy weather, after which a fresh S.W. gale carried us into the River Plata. Having obtained good chronometer sights in the afternoon, we steered on through the night, intending to pass to the westward of the Archimedes Shoal; which would have been rather a rash step, had we not been well assured of the correctness of our chronometrical reckoning. At this time Brazil and Buenos Ayres were at war, and some of the blockading squadron of the former were generally to be met with in the mouth of the river; but we saw none, until half-past two in the morning, when several vessels were observed at anchor to leeward, and we were soon close to a squadron of brigs and schooners, whose number was evident by a confusion of lights, rockets, and musketry, on board every vessel. I bore down to pass within hail of the nearest, which proved to be the Commodore's, the Marañao of eighteen guns; and on approaching, explained who and what we were; but they were so confused, I could not even make myself understood. The breeze, at the time, had fallen so light, that, fearing to get foul of the brig, the ship was hove up in the wind, and the anchor ordered to be let go. Unluckily a stopper was foul, and before another bower could drop, the Brazilians had fired several muskets into us, happily without doing any mischief; and threatened us, if we did not immediately anchor, with a broadside, which, in their utter confusion, I am astonished they did not fire. Having anchored, and lowered the topsails, I sent a boat to inform the Brazilian who we were, and to request, that in consequence of the number of

our sick (we had only ten serviceable men on deck), we might not be detained, as even a few hours might prove of serious consequence; but all I could urge was unavailing, and we were detained until daylight with trifling excuses. We were so situated, that unless the brig veered her cable, or dropped out of our way, we could not move without getting foul of her, else I should have proceeded without permission. After daylight, the brig gave us room, by tripping her anchor; and upon an officer coming on board to release us, I told him my opinion of the affair, and said I should report the captain's conduct to his admiral. This report was afterwards made, in a very spirited manner, by Captain Henry Dundas, of H.M.S. Sapphire; but the admiral defended the conduct of his officer by saying that he had merely acted, "magna componere parvis," as an English blockading squadron would have done in a similar case.

Whether the act was borne out, or not, by the law or custom of blockade, it was very uncivil; and one for which, after the explanation given, and the proofs offered, there could not be the slightest occasion. Owing to this detention, we did not reach the anchorage at Monte Video until too late in the day to procure refreshments for the sick. We found, to our sorrow, that fresh provisions were so extremely scarce, owing to the war, that none could be procured for our ships' companies; and had it not been for the kindness of Señor Juanico, a well-known, and highly esteemed resident at Monte Video, who supplied us plentifully with bitter (Seville) oranges, we might have been much distressed. The free use, however, of this fruit alone caused a rapid change in the health of those affected by scurvy, and in less than a week every man was at his duty.

A few days after our arrival, through the intervention of the British minister, a peace was concluded between the belligerents, in which Buenos Ayres gained all it had contended for, and Brazil gave up what she had so imperiously demanded.

I was extremely gratified by meeting, at this port, the late Captain Henry Foster, in H.M.S. Chanticleer, on his pendulum voyage. He was established at an observatory on a small island, called Rat, or Rabbit Island, whither I lost no

© The Complete Work of Charles Darwin Online

time in proceeding, and found him deeply engaged in that series of observations which has reflected so much honour upon his memory.

Before he sailed, I made an arrangement to meet the Chanticleer, either at Staten Land or Cape Horn, for the purpose of supplying her with provisions, to enable him to proceed thence to the Cape of Good Hope, without returning to Monte Video.

On the 13th of October, we sailed for Rio de Janeiro to procure some stores, which had been sent from England for our use, and to be caulked and refitted. The Beagle remained at Monte Video, to prepare for our next cruise. Before we were ready to leave Rio de Janeiro, the Commander-in-chief, Sir Robert Otway, arrived from Bahia, in his flag-ship, the Ganges. Sir Robert acquainted me, that he considered it necessary for the Beagle to be hove down and repaired;—that he intended to supersede Lieutenant Skyring; and had sent the requisite orders to Monte Video. When the Beagle arrived, Lieutenant Robert Fitz Roy, flag lieutenant of the Ganges, was appointed as commander; Mr. J. Kempe, mate, as lieutenant; and Mr. M. Murray, second master of the Ganges, as master.

Although this arrangement was undoubtedly the prerogative of the Commander-in-chief, and I had no reason to complain of the selection he had made to fill the vacancies, yet it seemed hard that Lieutenant Skyring, who had in every way so well earned his promotion, should be deprived of an appointment to which he very naturally considered himself entitled.

The conduct of Lieutenant Skyring, throughout the whole of his service in the Beagle,—especially during the survey of the Gulf of Peñas, and the melancholy illness of his captain,—deserved the highest praise and consideration; but he was obliged to return to his former station as assistant surveyor: and, to his honour be it said, with an equanimity and goodwill, which showed his thorough zeal for the service.

Captain FitzRoy was considered qualified to command the Beagle: and although I could not but feel much for the bitterness of Lieutenant Skyring's disappointment, I had no other cause for dissatisfaction.

CHAPTER XII.

Adventure sails from Rio de Janeiro to the River Plata—Gorriti—Maldonado—Extraordinary Pampero—Beagle's losses—Ganges arrives—Another pampero—Go up the river for water—Gale, and consequent detention—Sail from Monte Video—Part from our consorts—Port Desire—Tower Rock—Skeletons—Sea Bear Bay—Fire—Guanacoes—Port Desire Inlet—Indian graves—Vessels separate—Captain Foster Chanticleer—Cape Horn—Kater's Peak—Sail from St. Martin Cove—Tribute to Captain Foster—Valparaiso—Santiago—Pinto—Heights—Chilóe—Aldunate.

The Adventure sailed from Rio de Janeiro on the 27th of December 1828, leaving the Beagle to complete her repairs, and follow to the River Plata. The day before our arrival at Maldonado, we were overtaken by the Commander-in-chief, in H.M.S. Ganges, and entered the river in company. The Ganges proceeded to Monte Video; but we went into Maldonado Bay, where I had determined to wait for the Beagle.

Since our last visit to this place, the Island of Gorriti had been occupied by Brazilian troops, who, before going away, set fire to the buildings, and destroyed all the wood-work. As one object of my stay was to obtain observations for the latitude and longitude, I erected our portable observatory, and set up an azimuth altitude instrument.

On the 30th of January, after some intensely hot and sultry weather, we experienced a very severe 'Pampero.' It was preceded by the barometer falling to 29·50, and by a strong N.W. wind, which suddenly veered round to S.W., when the pampero burst upon us. Our ship and boats fortunately escaped any bad effects from the violence of the squall, which was so strong as to lay the former, at anchor, upon her broadside; but on shore our tent was blown down, and a boat that had been lately built, and fresh painted, on the Island Gorriti, was completely destroyed. The part above the thwarts, was torn away from the bottom of the boat, and carried, by the violence of the wind, for two hundred yards along the beach. A boat, also,

© The Complete Work of Charles Darwin Online

on the opposite shore, was blown to atoms. When the squall commenced, one of our boats was coming off from the island; the officer being quite unconscious of the approaching hurricane, and as she was overloaded with people, I felt very uneasy until after the squall cleared away, when I observed her beached on the opposite shore, many yards above high water mark, to which position she had been driven by the force of the wind. The violence of this pampero, during the twenty minutes it lasted, was terrific. Old inhabitants of Maldonado declared, that they had experienced nothing like it for the last twenty years. The spray was carried up by whirlwinds, threatening complete destruction to every thing that opposed them. In less than half an hour it had diminished to a strong S.W. gale, which lasted during the night.

Just before the pampero commenced, L'Aréthuse, French frigate, was observed over the point of land under all sail; but not being seen after the squall cleared off, we were much alarmed for her safety. At daylight, however, the next morning, she was seen at anchor under Lobos Island, and near her was our consort, the Beagle, of whose approach we had known nothing; bnt she appeared to be lying quietly, with topmasts struck, under the lee of the island. L'Aréthuse slipped her cable in the afternoon, and ran out to sea.

On the 1st of February the wind moderated, and enabled the Beagle to join us, when we found that she had been nearly capsized by the pampero; and had suffered a considerable loss of sails and masts, besides injury to her boats. Both topmasts, and jib-boom, with all the small spars, were carried away; and her jib and topsails, although furled, were blown to pieces. The vessel was on her beam ends for some time; but letting go both anchors brought her head to wind and righted her, which prevented the necessity of cutting away the lower masts. To add to their misfortune, two men were blown overboard, from aloft, and drowned.

These severe losses caused considerable detention; but, fortunately, the Ganges arrived, and rendered every assistance in repairing and replacing the Beagle's damages.

© The Complete Work of Charles Darwin Online

On the night of the 2d of February we experienced another very severe pampero, during which one of the Beagle's boats, hauled up on shore, was blown to atoms. The barometer had previously fallen to 29·39.

On the 9th of February, we went to Monte Video, and on the 17th ran up the north side of the river for water; but did not find it fresh until we were within four miles of Cape 'Jesus Maria.' The wind was against our return, so that we had to beat down the river, in doing which the Adelaide grounded, but without receiving any injury. We anchored twice in our passage out, and, at the second anchorage,* experienced a very heavy westerly gale. In attempting to weigh at its commencement, our windlass was so much injured, that we were obliged to ride the gale out, which we did by veering to one hundred and ten fathoms of chain cable; and the Beagle, to one hundred and fifty fathoms. Owing to a short heavy sea, in which the Adventure frequently pitched her bowsprit and stern alternately under water, her jolly-boat was washed away. This loss we could ill afford, as we were already three boats short of our establishment, and wants; and as the Adelaide had suffered severely, by losing her topmast and jib-boom, and carrying away the head of her bowsprit, we were obliged to return, very reluctantly, after the gale had subsided, to Monte Video; whence we finally sailed on the 1st of March. On the 5th a S.S.E. gale separated us from our consorts, our course, therefore, was directed for the first rendezvous, at Port Desire.

When off Cape Blanco, the high land of Espinosa, in the interior, was clearly distinguished at a distance of sixty miles, and might probably be seen twenty miles further; so that its height must be, at least, four thousand feet. This range is of irregular form, and has several peaked summits, so very different from the general features of this coast, where the heights are either flat-topped, or of an undulating outline, that I suppose the rock to be of a character unlike that of the porphyry hills common hereabouts.

* From which the Mount (at Monte Video) bore N. 11°. W., distant eight leagues.

© The Complete Work of Charles Darwin Online

On anchoring off Port Desire (14th), we found that the Beagle had arrived, but had not met the Adelaide. The following afternoon I landed to examine the Tower Rock, a very conspicuous object, on the south side of this harbour, having the appearance of an enormous dead tree with its branches lopped off. On our way to it we passed over an undulating plain, composed of a sandy light soil, lying on a rocky basis, which in many parts protruded. The soil was so poor, as only to produce a few tufts of grass, and here and there a straggling bush of Berberis, or Piccoli, a dwarf woody shrub, which is much esteemed as firewood by the sealers who frequent the coast. Sir John Narborough, in describing this place, says, "The soil is gravelly and sandy, with tufts of dry seared grass growing on it;" again: "from the tops of the hills I could see a great way into the land, which is all hills and downs, like Cornwall, toilsome travelling to those who were not used to it."

The Tower Rock is evidently the remains of what was once probably a considerable rocky mass, which has either been partially destroyed by some convulsion, or, more probably, has been gradually worn away by the effect of weather. Like all the débris around, it is of a fine-grained red porphyritic claystone, much decomposed, but very hard, and difficult to break.*

It stands erect at the summit of a mound or heap of broken stones, of all sizes, some being very large blocks, from ten to twenty, or thirty tons weight. It is about forty feet high, and twelve in diameter, having its upper portion cleft, as it were, for about one-third down the middle, which gives it a resemblance to the forked branch of an immense tree. It is covered with moss and lichen, and, from its peculiar shape and prominent situation, presents a very remarkable object.

Near it we observed traces of an Indian visit, among which was a horse's skull. From the sterility of the soil and absence of fresh water, it is probable that it is but little frequented by them. Port Desire is celebrated as being the place where

* Specimens of this rock are deposited in the Geological Society's Museum, Nos. 3 and 3—1.

© The Complete Work of Charles Darwin Online

Schouten, the Dutch navigator, is said to have found skeletons measuring eleven or twelve feet in length!

Captain Fitz Roy informed me that he had not seen the Adelaide since we separated. The Beagle had lost another boat in the gale; the eleventh we have lost in the expedition since leaving England. As the Adelaide did not make her appearance, I determined upon proceeding in the Adventure to Sea Bear Bay, a few miles to the southward of Port Desire, to await her arrival with the Beagle. While standing into the bay, we were amused by a chase of a novel description: a guanaco was observed following a fox, which had much difficulty in keeping his pursuer at a distance. As the guanaco is not carnivorous, it may have been in playfulness: Reynard, however, by his speed, and anxiety to escape, did not seem to think it an amusement. How the chase terminated we did not see, for they disappeared in a valley.

While the ship was being moored, I landed to examine some wells near the outer point, which have been said to afford some tuns of good water. I found them to be deep holes in the solid rock, within the wash of a heavy surf, and large enough to contain two hundred gallons of water; but in one only was the water fresh, the sea having broken into the others, and, of course, spoiled their contents. They receive the rain from the ravines, and are much depended upon by sealing vessels which frequent this coast.

Sea Bear Bay was discovered in the voyage of the Nodales, in the year 1618; they describe the place, but give it, as it deserves, a very poor character. "The port," they say, "for a short stay, is not bad, since it affords a good depth of water and a clear bottom; but otherwise it possesses nothing to make it worth a ship visiting it, for there is neither wood nor water, which are what ships most require." Nodales called the bay 'Sea Lion,' from the multitude of sea-lions (*Phoca jubata*) found on Penguin Island. Why it has been changed to Sea Bear Bay I cannot determine.

In one of Mr. Tarn's excursions into the country, he observed a sail in the offing, which he thought was a whale-boat; and

© The Complete Work of Charles Darwin Online

supposing it might be in distress, if not one of the Adelaide's, kindled a fire to attract attention. As the grass was very dry, it blazed furiously, and spread rapidly around, yet without exciting fear that it could do us any injury; but the next morning flames being observed on the crest of the hills, behind the valley in which our tent had been erected, a boat was sent to save it, and remove the instruments. Our men had just left the ship, when, fanned by a land breeze which rose with the sun, the flames flew on with rapidity, descended the valley, and before the boat reached the shore, had consumed every vestige of the tent, and several articles of minor consequence. The sextant and artificial horizon, lying on the ground, escaped destruction, and the dipping-needle had fortunately been taken on board. Before the fire burned itself out, the whole country for fifteen or twenty miles around was completely over-run, so that all hope of procuring guanacoes was destroyed. Previous to the fire, Mr. Tarn had shot one; but being young, the carcase only weighed one hundred pounds, and was scarcely worth the trouble of sending fifteen miles for; however, as an amusement to the people, I sent a party to bring it on board, and it proved sufficient to furnish the ship's company with a fresh meal.

We had seen several herds within four miles of the ship before the conflagration; but the country was so very level and open, that these shy animals were always warned of the approach of our people by their vigilant scouts. So watchful and attentive is the look-out at his post, that he never drops his head even to feed, and it is only with the greatest cunning and care a man can get near the herd. The best way is, to lie concealed near the water holes, and await their coming to drink. A small stream of fresh water trickled over the beach into the bay, fringed by a patch of grass which the fire had spared, at which having once observed a guanaco drinking, we set a watch; but whether the animals were aware of it or not, none came until the morning we sailed, when a small herd walked down to the place quite unconcernedly, having no doubt first ascertained that there was no danger.

© The Complete Work of Charles Darwin Online

The little vessel Mr. Tarn saw was an American sealer, which anchored in the bay next morning.

Besides the guanacoes, and fox, above-mentioned, we saw no quadrupeds, although two or three sorts of cavia and the puma are common in this neighbourhood. Of birds, nothing interesting was seen, except a plover (*Totanus fuscus?*), oyster-catcher (*Hæmatopus niger, rostro rubro, pedibus albis*), and one of the night bitterns, very much resembling the young of the European bird;* but these three species had previously been found at Port Famine. Several lizards were taken, and preserved.

This extremely sterile and barren country is very unfavourable for animals of any kind. The soil is like that already described about Port Desire. The rock is of the same character as at Port St. Elena and Port Desire: red porphyritic claystone.†

On the 23d of March, a week having passed since we came to Port Desire, my anxiety for the Adelaide's safety was much increased; especially as both wind and weather had been favourable for her approach to this rendezvous. I therefore despatched Lieut. Wickham overland to Port Desire to order the Beagle to join us, and proceed with us to the other points of rendezvous, Port San Julian and Cape Fairweather. Lieut. Wickham reached Port Desire after a fatiguing walk, and early next morning the Beagle was beating into Sea Bear Bay against a very strong wind which increased, and detained us. I seized this opportunity of completing our consort's provisions to five months. Captain Fitz Roy informed me that he had taken advantage of his stay at Port Desire, to ascend the inlet to the head. It extended for thirty miles, and the water was salt to its very extremity; but, from the height of the old banks on each side, it appeared likely that at times there may be considerable freshes. At the head of the river he lighted a fire,

* See Zoological Journal, vol. iv. p. 92.

† Nos. 1 and 2 in the Geological Society's Museum. A new species of Solen (*Solen Scalprum*, nob., Zool. Journ. V. 335. No. 5.) was found on the beach; and the camerated nidus of *Buccinum muriciforme*, nob., Zool. Journal, l. c. No. 62.

© The Complete Work of Charles Darwin Online

which spread, and soon joined that which Mr. Tarn had made. Their union probably burned many square leagues of country.

On the 27th, we were still detained by a southerly gale. Captain Fitz Roy accompanied me in search of Indian graves, which are described to be on the summits of the hills. We found the remains of two, one of which had been recently disturbed, but the other had been opened a considerable time.

No vestiges of bones were left. It is said that the corpse is extended in an east and west direction, on the top of the highest pinnacle of the hill, and then covered over with large stones until secure from beasts of prey. Decomposition takes place, or the flesh is consumed by small animals or insects, without the bones being removed, so that complete skeletons are formed. According to Falkner, the bones are collected at a certain period, and removed to some general cemetery, where the skeletons are set up, and tricked out with all the finery the Indians can collect. The avidity they evince for beads and other ornamental trifles is, perhaps, caused by this desire of adorning the remains of their ancestors.

The next morning we left Sea Bear Bay and proceeded to San Julian, off which we anchored for a few hours, while Captain Fitz Roy entered the port to look for the Adelaide, or for some vestige of Lieutenant Graves's visit. Finding nothing in the port, nor any tracks upon the shore, we went on towards Cape Fairweather, and in our way met the Adelaide. After parting from us during the gale in which all her sails were split, she went to Port Desire, where she arrived first, and, not seeing us, proceeded to the two other places of rendezvous, and had been lying at anchor eight days off Cape Fairweather. Finding we were not there, she was returning to Port San Julian, when we met her.

The weather being calm, so good an opportunity of supplying the Adelaide with provisions was not lost, and she was completed to six months.

On the 1st of April we were off Cape Virgins, and parted from the Beagle and Adelaide; Captain Fitz Roy having previously received orders from me to proceed through the Strait of Magalhaens, and despatch the Adelaide to survey the Mag-

© The Complete Work of Charles Darwin Online

dalen and Barbara Channels, while he was to survey part of the south shore of the Strait and the Jerome Channel, and then proceed, in company with the Adelaide, to Chilóe.

The Adventure then proceeded along the coast of Tierra del Fuego towards Staten Land, for the purpose of communicating with the Chanticleer, or obtaining some intelligence of her. The appointed rendezvous was New Year's Harbour, and the day on which I had promised to be there was past.

It was so foggy that no part of the coast of Tierra del Fuego could be seen; but as any detention might cause Captain Foster inconvenience, I did not wait for fair weather, but went at once to the place appointed.

When crossing Strait le Maire, we were very nearly drifted through by the tide, which, however, changed just in time to admit of our keeping on the north side of Staten Land.

With a strong squally breeze we entered New Year's Harbour, and seeing nothing of the Chanticleer, should have sailed without further investigation, had we not observed a cleared white space on one of the islands, which being near the place where I had requested Captain Foster to leave a document, I concluded was intended to attract our attention. The anchor was therefore dropped in twenty-five fathoms (the island bearing from N. to N.W. ¼ W.), nearly in the spot where Captain Cook anchored, and a boat was sent to the white mark, near which a flag-staff was observed, at whose foot was a tin canister, containing a letter from Captain Foster, which informed me of his having been obliged, in consequence of a longer detention here than he had anticipated, to alter his arrangements, and requesting me to meet him at St. Martin's Cove, near Cape Horn, about this day. We therefore lost no time in getting under weigh, but in doing so, broke an anchor. We passed round Cape St. John, and with a fair wind made rapid progress to the westward. At noon, the next day, being seventy-five miles from Cape Horn, bearing W. by S., the high mountains on the S.E. end of Tierra del Fuego came in sight, among which the 'Sugar Loaf' *(g)* was a conspicuous object.

(g) Campana, or Bell Mountain.—R. F.

© The Complete Work of Charles Darwin Online

By an angular measurement of its altitude, and the distance given by the chart, its height must be nearly five thousand feet, and the average height of its neighbouring mountains full three thousand.

A south-west gale now set in, and delayed our reaching Cape Horn until the 16th, when we anchored off the entrance of St. Martin's Cove and found the Chanticleer moored within. A boat soon after came with the welcome information of all being well on board her. We were not able to warp into the Cove until next day, and in doing so found much difficulty, owing to the violence of the squalls, which repeatedly obliged us to slacken the hawsers quickly, else we should have carried them away.

The Adventure was moored in seventeen fathoms, about a cable's length within the low green point on the south side: and the Chanticleer lay in ten fathoms near the head of the Cove. The summit of Cape Horn being in a line with the south point of entrance, we were quite land-locked, and perfectly sheltered from all winds, excepting the williwaws, or furious gusts from off the high land, which sometimes suddenly struck the ship, and threw her on her broadside; but being as momentary in duration as they were sudden in approach, we found them more disagreeable than dangerous.

During our stay here I made a partial survey of the Bay of St. Francis, which has since been completed by Captain Fitz Roy. St. Joachim's Cove, to the southward of St. Martin's Cove, is more exposed than the latter, but is of easier depth. These coves are separated from each other by a steep and precipitous mass of hills of greenstone, which in many parts appear to be stratified, the dip being to the westward, at an angle of 40°. I landed at the point, and ascended the hill, which I found more difficult to do than I supposed, the whole surface being covered with stunted beech bushes, so thickly matted or interwoven together, that I was obliged to walk or crawl over their tops. Among them were occasionally seen the berberis ilicifolia and veronica, the latter of very small size. Another day, Lieutenant Kendall, of the Chanticleer, accompanied me

© The Complete Work of Charles Darwin Online

to Weddel's Port Maxwell, which is evidently St. Bernard's Cove of D'Arquistade.*(h)* Port Maxwell is contained between Jerdan Island, Saddle Island, and a third island, forming a triangle. It has four entrances, the principal one being to the north of Jerdan Island, and affords tolerable anchorage in the centre, in nineteen and twenty fathoms, sand ;* nearer the shores of the island the depth is more moderate, but the bottom is very rocky.

The summit of Saddle Island, which I ascended for bearings, is composed of large blocks of greenstone rock, on one of which the compass (Kater's Azimuth, without a stand) was placed; but the needle was found to be so much influenced by the ferruginous nature of the rock, composed of quartz and feldspar, thickly studded with large crystals of hornblende, that the poles of the needle became exactly reversed. An experiment was then made, by taking bearings of a very distant object, at several stations around, about fifty yards from the magnetic rock, when the extreme difference of the results amounted to 127°. The block upon which the compass stood, in the first instance, is now conspicuously placed in the museum of the Geological Society.†

Saddle Island, like the others near it, is clothed with low stunted brushwood of beech, berberis, and arbutus, and the ground is covered with a species of chamitis, and other mountain plants. While Mr. Kendall and I were absent from the boat, the crew caught several kelp fish, which are very delicate and wholesome food. On the following day, while going with Mr. Kendall to Wollaston Island, we passed a great many whales, leaping and tumbling in the water. A blow from one

(h) I do not think the bay adjacent to Cape Horn is that which was named by D'Arquistade 'St. Francis,' and, if my supposition is correct, Port Maxwell is not the place which was called 'St. Bernard's Cove.' See Second volume.—R. F.

* According to Capt. Fitz Roy the best berth is in sixteen fathoms. (Sail. Directions.)

© The Complete Work of Charles Darwin Online

of them would have destroyed our boat, and I was glad to cross the Sound without getting within their reach. We returned by the west side of Jerdan Island, where there are bights which might afford shelter to a small vessel.

The Sound that separates Wollaston Island from the Bay of St. Francis, I named after Sir John Franklin, and the harbour to the east of the point on which we landed, after Lieutenant Kendall, who was one of Sir John Franklin's companions in his last journey to the north-west coast of America.

On the west point of Kendall Harbour, I observed a magnetic property in the rock, which is of the same character as that on Saddle Island. Weddel noticed the same at St. Martin's Cove; but I placed the compass in various parts of that cove, without observing any difference from the correct bearing. This was, perhaps, owing to the rock being much covered with soil; for, being of the same character with that of the places above-mentioned, it should cause a similar effect.

The next day S.W. gales and thick weather set in, and confined us almost to the ship. Taking advantage of a short interval of more moderate weather, I ascended the highest peak on the south side of the cove, immediately over the anchorage, taking two barometers, one of the Englefield construction, and the other a syphon barometer, on M. Gay Lussac's plan, made by Bunten, of Paris. Mr. Harrison accompanied me, taking charge of one barometer, whilst I carried the other. My coxswain carried a theodolite. On landing, the barometers were set up at the edge of the water and read off, and at the same moment the barometer on board was read off. We then ascended, but the rise was so precipitously steep as to offer very great impediments; and had it not been for a water-course, in whose bed we climbed for the first part, the ascent, with delicate instruments, would have been almost impracticable. We had ascended but little way, when the unfortunate theodolite escaped from my coxswain, rolled down the ravine, and was much damaged. It was an excellent magnetic transit, and for that purpose was irremediably injured; but, as a theodolite, it was yet useful. The first third of the ascent, from the com-

© The Complete Work of Charles Darwin Online

parative facility offered by the water-course, was only impeded by loose stones, which frequently yielded to the foot, and rolled down the gully, to the great danger of those who followed. The banks of the ravine were saturated with water, and covered either with spongy moss, or matted with plants,* which afforded no assistance; had it not therefore been for straggling shrubs of arbutus, or veronica, and tufts of rushes, growing on the steeper parts, we should have had many a fall; and however unimportant we might think bruises and scratches, a broken barometer would have been a serious accident, and much care was required to avoid it. We had to leave the bed of the torrent, when it became full of wood, and then our difficulty increased much; for in many places we had to scramble over the thickly-matted and interwoven branches of the stunted bushes of beech which frequently yielded to our weight, and entangled our legs so much, that it was no easy matter to extricate ourselves.

At the height of one thousand feet, vegetation became much more stunted; we found the plants and shrubs of very diminutive size, consisting principally of the deciduous-leaved beech, one plant of which, though not more than two inches high, occupied a space of four or five feet in diameter, its spreading branches insinuating themselves among wild cranberry, chamitis, donacia, arbutus, and escalonia, so closely matted together, as to form quite an elastic carpet. For the last two hundred feet, we walked over the bare rock, on which no other vegetation was observed than lichens. The summit of the peak is formed by a loose pile of green-stone rock, in which the hornblende appears in very varied forms, sometimes in large crystals, and again so small and disseminated, as to be scarcely visible; on the summit it is seen, in very long, narrow (? filiform) crystals, and the feldspar predominating, gives it a white appearance.†

The only living creatures we saw were a solitary hawk and

* A species of Gunnera (*Dysemore integrifolia*, Banks and Solander), and the green-stemmed Cineraria (*Cin. leucanthema*. Banks and Solander).

† Nos. 283 to 286, in Geol. Soc. Museum.

© The Complete Work of Charles Darwin Online

one insect, a species of Oniscus. Nothing, in fact, could be more desolate, and we had only the satisfaction of a good observation for the height, and an excellent bird's-eye view of the surrounding islands and channel, to repay us for the labour of the ascent. On reaching the top, the barometers were suspended under the lee of the rock, twelve feet below its summit, and I then proceeded to set up the theodolite, which I found more damaged than I had anticipated; but not so much as to deprive me of a very extensive round of angles, in which were contained bearings of the Ildefonso Islands. We were thus occupied about an hour and half, which afforded me an opportunity of obtaining two good readings of the barometer.

The view to the N.W. was very extensive, and bounded by long ranges of snow-clad mountains of great height; the atmosphere was remarkably clear, and every object unusually distinct. Bearings of the islands of Diego Ramirez would have been taken, but for the extreme force of the wind, which more than once blew me from the theodolite, and once actually threw me on the ground. The temperature was not below 38°; but, owing to the wind, the cold was intense, and the rapid evaporation produced the most painful sensations, particularly in our feet and legs, which were thoroughly wet when we reached the top.

Our descent was not effected in less than an hour and twenty minutes, owing to the difficulty of passing through the beech thickets; but we reached the base without injury to the barometers, which was being more fortunate than I expected. They were again set up on the beach, and read; after which we returned on board, amply gratified and rewarded for our fatigue.

The height of the peak, which, from its vicinity to the station selected by Captain Foster for the pendulum experiments, could not receive a more appropriate name than Kater's Peak, was found to be 1,742 feet above the high-water mark.*

* The changes of pressure, during the intervals of ascent and descent, were obtained by registering the ship's barometer, which was done by signal from the stations on shore, when the readings were taken. During the

© The Complete Work of Charles Darwin Online

The next day, after a beautifully clear and mild morning, with a fresh northerly breeze, the weather became cloudy, and the wind veered to the S.W. blowing excessively hard, with hail and rain. The gusts, or williwaws, rushed through the valley of the cove with inconceivable violence, heaving the ship over on her broadside every minute, so that we were obliged to have every thing lashed as if at sea. Fortunately, we had completed wood and water, and now only waited for observations, to rate the chronometers, for our run to Valparaiso, whither it was my intention to proceed. Days, however, passed without a glimpse of the stars, and the sun only appeared for a few minutes above the hills. Captain Foster had completed his observations, and embarked all his instruments, excepting the transit, which remained for taking the passages of stars; but the bad weather continued, with little intermission. On the 3d, the gale was most violent, and the williwaws became short hurricanes, in some of which the ship drifted and fouled her anchors. On the 10th, we had a dry and fair day, which permitted us to sight the anchors and moor again.

The fine weather was of only a few hours duration, when the gale again sprung up, and lasted, with little intermission, until the day of our departure (the 24th). From the 4th to the 22d the sky was so perpetually clouded, that the only transits obtained in that interval were, one of Antares, one of Regulus, and one of the limb of the moon, though Captain Foster even slept close to the telescope, in the greatest anxiety to obtain observations. On the night of the 22d four stars were

the ascent the column fell 0·039 inches, and during the descent rose 0·041 inches. Corrections were made for the dew point, as observed by Daniell's hygrometer at the base and summit, and the calculations were made according to the formula in Daniell's Meteorological Essay.

The following is the result:

	By Bunten's Syphon.	By Jones 509.
Ascent	1743·4	1749·3
Descent	1738·	1739·1
Mean	1741.	1744·2

Mean of the two instruments 1742·4 feet.

© The Complete Work of Charles Darwin Online

observed, by which the error of the clock was satisfactorily ascertained.

Captain Foster's pluviameter, a cubic foot in size, placed on a stand two feet above the ground, at an elevation of forty-five feet above the sea, contained eight inches and a quarter of rain, after standing thirty days; therefore, with the quantity evaporated, at least twelve inches must have fallen. The day after the above was registered, the vessel only contained seven inches and a quarter; so that in twenty-four hours one inch had evaporated, by which an idea may be formed of the sort of weather we experienced, and of the humidity of the climate.

With respect to the geological features, I can only add, that all the islands on which I landed, and, I believe, all the others, are composed of green-stone of various characters. The lower portion, or base, being less decomposed, is a fine-grained green-coloured rock, in which the component parts are so blended as not to be distinguished from each other. It appears sometimes in strata, dipping at various angles, from 20° to 45° from the vertical; and is very similar to the rock which alternates with granite in the Straits of Magalhaens, at the entrance of the Barbara; and also to that about Pond Harbour, and Bell Bay. At a greater elevation the feldspar predominates, the hornblende is observed in distinct crystals,* and the rock contains a considerable quantity of iron, which is observed in the reddish tinge of its surface. I have before noticed the magnetic property of this rock, which was more or less according to the quantity of hornblende: the beach-stones are different sorts of green-stone.

The lower parts of the hills, around St. Martin's Cove, are thickly wooded with the smooth-leaved, evergreen beech, which I have before described. Its leaves were as fresh and vivid, when we sailed, as if it were the height of summer; but those of the deciduous-leaved beech had assumed their autumnal tint, and were falling fast. Neither species attained a greater size, in diameter, than six or eight inches. The Winter's-bark was

* This rock is very similar to the boulders and pebbles which we found on the beach at Point St. Mary (Freshwater Bay).

© The Complete Work of Charles Darwin Online

found in sheltered places, but not larger in dimensions than the beech.* Where no trees are produced, the ground is covered with tufts of chamitis and donacia, which, being of a bright-green colour, give the sides of the hills a lively and verdant appearance. Had the state of the weather permitted our boats to leave the neighbourhood of the cove, or had the woods afforded any addition to collections for natural history, our detention would have been more agreeable; but, with the exception of a few corvorants, divers, and 'steamers,' with now and then a solitary hawk, or a Patagonian 'warbler,' we saw no traces of animal life. No Indians came near us, having been frightened away by the Chanticleer; for when Captain Foster was absent at night, after attempting to land at Cape Horn, several rockets were fired off as signals, and a few Indians who were then in the cove were so much alarmed, that they went away next day, and never afterwards showed themselves, although I dare say we were very narrowly watched by them.

Having supplied the Chanticleer with the provisions she required, we prepared to leave St. Martin's Cove. On the 24th the Chanticleer sailed, and in two hours after we also left this dismal cove, in which we experienced a succession of very bad weather, an almost constant S.W. wind, and for the last month a scarcely ceasing fall of either rain, hail, or snow. The Chanticleer bore away round Cape Horn, and was soon out of sight.

This was my last meeting with Captain Foster, who, the night before we sailed, communicated to me a presentiment, which he could not shake off, that he should not survive the voyage. I cannot now resist indulging in the melancholy satisfaction of saying a few words to the memory of my late excellent

* The underwood is composed chiefly of *Arbutus rigida*—*Berberis parvifolia* and *ilicifolia*—(*sempervirens* of Banks and Solander). *Veronica* (*decussata?*) and, in moist places, *Cineraria leucanthema*, and *Dysemore integrifolia*; both of which are found in all the sheltered corners of Tierra del Fuego. No *Fuchsia* was seen, but Mr. Anderson gathered the sweet-scented *Callixene marginata*, and a species of *Escalonia*, on the hill sides.

friend, and lamenting, with many others, the severe loss which science suffered in his death. He was a fellow of the Royal, and Astronomical Societies, and to the former had contributed, to use the words of His Royal Highness the Duke of Sussex, as President of the Royal Society, a most valuable and extensive series of observations upon the diurnal variation, diurnal intensity, and dip of the magnetic needle; and upon other subjects connected with the terrestrial magnetism and astronomical refraction, which formed an entire fourth part of the Philosophical Transactions for the year 1826. For these papers he received the Copley medal; and the Lords of the Admiralty acknowledged their sense of the honour which was thus conferred upon the profession to which he belonged, by immediately raising him to the rank of Commander, and by appointing him to the command of the Chanticleer, upon a voyage of discovery and observation in the South Seas. The address of the President of the Royal Astronomical Society, at the anniversary meeting,* also bears ample testimony to his active and useful services in the expedition, under Captain Parry, towards the North Pole; as well as to his ardent zeal, very great attention, and accuracy, in every thing which he undertook for the promotion of science; and concludes the notice of his death in the following words: "In the premature death of this young and accomplished officer, the Society has to deplore the loss of a zealous and active votary to science; and his memory will be long held dear by those who were more intimately acquainted with him in the relations of private life." Captain Foster was unfortunately drowned, near the close of his voyage, while descending the River Chagres in a canoe.

No sooner had we cleared the land, than we found a strong westerly wind, and a heavy sea; so that if we had entertained any expectation of making a quiet passage to the westward, we should have been disappointed.

The land of Hermite Island, and its vicinity, has a most remarkable appearance when seen from the south. Its outline is a series of peaks, following each other in regular succession,

* Ann. Meeting, 30th Nov. 1832.

© The Complete Work of Charles Darwin Online

and resembling the worn teeth of an old saw. Mount Hyde is made sufficiently distinct by its rounded apex, and by being higher than any land near it. Kater's Peak also is remarkable in this view, from its conical form and very pointed summit, and from being situated at the eastern end of the island. The 'Horn' itself needs no description; it cannot easily be mistaken.*

Westerly winds carried us as far as 60° south latitude before we could make any westing, and then we had a slant from the eastward, followed by variable winds. Our run to Valparaiso was much like all other voyages in this climate; we had the usual quantity of foul and fair winds, with a share of tempestuous weather, and arrived at Valparaiso Bay on the 22d of June. While remaining here our chronometers were cleaned, and some of them repaired; and the ship was refitted and provisioned, with a full supply for the Beagle and Adelaide as well as herself.

At the latter end of July, Lieutenant Wickham accompanied me to Santiago, the capital of Chile, ninety miles from the port, for the purpose of waiting upon General Pinto, the Director; and communicating to him the purpose of our voyage, to prevent exciting suspicion, or receiving any interruption on the part of the authorities of places we might visit, particularly Chiloé, where our stay might be viewed with distrust or apprehension; for rumour had already said that the English were about to take that island. Ridiculous as such a report was, I deemed it sufficiently important to induce me to explain to the Chilian Government our views and orders, which could be done better by personal explanation than by a correspondence.

We commenced our journey early on the 11th of July, travelling in a covered chaise, drawn by three horses, one in

* The Survey of this part now presents the navigator with the means of ascertaining his position, to a nicety, by angles taken with a sextant between Cape Horn summit and Jerdan's Peak, or Mount Hyde, and Kater's Peak; and if Jerdan's Peak and Mount Hyde be brought in a line, and an angle taken between them and Cape Horn summit, the operation will be still more simple.

© The Complete Work of Charles Darwin Online

the shafts, and the others outside, attached to the carriage by a single trace of hide; and preceded by a drove of horses, from which, at the end of every stage of twelve or fifteen miles, we selected a relay. The day was so very stormy, that we saw but little of the country. Immediately after leaving the Almendral, or suburbs of Valparaiso, we ascended twelve hundred feet, and then descended about four hundred feet to an extensive plain, reaching to the Cuesta de Zapato, the summit of which, at least the highest part of the road over it, we found by barometrical measurement to be 1,977 feet above the sea. In the interval we passed through the village of Casa Blanca, lying eight hundred and three feet above the sea. After passing the Cuesta de Zapato, between it and the Cuesta de Prado, is another extensive valley, through which runs the River Poangui. At Curacavi, where we crossed the river, the height above the sea is six hundred and thirty-three feet;* and the road proceeds by a gentle ascent to the foot of the Cuesta de Prado, near which is the village of Bustamente, eight hundred and eight feet above the sea.

This 'cuesta' is passed by a very steep road, and is ascended by twenty-seven traverses, which carry one to a height of 2,100 feet above the plain, or 2,950 feet above the sea. When we reached the summit of this mountain the weather was so cloudy, that the Andes were almost concealed from view. Beneath us was the extensive plain of Maypo, with the city of Santiago in the distance, a view of considerable extent, and possessing very great interest; but from the state of the weather, its beauty would not have been seen to advantage, had not portions of the towering Andes, raised by optical deception to apparently twice their height, appeared at intervals among the clouds. On

* Miers, in his account of Chile, gives a table of barometrical measurements of the heights of the land between Valparaiso and Mendoza, from which it appears that he has deduced the height of Curacavi to be 1,560 feet. As my determinations are the results of observations made on my way to and from Santiago, I have no doubt of their correctness, and think that the registered height of Miers's table should be 29·355 instead of 28·355.

© The Complete Work of Charles Darwin Online

a fine day, when the range of mountains is uncovered, the view is grand; but not so imposing as when their lower portions are concealed, and their summits partially exposed. This part of the Andes rises about 11,000 feet above the plain, and is covered half way down the sides with snow, the lower edge of which is regularly defined, and presents a change of colour so abrupt and horizontal as to appear unnatural, and therefore diminish the grandeur of the scene very much. But under whatever circumstances this view is seen from the Cuesta de Prado, it is magnificent, and produces an effect beyond description. The road descends down the eastern side of this Cuesta, to a plain about 1,100 feet below the summit. So much rain had fallen during the two preceding days, and last night, that our driver expressed some doubt whether we should be able to cross the Podaguel, a river which is frequently impassable from the strength of its current. The idea of spending a night at the miserable hovel we were leaving was enough to induce us to run a considerable risk, and we set off to make the attempt. The water was very deep, and the current sufficiently strong to render it a performance of some danger; but, this difficulty being passed, we soon reached the city of Santiago, and in the house of Mr. Caldcleugh, enjoyed the hospitality and society of a warm-hearted friend.

I waited on the Director (Pinto), who received me with the greatest politeness. He entered into the particulars of our past voyage with much interest, assuring me that every facility should be afforded, and every assistance rendered, whenever it might be required; and in this assurance we never found ourselves deceived, for on all occasions the conduct of the executive authorities towards us was marked in attention, and even kindness. I make this observation with the more pleasure, as it was very unusual in our communications with the authorities of those governments we had previously visited, to find the objects of our voyage considered in the least interesting.

Although the weather, during our visit to Santiago, was not there considered fine, we left the city and its neighbourhood with a strong impression of the salubrity of the climate, and the

© The Complete Work of Charles Darwin Online

mildness of its temperature, which even in the middle of winter, and at the height of nearly 2,000 feet above the sea, ranged no lower than 45° Fahrenheit, and during the day the maximum height of the thermometer never exceeded 62°.*(*k*)

We returned to Valparaiso on the 26th of July, and made preparations to sail; but were detained by a strong northerly gale for many days, in which we were enabled to render assistance to a large Indian trader that would otherwise have been wrecked. On the 10th of August, we sailed for Chilóe; and on our way were greatly delayed by southerly winds, which carried us in sight of the island of Juan Fernandez. We reached our destination on the 26th, and found the Beagle, to our great delight, arrived, and all well. Captain Fitz Roy came on board before we anchored, and gave me an outline of his proceedings, and those of the Adelaide, which had not

returned, but was daily expected, having been despatched to survey some interior channels on her way to Chilóe. Our anchorage was off Point Arenas, which is not only the best in the bay, but appeared to be well adapted to our wants. The Beagle had arrived early in July, and had sent to Valparaiso for stores with which to refit, and make preparations for another cruize to the south.

The harbour master, Mr. Williams, an Englishman, visited us soon after our anchoring, and by him I forwarded to the Yntendente (or governor), Don José Santiago Aldunate, the letters brought for him from Chile.

In the afternoon I received his acknowledgments, and offers of all the assistance in his power to render. As it was probable that our stay would occupy some weeks, I established myself at a house in the town, obtained by his kindness; and there fixed my portable observatory, and set up an azimuth altitude instrument.

CHAPTER XIII.

Beagle and Adelaide anchor in Possession Bay—Beagle passes the First Narrow—Fogs—Pecket Harbour—Adelaide arrives with Guanaco-meat—Portuguese Seamen—Peculiar light—Party missing—Return—Proceed towards Port Famine—Fuegians—Lieut. Skyring—Adelaide sails to survey Magdalen and Barbara Channels—Views—Lyell Sound—Kempe Harbour—Cascade Bay—San Pedro Sound—Port Gallant—Diet—Rain—Awnings—Boat cruise—Warning—Jerome Channel—Blanket bags—Otway Water—Frequent rain—Difficulty in lighting fires.

THE following is an account of the Beagle's and Adelaide's operations, after separating from the Adventure, on the 1st of April, at the entrance of the Strait of Magalhaens.

Light northerly winds were favourable for their entering the Strait, and they reached Possession Bay the first night. The following day was foggy, and almost calm, until the afternoon, when both vessels weighed, and proceeded with the tide. At sunset the Adelaide anchored on the north shore; but the Beagle stood on, and entered the Narrow. After dark, when within it, with a rapid tide running, the wind fell light, and an anchor was let go, under the north shore, in eight fathoms; but the cable being accidentally checked too soon, snapped like a small rope, and the vessel was hustled out into deep water. As it would have been both useless and imprudent to let go another anchor, the Beagle was kept underweigh, and worked to the westward, aided by a very powerful tide, which speedily carried her through the Narrow, without accident, although the night was dark; and they had no guide but the chart and lead. At eleven o'clock she was anchored within the Narrow, in twelve fathoms, soon after which the tide turned, and ran with great strength; but the night was calm, as well as the next morning.

While waiting for wind, and the change of tide, several Patagonian Indians were observed on horseback hunting gua-

© The Complete Work of Charles Darwin Online

nacoes. A very large dead cod-fish was also seen, floating past, which was taken on board; on its skin were several parasites.*

With the evening tide the Beagle reached Gregory Bay; and the next day (April 4th) worked through the Second Narrow, and anchored in Pecket Harbour.

As soon as she arrived people were sent on shore to make a large fire, to show the natives where the ship was, and attract them to her. Next morning, the 5th, it had spread very much, and overrun several acres of ground, which showed either a very dry soil, or that there had not been much rain for some time. The ground was covered with cranberries; so much so, that it had quite a red tinge; they were very good. Plenty of wild celery was found, but no wood of any kind. Water was obtained in small quantities, from a spring about eighty yards from the beach, abreast of the anchorage: it may also be procured by sinking wells. Early on the 6th of April the Adelaide anchored near the Beagle. Captain Fitz Roy went on board, and found that Lieutenant Graves had seen the Indians in Gregory Bay; and had anchored there for the purpose of obtaining guanaco meat, of which he got about nine hundred pounds weight. Thick fogs had prevented his getting through the First Narrow until the 4th. At Gregory Bay, Lieutenant Graves took three Portuguese seamen on board, who claimed his protection, having been left by an English sealing vessel nearly a year before. One of them asked to be again put ashore, and was landed on Quoin Hill to carry a message to the Indians, from whom he promised to bring a supply of meat in two days. The other two were entered on the books as supernumeraries, and employed in the Adelaide. Having given the Beagle two-thirds of the meat, the Adelaide weighed; and in two hours was out of sight, on her way to Port Famine.

* Probably they are the same as we observed on the fish taken by us off Cape Fairweather, and which, I believe, to be nearly allied to the one that is figured in Cuvier's Règne animal, Plate XV. figure 5, a species of *Lernæa*, or *Entomoda* of Lamarck, iii. 233. The species is new.

The following are extracts from Captain Fitz Roy's journal of this cruise of the Beagle.

"Monday 7th April. Several of our people were employed in gathering cranberries, and preserving them for future use; they are anti-scorbutic, as well as the wild celery, much of which has been used with our guanaco soup.

"Wednesday, 8th. I went to Oazy Harbour with Lieutenant Skyring, who surveyed the harbour while I examined the cove to the northward.

"Oazy Harbour appears large, but the part where there is anchorage is very small, and a strong tide sets in and round it, by which a bank is thrown up, a short distance inside the entrance; there is very little wood, and some difficulty in obtaining fresh water, even in a small quantity. The anchorage outside might be more convenient for procuring guanaco meat from the Indians than Gregory Bay, but it is exposed to winds between W.S.W. and S.S.E.

"At my return to the Beagle, I was much surprised to find that Lieutenant Kempe, Mr. Bynoe, and a boy, had not yet come back from a shooting excursion. A boat had been to the appointed place at sun-set, and had waited an hour without seeing them. At seven, a light was seen on the top of Quoin Hill, and I sent a boat to the spot, with cautions about landing, being in doubt whether it was shown by them or by the Indians; but the boatswain, who went with her, could find no person, nor any light. He waited some time, and returned on board.(*l*) A similar light was again seen, more than once, during the dark and gloomy weather, with small misty rain falling, and a light breeze from the westward, which we had all night.

"Thursday, 9th. No signs of our officers, nor any appearance of the Indians. Fearing that some accident had happened, I sent two boats away, with arms and provisions, to look for them all round the harbour, and the large lagoon which communicates

(*l*) This was a remarkable instance of what I often observed afterwards in those regions, a kind of 'ignis fatuus,' which sometimes was stationary, like the light of a lanthorn, and at others suddenly flitting, like the flashes of pistols, at a distance. It was only seen upon the lower hills.—R. F.

© The Complete Work of Charles Darwin Online

with it. Both boats were thoroughly cautioned about the Indians, for I had thoughts of their treachery. Just as the boats got out of sight, three people were observed on the ridge of a hill, about six miles distant; and, at the same time two other persons appeared, much nearer the ship, on the east side of the harbour. Which was our party, and who the others were, it was perplexing to say. Both disappeared again for about two hours, when our stragglers came over a hill, very near the ship. Upon their arrival on board, they were scarcely able to move: they had been on their legs, almost without food, and without shelter from the rain, since they left the ship. Their intention had been to walk round the harbour, which appeared an employment for two hours only; but at its head they found a lake, and beyond that lake a much larger one, joined to the first by a passage, which they could not cross. When they arrived at this passage, it was too late to return by the way they went, and their best chance seemed to be going on. After dark, they tried to make a fire, but the rain prevented them. It was too dark to see their way, and the cold rain obliged them to keep moving about, though in one place. When daylight came, they travelled on, and until they reached the ship at two o'clock, were constantly walking.

"The other people seen by us must have been Indians; none were met by our wanderers, but several places were passed where fires had been made by them.

"April 10th. Directly our boats returned, we weighed and made sail; but the wind soon failed, and the tide setting against us, obliged me to anchor.

"April 11th. Made sail towards the passage between Elizabeth Island and Cape Negro, and anchored there to wait for the tide, which ran past us when at anchor, at the rate of three knots an hour. About Cape Negro the appearance of the land entirely changes. A low barren country gives way to hills covered with wood, increasing in height, and becoming more rocky and mountainous as you go southward.

"On the 13th, when working near the land, against a light southerly breeze, we saw a small canoe paddling along shore,

© The Complete Work of Charles Darwin Online

and some people walking on the beach. While the ship was standing off, I went to them, being the first savages I had ever met. In the canoe were an old woman, her daughter, and a child, and on shore were two Fuegian men with several dogs. Their figures reminded me of drawings of the Esquimaux, being rather below the middle size, wrapped in rough skins, with their hair hanging down on all sides, like old thatch, and their skins of a reddish brown colour, smeared over with oil, and very dirty. Their features were bad, but peculiar; and, if physiognomy can be trusted, indicated cunning, indolence, passive fortitude, deficient intellect, and want of energy. I observed that the forehead was very small and ill-shaped; the nose was long, narrow between the eyes, and wide at the point; and the upper lip, long and protruding. They had small, retreating chins; bad teeth; high cheek-bones; small Chinese eyes, at an oblique angle with the nose; coarse hair; wide ill-formed mouths, and a laugh as if the upper lip were immoveable. The head was very small, especially at the top and back; there were very few bumps for a craniologist. They asked earnestly for 'tabac, tabac,' but seemed very timid. We bartered some biscuit and old knives for a few of their arrows, skins, spears, &c.

"Their canoes, twenty-two feet long, and about three wide, were curiously made of the branches of trees, covered with pieces of beech-tree bark, sewed together with intestines of seals. A fire was burning in the middle, upon some earth, and all their property, consisting of a few skins and bone-headed lances, was stowed at the ends.

"The young woman would not have been ill-looking, had she been well scrubbed, and all the yellow clay with which she was bedaubed, washed away. I think they use the clayey mixture for warmth rather than for show, as it stops the pores of the skin, preventing evaporation and keeping out the cold air. Their only clothing was a skin, thrown loosely about them; and their hair was much like a horse's mane, that has never been combed.

"April 14th. Anchored in Port Famine.

© The Complete Work of Charles Darwin Online

"April 16th. Lieutenant Skyring went on board the Adelaide with Mr. Kirke, five seamen, and one of the Beagle's whale-boats. Mr. Bynoe, the assistant-surgeon, also went as a volunteer.

"April 17th. The Adelaide sailed to survey the Magdalen and Barbara Channels; after which she was to rejoin the Beagle at Port Gallant. She soon got into a strong southerly wind, and could make no progress, as the current was against her; she therefore again stood into the bay, and anchored.

"A sharply cold night made us remember we were far south, although the weather by day had been mild. I have said little about this anchorage, as it has already been described. The appearance of the surrounding country is striking and picturesque. Mount Tarn, with its patches of snow, rising from thick woods, and the high snow-covered mountains in the distance, with dark blue sea at their base, are very remarkable objects.

"We sailed on the 19th with the Adelaide, which had been prevented from going sooner by strong and unfavourable winds: and about noon we parted from our consort, whose course was southerly, into the Magdalen Channel, while we went towards Lyell Sound.

"I cannot help here remarking, that the scenery this day appeared to me magnificent. Many ranges of mountains, besides Mount Sarmiento, were distinctly visible, and the continual change occurring in the views of the land, as clouds passed over the sun, with such a variety of tints of every colour, from that of the dazzling snow to the deep darkness of the still water, made me wish earnestly to be enabled to give an idea of it upon paper; but a necessary look-out for the vessel, not having a commissioned officer with me who had been in the Strait before, kept my attention too much occupied to allow me to make more than a few hasty outlines. Under the high land the Beagle had but little wind, and night closed upon us before we could gain an anchorage in Lyell Sound, so we shortened sail after dark, and kept near mid channel until the morning.

© The Complete Work of Charles Darwin Online

" The night was one of the most beautiful I have ever seen; nearly calm, the sky clear of clouds, excepting a few large white masses, which at times passed over the bright full moon: whose light striking upon the snow-covered summits of the mountains by which we were surrounded, contrasted strongly with their dark gloomy bases, and gave an effect to the scene which I shall never forget.

" At daylight, on the 20th, we were close to Lyell Sound, and stood along its west side, looking for an anchorage, until we found a very good harbour, about a mile inside Mazaredo Point.

" I then went away, with two boats, to examine the Sound, leaving the master to sound and plan the inner harbour.

" Kempe Harbour, within Lyell Sound, would hold six large ships in security; but, like most of the harbours hereabouts, access is difficult, on account of the squalls off the high land, which are so irregular, and often violent.

" During the night of the 21st, it blew strong in squalls, and the chain-cable kept us awake by rattling very much over rocks; yet when the anchor was hove to the bows next morning, it appeared to have been well bedded in stiff clay. To these sounds we afterwards became familiarised.

" Wednesday, 22d. Strong squalls from the south-eastward during the night, and in the morning; when, being anxious to reach Cascade Bay, I weighed, though the weather was thick, and the wind against us. The flaws were so variable, that we were two hours knocking the helm and sails about before we could clear the anchorage, and move half a mile in still water. I should recommend warping in and out of these harbours, in preference to making sail: as it is far easier, if a ship is provided with small hawsers and kedges: and the hawsers can often be made fast to the rocks, or roots of trees.

" The tide rises about four feet in Kempe Harbour; and there is a place where a vessel might be grounded or careened with perfect safety.

" Mazaredo Peak (Bougainville's Sugar Loaf) is an excellent guide to Kempe Harbour; the valley-like appearance of

© The Complete Work of Charles Darwin Online

the land also shows its situation to a vessel in the Straits. What at first appears to be Lyell Sound is Kempe Harbour, the Sound lies more to the left.

" After passing Mazaredo Point, the land is rugged and less woody; it is not very high, and has a peculiar, rounded appearance, like the tops of loaves of bread.

" There was slate in Kempe Harbour, which seemed to me fit for roofing purposes.

" In Cascade Bay we found the abundance of limpets and muscles usual on these shores, and of particularly good quality. The Indians live almost entirely upon them and sea-eggs, though birds, and occasionally a seal, add to their subsistence. Vegetation, both on shore and in the water, is most abundant. At every step one sinks knee-deep in moss, grass, fern, or low bushes. Trees seem to arrive but seldom at perfection; the climate is so moist that they rot while growing, before they attain any size. Moss grows every where; each bough is covered with it: and the water appears to be as favourable to the growth of kelp as the land is to that of plants. The large kind (*Fucus giganteus*) shoots up, from many fathoms depth, to the surface, with strong stalks and large leaves.

" 23d. A bad day; blowing strong, and at times raining. Mr. Murray, Mr. Stokes, and I, went with three boats to continue our work of exploring and sounding.

" Saturday, 25th. We weighed and made sail; but the breeze failed, and flaws came against us. While laying out warps, and hanging by the stream-cable, a squall took the ship and drove her against the rocks, but without doing her any injury, for they were quite wall-sided. The main-yard and spanker-boom were among the trees. We again laid out warps, and had made some progress, when another strong squall obliged us to go back into our anchorage, to remain until the hail, snow, wind, and rain should cease.

" 26th. An unpromising and wet morning; but the heavy rain being over, we weighed, and in a few hours reached the western side of San Pedro Sound.

" About a mile from the point we anchored in Murray Cove,

© The Complete Work of Charles Darwin Online

which affords good shelter from westerly winds, and is very easy of access, being a small roadstead rather than a harbour.

"27th. We set out early with the boats, but the weather was too bad to do much; however, something was done, and at dusk we went ashore on a small island in the Sound. It rained very hard all the afternoon and during part of the night. We sheltered ourselves as well as we could with the boat's sails and tarpaulins; but during the night the wind shifted, and blew so hard, that it threw down our slight shelter, and made me very anxious about the ship; for I was doubtful of the security of the anchorage where she lay.

"28th. This morning was very cold, it rained hard and blew strong; but when it cleared away for a short time, we set to work again, to explore what appeared to be a channel.

"After a three hours' pull against wind, snow, and hail, my channel proved to be only one of the numerous inlets which encroach upon the Fuegian territory; and the boats returned to the Beagle, with the help of strong squalls from the S.W. I was not a little glad to see the ship in the place where I had left her. During the night another anchor had been let go; but she had not moved from her position. This anchorage is so easy of access, that I hope it will be of use to vessels passing through the Strait. There is room for one large sized ship to lie conveniently, or for two or three small craft.

"The weather has not yet been so cold as I expected it would be: snow lies on the deck a short time, but the thermometer has not been lower than 31° (Fahrenheit).

"29th. A rainy, blowing morning: Mr. Stokes and I set out in the boats; but it rained so much, that we could only make a fire to dry our clothes, and remove the numbness, caused by sitting a long time in the wet.

"On the 3d of May, we anchored in Port Gallant: though perfectly secure, this is a dismal harbour in winter, being so surrounded by high mountains, that the sun is seldom visible. Until the 7th, in addition to our usual daily duties, we were occupied in preparing for an excursion, in boats, to the Jerome Channel. Salt provisions were entirely withheld from the crew

© The Complete Work of Charles Darwin Online

for three days, and instead of them, preserved meat, shell-fish, and a large pig, brought from Monte Video, were substituted. We found in this, as in almost every Fuegian harbour, abundance of muscles, limpets, and wild celery; some fish and some wild-fowl. Many of our party thought shags good eating, but only one person could be found daring enough to try whether old Sir John Narborough was quite warranted in saying that a fox was 'savoury food,' and that one repented of his experiment during a week's serious illness.

"My reason for entirely stopping the use of salt-meat, for a few days, was the belief that, at least, two or three days' change of diet is necessary to cause any real alteration in the system; and that it is better to give fresh provisions for three days in succession, and salt-meat during the remainder of three weeks, than to give fresh-meat at three separate intervals in the same period.

"During the wet weather of these regions, we derived great benefit from awnings, painted for the purpose, while refitting at Rio de Janeiro and Maldonado: they kept the lower, and a great part of the upper deck quite dry, even in heavy rain.

"May 7th. Mr. Stokes and I set out with a cutter and whale-boat, to explore the Jerome Channel. We were well provided, with as much as the boats could stow, of what we thought likely to be useful during a month's cruise. Of water we took but little, trusting to the wetness of these regions for a supply. Each man had his clothes covered with canvas, or duck, well painted; and instead of a hat, every one had a 'south-wester' (like a coal-heaver's cap).

"Our provisions, being sufficient for twenty-eight days, made the boats rather deep; and I soon found the cutter pulled very heavily, and was obliged to take her in tow. All our party slept in the cutter the first night, the whale-boat being made fast astern. Towards midnight it blew fresh, and as the boats were anchored near the wash of the beach, they rolled a good deal; and soon afterwards, feeling the whale-boat hanging heavily on her rope, I hauled her up alongside, and found she was almost swamped; in a few minutes she

© The Complete Work of Charles Darwin Online

must have sunk with all her heavy cargo, to us invaluable. The plug had worked out by her rolling:—I seldom left her afloat at night after this warning. Having saved the boat, made me think less of all our things being wetted, and of some of the instruments being almost spoiled.

"At daylight, on the 8th, we pulled along shore, with the wind against us, and reached Point York before the tide made strongly; but that place we could not pass; and sooner than give up an inch of ground, let go our grapnels, in the middle of a race of tide, that tumbled in over both gunwales, and ran past us at the rate of five knots. At one P.M. it slackened, and we pulled on into Bachelor River, very glad to get so good a place to dry our clothes, and put the boats to rights. Three deserted wigwams gave us shelter; and while some made fires, others went to collect shell-fish, or shoot birds. Though the season was so far advanced, some shrubs were in flower, particularly one, which is very like a jessamine, and has a sweet smell. Cranberries and berberis-berries were plentiful: I should have liked to pass some days at this place, it was so very pretty; the whole shore was like a shrubbery. I cannot account for the exaggerated accounts of the Fuegian coasts given by some voyagers: it is true that the peaks of the mountains are covered with snow, and those sides exposed to the prevailing west winds are barren, and rugged; but every sheltered spot is covered with vegetation, and large trees seem to grow almost upon the bare rock. I was strongly reminded of some of the Greek islands in winter, when they also have a share of snow on their mountains.

May 9th. The tide carried our boats rapidly up the Jerome Channel, which, though narrow, is quite free from danger. The west shore is very high, and steep, and well covered with wood; the eastern is lower, and less woody.

"Having passed this channel, we entered the mysterious Indian Sound, with all that anxiety one feels about a place, of which nothing is known, and much is imagined. I hoped to find a large river; and the strong tide setting up the channel convinced me that there was a body of water inland, but of what nature

© The Complete Work of Charles Darwin Online

remained to be discovered. At dusk we put into a small creek, and secured the boats, hauling up the whale-boat on the sand. When too late to remove, we found the place of our bivouac so wet and swampy, that nearly two hours were occupied in trying to light a fire. Supper and merry songs were succeeded by heavy rain, which continued throughout that night and the next day without intermission.

"10th. Continual hard rain prevented our moving: the whale-boat's men were thoroughly drenched in their tent during the night; but made a better one in the morning. The cutter, having a tarpaulin cover, gave her crew a better lodging; and although a small and loaded boat, only twenty-four feet long, could not be expected to allow much room to a dozen sleepers, during such weather, with the help of our blanket bags,(*m*) we did very well.

"11th. During this night, also, it rained very hard. Early the next morning, however, it cleared a little, and we got under-weigh. When in the fair-way our hopes were much excited; for beyond a high island, like a sugar-loaf, appeared an opening without land. I tasted the water repeatedly, fancying it less salt, and that we were approaching a river.

"Less salt it might have been, from the number of water-falls dashing down the mountains on each side of the channel, which is here about two miles wide, with a current, or rather stream of tide, running at the rate of two knots an hour.

"At noon, we reached the Sugar Loaf: it cost a struggle to get to the top with the instruments; but the view repaid me. For three points of the compass towards the north-east, I could see no land, except two islands; and the farthest extreme to the eastward, appeared to me distant, at least, thirty miles. No mountains or high land could be seen to the north or east; the country seemed there to change its character, and become

(*m*) Each officer and man, when detached from the Beagle during a night, carried a blanket, or large poncho (sewed up, and with a drawing-string, like a large bag), in which they slept, and found much comfort and warmth.—R. F.

© The Complete Work of Charles Darwin Online

lower and less wooded. This was, indeed, an animating view: I stood considering what might be the boundary of this water, till I recollected, that the longer I thought about it, the longer I should be finding it out; so we pushed on with the boats, of course taking the necessary bearings and angles, until we reached the 'Point of Islets' in 'Otway Water.'

"On the 12th, our oars were going early.

"The two islands, 'Englefield' and 'Vivian,' were the only land upon the horizon for six points of the compass. The southern coast trended away nearly east from Cape Charles, preserving the high mountainous character of the Fuegian shores, while that to the northward was low, though as yet well wooded.

"I was nearly tempted to try whether Fanny Bay led towards the Gulf of Xaultegua; but fortunately did not, as I should have regretted the time so employed.

"Point Hamond is thickly-wooded with evergreens, similar to those of the Strait; and with a species of pine, about thirty or forty feet in height.

"To the S.E. three remarkable promontories stand out in bold relief from the Fuegian shore; but beyond them the land sinks into the tame flatness of Patagonia.

"The water on the west shore is not deep; from ten to thirty fathoms at a quarter of a mile off shore, but getting more shallow advancing northward. There is anchorage for a vessel after passing Indian Channel, the whole way along; and as the prevailing winds are off shore, it would generally be safe. In Indian Channel I only know of two anchorages, Cutter Bay and Bending Cove.

"Such constant rain fell during this evening, that it was not until after much trouble that we at last made fires. Carrying dry fuel in the boats we found indispensable, and I would recommend any person who passes a night on shore in this wet climate, with a boat, to carry a sheet of copper, or a piece of flat iron, in preference to any boat-stove, as a fire can be lighted upon it much more easily, and it does not take much stowage: the great difficulty about fires here is getting fuel to burn when the ground is wet, or when snow lies on it.

© The Complete Work of Charles Darwin Online

"13th. Raining so steadily all day, that it was useless to proceed: I could neither see my way, nor notice any thing but wind and rain.

"14th. So mild was the weather, that I bathed this morning, and did not find the water colder than I have felt it in autumn on the English coast; its temperature, at a foot below the surface, averaged 42°; that of the air was 39°. From this place, Point Hamond, I saw seven points of the compass clear of land, my eye being twenty feet above the level of the sea. The water was quite salt, therefore we were certain of being in an unexpected inland sea, or large lagoon. Four miles from Point Hamond lie Englefield and Vivian Islands, rather low, but well wooded with evergreens. They are the only islands of any note in the Otway Water. The farthest point I could discern I called Cape Marvel, for much I wondered at the hitherto unsuspected extent of this inlet.

"At noon we were off the north end of Englefield Island. Mr. Stokes and I observed the sun's meridian altitude satisfactorily from the boats, so smooth was the water. This quiet day was too fine, for it was hard work pulling from nine till five, without any help from sails. Towards evening a breeze sprung up in our favour, and with its assistance we ran along the land about ten miles. Taking advantage of the moonlight, I did not look out for a resting-place till past seven o'clock, when we had a great deal of trouble in landing; the coast having quite changed its character; and instead of deep water with a rocky shore, we found a flat shingly beach and shoal water, with very large stones scattered between high and low water marks, so numerously as to make it dangerous for a boat, especially at night. Upon landing, we found the ground quite changed into a fine light soil, with stunted bushes and trees; and so dry was the wood, that a fire was easily kindled, but not a drop of water could be got any where to cook our supper. A considerable rise and fall of tide was observed, much greater than near Indian Channel.

"15th. No breakfast this morning,' for want of water—a decided proof of the change of climate and country. North of

© The Complete Work of Charles Darwin Online

us the sky was clear; but to the southward, over the Strait, hung thick clouds. The trees were not evergreen, and at this time their leaves were withered and falling.

"While pulling along shore, and passing a low projecting point, we saw the smoke of three fires, and approaching nearer, observed four canoes lying on the beach, near several wigwams. Their owners soon appeared, running along the shore, hallooing and jumping. The first who came near us reminded me of an old-fashioned sign of the 'Red Lion,' for he was painted red all over, and looked more like a wild beast than a human being; another was covered with a bluish mixture; a third was quite black. Several had the lower half of the face blacked, and the oldest men and women were painted entirely black. There were about eight men, six or eight boys, and perhaps a dozen women and girls. Some had a skin over their shoulders, but others had no covering at all, except paint; they seemed apprehensive, and hid several skins and other things in the wood, as soon as they saw us approaching.

"When they found we were peaceably disposed, and had tobacco and knives, they were eager to barter with us. How they have learned the use of tobacco is curious, but they are fond of it to excess. Guanaco, as well as seal and otter skins, are in their possession; therefore they probably barter with the Patagonians. They have also the skins and horns of a deer, which, as I understood them, inhabits their country.*(n)* They catch small animals with snares, made of whalebone, just like hare-snares. This tribe was very rich in Fuegian wealth, such as skins, arrows, lances, &c. They appeared to be of a race similar, but superior, to the Fuegians, being stronger, stouter, more lively, and more active. I persuaded one of their boys to have his face washed, and found his natural complexion was scarcely darker than that of a European. Their language sounds like that of the Fuegians, and the huts and weapons are precisely similar to their's. We asked them for water, and they pointed to a place about a mile further, mak-

(n) Like a roebuck; supposed to be the 'Huemul' mentioned by Molina.—R. F.

© The Complete Work of Charles Darwin Online

ing signs to us that we must dig in the earth for it. We went there, and near a green-looking spot some good water was found. We then landed, and enjoyed our breakfast at one o'clock, being not a little thirsty.

"The natives were still with us; they seemed inquisitive and cunning; and shewed great surprise at a sextant and artificial horizon, by which they sat down, attentively watching what was done. I put my watch to their ears; they were much astonished, and each came in his turn to hear it tick. I pointed to the watch and then to the sky; they shook their heads and suddenly looked so grave, that from their manner in this instance, and from what I could understand by their signs, I felt certain they had an idea of a Superior Being, although they have nothing like an image, and did not appear to us to have any form of worship. We could learn scarcely any words of their language, because of their trick of repeating whatever we said.

"They saw how we lighted a fire, by means of a tinder-box, and took an opportunity to tread it out of sight. Our loss was not known until leaving the spot, when that material necessary was missed. It was evident they had stolen it; and while I was meditating a reprisal, one of our men by chance trod upon the missing box, which was artfully hid under the sand. After this discovery, they seemed rather inclined for a skirmish, all having clubs, while our men appeared to have no weapons. However, we parted without a quarrel.

"The features of these people differed from those of the Fuegians whom I had previously seen, in being better formed, and having a less artful expression.

"We pulled hence along a low shore until evening, when distant land began to show itself, stretching to the northward and eastward, and bounding this supposed inland sea. At dusk we discovered an opening, which appeared to be either a river or a channel, and I steered for its north bank, securing the boats for the night in a place we named Donkin Cove, as a mark of respect to the preserver of meat, to whom we had been so often thankful. A little of this meat, mixed with wild fowl, and some wild celery, makes a wholesome and

© The Complete Work of Charles Darwin Online

agreeable mess. On boat service, meat preserved in tin is particularly useful, being already cooked, and therefore fit for dinner without the aid of fire.

" We were surprised at the mildness of the weather. Indeed, the change of climate was as pleasant as it was sudden and unexpected.

" 16th. At daylight, we found ourselves in the entrance of what was thought a river. Under this impression, I hoped to penetrate into the interior of the country, and meet some new tribes of Patagonians. As soon as we could get underweigh, we pulled and sailed along a winding channel, on one side of which was a pleasant-looking, woody country, extending towards Tierra del Fuego; and on the other, a low, barren district, like Eastern Patagonia. The banks on both shores were from five to forty feet high, sloping, and covered with grass.

" The current was in our favour, which with the saltness of the water, inclined me to think it a channel, and not the mouth of a river. In this opinion I was confirmed in a short time, by seeing surf breaking against some land beyond an opening, which showed that we were approaching a large body of water. Soon after, we reached the extreme west point of this small channel; and, to our surprise, saw an expanse, at least thirty miles across from east to west, and twenty from north to south. I thought it more at first, but probably was deceived. West and south of it I observed high snow-covered mountains; and the summit of one was remarkable, being like a castle with a high tower. Northward, the land was low; excepting a few ranges of down-like hills with large plains between them.

" It happened to be a very clear day, and all that could be seen at any time was visible. In two places there seemed to me to be openings to the westward; in the southernmost I could see no land at all; the other was backed by distant mountains, but still had the appearance of an opening. After this I went to the top of a hill near me, about three hundred feet high, to gain a better view, yet so small an elevation made but little difference, and I rather thought the opposite coast farther off than I had at first supposed.

© The Complete Work of Charles Darwin Online

"Having sent the cutter back a short distance, to make a fire and land our things, I crossed the channel to a fine level plain, and measured a base line. In crossing, I found a most rapid tide, at least five or six knots at neap tides, and to pull against it was out of the question. It caused a considerable swell and race at the entrance, which is not a quarter of a mile wide, though it averages twelve fathoms in depth. On the plain was growing thick grass, like that in the vicinity of the river Plata. So rich and good was the grass and trefoil, that I saved a few seeds, hoping some day to see their produce in England. No tree was seen; the soil seemed dry, rich, and light. Skunks, and a small kind of cavy, had burrowed every where, which proves the climate to be of a different nature from that of the Strait. The bones and traces of guanacoes were numerous, and some horses' tracks were found; as also part of a dead guanaco, which appeared to have been a prey to wild beasts. Water was not so plentiful as to the southward; but quite sufficient for all useful purposes, many small brooks being noticed, besides springs in the sides of the low hills. We shot a swan (*o*) and some coots; the swans were so fat, or so tame, that they would not rise from the water.

"17th. While on Whitestone Plain, a very heavy squall of wind and hail passed over from the S.W., so cuttingly cold, that it showed me one reason why these plains, swept by every wind from S.S.W. to N., are destitute of trees.

"After dark, we returned to the cutter and partook of a large mess, made of the swan we had shot, the coots, some limpets, and preserved meat. The shortness of the days was becoming very inconvenient; from eight to four were the only hours of daylight; but some of the nights were so fine, that I got many sets of observations of the moon and stars.

(*o*) Black-necked swan, noticed elsewhere by Captain King.—R.F.

CHAPTER XIV.

Place for a Settlement—Frost—Boats in danger—Narrow escape—Sudden change—Beagle Hills—Fuegian painting—Tides—Medicine—Water warmer than the air—Jerome Channel—Mr. Stokes returns to the Beagle—Cape Quod—Snowy Sound—Whale Sound—Choiseul Bay—Return to the Beagle—Adelaide returns—Plan of operations—Difficulties removed—Preparations—Wear and tear of clothing—Ascend the Mountain de la Cruz—Sail from Port Gallant—Tides—Borja Bay—Cape Quod—Gulf of Xaultegua—Frost and snow—Meet Adelaide—Part—Enter Pacific—Arrive at Chiloe.

"18th of May. VERY cold, raining heavily, and blowing strong from S.W. The tide turned this day (full moon), and set to the westward at 1.15. I only say 'turned,' because I could not distinguish the ebb from the flood, so little rise and fall was there. No sooner had the tide ceased to run in one direction, than it began to run as strongly in the other, for about six hours. For the last four nights I noticed, that soon after sunset the sky was suddenly overcast, a trifling shower fell, and afterwards the heavens became beautifully clear. The climate must be much like that of the east coast of Patagonia, as shrubs grow here like those I saw at Port Desire. While walking, the leaves and dry sticks crackled under foot, which is very different from what one observes about the Strait of Magalhaens, where everything is wet and spungy. I was inclined to think this place suitable for a settlement. There is water, wood, and good soil, fit for planting, besides pasture land; the climate is not bad; and probably the Patagonian Indians might be induced to trade in guanaco meat, as they now do at Gregory Bay; while any of their hostile incursions would be prevented by the channel.

"19th. Two natives, a man and a boy, came to our boats this morning; they seemed to have neither curiosity, nor fear, nor even a relish for tobacco. They took a piece of tinder, picked up a stone, and went away to some wigwams, at a little distance, where we soon afterwards saw a fire burning.

© The Complete Work of Charles Darwin Online

"During this night and the preceding it froze sharply; but the sky was so clear, that I observed many sets of distances, on each side the moon.

"20th. We went eastward through the little channel. Every thing was frozen; and the boat's sails were useless until thawed. We left Donkin Cove directly after noon, and with a fresh and fair wind, steered towards Pecket Harbour. I may as well mention here my reasons for taking this course, instead of going farther westward.

"Considering our very limited time, and provisions, I wished to do first what was most useful; and to find a new passage, seemed to me the primary object. Having surveyed the narrow winding channel, and proved its navigability for vessels of any class; I thought it desirable to ascertain next the nature of the separation between Otway Water and the Strait of Magalhaens, between Laredo Bay and Pecket Harbour.

"A western passage might be sought by the Adelaide schooner, or by myself, at a future time. If we tried to cross the Skyring Water, our success would be very doubtful, for during the whole time we had been in the channel, the wind blew strong from S.W., raising so much sea, that it was with great difficulty I could sound outside the western entrance, even in a whale-boat.

"A fine breeze carried us rapidly eastward; but it freshened too fast, reef after reef was taken in, until at two o'clock we were obliged to lower the sail, and pull to windward; for as far as we could see, the shore continued unbroken, flat, and low, with a high surf breaking on it. To have attempted to land, would have been folly; and as the wind continued to increase, and a current setting to windward caused a very short awkward sea, I sent Mr. Stokes off in the cutter, under his small close-reefed sails, to hang to windward as long as he could carry sail, while I kept the whale-boat head to wind. At three o'clock, we were embayed, and about a mile from the shore. My boat was deeply laden, and as our clothes and bags got soaked, pulled more heavily. We threw a bag of fuel overboard, but kept everything else to the last. At sunset the sea

© The Complete Work of Charles Darwin Online

was higher, and the wind as strong as ever. I saw the cutter a little before, about three miles from us, standing to the eastward on a wind; but whether she would clear the shore I could not make out.

"After dark, finding we could not well be worse off as to risk, I bore up, and pulled with the sea rather abaft the beam, twisting the boat 'end on' to each wave as it came, hoping to get into smoother water to the westward. Night, and having hung on our oars five hours, made me think of beaching the boat to save the men; for in a sea so short and breaking, it was not likely she would live much longer. At any time in the afternoon, momentary neglect, allowing a wave to take her improperly, would have swamped us; and after dark it was worse. Shortly after bearing up, a heavy sea broke over my back, and half filled the boat: we were baling away, expecting its successor, and had little thoughts of the boat living, when—quite suddenly—the sea fell, and soon after the wind became moderate. So extraordinary was the change, that the men, by one impulse, lay on their oars, and looked about to see what had happened. Probably we had passed the place where a tide was setting against the wind. I immediately put the boat's head towards the cove we left in the morning, and with thankful gladness the men pulled fast ahead. In ten minutes the sea was smooth, and the breeze so moderate, as not to impede our progress. Our only anxiety was then about the cutter; for we could not tell how she had weathered the gale. I was sure she would have prospered if kept by the wind; but some accident, or change of purpose, was to be feared.

"About an hour after midnight, we landed in safety at Donkin Cove; so tired, and numbed by the cold, for it was freezing sharply, that we could hardly get out of the boat. The embers of our morning fire were still burning; so we put on some wood, and lay down round them. No men could have behaved better than that boat's crew: not a word was uttered by one of them; nor did an oar flag at any time, although they acknowledged, after landing, that they never expected to see the shore again. We resolved to start early to look for

© The Complete Work of Charles Darwin Online

the cutter, and fell asleep: but before daylight I was roused by some one, and to my joy, saw Mr. Stokes standing by me. He had just arrived with the cutter, having kept his wind till the sea fell; and since that time had been pulling towards this spot: with what thankful feelings all hands lay down to sleep may be easily supposed.

"21st. This morning I believe no one waked before ten o'clock. Drying our clothes, and putting the boats to rights, occupied most of the day. Our time was now so short, besides having almost expended our provisions, that I gave up the idea of crossing the Otway Water, and decided to return nearly the way we came, after taking a view from the higher ground.

"22d. A sharp frost, during the past night and this day, hardened the ground, and with four of my boat's crew, I walked to the Beagle Hills. Our way led through a scattered wood, the only one seen on the north side of the channel, and in which most of the trees appeared to have been burned. We gained the summit of the heights soon after noon, and were amply rewarded by an extensive view.

"Although not more than eight hundred feet above the sea, I could discern the Gregory Hills (so plainly as to make out their yellowish brown colour); Cape Bartholomew, Nassau Island; Cape Monmouth; the high peaks over Cape Froward; the range of mountains thence to the Jerome Channel, and from the Jerome, westward to all those about Cape Phillip, and Cape Parker; and the whole extent of the Otway and Skyring Waters; the latter heing bounded to the N.W. by down-like hills, about six or eight hundred feet high. North of the Beagle Hills, a range of similar downs extended; and to the east was a succession of lagoons, completely intersecting the flat country towards Pecket Harbour.

"We left a memorial, cut in lead, at the foot of a post sunk in the ground; but the air was so cold, that the men, who wished to add their names, were unable to mark them on the lead. It was eight o'clock before we regained our bivouac, much fatigued by the day's work.

"23d. I went into a wigwam, where there was a woman

© The Complete Work of Charles Darwin Online

and two children. A rough likeness made of her did not please at all, because it was white: she took out her red paint, and put some on her own cheeks, as drawn on the paper, and then was quite satisfied, sitting as still as a mouse, while I made another sketch. In return for the compliment paid to her countenance, she daubed my face, as well as my coxswain's, with the same red mixture.

"24th. A sharp frost during the night. We left Donkin Cove, as soon as I had taken observations for the chronometers. A fine breeze in our favour carried us rapidly along, and at dusk we were near Englefield Island. The last few nights have been so clear, that two or three of the men, and myself, have slept in the open air without any other covering than our blanket-bags, and clothes. My cloak has been frozen hard over me every morning; yet I never slept more soundly, nor was in better health.

"We had a good view of Mount Misery this day. It is about 3,000 feet in height; twice as high as the surrounding mountains, and quite bare, even of snow, on the summit. The night tides here rise more than those of the day at this season: the times of high water do not differ much on the opposite shores. About an hour after dusk we reached Englefield Island, having made a capital run, with a fresh and fair wind. Creeping in the dark, along shore, we at last found shelter for the boats, and formed a snug place amongst the bushes for our tent and fires. One of my boat's crew was ill this day; the first man that had been seriously so, although several had been slightly affected by the muscles and limpets; and one had fits. A draught of hot port wine and Winter's-bark, certainly seemed to be an efficient medicine for the slighter complaints.

"25th. Blowing strong from the westward, with much rain. I forced a way, with much difficulty, among thick bushes, to the top of the island, and when I got there found, to my mortification, that by no possible contrivance could I see round, for I was encompassed by lofty trees of nearly equal height.

"26th. We crossed over to the east shore: the temperature of

© The Complete Work of Charles Darwin Online

the water, between Englefield Island and the nearest land, one foot beneath the surface, was 42°; the air at the same time being 38°. While the sea water preserves this temperature, it must tend much to moderate the severity of cold, one would naturally expect in this latitude, near so many snow-covered mountains. We arrived at the Point of Islets, soon after sunset, on the 27th.

"28th. Almost every night I observed that the wind subsided soon after sunset, the clouds passed away, and the first part of the night was very fine; but that, towards morning, wind and clouds generally succeeded. From Point of Islets, we sailed southward; and were again close to the mountains: from whose appearance at this spot, no one would suppose that any passage lay between them; so intricate and winding are the channels.

"I was sorry to leave the open country, behind me; but time pressed; and there was yet much to do with our loaded boats, which could not make very great progress in the short daylight afforded by this season. After passing Bennett Island the land became rugged, and mountainous on each side, covered, however, with wood and vegetation wherever it could grow; and we were again in the Magalhaenic regions.

"This day I examined as much of the west side of the channel, as time would allow, and reached Corona Creek at about eight o'clock. What I called the Sugar Loaf must be the Corona Island of Cordova's officers; for at some distance it looks somewhat like a crown. It is singular that they inserted (in their chart) an island near their Corona, which cannot be distinguished from the main-land, until one is within two miles of it; and as at that distance the Otway Water is plainly visible, must they not have seen the opening? Tired of their job, did they return without prosecuting the discovery, or was the weather too thick to see far? Their description of the Jerome Channel, leads to the supposition of a continual current setting through in one direction, instead of a regular ebb and flood; and the surest sign of a passage between places in Tierra del Fuego, is a current or stream.

© The Complete Work of Charles Darwin Online

Many large inlets and sounds look like channels; but on going a short distance into them, you find dead water.

"29th. We passed through Jerome Channel, and reached the bar, off Bachelor River, after dark; but the cutter got aground, and gave us some trouble to float her again. Afterwards one of the men was landed on the bar, and by his walking in the deepest water, and the whale-boat going next, we got into the little river at nine o'clock, not sorry to be in safety. There are tide races between the Jerome Channel, and Bachelor River, which are sometimes dangerous; but as the breeze was moderate, we passed them without difficulty.

"May 30th. Employed chiefly in stowing the cutter afresh, packing specimens, and preparing my boat to take what remained of our provisions. At two next morning, when the tide served, Mr. Stokes set out to return to the Beagle: and having both wind and tide in his favour arrived early at Port Gallant.

"The wind increased after daylight, and blew strong, with squalls. I waited a short time, but, having no hopes of its improving, left the river. My boat was much lumbered, having the chronometer-box, and more instruments than before; yet she pulled pretty well, even against the heavy squalls. After landing at the west side of the entrance to the Jerome Channel, to take bearings and angles, we pulled along shore to the westward, and at dark hauled the boat up in a small sheltered corner. After she was secured, we employed ourselves looking for limpets and muscles for supper, by the light of a lanthorn, as we had good appetites, and our provisions were scanty.

"June 1st. We pulled along shore against a strong and squally wind, and before evening nearly reached Cape Quod; but not being able to pass it, stopped in a cove on the east side.

"2d. At the oars again, early, having a fine clear morning, with the tide rather in our favour. By eleven, Cape Quod was astern of us; and a long view of the Strait presented itself. This part is very rugged and barren, and looks triste, indeed; still wherever a tree can take root it tries to grow. This night was passed on a small island at the west point of Snowy Sound.

© The Complete Work of Charles Darwin Online

"3d. We began at daylight, and worked, from point to point, up the sound, thinking it a channel. Two good anchorages were found on the west side, but none on the east, except a trifling cove between the little island and the land, which would only shelter a small vessel. The night was passed on an island five miles within the sound. It rained hard for an hour before we landed, and all the night afterwards. Our rest was not the most satisfactory, as the ground was wet and swampy.

"Two of the boat's crew got into a hole under a tree thinking they should be warm; but in the middle of the night they complained of not being able to get up, and of being half frozen.

"4th. The rain ceased at times this morning, but the wind continued. After going to the top of an island, we pulled and sailed onwards, not having a doubt of soon getting into Whale Sound. At noon, the passage appeared suspiciously small; yet I could not doubt the fine large opening laid down in our old charts, and proceeded until the shore made a sudden turn, when, to my astonishment, I saw a high black cliff stopping farther progress. After a hearty growl, we turned back, and landed to look for a sleeping place. Not a spot could we find that was not wet like a sponge; but night was closing in, and obliged us to stay where we were. It was bitterly cold, all of us were wet through, the ground was a mere swamp, we could not get a fire to burn, and the frost was sharp.

"After daylight on the 5th, we succeeded in making a large fire, and spent two hours drying our clothes and warming ourselves. In order to lighten the boat, no one carried more clothes, since leaving the cutter, than those he wore, except one shirt. We hastened back towards Charles Island, passing some very remarkable glaciers, one of which looked like an enormous frozen river, covering the whole side of a mountain. Many portions were of a transparent blue colour, which, contrasted with the snowy whiteness of others, and with the dark shadows of bare rocky places, had a very striking effect. At noon, we passed out of the sound, and steered for Charles Island, with a

© The Complete Work of Charles Darwin Online

light breeze in our favour. Seeing a canoe coming across, we made towards it, and found a wretched-looking family, consisting of a man, his wife, and three children, with some small dogs, seemingly more miserable than their owners. A few wooden-headed spears were all the property they possessed, excepting the worn-out skins thrown over their shoulders. The man sold me a little dog for a bit of tobacco, and afterwards wanted to have him again, because his wife would not consent to the bargain. However, I kept the dog, and they began to abuse us in right earnest, the woman alternately crying and scolding, and the man apparently calling on the wind and water to destroy us. His gestures were very expressive and animated. I was surprised to see so much feeling for a wretched little half-starved puppy, and made them happy by returning him, without asking for the tobacco.

"El Morrion *(p)* (the helmet) was certainly an excellent name for the promontory we passed this day. It reminded me of the 'Castle of Otranto.'

"We reached a small islet, at the west point of Charles Bay, and passed a good night on the top of a bare rock. So often had we slept in wet places, that a dry, though stony berth, was thought very comfortable. The boat's two sails, oars, and boat-hook, formed our tent.

"6th. We left the islet as soon after day-light as we could get breakfast, and take the required bearings and angles; went into Spot Cove, thence crossed to Charles Island, and to the narrow opening between it and the nearest land. Ulloa's memory can no longer be preserved here in an island, though it may in a peninsula. This small channel is narrow, and has a strong tide setting through it. There is anchorage all the way, though generally over a rocky bottom, and it is navigable for small vessels: its average width is a quarter of a mile, and its length about three miles. For a boat going westward through the Strait, it is far preferable to the regular channel. Two old Fuegians were living here, a man and a woman.

"When in Whale Sound, appearances were such that had I

(p) Noticed previously by Captain Stokes.—R. F.

© The Complete Work of Charles Darwin Online

not been to the bottom of Snowy Sound, I should have thought they joined. After going far enough, to see quite to the end, we returned, hauled the boat on a shingle beach, and secured her for the time. When a bit of shingle beach could be found, it was a prize; for on it we could always make a good tent, and have a dry bed, besides hauling the boat up easily. There is a greater rise and fall of tide here, than at the other side of Charles Island, being not less than seven or eight feet, at springs. During the night, a dog stole a small piece of pork, which we had reserved for our last dinner; and, until his track was discovered, there was no little distrust among our party.

"Whale Sound is a large and deep inlet, ending in a valley between mountains. On the south side, a vessel may anchor in one place, at the west side of Last Harbour; but there, though the harbour appears large, the anchorage is small, and close to the shore. We pulled and sailed along the south shore, landing occasionally to take bearings, until we reached Choiseul Bay, and in a cove, at its west side, we passed the night. This is a place no ship need approach: it is a large, deceiving bay, full of islets and patches of kelp, under which, probably, there are rocks, and between the islets the water is deep and unfit for anchorage. The temperature of the sea this day, in the middle of the sound, one foot below the surface, was 45°.

"8th. As it rained heavily, we remained under such shelter as we could obtain; and prepared for our return to the Beagle, by making use of the only razor we had. When the rain ceased, we left the cove and sailed across to Port Gallant, with a fresh breeze. The smoke of natives' fires was seen near the entrance of the Barbara Channel; and on Prince Island, where we stopped a few minutes, the first man seen had on an old pair of sailor's trowsers, which he had obtained from the Beagle tied round his legs in six places. The wigwam these people were living in was not half covered: both wind and rain passed through it. How they bear the cold is surprising, being without clothes: one minute sitting close to the fire, and the next perhaps up to the waist in water, getting muscles or sea-eggs. The women dive for sea-eggs, even in the middle of winter;

© The Complete Work of Charles Darwin Online

but the water is never very cold (42° to 44°).(q) In the afternoon we saw the Beagle's mast-heads, and soon afterwards arrived on board, and enjoyed the happiness of finding all hands well, and every thing ready for farther progress. Lieutenant Kempe had turned the few hours of light, each day afforded, to the best acccount. Those who have had the care of ships in remote places, will know my feelings at finding all as it should be, after a long absence, in a country little known. Not a man had been ill; and the weather had been very tolerable compared with what was expected. There was less snow on the mountains than when I left Port Gallant early in May. One thing only disappointed me,—the Adelaide had not arrived. It was past the time appointed for her, but she might have found much more to do than was expected, or might have been obliged to return by the Magdalen, instead of coming through the Barbara Channel.

"During my absence, two sealing vessels had been at Port Gallant, on their way through the Strait. From one (an American), which arrived on the 7th of May from Staten Land, information was received that the Adventure had not been there. The Chanticleer had remained some time, but had sailed for the Cape of Good Hope. The master of the American had a brother staying with a boat's crew in Staten Land, during the whole of April, who would probably have seen the Adventure, had she called. The other was Mr. Cutler's vessel, the Uxor, bound to the United States; he had been through a channel which leads from the Gulf of Trinidad to Cape Tamar, and spoke well of it; but could give no drawing, nor precise information; having passed through rapidly.

"Lieutenant Kempe had been at the summit of the Mountain de la Cruz, and left a memorial. No rare animals had been seen, nor any new birds. Small fish were still caught with hook and line, but very few with the seine.

"I never was fully aware of the comfort of a bed until this

(q) At the western entrance of the Strait the water is said to be generally a few degrees warmer than at the eastern.—R. F.

© The Complete Work of Charles Darwin Online

night. Not even a frost-bitten foot could prevent me from sleeping soundly for the first time during many nights.

"9th. At one o'clock this day, I heard an exclamation of 'The schooner!' and soon saw her standing across from the Barbara Channel with a fair wind. Before she anchored in Port Gallant, I went on board, and, to my joy, found Lieutenants Skyring and Graves, and all their companions well, having thoroughly completed the work they had to perform, without loss, or even an accident. The difficulty of their task was increased by very bad weather; but they succeeded in tracing and surveying the Magdalen Channel to its junction with the sea, and thence returned by the Barbara Channel to Port Gallant; carrying on a regular chain of triangles, and connecting their work with points previously fixed in the Strait of Magalhaens. A multitude of small islands, and much bad weather, detained them longer than was expected.

"While Lieutenants Skyring and Graves, assisted by Mr. Kirke, were employed surveying, Mr. Bynoe collected geological and other specimens.*

"11th. We had nearly reached the shortest day; the sun did not rise above the hills until past eleven; it disappeared again before two (the land being less high towards the N.W.), and even in those three hours was seldom visible.

"12th. Finding that Lieutenant Skyring agreed with me in thinking that the channel from Cape Tamar to the Gulf of Trinidad might be surveyed by the Adelaide, in her way to San Carlos de Chiloe, I resolved to send him and Lieutenant Graves on that service, hoping that it would lead to the discovery of a passage into the Skyring Water, and give vessels another way of getting into or out of the Strait, should thick weather or adverse winds oppose them in the usual channel.

"In making this arrangement there was much to be considered. As I had received no orders from Captain King to employ the Adelaide in surveying, after her return from the Magdalen Channel; and as I had been desired to repair, with her, to San Carlos, in Chiloe, during which voyage Lieutenant

* Geol. Soc. Museum, Nos. 176 to 205, and Zool. Mus.

© The Complete Work of Charles Darwin Online

Skyring was to be on board his own vessel, the Beagle, it would be incurring considerable responsibility, to order a new piece of service to be undertaken, which might not be successful; and would require officers, men, a boat, provisions, and stores from the Beagle.

"I did not doubt that the measure would be approved by Captain King, because he had discussed the feasibility of such a plan with me, and had expressed a wish that it should be tried; but as I had not received any orders, I could not decide without anxiety.

"Another, though a minor difficulty, arose from sending Lieutenant Skyring in command of the Adelaide, over Lieutenant Graves, her proper commander, who had expected to take her to Chiloé, and was quite competent to undertake this or any other service in which she might be employed. Both these officers excelled in their professional duties; but Skyring had been on the western coasts of Patagonia before, and was the senior.

"Much to the credit of Lieutenant Graves, he removed one weight, by volunteering to go any where I thought proper to direct, either alone or with Lieutenant Skyring, and the necessary orders were forthwith given. (See Appendix). Mr. Kirke was again to form one of their party, as well as Mr. Bynoe, who exchanged temporarily with Mr. Park. The Beagle's whale-boat was also lent, with five able seamen to man her; and good care was taken that nothing the ship could give should be wanting in their outfit for a service which, at that time of year, must be severe and tedious.

"Anchors and cables, hawsers and kedges, were abundantly supplied, because in warping into unknown places, or anchoring hastily, many an anchor is unavoidably broken or lost.

"The boat's crew, who had been away with the Adelaide, and were going in her again, were supplied with extra clothing at the expense of Government, the wear and tear of their clothes having been far beyond what they could be expected to make good out of their pay.

© The Complete Work of Charles Darwin Online

"As an instance, I may mention, that a careful north countryman carried with him, when he left the Beagle, two new pair of shoes (besides those on his feet), and three pair of new stockings: but brought back only a ragged pair of stockings and the remains of one shoe. The others had been fairly worn out, or lost, in scrambling over rocks and ascending mountains.

"One height ascended by Lieutenant Skyring was so steep, that the men were obliged to pass the instruments from one to another, at a great risk of their own lives; and when they reached the summit, the wind was so strong, that a heavy theodolite and stand, firmly placed, was blown over; and even a Kater's compass could scarcely be used.

"With good clothing and provisions, weather may be almost defied, and work may be done at the less unfavourable times; but without them, ill-humour and ill-health must inevitably appear in such a climate as this.

"14th, Sunday. I had the satisfaction of keeping this day in a proper manner, for the first time since we entered the Strait. So much had depended upon employing every minute of our time while the weather would allow, that there had been little distinction of days.

"17th. The morning being fine, with not much wind, though a sharp frost, I left the ship with Mr. Murray and four men, and landed in Fortescue Bay, intending to ascend the mountain 'De la Cruz,' if the snow and ice did not prevent me.

"On the beach, close to the water, I suspended the mountain barometer, and let it remain half an hour before we began the ascent, which, from the snow lying so deep, was troublesome; for at one step a hard rock received one's foot, and at the next, perhaps, a deep hole amongst broken trees. Sometimes we tumbled head foremost into soft snow, slightly covering rotten mossy boughs and swampy ground; and at others, slipped between the concealed trunks of trees, which, though much decayed, were hard enough to cause many a bruise. Each movement of our arms or legs shook down a shower of snow from the trees, among which we were forcing our way.

"At noon we gained the part that is clear of wood, but

© The Complete Work of Charles Darwin Online

so very steep and slippery was the summit, that we were obliged to go on our hands and knees, forcing them as deeply into the snow as possible, to avoid sliding down again. The highest point is not visible from Port Gallant.

"While I took angles with the theodolite, the seamen made a fire. It was well we carried some fuel and a tinder-box, with a sheet of copper, upon which to kindle it; for without a fire we should have been quite numbed. Standing in one place for two hours, after being much warmed by exertion, made us more sensible of the cold. The highest spot is but a few yards wide, and by barometrical measurement is 2,280 feet above the sea.* The height is, in truth, small; but as the mountain is so steep, and rises so abruptly from the sea, it appears considerable.

"When we had finished our observations with the barometer and theodolite, we deposited a Memorial, containing a list of the officers and crews of the Beagle and Adelaide—an account of the object of their voyage, how far it had succeeded, and where we were going—and a collection of coins, well-soldered up in a tin case—upon the bare rock; and made a great pile of stones over it.

"Having again examined the barometer, we began to descend; for the sun disappearing behind the distant mountains, warned us that it was time to return. We had enjoyed a magnificent view on all sides, and were reluctant to leave our station. In descending, we made rapid progress at first, sliding many yards together down the soft snow; but, by the time we reached the woody part, it was getting dark, and having foolishly tried to return by a straight line, instead of going round, we found steep cliffs, and ravines covered with rotten trees, which perplexed us exceedingly. Darkness, and the deep snow, much increased our dilemma; yet we could not resist laughing heartily at the ludicrous scrapes some of the party got into: one man was rather a-head, looking for a way to descend a steep place, when the snow slipped from under him, and down he went, about eighty feet, partly sliding,

* By angular measurement it was found to be 2,270 feet.

© The Complete Work of Charles Darwin Online

partly falling, but quite against his consent. What he did by accident, we were obliged to do, because there was no alternative; so away we slid, one after another, like so many sledges upon Russian ice-hills, holding the instruments as we could, by one hand, while the other was employed to check or steady us. With a little more of this sort of work, and some struggling through the wood at the bottom, we reached the shore, where a boat was waiting for us, and at about eight arrived on board, in a half-wet, half-frozen condition.*

"19th. Every thing was brought on board, the ship unmoored, and all made ready for our departure next morning.

"20th. Sailed from Port Gallant, leaving the Adelaide to rate her chronometers, and rejoin us before leaving the Strait. In the evening we anchored in Elizabeth Bay, after a severe day's struggle against a strong and contrary wind, with much rain.

"21st. Blowing hard again this morning from the N.W., with a great deal of rain. Weighed and made sail under reefed courses and treble reefed topsails, but the wind and tide were more than a match for us, so we stood across into Whale Sound, and worked up under the lee of Carlos Island, finding the tide there rather in our favour. The 'williwaws' (I know no better name for the sudden gusts that come off the high land) gave us some trouble, occasionally laying us almost on our beam ends. At half past two I was induced to anchor under the lee of the south-east extremity of Carlos Island, and thought our day's work was repaid by a snug position close to a weather-shore, besides having made some little progress; but after dark the wind became more violent, and a williwaw drove us out into deep water. We set the storm sails, which, with the weather-tide, known to be then making strongly, I hoped would take her a-head sufficiently to clear Rupert Island (lying under our lee), and all hands then went to the capstan; but while heaving-in the cable, our bower anchor again caught the ground and brought us up. We veered away cable

* The wristbands of our shirts, and all our outer clothes, were coated with ice, while our inner clothing was wet through.

© The Complete Work of Charles Darwin Online

directly, let go another anchor, and rode out the rest of the gale, which was extremely violent, without driving.

" The instant our anchor caught, I knew we must be on a ridge, of which Lieut. Skyring had spoken to me, lying between Rupert and Carlos Islands, across which the tide makes strongly, at the rate of about three knots. Rupert Island was still under our lee, distant less than half a mile.

" 22d. Blowing hard and raining. At 9 A.M. it cleared and moderated, but so strong a tide set past us, to the south, that we could not attempt to weigh. It differs here from that in mid-channel by two hours, which may much assist a vessel if she manages so as to take eight hours tide in her favour.

" At eleven we unmoored, and got ready for moving at the turn of tide.* At one we weighed and made sail with a moderate wind from N.W., and by keeping close to Carlos Island, and making short boards, we had a weather-tide, while in the fairway of the Strait the stream was running to the S.E. We anchored in Bachelor's Bay (or York Roads), choosing an outside berth in order to have more room to weigh again and work with the morning tide. It blew hard in the night, but we rode securely, although the tide ran at least three knots where we were.

" 23d. We started and worked to the westward, and at nine were abreast of Borja Bay; but by trying for too much, nearly lost all that we had gained, for in standing across from the bay, hoping to weather Cape Quod, the flood tide took us so strongly, that it cost three hours close working to get to an anchor even in Borja Bay. We had rain and sleet continually through the day, and it blew hard at night, but as plenty of chain was out, the topsails and courses were close reefed, and the top-gallant masts on deck, we were ready for anything.

" 24th. Heavy squalls, with almost constant rain, prevented our moving westward, and similar weather continued throughout the day, becoming worse at night. Had we had plenty of provisions I should not have minded this delay, because we might have remained at anchor till it was over; but so much

* On heaving up the best bower, we found it had lost one fluke.

© The Complete Work of Charles Darwin Online

had been said about the difficulty sometimes found in working through the Strait, that it concerned us greatly not to lose a chance of making progress. During this night the squalls were very heavy. The holding ground must have been excellent, for williwaws drove the ship from one side to the other as if she had been a chip upon the water.

"26th. Weighed this morning, weathered Cape Quod, and worked to the westward, the weather having cleared and become very fine. The part where most tide is felt was then past. Cape Quod projects so far south that the Strait is there extremely narrow, and though very deep, has a strong tide.

"27th. At daylight we found ourselves to windward of Marian's Cove. Looking eastward upon the land about Cape Quod, it has a very bleak and rugged appearance. The almost perennial west winds prevent vegetation from growing on the heights exposed to their action. Hence the desolate look of the western shores of Tierra del Fuego. We saw a sail beyond Cape Notch, and, just before we moored, close to the shore in Half-port Cove, we made her out to be the Adelaide.

"28th. A bad morning, snowy and blowing, but the wind being moderate between the squalls, I went in a whale boat to examine the Gulf of Xaultegua, and pulled along the south shore towards Cape Monday. Having gained some distance to windward, while the snow was so thick it was impossible to see the shore, we made sail across the Strait, and hit the place within a cable's length. When the snow ceased falling, we saw a large space of water before us, the land opposite being at least five miles distant. We sailed towards a strange looking islet in the middle of the gulf, very similar to the old mouldering figures of the fabled Sphinx, but the snow becoming again almost incessant, only allowing us to see our way at intervals, while the wind was too strong for even a close reefed sail, we landed, and hauled the boat up on an island. I was in hopes of finding an opening which would lead me to the Skyring Water; and my boat's crew, being almost as eager as I was, cared little for the wind or snow. This night we made a larger tent than usual, with a top-gallant studding sail, and

© The Complete Work of Charles Darwin Online

the consequence was, we were extremely cold, as there was a sharp frost, and the snow was lying every where very deep. Next night we were wiser, and reduced our tent to the smallest dimensions.

"29th. Early in the morning we resumed our search. I had a chronometer with me, but as we never saw the sun, nor even a star, I should have been as well without it. We pulled and sailed towards the northernmost corner first, but found no opening, and went thence to the eastward, with a strong and favourable breeze. Passing Still-hope Point I felt sure of finding a passage, for before me were the tops of mountains seen from the Otway Water. I was, however, deceived, the gulf ended in two bights, or inlets, unconnected with other waters: so we returned to Still-hope Point and hauled up the boat. The night passed very well, in a snug place among trees, although the snow was falling thickly. Early next morning we left the shore, having employed a quarter of an hour in clearing the snow out of our boat. When we started, it snowed fast but without wind, and we steered by compass for the Sphinx. I sketched what I could see of the south side of this gulf, but did not consider it worth delaying longer, in such weather, for so unimportant a place, while anxious that the Beagle should reach Chiloé before her provisions were expended, and that I should fall in with the Adelaide before leaving the Strait. If ever a minute survey is made of this gulf, it should be after all others have been examined, as it is utterly useless. The temperature of the water within it we found to be 40° Fahr. We landed on St. Anne's Island, having run near thirty miles since the morning, and thence we sailed across the Strait, reached His Majesty's little vessel, and found that the Adelaide had not yet passed by. All looked cold and wintry, every thing being covered with snow; and our sails were hard frozen, for the first time.

"July 1st. After beating loose the sails, we stood out in the ship to meet the Adelaide, which was seen coming towards us. I went on board, and found every one well. They too, in attempting to anchor off Carlos Island, had, like ourselves, been driven

© The Complete Work of Charles Darwin Online

out: we compared chronometers, and supplied her with a few things not thought of before (keeping under all sail meanwhile to profit by an easterly wind); and the Beagle's officers lent the Adelaide their own stove.

"In the afternoon, we parted company; the Adelaide stood towards Upright Bay, and anchored at dusk, while we steered out of the Strait, with a freshening breeze from the east, which increased much as we made westing. At midnight, we were in the Pacific, and all our anxiety about weeks of beating to windward upon short allowance of provisions, vanished as quickly as the land astern. The glass falling, with the wind in the S.E. quarter, foretold unusually bad weather; we therefore shortened sail by degrees, making all secure.

"2d. At six o'clock in the morning, it was blowing a gale of wind, with so much sea, that it was necessary to steer right before it,—or heave-to,—which with a fair wind was not preferable; and we found the vessel scud extremely well, under close reefed fore and main topsails, and double reefed foresail. Our quarter boats caused anxiety, for the davits were low, and at every lurch the boats were risked. Frequently they dipped in the sea, and sometimes were half filled; but they hung fast till by a moment's neglect of the steerage, a sea broke over the whale-boat, and carried her away. The other, being much smaller and stronger, held on well, though frequently under water. Towards midnight the gale broke; by the next morning the weather was more moderate; and from that time it continued fine, until our arrival at Chilóe.

"On the 5th, at daylight, we saw land at a great distance, which afterwards proved to be the Island of Guafo, and in the afternoon the south end of Chilóe was seen.

"On the 8th, we were working towards the Port of San Carlos, being off Point Huapilacuy, and next day (9th) anchored in the port of San Carlos, which seemed to be well sheltered by a country, the appearance of which was very agreeable when contrasted with that of Tierra del Fuego.

"The town reminded me of a Cornish village. I thought, from their appearance and colour, that the houses were built

© The Complete Work of Charles Darwin Online

of stone, and roofed with slate; but afterwards found they were of wood, from their foundations, to the tops of their roofs. Except a few cleared spaces, the island is entirely covered with trees, even on the highest hills. The Captain of the Port (an Englishman) boarded us as we neared the anchorage, and was very obliging in his offers. From him I learnt that the Adventure had not yet arrived, nor even been heard of on the coast. We anchored under the lee of Barcacura Heights, in a good berth, and moored ship. I went on shore immediately, and paid my respects to the Governor, Don José Santiago Aldunate, a brigadier-general in the Chilian Service, whose kind manner, and friendly offers of every assistance he could render us, were very gratifying. From the master of a merchant ship, lately arrived, I was surprised and concerned to learn, that the Adventure had not reached Valparaiso before the time of his sailing thence (20th of June).*

"Refitting the Beagle, repairing and building boats, occupied most of the officers, and all the crew, while Mr. Stokes and I were engaged in the work of the survey, during our stay in the Port of San Carlos. Our ship required caulking, which, in so rainy a climate, was difficult to accomplish. So continually wet was the weather, that had we not dried our sails, and unbent them, during three fine days which we had(r) on our arrival, they would not have been dry during our stay."

* The Adventure arrived on the 21st.—P. P. K.

(r) Por milagro (miraculously); as the inhabitants told me.—R. F.

CHAPTER XV.

Extracts from the Journals of Lieutenants Skyring and Graves—Magdalen Channel — Keats Sound — Mount Sarmiento — Barrow Head — Cockburn Channel — Prevalence of south-west winds — Melville Sound — Ascent of Mount Skyring — Memorial — Cockburn and Barbara Channels — Mass of Islets and Rocks — Hewett Bay — Cypress trees useful—Adelaide rejoins Beagle in Port Gallant—Captain King's narrative resumed — Plan of future proceedings — Adelaide arrives at Chilóe — Abstract of Lieutenant Skyring's account of her proceedings—Smyth Channel—Mount Burney—'Ancon sin Salida'—Natives—Kirke Narrows—Guia Narrows—Peculiar tides—Indians in plank canoes—Passage to Chilóe.

THE extracts from Captain Fitz Roy's first journal being ended, I shall now give some passages from the journals of Lieutenants Skyring and Graves, while employed in the Adelaide, exploring and surveying the Magdalen and Barbara Channels.

The reader will remember, that the Adelaide parted company with the Beagle, at the entrance of the Magdalen Channel, on the 19th of April; and steered to the southward under the direction of Lieutenant Skyring.

Lieutenant Graves says:—

"The east and west shores of the Magdalen Channel run nearly parallel to each other: but the east side is broken by a large opening, named Keats Sound, which runs into the land for eight miles, and appears very like a channel.*(s)*

"At the S.W. angle of the Magdalen Channel stands Mount Sarmiento: the most conspicuous, and the most splendid object in these regions. Rising abruptly from the sea, to a height of about 7,000 feet, it terminates in two sharp peaks, which seem absolutely in the sky: so lofty does the mountain appear, when you are close to its base.

(s) I do not think that there is any opening at the bottom of Keats Sound; which lies at the base of a chain of snow-covered mountains, whose southern side I have closely traced.—R. F.

© The Complete Work of Charles Darwin Online

"Two thirds of the height are covered with snow; and two enormous glaciers descend into the deep blue waters of the sea beneath. When the sun shines, it is a most brilliant and magnificent sight.

"Many days were almost lost to us, in consequence of heavy gales, accompanied by torrents of rain; but we profited by intervals of fine weather to move from cove to cove.

"On the 5th of May, while working out of Stormy Bay, we grounded, and remained fixed upon a rock several hours, but were lifted off again by the next tide, without having sustained material injury.

"To vessels navigating this channel, I should strongly recommend giving a preference to the south shore, where there are many openings, and I have no doubt good anchorages, which, as our time was limited, and the weather very tempestuous, we had not an opportunity of examining. If any such exist they would have a decided advantage over those on the north shore, from being generally to windward, and therefore easy to leave, as well as more secure. King and Fitz Roy Islands, lying in mid-channel, between Stormy and Park Bays, are of bold approach, as are also the Kirke Rocks, which lie further to the S.W.

"One morning, being anxious to obtain a more secure situation for the vessel, we started in search of a better berth, intending, if possible, to reach a bay on the other shore, near Barrow Head, apparently affording good anchorage; but after beating about, from nine until four o'clock, without being able to reach it, the breeze freshening, and sea increasing, we bore up, and again anchored under the lee of the same island. S.W. winds prevail in these parts throughout the year: in confirmation of which, besides the experience we ourselves have had, all the trees which stand exposed, are bent in an opposite direction; and on the S.W. side of all the land open to that point, not only does the vegetation commence much further from the water's edge, but it is scarcer, and more stunted. In sheltered places the trees grow to within a foot of high-water mark.

"May 11th. We remained at the above-mentioned anchorage; and while Lieutenant Skyring was examining a cluster of islands in the vicinity, I obtained observations for the latitude and longitude; and as it was the first fine day, indeed the only one since entering this channel in which we had a fair proportion of sunshine, it was taken advantage of to dry and air all our clothes and bedding, and clean out the vessel thoroughly.

"The next anchorage we took, was in a cove just large enough to hold the schooner, at the entrance of Dyneley Sound, on the north shore. In crossing over, we had a fine view of Mount Sarmiento; and looking to seaward, from the hill over this cove, the Tussac, and the Fury Rocks, at the entrance of Melville Sound, which are much resorted to by sealers, were clearly distinguishable.

"During our stay here, until May 15th, the neighbouring coast was examined, whenever the weather permitted. We also communicated with several canoes full of Indians, but gained no additional information respecting the habits of the natives.

"The next start carried us through the islands of Melville Sound, to an anchorage in a small cove, at the N.E. end of the largest of the Magill Islands, upon which is Mount Skyring. Having resolved to ascend to the top, as it offered so commanding a view, and was so centrally situated, we remained for that purpose." The weather, for several days, was very unfavourable, and it was not until the 21st, that there was any reasonable prospect of obtaining a view from the summit; when Lieutenant Skyring and Mr. Kirke had a most laborious excursion, and the latter was nearly frost-bitten in ascending the mountain; but they were fully recompensed for the trouble and difficulty they had experienced.

Lieutenant Skyring says:—

"We gained the summit after three hour's hard travelling. During the last five hundred feet of ascent, the mountain was almost precipitous, and we had the utmost difficulty in passing the instruments from hand to hand. Its formation is remarkable, although, I believe, the same structure exists throughout the hills around. The base is a coarse granite, but this solid

© The Complete Work of Charles Darwin Online

formation cannot be traced half the height; above is an immense heap of masses of rock, irregularly and wonderfully thrown together, many huge fragments overhanging, with apparently very little hold. This station was the most commanding we had chosen during the survey, and answered well for the object we desired; which being attained, we returned on board, and I rejoiced when all were safe, for it was neither an easy, nor a pleasant enterprise."

A document, of which the following is a copy, was enclosed in a bottle and a strong outer case, and left at the summit of the mountain.

(Copy.)

This Memorial was left by the officers of H.M. Schooner Adelaide, while employed on a survey of the Magdalen, Cockburn, and Barbara Channels; and any person finding it is requested to leave the original document, and build the pile, under which it is placed, at least six feet higher.

Signed this 16th day of May 1829, by

W. G. Skyring, Lieut. and assist. surveyor of H.M.S. Beagle.
Thomas Graves, Lieut. of H.M. Schooner Adelaide.
James Kirke, Midshipman H.M.S. Beagle.
Alex. Millar, Master assist. H.M.S. Adelaide.
Benj. Bynoe, Assist. surgeon H.M.S. Beagle.
Jno. Park, Assist. surgeon H.M.S. Adventure.

God save the King.

"In the Cockburn Channel,* the flood-tide sets to seaward;

* In the old Dutch charts, a passage was laid down near the place, and nearly in the direction of the Cockburn Channel, and named 'Jelouzelt:' but until some written authority can be produced to prove that this passage was explored, or, at the least, discovered by the person who gave the name of 'Jelouzelt' to one of the almost innumerable openings in Tierra del Fuego, it does not appear that the inlet so called has any claim to our consideration, greater than that of the non-existing San Sebastian Channel,—or a number of other imaginary passages which must have been laid down, upon supposition only, in many old charts.

The first person known to have passed through the Cockburn Channel was the mate of the Prince of Saxe Cobourg, who went in a boat (see page 66). It was afterwards passed by Mr. William Low, master of the Mercury, and has since been used by several vessels.

© The Complete Work of Charles Darwin Online

but it was not found to be of consequence to a vessel in working through. The rise and fall is not more than six, or at most, eight feet, at spring-tides.

" May 22d. We quitted this anchorage; and having worked to the westward, through the Adelaide Passage, took up a berth in a small bay, two miles and a half to the northward, where we remained during the night, and next morning; then, after examining the neighbouring coast sufficiently to carry on our triangulation, proceeded to an anchorage on the north side of Bynoe Island. From the summit of this place an extensive view was obtained of the islands in Melville Sound, as well as of the entrance to the Cockburn and Barbara Channels. Such a complicated mass of islands and rocks, I never before saw; to lay them all down correctly would occupy a long time. Sufficient, however, has been done to take the navigator through this labyrinth; but I am well aware, that very much is still wanting to complete the survey.

" Fury and North Harbours, of which the former became more particularly known to us from the Prince of Saxe Cobourg having been wrecked there in December 1826, were laid down from an eye-sketch only; but the peaks of the island, and its extremes, were fixed by triangulation.*

" Melville Sound is formed by the islands which separate the Cockburn from the Barbara Channels. Generally speaking, they, as well as the coasts in the immediate neighbourhood which are exposed to seaward, present a most barren and desolate appearance.

" Until the 26th of May, we were much occupied among the surrounding islands; but time being short, we took advantage of a southerly wind to run up the Barbara Channel, and soon reached an anchorage in Hewett Bay. While securing the vessel, a canoe, containing only a man, woman, and child, and three dogs, was seen coming round the south point of the bay. As they seemed very unwilling to pay us a visit, remaining at a distance, and vociferating as usual, ' Ho-say,' ' Ho-say!' Mr. Bynoe and I communicated with them in the dinghy; but

* Since surveyed by Capt. Fitz Roy in the Beagle, 1829-30.

© The Complete Work of Charles Darwin Online

finding they had not an article worth bartering for, we soon left them, and returned on board. It was suspected their companions were not far off, and indeed, the day after, Lieutenant Skyring saw several canoes; but the moment he was discovered, they were beached, and the men, taking to the woods, kept at a distance.

"On the 29th, we left Hewett Bay, and, after threading the needle through a multitude of islands, islets, and small rocks, for more than three miles, reached an anchorage in a small cove, at the north entrance of Brown Bay, where we were detained, and confined to the vessel, by heavy gales, and stormy weather, until June 2d; when, having a fine day, we reached a spot (marked in the chart as North anchorage) sufficiently secure for a small vessel; but not to be recommended to any other.

"Between Hewett Bay, and the above anchorage, there are several rocks, among patches of kelp, which, as they only show themselves at half ebb, or near low water, render the navigation rather intricate. A good maxim in these channels is, 'Avoid kelp, and you avoid danger.' Forty-three days had passed since we left Port Famine; and in this interval, I find we had nine favourable days, twelve partially favourable, some hours of which we could employ in the work about which we were engaged, and the remaining twenty-three were days of rain and wind, far too unfavourable to serve our purpose in the least.

"June 4th. While turning to windward, we, for the first time, felt the influence of the tide, which, from the channel's narrowing, begins to be sensible: here it was sufficiently strong to prevent our gaining ground in beating to windward, although with a good working breeze; we therefore ran into a bay on the west side, and anchored. The country around had rather a pleasing appearance, the shores being partially covered with the evergreen, and deciduous-leaved beech, and a few stunted cypress-trees. These last are serviceable for boat-hook spars, or boats' masts; and, when seasoned, work up very smoothly, and wear well: the beech-trees do not equal those found further northward in the Strait, except here and there in sheltered corners.

© The Complete Work of Charles Darwin Online

"With a leading wind, the next morning, we reached the south narrows of the Barbara Channel, through which we were carried by a strong tide, and anchored in Bedford Bay.

"Here, as well as throughout the Barbara channel, the flood tide sets to the southward. We obtained at this place angles which connected our triangulation with points fixed by Captain King during the previous year, and finished our examination of these channels within a very few days of the time allotted.

"On the 8th of June we attempted to pass through the Shag Narrows, but not saving the tide, were obliged to anchor for the night in Field Bay, which is small and much exposed to southerly winds; the bank also is very abrupt, and the water is deep close to the shore.

"On the 9th we succeeded in clearing the Narrows, and reached Port Gallant early in the afternoon, where we rejoined the Beagle."

Having given these brief extracts from Journals kept on board the Beagle and Adelaide, during the time occupied by the Adventure about Cape Horn, or on her way to Chiloé, I will resume my own narrative.

As it was my intention to remain at this port * until the Beagle and Adelaide were equipped, the Adventure was made snug, and, by way of relaxation, such of the officers as could be spared from the duties of the ship, resided in turns at the town, where also the ship's company had frequently permission to amuse themselves.

The Hoxsley schooner arrived from Valparaiso and brought me letters from the Admiralty, acquiescing in my request to return to England direct, instead of proceeding by way of New South Wales and the Cape of Good Hope, as was originally intended. I therefore determined to return to Valparaiso as soon as our consorts had taken their departure, proceed thence to Port Famine, where we were to be joined by the Adelaide, and afterwards repair to Rio de Janeiro to await the Beagle's arrival, when we should sail for England.

* San Carlos, in Chiloé.

© The Complete Work of Charles Darwin Online

On the 20th of September my anxiety for the Adelaide was relieved by her appearance, and by finding all on board her in good health. She had gone up the coast by the channels that communicate with the Strait of Magalhaens at Beaufort Bay, passing inside of Hanover Island and Madre de Dios; and Lieut. Skyring gave me a very interesting account of their discoveries, of which the following is an abstract.

It will be remembered that the Beagle left the Adelaide at anchor under Cape Upright. While there the wind freshened up from the eastward, and threw a swell into the bay, which rendered the anchorage very unsafe, as the schooner's stern was in the foam of the sea that broke on the rocky shore close to her. Much anxiety was felt for their safety, but the anchors held well. As soon as the weather permitted they sailed, entered Beaufort Bay, and steered towards a deep opening to the eastward of Cape Phillip, into which they ran with a steady S.E. wind, and found an anchorage on the west side in Deep Harbour.

On the 5th of July Lieut. Skyring and Mr. Kirke were absent in a whaleboat, exploring a deep opening eastward of Cape Tamar, which they found to terminate in two sounds, named by them Icy Sound and Glacier Bay; the first from its being covered with a sheet of ice, and the latter from its being full of large masses which had been detached from an extensive glacier occupying the bottom of the bay. The examination of this opening was made in search of a channel, through which, vessels had entered the Strait, and the schooner was to proceed to her rendezvous. The result proved that the Adelaide was already in the channel they were looking for, therefore they returned on board, and proceeded (7th) to the northward. In passing Mount Joy a strong tide was observed, the certain indication of a channel; for, as has been before remarked, within sounds the tide has no perceptible stream. To gain a better knowledge of their way they anchored early in Good's Bay; the course of the channel, from the intersection of points, and intervention of islands, being by no means distinct. Lieut. Graves made a plan of the bay, while

© The Complete Work of Charles Darwin Online

Lieut. Skyring, and his assistant,* completed the survey of the entrance to the passage, which was named Smyth Channel, as a compliment to Capt. W. H. Smyth, R. N., under whom, while surveying the Mediterranean, both Lieuts. Skyring and Graves had served.

The best channel they found to the eastward of Renouard Island, and the Adelaide took that course, but stopped a night in a small cove on the eastern side of the island, and in passing Shoal Island next day struck on a rock; she was got off however without injury, and anchored afterwards, for a night, on the north side of the Island of the Narrows.

The two following days (10th and 11th) were spent in examining the coast, and exploring Clapperton Inlet, which had the appearance of being a channel. From the hills at the bottom Lieut. Skyring noticed a considerable tract of low land and open plain, extending to the northward. On the 12th, being Sunday, they remained quiet, and on the 13th the weather was so calm that they only reached Hose Harbour, on the east side; and the next day Oake Bay. Thence crossing the channel in a whaleboat they explored some distance along that shore; and on the 15th anchored in Otter Bay. This slow progress was unavoidable, owing to the calm state of the weather, and to the survey being principally, if not entirely, carried on in boats.

On the 16th the schooner was towed onwards, and passing over an extensive shoal flat of three fathoms, reached the Summer Islands, where she might have stopped, but, as the tide was still favourable, she proceeded to an anchorage under Long Island, the most northern in the Elson group.

The eastern shore of the channel was there very different in character from what they had so long been accustomed to, being nearly level; and, extending for some distance off every low point, there was shoal water.

For some days a lofty mountain, covered with snow, had been in sight; which, by angular measurement, proved to

* Mr. Kirke.

© The Complete Work of Charles Darwin Online

be 5,800 feet in height. It was named Mount Burney, in compliment to the admiral.

On the 17th the Adelaide reached Fortune Bay, situated at the east extreme of a headland, on each side of which is a channel, leading, apparently, towards Cape Isabel. The northern seemed to be the principal one, and therefore was followed next day (18th) as far as Welcome Bay.

Continuing the survey onwards they reached Victory Passage, which they entered, thinking they were in the mouth of the 'Ancon sin Salida,' as laid down from Sarmiento's journal by Admiral Burney. The weather, however, became so bad, that they were obliged to take shelter in Island Bay, and the next day the wind setting in from the eastward, they gave up, for a time, their search for the 'Ancon sin salida,' and proceeded by Smyth Channel, as far as Hamper Bay, where they were again detained by bad weather. Here a few rock fish were caught, but at no other time during this cruise were the fishermen successful, although the channel was so filled by porpoises and seals, that it is probably well stocked with fish at the proper season: and there are many places where the seine might be shot. Proceeding slowly on the 25th, the Adelaide struck on a rock, and remained fast for a few hours, but as the tide rose she swung off without damage. Upon examining Rocky Bay they found it a complete bed of rocks; yet, bad as it was, the Adelaide was obliged to remain there five days, owing to the tempestuous state of the weather. On the 30th they reached the north end of Smyth Channel, and anchored in Narrow Creek.

On the 31st Lieut. Skyring went to a remarkable hill, which he called Mount Trafalgar, but thought it might have been the 'Monte Trigo'* of Sarmiento, so much did its appearance remind him of a corn stack. The day was most favourable: a round of angles, and an extensive view down Lord Nelson's Strait, were obtained from the summit. They remained on an island all night, sheltered by the boat, and next morning went to two points, called by Sarmiento 'Oueste,' and 'Mas

* A heap, or stack of corn.

© The Complete Work of Charles Darwin Online

al Oueste,' (west and more west,) returning to the Adelaide in the evening.

The following morning was fine, and the Adelaide moved out of Smyth Channel, the survey of which was completed very satisfactorily, although their progress was slow, owing to constant northerly winds.

By towing the Adelaide during tedious calms, they reached Montague Bay in the evening, and next day anchored in Relief Harbour, on the S.W. side of Vancouver Island.

As it was evident that the 'Ancon sin salida' was within Piazzi and Ceres Islands, up the west coasts of which they had passed, Lieut. Skyring left the schooner moored in Relief Harbour, and proceeded, on the 4th August, to the southward, in a whale-boat with Mr. Kirke; but he took no more than a week's provisions, that time being all he could devote to this exploration.

The 4th, 5th, and 6th, Lieutenant Skyring employed in pulling or sailing to the southward and eastward, through winding and intricate passages; although strong winds and much heavy rain annoyed him, and impeded his progress.

On the 7th the weather was much more favourable than it had lately been. The boat pulled and sailed to the southward, and at noon Lieutenant Skyring ascended a height,* having on each side of it a deep opening, but he was disappointed in the view; and, after taking bearings, pulled round the adjacent bights, one of which was exactly opposite Artist Bay, in Smyth Channel, and so near it that the two waters were only separated by a few hundred yards;† the other,‡ eastward of the height, was large, and closed at the bottom by very low lands. It was directly supposed to be the 'Ancon sin Salida;'§ but Sarmiento's description, and the chart compiled by Burney,

* No doubt the Mount Oracion of Sarmiento, p. 144.—P.P.K.

† This place is described in Sarmiento's journal, p. 144.—P.P.K.

‡ Ensenada de la Oracion of Sarmiento.—P.P.K.

§ This bay is also described by Sarmiento as an 'Ancon sin salida,' p. 143; but it is evidently not the one that bears that name on the chart. —P.P.K.

© The Complete Work of Charles Darwin Online

were insufficient to enable them to decide with any degree of certainty. After looking round this bay, they continued to the eastward, and passed a point beyond which there was apparently a wide channel; having run about six miles down it without discovering any termination, they hauled their boat up on the beach for the night.

On the 8th, two canoes were noticed on the west shore; but seeing strangers the natives, apparently much frightened, all landed, except an old man; and taking with them what they most valued, hid themselves among the brush-wood, leaving their canoes fastened to the sea-weed. By some Fuegian words of invitation, the men were, however, induced to approach and traffic, receiving for their otter skins whatever could be spared. In appearance and manner these Indians were exactly similar to the Fuegians; and by their canoes only, which were built of planks, could they be distinguished as belonging to another tribe.

After leaving the natives, the boat passed Cape Earnest, and Lieutenant Skyring observed a wide channel leading north and then N.N.W.;* also, another opening to the eastward. The wind being easterly, he ran some distance to the northward, to gain more knowledge of the first inlet; and having gone ten or twelve miles from Cape Earnest, and observing the opening for eight miles beyond to be as wide as where they then were, he concluded it to be a channel, or else a deep sound terminated by low land, for there was evidently a division in

* Here is certainly the Ancon sin salida of Sarmiento, whose journal describes the inlet as terminating in a cove to the north, p. 142. The mountain of Año Nuevo cannot be mistaken; indeed the whole of the coast is so well described by the ancient mariner, that we have little difficulty in determining the greater number of places he visited. In all cases we have, of course, preserved his names. The chart compiled by Admiral Burney is a remarkable instance of the care which that author took in arranging it, and how ingeniously and correctly he has displayed his judgment; it is also a proof that our favourite old voyager, Sarmiento, was at least correct in his descriptions, although he appears to have been quite ignorant of the variation of the compass. — See Burney Coll. Voyages, p. 31; and Sarmiento, p. 162.

© The Complete Work of Charles Darwin Online

the mountains, such as to justify this belief. Returning, they entered the smaller opening to the eastward, and were almost assured of its being a channel; for when they were between the points, many porpoises and seals were observed, and a tide was found setting westward, at the rate of two knots. At dark, they hauled their boat on the beach of an excellent bay, at the north side of the narrow reach, and secured her for the night.

On the 9th, shortly after daylight, they set out in a N.E. direction to ascertain the truth of their supposition; and before noon knew, beyond a doubt, that they were correct in their belief, being in the narrows of a channel before unknown, that had eluded Sarmiento's notice. These narrows, which Lieutenant Skyring felt assured would lead to a large opening, were upwards of three miles in length, and generally about one-third of a mile in breadth. A strong tide took the boat through; and at the N.E. extremity, where the narrows were reduced to four hundred yards in width, the water, although a neap-tide, rushed at the rate of four knots, forming whirling eddies, which were carefully avoided by Lieutenant Skyring. At spring-tide, the strength of these rapids would probably not be less than seven knots.

Having passed through them, a clear channel was seen, upwards of two miles wide, running to the N.b.E. for, at least, eight miles, and then turning directly eastward, between moderately high land. Another channel, nearly a mile and a half wide, trended to the S.E. for two or three miles, and then also turned to the eastward. Here they stopped. Lieutenant Skyring regretted extremely not being able to prosecute the discovery, and have one more view from the eastern point of the N.E. channel; but as only one day's provisions remained, it would have been imprudent to delay his return. It was evident, that they had passed through the range of the Cordilleras,* for to the eastward the country appeared totally different, the highest hill not being above seven hundred feet. The opening to the N.E. was thought to communicate with the waters' lately discovered by Captain Fitz Roy. The latitude

* 'Cordillera Nevada' of Sarmiento.

© The Complete Work of Charles Darwin Online

was obtained on Point Return; and in the afternoon, reluctantly but anxiously, they retraced their way, and passed that night at their former quarters, in Whale-boat Bay.

On the 10th, at daylight, they proceeded on their return. The wind was fair until they reached Cape Earnest, when it drew right against them; and they had the unpleasant prospect of a tedious pull to the schooner, with very little provision.

The 11th was a thoroughly wet day, and the wind was so strong from the northward, with a very heavy sea running, that it was impossible to proceed.

On the 12th, they left the bay soon after daylight, and having pulled along shore a few miles, crossed Union Sound, and gained the Narrows of San Benito, the wind being still fresh from the northward; thence they continued pulling until they hauled up, after dark, in a bay, opposite Point Benito, and waited till the morning of the 13th, when with a fresh S.W. wind they made good progress, which was of the more consequence, as their provisions were expended, although they had eked them out with corvorants and muscles. At last, the sight of the Adelaide rejoiced them, and they soon afterwards reached her. Their appearance was a relief to all who were on board, as they were becoming very anxious, and Lieut. Graves was preparing to send the other whale-boat in search of them. During their absence he had made the necessary astronomical observations, and finished the examination of those shores adjacent to the harbours.

From the 13th to the 17th, the schooner was detained by bad weather, and the following day only succeeded in reaching Escape Bay, in San Estevan Channel, which was found to be a good and well-sheltered anchorage, although small.

On the 19th, after angles had been taken on each side of the Channel, the Adelaide got under weigh, and steered up the Channel. At noon she passed the mount which they supposed to be Sarmiento's Monte Trigo, and soon after, nearing Esperanza Island, they sought for some mark by which to recognise the Mountain of the Fox ('Monte de la Zorra'). In the white part of a cliff, they fancied some resemblance to an

© The Complete Work of Charles Darwin Online

animal, and noticed a harbour opposite, in which they anchored. They had such trouble in getting to the northward, that this day's run, though only eighteen miles, was a cause of much satisfaction.

On the 20th, at daylight, the boats were employed around the anchorage, and at nine o'clock the vessel was underweigh, and working to the northward, although it rained hard then, as well as throughout the whole day, after beating until the evening, she anchored on the west shore.

Constant rain fell through the whole night, and during the 21st; it was therefore impossible to make any progress to the northward.

On the 22d the Adelaide weighed, and the weather being calm, was towed during the whole forenoon. At noon a southerly wind sprung up, and by the evening she was in the Guia Narrows (of Sarmiento). They tried for anchorage in Unfit Bay, conceiving it to be Sarmiento's Port Ochavario; but none being found, the vessel was towed into a cove, and securely moored.

Next day the boats surveyed the Guia Narrows. Although long, they did not appear hazardous to pass, for the tides are not very rapid. The ebb tide runs to the northward, but at the south entrance of the San Estevan Channel, the ebb sets to the southward; which difference in direction, within so short a distance, is extraordinary, and difficult to account for without knowing more of the coast. Certainly there is a meeting of tides between the two entrances; probably, all the land westward of San Estevan is a collection of large islands, and water flows into this channel, from the Pacific, through many openings, which may be the cause of this peculiarity.

24th. With light breezes from the eastward, the schooner weighed and stood through the Narrows; passed Point San Juan, and continued along the eastern shore of Concepcion Strait to Guard Bay, where she was moored.

25th. Rainy weather until near noon, when the boats were employed.

On the 26th the schooner was towed out, and, as it was calm,

© The Complete Work of Charles Darwin Online

kept a boat a-head the whole day. She anchored in a small bight, formed by Chance Islands, about seven miles from Guard Bay.

The 27th was rainy, but the boats went to different points, and angles were taken before the schooner weighed and worked northward. At noon she came to an anchor in a small bay, northward of the Hocico de Caiman. Constant rain during the remainder of the day.

On the 28th it rained too incessantly the whole morning, to allow the party to work, even in boats; and the day was passed in laying down former observations.

29th. After angles had been taken near the anchorage, the schooner was moved, and worked along the coast. A strong wind from the N.W., with a heavy sea, brought the vessel under close-reefed sails, and obliged her to anchor in Walker Bay.

On the 30th, the Adelaide anchored in Molyneux Sound. To give a clearer idea of the delays experienced in making progress to the northward through these intricate channels, I shall now extract part of Lieutenant Skyring's Journal, in his own words:

"31st. Wind N.N.W. with a heavy swell in the Strait; the boats at daylight went north and south of the anchorage, and angles were obtained. At nine, ready for starting; but the weather was too unfavourable, and continued so until the 4th of September, when, at seven o'clock in the morning, we weighed. At nine, squally—obliged to double-reef; but the tide serving, we gained a few miles to windward, and at one, P.M., stood among a mass of islands on the west side, and moored in Tom's Bay, steadying the vessel with the stream anchor. In the afternoon the survey was continued, and from the heights a view was obtained of the Gulf of Trinidad, and of several points observed last year. Another detention of two days, owing to bad weather.

"7th. Cloudy; weighed at daylight, and stood for the narrows. At eight, squally, with thick snowy weather; but, being once under weigh, we refrained from returning, until compelled. It certainly was not a favourable day for working

© The Complete Work of Charles Darwin Online

through; but the wind moderated, and our attempt succeeded. No anchorage being found by the boats on the north side of the narrows, we made for the weather-shore of the gulf, and anchored early in Windward Bay. In the afternoon, angles were taken on Middle Island, and east and west of the anchorage. The time of our departure drawing near, it became doubly necessary to work constantly, that we might join this survey with that of last year, in the Beagle.

"8th. Weighed at daylight; wind light from N.W.; but, falling calm, boats were detached for continuing the angles, and the latitude was observed on Red Beak Rocks. At five o'clock, we gained an anchorage, close to the eastward of the Ancon del Morro, on the S.E. side of Division Isle, in a bay which answered our purpose, although it was rather a confined place. Some angles were taken on Point Candelaria, preparatory to continuing our course next morning.

"9th. At daylight weighed and stood over to the northern shore, and at eleven, anchored in Neesham Bay, in eleven fathoms. Boats employed in the afternoon, on the survey. While at anchor, two canoes, containing together thirty-two Indians, came alongside; they were chiefly men, a finer race of people, better formed, and better featured than the Fuegians, and much less noisy. Their canoes were made of planks, the longest upwards of twenty-three feet in length: they appeared exceedingly buoyant, and pulled quickly.

"10th. At daylight, we sailed out of the bay, with a light breeze from the eastward; at seven, the wind increased, and a heavy sea rose in the gulf. It was my intention to get an anchorage under Mount Corso; but, as that was now a leeward coast, with a heavy sea setting upon the shore, it would have been improper to attempt seeking for one. If it had answered our purpose, we might have gone to Port Henry, and, indeed, this was the only safe course we could have pursued, if our object had been to remain in the gulf; but no time was left to wait for favourable weather; therefore I chose in preference to leave the gulf, and take advantage of the fair wind to gain an offing, the time of our return being so near.

© The Complete Work of Charles Darwin Online

"We left the gulf two days before I had expected to have done so; but we all rejoiced at our departure. No crew could have performed their duty more willingly than the Adelaide's; but such lengthened fatigue as they had undergone, was sufficient to make any men feel happy at the prospect of a respite.

"It was a pleasing reflection to Lieutenant Graves and myself, that the orders had been fully executed; that the coast we had passed was throughout well connected; and that this service was concluded without any illness or accident among the crew, without any damage to the vessel, without any loss of boats, or even the slightest misfortune."

During the Adelaide's passage to Chilóe, Lieutenant Skyring and his companion were assiduously employed in transferring their observations to paper, notwithstanding the violent motion of their little vessel, during ten days of rough weather.

CHAPTER XVI.

Chilóe—Its probable importance—Valdivia founds seven cities; afterwards destroyed by the Indians—Migration of Spanish settlers—Province and Islands of Chilóe—Districts and population—Government—Defence—Winds—Town—Durability of wooden buildings—Cultivation—Want of industry—Improvement—Dress—Habits of lower classes—Morality—Schools—Language—Produce—Manufactures—Exports and imports—Varieties of wood—Alerse—Roads—Piraguas Ploughs—Corn—Potatoes—Contributions—Birds—Shell-fish—Medical practitioners—Remedies—Climate.

As the Island of Chilóe was formerly shrouded from notice, by the policy of its master, the King of Spain, and therefore little known to the world; I have considered it not irrelevant to the narration of the voyage, to introduce a short account of its present state, particularly as since the trade of the whole coast has been opened, a new era has dawned upon this interesting island; and although it has been, as yet, the least frequented of the South American States, I think the time is not far distant, when it will become an important part of the Chilian territory.

After the foundation of the city of Penco, or Concepcion, by Don Pedro de Valdivia, in the year 1550, he passed on towards the south in search of convenient situations for other cities; and crossing the river Bio Bio, which separates Concepcion from the territory of the Araucanian Indians, successively founded Imperial, Valdivia, Villa Rica, Angol, Cañete, and Osorno; the last being effected in the year 1558. The necessary distribution of the Spanish forces, to protect so many points, made them comparatively defenceless, in a country inhabited by a large population of Indians, who contemplated the hostile occupation of their native land, by the invading army, with a deep dissatisfaction. They had for some time endured, with sullen patience, the yoke of the Spaniards; but at last, incensed by the servility and bondage to which they were reduced, and, probably, by no small portion of ill-treatment; the whole population rose simultaneously, and waged a most destructive and

© The Complete Work of Charles Darwin Online

harassing war against the Spaniards, in which the above-mentioned cities were all destroyed, and the greater number of their inhabitants put to death.

The destruction of the city of Osorno caused the province of Chilóe, or, at least, the adjacent districts of Calbuco and Carelmapu, to be occupied. This town, being more distant from the seat of war, where the main body of the Indian army was actively employed, was enabled to hold out for some time; but, at last, cut off from assistance, prevented from communicating with friends, and utterly destitute of supplies, the inhabitants retired to the fort, or citadel; which they maintained, until compelled, by absolute want of provisions, to abandon their position, and proceed to the south, with a view of establishing themselves in Carelmapu and Calbuco; where they hoped to be safe from attack.

Their retreat was attended by much suffering; many died from fatigue, and many were cut off by the Indians, who hovered about them and murdered all who fell into their hands.* At last they reached their destination, and established themselves first at Carelmapu, which is on the main-land, on the north side of the Boca de Chilóe, opposite to San Carlos; and afterwards at Calbuco, on an island at the entrance to the Gulf of Reloncavi. The latter position by its insularity, was effectually protected against any attack from Indian tribes, who, for many years, continually harassed the inhabitants of Carelmapu.

At what date this journey was made does not appear; nor is it certain that these places were occupied before the foundation of the city of Castro, in 1566, by the Licentiate Lope Garcia de Castro, in pursuance of an order from the Viceroy of Peru, Marshal Don Martin Ruiz de Gamboa.†

The island of Chilóe, from its situation, is a place of considerable importance, and may be termed the key of the Pacific.

* A very full and detailed account of this journey is given by Agüeros, in his 'History of the Province of Chilóe,' pp. 50 to 56, as well as in the 'Chronicles of the Province of Lima, by Padre Fr. Diego de Cordova,' Salinas, chap. xvii. p. 485.

† Agüeros, l. c. p. 57.

© The Complete Work of Charles Darwin Online

It is the northernmost of that vast archipelago, which borders the coast from latitude 42° south to Cape Horn.

The province of Chilóe, one of the eight divisions of the Chilian Republic, includes several islands, and extends on the main-land, as far as the south bank of the River Maullin;* which takes in the districts of Carelmapu and Calbuco. Its southern extent is not defined; but as the existence of Chilian authority is not known, to the southward of the Chonos Archipelago, certainly not farther south than the land of Tres Montes, the parallel of 47° may be considered its southern limit. The country thence, to the Strait of Magalhaens, is known by the appellation of Western Patagonia.

Besides the Isla Grande, as Chilóe is called, the following islands are inhabited:—Achao, or Quinchao, Lemuy, Quehuy, Chelin, Linlin, Llignua, Quenac, Meulin, Caguach or Cahuache, Alao, Apiao, Chaulinec, all in front of Castro; the Chaugues Islands, opposite to Tenoun; Calbuco, Llaichua, Quenu, Tabor, Abtao, Chiduapi (on which is the fort); Huar in the neighbourhood, and district of Calbuco; and, to the South, Tanqui, to which may be added Caylin, which is also called El fin de la Cristiandad.†

Of the above, next to the Isla Grande, the principal are Quinchao and Lemuy, both of which are very populous, and

* Agüeros describes its boundary thus:—It is situated between the latitudes 41° 30′ and 44°; from Point Capitanes to Quilan. On the north it is bounded by the territories of the Indian tribes Juncos and Rancos, which extend to Valdivia; on the N.E. by those of the ancient but destroyed city Osorno; on the south by the archipelago of Guaitecas and Guaianeco, and others which extend to the Strait of Magalhaens; on the east by the Cordillera; and on the west by the sea. (Agüeros, p. 61.)

† When the Yntendente, or governor of the province, visited Castro for the purpose of taking a census of the population, a family of Indians waited upon him to render an account of their property; who, upon being asked whence they came, replied, "Del fin de la Cristiandad." The name being new to the Yntendente, it was explained to him that they belonged to Caylin, which was more generally known by the above name, because there existed no Christian population beyond, or to the southward of, that island.

© The Complete Work of Charles Darwin Online

almost entirely cultivated. The other islands are small, and very close to each other; but separated by navigable channels, which offer many dangers to the frail vessels in which the islanders move about.

The province is divided into ten districts, or Partidos, as follows:—

1. San Carlos, containing the northern coast of the island, as far as Chacao.
2. Chacao. The N.E. part of the island.
3. Carelmapu and Maullin.
4. Calbuco.
5. Dalcahue, extending from Chacao to Tenoun.
6. Quenac.
7. Quinchao.
8. Castro.
9. Lemuy.
10. Chonchi, which extends from Castro to the south extremity of the island.

By the census of 1828, the population of the large island, and those in its neighbourhood would appear to be, comparatively, very considerable; the number of souls being 43,131:* particularly as the greater portion of the interior, and much of the sea-coast, are quite uninhabited. The population of the district of San Carlos is confined principally to the town; for between it and Chacao, there are very few inhabitants. At Chacao there are only about two hundred houses, and Dalcahue is but thinly occupied: but Castro, Quinchao, and Lemuy, are very populous. These three districts are the most fertile and productive part of the island, particularly for seven or eight miles round Castro. The peninsula opposite to that town, which is entirely cleared, would abundantly repay its cultivators, were industry more common among them.

Chilóe is governed by an 'Yntendente,' or civil governor, who exacts obedience to the constitutional laws, as well as to the orders of the executive powers, and the resolutions of the provincial assembly, which is composed of members, elected

* In the year 1783 there were 23,447 (Agüeros): and in 1832, 43,830.

© The Complete Work of Charles Darwin Online

by the people, at the rate of one deputy for 7,500 souls; but whatever the number may be, short of 90,000, twelve deputies are to be elected. The duration of the assembly is biennial, and its business is to superintend the civil regulations of the province.

Under the Yntendente each province has a local governor, whose principal duties are to maintain order, preside in the municipal meetings, see their regulations carried into execution, and obey the orders of the Yntendente of the province. Whilst we were at Chiloé, the duties of Yntendente, and military commandant, were performed by one person, Brigadier-general Don José Santiago Aldunate; but, upon his resignation, the offices were separated: the military commandant retaining the charge of the treasury. The duties of the military chief, are to dispose of the troops under his command, as he sees occasion, so as to ensure the quietness, and subordination of the province, for which he is responsible; and to render the Yntendente such assistance as he may require; but, for all ordinary purposes, the Militia, who are under the immediate control of the Yntendente, are employed. For the administration of the law there is a Judge (Juez de letras), who tries all civil as well criminal actions. The province sends two deputies to the Chilian congress, one from San Carlos, and the other from Castro. At the beginning of the year 1829, the Militia amounted to more than seven thousand men, and the regular troops to three hundred and thirty, which was quite sufficient for the province.

The port of San Carlos is capable of being well defended, and, during the time of the Spaniards, was in a good state of defence. The entrance was protected by a battery on the highland of the Corona, and by the castle of Aguy, which effectually commands it. Farther in, on the same side of the port, was the small, but well-placed, two-gun battery of Barcacura; close under which is the anchorage. On the town side there are several batteries; but, towards the Pudeto it is weak, although capable of being made very strong. Fort San Carlos, which, for some years past, has been used as a cemetery, was well-selected as to position, and constructed in a manner very

© The Complete Work of Charles Darwin Online

creditable to the engineer. It was surrounded by a deep and wide ditch; and under it lay two small batteries: one, San Antonio, commanding the passage between the small island of Cochinos, and the Main; and the other flanking the anchorage off the town. At the Mole were two guns, and opposite to it, under the governor's house, was the battery, Del Carmen, mounting twelve or fourteen guns. In the town, in a convenient situation, there were excellent barracks, capable of containing more than one thousand men.

The original establishment was at the Sandy Point, on the western side of the port, where the situation is better sheltered, and, perhaps, equally capable of being well defended. It is, also, on the windward side of the harbour, and close to the safest anchorage which the port affords; but the inconvenience of water-carriage was found to be so great, that the establishment was removed to its present site. A still better situation might have been selected opposite to Sandy Point, at Leche Agua; where the anchorage is perfectly safe, and the communication with Castro could be more advantageously made.

Northerly and westerly winds prevail, and the town is exposed to all their fury, which, at times, is extreme. The anchorage nearest to it, for the sake of convenience, and expedition in loading and unloading cargoes, is often taken up, but is very unsafe, many vessels having been lost there, from the bottom being shoal, and rocky; and the swell, during a northerly gale, is so short and deep, that anchors will not hold.

The town is built on two rising grounds, and in the valley that separates them; through which a rivulet runs into the bay, at a mole which affords sufficient protection to the boats and piraguas frequenting the port. The houses, which are all of wood, are generally small, and have but little comfort. The plaza, or square, without which no town in Chile of the least importance is to be found, is situated on a flat piece of ground at the summit of the southern hill, and commands an extensive view. It is about one hundred and eighty yards square, with a flag-staff in the centre.

On the north side there is a strong, well-built stone store-

© The Complete Work of Charles Darwin Online

house, and opposite to it is the church, also built of stone. On the side next the sea is the Yntendente's residence, a low range of wooden buildings, erected without regard to taste, convenience, or comfort; and opposite to this are two or three dwellings, very little superior to common huts, or ranchos.

Within the last few years, however, some substantial buildings have been erected by the more wealthy people in the town, an example which is likely to be followed. During our visit, several were built equally creditable for strength and convenience; and not a little remarkable for the rapidity, with which they were completed.

Wood, being abundant, and cheap, as well as easily worked, is the only material used in the construction of houses, which, with the exception of the provision-store, and the church, are all built of it; and notwithstanding the perishable nature of the material, which is not protected by paint, or any external coating, from the humidity of the climate, they are of extraordinary durability. The treasury, one of the oldest houses in the place, has been built upwards of seventy years; and is even now tight, and dry, and by no means unserviceable: but its removal has been ordered, and, probably ere this, it has been replaced by another. In Chacao, where, in former days, the Yntendente resided, the greater number of the government-buildings, not less than sixty or seventy years old, are still standing. This durability can only be accounted for by the nature of the wood, and the practice of charring the ends of the timbers before they are inserted in the ground. The lower frame is of 'Roble;' (*t*) the beams are of laurel, and the floors and partitions, as well as the weather-boarding and shingles, of 'Alerse:' the latter forms an excellent substitute for tiles, or slate, being much lighter, and almost as durable. Some of the houses are thatched with reeds; but this shift is only used by those who cannot afford the expense of shingling.

The inclosures, round the houses, are fenced with stakes of

(*t*) A kind of beech, found every where on these shores. The literal meaning of Roble, is oak.—R. F.

© The Complete Work of Charles Darwin Online

Luma, three or four yards in length, fastened above and below to cross-rails, by ligatures of creeping plants, of which there is an abundance in the woods close to the town: the general name for them is Buque.

The land in the vicinity of San Carlos, which is a peninsula, is cleared of timber, and partially cultivated. In the valley, through which the rivulet runs into the sea near the mole, there are a few attempts at gardens; but the extent to which the inhabitants cultivate, seems to be confined to a rood of potatoes and wheat, which, with a litter of pigs, and an inexhaustible store of shell-fish on the coast, are the principal support of their families. It is not surprising, when so little personal trouble is necessary to provide subsistence, that the Chilotes(*u*) should not be an industrious race. Byron, in his narrative of the loss of the Wager, has given a most excellent and correct account of the inhabitants of this island; which, excepting for those about San Carlos and Castro, may well serve at the present time. In the town, trade, a free communication with other parts of South America, and the residence of several Europeans, have introduced approaches towards refinement; and besides the articles of luxury that occasionally make their appearance, such as chairs and tables, crockery-ware, and similar domestic comforts; shoes and stockings are now, on feast days, in common use among the females; although in many instances one can easily observe, that the wearer is actuated by vanity, rather than by any comfort or pleasure she derives, from a confinement to which her feet have not been accustomed.* This is one of the steps towards civilization, which the Chilote peasantry are making, and among the higher classes 'el ultimo modo' (the latest fashion), is not less the theme of conversation than it is in other parts of the Republic.

In style of dress, among the upper ranks, the men are more advanced than the women, many having been in other countries.

(*u*) Native of Chilóe.—R. F.

* Agüeros says, "both men and women go generally with the foot and leg uncovered; with the exception of the principal families; but even those do not all wear shoes."—(Agüeros, p. 108.)

© The Complete Work of Charles Darwin Online

They have given up the use of the poncho, and in this particular, they say they are before the gentry at Concepcion, who wear it on all occasions: and probably are quite right, for, with respect to comfort, there is much to admire in the poncho, as, of all cloaks, it is the most generally convenient, and the best adapted for protecting the person, especially on horseback, where it is indispensable: its use, however, offers the wearer such an opportunity to neglect the other part of his dress, which it effectually conceals, that sometimes, beneath the poncho, the body is very ill-clothed.

The dress of men in the lower orders, consists of a pair of trowsers, and a shirt, over which is thrown the all-concealing poncho. The women are as slightly clad; but instead of a poncho, they wear a rebozo, or shawl, which, however, is very often dispensed with, and their persons are left too much exposed.

These lower classes, or Indians, as they, with much reason, are termed, are scarcely superior to the uncivilized savages of the southern coasts; and live principally upon shell-fish, with what little they are enabled to procure besides by the sale of a few pigs, or poultry, which they rear on the scanty store of potatoes and wheat, that remains after their new crop comes to maturity. One roof shelters a whole family. Father and mother, sons and daughters, dogs and pigs, all live and sleep in their only room, in the middle of which, a fire is made; whence the smoke escapes by numerous apertures in the roof and sides of the dwelling.

As to their morals, within the precincts of their habitations, I have reason to believe they have not much to boast of, although they are described, by Agüeros and other writers, as most innocent, and well-conducted. Agüeros speaks highly of their character; and cites Padre Ovalle, who, writing upon Chilóe, between the years 1629 and 1636, says: "The natives of these islands are the most docile and noble (dociles y nobles) of all Chile, and are the least given to drunkenness, and other vices; therefore they are best disposed to be edified by the light of the Gospel."

Since the province became subject to the Chilian Republic,

© The Complete Work of Charles Darwin Online

the government has made several attempts to improve the condition of the inhabitants; among which, the instruction of public schools, was not the least important. From an official report there appear to be ninety schools, in which 3,840 children receive an education, according to the abilities of the masters, who are employed; but these, from the small salary attached to the situation, cannot be expected to be superior.

The language in common use, is Spanish; the original Indian tongue being almost forgotten: but it is supposed to be the same as that spoken by the Indians of Madre de Dios; for, on a late occasion, a whaler which had been upon the coast of those islands, and had taken on board an Indian, as a pilot, called at Castro; and during her visit, the Indian communicated with those who understood the language of the Chonos, and by them was tolerably well understood. This Indian has been frequently embarked on board American or English sealers, which frequent those coasts, to serve as a pilot to the seal-rookeries.* He is known by the name of Dan.

The products of the island, for the year 1828, according to the census, and returns, officially made, were—

Wheat.. 64,935 fanegas (175 lbs. in a fanega) about 200,000 bushels.
Barley.. 21,645.
Potatoes 194,805.

and the muster of stock, and apple-trees, as follows:—

Horned cattle	5,411 head.
Sheep	86,580
Swine	21,645
Apple trees	75,754

The manufactures of the province are Carro, a coarse woollen cloth, two and a half, or three yards long, and three quarters of a yard wide, used for men's garments, and of very durable quality.

Ponchos—both these and the carro are manufactured by women, in a rude sort of loom, of wool dyed of various colours from plants that are found in the island, or imported for the

* Places where seal congregate—so called always by the sealers.

© The Complete Work of Charles Darwin Online

purpose. Of the latter indigo is much used, and it is the general colour for the ground-work of the ponchos.

Frezadas, bordillas, sabanillas, mantillas de lana, blankets or rather counterpanes of different textures, are also among the manufactures: none of the above are exported, being made merely for their own use.

Cables, hawsers, and rope, they make of a plant, called Quilineja, which is supposed to be the root of a species of *Callixene*.

No wine or spirit is made in the province, but Chicha (a very good cyder) is manufactured from apples. The only other fruit produced is the 'Frutilla,' a kind of strawberry.

The exports must very nearly amount to the value of foreign imports, which consist principally of sugar, wine, brandy, salt, wearing apparel, and household furniture. The import duty on European and North American produce is twenty-seven per cent.; from which, however, some articles, such as arms and munitions of war, instruments of music, and other things of less importance, are exempt. Spirits of all kinds, foreign wines, tobacco, tea, and cards, are monopolized by the government, and sold at an immense profit. The unauthorized sale of these goods is declared illegal, and is punishable by a heavy fine, and sequestration of goods.

The exports, during the year 1828, consisted of wood in beams, planks, and boards; hams, wheat, a small quantity of dried fish, fire-wood, and brooms,* to the amount of 52,320 dollars, of which 35,683 dollars were for wood, and 10,887 for wheat. These articles were exported in sixteen vessels under national, and eight under foreign flags. The exports are said to be increasing very much. In the year 1791, Agüeros describes the exports of alerse planks (tablones) to Lima, to be between fifty and sixty thousand in number; and some years previous to have been in a much greater quantity. The number of alerse boards exported, during the last year, was 328,928, but of planks only 2,623.

The island, and neighbouring part of the main land, produce

* Potatoes are not mentioned in the report, yet they must have been exported in considerable quantities.

© The Complete Work of Charles Darwin Online

a great abundance, as well as variety, of wood fit for exportation, as well as home consumption. The following is a list of the principal trees, with their qualities, and the use to which they are most adapted.

Avellana (*Quadra heterophylla*), a handsome tree, in appearance like the ash of Europe, of a light wood, which shrinks very much when dry, and may be used with advantage for oars, being light, strong, and springy, as well as for planking small vessels below the water, and for the ceiling within; it is bad for firewood, being too light. The seed is a nut, about the size of a cherry, the kernel of which is roasted and eaten. The tree abounds at Concepcion, and in the country to the south, and grows on the Peninsula of Lacuy.

Roble (*Fagus obliqua*, Mirb.), a large tree; and, from the durable quality of its timber, considered the best in the island, for ground-frames of houses, planks for vessels, and beams. The piraguas are built chiefly of this wood. There are two sorts, one an evergreen, and the other a deciduous-leaved tree. It is evidently a beech, and the same that grows in all parts of the Strait of Magalhaens; the smooth-leafed sort is *F. obliqua* of Mirb.—see Bertero, in Mercurio Chileno, No. 14, p. 640.

Tiqui, heavy wood; but esteemed strong and durable. Piraguas are sometimes built of it.

Laurel, used for house building in-doors, for beams and rafters, and posts; durable when not exposed to damp, in which it soon perishes.

Mañu, a tree of great dimensions, tall and straight, the leaf is like that of a yew; it is a very useful wood in ship-building, for planks, and, next to alerse, is the best for spars which the island produces; but the large trees have a great tendency to become rotten at the heart, owing possibly to the humidity of the climate, and to the very wet soil.

As the Adelaide wanted a mast, I sent her round to Castro for a mañu spar, for which I agreed to pay eighty dollars; but of twenty trees that were cut down, not one was sound at the heart. The wood is heavy, with large knots, which penetrate into the trunk to a great depth. A great deal of this timber grows in the Gulf of Peñas.

© The Complete Work of Charles Darwin Online

Muermo. There is no wood produced on the island more useful than the muermo. It is used for timbers, and knees, and all other purposes of ship-building: and is excellent for the planks of boats, as it bears wet and dry without suffering from either. It is abundant, and much used as firewood, for which it is well suited.

Luma (*Myrtus Luma*), a very tough and useful wood, used for tree-nails, for stakes in fencing, for rafters in the roofs of houses; and is exported in large quantities to Lima, for shafts and poles of carriages. The fruit is sweet, and might yield a strong spirit; it is called cauchao.

Ciruelillo, a small tree, used only for washing-bowls and boxes; it is of little value.

Quiaka. Of no value.

Tapu, a very crooked tree, growing along the ground in swampy places. It might serve for floors, and timbers for small vessels; but it is not used, from its being so very hard.

Tenu, something like muermo, and considered a good wood.

Peta, a species of *Myrtus*, of which hoops for barrels are made.

Ralral, considered to be like the wood of the walnut-tree, and of general use, on account of its toughness and durability; it is made into blocks for ships.

Meli, more tough than luma: of this the country people make pick-axes, for cultivating the ground (Agüeros, p. 127).

Pelu, also tough; useful for axle-trees and gun-carriages (Agüeros, p. 127).

Mayten, useful for turning; and lasts long under water.

The above mentioned are produced on the island; but the two following, alerse and cypress, are from the main-land, in the neighbourhood of the Cordilleras. They are not only in general use in Chiloé, but are exported in large quantities to all the ports to the northward. The alerse, near Chiloé, is of better quality than that which comes from Concepcion.

The Cypress is brought to the island in 'tablones' (or planks), seven or eight feet long, two inches thick, and nine or ten inches wide, as is also the alerse; but the latter, from the facility with

© The Complete Work of Charles Darwin Online

which it splits, is brought in boards also, four feet long, half an inch thick, and six inches broad, which, as I have before remarked, are the principal articles of barter.

The Alerse is found in great quantities near Calbuco; but at so great a distance from the beach that it cannot easily be conveyed thither for embarkation, except in the above form. The tree is cut down and squared, then hewn by the axe into as many logs of seven or eight feet long as it will afford; and these, with the assistance of iron wedges, are split into planks and boards, in which state, without being further trimmed, they are tied together in bundles, and carried on men's backs, or dragged over the ground to the beach.

The extraordinary straightness of the grain of this tree enables the natives to split it, so as to make it appear as if it had been dressed with an adze, or even with a plane; but, as I have said, the axe is the only instrument used. So great is the difficulty of obtaining a spar of this wood, that when I wished to procure a new mast for the Adelaide, I offered four times the value of an alerse spar to the natives, besides the assistance of twenty men, and tackles, &c. to assist in conveying it to the beach. The temptation was almost too great to be withstood; but the man to whom I applied, who had before been employed to get masts for a schooner in the Chilian service, and a flag-staff for the town, said that it would take his own party two months to bring one to the beach: with the assistance of our people, however, it might be done in a month. The trees were distant, and there were two or three ridges of heights to cross, that would cause much delay. The facility with which these people usually handle timber was a sufficient proof to me that such a task, if refused by them, must be very difficult indeed, and I gave it up, as the Yntendente was so obliging as to give me the flag-staff, which had taken the same party two months to procure.

The Hoxsley, a national schooner, built at Chiloé, for the government, was masted with alerse spars, which proved to be very strong.

Alerse is used principally for the floors, partitions, and

© The Complete Work of Charles Darwin Online

weather-boards of houses, also for shingling the roof; for which purpose it is very superior and durable: after exposure to the weather it turns blue, and has the appearance of slate. It does not shrink or warp; and though brittle, is of a very close grain, and well adapted for furniture. Of this wood the country people make staves for casks; and the bark of the tree is used for caulking the seams of vessels, for which it answers remarkably well, being extremely durable when constantly wet, though it soon decays when exposed to the sun and air.

Spars of alerse, eighty or ninety feet in length, may be procured; and from eight hundred to a thousand boards are frequently obtained from a single tree. I was told that as many as one thousand five hundred have sometimes been cut out of one trunk. Alerse is found on the island, but not of any size. It is also common in the Strait of Magalhaens, in all those parts west of Cape Froward; but there, from the poverty of the soil, it is of very stunted growth.

The cypress is thought to be a different tree, but I rather imagine it to be only a variety; the wood being white, whilst that of the alerse is of a deep red colour. As the trade of the island is principally carried on by water, roads are seldom used for that purpose, for which, indeed, the few that exist are far from being convenient. Between San Carlos and Castro there is a road cut through the forest, forty or fifty feet in width, in the middle of which is a causeway, four or five feet wide, formed of logs of wood, laid transversely. This is the only way of communication, unless, which rarely occurs, the weather has been dry during some days; for, off the causeway, there is a mere bog, in which a horse frequently sinks up to the girths in mud. In many parts of the causeway, indeed, where the logs have decayed, and have not been repaired, the passage is equally bad, so that in wet weather, only persons without a load are able to pass. For the greater part of the way, the trees on each side prevent an extensive view; but on approaching within five or six miles of Castro, the country becomes more open, having been cleared by cultivation, and there, of course, the road improves.

© The Complete Work of Charles Darwin Online

There is a track branching off from the main road to the district of Dalcahue; but on it, I believe, there is no causeway.

As the only mode of supplying the town of San Carlos with provisions is by water-carriage, it is frequently ill supplied during winter, when N.W. winds prevent the arrival of the piraguas. A southerly wind for two days, at that season, brings from fifty to a hundred piraguas from Dalcahue and Castro, laden with hams, potatoes, pigs, grain, fowls, calves, dried fish, and charcoal, which are sold at a cheap rate, paying one-tenth to the government.

The arrival of so many piraguas at San Carlos creates no slight bustle in the neighbourhood of the mole; and a stranger happening to arrive at the time would think it a place of considerable trade; the return, however, of the N.W. wind, with all its attendant "vapours, clouds, and storms," very soon dispels the illusion: the piraguas depart, one after another, and in two days all is dull and monotonous.

These piraguas, the boats used by the natives of the archipelago of Chiloé, are all similar in form and material; but vary much in size, according to the voyage they have to perform. The largest are from thirty-five to forty feet long. The head and stern are alike, and resemble those of a whale-boat, being sharp at both ends. The transverse section is that of a thick wedge, so that they have no bearings, and must be extremely unsafe,(*v*) particularly with so lofty a sail as they hoist; and yet these vessels have made long, and even dangerous passages, as is fully attested in Agüeros's account of the missionaries' visit to the archipelago southward of Tres Montes. These boats are literally sewn together, there is not a nail used in their construction; every portion of the hull is of a vegetable nature. The lower, or garboard strake, is sewn to the keel by strips of the stem of a creeping plant, called Pepoi,* and the seam is caulked with bark of the alerse, which, while under

(v) When moderately laden they are stiff under sail; and are not such very bad sea-boats, if properly managed.—R. F.

* Molina, i. 167. A species of 'Dolichos.'

© The Complete Work of Charles Darwin Online

water, is admirably adapted for the purpose. The upper planking consists of three or four broad boards on each side, sewn together, and their seams caulked. The wood of which they are made is the roble, or sometimes tiqui.

Agüeros's description of the construction of a piragua cannot be improved. "They are constructed of five or seven planks, each of which is from two to four fathoms long, half or three-fourths of a yard wide, and two or three inches thick. These are fashioned, or worked, narrow at each end, so as to form the bow and stern, and afterwards are exposed to the fire, in order to burn the outer surface on both sides. To unite these planks, they bore or burn holes, two inches from each other, along the edges of the planks, through which they sew them together with a rope of solid reeds (soquillas), or twisted cane (coligues), forming a junction as close as a seam of cloth. To prevent water from passing through the seams, they apply along the plank, within and without, pounded leaves of trees, over which they pass the stitches, and with the same preparation of leaves the holes are filled up. Thus constructed, it is in appearance a perfect boat, or vessel, but without keel or deck. That they may resist the pressure of the water, and retain their shape, curved pieces (curbas) of wood, called 'barrotes' are fitted inside, and fastened by wedges of wood, instead of nails. For all this, they are dangerous; and, since their sails, oars, and other furniture are very inferior to what boats require, they are much exposed to be easily sunk, and the risk is greatly increased by want of care and management in those who navigate them."

In the above description Agüeros has given a very good account of the rude manner in which they are built, and has not in the least magnified the danger attendant on their use. It is, indeed, a miserable and unsafe vessel; and for the rudeness of its construction, and the poverty of its equipment, is a perfect prototype of the crew which it conveys.

The largest have from eight to ten people, each of whom furnishes one poncho, and the 'patron,' who steers, and directs

© The Complete Work of Charles Darwin Online

the course and all their movements, provides two ponchos, all which are sewn together to form their sail, which is hoisted by 'lazos,' or thongs of bullock's hide.

These sails are generally in a wretched state, the name Santisima is applied to them all by the crews, with the hope of securing the protection of their patron saint. The anchor is of wood, formed of four crooked pieces, in the shape of a grapnel with four flukes, at the bottom, or crown of which a large stone is fastened, to increase its weight. The crews are exceedingly timid, and instead of making exertions to extricate their vessel from any impending danger, they throw themselves on their knees, beating their breasts and calling loudly upon their saint, for 'misericordia.'

I was given to understand that very few of them can swim, which seems extraordinary, since they are born and bred in the immediate vicinity of the sea, and depend chiefly upon its productions for subsistence. The fact speaks strongly for the indolence of their character, even although the rigour of the climate forms a bar to bathing as a mere amusement. Several piraguas were lost while we were at Chiloé, and, as may be inferred, their crews were all drowned.

With regard to the cultivation of land, they are very far behind, and, comparing the present state with the description of Byron (1740), and of Agüeros (1791), very little improvement seems to have been made. The ground is prepared by make-shift ploughs, of a very rude construction. Two poles of hard wood (luma), about three yards long and proportionably large, trimmed to a sharp point at one end and rounded at the other, are held by the middle, one in each hand, and pointed very obliquely into the ground; in this direction they are forced forward, by pressing against the blunt end with the abdomen, which is defended by a sheepskin, suspended in the form of an apron. After these have penetrated twelve or fourteen inches into the soil, a second person, generally a woman or a boy, places a stout stick under the poles, or 'lumas,' as they are called, close to the earth, to form a solid support for them.

The large ends are then forced down, the ground turned up, and the lumas pushed forward again, while the woman uses her stick to turn the clods over, to the right and left, alternately. These clods are afterwards broken up by a wooden tool, in the shape of a pick-axe, called 'hualate,' made of the wood named meli. Rude as this process is, the operation is rapidly performed, and I have seen a field, ploughed in this way, that would not do much discredit to an expert ploughman with a European plough.

The soil is a rich, sandy loam, of a dark red colour; and although rarely, if ever manured, produces fair average crops. According to the usual allowance of 175lbs for a fanega of wheat,* the weight of a bushel would not be more than 51$\frac{1}{2}$lbs., which shews that the grain is but poor. Wheat is sown in the month of April, and cut in the same month of the following year; but from the humidity of the climate, and constant rain, particularly at that season (the commencement of winter), it is frequently reaped before it is ripe, and almost always gathered in wet. Every subsequent sunny day is taken advantage of, to dry the grain, but a part must be spoiled by mildew. The evaporation, however, is so great, that merely moving it about, and keeping it thinly strewed in granaries, will effect much. It is trodden out by oxen, and to clean it, the grain is thrown up in the wind by means of broad wooden shovels, and effectually separated from the chaff. This rude winnowing takes place frequently in the principal streets of San Carlos, and even at the mole, where one would suppose that a great deal must be lost; but from the adroitness of the operation, it is not only well cleaned, but suffers no diminution.

Potatoes are planted in September, October, and November, and are fit to dig up in May.

Of the proceeds of harvest, one-tenth is paid as a tribute, or

* The fanega weighs 175 lbs. and contains twelve almudes, which being cubic measures of eight inches and a half, contain each 614·125 cubic inches; therefore a fanega contains 7369·5 cubic inches, and as an English bushel contains 2150·4 cubic inches $\frac{2150{\cdot}4 \times 175}{7369{\cdot}5} = 51\frac{6}{10}$ lbs. the weight of a bushel.

© The Complete Work of Charles Darwin Online

tax, to the government; but forced contributions may be required, when the necessities of the state demand them. These contributions are sometimes unfairly levied in Chile; for the subsidy is only taken from those who possess grain, or some equally tangible article which can easily be turned into money; so that persons who are rich enough to live without cultivating land, or trading for their support, contribute nothing towards the emergency of the State. How does this accord with republican principles? or how can a republican government, so conducted, expect to become respectable among nations?

I am not aware that such contributions have yet been levied in Chiloé. From the character of General Aldunate, I do not for a moment think he would commit such an act of injustice; but it is in the power of any Yntendente to call for them, and I afterwards witnessed an example of this, during my visit to Concepcion. A considerable quantity of wheat, purchased by a Russian vessel, for the use of their settlements on the coast of California, was brought down to the port, at a time when the government was much in want of money, and knew no just way of obtaining it. They therefore very unceremoniously seized the wheat, and applied its value in dollars to their own use, giving only an uncertain, almost a nominal security to the owner for the recovery of his money. The only way of accounting for such an arbitrary proceeding is, that the country was distracted by civil war, and that the person who owned the property was opposed to that party, which at the time happened to have the upper hand, and which held, by main strength alone, the reins of government.

Among the birds of Chiloé, the most remarkable are the 'Cagge,' the 'Cancania,' or 'Canqueña,' and the 'Barking bird.'*

* Molina notices the 'Cagge,' or 'Chiloé duck,' (*Anas antarctica*) vol. i. p. 268, and calls it *Anas hybrida*. M. Lesson, in his 'Manuel d'Ornithologie,' ii. 409, has taken great pains to describe it, and remarks, with reason, that much obscurity exists in the specific descriptions of the goose kind in the Malouine (Falkland) Islands, and the extreme southern land of America. The male, Lesson says, is white, the feet and beak of a bright

© The Complete Work of Charles Darwin Online

The shell-fish,* for which this island is justly famed, are principally brought from Calbuco, and consist of the finest

a bright yellow colour. All the specimens that we saw, and numbers were killed by us, had a black beak with a red cere—otherwise M. Lesson's description is correct. In many specimens, however, we found the tip of the primary wing feathers black, which is not to be wondered at when the colour of the female is considered, but which it is not an easy task to describe. M. Lesson, I think, has done it justice in a note to his vol. ii. p. 409:—"Anas antarctica. A capite griseo, genis gulo colloque albo et nigro acuti-striatis; oculorum circuitu nudo: pectore abdomineque omninò atris, atque vittis niveis notatis: tectricibus alarum nigris; dorso uropygio caudâ et ano albis; alis niveis cum speculo lato virescente, brunneo marginato; pennis longis aterrimis; rostro et pedibus, aurantiacis."

These birds are very common in the Straits of Magalhaens, and every where on the west coast between the Strait and Chiloé; also at the Falkland Islands.

The *Cancania* (or *Canqueña*) is the *Anas Magellanica*, *Anser Magellanicus* (Ency. Méth. p. 117). From Buffon's description, and a well-drawn but badly-coloured figure, in the Planches Enluminées, No. 1006, I have no hesitation in assigning it to that kind. The colour of the head, however, instead of being 'reddish purple,' is cinereous with a reddish hue; the feathers of the sides and thigh covers are white, with five black bars, the extremity being white; the central portion of the abdomen is white; the speculum of a splendid shining green. This bird is common to the Strait as well as to Chiloé, and is probably Byron's 'Painted Duck,' and the *Anser pictus* of the Ency. Méth., p. 117. M. Lesson considers *Anas leucoptera*, Gmel. as the male of *Anas Magellanica*, which may be doubted. The 'Barking Bird,' as our sailors called it, was first brought to me by Capt. Stokes, having been shot during the Beagle's visit to Port Otway, in the Gulf of Peñas. It was an imperfect specimen; but Mr. Tarn afterwards obtained for me several others. It seems to have a great affinity to the genus *Megapodius;* but no specimens of that genus being in England when I was last there, and the Barking Bird differing in essential points from M. Tenminck's description of the genus, and from the figured specimen of *Megapodius Freycinettii;*—particularly in the length and form of its wings, which are rounded, and so short as not to reach beyond the base of the tail;—also in the emargination of the upper mandible;—I have been induced, by Mr. Vigors' advice, to form it, provisionally, into a new genus, termed *Hylactes*. (See Proc. Zool. Soc., vol. i. p. 15.) There is another specimen in our collection (now in the Zoological Society's Museum), which will probably be placed in this genus, but there existed some uncertainty in essential points, which prevented my describing it before I left England.

* Among the numerous testaceous productions is a small shell, which

© The Complete Work of Charles Darwin Online

muscles, of which there are two sorts: the Choro (*Mytilus Choras*, Molina), and Cholgua (*Mytilus Magellanicus*, Lamarck), Picos (*Balanus psittacus nob. Lepas psittacus* Molina, 1, p. 223), a large barnacle,* and the oyster (*O. Edulis*), which is exceedingly well-flavoured. Besides which there are several kinds of shell-fish of less value, but equally abundant, such as Navajuelas (*Solen sp.*); Caracoles (*Turbo*); Cornes (*Pholas Chiloensis*, Molina); Campaña (*Calyptræa*); Lapas (*Crepidula*); Tacas (*Chama Thaca*, Molina); Locos (*Concholepas Peruviana*, *Murex Loco* of Molina); Quilmagues; Piures (*Pyura sp.* Molina); and others.

The apparently inexhaustible abundance of shell-fish with which nature has provided the inhabitants of these islands, the facility with which they are obtained, and their consequent cheapness, is the principal cause of that want of industry which is so remarkable in the Chilotes.

Of the above-mentioned shell-fish, those deserving more particular notice are the large muscle, the oyster, and the pico.

Molina has described the choro of Concepcion, which is not at all different from that of Chiloé. It is often found seven or eight inches long. The fish is as large as a goose's egg, and of a very rich flavour: there are two kinds, one of a dark brown, and the other of a yellow colour; but the last is most esteemed. There is also another sort, much larger than the choro, yet equally delicate and good, the fish of which is as large as a swan's egg: it is called cholgua; but as the shells seem to be of the same species, I think the distinction can only be owing to size. In Febres's Dictionary of the Chileno language, the word

constitutes a new genus. *Marinula*, nob. in Zool. Journal, vol. v. p. 343. It was found on the wooden piles which support the mole in the bay of San Carlos, below the wash of the high water. The mole stands out into the sea, and there is no fresh water near it, save a very little rill, which discharges its tiny stream more than fifty yards off. This shell was named *Marinula Pepita*, Zool. Journal, l. c. No. 43. The following is its generic character:—'Testa ovato-producta, sub-solida; apertura ovata, integra; columella bidentata et basin versus uniplicata; dentibus magnis subremotis conniventibus, superiori maximo; operculum nullum.'

* Zool. Journal, vol. v. p. 333.

© The Complete Work of Charles Darwin Online

cholchua is rendered into Spanish by "cascara de choros blancos," or shell of the white muscle. Cholhua, or cholgua (the letters g and h are indiscriminately used), must be a corruption; for it is now used in Chiloé to distinguish the large from the small choros.

The manner in which the natives of these islands, both Indians and descendants of foreigners, cook shell-fish, is very similar to that used for baking in the South Sea Islands, and on some parts of the coast of New Holland. A hole is dug in the ground, in which large smooth stones are laid, and upon them a fire is kindled. When they are sufficiently heated, the ashes are cleared away, and shell-fish are heaped upon the stones, and covered, first with leaves or straw, and then with earth. The fish, thus baked, are exceedingly tender and good; and this mode of cooking them is very superior to any other, as they retain, within the shell, all their own juiciness.

The oyster, which is a true *Ostrea edulis*, is found in beds, at low water, or taken with the dredge. It is about the size of the native oyster of England, and not at all inferior to it in flavour. In Agüeros's account of Chiloé, he notices this excellent shell-fish; but remarks, that the islanders are ignorant of the value at which it is appreciated. It is rather curious, that, excepting in the neighbourhood of Chiloé, the oyster is very rarely to be met with on the South American coast, while there it is in the greatest abundance. We have never observed any shells of this fish anywhere between the river Plata and Chiloé; nor is it known elsewhere upon the western coast, I believe, to the southward of Guayaquil, which is very near the equinoctial line.* The oyster-shells at Port San Julian are fossils. Of the Linnæan genus, Ostrea, there are many sorts, on all parts of the coast, both east and west, but they are what we call the pecten or scollop. At Coquimbo, a species of scollop is much used as an article of food, and called oyster; but it has no further right to the name than because Linnæus classed them all as *Ostrea*, and Molina describes this to be *Ostrea edulis*.

* Some have since been found on the north-east side of the Guaytecas Islands.

© The Complete Work of Charles Darwin Online

The pico, which is a barnacle, grows to a very large size; at Concepcion, however, it is still larger, being six or seven inches in length. It has, when properly cooked, very much the flavour of a crab, and by the inhabitants of this Archipelago is considered preferable to any other shell-fish.

Before concluding this imperfect description of the shell-fish of Chiloe, the piure claims some consideration, if it be only for its peculiar and disagreeable appearance. It was considered by Molina as a genus allied to *Ascidia* (Mol. i. 214), none of the varieties of which are inviting in their look, as an edible substance, but the piure is still less so. It is thus described by Molina: "The piure, scarcely deserving the name of a living animal, is as remarkable for its figure, as for the manner in which it is lodged. The body is about the size and shape of a small pear, an inch in diameter; or it may be described as a small, conical, fleshy bag, of a red colour, filled with saline liquor, and provided with two trunks or processes in the upper part, one of which is the mouth, similar to that of the Tetias; and between these processes are seen two small, black, and shining points, which are supposed to be the eyes. I could distinguish no other organs, nor any viscera in the fleshy substance of which it is composed, which is smooth without and spongy within. They are extremely sensitive, and when touched, spout water out of both apertures. These small animals are shut up in a firm, but glutinous case, of various shapes; one case often contains eight or ten distinct bodies, separated from each other by cells, formed of a strong membraneous substance. They are attached to rocks or stones, under water, excepting when left uncovered by a low tide. The natives eat them boiled, or roasted in their shells. They also dry them for exportation to the province of Cusco, where their flavour is much esteemed, and considered equal to that of the lobster."

At Chiloe, the piure is said to be a remedy for barrenness; and to such an extent has this idea prevailed, that a Chilote woman, eating this fish, literally says, if asked what she is doing, that "she is making children." One would not, however, suppose, from the number of children which are seen

© The Complete Work of Charles Darwin Online

crowding round the doors, that the Chilotes had any necessity for such food.

If one may judge from the few applications made to our medical men for advice, the climate is either very healthy, or the natives prefer their own mode of cure. They have very few medical advisers, and those few are not held in much estimation, being people of little or no education. A prejudice against medical men has been, even in late years, extended to foreign practitioners, and carried to great lengths. This illiberal feeling is, however, fast wearing away; but, among the lower orders, the application of herbs and other simples is yet wholly resorted to for the removal of their complaints. One day, when I was employed in making some astronomical observations, at Sandy Point, a woman passed me, and forcing her way through a thicket of thorny plants, began to gather branches of a species of arbutus (*A. rigida.*), a small shrubby plant, which is every where abundant, especially to the south, and in the Strait of Magalhaens. My curiosity prompted me to inquire her reason for collecting it with such apparent anxiety. She replied, with a desponding air, "It is chaura* for a poor, sick child. These branches," she said, "are to be put into the fire, and, being green, will produce a thick smoke, and yield a very strong aromatic smell. The child, who is only five months old, is to be held over it, which, as they say, is a good remedy; but," she added, with an air of doubt, "I know not (dicen que es bueno, pero yo no sé)." "Who says so?" I asked. "Los que saben (those who know)," replied the half-credulous mother, with a deep sigh, partly doubting the efficacy of the remedy, but unwilling to lose the advantages of whatever virtue it might possess, for the benefit of her sick infant.

The climate of Chiloé is considered, by those who live in other parts of Chile, to be "rigorous, cold, and damp." Certainly there is much reason for such an opinion, particularly in the winter months, when it almost always rains, and the wind, with little cessation, blows hard, from N. to N.W., and,

* Chaura. Una murta que no se come. Febres, Dict. of the Chileno language. It is, however, edible, and has rather a pleasant flavour.

© The Complete Work of Charles Darwin Online

by the W. to S.W.; but notwithstanding the great quantity of rain that falls, the evaporation is great, and it cannot therefore be called unhealthy; indeed, from experience, it is considered quite otherwise. Agüeros, to whose excellent account of Chiloé I have so often referred, dilates much upon this subject, and from having resided there a considerable time, may be taken as the best authority. Those who now reside upon the island speak very much against it, and all whom I met, previous to my visit, condemned it, as being "the worst in the world." Perhaps we, who had lately been experiencing a much more disagreeable climate, went to Chiloé with the expectation of finding it exceed in severity that to which we had been accustomed in the Strait of Magalhaens, but we found ourselves agreeably mistaken. Our visit certainly was in the better season, and we had, perhaps, no right to form a decided opinion upon the other part of the year. I shall, therefore, first quote Agüeros, and then describe what we found the weather from September to December; yet as these months were considered by the inhabitants to be finer than is usual at that season, we can only form a vague idea of the spring and summer. For the autumn and winter I must depend upon the accounts of others.

After explaining the contra-position of the seasons, to what is experienced north of the equator, with regard to the months of the year; Agüeros says, "Chiloé has also its four seasons, but does not enjoy the benefit of those changes, as do other parts of Chile; for there is neither that abundance of fruit, nor are its fields adorned with so many and such beautiful flowers, and useful medicinal plants. The summer is the best time; for in the month of January, from ten o'clock in the morning till three in the afternoon, the heat is excessive. Between these hours, however, a sea-breeze, which is called 'Vira-zon,' refreshes the air. In the winter the temperature is very cold; but the frosts are by no means so severe as in Europe. I have never seen ice, even in the small streams, nor does snow lie any length of time on the ground.

"In the winter months, as well as in other parts of the year, there are falls of rain, and heavy gales from N.N.W., and west,

© The Complete Work of Charles Darwin Online

which last frequently for the whole moon, with scarcely a cessation, and the wind, at times, is so furious, that the houses are not secure, and the largest trees are torn up by the roots. The weather, when it is fine, cannot be depended upon for any length of time; not even in summer; for in the month of January I have frequently experienced gales, and rain, as severe and copious as in the winter. During the summer months southerly winds are more prevalent, and, while they last, the weather is fine, and clear, and the air particularly dry.

"Although the winter months, and a considerable part of the other seasons, are very disagreeable, owing to the severity of the winds, and exceeding quantity of rain, it cannot be denied that the climate is healthy. In Chiloé no epidemic diseases are experienced. The small-pox and measles are not known;* nor have tertian fevers, so common in the north, ever been experienced on the island. Spotted fever (tabardillo), and acute pains in the stomach, are the only disorders to which the inhabitants of this archipelago are subject. Thunder and lightning are rarely experienced; but earthquakes have occurred at intervals. In the year 1633 the church and houses were destroyed, and in the year 1737 much damage to the village of Isla grande was caused by earthquakes."

So far Agüeros. On the whole, the climate is not so unfavourable as we had been led to expect from all that we had heard.

Captain Fitz Roy arrived there in July, during the latter part of which, and the month of August, the weather was very wet, with some heavy gales from the N.W.; but in his Meteorological Journal for those months there is no record of the thermometer falling below 38°, and it is recorded to have fallen to that degree only on one occasion, the general height being from 45° to 50°. The first part and the middle of September were boisterous and wet; but towards the end of the month the wind was chiefly from the southward, and the weather dry and

* The small-pox was introduced into the island, in the year 1776, by a ship from Lima; but it was confined to San Carlos, and was soon eradicated. The measles also were introduced by similar means, in the year 1769; but did not re-appear after once ceasing.

© The Complete Work of Charles Darwin Online

extremely fine. In October it was rather changeable; but for the last ten days, with the exception of one, on which there was a fresh gale with a heavy fall of rain, it was fine and dry, and the winds were moderate.

The month of November was generally fine, but the first half of December continued tempestuous and wet. The mean temperature of the months, and other meteorological remarks, are as follows:

1829.	Months.	Temperature. Mean at 9 A.M. Air.	Temperature. Mean at 9 A.M. 3 P.M. water at anch.	Temperature. Ex. of Temp. Max.	Temperature. Ex. of Temp. Min.	Pressure reduced to 32°. This table partly shows the state of the weather during three spring months. The greatest quantity of rain in the gage at the end of the month of November did not exceeed 2·6 inches. At St. Martin's Cove, near Cape Horn, after thirty days' observation, the rain-gage contained eight inches; so that although Chiloé bears the character of being a very wet place, it is not one-third so bad as Cape Horn. The time of our visit to San Carlos was certainly the finest part of the year; and I believe that the weather we experienced was unusually dry even for the season; therefore, the above table does not present a fair criterion of the climate: I do not, however, think it is by any means so bad as has been represented.

CHAPTER XVII.

Chilóe the last Spanish possession in South America—Freyre's Expedition—Failure—Second Expedition under Freyre and Blanco—Quintanilla's capitulation—Chilóe taken—Aldunate placed in command—Chilóe a dependency of Chile—Beagle sails to sea coast of Tierra del Fuego—Adelaide repaired—Adelaide sails—Adventure goes to Valparaiso—Juan Fernandez—Fishery—Goats—Dogs—Geology—Botany—Shells—Spanish accounts—Anson's voyage—Talcahuano—Concepcion—Pinoleo—Araucanian Indians—Re-enter the Strait of Maghalhaens—Fuegians.

The island of Chilóe was the last place the King of Spain possessed in South America; and even to this day he is not without friends there, who would gladly restore his absolute monarchy, notwithstanding the advantages that are acknowledged to have been derived from the change of masters, and the consequent opening of trade, which has added very much to the comfort, as well as civilization of the inhabitants.

During the struggle for independence, this island was too distant from the seat of war to render it important; but when all other parts of Chile were freed from the king's troops, the new government despatched an expedition, consisting of between three and four thousand men, commanded by the Director-General Freyre, to attack it. Upon the appearance of this expedition off the harbour of San Carlos, the Spanish governor, Quintanilla, was inclined to capitulate; but, instead of anchoring in the roads, the squadron proceeded to Chacao, landed troops there, and despatched some of their forces to Castro, where they were repulsed by the Spanish and native troops, and obliged to re-embark. In this interval, one of the ships left the squadron, and returned to Valparaiso, whence she was immediately ordered back; but meanwhile the Director had embarked his troops, and returned to Concepcion. Not long afterwards, in January 1826, a second expedition, under the same general, sailed from Valdivia, convoyed by a strong squadron, under the command of Admiral Blanco.

© The Complete Work of Charles Darwin Online

"Upon this occasion the troops landed, on the 8th, at the little inlet of the Bay of Huechucucuy; and Fort Corona was immediately taken. On the 10th, the disembarkation of the troops was completed. A battalion was left to mask Fort Aguy, while a force, under Colonel Aldunate, passed on, and took the battery of Barcacura. On the 10th, Admiral Blanco shifted his flag; and, leaving the O'Higgins outside, stood into the bay with the rest of the squadron, which anchored off Barcacura.

"The governor, Quintanilla, with upwards of three thousand Royalists, took up a strong position on a hill, at the S.E. side of the bay, flanked on the left by an impenetrable wood, on the right by the shore, and supported by three gun-boats in shallow water. These were taken by the boats of the squadron, under Captain Bell, and turned against the Royalists. Their position was thus enfiladed, and they retired. Freyre then advanced: some skirmishing took place: Quintanilla capitulated; and the territory of Chile was no longer sullied by the Spanish flag.

"Colonel Aldunate, Majors Maruri, Asagra, and Tupper (a native of Jersey); and Captain Bell, of the navy, greatly distinguished themselves."—Miller's Memoirs.

Colonel Aldunate was afterwards invested with the government of the island; but, owing to the disaffection of the troops, who were urged on by the King of Spain's agents, a revolution took place, Aldunate was imprisoned, and afterwards sent to Valparaiso, and the Spanish flag once more waved in Chilóe. It was, however, for a short time only; Aldunate was despatched once more, and with a small force of three hundred veteran troops, headed by Colonel Tupper, and accompanied by the Aquiles, brig of war, again obtained possession of the island, which he has since kept, though not quietly, for the Royalists were constantly on the alert, and made several futile attempts to recover the place for their king. Time has now reconciled the greater number to the change; and, I believe, Chilóe may be considered a contented dependency of the republic of Chile.

© The Complete Work of Charles Darwin Online

The Beagle being ready to resume her voyage, sailed on the 19th of November to survey the southern coasts of Tierra del Fuego; after which, she was to rejoin the Adventure at Rio de Janeiro.*

As the Adelaide had received some damage in getting aground, it was requisite to lay her on the beach for examination and repair. Her mainmast, also, was found to be sprung so badly, as to render a new one necessary; which we should have found much difficulty in obtaining, but for the kindness of General Aldunate, who, finding that we were at a loss, proposed to give us the flag-staff of the town, a beautiful spar of alerse, that was in every way suitable. Previously, however, to accepting his offer, being aware that such an act might expose him to much reproach from the people of the town, who were all very proud of it, I caused inquiry to be made whether a spar of the necessary dimensions could be brought from Calbuco; and in the meantime we proceeded with the repairs.

A creek behind Sandy Point offering every convenience for heaving her down, the Adelaide was moved into it, and laid on the beach. On stripping her copper off, the injury proved to be considerable; but not beyond our means to repair. Upon examination, the foremast was found to be in a bad state, but could be rendered effective by fishing it with the sound portion of the other mast, therefore our only real difficulty was to get a mainmast. From the account I received from Calbuco, I found that, without a great delay, not less than two months, and sending a portion of our people with ropes and tackles, there was no chance of procuring a spar: it could only be obtained at a considerable distance from the shore, and when felled must be dragged over several high ranges of hills, which might be called mountains, before it could be got to the water-side. General Aldunate, through whom this inquiry was made, then renewed his offer of the flag-staff, which I accepted most thankfully; and by his order it was taken down, and conveyed to the ship, soon after which it was converted into an excellent mainmast for the schooner. Before it was moved, a new, but

shorter staff, with a topmast, was fitted for the flag; notwithstanding which, many unpleasant observations were made, and absurd reports circulated, which spread to Chile, and even to Peru, that the English were about to take possession of Chiloé, and had already removed the flag-staff of San Carlos.

By Lieutenant Mitchell's activity in superintending the Adelaide's repairs, she was got ready for sea at the beginning of December, and sailed on the 8th, under the command of Lieutenant Skyring, with orders* to survey those parts of the Gulf of Peñas which had not been examined by the Beagle; particularly the River San Tadeo, in San Quintin's Sound; the openings behind Xavier Island; the Channel's Mouths; and the Guaianeco Islands, where the Wager was wrecked: and then to proceed down the Mesier Channel, behind the Island Campana, which was supposed to communicate with Concepcion Strait, by the Brazo Ancho (or Wide Channel) of Sarmiento. He was then to go to the Ancon sin Salida, examining all the openings into the main land, on his way, and search for a communication with the large waters, discovered by Captain Fitz Roy, through which he was to try to enter the Strait, and join the Adventure, at Port Famine, during the month of April.

Lieutenants Skyring and Graves again took with them, by Captain Fitz Roy's permission, Mr. Kirke and Mr. Bynoe, of the Beagle; Mr. Alexander Millar and Mr. Parke also accompanied them.

Having thus despatched our companions, we prepared, on board the Adventure, to return to Valparaiso; intending to proceed to Rio de Janeiro; by way of Concepcion, Port Famine, and Monte Video; for the sake of adding some links to our chronometric chain: with a view to which, I had taken the opportunity of having the chronometers cleaned at Valparaiso by Mr. Roskell, agent for Messrs. Roskell chronometer-makers at Liverpool. General Aldunate being on the point of returning to Valparaiso, I had an opportunity of obliging him, and showing my sense of the assistance, and essential kindness we had

* See orders to Lieut. Skyring, in the Appendix.

© The Complete Work of Charles Darwin Online

received, by offering him and all his family a passage in the Adventure, which he accepted; and on the 17th we left Chiloé. In our way we touched at Concepcion, and anchored at Valparaiso on the 2d of January.

We remained there until the 11th of February, and then sailed on our return to Rio de Janeiro, with the intention of passing though the Strait of Magalhaens, and taking that opportunity of completing some few parts, which our former surveys had left unfinished. As the breeze, which, on this coast, blows with the constancy of a trade wind, would carry us close to the island of Juan Fernandez, I determined upon visiting it, for a few days; and then proceeding again to Concepcion.

We reached Cumberland Bay, on the north side of Juan Fernandez, on the 16th, and anchored, within two cables lengths of the beach, in ten fathoms.

I have seldom seen a more remarkable and picturesque view, than is presented by the approach to Juan Fernandez. When seen from a distance, the mountain of the 'Yungue' (Anvil), so called from its resemblance to a blacksmith's anvil, appears conspicuously placed in the midst of a range of precipitous mountains, and is alone an object of interest. It rises three thousand feet above a shore, which is formed by an abrupt wall of dark-coloured bare rock, eight or nine hundred feet in height, through whose wild ravines, broken by the mountain torrents, views are caught of verdant glades, surrounded by luxuriant woodland.

The higher parts of the island are in general thickly-wooded; but in some places there are grassy plains of considerable extent, whose lively colour contrasts agreeably with the dark foliage of myrtle-trees, which abound on the island.

The Yungue is wooded, nearly from the summit to its base; whence an extensive and fertile valley extends to the shore, and is watered by two streams, which take their rise in the heights, and fall into the sea.

This valley appears to have been formerly cleared and cultivated by the Spaniards, who had a colony here; for the stone

© The Complete Work of Charles Darwin Online

walls, which served to divide their enclosures, still remain. From Walter's account of Anson's voyage, and the view given with it of the commodore's tent, there is no difficulty in determining this valley to be the spot on which his encampment was placed.

The island is now (1830) occupied, or rather rented from the governor of Chile for a term of years, by Don Joachim Larrain. The establishment consists of a superintendent (mayor-domo), there called, 'the governor;' and forty persons, who are employed in the seal and cod fishery, and in drying fish for the Chilian market. Their dwellings are erected on the flat land, at the north side of the bay, where the soil is richer than in other parts; and where it is more sheltered from the squalls, which, during strong southerly gales, rush down the valley of the Yungue, the situation of the former establishment, with great violence.

The remains of a fort, called San Juan Baptiste, are yet in a tolerable state; and from an inscription on the wall, it appears to have been repaired, or completed, in the year 1809. It is situated on a rising ground, about one hundred and thirty feet above the sea, at the S.W. part of the bay, and overlooks the village; there are now no guns mounted, but, with a few, it might be made very effective in a short time; and, from its situation, would command the bay.

In the middle of the beach are some ruins of a four-gun battery, and there are also traces of a fort at the N.W. end of the bay.

At present, except wild-goats, wild peaches, figs, abundance of fish, and excellent fresh water, no refreshments can be procured. An establishment of forty persons, with very little to do, might naturally be expected to cultivate the land, raise vegetables and fruit, and rear poultry and pigs, to supply the vessels, which frequently touch here for wood and water; but it is not the character of the Chileno to take any trouble, unless obliged, although his own comfort and advantage may be materially concerned.

The mayor-domo, however, told me that their attempts to

© The Complete Work of Charles Darwin Online

cultivate the soil, and raise potatoes, had been defeated by the destructive ravages of a worm.

By sending a boat to the east point of the bay, to fish in forty fathoms water, a most delicious kind of cod-fish may be taken, in such numbers, that two men, in half an hour, could fill the boat. Craw-fish, of large size, are almost equally abundant; they are taken with a hooked stick: one of our boats caught forty-five in a very short time. The inhabitants catch them, and cure their tails, by exposure to the sun, for exportation to Chile, where they are much esteemed, and fetch a high price.

Wild-goats are very numerous among the inaccessible parts of the island, but are not easily obtained; they are sometimes shot, or taken with a lazo. These animals, according to Woodes Rogers, and other writers, were originally left on the island by Juan Fernandez, who, for a short time, lived there. According to the 'Noticias Secretas,' p. 50 to 56, they are supposed to have been landed by the Buccaneers, who frequented this island. Certain it is, that, without such refreshments, the Buccaneers would not have been able to carry on their harassing war of plunder against the Spanish possessions on the American coast to such an extent; nor should we, perhaps, have heard anything more about Commodore Anson, and the crews of the Centurion and Gloucester, who were, on their arrival at this island, in the last stage of scurvy.

To prevent Juan Fernandez from being so tempting a resort to Buccaneers, the Viceroy of Peru caused a great many dogs to be landed, which hunted down and destroyed the goats in great numbers: this in some measure has prevented their subsequent increase. The dogs however drove the goats to places where they could not follow them, and were then obliged to destroy seals for food. Large troops of these dogs still range about the lower grounds; but the heights are in the undisturbed possession of wild-goats; which may be seen in numbers browsing on elevated and almost inaccessible places, where they live in safety.

The geological character of this island, according to Mr. Caldcleugh, who accompanied me in this trip, is of basaltic

© The Complete Work of Charles Darwin Online

green-stone, and trap, which appears, at first sight, to be volcanic; but, on a more particular examination, the lava-like appearance of the rock does not seem to arise from an igneous origin.

The green-stone is full of crystals of olivine, which, as they decompose, leave hollows, resembling those of scoriæ. Mr. Caldcleugh communicated an account of the structure to the Geological Society.* In Captain Hall's interesting journal, there is a list of Geological and Mineralogical specimens, of which one from Mas-a-fuéra† is named 'Vesicular Lava.' May it not be this same rock in a decomposed state?

The late Signor Bertero, whose botanical collections from Chile have enriched many of the principal herbaria in Europe, accompanied me to make a collection of the Flora of the island; and he considered that the character of the vegetation was very little allied to the Chilian, but partook more of that of California. The sandal-wood, which has been described as indigenous to this island, was not found by us, growing, but a large quantity was collected about the hills and vallies, in a dry state, and apparently very old. It is of the red kind, and still preserves a strong scent. The mayor-domo told me there were no sandal-wood trees in the island; but we had reason to think his information was incorrect, for one of the inhabitants would have taken us to a place where he said they were growing in large quantities, had not our arrangements for sailing interfered.

The island produces several kinds of grass; but the most abundant herbaceous plant is a species of oat, which grows very luxuriantly, and towards the westward covers the ground for many miles. The neighbourhood of Cumberland Bay is over-run with strawberry plants, wild radishes, mint, and balm, besides peach, apple, cherry, and fig trees, which are

* Phil. Journal, and Annals of Philosophy, for March 1831 (new series x.), 220.

† Juan Fernandez is called 'de Tierra,' because it is nearer the mainland than another adjacent island, which is called 'Mas-a-fuéra' (farther off, or more in the distance).

© The Complete Work of Charles Darwin Online

found wild every where, and remind one of Lord Anson's visit.*

Not only in its botanical productions does this island differ from the Chilian coast, but also in its shells: the shell fish being extremely scarce, and dissimilar in character. On the rocks we found a patella and a small chama, but we saw no mytilus. From the deep water I fished up some coral, and attached to one fragment was a new species of arca.† The fishing-lines brought up, from the depth of eighty fathoms, a branch of coralline, to which an infinite number of a species of caryophyllia were attached. The existence of coral is mentioned in Mr. Barry's translation of the 'Noticias Secretas de America; por Don J. Juan, y Don A. de Ulloa,' a work which contains a long and, generally speaking, good account of the island; but their description of the anchorage does not agree with ours. They say, "The distance between the two points, which form the bay, is two miles, and its depth about half a league; and, although the depth is nearly the same in all parts, the best berth to moor ships is in the front of the 'Playa del Este;' but it is necessary to be close to the stones of the beach, for at one or two cables' length there are fifty fathoms water, and the outer anchor is in the depth of seventy or eighty fathoms; but if the vessel is three or four cables off, it will be necessary to drop the outer anchor in one hundred fathoms, which, even with two cables an end, will scarcely secure the ship." Now, at three cables' length from the beach, we had only ten fathoms, our outer anchor was dropped in seventeen fathoms, and in a line between the two points of the bay there is not more than fifty fathoms.

If the accounts of those Spanish officers were correct, the earthquakes, which certainly affect these islands, must have caused a considerable uprising of the base of the island; but, on referring to the plan in Anson's voyage, the soundings in 1741 do not appear to have been different from ours. The innermost ship, whose berth we occupied, is, in that plan, at anchor in

* Anson's Voyage, p. 118.

† Arca angulata. See Zool. Journal, vol. v. p. 336.

© The Complete Work of Charles Darwin Online

nineteen fathoms, and the depth between the points of the bay is shown to be about fifty fathoms.

There are few persons who have not read, with much interest, Mr. Walter's account of the Centurion's voyage, and who are not well acquainted with his description of this island, which we found exceedingly correct. The views of the land, although old-fashioned in execution, are most correctly delineated, and the plan of the bay is quite sufficient for every common purpose of navigation; but as we had an opportunity of fixing its latitude and longitude more correctly, it became desirable to make a more detailed plan than Commodore Anson's.

The seals and sea-lions, which were so abundant formerly, are now reduced to such a small number, as to make the seal-fishery scarcely worth notice. They have been destroyed by taking them indiscriminately, without regard to age or sex, leaving none to propagate the race but those who by chance escaped. At present the island is let to a tenant, who is not permitted to kill them until the young have taken to the water, by which means an opportunity is given for them to increase.

I am not aware that there are any indigenous animals. Dogs, goats, and rats, have been imported. Land birds are not numerous; some pigeons, said to have been imported, and a few hawks, are occasionally seen, besides three species of humming-birds, two of which are new to science.* Of sea-birds we saw very few; but were informed that the 'Goat Islands,' at the south-west end of Juan Fernandez, are completely covered by them at the breeding season.

During our stay, several excursions were made, in various directions, from the village, and much facilitated by beaten paths, one of which leads up a valley, westward of that of the

© The Complete Work of Charles Darwin Online

Yungue, and thence to a pass over the principal range, communicating with the other side of the island. This pass, called the Puertozuela, is 1,800 feet high, and was visited several times by the officers. On one occasion, they went to the western part of the island, to hunt wild goats. The party set out in boats with the mayor-domo, or governor, as their guide; but before they reached the proper landing-place, became so impatient that they landed, intending to walk back. The governor, however, persevered, and returned, in the evening, with five fine she-goats, which he had taken with 'lazos.' Our pedestrians found their return by no means so easy as they had contemplated, being obliged to pass the night in a cave, which they fortunately found at sunset, and they did not reach the ship until the following afternoon, fatigued, but much pleased by their ramble.

The thermometer on board ranged, during the day, between 63° and 82°, and the barometer between 29·98, and 30·16. On shore the thermometer stood higher, in fine, unclouded weather, and lower when the summits of the hills were covered with clouds.

We put to sea on the 22d, anchored at Talcahuano on the 3d of March, and sailed again on the 17th, to proceed through the Strait of Magalhaens.

While at Concepcion I had an opportunity of seeing Pinoleo,* the Indian chief, from whom Captain Basil Hall endeavoured to obtain the release of a captured Araucanian female, whose husband had been murdered in cold blood before her eyes.†

Mr. Rouse, our consul, procured for me the necessary introduction, and, with one of the governor's aides-de-camp, accompanied us to the Indian quarters, situated on the out-

* Pinoleo (from 'Pino,' pisando; and 'leo,' rio; or, pisando sobre el rio, living close to the banks of a river), is the Chief of a small tribe, whose territory is near the River Imperial; but he generally lives in the confines of Concepcion. He has four wives in the interior (la tierra) and three in the town.

© The Complete Work of Charles Darwin Online

skirts of the town, towards the river Bio-Bio. We found the chief's residence (little better than a rancho, or hut of the country), surrounded by Indians, some of whom were armed; and at the door were his two daughters, young, and rather good-looking, whose persons and dress we had leisure to examine, whilst waiting the chief's pleasure to receive us. They were clothed with a mantle, or wrapper, of green baize, enveloping the body from the neck to the feet, and fastened at the breast by a toup, or tupu* (a silver pin, or skewer, headed with a round silver plate, three inches in diameter), over which hung a string of beads. Their hair, which was remarkably fine and clean, as well as neatly dressed, was divided into two plaited tails ('trensas'), and their foreheads were ornamented with a broad fillet, worked over with beads.† They also wore necklaces, bracelets, ear-rings, and anklets of similar manufacture.

Our names having been announced to Pinoleo, he came to the door to receive us, and invited us to enter. Some of our party he recognized, and seemed pleased at their visiting him. We were early, and found him sober; but from his bloated and haggard appearance, it seemed that he had not been long so. On entering the hut, we observed a number of Indians, scarcely sober, seated round, near the walls. Some turbid wine was presented to us, in a silver cup, which we sipped as it passed round; but the last of our party knowing that to return the cup without emptying it, would be an offence, was obliged to drink the contents, and a bitter potion they were. Pinoleo was then stout and rather corpulent, five feet ten inches in height, of a fairer complexion than the generality of his countrymen, and had lost much of his hair. He had laid aside the Indian

* In Febres 'Arte de la lengua de Chile' they are thus described "Ahujas grandes con una plancha redonda de plata como una hostia, ò mayor, con que prenden las mujeres sus mantas—Certain large bodkins, with a round silver plate, as large as, or larger than, an oyster, with which the women fasten their mantles."

† The ornament on the forehead, which is worn only by unmarried women, is called Trare-lonco, from the old Chilian words trarin, to fasten, and lonco, the head. The bracelet is called Anello cure; the anklets, Anelleo.

© The Complete Work of Charles Darwin Online

dress, and wore the deshabille of a Spaniard, a shirt and pair of trowsers, in a very slovenly manner. He spoke Spanish with great facility, and appeared to be quite at his ease in conversation. He has the rank of lieutenant-colonel in the Chilian army, and receives pay, as a retainer for his friendship.

A very short visit was sufficient to satisfy us, and we took the first opportunity of retiring, for fear of a second cup of wine. While leaving the hut, we were beset by some of his followers, asking for money. The Indian quarter is a scene of drunkenness the whole day; the women, however, are prevented from thus injuring themselves; they are industrious and cleanly, and are principally occupied in the manufacture of ponchos. These Indians are frequently at war with other tribes, who live on the south side of the Bio-Bio river, and who have never yet been conquered by white men, of which they are not a little proud. (*w*)

These Araucanians are by no means to be despised. The Cacique Mariloan,* who resides near San Carlos, on the Bio-Bio, has three hundred fighting men under his own command; and from the influence he holds over neighbouring Caciques, could bring upwards of one thousand men into the field. Upon the occasion of a late revolution in Chile, a deputation of chiefs was sent by the Araucanian Caciques to inquire into the cause of those disturbances, of which they had received intelligence. They first asked for an interpreter, whom they cautioned to give a true and literal translation of their speech; and then they made a long harangue, in which they explained the cause of their visit, and declared their willingness to assist their friends, if their aid should be required, to expel a foreign foe; but if the troubles were caused only by the quarrels and dissensions of parties, they would not take an active part. They were then given to understand that an attempt had been made by one party to put down another, upon which they declined assisting either. The conference being ended, some horses were

(*w*) Not since the first Spanish conquest, perhaps.—R. F.

* From 'Mari,' diez, and 'loan,' huapo: whence Mariloan means 'huapo como diez,' or, 'equal to ten men.'

© The Complete Work of Charles Darwin Online

slaughtered and skinned. Large holes were dug, and the skins put into them, to form substitutes for vessels, into which barrels of wine were poured, and the Indians commenced their feast of horses' flesh and turbid wine, which threw them rapidly into a state of excitement and intoxication, that lasted some hours after the wine was all drunk.

In this neighbourhood, the Araucanian pine (*Araucaria imbricata*) is found, but very few of the trees grow near the sea. One beautiful specimen which I saw in a garden was, at least, forty feet in height, with branches sweeping the ground. The cones of these trees, called piñones, are brought to the town from the mountains where they grow, and are roasted, to be sold in the streets.

On the 31st of March, the land about Cape Lucia was seen, and at noon it bore E. b. N., distant twelve miles, when the wind ceased, and a heavy swell setting us towards the land, made our situation an anxious one. A breeze, however, sprung up, and by carrying a press of sail, we succeeded in gaining an offing before dark. The night was very squally, but next morning (1st April) the weather was better, so we stood in, and made the Evangelists, which were seen from the mast-head, at a distance of twenty-two miles. Between these islands and Cape Pillar we found a most turbulent sea; yet no sooner had we entered the Strait, than the water became perfectly smooth. I intended anchoring in the Harbour of Mercy; but the night proved fine, and the wind was so favourable, that we proceeded by the chart, using a patent log, and passing within two miles of the headlands. Sail was reduced as much as possible, to give us space sufficient to run on during the night, steering E. $\frac{3}{4}$ S. by compass. Towards midnight the weather became cloudy, and occasionally the land was concealed from our view.

Abreast of Cape Tamar, and as far as Cape Providence, some sharp squalls raised a sea, rather heavy, considering we were in the Strait; but afterwards the water became smooth again. Off the latter cape, the patent log indicated a distance run equal to that shown by the chart, which proved that we had

© The Complete Work of Charles Darwin Online

experienced no current. At daylight we were in the entrance of the 'Long Reach,' abreast of Cape Monday.

While passing the opening opposite to Playa Parda, a schooner was observed at anchor, and a boat was seen coming out to us. It contained the mate of the schooner Industry, of New Bedford, who informed us that she had been lying there, weather-bound, for nearly a month. He came to make inquiries about good anchorages to the westward (having already lost two anchors), and to learn in what part of the Strait he was; his own idea being, that the vessel was under Cape Monday. Having given him the required information, we proceeded; but the wind fell light, and we were glad to anchor in the cove of Playa Parda. With our chains we found it safe; but the bottom, being rocky, would probably do much injury to hempen cables.

The opening opposite to us, where the schooner was lying, was evidently Sarmiento's 'Abra.' It appeared to us to be a mile and a half wide, with an island in the entrance. Within, it seemed to take a south, then a south-west direction, and afterwards to trend round a low hummocky point of the eastern shore, under a high, precipitous ridge, on the opposite or western shore, towards the S.E.; beyond this its course could not be observed. When passing through this part of the Strait, Captain Stokes found the weather so bad, that although the distance across was only two or three miles, the shores were often concealed by clouds and rain, so as to render it impossible for him to make any survey of them.

We were detained the two following days by bad weather. On the 5th we proceeded, but before we got abreast of Snowy Sound, heavy rain set in, which lasted all day.

As we passed Borja Bay, a schooner was observed at anchor in it, so like the Adelaide, that we altered our course to communicate with her. From a boat which came off to us, we learned that it was a sealing-vessel, called the Hope, of New York, going through the Strait, from Staten Land. She had seen nothing of the Adelaide.

When abreast of Bachelor River, a canoe, containing two

© The Complete Work of Charles Darwin Online

men and two women, came out to us; but we did not delay long, and at five the anchor was dropped in Fortescue Bay.

As it did not appear that the Adelaide had preceded us, I determined upon remaining, to make a chronometric measurement from Port Gallant to Port Famine; and the next morning Lieutenant Graves landed, and obtained a set of sights for time.

In the early part of the day, two canoes, containing eight or ten Fuegians, entered the bay. They came from the westward; but we did not recognize among them any of those who visited the ship as we passed Bachelor's River. Several had red baize shirts, and some had 'Union caps,' such as are supplied to our men-of-war; which they must have procured from the Beagle or Adelaide, or from the Chanticleer, at Cape Horn. (*x*) After hanging about us all day, they landed at sunset, and took up their quarters in some old wigwams in the inner harbour.

The canoes of these natives were very different in their construction from any we had seen to the eastward. Instead of being paddled, they were pulled with oars; one of which was an ash oar, probably obtained from some sealing-vessel. The canoes were large; at the bottom was a plank, twenty inches wide, to which were sewn the sides, in the manner of the piraguas, and they were caulked with bark, in a similar way.

We did not remark any thing peculiar among these people which we had not perceived in other natives of Tierra del Fuego, except that they frequently used the word 'pecheray,' a word particularly noticed by Bougainville, who thought that it meant the name of the tribe; and, in consequence, the Fuegians have been often called Pecherays.

On one of the officers cutting a lock of hair from a woman's head, the men became angry, and one of them taking it away, threw half of it into the fire, and, rolling up the other portion between the palms of his hands, swallowed it. Immediately

(*x*) I believe that the natives who have canoes of the kind described above, do not go near the Hermite Islands, on which Cape Horn is situated.—R. F.

© The Complete Work of Charles Darwin Online

afterwards, placing his hands to the fire, as if to warm them, and looking upwards, he uttered a few words, apparently of invocation: then, looking at us, pointed upwards, and exclaimed, with a tone and gesture of explanation, 'Pecheray, Pecheray.' After which, they cut off some hair from several of the officers who were present, and repeated a similar ceremony.

From this fact, one might suppose the word to be connected with their ideas of divine worship; but we had heard it used for so many opposite things, that I could not consider it of so much importance as some of the officers were inclined to think it.

The next day a party ascended the Mountain de la Cruz, to deposit a pewter plate, on which were cut the names of the ship and officers. At the summit they found the pile of stones made by Captain Fitz Roy, which they left undisturbed; but made another, in which a bottle was placed, containing the little Spanish coin, and copies, on vellum, of the memorials we had formerly taken from it, also several English coins, and some medals. The bottle was corked, covered with resin, and enveloped in sheet lead. Our party returned in the evening, having been seven hours in going up and descending.

The next day I obtained an angular measurement of the Mountain de la Cruz, with a theodolite, having measured a base of 2,608 feet, which gave for its elevation 2,364 feet, 74 feet more than Captain Fitz Roy's barometrical determination.

During the day several Fuegian families had arrived, and, by the evening, ten canoes, containing altogether about sixty natives, were collected. I landed to visit them, for I had never before seen so many assembled. We entered all the wigwams but one, which was said to be occupied by a woman in labour. In the opening stood her husband, painted all over with a red ochrous earth, and his head and breast ornamented with the white down of birds. The other Fuegians called him 'Pecheray;' and appeared to consider him, while in the character he had assumed, as a being superior to themselves.

© The Complete Work of Charles Darwin Online

Hence, there evidently is something of a superstitious nature connected with the word; but our frequent attempts to find out its precise meaning, were unsuccessful. On repeating this expression to a group of natives, one of them immediately coughed up a piece of blubber, which he had been eating, and gave it to another, who swallowed it with much ceremony, and with a peculiar guttural noise; then, looking up, and pointing with his finger to the skies, solemnly pronounced the talismanic 'Pecheray.' This word is also used in pointing to the sun.

On the 10th April, I went to Charles Islands, and surveyed them. There is very good anchorage for a small vessel, in eighteen fathoms, at the north end of the passage which separates them; and at the bottom, or elbow, under the eastern island, in thirteen or fourteen fathoms. The next day, a fresh arrival in two canoes increased the number of Indians to eighty; rather a formidable body for a small vessel to encounter. They conducted themselves, on the whole, very peaceably, but seemed determined that our curiosity should not be gratified by finding out the contents of the 'tabooed' wigwam. It was always guarded by the 'Pecheray,' who seemed ready and determined to dispute all access to it, by means of a heavy club. One of the midshipmen, however, with a little coaxing, persuaded the man to let him put his head in; but those who were inside, having received their lesson, threw ashes in his face, and nearly blinded him. After this, seeing they were determined on the point, I desired that no further attempt should be made to ascertain what was really going on inside the wigwam.

We sailed the next day (11th), not without some apprehension that the Adelaide might meet this large concourse of Indians before they separated; as Port Gallant was a place rarely passed by vessels without stopping, and the natives being all housed behind a point of land, could not be seen until too late.

We were abreast of Cape Froward at noon; in the evening we anchored in French Bay, and next day (13th) reached Port Famine. As I purposed remaining until the Adelaide should arrive, the tents were set up, the boats landed for repair, and the transit instrument was set up, in the hope that a comet

© The Complete Work of Charles Darwin Online

might be visible, which we had seen in our passage from Concepcion to the Strait; but the weather was at first too cloudy, and afterwards the comet itself was too faint to be discerned.*

On the 21st, nine canoes arrived in the bay, containing a large party of Fuegians, principally those who frequent the Magdalen Channel, and probably the sea-coast. They had generally shown themselves disposed to be mischievous, and I determined upon preventing their encamping near us; for their presence would greatly impede our watering and wooding parties, by distracting the attention of the people. I, therefore, went to meet them at the watering-place, under Point St. Anna, where they had landed, near one of our boats which was on the beach. Among them we only recognised three who had visited us before, and those three were brought to our remembrance by their former misconduct. I had always made it a rule to treat them kindly, with the view of obtaining their good-will; but I found it was the wrong way to gain their respect, for it only made them expect more from me, the consequence of which was, that when we separated, neither party was pleased with the other. I used on this occasion a more dictatorial tone than I had hitherto done; for, seeing several with slings in their hands, and a collection of large, round pebbles wrapped up in the corner of their mantles, I desired them to throw the stones away, which they did not hesitate to do. The Indians were now all landed, and evidently presuming upon their numerical strength, upwards of eighty being assembled, began to make themselves very familiar.

I thought it best to check their advances, by desiring them not to visit the side of the bay where our tents stood, but to go round Point St. Anna, to an adjoining cove. They seemed to understand me perfectly, and soon afterwards embarked, while I returned on board. The natives, however, landed again, in the middle of the bay, at the north side, and there encamped.

Next morning, the men of the tribe visited our tents, but found them surrounded by a rope I had caused to be fixed,

* The same comet was seen at the Mauritius; and its orbit calculated. See Ast. Soc. Proceedings, and Phil. Journal.

© The Complete Work of Charles Darwin Online

and which they were not permitted to pass. At noon, after observing the sun's transit, I went to the barrier, and while the people were at dinner, endeavoured to amuse our visitors, who were from fifteen to twenty in number, by showing them several trifles; among the rest, a pocket set of coloured glasses, belonging to the transit. They looked through them at the sun, but handled them rather roughly, and broke the frame; upon which I expressed my anger, and turned them away. Soon afterwards, however, I walked towards them, and selecting the Indian who had offended me, gave him a bunch of beads, and thus restored peace; but desired them, at the same time, to go to their wigwams, which they did. In their way, they mischievously broke down a part of my meridian mark; seeing which, I sent a carpenter, attended by a marine, to repair it, and went myself to inspect its being again set up. The natives were collected round it, evidently in expectation of my being angry, and awaited my approach. Upon my coming near, I showed them that I was much displeased, and ordered them into their canoes; when one of the party, muttering a few words, picked up a stone from the ground, and was fixing it in his sling, when I took the marine's musket, and presented it at him, upon which the whole took to their heels; the principal offender and another ran along the beach, and the rest to their canoes. I could not resist the opportunity of letting them know we were prepared for them, by firing over the heads of the two who were running near the water.

The report of the musket attracted the attention of Lieutenant Mitchell, who was on board on the look-out, expecting some fracas would, sooner or later, take place; and seeing four or five canoes paddling across, and the two Indians running along the beach, he manned a boat, and pulled towards the canoes, which tried to evade him, and stones were thrown at him as he approached. A musket fired over their heads, soon quieted them, when he pulled round their canoes, to show them they were in his power, but did not molest them, and then allowed the party to proceed.

This affair alarmed the women at the wigwams, and hastily

© The Complete Work of Charles Darwin Online

gathering up their effects, they hurried into their canoes, and joined the others, who all paddled round Point St. Anna. The men, however, landed there, and remained on shore, armed with slings, spears, and bows, ready to defend themselves, and, by their gestures, defying us to land. No attention was paid to them, and, after a short time, they went over the hills to the coves on the north side of the point. As we had now openly quarrelled, I thought it better that they should keep at a distance; and therefore, taking two boats, pulled round the point, to tell them to go five miles farther, to Rocky Bay; but the canoes were already beached, and the women had taken up their quarters. As we approached, the hills echoed with the screams of the women and the shouts of the men; all of whom, stark naked, armed, and daubed with white paint, their heads being stuck full of white feathers, hastened down to the point of the bay. The place, from its nature, offered a good defence, as the beach was lined by large rocks, behind which they could conceal themselves from our view, and yet assail us with stones. When within a few yards of the beach, we held a parley—the object of which was, that they should go farther to the northward; to this they vociferously replied, by desiring us to leave them. Seeing there was no chance of enforcing our demand, without shedding blood, I ordered the boats away; and on getting about a musket-shot from the beach, one of the Fuegians threw a stone, which fell close to us. In an instant, every one of them was concealed behind the rocks; but we returned their fire, and another large stone fell within two feet of the boat. A second musket was fired, and another stone was returned, with equal precision. After the interchange of a few more stones for bullets, they ceased throwing them, and we returned on board. It was very unlikely that any of our shot took effect; for we were at a long distance, and could only see their heads above the rocks. Fortunately, none of the stones struck us, for they were large enough to have caused a severe bruise. It is astonishing how very correctly they throw them, and to what a distance. When the first stone fell close to us, we all thought ourselves out of musket-shot.

© The Complete Work of Charles Darwin Online

The next morning, five or six natives were seen crouching down among high grass, on the hill over our watering-well, waiting for the people to go for water; probably with the intention of assailing them, for it appeared afterwards that their slings and bows were in readiness. To show them they were not out of our reach, I caused a six-pound shot to be fired over their heads, which, as it went high above them, made no impression. The gun was then pointed lower, and another ineffectual shot fired. A third, however, fell close to them, when they jumped up, shook their mantles in the air, with the most violent gestures, and, apparently in a furious rage, scampered off; but the last man, before he disappeared, threw an immense stone, which did not reach one quarter of the distance.

We saw nothing more of the natives until the evening, when Lieutenant Mitchell, who went to look for them, found they had moved away to Rocky Bay, where they had encamped on the open beach. The next day, I sent him to endeavour to make peace, which he very easily effected, by the interchange of a few trifles.

After this we had much bad weather, during which most of the Indians kept close to their wigwams; but a few occasionally communicated with our watering party, quite peaceably, as if nothing had happened. A day or two after, the weather improved, and the Fuegians dispersed, probably for want of food, some going to the northward, but the greater part along shore to the southward. These people pointed upwards to the sky, when they were going away, repeating the word 'Pecheray.'

This was our last interview with the wretched Fuegians. Naturally petulant and quarrelsome, they are also ever intent upon mischief; the fear of punishment alone restraining them. Weakly-manned vessels passing through this Strait should always avoid them, if they are numerous; for unless they are given what they want, they try to steal it, and any consequent punishment probably brings on a quarrel. Their conduct, and servile bearing, at our first seeing them, gave them an appearance of being timid and inactive; while, in reality, they

© The Complete Work of Charles Darwin Online

are the very reverse. Had we attempted to land on the last occasion, I do not think we should have effected our object, without receiving some severe contusions from their stones, which they sling with such extraordinary precision and force: so much so, that I consider the sling, in their dexterous hands, to be equal to a musket in ours. Indeed, with many of us, a native would have had the advantage. It has been too much the practice, when obliged to fire upon them, to fire over their heads; by which proceeding the savages are led to consider our weapons as so uncertain in their effect, that they become much depreciated in their estimation. It would be almost preferable to inflict a slight wound, in order to show the nature of our arms, and as a warning against further hostilities.

When the Uxbridge, sealer, was at anchor in a harbour in the Magdalen Channel, some Indians, who were on board, angry at being ordered out of the vessel at sunset, threw stones at the person who was walking the deck, as they returned to the shore. Several muskets were fired over their heads, at which they expressed neither fear nor concern; but paddled leisurely away, and the next morning came off again to the vessel, as if nothing had happened. At Port Famine, Duclos Guyot had a skirmish with natives, the particulars of which are described in Dom Pernetty's History (ii. 653). Three of the Indians were killed, and three of the French were severely wounded. It may be here remarked, that the chief's name, according to M. Duclos Guyot, was 'Pach-a-chui,' which is not unlike 'Pecheray;' the women were called 'Cap, cap,' probably a mistake for 'Cab, cab;' which evidently means 'no, no!' for it was an expression we frequently used, and was never misunderstood. Their cunning is sufficiently proved by the theft of the Adelaide's boat, in St. Simon's Sound (page 142).

The absence of the Fuegians permitted us to move about a little; and among other places, we visited their late encampment at Rocky Bay, our approach to which was offensively indicated by a most sickening smell. On our way, I found two fossils; one was very interesting, bearing the appearance of a

© The Complete Work of Charles Darwin Online

large orthoceratite:* the other was a Venus. From Rocky Point we descried a strange sail, which, by her movements, we thought must be the Beagle: I returned, therefore, and sent Lieutenant Mitchell out to her. She arrived in the evening, but proved to be a ship belonging to the Hudson Bay Company, called the Dryad, bound to the Columbia River, and last from the Falkland Islands. She came to wait for Mr. Low, of the Adeona, who had promised to pilot her through the Magdalen Channel. The Adeona arrived on the 3d of May; and the following day, to our great joy, the Adelaide hove in sight: and being becalmed, was towed to an anchorage.

The result of her cruise proved to be very interesting, although no communication had been discovered between the 'Ancon sin Salida,' and the Skyring Water. The only loss they had sustained was, however, a severe one; Mr. Alexander Millar having died of inflammation in the bowels. The death of this promising young man threw a damp over the happiness we felt at meeting again, after having so nearly completed this long and tedious voyage.

We had, for some days, been getting ready for sea, and now hastened to complete our preparations. The Dryad, after receiving some assistance from us, sailed in company with the Adeona, and passed out to the Pacific, by going through the Magdalen Channel. The day afterwards we took our final departure—crossed the shoal that extends off Magdalena Island, in five fathoms, sailed on rapidly, and passed Gregory Bay at noon. Seeing us approach, a large party of Patagonians, at least a hundred in number, assembled at the usual place of communication; but as both wind and tide were in our favour, and we could derive no novel information from them, we continued on our course. The Indians were probably much mortified and disappointed; but all on board were delighted by avoiding the anticipated delay. We showed our colours to them, but I dare say our friend, Maria, was not very well pleased with my want of courtesy, in passing by so old an acquaintance

* They are deposited in the Museum of the Geological Society.

© The Complete Work of Charles Darwin Online

without a salutation; or, what she coveted much more, such presents as she had always received when we anchored.

Just before entering the First Narrow, we passed through a furious 'tide-race,' which broke over the Adelaide, and not a little impeded her progress. No accident, however, was the consequence; and a rapid tide, running at the least nine knots an hour, swept us through the Narrow, and round the reef off Cape Orange: after which we proceeded rapidly, and rounded Cape Virgins at ten P.M., not a little elated by leaving behind us, with no expectation of ever seeing it again, the famous Strait of Magalhaens.

Our voyage to Monte Video was rather long; but we delayed there only to water the ship, in the usual place, off Cape Jesu Maria, and then proceeded to Rio de Janeiro, where we awaited the arrival of the Beagle. Our anxiety for her safety, during so hazardous a survey as that of the sea-coasts of Tierra del Fuego, was soon removed, by hearing that she had touched at Monte Video; and, on the 2d of August, our consort was seen entering the harbour; when we were delighted by finding all well on board, and the little vessel quite ready for sea, having refitted on her passage.

CHAPTER XVIII.

Adelaide's last cruise—Port Otway—San Quintin—Marine Islands—Unknown river or passage—San Tadeo—Isthmus of Ofqui—San Rafael—Sufferings and route of the Wager's party—Channel's Mouth—Byron—Cheap—Elliott—Hamilton—Campbell—Indian Cacique—Passage of the Desecho—Osorio—Xavier Island—Jesuit Sound—Kirke's report—Night tides—Guaianeco Islands—Site of the Wager's wreck—Bulkeley and Cummings—Speedwell Bay—Indigenous wild potato—Mesier Channel—Fatal Bay—Death of Mr. Millar—Fallos Channel—Lieutenant Skyring's illness—English Narrow—Fish—Wigwams—Indians—Level Bay——Brazo Ancho—Eyre Sound—Seal—Icebergs—Walker Bay—Nature of the country—Habits of the natives—Scarcity of population.

I WILL now relate the principal incidents of the Adelaide's last cruise. The following pages contain extracts from Lieutenant Skyring's journal, and also notices obtained from other sources.

The Adelaide sailed from Chiloe on the 8th of December 1829, made Cape Tres Montes on the 14th, and anchored in Port Otway the same evening. Of this place Lieutenant Skyring writes: "Good anchorage, wood, water, and shell-fish (such as muscles and clams), Port Otway affords: but no more. Excepting in one or two sandy bights, a landing is hardly to be effected; walking along shore is impossible, and it is scarcely practicable to enter the country, the land being so thickly wooded, from the summits of the hills down to the water-side. No soil is to be discovered; the shrubs, and even the trees, which are of large growth, rise out of moss, or decomposed vegetable substances. The climate is very wet; none but amphibious animals were seen, among which hair-seals were numerous. There were very few birds, excepting turkey buzzards; and not a trace of human beings; indeed, I do not believe Indians ever go there—(*y*) they rarely leave the direct channels; as a proof

(*y*) For evidence that Indians have been thereabouts, see Byron's account of the cave entered by the surgeon of the Wager. I believe that curious place was either in, or close to, Port Otway.—R. F.

© The Complete Work of Charles Darwin Online

of which, some articles left by the Beagle, in a conspicuous place, were found by us untouched." During the Adelaide's stay at Port Otway, the openings on the east side of Hoppner Sound were explored, yet they proved to be only small inlets. Mr. Kirke examined some, which appeared to communicate with San Quintin Sound; but found them to be merely channels dividing the group of the Marine Islands,* excepting the most southern, which is the entrance of Newman Inlet, a deep bight, without anchorage, but abounding with hair-seal.

From Byron's Narrative it would appear, that there is a channel somewhere hereabouts communicating with the Gulf of San Rafael, to the east of the Peninsula of Tres Montes; for the Indian guide wanted to conduct the Wager's barge through it, but was prevented by the strength of the current.

The Adelaide sailed from Port Otway on the 18th, and the same evening reached San Quintin Sound, anchoring opposite an opening northward of Dead-tree Island, that proved to be the mouth of the River San Tadeo, by which Byron and his unfortunate companions effected their escape to Chilóe.

The sufferings of this party, which are so affectingly described in Byron's narrative of the loss of the Wager, made so deep an impression on our minds, that I thought it not irrelevant to the object of this voyage to endeavour to trace their steps. Among the numerous incidents that occurred to them, the passage of the 'Desecho,' or carrying-place over the Isthmus of Ofqui, is, from all the circumstances connected with it, one of the most interesting. It may be remembered, that, upon the departure of Captain Cheap, and his shipwrecked crew, from the place of the wreck (Byron's Narrative, p. 69), they proceeded round the shores of the Gulf of Peñas, with an intention of tracing the Coast of Chilóe. They first attempted to steer for Cape Tres Montes, which headland they had seen, in one of the intervals of fair weather, from the summit of Mount Misery, and which appeared to be twenty or thirty leagues distant. The wind,

* The Marine Islands were so called, in remembrance of the four marines who were put on shore from the Wager's boats, and left behind. See Byron's Nar., p. 85.

© The Complete Work of Charles Darwin Online

however, freshened to a gale, and they were obliged to run before it, and throw all their provisions overboard to lighten the boat.

At night they took refuge in a small opening, which led to a secure harbour, and next day advanced a little farther, till they reached some small islands, where they were detained three or four days by bad weather.

After leaving that place, they found an opening, into which they rowed, flattering themselves it would prove to be a passage; but, being disappointed, they were obliged to return. This was probably the inlet, called 'Channel's Mouth.' Xavier Island was the next place they went to, named by them Montrose Island. Byron describes this island so exactly, that there cannot be the least doubt of its identity. "The next morning," he says, "being calm, we rowed out; but as soon as clear of the island, we found a great swell from the westward: we rowed to the bottom of a very large bay, which was to northward of us, the land very low, and we were in hopes of finding some inlet through, but did not; so kept along shore to the westward. This part, which I take to be fifty leagues from Wager Island, is the very bottom of the large bay it lies in. Here was the only passage to be found, which (if we could by any means have got information of it) would have saved us much fruitless labour. Of this passage I shall have occasion to say more hereafter."—Byron's Nar. p. 74. This is evidently San Quintin Sound. They proceeded to the westward and northward, entered a larger bay (Holloway Sound), and discovered another headland at a great distance to the westward (Cape Tres Montes), which they reached with much difficulty; but being unable to get round it, and losing the boat that accompanied them, besides being obliged to leave four of the marines behind, they became quite disheartened, and returned to Wager Island, to linger out their miserable lives, without the least prospect of again seeing home. This expedition occupied two months, during which they lived principally upon sea-weed, called 'tangle;' but sometimes passed whole days without eating anything at all. While they

© The Complete Work of Charles Darwin Online

were absent, some Indians had visited the wreck; and, about a fortnight after their return, they arrived a second time, in two canoes. Among them was an Indian Cacique of the Chonos tribe, who live in the neighbourhood of Chilóe. It was supposed that a report of the wreck had reached that place; and that this Cacique, and another Indian, had come to derive some advantage from it. As the Cacique spoke Spanish, the surgeon, Mr. Elliot, made himself so far understood, as to let him know that they wished to reach some of the Spanish settlements; and eventually bargained to give him the barge, and every thing in it, if he would conduct them to Chilóe. The party consisted of Captain Cheap; Mr. Elliot, the surgeon; Mr. Campbell, Mr. Hamilton, and Mr. Byron, midshipmen; and eight men, besides the two Indians; in all fifteen. The first night they slept on an island, and the next laid upon their oars, to the westward of Montrose Island, not being able to land.

They then pulled, "to the bottom of a great bay, where the Indian guide had left his family, a wife and two children." There they staid two or three days; after which, taking on board the family, they proceeded to a river, "the stream of which," Byron says, "was so rapid, that after our utmost efforts, from morning to evening, we gained little upon the current; and, at last, were obliged to desist from our attempts, and return."

This was probably a river, or channel, to the westward of San Quintin Sound, which eluded our search; and, if so, it must communicate with channels north-eastward of the Peninsula of Tres Montes. The Indians, anxious to get the barge to the Chonos, had no other way to effect their purpose; for the usual route was over the 'Desecho;' to pass which, it was necessary to take a boat or canoe to pieces, and carry her, piecemeal, over a high mountain.

After losing the barge, they crossed the Peninsula of Forelius, by hauling canoes over a narrow neck of land, and reached the water of San Quintin Sound; where they met another native family, with whom they proceeded to the River San Tadeo, "up which they rowed four or five leagues; and then

© The Complete Work of Charles Darwin Online

took to a branch of it that ran first to the eastward, and then to the northward." There they landed, took the canoes to pieces, and carried them over the isthmus; then putting them together again, re-embarked, and proceeded through the Chonos Archipelago to Chilóe.

When at Chilóe, I saw an old man, Pedro Osorio, who had been in two of the last missionary voyages (in 1769 and 1778), to the Guaineco Islands; where the Wager was wrecked. He related to me the particulars of these voyages, and gave me an account of the 'Desecho,' over which the missionaries transported their piraguas. He also remembered Byron and his companions; and described them by the following names:—Don David (Captain David Cheap); Don Juan (John Byron); Hamerton (Hamilton); and Plasta. The name Plasta is not once mentioned in Byron's Narrative; but on referring to Bulkeley's and Cumming's account, one Plastow is described as the captain's servant; and perhaps he was one of the number who remained with Captain Cheap.(*z*) Pedro Osorio must have been upwards of ninety years of age, in 1829.(*a*) A detailed account of these voyages is given in Agüeros's Historical Description of the province of Chilóe, p. 205.

Captain Stokes's 'Dead-tree Island,' in the entrance of San Estevan Gulf, is near the 'Cirujano Island' (Surgeon Island) of those voyages. Pedro Osorio told me that it was so called, because the surgeon of the Wager died there. From Byron's Narrative it would appear, that the surgeon died, and was buried, just before they embarked to cross the sound.—See Byron, p. 147.

As the examination of the River San Tadeo, and the discovery of the 'Desecho,' formed a part of Lieutenant Skyring's instructions, he proceeded up it, in a whale-boat, accompanied by Mr. Kirke. The entrance of the river is blocked up by a bar of sand and stones, which, at low spring-tide, must be nearly dry; and a heavy swell breaks upon its whole length, joining the surf of the beach, on each side; so that there is

(*z*) Could 'Plasta' refer to Alexander Campbell?—R. F.

(*a*) Pedro Osorio died at San Carlos in 1832.—R. F.

© The Complete Work of Charles Darwin Online

no deep channel; and, except in very fine weather, an attempt to cross is hazardous.

At its mouth, the breadth is about a quarter of a mile, but within the entrance it increases for a short distance: at three miles up, it is three hundred yards, and thence gradually diminishes. The shores are a mixture of clay and sand; and the country, on both sides, is low and marshy, abounding with brant-geese, ducks, teal, and snipe.

The land, near the mouth of the river, is studded with dead trees (a species of pine, about twenty feet high), which appear to have been killed by the sea overflowing the banks;(*b*) as it does at high-water for several miles.

Three miles from the entrance this river divides into two branches, one leading N.W., and the other eastward. Considering the latter, from Byron's description, to be the proper course, Lieutenant Skyring followed it. At nine miles from the mouth, a stream was found falling into the river from the north, in every respect differing from the principal stream; the water being fresh, dark, and clear, and the current constantly running down, uninfluenced by the tide; while the water of the river was brackish and turbid, and affected by the ebbing and flowing of the tide, although, at that distance, its effect was much diminished.

The shores of the Black River, as this new stream was called, are thickly wooded, which is not the case with the principal stream. They had entered it about a hundred yards before they discovered that they had left the main river; but being desirous of proceeding, they followed its windings, the next day, for three leagues; during the greater part of which distance, they found a strong current against them, and were also much impeded by fallen trees lying in the bed of the river. In many parts they dragged their boat along by the help of overhanging branches, or projecting roots; and the width, generally, was not more than fifty yards. As no piragua could pass there, Lieutenant Skyring felt assured that he was not in the right stream; therefore, returning to the main river, he proceeded

(*b*) Or by an earthquake wave.—R. F

© The Complete Work of Charles Darwin Online

up it during the next two days. At two miles above the junction, the tide ceased to be felt; and a rapid current met them, which increased in strength until they were unable to stem it; and as they were prevented from tracking the boats, by trees growing on the banks, they could ascend no farther.

This place was not more than eleven miles from the sea; although, from the tortuous course of the stream, they had gone double that distance, and were about two miles from the foot of a mountain, whence the river descends. The mountain was very high, and the vallies, or ravines, were filled with glaciers. From Byron's description, it seems probable that Lieutenant Skyring was near the carrying place; but as further delay could answer no good end, he very prudently returned, looking carefully about, as he proceeded, for some signs of a landing-place, but without success. He re-crossed the bar, reached the Adelaide without accident, and the next day went on in her to Xavier Island. On the way they passed Dead-tree Island; where, observing seal on the rocks, a boat was sent ashore, and her crew succeeded in killing a few sea-elephants, twenty feet long.

Favoured with fine weather, they were enabled to land on the north side of Xavier Island, to improve the former survey; and in the evening anchored in Xavier Bay, where they remained four days; during which, Jesuit Sound was explored, and found to terminate in two narrow inlets. Being a leewardly opening, it is unfit for any vessel to enter.

The name Jesuit Sound, and those of the two inlets at the bottom, Benito and Julian, are memorials of the missionaries, who, in the expedition of 1778, entered and explored it.* (Agüeros, p. 232.)

The Adelaide anchored the next night in Ygnacio Bay, at the south end of Xavier Island, which Lieutenant Skyring

* Mr. Kirke, who examined them, says, "There are two openings opposite Xavier Island, on the main land: the northernmost runs through high land, and is terminated by a low sandy beach, with a river in the middle, running from a large glacier; the southern inlet is ended by high mountainous land."

© The Complete Work of Charles Darwin Online

recommends for small vessels; the depth of water being six or eight fathoms, and the anchorage well sheltered from the wind.

On the 31st they anchored under the Hazard Islands, in the Channel's Mouth: "preparatory," writes Lieutenant Skyring, "to commencing new work with the new year; for since entering the gulf, except while examining the San Tadeo, we had followed the Beagle's track, and only completed what she left unfinished; but from this place all would be new. This was the last wild anchorage she had taken; and although now fixed in the best situation, and in the height of summer, we found our position almost as dangerous as hers.

"Early on the 1st of January 1830, Mr. Kirke went in a whale-boat to examine the openings, at the mouth of which we had anchored: he returned on the 9th, having traced to the end, all which had the least appearance of being channels. The two largest, the south and the east, penetrated into the Cordillera for thirty miles. All these inlets are narrow but deep arms of the sea, running between ranges of very steep hills; their sides affording not the least shelter, even for a boat, and apparently deserted; for neither seal, nor birds of any kind were seen, nor were there even muscles on the rocks."

Mr. Kirke, in his report, says: "The three northernmost of the inlets of the Channel's Mouth end with high land on each side, and low sandy beaches at the head, beyond which there rises a ridge of high mountains, about two miles from the beach. The S.E. inlets end in rivers rushing down from the mountains, and a rocky shore: not the smallest shelter could I find, even for the boat. Two days and nights I was forced to keep her hauled up on a rock, just above high-water mark, in a strong gale, while the williwaws were so violent, that we were all obliged to add our weight to that of the boat, to prevent her from being blown off: and twice we were washed out of our resting-places, on the beach, by the night tide rising about fifteen or sixteen inches above that of the day."

This opening in the coast is noticed by the pilot Machado (Agüeros, p. 210); but by whom the name of Channel's Mouth was given, does not appear. It is by no means descriptive of

© The Complete Work of Charles Darwin Online

what it has been proved to be; but as Lieutenant Skyring thought that a change in the name would not answer any good purpose, he very properly left it unaltered.

The day after Mr. Kirke returned, very bad weather set in, and detained the Adelaide nine days, during which nothing could be done, out of the vessel.

"January 19th," Lieutenant Skyring writes, "with moderate weather, and an easterly wind, we left the Channel's Mouth, and, standing for the Guaianeco Islands, passed those of Ayautau (between which and the mainland are several rocky reefs, though the passage seems to be sufficiently clear for any vessel); and skirting Tarn Bay, we distinguished the Mesier Channel, and could see many leagues down it. The entrance of the Mesier Channel is very remarkable, from having two high and singular peaks on the islands at its mouth: the northernmost very much resembling (although higher than) Nelson's monument, near the Strait; and the other, more to the southward, and much higher, resembling a church with a cupola, instead of a spire. Both are easily made out from the westward, at a distance of twenty or thirty miles.

"We reached the Guaianeco Islands in the afternoon. The two largest are divided by a narrow passage, on the west side of which we anchored, in ten fathoms, in a spacious and secure haven, which proved to be Speedwell Bay of Bulkeley and Cummings; the boats were employed next day, and, while the examination of the coast was pursued, I sought to ascertain the exact spot of the wreck of the Wager, but never could discover it: not a fragment of that ill-fated vessel was seen in any of our excursions. A few pieces of the boat lost by the Beagle last year were picked up; but nothing more that could tend to denote the misfortunes which have occurred near these islands.

"From the description of the Wager's wreck, in Bulkeley and Cummings, there seems to be little doubt of the place being at the N.W. end of the eastern Guaianeco Island, near my Rundle's Passage, which is the place so often mentioned in their account as the 'Lagoon.'

© The Complete Work of Charles Darwin Online

"Being well supplied with powder and small shot, the people provided themselves plentifully, during our stay at Speedwell Bay, with a variety of wild-fowl, namely, geese, ducks, red-beaks, shags, and the ibis; curlew, snipe, plover, and moorhens, were also met with, and fish were observed in shoals near the vessel, but, as we had no seine, they escaped. With hooks and lines our fishermen had no luck; the baits were no sooner at the bottom, than they were taken away, and for a day or two the cause of their loss was unknown; but being accidentally ascertained, small trap-nets were made, and great numbers of crabs were taken, about a pound each in weight.

"In almost every bay we noticed the potato, growing among wild celery, close above high-water mark: but in so unfavourable a situation, choked by other vegetables, its produce was very small.

"The trees are not of large growth in these islands, neither is the land thickly wooded; but above the beach, and almost round the coast, there is a breast-work of jungle and underwood, from fifty to one hundred yards broad, and nearly impenetrable; beyond which is a great extent of clear, but low and swampy ground.

"On the 25th, we left this port, and ran to the S.E., through what I have named Rundle's Passage. This small channel, where the islands approach each other, is about a quarter of a mile wide, perfectly clear in the whole extent, and also at its southern entrance; but at the northern there are many detached rocks, which are obstacles to entering Speedwell Bay, except in daylight. Rounding the islets, at the S.E. extreme of Byron Islands, we anchored in Muscle Bay, which lies on the northern side: by no means a secure place,—but the only one that could be found, by the boats, after many hours' search. I selected this situation in order that the entrance to the Fallos Channel, and the whole outline of these islands, might be laid down, and properly connected with the land of Port Barbara; which was thoroughly executed by Mr. Kirke and Mr. Millar, although delayed in the completion of their

© The Complete Work of Charles Darwin Online

work until the 1st of February. (c) On that day we sailed, and entered the Mesier Channel, anchoring in a small open bay, the only stopping-place we could perceive; which, from the loss we sustained shortly after our arrival, was called Fatal Bay. It is insecure, and the anchorage ground confined: the only convenience was, that wood and fresh-water were near. During our stay we had much rain, which retarded us. Mr. Kirke went away in a boat, whenever the weather permitted, and, on the 8th, we sailed for an anchorage, about ten miles to the southward, where he had previously been; but a sad event happened before our departure.

"On the afternoon of the 3d, we had the misfortune to lose Mr. Alexander Millar, who died in consequence of a severe attack of inflammation of the bowels, which carried him off, after an illness of only three days.

"On Thursday afternoon he was buried, close to the shore, near the anchorage, and just within the edge of the wood.

"That our progress had been so slow during the last month, was a great disappointment; but we had had many causes of detention. All the early part of January the weather was stormy: eighteen days we were anchored within the Channel's Mouth; yet during two only could our boats leave the vessel.

"Among the Guaianeco islands we had moderate weather, but also much wet: still the chief cause of our delay, I fear, was my own illness. From the beginning of January, I had been confined to my bed, with a tedious and obstinate disease; and from that time most of the angles were taken, and all the observations were made, by Mr. Kirke, who was ever exceedingly willing and indefatigable. After the loss of Mr. Millar, not only almost the whole duty of surveying fell upon him, but much of the duty of the vessel.

"At noon this day (8th), we moored in Island Harbour, a small but excellent landlocked anchorage, with good holding

(c) During much of this cruise, Lieutenant Skyring was so ill that he was unable to leave the Adelaide; and for a month he was confined to bed. His illness was caused by fatigue, and by sitting too long while constructing charts.—R. F.

© The Complete Work of Charles Darwin Online

ground, and abundance of wood and water. The two following days, Mr. Kirke was away examining the coast; the third we were confined by bad weather; and, indeed, during our whole continuance at this place, we had very much rain.

"We sailed early on the 12th from Island Harbour, and by night reached Waterfall Bay, an anchorage about fifteen miles to the southward: the wind all day was light, and the tide, the greater part of the time, against us; so that, with every exertion, we scarcely gained anchoring ground before it was quite dark: the strength of the tide was upwards of a mile an hour, at neap-tides: the ebb and flood were of equal duration, the former running to the S. b. E., the latter N. b. W. Thirty miles within the Mesier Channel it is as wide as at the entrance, and for several miles to the southward appears clear: so that no one is liable thus far to mistake its course.

"The land on the west side appears to be a number of large islands, with here and there wide passages leading to the S.W., rendering it probable that there are many (although not direct) communications between the Mesier and the Fallos Channels. Our anchorages were chiefly on the eastern shore, that the openings on that side might be more readily examined; but all which appeared to run far inland were found to be merely narrow inlets, or sounds ending abruptly. On each side the land is hilly, but not high; and this distinguishes the Mesier Channel from many others, whose shores for miles are formed by ranges of steep-sided mountains. Here, in many places, there is much low land, which is generally thickly wooded, yet with no greater variety of trees than is to met with in the Strait of Magalhaens. The beech, birch, pine, or cypress, Winter's-bark, and a kind of red-wood, form the forests; but none were observed that could be at all serviceable for the larger spars of a vessel.

"(16th). Left Waterfall Bay, and with a N.W. breeze passed Middle Island, entered Lion Bay, and moored in White Kelp Cove. The coast survey was soon finished, but we were confined at our anchors here four days; not by bad, but by extraordinarily fine weather. During such intervals, so very rare

© The Complete Work of Charles Darwin Online

in these regions, the wind, if there is any, is almost always southerly, and light.

"At every anchorage we had found Indian wigwams, but as yet had not met with any natives. Here we took a great number of fish; and, among them, one like the ling, found on the east coast of Patagonia, off Cape Fairweather, but of smaller size, for the largest did not weigh more than two pounds. Very few water-fowl were seen; steamers and shags were the only ones shot; but in the woods we noticed king-fishers, wood-peckers, barking-birds, parroquets, and humming-birds.

"(21st.) With a light northerly wind we left this cove, and about ten miles to the southward the appearance of the channel changed greatly. Instead of sailing through unconnected land, of moderate height, we were confined between two mountainous ridges.* At noon we were obliged to anchor in Halt Bay, no opening appearing to the right or left, and being apparently embayed. On the west side, the high land was skirted by several low islands, among which our only way of proceeding seemed to lie. This day and the next Mr. Kirke was away, seeking a passage; and having found one, and noticed the tides, we sailed through on the 23d, and gave it the name of the English Narrow. It is long and intricate, chiefly formed by islands; and in three places, where the shores approach each other, the distance across is less than four hundred yards, yet with a fair wind and slack tide, there is no hazard in passing. In the afternoon, we moored in ten or twelve fathoms in Level Bay, a spacious anchorage near the southern entrance of the Narrow; the bottom mud and sand, and the depth of water equal throughout. Mr. Kirke, who was among the islands opposite this bay, saw numerous shoals

* On the west shore Mr. Kirke noticed what appeared to be a channel, about twelve miles N.W. of Halt Bay, in the mouth of which was a considerable tide-ripple; an almost certain indication of such an opening. "I thought the inlet about twelve miles north-west of Halt Bay much like a channel. I also noticed a distinct tide ripple, which I did not remark near any other opening. To me this appeared the southernmost inlet, of any depth; or at all likely to be a channel."—Kirke MS.

© The Complete Work of Charles Darwin Online

of fish in many of the bights; with a seine, therefore, an abundant supply might be obtained.

"The woodland eastward of our anchorage had very recently been on fire, and the conflagration must have been extensive, and very destructive; for throughout a space of ten or twelve miles along shore, all the trees had been consumed, the dead trunks of the larger ones alone remaining. We left Level Bay on the morning of the 25th, and passed a canoe full of Indians; but they pulled to the shore, and ran into the woods; therefore, since they avoided us, and we had a fair wind, I did not seek their acquaintance. We had noticed traces of them in the neighbourhood of the Narrow, on each side of which many wigwams, that had been recently occupied, were seen.

"For the next ten or twelve miles we went through a fine reach, whose shores were low, and whose channel was interspersed with several islands, affording probably excellent anchorages; but to the southward the hills became more steep, and, except in the ravines, were destitute of vegetation. At four or five leagues to the E.S.E., beyond the English Narrow, an opening, apparently a channel, presented itself, and the reach in which we were sailing seemed to end. Doubtful which course to follow, we anchored the vessel in Rocky Bight, and despatched the boats to examine both passages. That to the E.S.E. was found to run direct nearly ten miles, and to communicate with a fine clear channel, trending to the S.S.W., which proved afterwards to be the Wide Channel (Brazo Ancho) of Sarmiento. At the junction, a considerable arm extended to the N.N.E., apparently a continuation of the Wide Channel.

"On Mr. Kirke's return from examining the passage in which we were sailing, I learnt that the same width continued about five miles southward of our present anchorage, and that there the shores approached closely, forming the intricate passage called Rowlett Narrow; which, after a S.E. course of many miles, also joins Wide Channel. The island formed by the two channels was named Saumarez Island, in honour of the gallant admiral.

"It rained hard and blew strongly the whole day, which

© The Complete Work of Charles Darwin Online

prevented our moving; but on the 27th we shifted our anchorage to Fury Cove, in Wide Channel.

"Mr. Kirke, on the 28th, examined an opening to the northward, called Sir George Eyre Sound, which terminates in a wide fresh-water river, running through low land from a large glacier. The low grounds extend two or three miles from it, and then the land becomes high. Behind the glacier there is a ridge of high mountains, covered with snow, which we had seen twice before; first, from near White Kelp Cove, and again from Halt Bay. In the sound, we saw three whales, and being the first we had observed, since leaving the Gulf of Peñas, they inclined us to think we were near the Gulf of Trinidad. A great number of fur seal, besides two of their rookeries, or breeding-places, were also seen. Several icebergs were floating out of the sound, some of which were dark-coloured; and upon one I found a quantity of rock that had come down with it from the mountains. There was serpentine and granite, specimens of which were collected, and given to Captain King. One of the bergs, which was large, was aground. It was nearly seven fathoms above the water, and bottom could not be found by sounding round it with twenty-one fathoms of line.

"Fury Cove is diminutive; there is not more than sufficient space for two small vessels; but the ground is good, and in every other respect it is a secure haven. We sailed on the 3d of March with the expectation of soon recognizing some known points in the Gulf of Trinidad; but as the wind failed, we were obliged to anchor for the night in Sandy Bay, in eight fathoms.

"As we proceeded to the southward, the appearance of the country gradually changed: the mountains seemed more barren, the trees and shrubs more stunted, the land rose more suddenly, and the shores of the channel became bolder, and presented an uniform rocky line of coast.

"(4th.) We again steered southward, and at noon an opening appearing on the east side, which ran several miles inland, I sought an adjacent anchorage, in order that it might be explored. Our boats were examining the shore all day, and

© The Complete Work of Charles Darwin Online

sounding in the coves, but no fit spot was found; therefore we were forced to stop in an ill-sheltered nook, termed Small Craft Bight, which just served us (having fair weather) as a resting-place until morning (5th), when we set out again to find a better anchorage; for I still desired to ascertain whether the opening to the eastward was a sound or a channel. In our course to the southward we traced both shores in search of a stopping-place; but there was neither bight nor cove where it was possible to anchor, until we arrived at Open Bay, which lies near the entrance of Wide Channel. Even this was such a very insecure place, that although I remained the next day, to examine the neighbouring coast, it was far too exposed an anchorage for the vessel to continue in while the boats were away at a distance.

"Disappointed by not finding a place for the schooner near the opening I wished to explore, I was yet averse to leaving it unexamined, having traced every inlet to its extremity for upwards of two hundred miles along the continent. I wished to continue so sure a mode of proceeding; and although I felt certain that this opening terminated like the rest, and Mr. Kirke held the same opinion, I would gladly have prevented any doubt by following its course in the boats, could we have gained a safe anchorage for the vessel. The nearest harbour that could be found was thirty miles from the opening, and it would have detained us too long to send the boats such a distance; so considering that we had yet a great extent of coast to examine; that my state of health did not permit me to undertake any very exposed or arduous service; and that Mr. Kirke was the only person to whom such duty could be entrusted, I was induced to relinquish our former practice of exploring every opening to its end.

"We left Open Bay on the 7th, and soon entered Concepcion Strait, keeping along the east shore, and sending a boat, at every opening, to seek a situation for the vessel. In the afternoon, a tolerably sheltered bay was found, at the south end of the North Canning Island, open only from S.E. to S.W.; but those winds being frequent and violent, and the

© The Complete Work of Charles Darwin Online

bay exposed to a long reach of sea from that quarter, it cannot be accounted a safe harbour; yet it was very far preferable to many places in which we had been obliged to anchor.

"This bay (Portland Bay) is on the north side of an opening called by Sarmiento 'Canal de Tres Cerros,' and from the broken state of the interior high land, one is led to imagine a channel might be found there. His conclusion, I have no doubt, was drawn from this appearance, since the view down the opening is very limited, and, at the distance of three or four miles within the entrance, is interrupted by several small islands. Mr. Kirke passed between those islets, and followed an opening to the S.E., for upwards of eight leagues. On his return, he reported that he had found a fine channel, of which the principal entrance was the opening of Sarmiento's 'Canal San Andres.'

"On the 12th, in full anticipation of making some interesting discovery, we sailed into the 'Canal San Andres,' anchoring in the afternoon in Expectation Bay, where we remained until the 15th. During that time, Mr. Kirke was employed examining the different openings, and tracing this supposed channel farther. At his return, he said that he had found a termination to every opening, even to that in which we then were, which he had previously thought to be a channel. Like the rest, it extended only to the base of the snowy Cordillera, and then was suddenly closed by immense glaciers.

"This information caused great disappointment, as all hope of passing through the Cordillera, thus far northward, was now given up; and I was fearful we should be delayed many more days before we could extricate ourselves from this (as we then supposed) false channel. We were many miles within the entrance; in that distance there were no anchorages, and the wind being generally from the westward, I anticipated much labour before we could effect our return; but the very next day we were so fortunate as to have a slant of fair wind, by which we cleared this opening, and a second time entered Concepcion Strait. Knowing, by our former survey, that there was no anchorage along the coast to the southward of Cape San Andres before reaching Guard Bay, I ran over to Madre

© The Complete Work of Charles Darwin Online

de Dios, and brought up in Walker Bay. Fortunate we were, too; for before midnight the weather became so stormy as to oblige us to strike the topmasts and yard, let go a second anchor, and veer a long scope of cable. At few places in these channels where we had anchored, could we have veered even half a cable. We remained the following day, and on the 21st, the weather being moderate, ran for the Guia Narrow, and having a favourable tide, passed through easily.

"It was my wish to have anchored among the islands to the southward of Cape Charles, since that would have been the most convenient place for the Adelaide, while examining the opening beyond Cape San Antonio; but hauling round the headland into a bay formed by those islands, no soundings could be gained; and not perceiving any bight at all likely to afford shelter, I continued my course for Puerto Bueno, where Sarmiento thought there was good anchorage. In the evening, with the assistance of the boats, we moored in Schooner Cove, Puerto Bueno, and the next day, Mr. Kirke went to examine the opening north of San Antonio.

"While we remained, a plan was made of this port, which lies five miles S.E. from Cape Charles and three and a-half from Bonduca Island. The shore is steep, and without any indenture. To the southward is Lear Bay, a mile in extent, affording anchorage, but not to be chosen when such an excellent haven as Puerto Bueno is near. The south extreme of this bay forms the north point of Puerto Bueno, and a few hundred yards south of that point is Rosamond Island, which is low and pointed; four hundred yards S.S.E. of this, is a small round islet, bold to on every side; and between this islet and a low point, a quarter of a mile to the S.E., is the widest channel to the anchorage. Sarmiento, indeed, most appropriately named it Puerto Bueno. It has both an inner and an outer port, the depth of water throughout is from nine to six fathoms, and any position in either I consider safe; but excepting that it affords better shelter, it differs in no respect from other anchorages in these regions. Wood and water are generally found in abundance near them all: fish may be caught; geese, ducks, shags, and

© The Complete Work of Charles Darwin Online

steamers may be shot; and shell-fish gathered. The country, also, has the same appearance, and is of a similar nature; for if you force a passage through the woods, it is over fallen trees and moss; if you walk over clear flat ground, the place is found to be a swamp; and if you ascend the hills, it is by climbing over rocks, partially covered with spongy moss.

"Mr. Kirke returned on the 24th, having found that the opening beyond San Antonio led to the N.E., and at ten miles from the cape communicated with that called the Canal San Andres.

"At daylight we left Schooner Cove, and in passing down Sarmiento Channel I tried, though unsuccessfully, to reconcile some of his remarks with our own observations. South of San Marco and San Lucas there are two extensive bays, which we afterwards found communicated with an opening between San Mateo and San Vicente, separating the greater part of the eastern shore of this channel from the main land.

"I wished to anchor near Cape San Lucas, but around that opening no place could be distinguished likely to afford shelter, the shore in every part being bold, steep, and rocky. A like uniformity of coast presented itself as far as Cape San Mateo; but on the west side, along both Esperanza and Vancouver Island, lie many bays that are well adapted for vessels. Sailing, however, under Cape San Lucas, we stood for San Mateo, and succeeded in anchoring in a small port, formed by Weasel Island, scarcely large enough, but perfectly safe, when once we were secured. From this place the boats were despatched. An opening east of our present station was to be traced, and this part of Sarmiento Channel, with the entrance between San Mateo and San Vicente, was to be laid down. These operations, which in moderately fair weather would not have occupied three days, were not completed before the 31st, from our being delayed by violent winds, and almost continual rain. We had also had exceedingly bad weather during our stay in Puerto Bueno, and those employed in the boats had undergone very severe fatigue, and had suffered much from wet and cold. A short distance within the entrance of the

© The Complete Work of Charles Darwin Online

opening, between Cape San Mateo and San Vincent, it turns suddenly to the south and S.b.E., continues in that direction for nearly thirty miles, washing the base of the Cordillera which rises from it precipitously, and is closed by a low isthmus, two miles across, dividing this inlet from Stewart Bay, and over which Mr. Kirke passed to take the bearings of several points that he recognised in Collingwood Strait.

"In the prosecution of the survey northward of our anchorage, those passages were discovered which separate so much of the east coast of Sarmiento Channel from the main land; and the islands thus made known I named after Commodore Sir Edward Owen,* the channel of separation being called Blanche Passage.

"One of the boats met with a canoe containing eight Indians; this was only the second that had yet been seen during our cruise.

"An interview, which two of the schooner's men had with these people, is so characteristic of the habits of the natives who wander in canoes, that I add the account, as given by one of those men: 'When we arrived at the wigwam, there were two women and five children inside, and a dozen dogs near it. At our entrance, the children crept close to one side of the wigwam, behind their mothers, who made signs for us to sit down on the opposite side, which we did. The women, seeing that we were wet, and meant to do them no harm, sent the two eldest children out to gather sticks, and made up a large fire; so we cut some pieces of bread from a loaf which we had, and distributed them. They all appeared to like the bread, particularly the youngest, which was sucking at the breast; for it eat its own slice, besides one we gave its mother. After we had been there about half an hour, and had given them some beads and buttons, a man came in from behind the wigwam, where he had concealed himself when we entered, and sat down beside us. By signs, he asked where our boat was, and how many men there were with us. We told him the men and boat were a little way off, and made signs that we wanted to

* At the request of Lieutenant Mitchell, of the Adventure.

© The Complete Work of Charles Darwin Online

stay all night with him. We then gave him some bread, which he smelt, and afterwards eat. He offered us some sea-elephant blubber, about two inches and a-half thick ; we took it, and making signs it was not good, flung it on the fire. As soon as it began to melt, he took it from the fire, put one part in his mouth, and holding the other drew it back again, squeezing out the oil with his teeth, which were nearly shut. He put the same piece on the fire again, and, after an addition to it, too offensive to mention, again sucked it. Several more pieces were served the same way, and the women and children partook of them. They drank large draughts of water as soon as they had done eating. As it grew dark at about eight o'clock, the man began to talk to the women about our 'sherroo' or boat, and our men, who he thought were near. They seemed to be alarmed, for the women shortly after left the wigwam, and did not return. They were quite naked. The man took the youngest child in his arms, squatted down with the rest, and making signs that he was going to sleep, stretched himself by the fire, the children lying between him and the side of the wigwam. Soon afterwards another man came in, who seemed to be about twenty-two years of age, younger by ten years than the first we saw. He had a piece of platted grass round his head, in the form of a band. After talking some time with his companion, he talked and laughed with us, ate some bread, and would have eaten all we had, if we had not kept it from him. He ate about two pounds of blubber, broiling and squeezing it, as the other had done, and drank three or four pints of water. We had only one case knife, which he was very fond of borrowing now and then, to cut the blubber, pretending that the muscle shells, which he broke for the purpose, were not sharp enough. He examined all our clothes, felt our limbs and breasts, and would have taken our clothes off, if we had let him. He wanted a knife, and was continually feeling about us for one, as we did not let him know that we had only one. He opened a rush basket, and took out several trifles, such as fire-stone,* feathers, spear-heads, a sailor's old mitten, part of

* Iron pyrites.

© The Complete Work of Charles Darwin Online

a Guernsey-frock, and other things, some of which he offered for the knife.

" 'About midnight it rained very hard, and the inside of the wigwam became soaked with wet; so they all roused up, and made a large fire; then ate some blubber, and drank some more water. They always carried a firebrand with them when they went out in the dark to get water, or for any thing else they might want. When they had well warmed themselves they lay down again. The young man lay close to us, and, when he supposed we were asleep, began to search the man who had the knife, but we kept watch and he could not get it. About two hours afterwards he made up the fire, and went out, as we thought, for firewood: but for no other purpose than to take away bushes from the side of the wigwam, that he might have a clear passage for what he intended to do. Returning, he took up a piece of blubber, and asked for the knife to cut it. As soon as he had cut a slice, and put it on the fire, he darted through the part of the wigwam, which he had weakened, like an arrow. The other man seemed to be very much vexed, and thinking, perhaps, that we should do some mischief in consequence of the loss of the knife, watched an opportunity, when he thought we were asleep, to take out all the children, and leave us quite by ourselves. About two hours after, he returned, and pulling down dry branches, from the inside of the wigwam, made up a large fire. We had no doubt that the younger man was at hand watching us, and just at daybreak, as we were preparing to start, he jumped into the wigwam with his face streaked almost all over with black, and pretended to be quite a stranger. When we asked for the knife, he would not know what we meant, but took up one of our shoes that lay on the ground, and gave it to us. The band of grass was taken off his head, and his hair was quite loose. There were neither skins, spears, nor arrows in the wigwam, but no doubt they were in the bushes; for when we threatened to take the canoe he jumped into the wood, resting on one knee, with his right hand on the ground, and eyed us sharply till we were out of sight.'

© The Complete Work of Charles Darwin Online

"The other family seen in the Mesier Channel we did not communicate with, and it may be remarked that in this passage, although between four and five hundred miles in extent, we did not meet twenty human beings; a strong evidence that these regions are very thinly inhabited, particularly when it is considered that we made no rapid progress, and that our boats traversed, through different channels, at least twice the distance run by the vessel."

CHAPTER XIX.

Sarmiento Channel—Ancon sin Salida—Cape Earnest—Canal of the Mountains—Termination of the Andes—Kirke Narrow—Easter Bay—Disappointment Bay—Obstruction Sound—Last Hope Inlet—Swans—Coots—Deer—River—Lagoon—Singular eddies—Passage of the Narrow—Arrival at Port Famine—Zoological remarks.

"(April 1st). THIS morning the weather was very unsettled, squally, and thick: but as no delay could be admitted, when there was a possibility of moving, we left at eight o'clock, and followed the course of Sarmiento Channel. I have no doubt that a passage exists eastward of Point San Gaspar, leading to Collingwood Strait, and forming an island between that point and Cape San Bartolomé: but with the N.W. wind and bad weather we then had, that bight was too leewardly for us to venture into.

"The knowledge of an opening there could be of no great importance, yet had I been able to find an anchorage near Cape San Bartolomé I would gladly have profited by it, in order to assure myself of the existence of a passage. In hauling round, the appearance of the land favoured my impression; but our chief object being to seek a channel through the high mountains, I stood toward Stewart Bay, the most southern part examined by the boats. Finding I could not anchor there without entering the bight and risking delay, which I was unwilling to do, as I wished to reach Whale-boat Bay as soon as possible, we proceeded and anchored in the evening in Shingle Roads, ready for moving the next morning. Having, last year, passed along the whole line of coast, from Cape Earnest to this place, there seemed to me no necessity for a closer examination, for I knew there was no opening within that distance, and I could very little improve what was then laid down on the

© The Complete Work of Charles Darwin Online

chart. The weather was very unpromising, and at daylight the next morning it blew hard from the N.W., but we weighed and ran to the southward. When in the 'Ancon sin Salida' of Sarmiento the wind suddenly shifted to the S.E., and was so strong that we were quite unable to beat between Cape Earnest and the northern island of the 'Ancon,' but passing round, found anchorage near the east end in a small bay: however, as the wind had moderated, and the Canal of the Mountains was open to us, on the east side of which there appeared to be several secure bays, we kept under sail, and in the evening anchored in Leeward Bay, which we at first thought would afford excellent shelter, but on reaching it found we had erred exceedingly. There was no time to look for another, so we moored, and prepared for bad weather, which, as usual, was soon experienced; and we were kept two days without a possibility of moving, or doing any thing to make our situation more secure. We had heavy squalls during the whole time; the wind being generally west or W.N.W., but at times nearly S.W., when more swell was thrown into the bay.

"On the 5th we got clear of this bad and leewardly anchorage, the wind being more to the N.W.; but we had still such very squally weather, with rain, that it was a work of several hours to beat to Whale-boat Bay, where we moored in the evening, and prepared for examining the coast with our boats, both to the east and west. Before leaving Leeward Bay, a round of angles was taken from high ground north of the anchorage, and it was satisfactory to reflect that the 'Ancon sin Salida' was traced far more correctly than could be done in our former visit. There was constant rain and squally weather all the morning, and only in the latter part of the day could any work be performed in the boats. On the following morning Mr. Kirke went to trace the Canal of the Mountains, and I rejoice to say that I was again able to assist in the boat service, and went to examine some openings. After leaving Kirke Narrow on the right hand a wide sound appeared, about nine miles in length; and having traversed it, we turned to the east, through a narrow intricate channel (White Narrow),

© The Complete Work of Charles Darwin Online

obstructed by several small islets, and passed suddenly out into a clear, open bay. Our prospect here became wholly different to that which for months before we had daily witnessed. North and south of us were deep bays, while to the east, between two points seven or eight miles apart, our view was unobstructed by land, and we were sanguine in hoping that we had discovered an extensive body of water. There was also a considerable change in the appearance of the country, which no less delighted than astonished us; for so gratifying a prospect had not been seen since leaving Chiloé. Eastward, as I said before, we could perceive no land; to the north-east and south-eastward lay a low flat country, and the hills in the interior were long, level ranges, similar to that near Cape Gregory, while behind us, in every direction westward, rose high rugged mountains. I fully believed that our course hereafter would be in open water, along the shores of a low country, and that we had taken leave of narrow straits, enclosed by snow-capped mountains: the only difficulty to be now overcome was, I imagined, that of getting the vessel safely through the Kirke Narrow; which, hazardous as I thought the pass, was preferable to the intricate White Narrow, through which we had just passed. Such were my expectations; and with so noble a prospect in view, I hastened to look for anchorage for the schooner, which I succeeded in finding at a place named by me Easter Bay, and returned on board the next day through Kirke Narrow. Mr. Kirke employed three days about his work, having traced the inlet, which trended northward from Cape Grey for nearly eleven leagues. He found that it was bordered on each side by a steep range of mountains, broken here and there by deep ravines, which were filled with frozen snow, and surmounted by extensive glaciers, whence huge avalanches were continually falling. The western side of this canal is formed by the southern termination of the Andes. At the northern end are two bays, with sandy beaches, backed by low land, which, however, rises gradually to high peaked mountains, distant about two miles.

"Early on Easter Tuesday we left Whale-boat Bay, and

© The Complete Work of Charles Darwin Online

proceeded towards the Kirke Narrow. We had been unvarying in watching and trying the strength of the tides during our stay; but the observations never accorded with those in the narrow, and our calculations this morning, after all the trouble we had taken, were found to be erroneous. On approaching the place we met a stream of tide setting to the S.W. between two and three knots; the wind was light; we sometimes gained ground—at others were forced back by the strength of the tide—and thus kept hovering near the entrance until eleven o'clock; when the tide slackened, and we neared the eastern end, which is by far the narrowest part, and where, I apprehended, every exertion would be required to clear the rocks; but fortunately it was at the moment of slack water—we passed through easily, and our anticipated difficulty vanished. This eastern entrance is narrowed by two islands, which contract the width, at one part, to a hundred and fifty yards. When clear of this passage, Point Return, Point Desire, and Easter Bay were in sight, and we found ourselves in a channel much wider than those to which we had been lately accustomed. To the south was a deep sound, apparently branching in different directions between high land, but our principal object was the low country to the N.E., and through this we were so sanguine as to make sure of finding a passage. In the evening we anchored in Easter Bay, and moored the schooner in four and six fathoms, over a muddy bottom.

"Next morning (12th) the boats were prepared for going away to gain a better knowledge of the country around, to find out the best anchorage, and to become acquainted with some of the many advantages that, from the prospect before us, we considered ourselves sure of experiencing. Mr. Kirke went to examine Worsley Sound, and he was desired to examine every opening as he proceeded eastward. As soon as he was gone, I set about measuring a base between Easter Bay and Focus Island; which, being of moderate height, appeared to be a favourable position for extending the triangulation. This work was soon finished; but I was greatly disappointed, when on the summit of the island, with the view that presented itself

© The Complete Work of Charles Darwin Online

to the eastward. The low points, before mentioned, beyond which, from Easter Bay, we could distinguish no land, and between which we expected to make good our course to the S.E., appeared to be connected by a low flat country. An extensive sheet of water was indeed observed to the eastward, yet I could only, from its appearance, conclude that it was a spacious bay.

"My attention was next drawn to the southward, in which direction, to the east of Woolley Peninsula, appeared a wide and deep opening, and this I determined to explore on the morrow; for it was now the only course likely to lead us to Fitz Roy Passage, where it became every day more indispensable that we should arrive, since our provisions were getting short. At my return on board, I learnt from Mr. Kirke that he had examined the greater part of Worsley Sound, whose eastern shore formed a line of coast almost connected with that of the bight before us, to which the name of Disappointment Bay was given.

"It was arranged that he should proceed from his last point, and carefully trace the shore of Disappointment Bay to the eastern headland of the southern opening, down which it was my intention to proceed. With these objects in view, we left the schooner next morning. A fair wind soon brought me to the entrance, where I landed to take bearings on the west side, and arrived at the promontory of 'Hope' by noon. There I ascended to the summit of the hills, but found them so thickly wooded, that my anticipated view of the land was almost intercepted, and the angles taken were in consequence very limited.

"At this promontory the course of the channel trends slightly to the eastward; and its direction is afterwards to the S.S.E., being open and clear for eight or ten miles, when low land stretching across from the west side intercepts the view. In passing to the southward, I landed frequently to continue the angles, and hauled up, at the close of day, in Rara Avis Bay, still doubtful of the nature of the opening.

"Next morning, passing Point Intervene, we pulled into an extensive reach; and having landed, to take bearings, on the

© The Complete Work of Charles Darwin Online

east side, near Cape Thomas, I proceeded, in hopes that beyond the next point some better prospect would be gained: on arriving there, however, my expectations were instantly checked by a bold rising shore, continuing uninterruptedly as far as the Oliver Islands, which we passed soon afterwards.

"The width of the channel between the Oliver Islands and the northern shore is not more than a mile, but it afterwards increases, and turns sharply first to the west, and then S.S.W. In the west reach there are many small islands, and the high ranges on both sides being detached from each other, gave me yet some hopes of finding a passage between them. Proceeding in the afternoon, a bight appeared to the S.S.E., about two miles to the westward of Cape Up-an'down, which was examined, although there was no prospect of meeting with success by tracing it, and in it were found two small passages leading to the S.E., suitable only for boats. We ran down the largest, and a mile within the entrance were embayed. At the bottom of this bight the land was low, and I tried to get on some eminence, that I might command a view to the S.E., but was always impeded by an impervious wood. I observed, however, distant high land in that direction, and could see a sheet of water, about six miles from me: but whether it was a lagoon, or a part of the Skyring Water, was doubtful. I could not, at this prospect, rejoice as Magalhaens did, when he first saw the Pacific, for my situation, I began to think, resembled that of Sterne's starling.

"Keeping along the south shore, until late in the evening, we gained the west end of this reach, and finding no shelter for the boat, crossed to the broken land on the west side, and passed that night in Hewitt Harbour.

"On the following morning, we pursued our course to the S.S.W., and at eleven o'clock reached the extremity of this extensive sound. All our suspense was then removed, and all our hopes destroyed; for the closing shores formed but a small bay in the S.W., and high land encircled every part without leaving an opening.

"Throughout the examination of this sound, we did not

© The Complete Work of Charles Darwin Online

distinguish any decided stream of tide, and the rise and fall did not appear to have ever exceeded a foot: that there was a slight tidal movement of the water seemed evident, from the streams of foam coming from the cascades; and also from the fallen leaves which were borne on the water, from the shores of the bays, in long lines; but signs like these are indicative of there being no strength of tide: I have frequently noticed such appearances in large sounds, or inlets, but never in any channel where there was a current.

"The bays between Hope Promontory and Point Intervene are frequented by immense numbers of black-necked swans (*Anser nigricollis*): hundreds were seen together; they appeared not at all wild when we first passed; but, on our return, there was no approaching them within musket shot. Many ducks and coots were also observed. On a rock, near the Oliver Islands, was a small 'rookery' of hair-seal; and, in our progress down the sound, we passed some few shags and divers. This is the enumeration of all we saw, and these few species seem to possess, undisturbed, this Obstruction Sound; for we neither observed any wigwams, nor saw any traces of inhabitants.

"Having no interest in remaining, after some necessary angles were taken on Meta Islet, we commenced our return; and, with a fair wind, made good progress, landing only where it was necessary for angles, and reached the vessel on the evening of the next day (16th). I have fully stated the examination of this sound, and have been, perhaps, unnecessarily particular and diffuse; but I think that when its near approach to the Skyring Water is known by others, it will be considered very singular that no communication exists between them. To every one on board the Adelaide it was a great disappointment. The only inlet now remaining to be explored was through the S.S.E. opening, east of Point Return; which, on the 18th, I went to examine. Mr. Kirke returned on the same day as myself, having traced the coast as far as he had been directed, and found the large expanse of Disappointment Bay nearly bounded by a flat stony beach; and the water so shallow, that even his whale-boat could seldom approach the shore within a quarter of a

© The Complete Work of Charles Darwin Online

mile; but he had left a small opening in the N.E. unexplored, which, as our last hope, I thought it necessary to examine; and he went for that purpose the next morning. Situated as we were, we had great reason to be very earnest in the search for a passage; and, I think, that no channel into the Skyring Water, however small and intricate, would have been left unattempted at this crisis. During the vessel's continuance in Easter Bay, the men, who remained on board, were employed in clearing the hold, and completing wood and water to the utmost, in order that we might not be delayed at any anchorage after our departure thence.

"On the 18th, I went, in a boat, down the opening east of Point Return; and by noon reached Virginia Island. Two miles to the southward the channel branches to the S.E., and to the S.W.; I followed the latter branch, landing where necessary to continue the angles, and arrived in the evening at the extremity, which was closed by low land; in the middle was a wide and rapid stream. The slot of a deer was seen along the margin of the shore. Next day we proceeded down the S.E. branch to the Centre Island, thence steered towards an opening that appeared in the S.W., and passing through a narrow winding passage, entered a large bay, which was closed at the bottom by low land, similarly to the branch examined yesterday. Only an opening to the N.E. now remained to be explored; but night coming on, we hauled up in Tranquil Bay, near the northern extremity. The N.E. opening was found to trend eastward for three miles, and then turn to the S.E., forming an extensive bay, whose shores were encircled by low land, and only separated from Obstruction Sound, by an isthmus two miles broad. Our search being concluded, I hastened back, and arrived on board the schooner late in the evening. Finding Mr. Kirke had not returned, I still entertained some little hope, and the vessel was prepared to move either one way or the other as soon as he came back.

"Late on the 21st, Mr. Kirke arrived. The opening in the N.E. had been traced for nearly thirty miles from the entrance, first to the N.E., and then to the W.N.W., till it was closed

© The Complete Work of Charles Darwin Online

by high land far to the northward of Worsley Bay. Many deer were seen on the plains eastward of the inlet, and some were shot at, but escaped. Swans, ducks, and coots had been killed in such numbers, that on their return all the schooner's crew were plentifully supplied. Of this place Mr. Kirke says: 'At the commencement of the N.E. sound there is low land, which extends about thirteen miles up its shores. The entrance is three or four miles wide; but five miles up, the inlet is contracted to about half a mile in width, by a shoal connecting three islets with the western shore. These islets were literally surrounded by black-necked swans, mixed with a few which had black-tipped wings: the male of the latter has a peculiar note, which sounds like 'ken kank,' but the female only sounds 'kank.'

"'A few coots were shot in this neighbourhood, out of an immense quantity seen. In each of two flocks, I think, there must have been upwards of a thousand.

"'From these islets the sound trends nearly north for seven or eight miles, when it is again narrowed by an island, on each side of which there is a narrow passage for a vessel; but the eastern one is the best. The few bays near here are fit for small vessels only.

"'Beyond this island the face of the country begins to alter from low to mountainous land, with long flats in the valleys, and the sound also changes its course more to the N.W. Near a high bluff on the eastern shore, eight miles further up the sound, the land becomes higher and covered with snow; yet there are still a few level patches between the mountains. From this bluff the sound trends about a point more westerly for five or six miles, to a place where there is a small inlet, on the left, between two snow-covered, mountainous ridges. The water there was changed to a clayey-colour, and had a brackish taste. Continuing our course for two miles, I found a large expanse of water, the north end of which was limited by low land, backed by high snowy mountains in the distance; its southern extreme terminated at the foot of high mountains, also covered with snow; and had a large run of water from a

© The Complete Work of Charles Darwin Online

glacier on the western side. In returning we saw some deer on the eastern shore of the low land, between the islands of the second reach, but could not get within gun-shot: they appeared to be of a dark colour, and fully as large as a guanaco. Some of our men thought they could distinguish small straight horns, but I could not myself see them.(*d*) I endeavoured to cross the isthmus, where Lieutenant Skyring had seen water from Focus Island, near Easter Bay, and first attempted it by the course of a fresh water river, at the head of the bay; but I found the country so thickly covered with stunted wood, about eight feet high, and exceedingly prickly, that I lost my way twice, and returned to the shore; I tried again however, about half a mile more to the eastward, and at last got to a high part of the land. When there, and mounted on another man's shoulders, I could scarcely see above the trees (which, at the roots, were not thicker than a man's wrist): there was evidently a large expanse of water, but I could not distinguish much of it. I think it probable that it is fresh, as the river, fifty yards wide, is rapid, and appears to run out of it. There is not any high land in the neighbourhood, whence such a run of fresh water could be supplied.

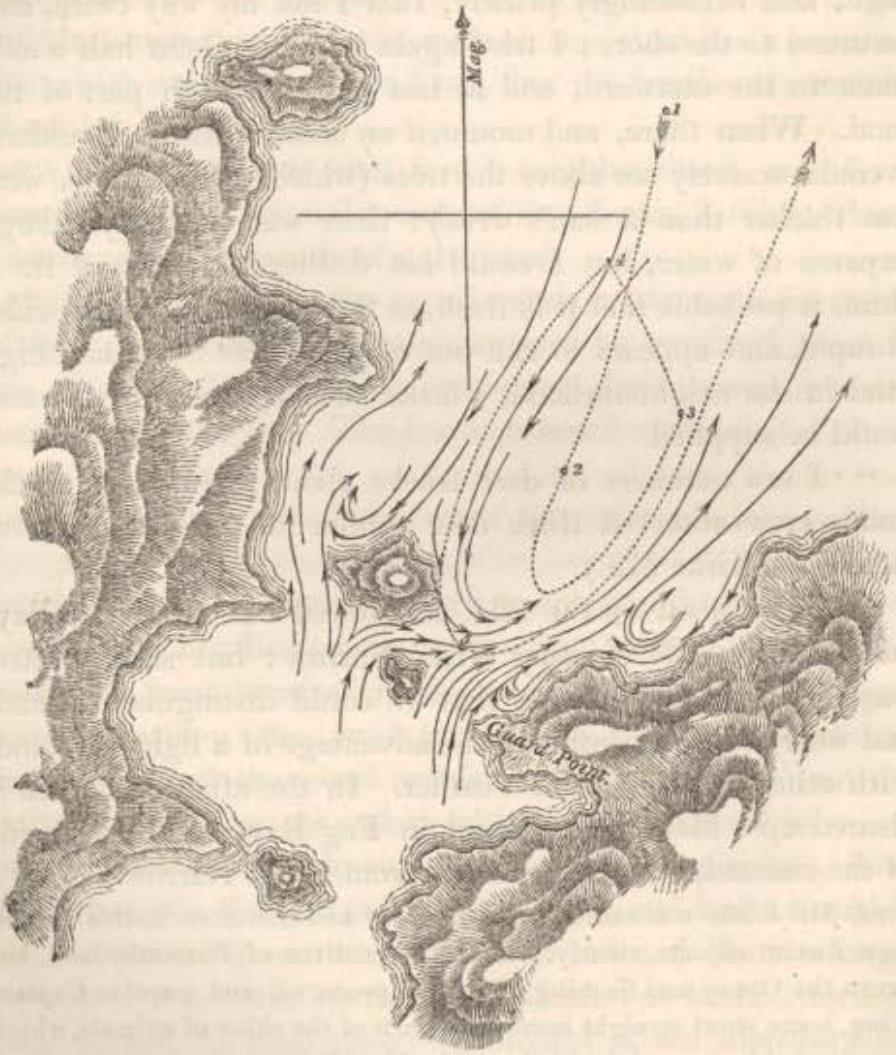
"'I saw numbers of deer tracks about this place, and the boat's crew observed three deer similar to those above-mentioned.'—(Kirke MS.)

"We weighed on the 22d, and towed out of Easter Bay, with the hope of repassing Kirke Narrow; but shortly afterwards so dense a fog arose, that we could distinguish no land, and were unable to profit by the advantage of a light fair wind, with otherwise favourable weather. In the afternoon, when it cleared up a little, we anchored in Fog Bay, on the west side of the channel, about three miles from Kirke Narrow.

(d) Mr. Kirke was rather short-sighted, and therefore unable to discern distant objects clearly. From the natives of Ponsonby land, between the Otway and Skyring Waters, I procured, and gave to Captain King, some short straight horns, and parts of the skins of animals, which were probably deer of the kind seen by Mr. Kirke, and, since that time, by Mr. Low, when he followed my track into the Skyring Water with his sealing vessel, the Unicorn schooner.—R. F.

© The Complete Work of Charles Darwin Online

" (23d.) A thick fog confined us at our anchorage till eight, when, having some hopes of the weather clearing, we weighed, and stood for the Narrow, but a continued haze prevented us from entering until after noon. As we approached, no tide could be perceived, and again we were doubtful of our calculations, having expected to find it favourable, however, we steered for the islands. To give a better idea how we were driven about as we tried to approach this Narrow, I have attempted, in the subjoined plan, to show the direction of the currents, and the courses we were carried by the eddies.



" The wind was light from the north-eastward. Upon our reaching the station marked 1, without having previously

© The Complete Work of Charles Darwin Online

noticed any current, we observed a strong rippling in the Narrow, and immediately sent the boats a-head to tow us towards mid-channel. We proceeded rather quickly until we arrived at 2, when our progress was checked, and we were carried rapidly back, as far as 3. In the Narrow the tide was evidently against us; but in crossing to the N.W. at 4, we were forced by the counter-current against all the efforts of the boats—were carried close to the large island—and for the space of thirty yards, were brushing the overhanging trees with our main-boom. This part was, most fortunately, quite steep; for had the vessel touched in her swift course, she must have been swung with violence against the rocks, and much damaged, perhaps irreparably.

"No sooner had we passed the end of this island, than we were shot into mid-channel to 5, and then as suddenly and swiftly carried back by the stream of the tide. The boats could never keep hold of the vessel while in these whirlpools; and it was several times fortunate that they had cast off the tow-rope in time, for thrice we were twisted round, as if on a pivot, by those violent eddies.

"A favourable moment was seized, the boats were again sent a-head; and, by great exertions, we were towed out of the influence of the tide, and then waited for the time of slack water.

"At three o'clock Mr. Kirke was sent to Guard Point, to ascertain the time of high water; and at half-past four, in consequence of his signal, we towed in with both boats, and passed the islands with a favouring tide; but one quarter of a mile farther, we met ripplings, which we had no sooner entered than a reverse of tide was found, as if the waters from the sounds were gradually forcing back the tide of the channel. We still, however, made progress to the S.W.; but it was not before eight o'clock that we anchored in the west entrance of this Narrow, pleased, indeed, to be again secure, and to have escaped unharmed.

"24th. Thick, hazy weather in the morning; but at eight o'clock it cleared a little, so we weighed, and soon reached the

© The Complete Work of Charles Darwin Online

Ancon of Sarmiento. A strong S.E. wind, during the forenoon, carried us past Cape Año Nuevo, and at noon we were near the opening into Smyth Channel, which I have called Victory Passage. We moored in Sandy Bay, in eight fathoms, purposing to remain during the next day (Sunday); and on the 26th, with a moderate wind from the northward, we left Sandy Bay, and stood to the south, passed the Elson Islands by noon, and at three moored in Hose Harbour. Next day we cleared Smyth Channel, and anchored in Deep Harbour.

"(28th.) Wind light and northerly. We towed out of Deep Harbour at daylight, stood across Beaufort Bay, and anchored in Tamar Bay; where, the weather being unfavourable, we remained during all the next day, filling water and cutting wood,—preparatory to our run to Monte Video,—in case of not finding the Adventure at the appointed rendezvous, Port Famine.

"On the 30th, with a moderate breeze from the N.W., we left Tamar Bay; but the wind soon after becoming contrary, we made but little progress, and anchored that evening in a small cove, near the east point of Upright Bay, where we passed the following day, in consequence of the wind continuing easterly, and causing much sea in the Strait.

"2d. Weighed, stood out, and made all sail, steering through the Strait. We passed Playa Parda early that afternoon, and Cape Quod soon afterwards, and as there was every appearance of a moderately fine night, continued our course. We hauled in near Port Gallant, when it grew dark, and burned a blue light, to call the attention of any vessel lying there; but no return was made, so we passed on. At midnight we were between Cape Holland and Cape Froward, the wind being light and the weather moderate.

"3d. On rounding Cape Froward, we beat up in-shore against a N.N.E. breeze, and in the evening were three or four miles to the northward of Point St. Isidro. After a tempestuous night, we reached Port Famine, where, to our great joy, we found the Adventure."

With the exception of such fish and birds as had been pre-

© The Complete Work of Charles Darwin Online

viously observed near the Strait, Lieutenant Skyring and his party saw few living creatures. One novelty which Mr. Bynoe gave me was a splendid corvorant, which, being quite new, and the most beautiful of the genus, I named *Phalacrocorax Imperialis.**

I also received a species of swan, quite distinct from the common one of the Strait, which has been long known as the black-necked swan (*Anser nigricollis* of Ind. Orn., ii. 834; and Latham, x. 223). Considering it an undescribed species, it was named *Cygnus anatodoides.*†

Several deer were seen, but none obtained. There is reason, however, to suppose them to be of a novel species. The horns are short and straight.

* *Phal: capite cristato, collo posteriori, corporeque supra intensè purpureis; alis scapularibusque viridi-atris; remigibus rectricibusque duodecim fusco-atris; corpore subtus, fasciâ alarum maculâque dorsi medii sericeo-albis; rostro nigro; pedibus flavescentibus. Staluria Phal. Carbonis.* It was found in the Inner Sounds, within the 'Ancon sin Salida.'—Proceed. of the Zool. Society, vol. i.; also Phil. Magazine, for March 1831, p. 227.

† *C. albus remigibus primariis ad apicem nigris, rostro pedibusque rubris, illo lato subdepresso.* Molina describes a Chilian duck thus. Anas Coscoroba—*A. rostro extremo dilatato rotundato, corpore albo,* but I do not think it is the same as my specimen; certainly it is not *Anser Candidus* of Veillos, the ganso blanco of D'Azara, which the author of the Dict. D'Hist. Nat. (xxiii. 331.) supposes to be the same as A. Coscoroba (id. p. 332). Molina's description is very short, and does not mention the tips of the primary wing feathers being black.

CHAPTER XX.

Beagle sails from San Carlos—Enter Strait—Harbour of Mercy—Cape Pillar—Apostles—Judges—Landfall Island—Cape Gloucester—Dislocation Harbour—Week Islands—Fuegians—Latitude Bay—Boat's crew in distress—Petrel—Passages—Otway Bay—Cape Tate—Fincham Islands—Deepwater Sound—Breaker Bay—Grafton Islands—Geological remarks—Barbara Channel—Mount Skyring—Compasses affected—Drawings—Provisions—Opportunities lost.

Captain Fitz Roy having received his orders on the 18th of November (see Appendix), sailed the following morning from San Carlos, and proceeding to the southward, approached the entrance of the Strait of Magalhaens on the night of the 24th. The following are extracts from his Journal :—

" At daylight on the 25th, with the wind at S.W., we made Cape Pillar right a-head (E.N.E. by compass), distant seven or eight leagues. The wind became lighter, and we were set by a current to the S.W , which obliged us, in nearing the Cape, to alter our course from E.N.E. to N.N.E., to avoid being carried too near the Apostle Rocks. A dangerous rock, under water, on which the sea breaks, lies half a mile more towards the north than either of the Apostles. Cape Pillar is a detached headland, and so very remarkable that no person can fail to know it easily.

" A very good latitude was obtained at noon, from which, and the astronomical bearing of the Cape, we made its latitude within half a mile of that given in the chart by Captain Stokes and Lieutenant Skyring ; and the weather being clear and fine, sketches were taken of all the surrounding land. At one, we passed the Cape, and at three, anchored in the Harbour of Mercy. By the distance we had run, as shown by the patent log and compared with the chart, there had been a current against us of more than a knot an hour.

© The Complete Work of Charles Darwin Online

" In working into the harbour we passed over several patches of kelp, under which the bottom was plainly visible; but the lead never showed less than five fathoms, until we were about to anchor, when the vessel shot a-head into a weedy place, where we had three fathoms. This was about a cable's length in-shore (towards the highest mountain) of the spot marked by Lieutenant Skyring as good holding ground, to which we warped and anchored. It proved to be very good ground, being extremely tough clay.

" 27th. A promising morning tempted me to try to obtain observations and a round of angles on or near Cape Pillar. I therefore left the ship with the master, and went in a boat to the Cape. To land near it in much swell was not easy upon such steep and slippery rocks: at last we got ashore in a cove, and hauled the instruments up the rocks by lines, but could get no further, on account of precipices. I, therefore, gave up that attempt, and went outside the Cape, to look for a better place; but every part seemed similar, and, as the weather was getting foggy, it was useless to persevere. In going to the Cape, and in returning, I measured the distance by a patent log, and found the mean of the two measurements agree with the chart. What current there was, ran to the westward.

" A small ox, which we had carried from Chilóe, was doomed to end his voyage at this place, and probably we were the first people who ever eat fresh beef in the Strait of Magalhaens.

" 28th and 29th. Gloomy days, with much wind and rain; and the gusts coming so violently over the mountains, that we were unable to do any work, out of the ship.

" 30th. Still blowing and raining.

" Dec. 1st and 2d. Cloudy days, with strong wind; but one short interval of sunshine was gladly made use of for rating our chronometers.

" 3d. This morning we weighed, and worked out; and at one P.M. we were three miles westward of Cape Pillar, with every appearance of a N.W. gale. Shortly after, the weather became so thick, that I could not see any part of the coast; and therefore stood off shore, under low sail, expecting a bad

© The Complete Work of Charles Darwin Online

night. Contrary to my expectation, the wind did not much increase; but the thick weather, and a heavy swell, induced me to stand farther out than I had at first intended. At eleven, P.M., we wore and stood in until daylight on the 4th, when we found ourselves so much to the southward, that the land about Cape Pillar bore N. b. W., the Cape itself being shut in. We steered for the land, hoping to turn the day to some account; but those hopes soon ceased, for before we had run sufficient distance to make a serviceable base line, the weather became so thick as to oblige us to haul our wind. We saw just enough to make out a number of rocks and breakers, lying at a considerable distance off shore. After noon it was clearer, and we again stood in-shore; but found that the current was setting us so fast to the southward, that it was necessary to carry all sail and keep on a wind, to avoid losing ground; yet, with a fresh, double-reefed topsail breeze and a deeply laden weatherly vessel, we could not hold our own, and at seven in the evening were close to an islet which lies off Cape Sunday. We had seen very little of the coast thus far: the current had rendered the patent log useless for measuring bases, and the weather was very unfavourable for astronomical observations. The land appeared to be high and mountainous, as far as Cape Deseado, whence it seemed lower and more broken, forming a large bay between that cape and Cape Sunday. Many rocks on which the sea breaks violently lie at a distance from the shore, besides those two clusters called the 'Apostles' and the 'Judges:' the latter off Cape Deseado, and the former off Apostle Point, a little south of Cape Pillar.

"5th. To our mortification, we found ourselves a great way off shore; and Landfall Island, which was eight miles to leeward the last evening, was now in the wind's eye, at a distance of about six leagues. A strong wind, with much swell, prevented our regaining lost ground in a northerly direction, I therefore preferred standing to the S.E. by the wind, intending to seek for a harbour, as it seemed hopeless to try to survey this coast while under sail, with such obstacles to contend against as a current setting about a mile an hour, and a sky

© The Complete Work of Charles Darwin Online

generally clouded over. Our only chance appeared to be, going from harbour to harbour and keeping close in-shore.

"Behind Landfall Island the coast forms a deep bay, apparently full of islands, and it is said there is in that part a communication with the Strait of Magalhaens. Looking from seaward there seems to be an opening.

"From the southern point of this bay the coast presents a high and regular line for a few miles, and then there is a succession of islets, rocks, and broken land. We stood in close to the breakers, but too late in the evening to find an anchorage. I observed kelp on the surface of the water, growing up from the bottom, while the lead gave a depth of forty-five fathoms. This was in a wild-looking, open bight, full of rocks and breakers, and much exposed.

"We stood off, close to the wind, hoping to make northing and westing during the night; but at midnight it fell calm, and at day-break on the 6th, to our astonishment, we found ourselves to the southward of Cape Gloucester, a high, remarkable promontory, standing out from the land as if it were an island, with a peaked top, which, from the southward, appears notched. The day proved very fine, and as a breeze sprung up from the S.E. and gradually increased, I had hopes of seeing more of the coast, along which we had been hustled so fast, and so much against our inclination.

"In running along shore, I noticed several inlets that seemed likely to afford good harbours. This coast has not, by any means, such a rugged and harsh appearance as I expected; but the number of islets and breakers is quite enough to give it a most dangerous character. The land is not very high near the sea, and seems to be wooded wherever the prevailing winds will allow trees to grow. Soundings were taken at various distances within four miles of the shore, and the depth generally was between twenty and one hundred fathoms. A good idea may be formed of the current which had taken us to the S.E., when I say that, even with a fresh and fair wind, it occupied us the whole of the 6th to regain the place we had left the previous evening.

© The Complete Work of Charles Darwin Online

"7th. At daylight it blew half a gale of wind; but we stood in, a little south of the cluster of rocks, called the Judges, towards a part of the shore which promised to afford a harbour. On closing it we saw an inlet, apparently large; but so fortified at the entrance by rocks and breakers, that I did not like to run in, without first sending a boat; yet it blew too strong, and there was too much sea, to lower one; therefore I stood off to wait for more moderate weather, for the place suited my purpose exactly, being near enough to the Judges, and Apostles, to fix their situation. This morning, Mr. Murray slipped across the forecastle and dislocated his shoulder: an accident which deprived us of his services for some time, and on account of it, we called the place where we anchored soon afterwards, Dislocation Harbour. So many rocks lie off this coast, that a vessel ought not to approach it unless she has daylight and clear weather. The lead will give warning, should the weather be thick, as soundings extend at least to four miles off shore, at which distance there are from thirty to one hundred fathoms, and generally speaking, there is less water as you approach the land.

"On the 8th, 9th, and 10th, we were busily occupied in surveying the harbour and adjacent coast. In this place water may be obtained very easily, as boats can lie in a fresh water stream which runs from the mountains. Wood is also plentiful. The harbour is large enough for four small vessels, and the bottom is very even, from fifteen to twenty-five fathoms, fine white sand. The entrance is narrow, but all dangers are visible, and now are laid down in the chart. It is much exposed to west winds, and the westerly swell, which might for weeks together prevent a vessel from getting out to sea.

"11th. A strong wind and much haziness prevented my weighing until near noon, when it became more moderate, though the weather was still thick. We then worked out with a light and variable breeze, which baffled us near the entrance, but at last we gained a good offing. I rejoiced to be outside, for our business in the harbour was over, and I had feared that west winds would detain us. The promontory, just to the southward of Dislocation Harbour, appeared to me to be 'Cape

© The Complete Work of Charles Darwin Online

Deseado,' and that to the northward I called Chancery Point. Mr. Wilson ascended some heights at the back of the harbour, from which he saw many lakes, among barren and rugged hills; but a farther view was obstructed by other mountains.

"An oar was picked up near the watering place, and recognised by one of the men as the same which was left on a rock near Cape Pillar (in Observation Cove) by Captain Stokes, in January 1827. There could be no doubt of the fact, as the man's initials were on the oar, and it is curious as a proof of an outset along the south side of the Strait (near Cape Pillar), and of its continuation along shore. Traces of a fire were found, which showed that the natives visit even this most exposed part of the coast. The land about here is high, and craggy; and very barren, except in the valleys, where much wood grows. Some wild fowl were seen and shot.

"From Cape Deseado, the coast is high and unbroken for three miles; (a rocky islet lies about a mile from the shore) then there is an opening which probably leads into a good harbour behind a number of islands. Several islands succeed, for a space of two miles, after which is Barrister Bay; an exposed place, full of islets, rocks, and breakers, extending nearly to Murray Passage. In sailing along this coast we passed inside of several breakers; and, I hope, noted all that lie in the offing: but, we cannot be sure, for breakers on rocks which are under the surface of the sea do not always show themselves. As it was getting dark, we hauled to the wind, near Cape Sunday, and, in doing so, were startled by a huge breaker which suddenly foamed up at a small ship's length from us. Although looking out on all sides we had not previously seen any break near that spot. During the night we carried a heavy press of sail to avoid being drifted to the S.E., and at daylight I rejoiced to find that we had not lost ground, so we steered for the land, and rounded Graves' Island. Observing several openings, I hauled close round a point, and tried to enter one of them; the wind, however, baffled us, and our anchor was let go in an exposed berth, but on good holding ground. We found a cluster of islands with so many anchorages between

© The Complete Work of Charles Darwin Online

them, that thinking they ought to be surveyed, I returned on board, weighed, and worked towards the nearest opening. We shot into it, and warped to a berth four cables' lengths up a narrow passage, and anchored in twenty-four fathoms, upon sand and clayey mud.

"13th. Many wigwams were found in this neighbourhood, which showed that our Fuegian acquaintances were occasional visitors. The inner harbour seemed to be a fine basin; but the bottom was found inferior to that of the anchorage at which the Beagle lay moored.

"15th. Strong wind and frequent rain prevented much being done out of the ship this day. I went to the top of a mountain near the ship, but could not take many angles because of the violent squalls and the rain. At night it blew a hard gale: the squalls came furiously over the heights, and obliged us to let go a third anchor and strike topmasts. We were quite sheltered from the true wind; but were reached most effectually by the williwaws, which came down with great force. However vexed we might have been at not being able to go far from the ship, we were certainly very fortunate in escaping this gale at a secure anchorage. It appeared to be blowing very heavily at sea.

"16th. A strong gale all day, with much rain, prevented our leaving the ship. In coming down a height on the 15th, I found some red porphyry rock, like that about Port Desire; and the first I had seen in these parts. Another novelty was a tract of about two acres of pure white sand thinly covered with grass.

"Though the middle of summer, the weather was not much warmer than in winter. The average height of the thermometer was about ten degrees greater; being nearly the same, as during the months of August and September, in Chiloé.

"17th. A continuance of bad weather: no work was done in the boats this day. In the afternoon I tried to go up the mountain I had ascended on Tuesday, to bring down a theodolite which I had left at the top; but the wind obliged me to return unsuccessful.

"18th. Similar weather continued until noon: frequent strong

© The Complete Work of Charles Darwin Online

squalls, and rain: the sky being so constantly overcast that we saw neither sun nor stars. Although no progress was made in this weather, it was some satisfaction to think that we lost nothing but time; and that we saved much wear of the vessel by lying at anchor instead of being at sea. Being more moderate in the afternoon, our boats went away, and the ship was prepared for sailing. We tried to get some fur-seal, which were seen on a rock near the harbour, but they were too wary.

"My boat was almost capsized by a 'blind breaker,' which rose suddenly underneath her, and in an instant she was surrounded by and floated upon a white wave of foam, which broke all round and over, but without upsetting or swamping her.

"19th. Weighed and ran across to an anchorage in Landfall Island which I had seen from the heights. We anchored in a sheltered bay lying on the north side of the larger island, at the east opening of a passage which separates it from the smaller. These islands are high and, towards the sea, barren; but the sides of the hills, towards the east, are thickly wooded.

"A large smoke made near the bay showed us, that the Fuegians were in possession of our intended quarters; and soon after we anchored, a canoe came off to us full of men, women, and children, sixteen in all. They were in every respect similar to those we had so frequently met before; and from their unwillingness to part with furs or skins, unless for serviceable articles, such as knives, &c. appeared to have had dealings with Europeans: beads and trinkets they did not value. They had, in the canoe, many eggs, and dead birds, which they eat raw: the birds were a light blue, or dove-coloured, petrel, about eight inches long, which goes on land for a part of the year to lay eggs in holes in the ground. During this and the following day, we were fortunate enough to obtain observations, and nearly all the necessary bearings and angles.

"As yet I was pleased with the anchorage; the bottom shoaled gradually from twenty to five fathoms (fine sand), and it was sheltered from west winds, besides others, except north. Having obtained particularly good observations for latitude at

© The Complete Work of Charles Darwin Online

this spot; I called it Latitude Bay. It is remarkably easy of access, and is also easy to leave: rather rare qualities in a Fuegian Harbour. Cape Inman being prominently situated, is a good guide to the anchorage.

"Sunday 20th. A fine day; and, knowing its value, we turned it to account. From a height I saw Cape Gloucester and the point of land on this (the northern) side of it; and to the northward I could distinguish the land about the entrance to the Strait. The Landfall Islands appeared to be the top of a ridge of mountains lying (partly below the sea) in the same direction as most of the neighbouring ranges. Many dangerous rocks lie off the S.W. side; and there is no passage for a ship between the islands, for the opening is narrow, and has only two fathoms in some places.

"21st. This morning I sent the master and Mr. Wilson* in a whale-boat to the east end of the island, to make a plan of that part, and get some angles and bearings necessary for continuing the survey.

"22d. A bad day, blowing hard and raining. The wind being from north and N.N.W. threw in a swell; and as we were not yet sure of the quality of the bottom, though apparently good, we struck topmasts and veered away a long scope of cable.

"24th. The wind shifted to the S.W. and became rather more moderate, though still squally, with much rain. It freshened again in the night, and backed to the northward.

"Christmas-day. Blowing strong from N.N.W. with a thickly clouded sky and heavy rain. I was very anxious to see the master return, but he could not in such weather. I feared that his provisions would be exhausted, having taken only enough for four days; yet they had a good tent, guns, and ammunition.

"26th. A strong wind with thick weather and much rain throughout the whole day. There was no possibility of sending a boat to the master, or of his returning by water. The island being very narrow he, or some of his party, could walk across,

* Mate, lent to the Beagle, from the Adventure.

© The Complete Work of Charles Darwin Online

if they were in want of provisions, so as we did not hear from them I trusted that they had found wild fowl enough, and were not in distress.

"27th. Rather a more moderate morning with clearer weather. We looked out anxiously for the whale-boat, as, in such weather, she might get back to the ship without much difficulty. Before noon Mr. Wilson and the coxswain were seen on shore making signals to the ship; and a boat was sent immediately to bring them on board. They were very weak and tired, having walked across the island during the preceding afternoon and night, and having had no food for the last two days. The master and the other four men were said to be in a cove at the back of the island, and to have been without provisions since the 24th, not having been able to find either shellfish or wild fowl.

"At the time Mr. Wilson arrived on board, I was absent taking angles and bearings, but was soon informed of his return, and at noon left the ship with a week's provisions for the master's party and my own boat's crew. I had not lost sight of the Beagle when I met the former returning. Having given them some food, and two fresh hands to help them in pulling to the ship (it being then quite moderate and fine) I continued my course to the place they had left, in order to do what the bad weather had prevented the master from doing. Being favoured with a fine afternoon I succeeded in obtaining the necessary angles and bearings, and returned to our vessel the following morning.

"28th. At my return I found the master and his party nearly recovered. They had tried every day to return to the ship, but had been repeatedly forced back, at the risk of being driven out to sea. The gusts of wind from off the high land were so powerful as almost to upset the boat, although she had not even a mast up. Continual rain had wetted their ammunition and tinder, and they were then without fire or victuals: upon which Mr. Wilson and the coxswain set out, on Saturday afternoon, to acquaint us with their situation.

"When they came down to the sea-side the Fuegians took

© The Complete Work of Charles Darwin Online

advantage of their weak state to beat the coxswain and take away some of his clothes; therefore after my return I went in search of them. They had however taken the alarm, and were all gone away. This party consisted of about twenty persons, eight of whom were men, and the rest women and children. When some of our officers went to their wigwams they appeared armed with clubs, spears, and swords, which seemed to have been made out of iron hoops, or else were old cutlasses worn very thin by frequent cleaning. They must have obtained these, and many trifles we noticed, from sealing vessels. By the visits of those vessels, I suppose, they have been taught to hide their furs and other skins, and have learned the effects of fire-arms. The chief part of their subsistence on this island appeared to be penguins, seal, young birds, and petrel which they take in a curious way. Having caught a small bird they tie a string to its leg and put it into a hole where blue petrels lay eggs. Several old birds instantly fasten upon the intruder, and are drawn out with him by the string.

"We weighed and worked out of the bay, increasing our depth of water very gradually as we left the shore, but having always the same bottom, fine speckled sand. I can safely recommend this bay as a good anchorage for shipping, and two cable's lengths N.N.W. of the Beagle's berth as the best place. Wood and water are not to be found so close to the anchorage as in other Fuegian harbours, but they may be obtained with very little trouble, and in any quantity, by going up the passage (between the islands) to one of many streams which run from the high land. There is plenty of water also very near the best berth, on the south side, but frequently a surf breaks on that beach. Two particular advantages which this roadstead* possesses, consist in the ease with which a vessel can enter or leave it, during any wind; and in its situation being well pointed out by a remarkable headland, named Cape Inman (in compliment to the Professor), which is high, with perpendicular cliffs, and almost detached from other land; so that a vessel,

* A small vessel may moor between the islands, instead of lying in the outer road.

© The Complete Work of Charles Darwin Online

knowing her latitude within five miles of the truth, cannot fail to make it out, if the weather is tolerably clear. Wild fowl and shell-fish were very scarce there, probably because the Fuegians had scared or consumed them. From the top of a mountain, at the east end of the large island, I saw a great way down two channels or openings, which appeared to run far to the eastward, among many islands and very broken land. Such a succession of islets, rocks, and breakers, as the coast presented, was astonishing: many hundreds were counted while looking eastward from one station only.

"I wished much to know where these openings led, and whether there was a direct communication through them to the Strait, as seemed almost certain; but considering the time already spent, the extent of coast to be surveyed, and the small advantage of such information, except to satisfy curiosity, I determined to proceed to the next prominent headland, a mountain at the S.E. extremity of Otway Bay, whose position I had already fixed with respect to stations on Landfall Island.

"If there is a passage through those openings into Otway Bay, it must be unfit for vessels, being hampered with outlying rocks and breakers among which she could find no shelter in the event of rainy weather coming on before she cleared them; and clouds and rain are prevalent. As yet we had been extremely fortunate, in being under sail at intervals of fine weather, and anchored during the gales; but this was partly owing to a very careful attention to the barometer and sympiesometer.

"Having left Latitude Bay, we stood off until midnight, and then in shore again, carrying a press of sail all the time, in order to 'hold our own' against our old enemy, the current.

"At daylight (29th), not having been swept to leeward by the current, we were in a good position for continuing the survey from the place left the previous night. We bore up as soon as the land could be distinctly seen,—rounded Landfall Island very near the outer rocks, and then steered for Cape Tate (the extremity of the mountain I mentioned yesterday). Those outlying rocks are not very dangerous, as the sea

© The Complete Work of Charles Darwin Online

always breaks violently upon them. In crossing Otway Bay, the morning being clear, I was enabled to add considerably to what had been already learned respecting the shores and dangers around it.(*e*)

"Off Cape Tate, to the north and west, lie the College Rocks. Those nearest the Cape are also nearest the track of a ship running along the land, and half a mile west of them lies a detached and dangerous rock, under water. The sea generally breaks on it.

"We had very thick weather when close to those rocks, which obliged us to 'haul our wind' for half an hour; when, as it cleared, we steered round Cape Tate, about a mile off shore. I was in hopes of gaining an anchorage between it and the Fincham Islands, and therefore kept as near the land as I could; but seeing numerous breakers a-head and outside of me, I altered our course, and steered to go outside of all the rocks. After we had passed some of them, a large bight opened out to the north-eastward, and tempted me to haul up for it. We entered the sound at noon, and stood on for nearly four miles without finding an anchorage, or even gaining bottom with fifty fathoms of line, although at the entrance we had from twenty to ten fathoms. Thick weather coming on, made me very anxious to anchor somewhere, and we were now too much hampered to stand out again. We appeared to be among a multitude of islands, very near each other, yet without any anchorage between them; therefore, having no other resource, we let go both anchors upon the end of a steep-sided islet, where one fell into seven, the other into ten fathoms water, and hooked the rocks. Veering half a cable on each, we found forty fathoms under the stern, with a similar rocky bottom; so that we had the pleasant prospect of shouldering both our anchors, and drifting into deep water, with the first strong squall. During the remainder of that day, our boats were looking for better anchorage, but without success; they found patches of rocky

(*e*) In Otway Bay, not far from Landfall Island, is a rock on which Mr. Low found Fuegians living among a number of (apparently) tame seals. See second volume.—R. F.

© The Complete Work of Charles Darwin Online

ground with from ten to twenty fathoms here and there, but not one that could be preferred to our islet.

"30th. One Fuegian family was found here, consisting of a man and woman, with their children. During this day it rained too hard for anything to be done out of the ship; the wind was moderate; yet much as I disliked our rocky berth, it could not be changed.

"31st. Moderate wind, with clearer weather. Mr. Murray and Mr. Stokes went away to different parts of the sound, while I was employed near the ship. Observations for latitude, longitude, and variation were made.

"1st January. During part of the last night and this morning, the wind blew strongly in squalls, and made me very anxious; but the weather rendered it impossible to move voluntarily, for it was raining hard as well as blowing. At about eight it cleared, and the wind shifted to the southward, when we weighed, and worked down the sound; but it was after noon before we had cleared its entrance, and seven in the evening before we were outside of all the breakers, the wind having been light and contrary the whole time.

"(2d.) At five this morning, being close to the Fincham Islands, with clear weather, and a fresh breeze from the N.W., we steered into Breaker Bay, towards a ragged-looking projecting point. Having approached as near as we could, and sounded, and taken angles, we steered so as to pass outside of some very outlying rocks, near the middle of the bay; for in-shore of them, I saw from the mast-head numerous breakers, rocks, and islets, in every direction. A worse place for a ship could scarcely be found; for, supposing thick weather to come on when in the depth of the bay, she would have lurking rocks and islets just awash with the water, on all sides of her, and no guide to take her clear of them, for soundings would be useless; and in such weather, the best chart that could be constructed would not help her. With this idea of the place, and for reasons similar to those which induced me to pass hastily across Otway Bay, I steered for Cape Gloucester, after passing the Midbay Rocks, at the distance of a quarter of a

© The Complete Work of Charles Darwin Online

mile. The land at the bottom of the bay appeared to be distant, and much broken. Indeed, from the Week Islands to Cape Gloucester,(*f*) there is an almost innumerable succession of islands and rocks, without any continued tract of land, so that channels might be found in all directions; valuable, no doubt, to Fuegians in their canoes, but not often to seamen in ships, nor even to sealers; for where the natives go with their canoes, seals are never found in any numbers.

"In crossing Breaker Bay, even with a moderate wind, there was a very cross and awkward sea, owing, doubtless, to the ocean swell rolling into this deep bight. Such a swell would add much to the difficulty which vessels might find in getting out of this bay: I should therefore recommend them to avoid it particularly. Cape Gloucester is a most remarkable promontory, which can never be mistaken, after seeing even an indifferent sketch of it. At a distance it makes like a mountain rising out of the sea, but, on approaching nearer to it, a narrow neck of land appears.

"We found from twenty to thirty fathoms water, at the distance of a mile from the cape; and saw several outlying breakers about half a mile off shore. From the steep and rocky nature of these coasts one would not expect to find soundings until close to the land: but on every outer part of this coast, that we have visited, the bottom may be reached with the sounding line. Some natives were seen under the cape, who made a large fire. We stood into two bights, looking for anchorage, but, finding only rocks and breakers, steered along shore, rounded Ipswich Island, and hauled into a spacious bay, at the northern side of which there appeared to be several openings like harbours. In working across, we were agreeably surprised to find it a continued roadstead, open only towards the S.E., and having regular soundings, from twenty to fourteen fathoms. We anchored about a mile from the entrance of what seemed to be a harbour, at the N.W. corner, having worked up against a fresh N.W. wind. Our anchor was dropped in sixteen fathoms, and held well. I went directly to

(*f*) And thence to the Strait of Le Maire.—R. F.

© The Complete Work of Charles Darwin Online

look at the opening, and found a passage, in which were good soundings, leading into a very snug basin, perfectly sheltered from wind and sea, in which the bottom was composed of sand and clay, and the depth of water from five to fifteen fathoms. As soon as I returned we weighed and worked up to the entrance of the basin; then anchored, warped into it, and moored with half a cable each way.

"This was the most secure and sheltered cove I had yet seen. It was called Laura Basin; and the bay we had crossed was named Euston Bay. I was very glad to discover so safe a place, because it enabled me to ascertain the position of Cape Gloucester and the neighbouring land, with the correctness which so prominent a place required, and because I hoped that it would prove useful as a harbour for vessels. From the top of a high ridge surrounding the basin, I thought Cape Gloucester seemed to be about seven miles off, and seeing a valley lead some distance in the desired direction, determined to go to it overland. I was so much pleased with the bay and the basin, that I did not hesitate to spend some time in the examination of their vicinity. The mountains hitherto examined between Cape Pillar and these (the Grafton) islands, consist of greenstone, slate, or sandstone (excepting those near Deep-water Sound, which are of very coarse-grained whitish granite); and from the continual action of such heavy seas as break on those shores, the sandstone and slate rocks wear away, and by their detritus not only the bottoms of harbours are covered, but a bank is formed which extends into the offing. A moderate depth of water and good anchorages were found near slaty or sandstone hills, but exactly the reverse in the vicinity of granite.(*g*)

"4th. Early this morning I sent Mr. Murray in a whaleboat to examine and plan some openings I had noticed on the north side of Euston Bay; and Mr. Stokes to make a plan of the harbour, and the basin in which we were lying. The master carried six days' provisions with him, in case he should be detained, as on a former occasion, by bad weather. No place

(*g*) See second volume for further remarks on this subject.—R. F.

© The Complete Work of Charles Darwin Online

could be more convenient than this for such purposes as wooding and watering; and we took advantage of it to the utmost by filling the ship's hold. The water casks were filled in our boat, in perfectly smooth water, and the wood was cut close to the water side.

"6th. A party of twelve, consisting of the Purser, Mr. W. Wilson, Mr. Megget, eight seamen and myself, set out from the ship, intending to walk to Cape Gloucester. We landed in a valley at the N.W. corner of the harbour and began our march, two men carrying the tent, and the others our instruments and provisions: we had arms also, in case of meeting Indians. Difficult travelling, with such a cargo, very soon obliged us to stop and rest, but by continual changes with the heaviest loads, and great exertion on the part of those who carried them, we got over two-thirds of our journey in the course of the day, and at night pitched our tent, and defied the rain which poured incessantly until seven the following morning: when every height was covered with snow, as if it had been the middle of winter.

"7th. As soon as we had breakfasted we moved on again, and at noon reached the foot of a mountain which forms the Cape. Leaving the others to pitch our tent and cook some victuals, Mr. Wilson, Mr. Megget, and two seamen, ascended the mountain with me. A very severe task we had, but at last gained the highest pinnacle, where there was just room to place the theodolite and kneel by it, at the risk of a puff of wind canting us over either side. A stone moved from its place, would have reached the water as soon from one side as from the other. It was not a very clear day, but sufficiently so to enable me to gain the desired angles and bearings. From this summit I had a clear view of that dangerous place Breaker Bay, and was more confirmed in the idea I had formed of it, and rejoiced that I did not stand farther in with the Beagle. Having thus succeeded, and buried two memorials, one cased in tin and the other in a bottle, we filled our pockets with pieces of the rock and returned; rather too quickly, for the steepness of the hill assisted us more than we wished. During our absence some Fuegians had appeared, who were quiet and

© The Complete Work of Charles Darwin Online

inoffensive; but they seemed very distrustful of us, and, before sun-rise next morning, were all gone except one man. These natives seemed to be very active and went up the mountain in about half the time that our party required. They had two canoes with them, but how they had reached this place by water was puzzling, when the exposed bay they must have crossed and the prevailing weather were considered. Perhaps they had carried their canoes overland, being rather like the Chilote piraguas, made of boards sewed together.

"8th. We heard the voices of the Fuegians at day-break this morning; but at four o'clock only one old man remained, who was probably left to watch us. We began our return, rather stiff from previous days' exertions, and looking dismally at the high rugged hills between the Beagle and ourselves. The first ascent on our way back was the worst of all: how the men carried their cargo so well astonished me, for with a very light load I was glad to rest frequently. Breakfast revived us, and by taking afterwards a better line we avoided the steepest hills and found much easier walking. While resting at our meal the weather was so clear that I got bearings of Cape Inman and other points more than fifty miles distant. There was very little variety or novelty in this walk through a Fuegian island. The same kind of scenery and the same species of plants and shrubs were found which we had seen every where else in Tierra del Fuego. Being more or less rocky made the only change. Of quadrupeds, excepting otters and dogs, I saw no traces, nor do I think any were to be found. A large kind of snipe, by some called a woodcock, and quails, of a large and, I think, peculiar species, were often seen and shot. The latter are not by any means so well tasted as the European quail, and their flesh is darker and coarser. At seven this evening we were again on board the Beagle, not a little tired.

"Should any future voyager feel inclined to make a similar excursion towards Cape Gloucester, he had better not think too lightly of his task.

"9th. Mr. Murray returned, having been into many openings between the islands to the eastward, and having collected

© The Complete Work of Charles Darwin Online

much information. This afternoon it blew a heavy gale, but in such a sheltered place we only felt a few williwaws. From Mr. Murray's account it appeared that this island and those adjoining it to the eastward are a cluster lying together, but quite separated from the mainland, or rather the main body of islands, by a channel opening northward into Breaker Bay, and to the southward into Stokes Bay. They were called the Grafton Islands.

"10th. We had a heavy gale throughout this day with much rain. Bad weather, while at a good anchorage, I did not at that time regret, as the materials for our charts accumulated fast, and afforded no leisure time while we were detained on board.

"11th. A favourable day allowed us to examine and sound the outer roads, and obtain a round of angles from the western extreme of Ipswich Island, which completed my triangulation. Landing there was dangerous, and ascending the hill extremely difficult, on account of thick tangled brushwood which grows about three or four feet high on every part of the east side, and is so matted together as to be almost impenetrable. We generally scrambled over this jungle, but sometimes crept under it.

"12th. A tolerably fine day. The sun was visible both in the morning and afternoon; and from different summits Mr. Stokes and I took angles. The sky being clear near the horizon gave us a wide range. Meanwhile the ship was prepared to sail in search of a new place at which to employ our instruments. I hoped that this basin, harbour, and roadstead, might be of service, and therefore spared no pains about them. Eight latitudes were obtained by sets of circum-meridional altitudes; with four different sextants: two by Mr. Stokes, the rest by me: and as they all agreed, within fifteen seconds, I supposed their mean to be nearly correct. The sights for time were good, and the chronometers were going so steadily that dependence may be placed upon the accuracy of their results. To a vessel bound round Cape Horn and meeting with an accident, or in want of wood or water, this place might be useful. It is very easy to find, and easy to enter or depart from with the prevailing westerly winds.

© The Complete Work of Charles Darwin Online

"13th. We weighed and left the harbour, but the morning proved too hazy to allow of our running down the coast, therefore until eight o'clock we kept under easy sail in the roads. Being clear and moderate after that time, we passed Leading Island, and hove-to, to watch for a breaker near it. It broke but twice during the hour that we waited, therefore probably there is water enough to allow any vessel to pass in safety. At ten we bore up, and ran towards Isabella Island; my first object being to look for a place called by sealers 'Hope Harbour,' which, from what I could learn, ought to lie thereabouts. Its situation was not recognised by our boatswain,(*h*) who had been in it when sealing on this coast; so passing close to Isabella Island, we hauled our wind under the lee of the land, and came to an anchor in fifteen fathoms, sheltered from north to S.W. b. S. A high peaked hill, over the cove where I took observations, made this a suitable place for the business of the survey. Mr. Murray went up the height, while Mr. Stokes and I were employed near the water, till rain set in and drove us on board. This is the easternmost of the Grafton Islands. Beyond the channel, which separates them from the main body of islands, appeared a succession of broken land, not very high, but reaching apparently to a distant range of snowy mountains. The part nearest to us was a labyrinth of islets and rocks. Towards night the wind increased much, and drew to the S.W. and S.W. b. S. I was doubtful of our anchorage, and had the wind drawn one point more to the southward, we should have had a heavy sea to deal with, and must have slipped our cable.

"14th. It moderated again, and the sun showed himself enough to enable us to get sights, and be on board in time to weigh at nine. We had reason to think a sealing vessel had been along this coast not long before us, by the traces our boats found in several places. Indians also had frequented these islands, for their wigwams were found everywhere. Observations on shore made our anchoring here of some consequence, although as a

(*h*) Mr. Sorrell, formerly with Mr. Weddell, and since that time with Mr. Brisbane.—R. F.

© The Complete Work of Charles Darwin Online

safe anchorage for other vessels, it is out of the question, being an exposed roadstead, with many rocks, both to seaward and in-shore. A sealer might use it, but not willingly I should think. As we ran towards the Agnes Islands, before a strong W.N.W. wind, many rocks and breakers showed themselves, and when we neared the islands, became numerous on each side of us. It would have been more prudent to have kept outside all of them; but I was anxious to find Hope Harbour, or run into the entrance of the Barbara Channel, and anchor in the north cove of Fury Island. Having passed the three Agnes Islands, and being nearly abreast of Cape Kempe,* our view became far from agreeable, for the sea, on all sides, seemed strewed with breakers; and how to steer so as to pass between them was perplexing. We were at this time running free, under treble reefed topsails, with top-gallant yards and masts on deck; the wind being strong from W.N.W., but the weather tolerably clear. Suddenly the boatswain hailed, 'Hard-a-port, a rock under the bows!' Round the little vessel turned, almost as fast as the order was given; but the thrill that shot through us was happily not the precursor of our destruction; for the supposed rock proved to be a huge whale which had risen close to the bows, and was mistaken for the top of a rock by the boatswain, who was looking out on the forecastle, while I was at the mast-head, and the 'hands' were upon deck. This part of the coast, from the Agnes Islands to Cape Schomberg, is the worst I have seen, it is so very broken, and has so many rocks and dangerous breakers lying at a long distance from the shore.

"At noon we were close to Fury Island; but the wind fell and prevented our making much progress. Fury Harbour, where the Saxe Cobourg was lost, is a wild exposed place, and, as the bottom is bad, it ought to be avoided by all vessels: there is but one patch of good ground, and that is very small.

"Passing round Fury Island, we entered the Barbara Channel, at the entrance to which stands Mount Skyring, a high, peaked, and most barren mountain, visible at a great distance.

* The three peaks, in-shore of Cape Kempe, are very remarkable.

© The Complete Work of Charles Darwin Online

We all felt much additional interest in what was then seen, on account of the late survey in the Adelaide. Cape Schomberg and the Astrea Rock were easily known by Lieutenant Graves's sketch. To a high mountain, which in some views very much resembled the dome of St. Paul's, I gave that name (finding it out of the limits of Lieutenant Skyring's survey): it lies a short distance east of Cape Schomberg. A passage appeared to go to the eastward, passing from the Barbara channel, northward of Cape Schomberg and St. Paul's. Light baffling winds and an ebb-tide, of about a knot an hour, setting out of the Barbara, detained us until six P.M., between the Magill and Fury Islands; but soon after that hour we anchored in North Cove, a small but perfectly secure place. By reaching this anchorage, I had the satisfaction of being enabled to connect my work with Lieutenant Skyring's, and to take a fresh start for the next piece of coast. Hitherto we had been extremely fortunate, both with the ship and the boats; but such success could not be expected always.

"15th. Early this morning, Mr. Murray went in a whale-boat to the islands, near Cape Kempe, to ascertain the situations of some reefs and islets thereabouts, and sketch the outer coast. Mr. Stokes went in another boat to look for Hope Harbour, and examine part of the coast. The boatswain accompanied him, as he thought he knew his way by passages among the islands, although he had failed to recognise the place from the offing.

"16th. Bad weather, blowing a gale of wind and raining nearly all the day.

"17th. A squally and disagreeable day; but our boats made some progress.

"18th. Some Natives came alongside for a short time. As usual, we would not allow them to come on board, because of their being such dexterous thieves. A man to whom the canoe appeared to belong was far better featured, and more stoutly made, than any we had seen among the Fuegians. After bartering some of their very valuable property they left us.

"19th. Early this morning Mr. Stokes returned: he had

© The Complete Work of Charles Darwin Online

been near enough to Hope Harbour, to see that it was in the Grafton Islands, and was one of the coves examined by Mr. Murray. He then returned as he had been desired; but made very good use of his time while away, by collecting materials for the charts. He fell in with a canoe under sail (the sail being a seal-skin); the first instance I had then known of a Fuegian canoe sailing. As far as Mr. Stokes could see to the northward, the land was very broken, or rather it was a mass of islands reaching to the base of a range of snowy mountains.

"North Cove is large enough to hold any vessel when moored; but the passage, in and out, is too narrow and difficult for a ship of more than three or four hundred tons, unless she uses warps. Being on the weather side of high land, but sheltered by low islands, williwaws do not annoy during westerly winds; but in a southerly gale I think they would be furious.

"My next task was to ascend Mount Skyring. As there was but little snow on it, and the ground quite clear of wood, the ascent was easy; but when at the summit I could not see far, because of low misty clouds. I had taken only a compass with me, intending to look round, and ascend a second time with my usual companion, a theodolite. After taking a few bearings, I moved the compass off its stand, and placed it on a stone; when, to my surprise, I found the bearing of a point, I had just been looking at, altered twenty degrees. Suspecting the cause, I put it on another stone, a few feet distant, and found the bearing again altered many degrees. I then examined the stones, and found there was much pyrites in them;* and that when broken, or struck against one another, they smelt strongly of sulphur. The compass was then replaced on its stand, and bearings of the same point taken from various spots, only a few feet apart, the point being many miles distant, and at each spot the compass gave a different bearing, and was very dull and sluggish, although it was a good Kater's compass, with a light card. Having thus satisfied myself of the very strong local attraction existing, I returned to the ship, intend-

* Specimens of the rock at the summit are in the collection at the Geological Society, numbered 184 and 188.

© The Complete Work of Charles Darwin Online

ing to make no further use of a compass in this place; and as Lieutenant Skyring might have been deceived in his bearings from a similar cause, I hoped to procure a round of angles, with a theodolite set to a true bearing, which might be serviceable for his work, as well as my own. Many pieces of the stone, from different heights, were brought down; and in most of them were traces of metal.

"The peaked top of this mountain is a mere heap of loose stones of all sizes. Whether the rock has been shattered in this manner by frost, by volcanic fire, or by lightning, I cannot tell; but I should think, from its appearance, by all three. Many of the stones are vitrified, and many are porous, like pumice-stones, although not so light.

"20th. I again went up Mount Skyring, taking a theodolite with me; and as the day was perfectly clear, and free from clouds, every point of land was visible, which can at any time be seen from that summit. Mount Sarmiento appeared in all its grandeur, towering above the other mountains to at least twice their height, and entirely covered with snow. Having set the theodolite to a painted post, fixed on shore near the Beagle (five miles distant), from which I had previously obtained the exact astronomical bearing of the spot on which the theodolite was placed; I obtained a most satisfactory round of angles, including most of the remarkable peaks, islands, and capes, within a range of forty miles from the mountain. The day was so fine, that it was not cold on the height, nor was there any wind to disturb the adjustment of the instrument.

This business being completed, I returned on board with Mr. Wilson, who, during the time I was on the height, made some very good sketches. Even at this early period his drawings were becoming a valuable addition to the gleanings of our cruise, and their number increased fast; for he took much pains with them, and produced not only good drawings, but most accurate delineations of the coast.

"21st. Fine weather for this climate. Mr. Murray returned in the whale-boat, having had a successful trip.

"By shooting and fishing we obtained frequent change of

© The Complete Work of Charles Darwin Online

diet, for we shot much wild fowl (geese, shags, and ducks), and caught fish in the kelp, which were excellent eating. All that could be procured was regularly and equally distributed to the different messes in turn, and an account kept in a 'game book.' (Appendix.)

"22d. Mr. Stokes went to examine Fury Harbour, and returned late at night. In consequence of his account of the remains of the Saxe Cobourg sealing schooner, lost in that harbour, I sent a boat with the carpenter to collect from it some wood and bolts which might be useful to our ship, and remained at anchor for a day longer than I had intended.

"This day all hands were put upon two-thirds' allowance, but as it was a measure which affected the crew much and myself not at all, I was reluctant to give the necessary order, without first proposing the measure openly, and giving the following reasons:—

"Having succeeded beyond expectation in the examination of the coast thus far, and hoping to be able to continue the survey in the same manner, while our provisions lasted, I thought it better to shorten the allowance while all hands were well and hearty, and could obtain supplies of fish and wild fowl, rather than at a later period, when we might be otherwise situated. An extent of coast lay before us, and the parts particularly pointed out by Captain King, were yet unexamined.

"24th. A tolerably fine day; I tried all the compasses on shore, in three different places, placing them in a line to a distant mark; because in taking bearings, for the variation of the compass, during previous days, I had found very wide differences between the results of the same, as well as different compasses; and they were also very sluggish; the light cards being more so than the heavy ones. I found it impossible to reconcile their results by change of place or position, therefore it is probable that all the rock affected the needle; and I suspect that not only this island and the one on which Mount Skyring is situated, but most of the islands near are magnetic: particularly a cluster lying about a mile to seaward of the Magill Islands, on which, I believe, Lieutenant Skyring, or some of his party, took bearings. A boat was sent to

© The Complete Work of Charles Darwin Online

watch the tide, on the day of new moon, at the entrance of the channel, and brought back a piece of the rock of which the last-mentioned cluster of islets consists. It is similar to that of Fury Island and Mount Skyring, apparently metallic, with a sulphureous smell, when struck or broken.* Small pieces put near the compass did not seem to affect it sensibly; but I did not spend time in trying the experiment with nicety, being satisfied of the general result. There may be metal in many of the Fuegian mountains, and I much regret that no person in the vessel was skilled in mineralogy, or at all acquainted with geology. It is a pity that so good an opportunity of ascertaining the nature of the rocks and earths of these regions should have been almost lost.

"I could not avoid often thinking of the talent and experience required for such scientific researches, of which we were wholly destitute; and inwardly resolving, that if ever I left England again on a similar expedition, I would endeavour to carry out a person qualified to examine the land; while the officers, and myself, would attend to hydrography."

* Geological Society, Coll. No. 197.

CHAPTER XXI.

Skyring's chart — Noir Island — Penguins — Fuegians — Sarmiento — Townshend Harbour—Horace Peaks—Cape Desolation—Boat lost—Basket—Search in Desolate Bay—Natives—Heavy gale—Surprise—Seizure—Consequences—Return to Beagle—Sail to Stewart Harbour—Set out again—Escape of Natives—Unavailing search—Discomforts—Tides—Nature of Coast—Doris Cove—Christmas Sound—Cook—York-Minster—March Harbour—Build a boat—Treacherous rocks—Skirmish with the Natives—Captives—Boat-memory—Petrel.

"25th. We weighed, and went round to Fury Harbour, for the carpenter and his cargo, and met him with a spar and a raft of plank, taken from the wreck. Having hoisted the boat up, and got the plank on board, we stood out towards the West Furies, by the wind; my intention being either to sail round Noir Island, or anchor under it, before running to the eastward, in order that no part of the sea-coast might be left unexamined. We passed very near some of the rocks, but as the day was fine and the weather clear, a good look-out at the mast-head could be trusted.

"Before leaving the vicinity of Mount Skyring, I should remark that the true bearing of Mount Sarmiento's summit, which I obtained from the top of Mount Skyring, laid off on Lieutenant Skyring's chart, passed as truly through his position of the summit as if the line had been merely drawn between them. This is highly creditable to his work, for I know he did not himself see Mount Sarmiento, when upon Mount Skyring.

"The breeze freshened, and drew more to the westward towards evening, I had therefore no hopes of nearing Noir Island. We saw the Tower Rocks distinctly before dark, and stood on towards them until ten o'clock, closing Scylla to avoid Charybdis, for in-shore of us lay all those scattered rocks,

© The Complete Work of Charles Darwin Online

among which we had steered when passing the Agnes Islands and Cape Kempe.

"The night was spent in making short boards, under reefed topsails, over the same two miles of ground, as nearly as possible, with the lead going, and a thoroughly good look-out. At daylight next morning the wind became strong and the weather thick, with rain, but we made as much sail as we could carry, and worked to windward all the day. In the afternoon it moderated, and before dark we anchored in a very good roadstead, at the east end of Noir Island, sheltered from all winds from N. to S. b. E. (by the west); over a clear, sandy bottom; and with a sheltered cove near us where boats may land easily, and get plenty of wood and water. In working up to the Island, we passed very near a dangerous rock, under water, lying four miles off shore; and another, near the anchorage. The sea does not break on either of them when there is not much swell.

"27th. A fine day favoured us; the master went to one part of the island, and Mr. Stokes to another, while I went to a third. Having taken angles at the extreme west point (which ends in a cluster of rocks like needles), I passed quite round the island, and returned to the anchorage after dusk, landing here and there for bearings, in my way.

"There is a cove at the south part of the island, where boats would be perfectly safe in any weather, but the entrance is too narrow for decked vessels. The island itself is narrow and long, apparently the top of a ridge of mountains, and formed of sandstone,* which accounts for the bottom near it being so good, and for the needle-like appearance of the rocks at the west end; as the sand-stone, being very soft, is continually wearing away by the action of the water.

"Multitudes of penguins were swarming together in some parts of the island, among the bushes and 'tussac'† near the shore, having gone there for the purposes of moulting and rear-

* Geological Society, No. 238 to 240, (perhaps clay-slate. P.P.K.)

† Name given by sealers to a thick rushy kind of grass, which grows near the sea, in these latitudes.

© The Complete Work of Charles Darwin Online

ing their young. They were very valiant in self-defence, and ran open-mouthed, by dozens, at any one who invaded their territory, little knowing how soon a stick could scatter them on the ground. The young were good eating, but the others proved to be black and tough, when cooked. The manner in which they feed their young is curious, and rather amusing. The old bird gets on a little eminence, and makes a great noise (between quacking and braying), holding its head up in the air, as if it were haranguing the penguinnery, while the young one stands close to it, but a little lower. The old bird having continued its clatter for about a minute, puts its head down, and opens its mouth widely, into which the young one thrusts its head, and then appears to suck from the throat of its mother for a minute or two, after which the clatter is repeated, and the young one is again fed; this continues for about ten minutes. I observed some which were moulting make the same noise, and then apparently swallow what they thus supplied themselves with; so in this way I suppose they are furnished with subsistence during the time they cannot seek it in the water. Many hair seal were seen about the island, and three were killed. Wild fowl were very numerous. Strange to say, traces of the Fuegians (a wigwam, &c.) were found, which shows how far they will at times venture in their canoes.

"No danger lies outside of Noir Island, except in the Tower Rocks, which are above water, and 'steep-to,' but many perils lie to the south-eastward. Indeed, a worse place than the neighbourhood of Cape Kempe and the Agnes Islands could not often be found, I think: the chart of it, with all its stars to mark the rocks, looks like a map of part of the heavens, rather than part of the earth.

"28th. At daylight we sailed from these roads, and passed close to the Tower Rocks (within half a cable's length): they are two only in number, a mile and a half apart, and steep-sided. Thence we steered towards St. Paul's, my intention being to seek an anchorage in that direction. This day proved very fine and so clear that when we were becalmed, off St. Paul's, we saw Mount Sarmiento distinctly from the deck. A breeze

© The Complete Work of Charles Darwin Online

carried us through Pratt Passage, which separates London Island from Sydney Island, to an anchorage in a good harbour, under a high peaked hill (Horace Peaks), which is a good mark for it. Finding no soundings in the Passage as we approached, gave us reason to be anxious; but in the harbour, the bottom proved to be excellent, and the water only of a moderate depth. As soon as we anchored, I tried to ascend Horace Peaks, but returned without having reached their summits before dark; however, I saw enough to give me a general idea of the distribution of the land and water near us. I thought that this anchorage would be favourable for ascertaining the latitude of Cape Schomberg* with exactness: having found a considerable difference between our chart and that of Lieutenant Skyring, respecting the latitude of that promontory.

"Meanwhile I contemplated sending the master to a headland called by Cook, Cape Desolation, and which well deserves the name, being a high, craggy, barren range of land. I was not sorry to find myself in a safe anchorage, for the weather seemed lowering; and after being favoured with some moderate days, we could not but expect a share of wind and rain.

"29th. This morning the weather looked as if we should be repaid for the few fine days which we had enjoyed; but as we felt it necessary to work in bad weather as well as in good, it did not prevent the master from setting out on his way to Cape Desolation; near which, as a conspicuous headland, whose position would be of great consequence, he was to search for a harbour, and obtain observations for connecting the survey. He could not have been in a finer boat (a whale-boat built by Mr. May, at San Carlos); and as he well knew what to do with her, I did not feel uneasy for his safety, although after his departure the wind increased rapidly, and towards evening blew a hard gale. The barometer had not given so much warning as usual; but it had been falling gradually since our arrival in this harbour, and continued to fall. The sympiesometer had been more on the alert, and had fallen more rapidly.

"(30th.) A continued gale, with rain and thick weather

* A high mountain at the N.W. end of London Island.

© The Complete Work of Charles Darwin Online

throughout the day. During the night the weather became rather more moderate; but on the morning of the 31st, the wind again increased to a gale, and towards noon, the williwaws were so violent, that our small cutter, lying astern of the ship, was fairly capsized, though she had not even a mast standing. The ship herself careened, as if under a press of sail, sending all loose things to leeward with a general crash (not being secured for sea, while moored in so small a cove), but so rapidly did these blasts from the mountains pass by, that with a good scope of chain out, it was hardly strained to its utmost before the squall was over. While the gale was increasing, in the afternoon, the topmasts were struck; yet still, in the squalls, the vessel heeled many strakes when they caught her a-beam. At night they followed in such rapid succession, that if the holding-ground had not been excellent, and our ground-tackle very strong, we must have been driven on the rocks.

"Under the lee of high land is not the best anchorage in these regions. When good holding-ground can be found to windward of a height, and low land lies to windward of the anchorage, sufficient to break the sea, the place is much to be preferred; because the wind is steady and does not blow home against the height. The lee side of these heights is a great deal worse than the west side of Gibraltar Rock while the strongest Levanter is blowing.

"Considering that this month corresponds to August in our climate, it is natural to compare them, and to think how hay and corn would prosper in a Fuegian summer. As yet I have found no difference in Tierra del Fuego between summer and winter, excepting that in the former the days are longer, and the average temperature is perhaps ten degrees higher, but there is also then more wind and rain.

"The gale still continued, and prevented any thing being done out of the ship. However safe a cove Mr. Murray might have found, his time, I knew, must be passing most irksomely, as he could not have moved about since the day he left us. He had a week's provisions, but with moderate weather would have returned in three days.

" Feb. 2d. Still very squally and unsettled. This gale began at N.N.W., and drew round to S.S.W. Much rain comes usually from the N.W. quarter; and as the wind draws southward, the weather becomes clearer. The squalls from the southern quarter bring a great deal of hail with them.

" 3d. I was enabled to take a round of angles from Horace Peaks, over the ship, the sky being clear near the horizon. The theodolite had been left near the top since the 28th, each day having been too bad to use it. These peaked hills required time and exertion in the ascent; but the wide range of view obtained from their summits on a clear day, amply repaid us for both. If the height was sufficient, it gave a bird's-eye view of many leagues, and showed at a glance where channels lay, which were islands, and what was the nature of the surrounding land and water. The shattered state of all these peaks is remarkable: frost, I think, must be the chief cause.

" After being deceived by the magnetism of Mount Skyring and other places, I never trusted the compass on a height, but always set up a mark near the water, at some distance, and from it obtained the astronomical bearing of my station at the summit. This afternoon we prepared the ship to proceed as soon as the master should arrive.

" 4th. Moderate weather. I was surprised that the master did not make his appearance; yet, having full confidence in his prudent management, and knowing that he had been all the time among islands, upon any one of which he could haul up his boat and remain in safety during the gales, I did not feel much anxiety, but supposed he was staying to take the necessary angles and observations, in which he had been delayed by the very bad weather we had lately experienced.

" At three this morning (5th), I was called up to hear that the whale-boat was lost—stolen by the natives; and that her coxswain and two men had just reached the ship in a clumsy canoe, made like a large basket, of wicker-work covered with pieces of canvas, and lined with clay, very leaky, and difficult to paddle. They had been sent by the master, who, with the other people, was at the cove under Cape Desolation, where

© The Complete Work of Charles Darwin Online

they stopped on the first day. Their provisions were all consumed, two-thirds having been stolen with the boat, and the return of the natives, to plunder, and perhaps kill them, was expected daily.

"The basket, I cannot call it a canoe, left the Cape (now doubly deserving of its name) early on the morning of the 4th, and worked its way slowly and heavily amongst the islands, the men having only one biscuit each with them. They paddled all day, and the following night, until two o'clock this morning (5th), when in passing the cove where the ship lay, they heard one of our dogs bark, and found their way to us quite worn out by fatigue and hunger. Not a moment was lost, my boat was immediately prepared, and I hastened away with a fortnight's provisions for eleven men, intending to relieve the master, and then go in search of the stolen boat. The weather was rainy, and the wind fresh and squally; but at eleven o'clock I reached the cove, having passed to seaward of the cape, and there found Mr. Murray anxiously, but doubtfully, awaiting my arrival. My first object, after inquiring into the business, was to scrutinize minutely the place where the boat had been moored, (for I could not believe that she had been stolen;) but I was soon convinced that she had been well secured in a perfectly safe place, and that she must, indeed, have been taken away, just before daylight, by the natives. Her mast and sails, and part of the provisions were in her; but the men's clothes and the instruments had fortunately been landed. It was the usual custom with our boats, when away from the ship, to keep a watch at night; but this place appeared so isolated and desolate, that such a precaution did not seem necessary. Had I been with the boat, I should probably have lost her in the same manner; for I only kept a watch when I thought there was occasion, as I would not harass the boat's crew unnecessarily; and on this exposed and sea-beaten island, I should not have suspected that Indians would be found. It appeared that a party of them were living in two wigwams, in a little cove about a mile from that in which our boat lay, and must have seen her arrive;

© The Complete Work of Charles Darwin Online

while their wigwams were so hidden as to escape the observation of the whale-boat's crew. At two o'clock on the first morning, Mr. Murray sent one of the men out of the tent to see if the boat rode well at her moorings in the cove, and he found her secure. At four another man went to look out, but she was then gone. The crew, doubtful what had been her fate, immediately spread about the shore of the island to seek for traces of her, and in their search they found the wigwams, evidently just deserted: the fire not being extinguished. This at once explained the mystery, and some proceeding along the shore, others went up on the hills to look for her in the offing; but all in vain. The next morning Mr. Murray began the basket, which was made chiefly by two of his men out of small boughs, and some parts of the tent, with a lining of clayey earth at the bottom. Being on an island, about fifteen miles from the Beagle, their plan was as necessary as it was ingenious: though certainly something more like a canoe than a coracle could have been paddled faster.

"The chronometer, theodolite, and other instruments having been saved, Mr. Murray had made observations for fixing the position of the place, and had done all that was required before I arrived, when they embarked, with their things, in my boat, which then contained altogether eleven men, a fortnight's provisions, two tents,* and clothing; yet with this load she travelled many a long mile, during the following week, a proof of the qualities of this five-oared whale-boat, which was also built by Mr. Jonathan May, our carpenter, while we were at San Carlos.

"The very first place we went to, a small island about two miles distant, convinced us still more decidedly of the fate of our lost boat, and gave us hopes of retrieving her; for near a lately used wigwam, we found her mast, part of which had been cut off with an axe that was in the boat. Our next point was then to be considered, for to chase the thieves I was determined. North and east of us, as far as the eye could reach, lay an extensive

* I carried two tents from the Beagle, theirs having been cut up for the basket.

© The Complete Work of Charles Darwin Online

bay in which were many islands, large and small; and westward was a more connected mass of large islands reaching, apparently, to the foot of that grand chain of snowy mountains, which runs eastward from the Barbara Channel, and over the midst of which Sarmiento proudly towers. I resolved to trace the confines of the bay, from the west, towards the north and east, thinking it probable that the thieves would hasten to some secure cove, at a distance, rather than remain upon an outlying island, whence their retreat might be cut off. In the evening we met a canoe containing two Fuegians, a man and a woman, who made us understand, by signs, that several canoes were gone to the northward. This raised our hopes, and we pushed on. The woman, just mentioned, was the best looking I have seen among the Fuegians, and really well-featured: her voice was pleasing, and her manner neither so suspicious nor timid as that of the rest. Though young she was uncommonly fat, and did justice to a diet of limpets and muscles. Both she and her husband were perfectly naked. Having searched the coves for some distance farther, night came on, and we landed in a sheltered spot.

"The next day (6th), we found some rather doubtful traces of the thieves. Towards night it blew a strong gale, with hail-squalls and rain.

"On the 7th, at a place more than thirty miles E.N.E. of Cape Desolation, we fell in with a native family, and on searching their two canoes found our boat's lead line. This was a prize indeed; and we immediately took the man who had it into our boat, making him comprehend that he must show us where the people were, from whom he got it. He understood our meaning well enough, and following his guidance we reached a cove that afternoon, in which were two canoes full of women and children; but only one old man, and a lad of seventeen or eighteen. As usual with the Fuegians, upon perceiving us they all ran away into the bushes, carrying off as much of their property as possible—returning again naked, and huddling together in a corner. After a minute search, some of the boat's gear was found, part of her sail, and

© The Complete Work of Charles Darwin Online

an oar, the loom of which had been made into a seal-club, and the blade into a paddle. The axe, and the boat's tool-bag were also found, which convinced us that this was the resort of those who had stolen our boat; and that the women, six in number, were their wives. The men were probably absent, in our boat, on a sealing expedition; as a fine large canoe, made of fir-plank, perhaps from the wreck of the Saxe Cobourg, was lying on the beach without paddles or spears. She did not come there without paddles: and where were the spears of which every Fuegian family has plenty? It was evident that the men of the party had taken them in our boat, and had cut up our oars like the one they had accidentally left. The women understood what we wanted, and made eager signs to explain to us where our boat was gone. I did not like to injure them, and only took away our own gear, and the young man, who came very readily, to show us where our boat was, and, with the man who had brought us to the place, squatted down in the boat apparently much pleased with some clothes and red caps, which were given to them. We had always behaved kindly to the Fuegians wherever we met them, and did not yet know how to treat them as they deserved, although they had robbed us of so great a treasure, upon the recovery or loss of which much of the success of our voyage depended. Following the guidance of these two natives, we pulled against wind and rain until dark, when it became absolutely necessary to secure our boat for the night, deeply laden as she was with thirteen people. As we were then at a great distance from the place, whence we brought the natives, having pulled for four hours alongshore, and as they seemed to be quite at their ease, and contented, I would not secure our guides as prisoners, but allowed them to lie by the fire in charge of the man on watch. About an hour before daylight, although the look-out man was only a few yards distant from the fire, they slipped into the bushes, and as it was almost dark were immediately out of sight. Their escape was discovered directly, but to search for them during darkness, in a thick wood, would have been useless; besides, our men were tired with their day's work, and wanted rest, so

© The Complete Work of Charles Darwin Online

I would not disturb them until daylight (8th), when we continued our search in the direction the natives had indicated; but after examining several coves without finding any traces of Fuegians, we hastened back towards the wigwams we had visited on the previous day. Sailing close along-shore, a large smoke suddenly rose up, out of a small cove close by us, where we immediately landed, and looked all round; but found only the foot-prints of two Fuegians, probably the runaways, who had just succeeded in lighting a fire at the moment we passed by. This shows how quickly they find materials for the purpose, for when they left us, they had neither iron nor fire-stone (pyrites), nor any kind of tinder. They had carried off two tarpaulin coats, which Mr. Murray had kindly put on to keep them warm; although, treated as he had so lately been, one might have thought he would not have been the first to care for their comfort. I mention these incidents to show what was our behaviour to these savages, and that no wanton cruelty was exercised towards them.

"After looking for these two natives, and for Mr. Murray's coats, which at that time he could ill spare, we returned to our boat, and pushed on towards the wigwams. The moment the inmates saw us, they ran away, and we gave chase, trying, in vain, to make them stop. Disappointed in the hope of obtaining a guide, we determined to prevent these people from escaping far, and spreading any intelligence likely to impede the return of our boat, which we daily expected: we therefore destroyed two canoes, and part of a third, that the natives were building, and burned every material which could be useful to them in making another canoe.

"(9th). Next day, we went straight across the bay to Cape Desolation, against a fresh breeze: by pulling in turns, the boat was kept going fast through the water, and late in the evening we reached the cove from which the thieves had first started, when they stole the boat; but no traces of their having been there again, were found. I thought it probable that they would return to see what had become of our party, and whether our people were weak enough to be plundered again, or perhaps attacked.

© The Complete Work of Charles Darwin Online

"This idea proving wrong, we retraced (10th) much of our former course, because the direction pointed out by the Fuegians who ran away from us seemed to lead towards the place we now steered for, Courtenay Sound, and was a probable line for the thieves to take. During the night it blew a gale from the southward, which increased next day (11th), and became more and more violent until the morning of the 12th, when it abated.

"We continued our search, however, sometimes under a close-reefed sail; sometimes on our oars, and sometimes scudding with only the mast up. Although the wind was very violent, too strong for a close reefed sail (with four reefs), the water was too much confined by islands to rise into a sea, but it was blown, as 'spoon drift,' in all directions. This day the Beagle had her topmasts and lower yards struck, for the gale was extremely heavy where she lay. The barometer foretold it very well, falling more than I had previously seen, although the wind was southerly. In an exposed anchorage, I do not think any vessel could have rode it out, however good the holding ground.

"12th. This morning the weather was better, and improving fast. We went over much ground without the smallest success, and in the afternoon steered to the eastward again, for a third visit to the boat stealers' family. As it was late when we approached the place, I landed half our party, and with the rest went to reconnoitre. After a long search we discovered the Indians in a cove, at some distance from that in which they were on the previous day; and having ascertained this point, taken a good view of the ground, and formed our plans, we returned to our companions, and prepared for surprising the natives and making them prisoners. My wish was to surround them unawares, and take as many as possible, to be kept as hostages for the return of our boat, or else to make them show us where she was; and, meanwhile, it was an object to prevent any from escaping to give the alarm.

"13th. Whether the men belonging to the tribe had returned during our absence, was uncertain, as we could not,

© The Complete Work of Charles Darwin Online

without risk of discovery, get near enough to ascertain: but, in case we should find them, we went armed, each with a pistol or gun, a cutlass, and a piece of rope to secure a prisoner. We landed at some distance from the cove, and, leaving two men with our boat, crept quietly through the bushes for a long distance round, until we were quite at the back of the new wigwams; then closing gradually in a circle, we reached almost to the spot undiscovered; but their dogs winded us, and all at once ran towards us barking loudly. Further concealment was impossible, so we rushed on as fast as we could through the bushes. At first the Indians began to run away; but hearing us shout on both sides, some tried to hide themselves, by squatting under the banks of a stream of water. The foremost of our party, Elsmore by name, in jumping across this stream, slipped, and fell in just where two men and a woman were concealed: they instantly attacked him, trying to hold him down and beat out his brains with stones; and before any one could assist him, he had received several severe blows, and one eye was almost destroyed, by a dangerous stroke near the temple. Mr. Murray, seeing the man's danger, fired at one of the Fuegians, who staggered back and let Elsmore escape; but immediately recovering himself, picked up stones from the bed of the stream, or was supplied with them by those who stood close to him, and threw them from each hand with astonishing force and precision. His first stone struck the master with much force, broke a powder-horn hung round his neck, and nearly knocked him backwards: and two others were thrown so truly at the heads of those nearest him, that they barely saved themselves by dropping down. All this passed in a few seconds, so quick was he with each hand: but, poor fellow, it was his last struggle; unfortunately he was mortally wounded, and, throwing one more stone, he fell against the bank and expired. After some struggling, and a few hard blows, those who tried to secrete themselves were taken, but several who ran away along the beach escaped: so strong and stout were the females, that I, for one, had no idea that it was a woman, whose arms I and my coxswain endeavoured to pinion, until I heard some

© The Complete Work of Charles Darwin Online

one say so. The oldest woman of the tribe was so powerful, that two of the strongest men of our party could scarcely pull her out from under the bank of the stream. The man who was shot was one of those whom we had taken in the boat as a guide, and the other was among our prisoners. Mr. Murray's coats were found in the wigwams divided into wrappers to throw over the shoulders. We embarked the Indians (two men, three women, and six children), and returned to the spot where we had passed the preceding night. One man who escaped was a one-eyed man we had seen before; he was more active than any, and soon out of our reach. Two or three others escaped with him, whom I did not see distinctly.

"That a life should have been lost in the struggle, I lament deeply; but if the Fuegian had not been shot at that moment, his next blow might have killed Elsmore, who was almost under water, and more than half stunned, for he had scarcely sense to struggle away, upon feeling the man's grasp relax. When fairly embarked, and before we asked any questions, the natives seemed very anxious to tell us where our boat was; but pointed in a direction quite opposite to that which they had previously shown us. We guarded them carefully through the night, and next morning (14th) set out upon our return to the Beagle, with twenty-two souls in the boat. My object was, to put them in security on board, run down the coast with the ship to some harbour more to the eastward, and then set out again upon another search; carrying some of my prisoners as guides, and leaving the rest on board to ensure the former remaining, and not deceiving us. We made tolerable progress, though the boat was so over-loaded, and on the 15th reached the Beagle with our living cargo. In our way we fell in with a family of natives, whose wigwams and canoes we searched; but finding none of our property, we left them not only unmolested, but gave them a few things, which in their eyes were valuable.

"This conduct appeared to surprise our prisoners, who, as far as we could make out, received a wholesome lecture, instead

© The Complete Work of Charles Darwin Online

of assistance, from the strangers. At all events, when they parted, our passengers were as discontented as the others were cheerful. When we got on board, we fed our prisoners with fat pork and shell-fish, which they liked better than any thing else, and clothed them with old blankets.*

"Next morning (16th) we weighed, and sailed along the coast towards Cape Castlereagh, at the east side of Desolate Bay. Many straggling rocks and rocky islets were observed lying off Cape Desolation and in the Bay. That afternoon, we stood into a narrow opening, which appeared to be the outlet of a harbour close to Cape Castlereagh, and found a very good anchorage, well suited for the purposes both of continuing the survey and looking for the lost boat.

"(17th.) The master and I, with the cutter and a whale-boat, set out upon a second chase, taking a week's provisions. In the first cove I searched, not two miles from the Beagle, I found a piece of the boat's lead-line, which had been left in a lately deserted wigwam. This raised our hopes; and, in addition to the signs made by our prisoners, convinced us we were on the right track.

"I took with me a young man as a guide, and in the cutter the master carried the two stoutest of the women, having left all the rest of our prisoners on board. As far as we could make out, they appeared to understand perfectly that their safety and future freedom depended upon their showing us where to find the boat.

"We intended to go round the Stewart Islands; and after examining many coves, and finding signs that a party of natives had passed along the same route within the last two days, we stopped in a sheltered place for the night. Having given our prisoners as much food as they could eat, muscles, limpets, and pork, we let them lie down close to the fire, all three together. I would not tie them, neither did I think it necessary to keep an unusual watch, supposing that their children being

* It afterwards appeared that we had taken the families of the very men who stole the boat from Mr. Murray.

© The Complete Work of Charles Darwin Online

left in our vessel was a security for the mothers far stronger than rope or iron. I kept watch myself during the first part of the night, as the men were tired by pulling all day, and incautiously allowed the Fuegians to lie between the fire and the bushes, having covered them up so snugly, with old blankets and my own poncho, that their bodies were entirely hidden. About midnight, while standing on the opposite side of the fire, looking at the boats, with my back to the Fuegians, I heard a rustling noise, and turned round; but seeing the heap of blankets unmoved, satisfied me, and I stooped down to the fire to look at my watch. At this moment, another rustle, and my dog jumping up and barking, told me that the natives had escaped. Still the blankets looked the same, for they were artfully propped up by bushes. All our party began immediately to search for them; but as the night was quite dark, and there was a thick wood close to us, our exertions were unavailing.

"Believing that we could not be far from the place where the natives supposed our boat to be, I thought that they would go directly and warn their people of our approach; and as the island was narrow, though long, a very little travelling would take them across to the part they had pointed out to us, while it might take a boat a considerable time to go round; I therefore started immediately to continue the search in that direction, and left the master to examine every place near our tents.

"In the afternoon of the same day I returned to him, having traversed a long extent of coast without finding an outlet to sea-ward, or any traces of the lost boat. Meanwhile Mr. Murray had searched every place near our bivouac without success; but he found the spot where the Fuegians had concealed themselves during the night, under the roots of a large tree, only a dozen yards from our fire.

"As it was possible that the thieves might have returned to the place whence we had taken the natives, I desired the master to cross the sound and go there, and afterwards return to meet me, while I continued the search eastward. With a fair and fresh wind I made a good run that evening, found a pas-

© The Complete Work of Charles Darwin Online

sage opening to the sea,* and a wigwam just deserted. Here was cause for hope; and seeing, beyond the passage, some large islands lying to seaward of that which we had been coasting, it appeared probable that our boat had been taken there for seal-fishing. Our prisoners had given us to understand plainly enough that such was the object of those who had stolen her, and outlying islands were the most likely to be visited, as on them most seal are found.

"Next day (19th) I passed over to Gilbert Island, and in a cove found such recent marks of natives, that I felt sure of coming up with the chase in the course of the day. When the Fuegians stop anywhere, they generally bark a few trees, to repair their canoes or cover their wigwams; but those whose traces we were following, had made long journeys without stopping; and, where they did stay, barked no trees, which was one reason for supposing them to be the party in our boat. In the course of the day we pulled nearly round the islands,† looking into every cove.

"On the 20th, we discovered three small canoes with their owners in a cove.‡ All the men ran away, except two. As we saw that there were no more persons than the canoes required, we did not try to catch them, knowing that this could not be the party we were in search of. We had now examined every nook and corner about these islands, and I began to give up all hope of finding our boat in this direction. Having no clue to guide me farther, and much time having been lost, I reluctantly decided to return to the Beagle. Our only remaining hope, that the master might have met with the boat, was but very feeble.

"(21st.) All this day we were pulling to the westward, to regain the Beagle. At night-fall I met Mr. Murray, with the cutter, in the cove where I had appointed a rendezvous. He had not found any signs of the boat upon the opposite shore, and therefore returned; but he saw the people who had escaped from us when we surprised the whole family. They fled as soon as his boat was seen. Leaving, therefore, three men to

* Adventure Passage. † Gilbert Islands. ‡ Doris Cove.

© The Complete Work of Charles Darwin Online

watch in the bushes, he stood out to sea in the boat; and the stratagem succeeded sufficiently to enable our men to get very near to the natives, but not to catch any of them. One old man squinted very much, and in other respects exactly answered the description of a Fuegian who ill-treated some of the Saxe-Cobourg's crew, when they were cast away in Fury Harbour. I wish we could have secured him; but he was always on the alert, and too nimble for our people. In their canoe, which was taken, was found the sleeve of Mr. Murray's tarpaulin coat, a proof that these people belonged to the tribe which had stolen our boat. The canoe was a wretchedly patched affair, evidently put together in a great hurry.

"Next morning (22d) the master and I set out on our return to the Beagle; but seeing a great smoke on the opposite shore, in Thieves' Sound, I thought it must be made by the offenders, who, having returned and found their home desolate, were making signals to discover where their family was gone: sending the cutter therefore on board, I pulled across the sound towards the smoke. As the distance was long, and the wind fresh against us, it was late before I arrived; yet the smoke rose as thickly as ever, exciting our expectations to the utmost: —but, to our disappointment, not a living creature could be seen near the fire, nor could any traces of natives be found. The fire must have been kindled in the morning, and as the weather was dry, had continued to burn all day.

"We were then just as much at a loss as ever, for probably (if that was the party), they had seen us, and would, for the future, be doubly watchful. At first we had a chance of coming upon them unawares, but the time for that had passed: every canoe in the sound had been examined, and all its inhabitants knew well what we were seeking.

"It blew too strong, and it was too late, to recross Whaleboat Sound that night, so I ascended a height to look round. Next morning (23d) we again searched many miles of the shores of Thieves' Sound without any success; and afterwards sailed across to Stewart Harbour. We reached the Beagle in the evening, but found that all the other prisoners, excepting

© The Complete Work of Charles Darwin Online

three children, had escaped by swimming ashore during the preceding night. Thus, after much trouble and anxiety, much valuable time lost, and as fine a boat of her kind as ever was seen being stolen from us by these savages, I found myself with three young children to take care of, and no prospect whatever of recovering the boat. It was very hard work for the boats' crews, for during the first ten days we had incessant rainy weather, with gales of wind; and though the last few days had been uncommonly fine, the men's exertions in pulling about among the coves, and in ascending hills, had been extremely fatiguing.

"While the bad weather lasted, the men's clothes were seldom dry, either by day or night. Frequently they were soaked by rain during the greater part of the day, and at night they were in no better condition; for although a large fire (when made) might dry one side, the other as quickly became wet. Obliged, as we were, to pitch our small tent close to the water in order to be near our boat;—and because every other place was either rocky or covered with wood;—we were more than once awakened out of a sound sleep by finding that we were lying partly in the water, the night-tide having risen very much above that of the preceding day: although the tides should have been at that time 'taking off' (diminishing).

"Sometimes extreme difficulty was found in lighting a fire, because every thing was saturated with moisture; and hours have been passed in vain attempts, while every one was shivering with cold,—having no shelter from the pouring rain,—and after having been cramped in a small boat during the whole day.

"In Courtenay Sound I saw many nests of shags (corvorants) among the branches of trees near the water: until then, I had understood that those birds usually, if not invariably, built their nests on the ground or in cliffs.

"Much time had certainly been spent in this search, yet it ought not to be considered as altogether lost. Mr. Stokes had been hard at work during my absence, making plans of the harbours, and taking observations, and I am happy to say, that

© The Complete Work of Charles Darwin Online

I had reason to place great confidence in his work, for he had always taken the utmost pains, and had been most careful. My wanderings had shown me that from the apparent sea coast to the base of that snowy chain of mountains which runs eastward from the Barbara Channel, there is much more water than land, and that a number of islands, lying near together, form the apparently connected coast; within which a wide sound-like passage extends, opening in places into bays and gulfs, where islands, islets, rocks and breakers, are very numerous. These waters wash the foot of the snowy chain which forms a continued barrier from the Barbara Channel to the Strait of Le Maire. This cruise had also given me more insight into the real character of the Fuegians, than I had then acquired by other means, and gave us all a severe warning which might prove very useful at a future day, when among more numerous tribes who would not be contented with a boat alone. Considering the extent of coast we had already examined, we ought to be thankful for having experienced no other disaster of any kind, and for having had the means of replacing this loss.

"I became convinced that so long as we were ignorant of the Fuegian language, and the natives were equally ignorant of ours, we should never know much about them, or the interior of their country; nor would there be the slightest chance of their being raised one step above the low place which they then held in our estimation. Their words seemed to be short, but to have many meanings, and their pronunciation was harsh and guttural.

"Stewart Harbour, in which the Beagle remained during the last boat cruise, proved to be a good one, and, having three outlets, may be entered or quitted with any wind, and without warping. Wood and water are as abundant as in other Fuegian harbours; and it may be easily known by the remarkable appearance of Cape Castlereagh, which is on the island that shelters the anchorage from the S.W. wind and sea. The outlets are narrow, and can only be passed with a leading wind; but if one does not serve, another will answer. It should be

© The Complete Work of Charles Darwin Online

noticed, that there are two rocks nearly in the middle of the harbour, which are just awash at high water. A heavy swell is generally found outside, owing to the comparatively shallow water, in which there are soundings to about three miles from the Cape. In the entrances are from ten to twenty fathoms, therefore if the wind should baffle, or fail, an anchor may be dropped at any moment.

"In my last search among the Gilbert Islands, I found a good harbour for shipping, conveniently situated for carrying on the survey, in a place which otherwise I should certainly have overlooked: and to that harbour I decided on proceeding.

"For two miles to the eastward of Stewart Harbour, the shore projects, and is rocky and broken, then it retreats, forming a large bay, in which are the Gilbert Islands, and many rocky islets. We passed between Gilbert and Stewart Islands, anchored at noon under a point at the west entrance of the passage, and in the afternoon moved the Beagle to Doris Cove, and there moored her.

"I had decided to build another boat as quickly as possible, for I found it so much the best way to anchor the vessel in a safe place and then work with the boats on each side, that another good one was most necessary. Our cutter required too many men, and was neither so handy, nor could she pull to windward so well as a whale-boat; and our small boat was only fit for harbour duty. The weather on this coast was generally so thick and blowing, as not to admit of any thing like exact surveying while the vessel was under sail: the swell alone being usually too high to allow of a bearing being taken within six or eight degrees: and the sun we seldom saw. If caught by one of the very frequent gales, we might have been blown so far to the eastward that I know not how much time would have been lost in trying to regain our position. These coasts, which are composed of islands, allow boats to go a long distance in safety, and, from the heights near the sea, rocks and breakers may be seen, and their places ascertained, much better than can possibly be done at sea. For building a new boat we had all the materials on board, except prepared plank;

and for this we cut up a spare spar, which was intended to supply the place of a defective or injured lower mast or bowsprit. With reluctance this fine spar, which had been the Doris's main-topmast, was condemned to the teeth of the saw; but I felt certain that the boat Mr. May would produce from it, would be valuable in any part of the world, and that for our voyage it was indispensable.

"Profiting by a clear day, I went to a height in the neighbourhood, whence I could see to a great distance in-shore, as well as along the coast, and got a view of Mount Sarmiento. While away from the Beagle, in search of the lost boat, we had enjoyed four succeeding days of fine weather, during which that noble mountain had been often seen by our party. The astronomical bearing of its summit was very useful in connecting this coast survey with that of the Strait of Magalhaens.

"25th and 26th. Mr. Murray went to the S.W. part of the island, taking three days' provisions. Mr. Stokes and I were employed near the ship, while every man who could use carpenter's tools was occupied in preparing materials for our new boat. The rock near here is greenstone, in which are many veins of pyrites. Specimens are deposited in the museum of the Geological Society.

"28th. Weighed, warped to windward, and made sail out of Adventure Passage. I was very anxious to reach Christmas Sound, because it seemed to me a good situation for the Beagle, while the boats could go east and west of her, and the new boat might be built. Running along the land, before a fresh breeze, we soon saw York Minster, and in the evening entered Christmas Sound, and anchored in the very spot where the Adventure lay when Cook was here. His sketch of the sound, and description of York Minster, are very good, and quite enough to guide a ship to the anchoring place. I fancied that the high part of the Minster must have crumbled away since he saw it, as it no longer resembled 'two towers,' but had a ragged, notched summit, when seen from the westward. It was some satisfaction to find ourselves at anchor at this spot in

February, notwithstanding the vexatious delays we had so often experienced.

"As we had not sufficiently examined the coast between this sound and Gilbert Islands, I proposed sending Mr. Murray there with the cutter, while I should go to the eastward, during which time our new boat would be finished.

"1st March. This morning I went to look for a better anchorage for our vessel, that in which we lay being rather exposed, and very small. Neither Pickersgill Cove nor Port Clerke suited; so I looked further, and found another harbour, nearer to York Minster, easier of access for a ship arriving from sea, and with a cove in one corner where a vessel could lie in security, close to a woody point. Having sounded this harbour, I returned to move our ship. Cook says, speaking of Port Clerke, 'South of this inlet is another, which I did not examine:'—and into that inlet, named March Harbour, the Beagle prepared to go, but before we could weigh and work to windward, the weather became bad, which made our passage round the N.W. end of Shag Island rather difficult, as we had to contend with squalls, rain, and a narrow passage between rocks. The passage between Waterman Island and the south end of Shag Island is more roomy; but there is a rock near the middle which had not then been examined. We worked up to the innermost part of the harbour, and moored close to a woody point, in the most sheltered cove. Finding this to be a very convenient spot for building our boat, and in every point of view a good place for passing part of the month of March, I decided to keep the Beagle here for that purpose. This harbour might be useful to other vessels, its situation being well pointed out by York Minster (one of the most remarkable promontories on the coast), and affording wood and water with as little trouble as any place in which the Beagle had anchored.

"March 2d. The master set out in the large cutter, with a fortnight's provisions, to examine the coast between the north part of Christmas Sound and Point Alikhoolip, near which we passed on the 28th, without seeing much of it. With

© The Complete Work of Charles Darwin Online

moderate weather and a little sunshine, he might have been expected to return in a week or ten days. He carried a chronometer and other necessary instruments. Two of the three children, left by their mother at Stewart Harbour, I sent with Mr. Murray, to be left with any Fuegians he might find most to the westward, whence they would soon find their friends. The third, who was about eight years old, was still with us: she seemed to be so happy and healthy, that I determined to detain her as a hostage for the stolen boat, and try to teach her English. Lieutenant Kempe built a temporary house for the carpenters, and other workmen, near the ship and the spot chosen for observations, so that all our little establishment was close together. The greater part of the boat's materials being already prepared, she was not expected to be long in building, under the able direction and assistance of Mr. May.

"3d. Some Fuegians in a canoe approached us this morning, seeming anxious to come on board. I had no wish for their company, and was sorry to see that they had found us out; for it was to be expected that they would soon pay us nightly as well as daily visits, and steal every thing left within their reach. Having made signs for them to leave us, without effect, I sent Mr. Wilson to drive them away, and fire a pistol over their heads, to frighten them. They then went back, but only round a point of land near the ship; so I sent the boat again to drive them out of the harbour, and deter them from paying us another visit. Reflecting, while Mr. Wilson was following them, that by getting one of these natives on board, there would be a chance of his learning enough English to be an interpreter, and that by his means we might recover our lost boat, I resolved to take the youngest man on board, as he, in all probability, had less strong ties to bind him to his people than others who were older, and might have families. With these ideas I went after them, and hauling their canoe alongside of my boat, told a young man to come into it; he did so, quite unconcernedly, and sat down, apparently contented and at his ease. The others said nothing, either to me or to him, but paddled out of the harbour as fast as they could.

© The Complete Work of Charles Darwin Online

They seemed to belong to the same tribe as those we had last seen.

"4th. This afternoon our boat's keel was laid down, and her moulds were set up. Fuegia Basket* told 'York Minster'† all her story; at some parts of which he laughed heartily. Fuegia, cleaned and dressed, was much improved in appearance: she was already a pet on the lower deck, and appeared to be quite contented. York Minster was sullen at first, yet his appetite did not fail; and whatever he received more than he could eat, he stowed away in a corner; but as soon as he was well cleaned and clothed, and allowed to go about where he liked in the vessel, he became much more cheerful.

"At Cape Castlereagh and the heights over Doris Cove in Gilbert Island, the rock seemed to contain so much metal, that I spent the greater part of one day in trying experiments on pieces of it, with a blowpipe and mercury. By pounding and washing I separated about a tea-spoonful of metal from a piece of rock (taken at random) the size of a small cup. I put the powder by carefully, with some specimens of the rock—thinking that some of these otherwise barren mountains might be rich in metals. It would not be in conformity with most other parts of the world were the tract of mountainous islands composing the Archipelago of Tierra del Fuego condemned to internal as well as external unprofitableness. From the nature of the climate agriculture could seldom succeed; and perhaps no quadrupeds fit for man's use, except goats and dogs, could thrive in it: externally too, the land is unfit for the use of civilized man. In a few years its shores will be destitute of seal: and then, what benefit will be derived from it?—unless it prove internally rich, not in gold or silver, but perhaps in copper, iron, or other metals.

"5th. This day all hands were put on full allowance, our savings since we left San Carlos having secured a sufficient

* So called in remembrance of the basket-like canoe by which we received intelligence of the loss of our boat.

† The man I took out of the canoe.

stock of provisions to last more than the time allotted for the the remainder of our solitary cruise.

" By using substitutes for the mens' shoes, made of sealskin, we secured enough to last as long as we should want them. I have never mentioned the state of our sick list, because it was always so trifling. There had been very little doing in the surgeon's department; nothing indeed of consequence, since Mr. Murray dislocated his shoulder.

" The promontory of York Minster is a black irregularly-shaped rocky cliff, eight hundred feet in height, rising almost perpendicularly from the sea. It is nearly the loftiest as well as the most projecting part of the land about Christmas Sound, which, generally speaking, is not near so high as that further west, but it is very barren. Granite is prevalent, and I could find no sandstone. Coming from the westward, we thought the heights about here inconsiderable; but Cook, coming from the South Sea, called them 'high and savage.' Had he made the land nearer the Barbara Channel, where the mountains are much higher, he would have spoken still more strongly of the wild and disagreeable appearance of the coast.

" 6th. During the past night it blew very hard, making our vessel jerk her cables with unusual violence, though we had a good scope out, and the water was perfectly smooth. We saw that the best bower-anchor had been dragged some distance, it was therefore hove to the bows when its stock was found to be broken, by a rock, in the midst of good ground, having caught the anchor. It had been obtained at San Carlos from a merchant brig, but being much too light for our vessel, had been woulded round with chains to give it weight: its place was taken by a frigate's stream-anchor, well made and well tried, which I had procured from Valparaiso.* In shifting our berth, the small bower chain was found to be so firmly fixed round another rock that for several hours we could not clear it. Such rocks as these are very treacherous and not easily detected, except by sweeping the bottom with a line and weights. A very

* It had formerly belonged to H.M.S. Doris, which was condemned at Valparaiso; being unserviceable.

© The Complete Work of Charles Darwin Online

heavy squall, with lightning and thunder, passed over the ship this afternoon, depressing the sympiesometer more than I had ever witnessed. Very heavy rain followed.

"8th. In the forenoon I was on a height taking angles, when a large smoke was made by natives on a point at the entrance of the harbour; and at my return on board the ship, I found that two canoes had been seen, which appeared to be full of people. Supposing that they were strangers, I went in a small boat with two men to see them, and find out if they possessed any thing obtained from our lost whale-boat, for I thought it probable she might have been taken along the coast eastward, to elude our pursuit. I found them in a cove very near where our carpenters were at work. They had just landed, and were breaking boughs from the trees. I was surprised to see rather a large party, about fourteen in number, all of whom seemed to be men, except two women who were keeping the canoes. They wanted me to go to them, but I remained at a little distance, holding up bits of iron and knives, to induce them to come to me, for on the water we were less unequal to them. They were getting very bold and threatening in their manner, and I think would have tried to seize me and my boat, had not Lieutenant Kempe come into the cove with six men in the cutter, when their manner altered directly, and they began to consult together. They were at this time on a rock rising abruptly from the water, and the canoes, which I wanted to search, were at the foot of the rock. Under such local disadvantages I could not persevere without arms, for they had stones, slings, and spears, ready in their hands. Lieutenant Kempe and myself then returned on board for arms and more men, for I resolved to drive them out of the harbour, as it was absolutely necessary. Already they, or their countrymen, had robbed us of a boat, and endangered the lives of several persons; and had they been allowed to remain near us, the loss of that part of another boat which was already built would have followed, besides many things belonging to the carpenters and armourer, which they were using daily on shore.

"Another motive for searching the canoes, arose from see-

© The Complete Work of Charles Darwin Online

ing so many men without women, for I concluded that some of the whale-boat thieves were among them, who, having seen our cutter go to the westward full of people, might suppose we had not many left on board: one boat's crew, as they perhaps imagined, being left on an island, and another away in search of them. They had hitherto seen only merchant-vessels on this coast, and judging of the number of a crew by them, might think there could not be many persons on board, and that the vessel would be easy to take. At all events they came prepared for war, being much painted, wearing white bands on their heads, carrying their slings and spears, and having left all their children and dogs, with most of their women, in some other place.

"Two boats being manned and armed, I went with Lieut. Kempe and Mr. Wilson to chase the Fuegians, who were paddling towards another part of the harbour. Seeing the boats approaching, they landed and got on the top of a rock, leaving the canoes underneath with the two women. From their manner I saw they were disposed to be hostile, and we therefore approached leisurely. Their canoes being within our reach, I told the bowman to haul one alongside that we might search it; but no sooner did his boathook touch it, than a shower of stones of all sizes came upon us, and one man was knocked down, apparently killed, by the blow of a large stone on the temple. We returned their volley with our fire-arms, but I believe without hitting one of them. Stones and balls continued to be exchanged till the cutter came to our assistance. The Fuegians then got behind a rock, where we could not see them, and kept close. Their canoes we took, and finding in them some bottles* and part of our lost boat's gear, we destroyed them. The man of my crew who was knocked down by a stone was only stunned, and soon recovered, but the blow was very severe and dangerous. Not choosing to risk any further injury to our people, and seeing no object to be gained, I would not land, though our numbers were much superior, and we had fire-

* Mr. Murray had some bottles of beer in his boat—besides those in which the men's allowance of spirits was kept.

© The Complete Work of Charles Darwin Online

arms. It appeared that the savages knew of no alternative but escape or death, and that in trying to take them they would certainly do material injury to some of our party with their spears, stones, or large knives made of pieces of iron hoops. Remaining therefore with Lieut. Kempe, in the cutter, to watch their motions, I sent my boat on board with the man who was hurt. The Fuegians made their escape separately through the bushes, and were quickly out of sight and reach: we fired a few shots to frighten them, watched their retreat over the barren upper part of the hills, and then went to look for their wigwams, which could not be far distant, as I thought; but after unsuccessfully searching all the coves near us, a smoke was seen at the opposite side of the sound, on one of the Whittlebury islands; so concluding it was made by the rest of their tribe, and being late, I returned on board.

"9th. At daylight, next morning, I went to look for the wigwams, on the Whittlebury Islands, at the north side of the sound: we saw their smoke when we were half-way across, but no longer. The natives had probably seen us, and put out their fire directly, well knowing the difference between our boat and their own canoes, and noticing her coming from a part of the sound distant from the point whence they would expect their own people, and crossing over against a fresh breeze, which a canoe could not attempt to do. The wigwams were entirely deserted, and almost every thing was taken away; but near their huts a piece of 'King's white line,' quite new, was picked up; therefore our boat* had been there, or these were some of the people who stole her. For the late inmates of the wigwams we searched in vain—only their dogs remained, they themselves being hidden. Looking round on the other side of that islet, we saw two canoes paddling right away from the islands, though it was blowing a fresh breeze, and a considerable sea was running. Knowing, from the place they were in, and their course, that they were the fugitives from the wigwams, we gave chase, and came up with them before

* In the lost boat were several pieces of spare line, 'King's white line,' quite new.

© The Complete Work of Charles Darwin Online

they could land, but so close to the shore that while securing one canoe, the other escaped. From that which we seized a young man and a girl jumped overboard, deserting an old woman and a child, whom we left in order to chase the young man; but he was so active in the water that it was fully a quarter of an hour before we could get him into our boat. Having at last secured him, we followed the others, but they had all landed and hidden, so we returned across the sound with our captive. In our way a smoke was seen in a cove of Waterman Island, and knowing that it must be made by those who escaped us yesterday, as there were no other natives there, we made sail for it; but the rogues saw us, and put out their fire. When we reached the spot, however, we found two wigwams just built, and covered with bark; so that there they had passed the night after their skirmish. I would not let any one land, as the Fuegians might be lurking in the bushes, and might be too much for two or three of us on shore,—but left the place. They would think us gone for more boats, as at the former meeting, and would shift their quarters immediately; so by thus harassing them, I hoped to be freed from any more of their visits while we remained in the neighbourhood.

"The bodily strength of these savages is very great ('York Minster' is as strong as any two of our stoutest men), which, with their agility, both on shore and in the water, and their quickness in attack and defence with stones and sticks, makes them difficult to deal with when out of their canoes. They are a brave, hardy race, and fight to the last struggle; though in the manner of a wild beast, it must be owned, else they would not, when excited, defy a whole boat's crew, and, single-handed, try to kill the men; as I have witnessed. That kindness towards these beings, and good treatment of them, is as yet useless, I almost think, both from my own experience and from much that I have heard of their conduct to sealing vessels. Until a mutual understanding can be established, moral fear is the only means by which they can be kept peaceable. As they see only vessels which when their boats are away have

© The Complete Work of Charles Darwin Online

but a few people on board, their idea of the power of Europeans is very poor, and their dread of fire-arms not nearly so great as might be imagined.

"From this cove we returned to the Beagle. My Fuegian captive, whom I named 'Boat Memory,' seemed frightened, but not low-spirited; he eat enormously, and soon fell fast asleep. The meeting between him and York Minster was very tame, for, at first, they would not appear to recognise or speak to each other. 'Boat' was the best-featured Fuegian I had seen, and being young and well made, was a very favourable specimen of the race: 'York' was one of the stoutest men I had observed among them; but little Fuegia was almost as broad as she was high: she seemed to be so merry and happy, that I do not think she would willingly have quitted us. Three natives of Tierra del Fuego, better suited for the purpose of instruction, and for giving, as well as receiving information, could not, I think, have been found.

"10th. This morning, having been well cleaned and dressed, 'Boat' appeared contented and easy; and being together, kept York and him in better spirits than they would probably otherwise have been, for they laughed, and tried to talk, by imitating whatever was said. Fuegia soon began to learn English, and to say several things very well. She laughed and talked with her countrymen incessantly.

"12th. Some evenings, at dusk, I observed large flights of birds, of the petrel kind, skimming over the sea (like swallows), as if in chase of insects. These birds were black, about the size of a 'Cape Pigeon.' We tried to shoot one, but did not succeed."

CHAPTER XXII.

Mr. Murray returns—Go to New Year Sound—See Diego Ramirez Islands from Henderson Island—Weddell's Indian Cove—Sympiesometer—Return to Christmas Sound—Beagle sails—Passes the Ildefonso and Diego Ramirez Islands—Anchors in Nassau Bay—Orange Bay—Yapoos—Mr. Murray discovers the Beagle Channel—Numerous Natives—Guanacoes—Compasses affected—Cape Horn—Specimens—Chanticleer—Mistake about St. Francis Bay—Diego Ramirez Islands Climate—San Joachim Cove—Barnevelt Isles—Evouts Isle—Lennox Harbour.

"14th. This morning the master returned, having succeeded in tracing the coast far enough to join our former work, although the weather had been very unfavourable. He met with many Fuegians, most of whom were armed with slings, spears, and cutting weapons made with pieces of iron hoop fastened on a stick. They were very troublesome, especially at night, and obliged him to keep them at a distance. Their respect for a musket was not so great as might have been expected, and unless they saw it tolerably close, and pointed directly at them, they cared not. The boat's crew bought some fish from them, for buttons and other trifles. From forty to fifty men, besides women and children, were seen in one place alone; and many were met elsewhere.

"Mr. Murray penetrated nearly to the base of the snow-covered mountains, which extend to the eastward in an unbroken chain, and ascertained that there are passages leading from Christmas Sound to the large bay where the whale-boat was stolen; and that they run near the foot of the mountains. He also saw a channel leading farther to the eastward than eye-sight could reach, whose average width seemed to be about a mile. He left the two children in charge of an old woman whom they met near the westernmost part which his party reached, who appeared to know them well, and to be very much pleased at having them placed in her care.

"15th. Raining and blowing:—as usual, I might say. When

© The Complete Work of Charles Darwin Online

it moderated I left the Beagle, and set out in a boat with Mr. Wilson (mate), taking a fortnight's provisions; though I hoped to be again on board in less than ten days, by which time our new boat would be finished, and Mr. Stokes, as well as Mr. Murray, would have laid down his last work. My object was to go eastward towards Indian Sound and Nassau Bay, but the weather soon stopped our progress, and obliged us to put into a small cove on the west side of Point Nativity, where we hoped to get shelter from the increasing wind, though not from the rain, which poured down in torrents. The cove proved to be much exposed, but we staid there till daylight on the following morning, when we pulled out, and round the point to the eastward, gladly enough, for we had been in a bad berth during the night, exposed to wind and rain, besides swell. We ran along the land, with a moderate westerly wind, stopped for a time near Cape Rolle, the point of land next to Weddell's 'Hope Island;' and in the evening went into some openings among the adjacent islands.

"17th. At daylight we set out again, and ran along-shore with a fresh west wind, crossed the mouth of a bay which seemed likely to afford shelter, but did not then delay to look at it closely. Soon after noon we passed Weddell's 'Leading Hill,' which is a very singular double-peaked height, conspicuous from a long distance, and remarkable in every point of view. Between it and Black Point (a projecting craggy rock) lies a bay or sound, which appears to extend some distance northward. This part of the coast is bad for vessels to close with, being much broken, and having several rocky islets scattered near it; but two miles off shore there is no danger. Having found a secure cove near Leading Hill, we landed, and the men set up our tent, while Mr. Wilson and I ascended the heights to look round. The wind soon freshened to a gale, and made us rejoice at having reached a sheltered place.

"18th. The whole of this day was lost by us, for it blew a strong gale with continual rain. Collecting limpets and muscles—cutting wood—and drying our clothes on one side by the fire, while the other got wet, were our only occupations.

© The Complete Work of Charles Darwin Online

19th. Still a strong wind, but less rain. Between the squalls I obtained a few sights of the sun, for time, and at noon a tolerably good set for latitude. Being then better weather, and likely to improve, we crossed in the boat to Leading Hill, and from its summit took the necessary angles. It was very cold and windy, but we effected all that was then required.

"20th. Decamped very early and ran across Duff Bay, towards Henderson Island, with a moderately fresh breeze off the land; and as my object was to obtain a good view and a round of angles from the summit of a height on that island, I passed Weddell's Morton Isle, Blunder Cove, &c. without stopping, and reached the north end of Henderson Island soon enough to get sights for time. From that spot we went a short distance to a cove, where the boat might remain during my absence on the hill, observed the latitude, and then ascended. Before we were half-way up, a squall came on from S.W. and increased rapidly, but having ascended so far, I was not disposed to turn back, so we pushed on and reached the summit; yet, when there, I could not use a theodolite, on account of the wind. Towards the east I could see a long distance, to the farthest of the Hermite Islands; but towards the west the view was obscured by haze; so leaving the instruments, I hastened down to the boat and found her safe, though she had been in great danger. By this time the wind had moderated, and before dark we measured the distance between the morning and noon stations: that from the latter to the summit of the hill I had measured, when at the top, by a micrometer. We then passed round the north end of the island, and in the dark searched the east side for a resting-place, which after some time was found.

"21st. A fine clear day enabled me to make the necessary observations, and I then went up the height and succeeded in obtaining a distinct view of the Diego Ramirez Islands. As this hill is distant from them between fifty and sixty miles, I felt sure of getting a good cross bearing from the south end of the Hermite Islands, distant from them, as I then thought, only about forty, and thus fixing their position.

"New Year Sound appears to be a large body of water ex-

© The Complete Work of Charles Darwin Online

tending towards the N.W., with a multitude of islands scattered about it. From its east side the land trends away towards a point which is curiously peaked, like a horn, and which I supposed to be the western point of Nassau Bay.*

"22d. We had hardly left our cove, when steady rain set in; however, we went across towards New Year Sound, sometimes favoured by the wind, but could do little. As far as I saw the day before, the snowy chain of mountains continued to the eastward, therefore I had little hope of finding a body of water in the interior of Tierra del Fuego, about the head of Nassau Bay. About noon we were near Weddell's 'Indian Cove,' but the weather being thick I did not recognise it, so we stood up the sound with a fresh breeze from the W.S.W. I soon found that it led only to the north and west, and probably communicated with some of the passages which Mr. Murray saw leading to the eastward from the neighbourhood of Christmas Sound. Towards the north and east I had already noticed a long range of mountains. Concluding therefore from what I then observed, and from views obtained from the heights, that no passage leads from this sound direct to Christmas Sound, and that to return to the Beagle I must go part of the way by the sea-coast, or else go round, by a series of intricate passages, to the places which Mr. Murray had seen in the cutter; I preferred the coast, as a second view of it would be of use, while a traverse among the islands could not be very beneficial.

"Putting about, we returned down the sound, the breeze still allowing us to sail fast. We closed the western shore to look for Indian Cove, and, as the weather had cleared up, found it without difficulty. It is not so good a place as I expected; for except at the inner corner close to a run of water, I found only rocky soundings. The few casts of good ground were so close to the shore that the place can only be considered fit for a cutter, or small craft, which could lie quite close to the land. This cove is, in my opinion, too far inland to be of general use; and an anchorage under Morton Island would be far preferable

* False Cape Horn, or Cape False.

© The Complete Work of Charles Darwin Online

for a vessel arriving from sea. We found an empty North-American cask, apparently left that season: on a height near the cove there was a pile of stones we had not time to examine: and much wood appeared to have been cut down lately by the crew of some vessel. We saw several wigwams, but no Indians. That night we stopped near the S.W. point of the sound, close to Gold-dust Island.

"23d. After examining the cove, in which we passed the night, and taking observations, we crossed Duff Bay, towards Leading Hill. I wished to have seen more of a promising bay on the east side of Morton Island, where I thought there was good anchorage, but could not afford time, as it was probable that we should be delayed in our return along this exposed part of the coast against the prevailing winds. There is a considerable tide between Morton Isle and the point next to Gold-dust Isle. The flood comes from the westward, about one knot, or at times two knots, an hour. With the ebb it is nearly slack water, or perhaps there is a slight tendency towards the west; and such appears to be the case all along this coast, from Christmas Sound. We reached Leading Hill late in the afternoon, although the wind had increased much and was directly against us: at night it blew a gale from the westward.

"24th. A strong gale prevented our moving, or making any beneficial use of our time.

"25th. Still blowing very fresh; but I thought we could pull round into the next bay, and there do some good by planning the harbour, &c., although we might get no farther for some days. From the season, the state of the sympiesometer, and the appearance of the weather, I did not expect any favourable change until about the end of the month. The sympiesometer was my constant companion: I preferred it to a barometer, as being much more portable and quicker in its motions. By great exertion on the part of the men, for it required five hours' hard pulling, we got round a headland into the next bay, a distance of only four miles. It rained great part of the time, and in the afternoon poured steadily, but we succeeded in finding a sheltered spot for our lodging, and soon put ourselves into

© The Complete Work of Charles Darwin Online

somewhat better plight than we had been in during the greater part of the day, the men having been constantly soaked through, and their hands quite numbed with cold and wet. I was disappointed by this place; the various coves were sounded, without getting bottom with twenty-five fathoms of line; and I could find no anchorage without going further up the inlet than would suit any vessel running in from sea for a temporary shelter.

"26th. A strong gale prevented our going outside, but in hopes that there might be an inland passage I set out to look for one. Having pulled and sailed about six miles up the inlet, we reached its termination, and thence returned to our bivouac. There seemed to be an opening into Duff Bay not previously seen, which would have saved us some time and trouble had we known of its existence.

"27th. The gale continued with more or less violence, and during the greater part of the day we were occupied in gathering limpets and muscles, as a stock of food in case of being detained longer than our provisions would last. Shooting did not succeed, because the sea-birds were very wild and scarce. I regretted that there was no harbour in the inlet which could be planned during our stay. Every cove we could find had deep water, and so rocky a bottom that we found difficulty in securing even our small boat; for this continued gale raised so much swell that we were kept on the alert at night to shift her berth as often as the wind changed.

"28th. This day, and the preceding night, the wind was exceedingly violent, from N.W. to S.W., but generally southward of west. In pulling across the cove to get limpets, the squalls at times forced the oars out of the men's hands, and blew them across or away from the boat. Much rain fell during most nights, but after sunrise it generally ceased; sometimes however the rain poured down by day as much as by night.

"I here saw many seals teaching their young ones to swim. It was curious to see the old seal supporting the pup by its flipper, as if to let it breathe and rest, and then pushing it away into deep water to shift for itself.

© The Complete Work of Charles Darwin Online

"29th. This morning, with better weather, we sailed very early in hopes to get round Black Point; the wind being moderate promised well, but, with the sun, it rose again. However, we tried hard for about six hours, during four of which I hardly hoped to succeed, for it blew strong, and the tide race was dangerous: but before evening we gained the sheltered part of Trefusis Bay. The men were on their oars from five in the morning till four in the afternoon, and, excepting two rests of a quarter of an hour each, pulling hard all the time. We landed in a sheltered spot, about half a mile within the entrance of a passage which leads from Trefusis Bay to Christmas Sound. Our fatigue and thorough drenching, by sea and rain, was then little cared for, having gained our point, and being only a day's pull from the Beagle.

"I had seen along this passage from Christmas Sound, as well as from Leading Hill, and rejoiced to get into it, for the outer coast is a wild one for a boat at any period of the year —and this was the month of March; about the worst time.

"30th. A fine clear morning. We started with the sun, and pulled so fast along in the smooth water, that by the evening we reached our little vessel, and found that all was well on board; that there had been no more visits from the Fuegians, nor any troubles. The new boat was finished on the 23d, only twenty days having been occupied by Mr. May and three men in building her. Appearance was very much in her favour, notwithstanding the disadvantages under which she was built. Lieutenant Kempe had finished all the ship's work with his usual promptness: new topmast rigging had been fitted, and every thing prepared for sea. I was two days over the time for which we carried provisions, but by my coxswain's care of them, and by using limpets and other shell-fish, we still had a sufficiency.

"Having seen as much as seemed necessary of the coast between Christmas Sound and Nassau Bay (I mean necessary in proportion to our limited time and provisions), the Ildefonsos and Diego Ramirez Isles were to be our next objects.

"31st. A strong wind, with much rain, prevented our mov-

© The Complete Work of Charles Darwin Online

ing early—but as the sun rose higher the weather improved, and we tried to weigh,—yet were provokingly delayed, for the chain was so fast round a rock, that for nearly an hour we could not move it. At last we succeeded, without injury to anything—left the harbour, and stood away for the Ildefonsos with a strong W.S.W. wind and a confused high swell.

"March Harbour (so called from our having passed the month of March in it) is not so good as I at first thought. The bottom is certainly excellent in some parts; it is well sheltered, and easy of access, but there are many rocky places which would injure a hemp cable. Besides, there is a dangerous rock under water in the wide part of the harbour, hidden by a large patch of kelp.

"We passed along the S.W. side of the Ildefonsos, at the distance of half a mile. They appeared like the higher parts of a mountain almost under water, lying N.W. and S.E., nearly broken through by the sea in several places, so as to form several islets, of which the highest and largest is about two hundred feet above the sea, and one-third of a mile in length; another is about one-quarter of a mile long; the rest are mere rocks. The two larger are covered with tussac,* among which we saw numerous seal which had scrambled up to the very summits. Having seen enough of these islets, we hauled our wind, and shortened sail, to prepare for the night: for it blew a fresh gale, with every appearance of its increasing and drawing to the southward. I wished to make the Diego Ramirez Islands the next morning, and thence run to the north-eastward; and, had the wind been moderate, could have done so without difficulty; but after carrying a press of sail during the night, and making southing, with as little easting as possible, I found myself, at daylight next morning, five miles to leeward of the above-mentioned islands, with the wind strong from the N.W., and too much sea to allow me to hope to see more of them without remaining under sail until the weather moderated. This would not have

* A rushy kind of coarse grass.

© The Complete Work of Charles Darwin Online

suited the chronometers, or our limited time; therefore we wore round and steered (by Weddell's chart) for the western part of the Hermite Islands, intending to run along the land from West Cape. The wind became more moderate towards noon, but the weather got so thick that no part of the land could be made out distinctly; and supposing that a point of land which I saw was Cape Spencer, we steered directly for it, as the day was drawing to a close and obliged me to give up my intention of coasting. Nearing the land, I found it resembled the point I had seen from Henderson Island, and supposed to be the S.W. extreme of Nassau Bay, but did not correspond to any part of the Hermite Islands, as shewn by Captain King's plan. Evening was approaching, thick misty clouds shut out other land from our view, but being a weather shore, I trusted to finding anchorage somewhere, and stood on.

"The wind increased, and blew in very strong squalls off shore, obliging us to carry low sail until we had run several miles along the land in smooth water, when we anchored at the entrance of a bay, in thirteen fathoms water, over a coarse sandy bottom. A low projecting point covered us from the force of the wind as it then blew; and the land on each side from all other westerly winds: but the squalls increased so violently in the early part of the night, that although in smooth water, with eighty fathoms of chain out, the top-gallant masts down, and yards braced up, the vessel drove, and we were obliged to let go another anchor, and veer a long scope of cable; after which she held on firmly through the night.

"2d. At daylight we hove up the best bower, but found one fluke broken off. After getting the sheet anchor to the bows, and the broken one in-board, we weighed and made sail to windward, in search of a good anchorage. When the weather cleared in the morning, I had discovered that we were in Nassau Bay, near Orange Bay, and that the curiously-peaked headland we had passed was 'False Cape Horn,' the same which I had seen from Henderson Island. Finding this the case, I determined to turn the mistake to account, and at once set to work in this quarter, postponing our visit to the Hermite

© The Complete Work of Charles Darwin Online

Islands. Short runs were essential, because of the chronometers, and this last had been a long one for them, with much motion, therefore it was necessary I should get observations.

" Towards noon the weather cleared and became very fine, with a light breeze from the northward. We stood across near the north end of the Hermite Islands, carrying soundings right across; but the view we obtained of the head of Nassau Bay, did not encourage us to hope for either interior waters or a passage, as the mountains seemed to continue in an unbroken chain to the eastward of New Island, and from the mast-head I saw other high mountains far to the eastward. In the afternoon we stood into a fine-looking clear bay, well sheltered, and with regular soundings, from twelve to twenty fathoms over fine sand. I afterwards found that this was Orange Bay, and that the bay at the south point of which we anchored last night was that called, by the Dutch, Schapenham Bay. Being a large, roomy place, with even bottom, we remained at single anchor; but the glass had been falling so much, and was then so extremely low, that I thought it prudent to prepare for the worst, and struck topmasts.

" During the latter part of our stay in Christmas Sound, and up to the present time, our sick-list had been considerable, therefore I was not sorry to gain a safe anchorage in a place which appeared likely to afford the means of recruiting our invalids, and restoring them to health. Colds and rheumatisms, owing to bleak winds and much wet, were the chief complaints. This was the only time since the Beagle left Rio de Janeiro that her sick-list had been worthy of notice.

" Notwithstanding the unusual fall of the barometer and sympiesometer and their still continuing to sink, this day was as fine, and seemed as likely to continue so, as any day I had ever seen, therefore we took advantage of it, by getting the necessary observations for time, latitude, and true bearing; by airing bedding, and cleaning the ship throughout. This appeared to be an excellent place for vessels: the land around is rather low, and looked much more cheerful than the high dismal mountains under which we last anchored. Wood and water

© The Complete Work of Charles Darwin Online

were plentiful, and easily obtained. Wild-fowl were numerous, and our people brought on board a serviceable supply, enough for all the sick, and for most of those who were in health.

"3d and 4th. Still very fine weather, although the barometer and sympiesometer were lower than I had yet seen them in this country. Our Fuegians were becoming very cheerful, and apparently contented. We gave them as much fresh provision (birds and fish) as we could obtain with guns and lines, and hitherto they had fared very well. All that was shot went to one stock, from which it was divided in rotation to the messes, the sick being first provided for, and then the Fuegians.

"5th and 6th. Two more fine days, with a very low glass, shook my faith in the certainty of the barometer and sympiesometer.* During those days, the wind had been light from N.N.W., and twice before I had known these instruments to be similarly affected during exactly similar wind and weather: once at Port Desire, on the coast of Patagonia; and once at Port Gallant, while I was in the Otway Water.

"The master went towards the head of Nassau Bay, and Mr. Stokes set out in the opposite direction. Mr. Murray had one of our best chronometers, kept in a box, well packed in wool, but exposed to the temperature of the air. Before going away and after returning, it was kept and rated in the same box on deck, because the variations of temperature in the open air of this climate are small; much less than a chronometer would experience if alternating between a warm cabin and a cold boat. I was sadly grieved at finding that some Fuegians who arrived were not of the same tribe as our captives, nor even spoke the same language. On the contrary, much enmity appeared to exist between them; though their colour, features, and habits were similar. At first, 'York' and 'Boat' would not go near them; but afterwards took delight in trying to cheat them out of the things they offered to barter; and mocked their way of speaking and laughing; point-

* The mercury in the barometer fell to 28,94, and the oil in the sympiesometer to 28,52; the thermometer ranging from 40° to 48° (Faht.)

© The Complete Work of Charles Darwin Online

ing at them, and calling them 'Yapoo, yapoo.' 'Fuegia' went on deck; but the instant she saw them, screamed and ran away. Some one told her, in jest, to go into their canoe and live with them, which frightened her so much, that she burst into tears and ran below to hide herself. After they were gone, 'Boat' and 'York' made us understand they had had fights with that tribe, and shewed the scars of wounds received from them. By the help of signs we could comprehend much of their meaning; but very few words were yet learned on either side. We afterwards found that these Yapoos built their wigwams in a manner differing from that of the western tribes, being made of a number of poles, or pieces of wood, placed on end around a small space, and meeting at the top.

"Our Yapoo acquaintances established themselves in the bay near our forge, but without attempting to steal any thing. They frequently came alongside the ship with fish, which they caught in the kelp. They take these fish by means of a line without a hook, having only a small piece of bait at the end, with which to entice them to the top of the water, close to the side of the canoe. A fish bites, and before it can detach its small teeth from the soft, tough bait, the hand holding the line jerks the prize above the water, and the other catches it. The fisher then bites out a large piece of its belly, takes out the inside, and hangs the fish on a stick by the fire in the canoe.

"10th. Still fine steady weather, notwithstanding the unusually low fall of the barometer already mentioned.

"12th. By the assistance of Mr. May, at the forge, we made one good anchor out of two broken ones, and fitted new hawse-plates where they were worn through, by constantly using the chains. Fortunately, we brought from San Carlos a good supply of iron and coals, and applied the latter only to the use of the armourer and the small stoves, so that we were enabled to use the forge very often; and between the wants of the ship and those of the boats, there was always much work for that most useful appendage.

© The Complete Work of Charles Darwin Online

"The glasses had at last been rising; and during the past night and this day, the wind was very strong with much rain. The wind shifted from the northern quarter into the southern, drawing round to the S.E.; which, of course, would make the mercury rise higher after being so very low, though the weather might prove extremely bad.

"14th. The master returned, and surprised me with the information that he had been through and far beyond Nassau Bay. He had gone very little to the northward, but a long distance to the east, having passed through a narrow passage, about one-third of a mile wide, which led him into a straight channel, averaging about two miles or more in width, and extending nearly east and west as far as the eye could reach. Westward of the passage by which he entered, was an opening to the northwest; but as his orders specified north and east, he followed the eastern branch of the channel, looking for an opening on either side, without success. Northward of him lay a range of mountains, whose summits were covered with snow, which extended about forty miles, and then sunk into ordinary hills that, near the place which he reached, shewed earthy or clayey cliffs towards the water. From the clay cliffs his view was unbroken by any land in an E.S.E. direction, therefore he must have looked through an opening at the outer sea. His provisions being almost exhausted, he hastened back.

"On the south side of the channel there were likewise mountains of considerable elevation; but, generally speaking, that shore was lower than the opposite. Mr. Murray saw great numbers of natives near the narrow passage and upwards of a hundred canoes were seen in one day, each containing from two to six people. These Fuegians had much guanaco skin, and many of the bones of that animal made into spear-heads, but very little seal-skin. The wigwams were large and commodious, compared with those of the western tribes, being built of small trees piled up endwise, and tied together at the top, their outside being covered with bushes, grass, &c. to keep out the cold, and the earth inside scooped out much below the surface of the ground. Some could hold about twice as many people

© The Complete Work of Charles Darwin Online

as the western wigwams: but all were not so large. Every canoe gave chase to our boat, eager to see the strangers, and exchange small fish, spear-heads, or arrows, for buttons, beads, and other trifles. No arms or offensive weapons were seen among them, excepting fish spears, bows, arrows, and slings: they had not even clubs, nor such lances as are used by the western tribes. They seemed to be more tractable, and less disposed to quarrel than those of the west. Wherever the boat went, she was followed by a train of canoes, each full of people, and having a fire smoking in the middle. Where they got the guanaco skins was a question not easy to answer. Was there a passage to the northward, by which they could trade with the people living there?—or were there guanacoes in the southern part of Tierra del Fuego? Both the bones and skins seemed abundant; but the people made signs to Mr. Murray that they came from the eastward:—none pointed towards the north. One native showed how they ran, and their shape, and how they were killed, also the kind of noise they made.

"15th. Mr. Stokes returned, after going a long way to the north and west, without finding a passage into New Year Sound. His examination, united to Mr. Murray's, almost completed the north and west part of Nassau Bay; and only the east side remained to be explored. Our anchorage, called Orange Bay, is excellent; and one of the few on this coast which are fit for a squadron of line-of-battle ships. Its approach from the sea is as easy as the harbour is commodious. There are three fathoms close to the shore; yet in no part are there more than twenty; and every where there is a sandy bottom. Water is abundant; wood grows close to the sea; wild-fowl are numerous; and although shell-fish are scarce, plenty of small fish may be caught with hook and line among the kelp, and in the summer a seine will furnish abundance.

"On the 16th we left Orange Bay, but light winds prevented our reaching the open sea that day, or during the following night. I was equally disposed to run out again to the Diego Ramirez—to look at the coast west of False Cape for about ten miles—or to run for the Bay of St. Francis; but the

© The Complete Work of Charles Darwin Online

wind failed entirely. During the night we had a breeze that would have carried us down to the latter spot, but wishing to see, and take bearings of the land as I went, I did not profit by it; and in the morning was baffled with light airs and a current setting to the northward.

"17th. During the early part of the day we had light variable winds, scarcely sufficient to help us against the current which seemed to set constantly into the bay, from the sea, at the rate of about one knot an hour. The manner in which our compasses were affected in this bay was remarkable; all of them being extremely sluggish, and, unless continually shaken, they did not show the proper magnetic bearings, or agree together, nearer than two points. I sharpened the centres with much care, and examined the agate caps, without improving the results. The compasses considered the best in other places, were here as bad as the worst; an excellent one, upon Alexander's principle, with central jimbals, being nearly useless. In trying the compasses on shore, the heavy cards with large needles had been less affected by local influence than light delicate cards of Kater: the heavy ones having averaged 24° variation along the whole coast, though Kater's differed in some places as much as from 19° to 28°; agreeing nearly with each other, but not with Gilbert's or Alexander's compasses, in both of which were cards comparatively heavy.

"We passed much too close to West Cape, but having fortunately cleared it, ran along the land before a moderate breeze, and rounded Cape Spencer at dusk. The weather was so thick that Cape Horn could not be seen, and we mistook the former for the famous cape; especially as, in that view, the lower part of Cape Spencer looked like the head of a double-horned rhinoceros: but as we drew nearer, Cape Horn appeared. The wind failed as we entered the Bay of St. Francis, and left us to the alternative of anchoring in deep water, or driving about with the current: we therefore anchored off San Joachim Cove, near the Seal Rock. The night proved fine, so we lay quietly till next morning, and then made sail to a breeze from the northward and anchored in San Martin

© The Complete Work of Charles Darwin Online

Cove. I afterwards went in a boat to Horn Island, to ascertain the nature of the landing, and whether it was practicable to carry any instruments to the summit of the Cape. Many places were found where a boat might land; and more than one spot where she could be hauled ashore: so that taking instruments to the summit did not seem likely to be a very difficult task. As the weather continued favourable I returned on board that night, and the next morning (19th) arranged for a visit to Cape Horn; a memorial having been previously prepared, and securely enclosed in a stone jar.

After taking observations at noon for latitude, we set out, carrying five days' provisions, a good chronometer, and other instruments. We landed before dark, hauled our boat up in safety on the north-east side, and established ourselves for the night on Horn Island.

"20th. At daybreak we commenced our walk across the island, each carrying his load; and by the time the sun was high enough for observing, were near the summit, and exactly in its meridian; so we stopped while I took two sets of sights and a round of angles. Soon afterwards we reached the highest point of the Cape, and immediately began our work; I and my coxswain, with the instruments; and Lieut. Kempe with the boat's crew raising a pile of stones over the memorial.

"At first the Diego Ramirez Islands were seen, but before I could get the theodolite fixed and adjusted, the horizon became hazy. At noon satisfactory sets of circum-meridional altitudes were obtained with two good sextants. A round of angles, compass bearings for the variation, and good afternoon sights for time completed our success. The pile made over our memorial was eight feet high, and in it were stones which required the united exertions of all seven men to raise to the top. We drank the health of His Majesty King George the Fourth, and gave three hearty cheers, standing round the Union Jack. Directly all was finished we travelled towards our boat as fast as possible: but darkness surrounded us before we were more than half-way. Those who had loads which would not be hurt by tumbling about among bushes, travelled

on; but, having the chronometer and a sextant to take care of, I waited till one of the men returned with a lantern. All reached the boat before nine o'clock, without losing or injuring any thing; but the cargo of stones, for specimens, which each brought back, delayed our returning progress materially.

"At day-light (21st) we launched and stowed our boat, and set out on our return. We reached the ship that afternoon, well laden with fragments of Cape Horn.

"22d. Since the end of March the weather had been more settled, and much finer than we had yet had it on any part of the coast; but our visit to Horn Island was only just in time, for it soon changed again to blowing and raining. Being close to the head of the cove, we did not feel the williwaws—though they appeared to blow sharply enough about the middle of it. I did not wonder at the American, whom we met in the Strait of Magalhaens, saying that he saw 'marks of a very large establishment;' for the head of this cove appeared to have been colonized by the Chanticleer, so many remains of wooden roads and wooden houses were visible every where.

"23d—24th. Bad weather. I was waiting anxiously for an opportunity of getting a true bearing of Diego Ramirez, from the top of Kater Peak, or Cape Spencer, to cross the bearings obtained from Henderson Island.

"25th. I went up to the summit of the Peak, but found so thick a haze, that no distant object could be seen. Leaving the instruments at the top, after taking a few angles, and observations of the sun for true bearings, I descended, and afterwards examined St. Bernard Cove, which appeared to be a good harbour. By comparing the old charts with this place and Nassau Bay, I became convinced that there had been a great mistake, and that the Bay of Nassau is, or rather was, the bay of St. Francis; and that the plan given in the Admiralty charts is a very fair sketch of its west side, from False Cape to Packsaddle Island; but the bottom and east side of the bay are evidently put in at random, and would have been better left out to give place to the words, 'Land was seen in this direction.' Neither in shape, bearings, distance, or

© The Complete Work of Charles Darwin Online

soundings, does that plan correspond with the place now called St. Francis Bay; but it does agree very closely, considering the date of its being made, with the part I have mentioned. The words Cape Horn may have misled the compiler, as the plan does not show any latitude or longitude, and those who since visited the place, previously to the Beagle's arrival, had not been in Nassau Bay.

"26th. Another fine day. I went up the peak again and obtained the desired angles; but Diego Ramirez appeared nearly as distant as when seen from the top of Henderson Island. Meanwhile the Beagle was unmoored and got under sail. I reached her outside the cove, and stood to seaward; but the day was too fine, there being little or no wind till dark, when a light breeze carried us out of the bay. I steered for the Diego Ramirez Islands, anxious to profit by the fine weather, and examine them more closely.

"27th. The water being smooth, we had a good opportunity of taking angles for placing the coast between West Cape and Cape Spencer, which completed what was wanting in that part; afterwards, we again steered towards the Diego Ramirez.

"28th. A fine morning with a fresh breeze, just such as we desired. Having kept our wind under easy sail during the night, we bore up, and, at daylight, ran along the east side of the rocky cluster, the wind being from the N.E. We hove-to frequently to take angles and soundings, and sailed quite round the islands at the average distance of half a mile, and then stood away to the northward. They are quite similar to the Ildefonsos; the top of a ridge of hills showing above the water, and broken through by the sea. The two largest are about two hundred feet high, and are covered with tussac: there is a shingle beach on one (the second in size), where a boat may be hauled up in safety; and there is enough good water on the east side of the same island to supply thirty men. A furious surf breaks against the west shore, and sends a spray over the whole island. There is no sheltered anchorage for a vessel: for though she might bring up in deep water, on the eastern side of the group, for a short time, she would even then risk

© The Complete Work of Charles Darwin Online

losing her anchor. The least water I found was fifty fathoms, though Weddell's chart shows that there is less than forty off the S.E. end. The heavy swell prevented my landing; but the appearance of the rocks induced me to suppose that they were greenstone. If not of that nature, and similar to the rock about Cape Horn, they may be of very hard sandstone.

"29th. In this climate, during the few intervals of settled fine weather, the sky is frequently overcast soon after sunset, and a slight shower falls. I noticed this frequently here, as well as during the preceding April, May, and June, in the Strait.

"We stood into the bay which lies between False Cape and New Year Sound; but it offered nothing inviting to a ship, being a leeward bight, with rocks and islets scattered along it near the shore. Perhaps there is shelter for a vessel amongst them; but I would not choose their neighbourhood, if it could be avoided, as the bay is exposed to the S.W. winds, which on this coast are the worst. The breeze freshening, and drawing to the northward, enabled us to reach Cape Spencer in the evening, when, as the weather promised ill, I was glad to anchor in eighteen fathoms, over a sandy bottom, off the entrance of San Joachim Cove.

"Expecting wind, we sent top-gallant masts on deck, braced up, and veered to eighty fathoms. After eight the weather cleared, and appeared likely to remain fine, but the glasses continued to fall. At ten a sudden heavy squall came over the land, and the tops of the hills became thickly covered with clouds. Successive furious gusts followed: we let go a second anchor, and veered a whole cable on each. The squalls came most violently from the S.W., and in half an hour the bank of clouds disappeared; but a strong gale from S.W. continued till daylight, when it moderated. Cape Spencer protected us very well, both from wind and sea: should a ship wish to enter San Martin Cove, and the wind or daylight fail her, she will find this spot a convenient stopping-place.

"30th. The Beagle unmoored, got under sail, and stood towards Cape Horn: at noon she was close to the famous Cape, with beautifully fine weather, more like the climate of

© The Complete Work of Charles Darwin Online

Madeira than that of fifty-six south latitude. During this day I had excellent opportunities of taking angles, bearings, and soundings, which I hoped would be sufficient for the south and east sides of the Hermite Islands. The following night we worked to the northward, near the Barnevelt Islands, the weather being fine, and the moon shining brightly.

"May 1st. A beautiful day—May-day indeed. I landed on the Barnevelt Islands, and took sights for time, latitude, and true bearing, besides a round of angles, while the Beagle was making slow progress to the northward, the wind being very light, and variable. There is no good landing-place on those islands; but as the water was then comparatively smooth, we were enabled to land upon a steep rocky part, where the surf did not break much. They are two low islets, lying nearly north and south, covered with grass, tussac, and weeds. The largest is about half a mile long, and one-third of a mile wide; the other is about two cables' length square. Several rocks lie off the south end, towards both the east and west; and one above water lies detached, towards the Hermite Islands, nearly in mid-channel: but no other appearance of danger was visible. The angles gained here, crossing those from Orange Bay, bounded the Hermite Islands towards the north—though the detail of their coast-line, northwards, yet remained to be ascertained.

"2d. As fine a day as the preceding. We were close to Evouts, an islet similar to the Barnevelts, but rather higher. The weather enabled Mr. Wilson to continue his sketches of the coast: but indeed no part along which we sailed had been quite omitted. In the afternoon we closed the shore near New Island, and were looking out sharply for banks and shoals, fancying, because the land looked lower, and the Nassau flat had shoal soundings, that we should find banks detached from the land. Shoaler water we certainly found, compared with that to which we had been lately accustomed, namely, from fifteen to twenty fathoms, gradually decreasing as we neared the shore, but we never had less than ten till we were standing into a harbour in the evening. I could here trace no

© The Complete Work of Charles Darwin Online

resemblance whatever to any published chart; but seeing a place at the back of some low islets which appeared likely to afford sheltered anchorage, we steered for it, and at sunset anchored in a well-sheltered harbour on the east side of a large island, to the west of New Island. The water shoaled gradually, over a fine sandy bottom; but we ran in rather too far, and had only three fathoms after veering cable, so we were obliged to shift our berth.

"3d. Mr. Murray prepared to go along the coast towards Cape Good Success, carrying one of the chronometers, and other necessary instruments, and taking three weeks' provisions. He set out, in a whale-boat, with six men, well armed and equipped in every way. Having despatched the master, I prepared for an excursion into the interior passages of this part of Tierra del Fuego: while Mr. Stokes, in another boat, was to contiue the survey of the coast from the east side of the head of Nassau Bay to the vicinity of New Island; and Lieut. Kempe would take care of the ship, and forward her refitting, besides wooding and watering.

CHAPTER XXIII.

Set out in boats—Find Guanacoes—Murray Narrow—Birch Fungus—Tide—Channel—Glaciers—View—Mountains—Unbroken chain—Passages—Steam-vessels—Jemmy Button—Puma—Nest—Accident—Natives—Murray's Journal—Cape Graham—Cape Kinnaird—Spaniard Harbour—Valentyn Bay—Cape Good Success—Natives—Lennox Island—Strait Le Maire—Good Success Bay—Accident—Tide Race—San Vicente—San Diego—Tides—Soundings—North-east Coast—San Sebastian—Reflections—Port Desire—Monte Video—Santa Catalina—Rio de Janeiro.

"4th. Mr. Stokes and I each began another trip in the boats, taking chronometers, and the necessary instruments. He steered to the northward, to get to the mainland; I kept outside to the south-westward, to make the most direct course towards the communication between Nassau Bay and the newly discovered passage or channel. I was surprised to find that the eastern shore of Nassau Bay resembled much of the coast of Patagonia (being a stratum of earth without rock), and differed entirely from the general character of the coasts and islands of Tierra del Fuego. At sunset we landed, and hauled up our boat on a shingle beach which extended several miles, and upon walking only a few yards inland I saw the prints of large cloven hoofs, almost the size of those of a cow. This discovery gave an answer to the question about the guanaco skins and bones found among the Fuegians, but made me less sanguine of finding a passage northward through the interior of the country. Much brushwood was found near this place; and a profusion of rich grass covered an extensive plain.

"5th. We launched the boat, and continued our course along-shore, finding rather shoal water (three to six fathoms within about half a mile), with a very thick bed of kelp, through which it was difficult to force the boat. We had not advanced far, when, passing round a low point of land, we saw

© The Complete Work of Charles Darwin Online

four fine guanacoes feeding close to the water. They did not seem to be much alarmed; but walked away from us round a projecting part of the shore, which prevented our getting a shot at them. They appeared to be much larger than those I had seen near Port Desire, on the Patagonian coast, their bodies being far heavier, and their tails longer and more bushy. These differences might be the natural result of a different climate, as cool weather, with plenty of food and water, would probably increase their size. I would not delay, on their account, hoping to fall in with others, but pushed on along the shore. These animals were near what is called in the chart 'Windhond Bay.' In the afternoon, we were again among rocky mountains and deep-water shores, and being so fortunate as to get a fresh breeze from the S.E., made much progress before night. We saw several canoes, full of natives; but did not turn aside to speak to them, as time was too precious.

"6th. A very cold and blowing morning, the wind being against us, yet we made better progress than I had hoped for, as our boat proved to be so excellent; and whether sailing or pulling, was all we could wish for. This night we bivouacked close to the Murray Narrow, but took care not to land till after dark, and then carefully concealed the fire, so that our rest might not be disturbed by visits from the Fuegians. A sharp look-out was, of course, kept by the watch; and by my two dogs, who were very useful in that way.

"7th. Soon after we set out, many canoes were seen in chase of us; but though they paddled fast in smooth water, our boat moved too quickly for them to succeed in their endeavours to barter with us, or to gratify their curiosity. The Murray Narrow is the only passage into the long channel which runs so nearly east and west. A strong tide sets through it, the flood coming from the channel. On each side is rather low land, rising quickly into hills, behind which are mountains: those on the west side being high, and covered with snow. When we stopped to cook and eat our dinner, canoes came from all sides, bringing plenty of fish for barter. None of the natives had any arms; they seemed to be smaller in size, and less disposed

© The Complete Work of Charles Darwin Online

to be mischievous, than the western race: their language sounded similar to that of the natives whom we saw in Orange Bay. We found a very large wigwam, built in a substantial manner, and a much better place to live in than many of the huts which are called houses in Chilóe. I think twenty men might have stood upright in it, in a circle; but, probably, of these Fuegians, it would house thirty or forty in the cold weather.

"While our men were making a fire and cooking, I walked into the wood, but found it bore little resemblance to that which our eyes had lately been accustomed to. The trees were mostly birch, but grew tall and straight. The ground was dry and covered with withered leaves, which crackled as I walked; whereas, in other parts where we had lately passed our time, the splashing sound of wet, marshy soil had always attended our footsteps, when not on rock. These Fuegians appeared to think the excrescences which grow on the birch trees, like the gall-nuts on an oak, an estimable dainty. They offered us several, some as large as an apple, and seemed surprised at our refusal. Most of them had a small piece of guanaco, or seal-skin, on their shoulders or bodies, but not enough for warmth: perhaps they did not willingly approach strangers with their usual skin dress about them, their first impulse, on seeing us, being to hide it. Several, whom I surprised at their wigwams, had large skins round their bodies, which they concealed directly they saw me. Fish and the birch fungus must be their chief food, for shell-fish are scarce and small; but they catch an abundance of excellent rock-fish, smelt, and what might be called a yellow mullet. Guanaco meat may occasionally be obtained by them, but not in sufficient quantity to be depended upon as an article of daily subsistence.

"Leaving the natives, we sailed across towards the western arm of the long channel, and continued making our way westward, with oar and sail, until dusk, when we landed, unperceived, as we thought, and established ourselves for the night. Just as we had moored the boat, kindled a fire, and pitched our tent, a canoe came into the cove; another and another followed, until we were surrounded with natives. Knowing

© The Complete Work of Charles Darwin Online

we must either drive them away by force, or be plagued with them all night, we at once packed up our things, and wished them good evening. About three miles further westward, we again landed, and fixed our tent in a cove, which gave us good shelter through the night, without any interruption. It was high water this afternoon at four o'clock (being the day of full moon), and the tide rose three feet. The channel here, and opposite the Narrow, is about three miles wide; on its north side is an unbroken line of high mountains, covered with snow to within about a thousand feet of the water. Southward are likewise snow-covered heights, so that the channel is formed by the valley lying between two parallel ridges of high mountains.

"8th. This morning it froze very sharply. We started at sun-rise, with a fine breeze from the eastward, and made a long run before it. The channel preserved the same character, and nearly the same width; on the north, the mountains continued without any opening; but a few miles farther, we saw what appeared to be one. I soon found that there was one passage leading westward, and another rather to the southward of west, which appeared to open into the sea. The easterly breeze failing, and squalls from the N.W. succeeding, we did not make much progress in the afternoon; yet before dark had reached the place where the two channels commence, and stopped for the night on a small island. Soon after dark, one of the boat's crew was startled by two large eyes staring at him, out of a thick bush, and he ran to his companions, saying he had seen the devil! A hearty laugh at his expense was followed by a shot at the bush, which brought to the ground a magnificent horned owl.

"Next day, we continued our westerly route. No natives were seen, though a few wigwams, of the round-topped kind, were passed. The westernmost sharp-pointed, or Yapoo wigwam, was on the main-land, close to the island of the Devil; it was made of small trees, piled up in a circle (the branches and roots having been broken off) with the smaller ends meeting at the top. The boat's crew said it had been a 'Meeting-House,' and perhaps they were not far wrong; for being so

© The Complete Work of Charles Darwin Online

large, and just on what might be called neutral ground between the two tribes, it is not unlikely that there may have been many a meeting there—perhaps many a battle. At the separation, or meeting of the two channels, it was high water at a quarter before five this morning, and the flood came from the west, about a knot an hour; the ebb-tide set to the west at about half that strength. Much drift-wood and large fragments of ice were carried along with it. Between some of the mountains the ice extended so widely as to form immense glaciers, which were faced, towards the water, by lofty cliffs. During a beautifully fine and still night, the view from our fireside, in this narrow channel, was most striking, though confined. Thickly-wooded and very steep mountains shut us in on three sides, and opposite, distant only a few miles, rose an immense barrier of snow-covered mountains, on which the moon was shining brightly. The water between was so glassy, that their outline might be distinctly traced in it: but a death-like stillness was sometimes broken by masses of ice falling from the opposite glaciers, which crashed, and reverberated around—like eruptions of a distant volcano.

"10. Before daylight this morning, we were on our oars; and by the time the sun was high enough for observing, were many miles westward of our resting-place. After sights, while the men were cooking, I obtained a few bearings, and prepared to return, not intending to go further westward. I saw water from that spot, more than twenty miles to the west (by compass); and then my view was limited by the channel turning towards the south. In those twenty miles, not the slightest appearance of an opening to the northward could be seen; mountain succeeded mountain, in unbroken succession. Three ridges, or ranges, could be traced, lying parallel to each other; and the nearest summits of those in the third, or furthest range, stretching from the northward and eastward of me, and continuing, as far as eye could reach, towards the north and west, were at least five leagues distant. Their height I supposed to be about four thousand feet: that of those nearest to me, about two thousand: and of those in the middle range, mentioned

© The Complete Work of Charles Darwin Online

just now, about three thousand. At a distance, the channel appeared to trend to the southward of west, and there the sides of the mountains seemed to be very bare, and weather-beaten, while near me they were covered with wood. This led me to conclude that farther westward they were open to the sea winds, and that there the channel ended. By the observations, I found that we were* nearly in the longitude of Christmas Sound, and in latitude 54° 54′ S., being therefore twenty miles south of the end of Admiralty Sound, but considerably to the westward of it. This position, and the bearings and estimated distances, showed me that the other arm of this long channel opened near the spot where Mr. Murray laid down (near the head of Christmas Sound) a 'channel, running to the eastward, beyond eyesight;' and that the branch in which I was must lead towards the bay or sound to the N.W. of Christmas Sound, at the base of very high land, which Mr. Murray laid down as 'an unbroken range of snow-covered mountains.' The time of high water in this channel exactly corresponded with that on the adjacent sea-coast, but did not nearly agree wit that of the Strait of Magalhaens. These facts, and the appearance of the land, removed every doubt in my mind of the existence of an unbroken chain of mountains, reaching from the Barbara Channel to the Bell Mountain, and I therefore decided to spend no further time in searching thereabouts for a passage northward, but make all haste to examine the exterior shores.

"The channel here was about a mile wide, but the mountains on each side rising so abruptly, made it appear much narrower. It might be a good passage for a ship to sail through, from the westward, were it not for the trouble and anxiety of getting in with the land at the right place; and that a ship might sail on her course, in the open sea, by night as well as by day; but here she could hardly choose to run at night, because there are a few low islets, near mid-channel, in some parts. For a boat, in case of shipwreck, or other urgent reason, it might be convenient: but going through to the westward would be very difficult, because it would be

* In longitude 69.20. W.

© The Complete Work of Charles Darwin Online

necessary to ply to windward all day, and every day, making half-mile boards in defiance of squalls strong enough to capsize a vessel. A steam-vessel might answer in this region, as there is plenty of wood every where. Directly the noon observations were finished, and the instruments safely stowed, we began our return, and as a fresh breeze sprung up from the westward, we dashed along with a favouring tide at a great rate.

"11th. Next day we landed, for dinner and rest, near the Murray Narrow, and close to a wigwam, whose inmates ran away; but soon returned, on seeing us seated quietly by their fire. We bought fish from them for beads, buttons, &c., and gave a knife for a very fine dog, which they were extremely reluctant to part with; but the knife was too great a temptation to be resisted, though dogs seemed very scarce and proportionably valuable. Afterwards we continued our route, but were stopped when in sight of the Narrow by three canoes full of natives, anxious for barter. We gave them a few beads and buttons, for some fish; and, without any previous intention, I told one of the boys in a canoe to come into our boat, and gave the man who was with him a large shining mother-of-pearl button. The boy got into my boat directly, and sat down. Seeing him and his friends seem quite contented, I pulled onwards, and, a light breeze springing up, made sail. Thinking that this accidental occurrence might prove useful to the natives, as well as to ourselves, I determined to take advantage of it. The canoe, from which the boy came, paddled towards the shore; but the others still paddled after us, holding up fish and skins to tempt us to trade with them. The breeze freshening in our favour, and a strong tide, soon carried us through the Narrow, and half an hour after dark we stopped in a cove, where we had passed the second night of this excursion. 'Jemmy Button,' as the boat's crew called him, on account of his price, seemed to be pleased at his change, and fancied he was going to kill guanaco, or wănăkāye, as he called them—as they were to be found near that place.

"12th. We continued our course with a fresh and favouring

© The Complete Work of Charles Darwin Online

breeze from the N.E.; passed Windhond Bay, and at sunset hauled the boat up, though a surf on the stony beach made it a difficult task. Several guanacoes were seen near the shore as we passed along.

"At daylight this morning (13th), we went in search of guanacoes; but, seeing none, soon returned to the boat, and launched her. I lost my new dog in the bushes, yet we could not stop to recover him. During our walk this morning, I observed traces of a large land-animal, which I supposed to be a puma; and two of the men noticed a place, like a large nest, made in the trees by the natives, in which I have no doubt they watch for the guanacoes, to spear them as they pass underneath. We reached the Beagle in the evening, and found all well on board excepting one man, who, in carrying a guanaco,* shot by the cutter's crew, had slipped and broken his leg. Mr. Stokes, with whom he was, contrived to set it for him; but very properly made the best of his way to our ship with the man, whose leg was there found to be so well set, and bandaged up with splints, by those in the boat, that the surgeon had nothing to alter. Mr. Stokes went away again directly; and both he and Mr. Murray were absent at my return; but Lieut. Kempe, with the few men left on board, had done what was required, and gave a good account of the harbour, with respect to safety as well as shelter from wind. Ten canoes had come, at different times, to the ship; but the natives were extremely quiet and inoffensive, and sold our people a large quantity of fish. By success in shooting, Lieut. Kempe had been enabled to stop the issue of salt provisions for two days. Our Fuegians were in high spirits, and the meeting between them and Jemmy Button was droll enough: they laughed at him, called him Yapoo, and told us to put more clothes on him directly.

"17th. Mr. Murray returned from his excursion to Cape Good Success, having done all that was expected, but not without incurring considerable danger on so exposed a coast. Had not his boat been a very fine one, his crew good, and

* The stuffed skin is now in the British Museum.

© The Complete Work of Charles Darwin Online

he himself a most skilful manager, I do not think he could have gone so far along an unprotected shore, through 'races' of tide, and yet have returned in safety."

The following are extracts from his Journal.

"'Near Cape Graham we saw a large party of Indians, with several canoes, one of which, paddled by two men and a woman, came alongside of our boat, and they sold us some fine fish, for the large price of two metal buttons and a small string of beads. Finding no place at which I could land, on account of the rocks and heavy swell, we steered for the shore about fifteen miles to the northward. Approaching a flat-topped bluff, covered with grass, I saw a large guanaco, and just afterwards a whole herd feeding, for which he seemed to be doing the duty of a sentinel. The shore was inviting, and earthy soil seemed abundant; but too many rocks showed their sharp points at the water's edge to allow of our landing. At last we found a small patch of shingle between two reefs of rocks, and there we succeeded in beaching the boat, through a heavy surf. I ascended a steep woody height to obtain a view of the neighbourhood, and found that for some miles the country was level, and apparently covered by thick grass. Traces of, and paths made by, guanacoes, were very numerous in every direction. Next day we pulled to the eastward against a tumbling sea, caused by a weather tide, and at sunset tried to land; but were disappointed, by finding that the shore was so fronted every where by rocks, that we could not approach. We therefore hastened towards a long reef of outlying rocks, which might afford some shelter, as a breakwater, during the night, but found such overfalls near them, that we were again obliged to continue our route alongshore in the dark. At last I heard the noise of a large waterfall, between the breakings of high surf on the rocks, and fancied a cove could be made out, towards which we cautiously advanced, sounding with the lead and a long pole, and succeeded in obtaining a place of temporary security.

"'In passing along the shore on the following day, many herds of guanacoes were seen feeding. At night we again had

© The Complete Work of Charles Darwin Online

much embarrassment in obtaining a place for the boat. On the 7th there was too much sea and wind to admit of our proceeding, so I went to various points suited for obtaining angles and bearings. One of these stations was a large rock, looking like a tower, which stood alone on a level plain.

"'The weather being less unfavourable and the sea smoother on the 8th, we launched our boat and sailed to the eastward. In passing round Cape Kinnaird, great numbers of fur-seal were observed, so many indeed that they completely covered several of the large rocks.

"'Spaniard Harbour proved to be a shallow bay, full of rocks, and dangerous reefs lining the shore, and without shelter, although there is anchorage for a vessel.

"'In a large cave in a rock, which forms the south head of a little cove where our boat was secured, I found the recent traces of Indians, who had left bones of guanacoes and birds lying about near the ashes of a large fire. I went into the cave for a considerable distance, until it became too dark to find my way farther, but did not reach the end. Afterwards we sailed to the eastward again, under a treble reefed sail, and landed before dark in a corner between projecting rocks. Numbers of guanacoes were feeding around; but, after our shooting one of them, they made off. In every place at which we landed, traces of Indians had been found; yet hitherto we had seen only one party during this trip. The country near us, on the east side of Spaniard Harbour, or rather Bay, seemed level, though here and there were low hills, whose eastern sides were thickly covered with wood: some of the trees (beech) growing large and straight enough to make topmasts or lower yards for a small ship; though probably their qualities would be unsuitable.

"'May 10th. During a heavy gale, I ascended the highest hill, near the sea, and noticed many rocks, on which the sea was breaking, that I had not seen before. On the 11th we passed through a very dangerous 'tide-race' off Bell Cape. There was little or no wind, but it was scarcely possible to use our oars, so much was the water agitated: it was heaving

© The Complete Work of Charles Darwin Online

and breaking in all directions, like water boiling in an immense caldron. When through, and again in safety, I was astonished at our fortunate escape. Looking back upon it, only a mass of breakers could be seen, which passed rapidly to the westward, and therefore led me to suppose that the 'race' was caused by a meeting of tides; not by a strong tide passing over a rocky ledge.

"'The land near Bell Cape is steep, high, and so rocky, that we could not find any place at which to land. We went into all the small coves, but they were so guarded by rocks as to be impracticable. Sailing eastward, I at last found a small cove, near Valentyn Bay, in which we hauled the boat ashore. A small stream ran into it, near which were many wigwams, but no natives could be seen.

"'12th. We crossed Valentyn Bay, and landed near Cape Good Success. I walked to the summit, and thence obtained a good view of Staten Island, on the east; and all the coast westward, as far as New Island. In the north-east corner of Valentyn Bay, we found some Indians, living in one large wigwam, without any canoes. There were eight men, each of whom had a bow and a few arrows in his hand, and all, except one, were clothed in guanaco-skins hanging down to their heels, the woolly side being outwards. We obtained several bows from them, by barter, but they were reluctant to part with many arrows. One of the number wore a large seal-skin, that I purchased with a knife, which, to my surprise, he distinctly called 'cuchillo.' They had some fine dogs, one being much like a young lion; but nothing we could offer seemed, in their eyes, to be considered an equivalent for his value. Afterwards we examined Valentyn Bay, and found it unfit for vessels, being exposed to a heavy swell, and affording but bad anchorage.

"'On the 13th and 14th, a heavy gale confined us to our cove, into which such numbers of wild-fowl came, for shelter I suppose, that we shot as many as we wanted.

"'On the 15th, 16th, and 17th, we were returning to the Beagle, not without meeting difficulties and risks similar to

© The Complete Work of Charles Darwin Online

those already mentioned, but which it would be as tedious as unnecessary to relate.'"

"Soon after the Master came alongside, Mr. Stokes also returned, having been a long way into the channel first discovered by Mr. Murray, and having examined all the shores about its eastern communication with the sea. He met many groups of Indians, but managed so as not to have any collision or trouble with them.

"18th. Digging in various places on Lennox Island, showed me that the soil is unlike that where the guanacoes were seen on Navarin island, which is fit for cultivation; this being very moist, and too full of tussac and other roots, to be serviceable in any agricultural point of view.

"19th. Natives had come alongside at various times, during the last few days, to sell fish for old buttons and other trifles. It was amusing to witness York and Boat taking in these people, by their bargains. The same men who, two months back, would themselves have sold a number of fish for a bit of glass, were seen going about the decks collecting broken crockery-ware, or any trash, to exchange for the fish brought alongside by these 'Yapoos,' as they called them; not one word of whose language did they appear to comprehend. Lieut. Kempe returned from an unsuccessful excursion to Navarin island in search of guanacoes. He saw many, but could not get within shot. The footmarks of a puma were noticed by him in several places.

"23d. After obtaining a few sights of the sun, for the chronometer rates, we sailed from Lennox harbour, a very secure place for small vessels; but, as it is rather shallow, ships drawing more than fourteen feet of water should anchor outside the entrance, where they would be safe, and in smooth water, excepting when a south-east gale blows, with which wind they would not, in all probability, wish to remain at anchor. The soundings are regular in the offing, and there is anchoring ground every where in the vicinity. Wood and water may be obtained, in any quantity: wild fowl and fish are also to be had, but not in abundance. The easiest way

© The Complete Work of Charles Darwin Online

of getting fish is to give bits of broken glass or buttons to the natives, who catch them in the kelp, by a baited line, without a hook, enticing the fish to the top of the water and then seizing them with the hand, or, if the fish has swallowed the bait, jerking it out of the water before it can disengage itself; as I mentioned before.

"At daylight (24th), being off Cape Good Success, we bore up, and ran towards the Strait of Le Maire, with a fresh gale at south, and thick snow squalls. The strait appeared clear of all obstacles, no rocks, nor even kelp being visible. The shore from Cape Success to the north head of Success Bay is high and bold, with water for a ship as near to it as she could desire, or ought to go. We hauled our wind during a severe snow squall, lest we should run beyond the harbour, and afterwards bearing up, ran into Good Success Bay, and anchored under the lee of its south head as a temporary berth. As soon as the ship was secure, I went to look for the best anchorage; and when it moderated, we weighed and shifted to a position where I supposed the ship secure when moored in smooth water, with sixty fathoms on our seaward anchor, and fifty on the other, the anchors lying respectively in eight and seven fathoms, over a clear, sandy bottom. The gale continued during the day, and towards night increased, drawing more to the eastward, and sending a swell into the bay. The wind was very cold, and the snow and hail froze fast, as they lodged upon any exposed part of the ship. Between eight and nine it blew heavily; afterwards it became much more moderate; and at midnight there was only a fresh wind from E.S.E. A long swell then began to set into the bay from the same quarter; but the ship rode so easily, and the night seemed to be improving so fast, with the glass rising steadily, that I went to bed without an anxious thought respecting her safety: however, I was hardly asleep when I was told that the small bower, our seaward cable, had parted. I ran instantly upon deck, when finding the night fine, and no increase of swell, I thought at first it was a mistake; but was quickly set right by the ship turning her broadside to the swell, and dropping

© The Complete Work of Charles Darwin Online

down upon her lee anchor. The critical nature of our situation at once struck me: it was evident, that the frost had rendered our chains, so often tried, a doubtful security against the jerk of rollers which occasionally set into the bay—one or two, perhaps, in half an hour—though the swell was at other times trifling. We veered a whole cable on the in-shore anchor (a small one, got at San Carlos), cleared away and let go the sheet-anchor, shackled the remainder of the small bower chain to the best bower, and rode with two-thirds of a cable on the sheet, and a cable and a half on the bower, close to the beach, though in six fathoms water, keeping the cables constantly streaming wet at the hawse-holes, with sea-water, to prevent their freezing: the temperature of the water being 44°, though the snow and hail lay frozen on the weather-side of the masts. The link that broke, of the chain, was in the hawse exposed to a current of cold air through the hawse-hole. It certainly appeared defective, when examined next day; but as it had withstood many a heavy strain, I attribute its parting to the action of the frost, and would caution seamen to be on their guard when using chain cables in similar weather. The wind moderated, and the swell decreased towards morning; so we became again at ease with respect to the safety of the ship, after a few hours of anxious suspense, for we had no hemp cables, and were close to the surf of the shore.

"25th. The wind drawing southward brought the vessel's broadside to the swell, and prevented our getting the boats out for some time, as she rolled heavily, and I would not risk their being injured without absolute necessity. In the evening we crept for the end of the chain, weighed, and bent a stout hawser to it; and next day hove up the sheet anchor, and moored afresh, at a greater distance from the land.

"27th and 28th. Blowing a furious gale of wind.

"May 29th. The first tolerable day in this place was employed by the officers in taking bearings and soundings in the bay; and by the ship's company in wooding and watering. Some wigwams and the traces of guanacoes' hoofs were seen, but the land is high, and being thickly wooded shut us out

© The Complete Work of Charles Darwin Online

from the best guanaco country. I was not sure which was the height Mr. Banks ascended; but the broad road mentioned by Cook is still a good mark for the bay, if the inbend of the land does not show it sufficiently. The weather here was colder than we had yet found it, the wind being so much in the south quarter; there were very sharp frosts at night, and snow lay deep, even close to the sea water-mark.

"May 30th. I was in hopes of finding a harbour between Cape San Diego and Cape San Vicente, or a little farther along the coast, where we might be able to fix the position of Cape San Diego and the adjacent land; for I did not like sending a boat along this coast, the tides being so very strong, and the shore so rocky, without any inlets, where she could be secured at night. (During Mr. Murray's last trip, he was extremely fortunate in having a fine interval; as the coast he passed would have been impracticable for a boat in blowing weather. Had these last strong southerly gales begun before he came back, his situation would have been extremely critical.) We therefore stood into the strait, the wind being variable and light with us, though blowing strongly over the tops of the hills, and striking the water nearest them in strong squalls. At half a mile from the land there was little wind; but from that distance to the shore was torn up by williwaws. This strange appearance must have been caused by the cold air rushing from the snow-covered hills and displacing the warmer air near the surface of the water.

"With the ebb tide and what flaws of wind we could catch we stood to the southward, to get some angles and bearings, and see more of the shore between Cape Good Success and the bay. In the afternoon we had a steady wind from N.N.W.; and having done what was necessary, to the southward, returned, and anchored after dark near the middle of the bay.

"May 31st. At daylight this morning, we weighed and made sail with a fresh northerly breeze. I trusted to the weather improving, as the glasses were rising; but, indeed, our time was becoming too short to allow of a choice of days. We worked to the northward with the flood-tide, taking the required

© The Complete Work of Charles Darwin Online

angles and bearings, and at noon were close to Cape San Diego, where the flood-tide opposed the north wind very strongly, and in addition to a heavy swell from the northward, made such an irregular high sea, as nearly caused the loss of our new boat, and would have damaged many a vessel. The weather became worse; and as the swell continued high from the northward, I was obliged to stand to sea, and carry a press of sail to keep off the land, which by that time was too much obscured by haze and clouds to admit of our running back.

"June 1st. Bad weather, with rain nearly all day. At about twelve miles to the northward of Cape San Vicente, by estimation, we stood off and on until in the latter part of the day we got a breeze from south, to which sail was made to close the land about Cape San Vicente.

"At noon, on the 2d, we were well in-shore, and stood along the land, looking for a harbour. Seeing a promising place, we anchored off it, in twenty-two fathoms water; and, as the night proved to be fine, remained quiet in smooth water, with the wind off the land, and a regular tide setting past the ship.

"At daylight next morning, I went to look at the opening, which, from the masthead, seemed like a spacious harbour; but I found it to be so shallow an inlet, that at its entrance, just within the heads, there was no more than one fathom of water. Nevertheless this cove must be the place which the Spaniards dignified with the name of Port San Policarpo.

"We weighed and sailed along-shore, but the wind being scant, and the tide against us, it was late before we could get into San Vicente Bay, where we anchored in a line between that cape and Cape San Diego, but nearest to the former. In a cove at the head of this bay, Mr. Banks landed when Cook was here. During the night we were tossed about by a very heavy swell, opposing a strong tide; the wind being moderate, not enough to steady the vessel.

"Finding this morning (June 4th), that the swell was too high to allow a boat to be lowered in safety, I gave up my intention of examining the cove, and hastened back to the Bay

© The Complete Work of Charles Darwin Online

of Good Success, to complete wood and water, and obtain rates for the chronometers, previously to leaving the coast. Wind and tide favoured us, and at noon we were moored in Good Success Bay. Soon afterwards I left the Beagle, in my boat, with a week's provisions, intending to try to land near Cape San Diego, and thence walk to the cape with the instruments; but I found a cross swell in the strait, and a rocky shore without a place in which the boat could land: though I risked knocking her to pieces by trying to land in the only corner where there seemed to be any chance. After this escape I tried farther on, without success; by which time it became dark, and if I had not returned immediately, while the ebb-tide made, the flood would have begun and obliged me to lie at a grapnel, during a frosty night, in a strong tide-way, with the boat's crew wet through: I turned back, therefore, and pulled towards Success Bay, assisted by the tide, but the cockling sea it made half filled the boat more than once, and we were thankful when again safely on board the Beagle.

"Having failed in this scheme for settling the latitude of Cape San Diego, I thought of effecting it by bringing the Beagle to an anchor in the strait, two or three miles to the eastward of Good Success Bay, and thence connecting the Cape to known points by triangulation; the heads of this bay and Cape Good Success, quite correctly placed, serving as the foundation.

"June 5th. I obtained some sights of the sun this morning and observations at noon, besides bearings and angles to verify former ones. All hands were busy wooding and watering, preparatory to returning to Monte Video. A large albatross was shot by my coxswain, which measured nearly fourteen feet across the wings.

"6th. The snow which covered the ground when we were first here was quite gone, and the weather was comparatively mild. The frost at night was not more than in a common winter's night in England, the thermometer ranging from 27° to 32°. The tide was carefully noticed this day, being full

© The Complete Work of Charles Darwin Online

moon. It was high water at a quarter past four, and the tide rose seven feet.

"7th. We unmoored, weighed, stood to the eastward and anchored with the stream anchor, and a large hawser, in fifty fathoms water, about three miles from Success Bay. After taking the required angles and bearings we weighed at eleven, and stood towards Cape San Diego with the first of the flood. The tide being strong, we made rapid progress, and were soon out of the strait; but wishing to see as much of the N.E. coast as possible, in our progress northward, we hauled to the wind and kept near the land during the night, as the weather was fine and settled.

"Before leaving Good Success Bay and the Strait of Le Maire, I felt satisfied that we had acquainted ourselves with the tides, which are as regular and as little to be dreaded as in any part of the world where they run with strength. They will materially assist any vessel in her passage through the strait; which is very wide, perfectly free from obstacles of any kind, and has Good Success Bay close at hand, in case wind or tide should fail. When the tide opposes the wind and swell, there is always a heavy, and, for small vessels, dangerous 'race' off Cape San Diego, where the water is more shoal than elsewhere (*k*), we found it so at a neap flood-tide, but let it be remembered that on another day, at the top of the springs, being the day after full moon, we passed the same spot, at half flood, with the water perfectly smooth, and although strong eddies were seen in every direction, the vessel's steerage was but little affected by them. It is high water in Success Bay soon after four in the afternoon, on the full and change days, and low water exactly at ten in the morning. The flood tide-stream begins to make to the northward about an hour after low water, and the ebb, to the southward, about the same time after high water. The tides rise from six to eight feet, perpendicularly. At Cape Pillar the turn of tide, with high water, is at noon: but along the S.W. and S.E. coast the time

(*k*) Five fathoms only were found in one spot during the Beagle's last voyage.—R. F.

© The Complete Work of Charles Darwin Online

gradually increases to this coast. From Cape San Diego the flood tide sets north and west along the shore, from one knot to three knots each hour, as far as twenty miles along shore; and the ebb in a contrary direction, but not so strongly, except in San Vicente Bay. The flood in the Strait of Le Maire runs about two knots in mid channel, more or less according to the wind, and the ebb about one knot an hour. Perhaps, at times, when a strong spring tide is retarded in its progress by a northerly wind, there will be a dangerous overfall off Cape San Diego, like the bores in some parts of the world.

"The soundings are tolerably regular, and may give notice of an approach to Staten Land, or to the N. E. coast, and may guide a ship to the fairway of the strait; but I should not place much confidence in them, near such a rocky coast as that of Staten Land.

"Good Success Bay is an excellent anchorage for vessels of any size to stop in for wood or water; but it would not answer if a vessel required to lie steady for repair, as a swell frequently rolls in. It is quite safe, yet, in the winter season, when easterly gales are common, no vessel should anchor so near the head of the bay as she might in summer; for heavy rollers at times (though rarely) set in. Fish we did not try to get, not having spare time, and only a few birds were shot.

"On the 8th, a very fine day with but little wind, we were off the flat-topped hill, called the Table of Orozco; and, from the mast-head, I had an extensive view of the adjacent country. About Success Bay and Bell Mount the land is high, but north of Success Bay it slopes away towards Cape San Diego, which is a long, low, projecting point. Thence, as far as I could see, the N.E. coast extended, low, excepting a few hills here and there, and unbroken by inlets; the country near it being a pleasant looking hill and dale land, well wooded and quite free from snow. I could distinguish a snow-covered chain of mountains which must have lain near Admiralty Sound, the country on this side of them appearing to be a continued succession of hill and valley, with only a few of the hills capped with snow, although this was the depth of winter.

© The Complete Work of Charles Darwin Online

Smoke was seen at but one place, about two miles inland. In the evening we got a breeze off shore, and stood along the coast, the moon shining brightly and the weather being fine. I kept rather close to the land, during the night, in order to be near the entrance of the supposed St. Sebastian Channel in the morning.

"At midnight Cape Santa Inez was distant from us three or four miles, but thence we saw very little of the land, till three, near Cape Peñas, after which the weather became thick, and the wind drew round to the N.E., which made me keep more off shore until daylight (9th), when we bore up and stood for the land. Having found Cape Santa Inez and Cape Peñas correctly laid down on the chart we used, I thought Cape St. Sebastian would not be far wrong, and we had taken several observations during the early part of the night to correct our reckoning. Standing towards the shore, we quickly shoaled our water, and found a ground swell increasing. Having made what I supposed to be Cape Sebastian, and seeing from the mast-head a large opening to the northward of it similar to that laid down in the chart, with low distant land yet farther northward corresponding to the shores of 'Bahia de Nombre de Jesus,' I stood on confidently, thinking how well the chart of this coast had been laid down, and regardless of the soundings decreasing as we went on. Seeing, however, from the mast-head, what seemed to be a tide-ripple, two or three miles distant, I called the boatswain, who had been much among the tide-races on this coast, to ask his opinion of it: but before he could get up aloft to me, I saw that it was very low land, almost level with the sea, and what I thought the ripple, was the surf on the beach. Standing on a little farther we had but seven fathoms water over a bottom of dark muddy sand, with bits of black slate. At this time, the weather had cleared enough to see the land fifteen or twenty miles on each side, but nothing like an opening appearing, on the contrary, a plain extending to the westward, as horizontal as the sea, I hauled to the wind and stood alongshore to the S.E., to look for an inlet, fancying

© The Complete Work of Charles Darwin Online

I had overshot the proper place; especially as the land continued flat, and unbroken, for many miles to the N.W., while to the S.E. it seemed hilly and irregular.

"Having ranged along shore several miles, yet still seeing from the mast-head a continuation of the same kind of coast-line, as far as an eye could trace the surf on the beach, without any opening, we wore ship and stood to the northward, satisfied that the St. Sebastian channel did not exist within many miles of the position laid down in the chart.

"In the afternoon the weather became very thick, with rain, a fresh wind blowing right on shore, and the glasses falling; so we carried sail to get off the land and out of the shoal water, in which there was a heavy ground swell. At midnight we had obtained a good offing.

"On the 10th, a fresh breeze from the N.E., a low glass, and thick weather, with constant rain, would have prevented my nearing the land again if I had been disposed to do so. Though reluctant to leave any part of the coast of Tierra del Fuego unexplored, while I had so effective a vessel, and all with me in good health, I was bound to remember our distance from the appointed rendezvous; the state of our provisions, of which we had only three weeks left on board; and that I was ordered to be at Rio de Janeiro on the 20th of this month. I therefore decided to hasten to Port Desire, for the sake of the chronometer measurements; and from thence proceed to Monte Video and Rio de Janeiro. I had previously made up my mind to carry the Fuegians, whom we had with us, to England; trusting that the ultimate benefits arising from their acquaintance with our habits and language, would make up for the temporary separation from their own country. But this decision was not contemplated when I first took them on board; I then only thought of detaining them while we were on their coasts; yet afterwards finding that they were happy and in good health, I began to think of the various advantages which might result to them and their countrymen, as well as to us, by taking them to England, educating them there as far as might be practicable, and then

© The Complete Work of Charles Darwin Online

bringing them back to Tierra del Fuego. These ideas were confirmed by finding that the tribes of Fuegians, eastward of Christmas Sound, were hostile to York Minster's tribe, and that therefore we could not, in common humanity, land them in Nassau Bay or near the Strait of Le Maire. Neither could I put the boy ashore again, when once to the eastward of Nassau Bay, without risking his life; hence I had only the alternative of beating to the westward, to land them in their own districts, which circumstances rendered impracticable, or that of taking them to England. In adopting the latter course I incurred a deep responsibility, but was fully aware of what I was undertaking.

"The Fuegians were much slower in learning English than I expected from their quickness in mimickry, but they understood clearly when we left the coast that they would return to their country at a future time, with iron, tools, clothes, and knowledge which they might spread among their countrymen. They helped the crew whenever required; were extremely tractable and good-humoured, even taking pains to walk properly, and get over the crouching posture of their countrymen.

"When we were at anchor in Good Success Bay, they went ashore with me more than once, and occasionally took an oar in the boat, without appearing to harbour a thought of escape.

"During the night of the 13th, we were near the land about Sea Bear Bay; the wind, however, drew to the northward, and with a strong current setting to the S.E., drove us off again.

"The 14th was foggy; clouds preventing any observations, but at three in the afternoon we made the land, a little north of Port Desire, near what is called in the chart 'Rivers Peak.' The wind having hauled to the southward, and the current setting northward, prevented our approaching nearer to the port on that day.

"At daylight on the 15th, we were again off Rivers Peak, notwithstanding our having carried a press of sail in order to make southing during the night. We were set twenty miles to the northward during that time; but a slant of wind and

© The Complete Work of Charles Darwin Online

the turn of tide in our favour carried us towards the entrance of the harbour, into which we worked, the tide of ebb having just ended; and we moored abreast of the ruins. My first care was to look for traces of the Adventure or Adelaide, but I found none. A bottle which I had deposited for the Adelaide, at our last visit, by Captain King's direction, was exactly where I then left it, and the papers it contained were untouched. While in this port I got good observations, the weather being clear, though very cold. No guanacoes were shot although many were seen, but numbers of sea-birds were brought on board.* A quince was given to me which was found in a place where the Spanish colony had made a garden. We remarked that the tracks of the guanacoes on shore here were not so large, by one-half, as those we had so lately seen in Tierra del Fuego. Having noticed the currents particularly, in order to compare them with what I observed formerly and with the tide in the port; I can now say, decidedly, that the flood tide comes from the southward, and that the ebb sets to the south-east. North of Port Desire, or from Port Desire to Cape Blanco, the flood is much the strongest, but off Penguin Island the ebb is, I think, the strongest, setting two or three knots an hour. It is high-water and slack-water, in Port Desire, at half-past twelve, on the days of full and change. The tides, if not attended to, would baffle a ship much in making this port.

"On the 21st we sailed, with a fresh breeze from the S.W.; and at nine A.M. on the 25th when about one mile southward of the alleged position of the Ariel rocks, and near the nominal longitude, I hauled to the wind and ran some distance on their parallel, looking out for broken water. There was a very irregular and heavy swell, as much as would be raised by a gale of wind, but caused apparently by a current; and while waiting for the meridian altitude, before bearing up, having run twenty miles on the same parallel, a heavy swell rose on the quarter, which struck our weather quarter boat, and turned

* The powder and shot expended here procured four meals of fresh provisions for all hands.

© The Complete Work of Charles Darwin Online

her in upon the deck, breaking both iron davits. One of the davits of the lee-boat was also unshipped by the jerk, and the after-part of the vessel well drenched with water. We secured both boats again, but the one to windward was badly stove. For a moment, I thought we had indeed found the rocks, and the huge black back of a dead whale which just then shewed itself very near the vessel, much increased the sensation. I imagined that we were in a meeting of tides or currents; where old trees, dead whales, &c. are often found, and have frequently caused reports of rocks; for the water was not more shallow than we had found it during the day, the soundings having varied from forty to fifty fathoms; so having obtained the meridional altitude we bore up, and steered our course again.

"On the 26th we entered the Plata, and at one A.M. on the 27th, Lobos Island was seen, and soon afterwards the high land about Pan de Azucar. We continued working to the westward, and at daylight were off Whale Point, but the wind fell light, and the current being against us, we lost during the day what had been gained in the night. At seven P.M. the current set so strongly out of the river that we were obliged to drop a kedge with a stout hawser, and ride by it, though keeping all sail set and going between four and five knots through the water. When the hawser bore a strain, the log was hove, and the current found to be setting more than five knots. This was off Maldonado; Lobos bearing N.N.E., distant four miles. Soon after nine the stream slacked, we tripped the kedge and worked up the river, the wind being still westerly, but the current having turned in our favour. The U. S. frigate Hudson passed, steering to the eastward:—she was the first sail we had seen since leaving San Carlos de Chiloe. At daylight next morning (28th), we were in sight of Flores Lighthouse, which was reported to be a vessel under sail. Soon after which another vessel was reported as being under all studding sails; this was the Mount itself: so curiously were objects distorted by the haze. Soon after noon we anchored off Monte Video, and from Captain Talbot, of H.M.S. Algerine, I heard of the arrival there, and subsequent departure of the Adventure and the Adelaide.

© The Complete Work of Charles Darwin Online

On the 9th of July we sailed from Monte Video,—on the 18th made the high land over the island of Santa Catalina, and after dark anchored in the bay. My object in calling there was to continue the chronometric chain, between Tierra del Fuego and Rio de Janeiro, by as short intervals as possible: and the results so obtained proved to be very satisfactory.

"While in Monte Video I tried to have the Fuegians vaccinated, but the virus did not take any effect on them. Little Fuegia was living several days with an English family, who were extremely kind to her; and the others were on shore at different times with me. No one noticed them; being so very like the Indians of the neighbourhood.

"The apparent astonishment and curiosity excited by what they saw, extraordinary to them as the whole scene must have been, were much less than I had anticipated; yet their conduct was interesting, and each day they became more communicative. It was here that I first learned from them that they made a practice of eating their enemies taken in war. The women, they explained to me, eat the arms; and the men the legs; the trunk and head were always thrown into the sea.

"On the 23d we sailed from Santa Catalina; and on the 2d of August anchored in the harbour of Rio de Janeiro."

Here the extracts from Captain Fitz Roy's Journal end.

The Adventure and the Beagle sailed together from Rio de Janeiro on the 6th of August, having left the Adelaide as a tender to the flag-ship, but reimbarked her officers and crew; and, after a most tedious passage, anchored in Plymouth Sound on the 14th of October. Both vessels were soon afterwards paid off; the Beagle at Plymouth, and the Adventure at Woolwich.

CHAPTER XXIV.

A FEW NAUTICAL REMARKS UPON THE PASSAGE ROUND CAPE HORN; AND UPON THAT THROUGH THE STRAIT OF MAGALHAENS, OR MAGELLAN.

Ships bound from the Atlantic to any of the ports in the Pacific, will find it advantageous to keep within one hundred miles of the coast of Eastern Patagonia, as well to avoid the heavy sea that is raised by the westerly gales, which prevail to the eastward, and increase in strength according to the distance from the land, as to profit by the variableness of the wind when it is in the western board. Near the coast, from April to September, when the sun has north declination, the winds prevail more from the W.N.W. to N.N.W. than from any other quarter. Easterly gales are of very rare occurrence, but even when they do blow, the direction being obliquely upon the coast, I do not consider it at all hazardous to keep the land on board. In the opposite season, when the sun has south declination, the winds will incline from the southward of west, and frequently blow hard; but, as the coast is a weather shore, the sea goes down immediately after the gale. In this season, although the winds are generally against a ship's making quick progress, yet as they seldom remain fixed in one point, and frequently shift backward and forward six or eight points in as many hours, advantage may be taken of the change so as to keep close in with the coast.

Having once made the land, which should be done to the southward of Cape Blanco, it will be beneficial to keep it topping on the horizon, until the entrance of the Strait of Magalhaens be passed.

With respect to this part of the voyage, whether to pass through Strait Le Maire or round Staten Island, much difference of opinion exists. Prudence, I think, suggests the

© The Complete Work of Charles Darwin Online

latter; yet I should very reluctantly give up the opportunity that might offer of clearing the strait, and therefore of being so much more to windward. With a southerly wind it would not be advisable to attempt the strait; for, with a weather tide, the sea runs very cross and deep, and might severely injure and endanger the safety of a small vessel, and to a large one do much damage. In calm weather it would be still more imprudent (unless the western side of the strait can be reached, where a ship might anchor), on account of the tides setting over to the Staten Island side; where, if it becomes advisable to anchor, it would necessarily be in very deep water, and close to the land. With a northerly wind the route seems not only practicable, but very advantageous, and it would require some resolution to give up the opportunity so invitingly offered. I doubt whether northerly winds, unless they are very strong, blow through the strait—if not, a ship is drifted over to the eastern shores, where, from the force of the tides, she must be quite unmanageable.

Captain Fitz Roy seems to think there is neither difficulty nor risk in passing the strait. The only danger that does exist, and that may be an imaginary one, is the failure of the wind. Ships passing through it from the south, are not so liable to the failure of the south-westerly wind, unless it be light, and then a breeze will probably be found from N.W., at the northern end of the strait. The anchorage in Good Success Bay, however, is at hand, should the wind or tide fail.

In passing to leeward of Staten Island, the tide race, which extends for some distance off Cape St. John, at the N.E. end of the island, must be avoided: otherwise there exist no dangers.

The anchorage under New Year Islands, although it is a wild one, the bottom bad, and the tide very strong, yet offers good shelter from south-west winds, and might be occupied with advantage during the existence of a gale from that quarter, which is so unfavourable for ships bound round the Horn.

After passing Staten Island, if the wind be westerly, the

© The Complete Work of Charles Darwin Online

ship should be kept upon the starboard tack, unless it veer to the southward of S.S.W., until she reaches the latitude of 60° south, and then upon that tack on which most westing may be made. In this parallel, however, the wind is thought to prevail more from the eastward than from any other quarter. Never having passed round Cape Horn in the summer season, I may not perhaps be justified in opposing my opinion to that of others, who, having tried both seasons, give the preference to the summer months. The advantage of long days is certainly very great, but, from my experience of the winds and weather during these opposite seasons at Port Famine, I preferred the winter passage, and in our subsequent experience of it, found no reason to alter my opinion. Easterly and northerly winds prevail in the winter off the cape, whilst southerly and westerly winds are constant during the summer months; and not only are the winds more favourable in the winter, but they are moderate in comparison to the fury of the summer gales.

Having passed the meridian of Cape Pillar, it will yet be advisable to take every opportunity of making westing in preference to northing until the meridian of 82° or 84° be reached, which will enable a ship to steer through the North-westerly winds that prevail between the parallels of 50° and 54°. (See Hall's South America, Appendix.)

With respect to the utility of the barometer as an indicator of the weather that is experienced off Cape Horn, I do not think it can be considered so unfailing a guide as it is in the lower or middle latitudes. Captain Fitz-Roy, however, has a better opinion of the indications shewn by this valuable instrument: my opinion is, that although the rise or fall at times precedes the change, yet it more frequently accompanies it. The following sketch of the movement of the barometer, and of the weather that we experienced, may be not without its use.

Being to the north of Staten Island for three days preceding full moon, which occurred on the 3d April (1829), we had very foggy weather, with light winds from the eastward and

© The Complete Work of Charles Darwin Online

northward, causing a fall of the mercury from 29·90 to 29·56. On the day of full moon the column rose, and we had a beautiful morning, during which the high mountains of Staten Island were quite unclouded, as were also those of Tierra del Fuego. At noon, however, a fresh gale from the S.W. set in, and enveloped the land with a dense mist. No sooner had the wind changed, than the mercury rose to 29·95, but fell again the next morning; and with the descent the wind veered round to N.W., and blew strongly with thick cloudy weather and rain, which continued until the following noon, when the wind veered to S.W., the barometer at 29·54, having slightly risen; but after the change it fell, and continued to descend gradually until midnight, when we had a fresh gale from W.S.W. When this wind set in, the mercury rose, and continued to rise, as the wind veered without decreasing in strength to S.S.W., until it reached 29·95, when it fell again and the weather moderated, but without any change of wind. During the descent of the mercury, the sky with us was dull and overcast, with squalls of wind and rain, but on shore it seemed to be very fine sunshiny weather.

The column now fell to 29·23, and during its descent the weather remained the same, dull and showery; but as soon as the mercury became stationary, a fresh breeze set in from the southward, with fine weather.

After this to new moon the weather was very unsettled, the wind veering between South and W.S.W.; the barometer rising as it veered to the former, and falling as it became more westerly; but on no occasion did it precede the change.

The mean height of the barometer is about 29·5.

The mercury stands lowest with N.W. winds, and highest with S.E.

With the wind at N.W. or northerly the mercury is low; if it falls to 29 inches or 28·80, a S.W. gale may be expected, but it will not commence until the column has ceased to descend. It frequently, however, falls without being followed by this change. In the month of June, at Port Famine, the barometer fell to 28·17, and afterwards gradually rose to 30·5,

© The Complete Work of Charles Darwin Online

which was followed by cold weather, in which the thermometer stood at 12°.

The following Table shews the mean temperature and pressure as registered at the Observatory at Port Famine in the Strait.

1828.	Temperature.	Pressure.
February	51·1	29·40
March	49·4	29·64
April	41·2	29·57
May	35·5	29·30
June	32·9	29·28
July	33·0	29·57
August	33·2	29·28

The difficulties that present themselves to Navigators in passing round Cape Horn, as well from adverse winds as the severe gales and heavy sea to which they are exposed, are so great, that the Strait of Magalhaens has naturally been looked to as a route by which they may be avoided. Hitherto no chart has existed in which much confidence could be placed; but by the present survey, the navigation through it, independent of wind and weather, has been rendered much easier; since a correct delineation of its shores, and plans of the anchorages, have been made; and in the preceding pages, sufficient descriptions of them have been given to assure the navigator of his place, and furnish him with advice as to his proceedings. The local difficulties therefore have been removed; but there remain much more serious ones, which I should not recommend a large, or even any but a very active and fast-sailing square-rigged vessel to encounter, unless detention be not an object of importance.

For a square-rigged vessel bound through the Strait, the following directions will be useful:—

© The Complete Work of Charles Darwin Online

In the eastern entrance the winds will frequently favour a ship's arrival off the First Narrow; where, if she selects a good anchorage on the bank which bounds the northern side of the channel, she may await an opportunity of passing through the First Narrow and of reaching Gregory Bay; where also a delay may safely be made for the purpose of passing the Second Narrow and arriving at the neighbourhood of Cape Negro; at which place the difficulties and dangers of the eastern entrance cease.

The dangers being carefully placed on the chart, and now sufficiently described, nothing need be repeated here; and indeed much must be left to the judgment and discretion of the navigator.

The tides answer best for vessels entering the Strait at the period of full and change of the moon, since there are two westerly tides in the day. In the winter season, if the morning tide be not sufficient to carry a vessel through the First Narrow, she may return to Possession Bay, select an anchorage, and be secured again before night; or, in the summer, if she has passed the Narrow, and has been enabled to anchor for the tide, there will be sufficient daylight for her to proceed with the following tide to Gregory Bay, or at least to a safe anchorage off the peaked hillocks on the north shore.

I have twice attempted to pass the First Narrow, and been obliged to return to the anchorage in Possession Bay; and twice I have passed through it against a strong breeze blowing directly through, by aid of the tide; which runs, in the narrower parts, at the rate of ten or twelve miles an hour. When the tide and wind are opposed to each other, the sea is very deep and heavy, and breaks high over the decks; it is therefore advisable to close reef, or lower the topsails on the cap, and drift through; for the tide, if at the springs, will generally be sufficient to carry a ship to an anchorage, although, not always to one where it would be safe to pass the night. On this account, it would be prudent to return; for, although the holding ground is exceedingly good, yet, to part in the night, or drift towards, or through the Narrow, could scarcely happen without accident.

© The Complete Work of Charles Darwin Online

In leaving the anchorage in Gregory Bay, attention must be paid to the tide, which continues to run to the eastward in the Second Narrow, three hours after it has commenced setting to the S.W. at the anchorage.

With a leading wind through the Second Narrow, a ship will easily reach an anchorage off Laredo Bay, but, if the tide fails upon emerging from it, she should seek for a berth in the bay to the north of Elizabeth Island, as near to the island as possible, but to the westward of its N.E. end, to be out of the influence of the tide. The depth of water, however, will be the best guide.

Directions for passing round the south side of Elizabeth Island are given elsewhere; and as this part offers some dangers, the chart and the description should be carefully referred to.

The only advice that seems wanting, to improve the directions for the coast from this to Port Famine, is, with a south-westerly wind, to keep close to the weather shore, in order to benefit by the flaws down the valleys; but this must be done with caution, in consequence of the squalls off the high land, the violence of which cannot be well imagined by a person unaccustomed to them.

Of the anchorages between Port Famine and Cape Froward, the only convenient one for a ship is St. Nicholas Bay, to which, if defeated in passing round the Cape, she had better return; for it is easy to reach as well as to leave, and extremely convenient for stopping at, to await an opportunity of proceeding.

From Cape Froward to the westward, unless favoured by a fair wind, it is necessary to persevere and take advantage of every opportunity of advancing step by step. There are several anchorages that a ship may take up, such as Snug Bay, off Woods Bay, near Cape Coventry, in Fortescue Bay, Elizabeth Bay, and York Roads. To the westward, in Crooked Reach, the anchorages are not so good, and excepting Borja Bay, none seem to offer much convenience. Borja Bay, however, is well calculated to supply the deficiency, although for a square-rigged vessel there must be some difficulty in reaching it.

© The Complete Work of Charles Darwin Online

Long Reach is both long and narrow, and ill supplied with anchorages for a ship; such as they are, Swallow Harbour, Playa Parda, Marian Cove, and Half Port Bay, seem to be the best. In thick weather, although the channel is very narrow, yet one side is scarcely visible from the other, and the only advantage it has over other parts of the strait is the smoothness of the water. In Sea Reach there is a heavy rolling swell, with a short and deep sea, which renders it very difficult to beat to windward.

Tamar Harbour, Valentine Harbour, Tuesday Cove, and the Harbour of Mercy, are the best anchorages; and the latter is particularly convenient to occupy, while awaiting an opportunity of sailing out of the strait.

In the entrance, the sea runs very heavy and irregularly during and after a gale; so that a ship should not leave her anchorage in the Harbour of Mercy, without a fair or a leading wind to get her quickly through it.

For small vessels, particularly if they be fore-and-aft rigged, many, if not all of the local difficulties vanish; and inlets which a ship dare not or cannot approach, may be entered with safety, and anchorage easily obtained by them. A large ship will perhaps be better off in entering and leaving the Strait where there is open space and frequently a heavy sea; but for the navigation of the Strait, a small vessel has considerably the advantage. She has also the opportunity of passing through the Cockburn Channel should the wind be north-westerly, which will very much reduce the length of the passage into the Pacific.

One very great advantage to be derived from the passage through the Strait is, the opportunity of obtaining as much wood and water as can be required, without the least difficulty; and another benefit is, that by hauling the seine during the summer months, from January to May, at the mouth of the river or along the beaches in Port Famine, at the first quarter flood, a plentiful supply of fish may be obtained. Excellent fish are also caught at the anchorage with the hook and line, at all seasons, early in the morning or late in the

© The Complete Work of Charles Darwin Online

evening. Fish may also be obtained with the seine at any other place where there are rivers. Freshwater Bay and Port Gallant are equally productive. On the outer coast of Tierra del Fuego an excellent fish may be caught in the kelp.

The advantage which a ship will derive from passing through the Strait, from the Pacific to the Atlantic is very great; and it ought to be great to induce the seaman to entangle his ship with the land when fair winds and an open sea are before him. After passing through the Strait, the prevailing winds being westerly, and more frequently from the northward than from the southward of west, they are fair for his running up the coast; or if not, the ship is not liable to receive much injury from the sea, which is comparatively smooth; whereas, to a ship passing round the Horn, if the wind be north-west she must go to the eastward of the Falkland Islands, and be exposed to strong gales and a heavy beam sea, and hug the wind to make her northing. To a small vessel the advantage is incalculable; for, besides filling her hold with wood and water, she is enabled to escape the severe weather that so constantly reigns in the higher latitudes of the South Atlantic Ocean.

Coming from the northward, it will be advisable to keep an offing until the western entrance of the Strait is well under the lee, to avoid being thrown upon the coast to the northward of Cape Victory, which is rugged and inhospitable, and, forming as it were a breakwater to the deep rolling swell of the ocean, is for some miles off fringed by a cross hollow sea almost amounting to breakers.

The land of Cape Victory is high and rugged, and much broken; and if the weather be not very thick, will be seen long before the Evangelists, which are not visible above the horizon, from a ship's deck, for more than four or five leagues.* Pass to the southward of them, and steer for Cape Pillar,

* From the Adventure's deck, the eye being thirteen feet above the water, they were seen on the horizon at the distance of fourteen miles.

which makes like a high island. In calm weather do not pass too near to the cape, for the current sometimes sets out, and round the cape to the southward; but with a strong wind, get under the lee of it as soon as you please, and steer along the shore. In the night it will be advisable to keep close to the land of the south shore; and if a patent log be used, which no ship should be without, your distance will be correctly known. The course along-shore, by compass, is E. $\frac{3}{4}$ S.; and if the weather be hazy, by keeping sight of the south shore, there will be no difficulty in proceeding with safety.

The Adventure entered the Strait on the 1st of April, 1830, at sunset; and after passing within half a mile of the islets off the Harbour of Mercy, steered E. $\frac{3}{4}$ S. magnetic, under close-reefed topsails, braced by, the weather being so squally and thick that the land was frequently concealed from us; but being occasionally seen, the water being quite smooth, and the course steadily steered, with the patent log to mark the distance run, we proceeded without the least anxiety, although the night was dark, and the squalls of wind and rain frequent and violent. When abreast of Cape Tamar, that projection was clearly distinguished, as was also the land of Cape Providence, which served to check the distance shewn by the patent log; but both giving the same results, proved that we had not been subjected to any current; whereas the account by the ship's log was very much in error, in consequence of the violence of the squalls and the long intervals of light winds, which rendered it impossible to keep a correct account of the distance. At daybreak we were between Cape Monday and the Gulf of Xaultegua; and at eight o'clock we were abreast of Playa Parda, in which, after a calm day, the ship was anchored.

In the summer season there is no occasion to anchor any where, unless the weather be very tempestuous, for the nights are short, and hardly dark enough to require it, unless as a precautionary measure, or for the purpose of procuring wood and water; the best place for which is Port Famine, where

© The Complete Work of Charles Darwin Online

the beaches are strewed with abundance of logs of well-seasoned wood, which is very superior to the green wood that must otherwise be used.

Notwithstanding that the Adventure experienced no current in the western part of the Strait, there is generally a set to the eastward, which is more or less felt according to circumstances. The direction and strength of the currents are caused by the duration of the gales.

The chart will be a sufficient guide for vessels bound through from the westward as far as Laredo Bay; after which a few directions will be necessary. The land here should be kept close on board, to avoid the Reef off the south-west end of Santa Magdalena. Being abreast of it, bear away, keeping the N.E. extremity of Elizabeth Island on the starboard bow, until you see Santa Marta in one with, or a little to the southward of, the south trend of the Second Narrow (Cape St. Vincent), which is leading mark for the fair channel until you pass the spit of shoal soundings, which extends across to Santa Magdalena. There are also shoal soundings towards the south-west end of Elizabeth Island; at half a mile off we had five fathoms,—Cape St. Vincent being then the breadth of Santa Marta open to the northward of that island. Keeping the cape just in sight to the northward of Santa Marta, steer on and pass round the low N.E. extremity of Elizabeth Island, off which are several tide eddies. The tide here sets across the channel.

Now steer for the Second Narrow, keeping Cape Gregory, which will be just discernible as the low projecting extreme of the north side of the Second Narrow, on the starboard bow, until you are three miles past Santa Marta; the course may then be directed for the cape, opening it gradually on the larboard bow as you approach it, to avoid the shoal that extends off it.

If you anchor in Gregory Bay, which is advisable, in order to have the whole of the tide for running through the First Narrow, haul up and keep at a mile and a half from the shore. When

© The Complete Work of Charles Darwin Online

the north extremity of the sandy land of the Cape is in a line with the west extreme of the high table-land, you will be near the anchorage; then shorten sail, and when the green slope begins to open, you will have fourteen fathoms: you may then anchor or keep away to the N.E., and choose a convenient depth, taking care not to approach the shore, so as to bring Cape Gregory to the southward of S. by W.$\frac{1}{4}$W. (by compass). The best berth is with the Cape bearing S.S.W.

Hence to the First Narrow, the course by compass is due N.E. by E.* The land at the entrance being low, will not at first be perceived; but, steering on, you will first see some hummocky land, making like islands. These are hills on the eastern, or Fuegian side of the Narrow. Soon afterwards, a flat, low sand-hill will be seen to the northward, and this is at the S.W. extremity of Point Barranca. On approaching the narrow, at four miles off, keep a cliffy head, four or five miles within the east side of the narrow, open of the trend of Point Barranca, by which you will avoid the shoal that extends off the latter point. You should not go into less depth than six fathoms. At most times of the tide there are long lines and patches of strong ripplings, through which you must pass. The shoal is easily distinguished by the kelp.

When the channel through the narrow bears by compass N. by E.$\frac{3}{4}$E., steer through it; and that, or a N.N.E. course, will carry you through. On each side, the bank extends off for some distance; but by keeping in mid-channel, there is no danger until the cliffy coast be past, when reefs extend off either shore for some distance, particularly off Cape Orange. The N.N.E. course must be kept until the peak of Cape Orange bears south, and the northern Direction Hill W.S.W., or W. by S.$\frac{1}{2}$S. by compass. Then steer E.N.E. for Cape Possession, taking care not to approach too near to the bank

* If from the Second Narrow, N.E.$\frac{1}{4}$E. will be the compass course; but I should recommend a ship to haul up to the northward until abreast of Cape Gregory, and then to steer as above.

© The Complete Work of Charles Darwin Online

off Cape Orange, or to that on the north side of Possession Bay, for which the chart must be consulted.

For a small vessel, the passage through the strait, from west to east, is not only easy, but strongly to be recommended as the best and safest route. Indeed, I think the passage would be quite as expeditious, and perhaps much safer, to enter the Gulf of Trinidad, and pass down the Concepçion Strait, the Sarmiento or St. Estevan Channels, and Smyth Channel, and enter the Strait at Cape Tamar. In these channels northerly winds prevail, and there is no want of convenient and well-sheltered anchorages for the night, many of which have already been mentioned, and multitudes of others, perhaps much better ones, might be found.

TABLES

OF

LATITUDE AND LONGITUDE, VARIATION OF THE COMPASS, AND TIDE.

I.

COASTS OF BRAZIL, RIVER PLATA, AND EASTERN PATAGONIA.

The Latitudes to which the character ⊙ is prefixed, have resulted from Astronomical Observation. The Longitudes which have been determined by Chronometers, are designated by C.; and those by Lunar Distances by ⊙☽. Those without distinguishing marks are the result of Triangulation.

The Longitudes in the following Tables depend upon that of Villegagnon Island at Rio de Janeiro, which was found by fourteen Chronometers from Plymouth to be 43° 05′ 03″ West of Greenwich.

Coast, &c.	Name of Place.	Name of Particular Spot.	Latitude South.	Longitude West.	Variat. East.	Tide. H. W. at F. & C.	Tide. Direction of Flood, and Rise of Tide.

TABLE IV.

OUTER, OR SEA COAST, OF TIERRA DEL FUEGO.

In order to adapt the longitudes of the places mentioned in this Table to the meridians of Port Famine and St. Martin Cove, at Cape Horn, the following corrections* have been made to Captain Fitz-Roy's chronometrical results, *viz* :—

Townshend Harbour, Stewart Harbour, Doris Cove, March Harbour, Good Success Bay } have been placed { 0′ 11″ / 0 23 / 0 33 / 1 6 / 2 0 } to the Eastward of Captain Fitz-Roy's chronometrical deductions.

By Captain Fitz-Roy's observations St. Martin Cove would be in long. 67° 31′ 18″, which is 2′ 15″ to the Westward of the mean of upwards of thirty chronometrical results from Monte Video. The difference has, therefore, been equally divided between North Cove and St. Martin Cove; the longitude of the latter being taken at 67° 29′ 03″, and of Port Famine at 70° 54′.

MAGNETIC OBSERVATIONS,

DISCUSSED BY

MAJOR SABINE, R.A., F.R.S.

1. *Observations of the Dip.*

Captain Fitz-Roy was furnished with two Dip Circles, one by Gambey, and the other by Dollond; the latter supplied by Government, and Gambey's purchased by himself.

Gambey's, being found to give results more accordant with each other than Dollond's, was used at all the stations, except Rio de Janeiro. The Circle was nine and a-half inches in diameter, and was furnished with two needles. This instrument was, in all respects, a very superior one. It was placed for observation on a stand, which raised it from two to three feet above the ground. The needle was observed in eight positions, and as the readings accorded sufficiently well with each other, their arithmetical mean has been taken as the dip resulting from the observation. The eight positions were as follows: 1, with the graduated face of the circle towards the east; 2, with the same towards the west. The needle was then taken out and replaced with the ends of the axle changed, so that each end rested on a different plane to what it did before; it was then observed, 3, with the face of the circle towards the west, and 4, with the same to the east. The poles were then inverted, so that the end of the needle which was before a north pole became a south pole, and the four positions were again repeated. The arc indicated by both ends of the needle was read in every position: an observation of the dip consisted, consequently, of sixteen readings. In the subjoined tabular record these are comprised in four entries, a mean being taken of the arc read at the two extremities of the needle, and of the positions 1 and 3, 2 and 4: 1 and 3 form the column, a; 2 and 4 the column, a′; and the same positions, with the poles reversed, the columns a″ and a‴.

2. *Observations of Intensity.*

The method employed by Captain Fitz-Roy to determine the variations of the magnetic force was that of noting the time of vibration of a magnetic cylinder suspended horizontally.

The cylinder was one which had been given by M. Hansteen, in 1826, to Captain Phillip Parker King, R.N., and had been used by him during the survey of the coast of South America, which he conducted from 1826 to 1830. The apparatus in which it was vibrated, both in Captain King's and Captain Fitz-Roy's voyages, was the well-known one of M. Hansteen.

By observations made with this cylinder on the 22d March 1826, and again on the 24th January 1830, in the garden of the Royal Observatory at Greenwich, it appeared that its time of performing 300 vibrations had increased from 734,45 seconds in 1826, to 775,80 seconds in 1831; or 41,35 seconds in 1,770 days. A change of such magnitude in the magnetic intensity of the instrument employed to measure the variations of the terrestrial intensity, and which ought itself, therefore, to be invariable, would, in the generality of cases, have prevented any satisfactory conclusion whatsoever being drawn from the observations. Fortunately from the nature of the duties in which Captain King was engaged, he had occasion to return frequently to the same anchorages, and by his extreme care to repeat observations on every such return, he has provided a means of computing the decrease of the intensity of the cylinder, proportioned to intervals of time, between 1826 and 1831; and of thus introducing compensations for it, which render the results on the whole nearly as satisfactory as if the cylinder had preserved an uniform magnetic condition throughout.

The voyage which Captain Fitz-Roy had to perform promised to furnish few, if any, such opportunities of examining the state of the magnetism of the cylinder, between the departure from and the return to England; and,—as it cannot but be extremely discouraging to officers to make observations which they have reason to apprehend may prove unavailing from defect in the instrument employed,—it must be regarded as exceedingly creditable to Captain Fitz-Roy and his officers, that, with the knowledge of the

© The Complete Work of Charles Darwin Online

change which the cylinder had undergone in the preceding voyage, they persevered in diligently observing, and carefully recording, its time of vibration, at most of the principal ports which they visited in their voyage of five years' duration. Nor was it until their return to the Cape Verd Islands, in September 1836, that they could infer, from observations repeated at the same spot as in their outward passage in 1832, that the cylinder had not varied in any thing like the degree that it had done in the preceding voyage, and that the care and pains they had bestowed were therefore likely to be recompensed by success.

This appears a fitting opportunity to remark, how much the establishment in England of a depository for magnetic needles is needed; whence officers, and persons desirous of making such observations, might be supplied with instruments, which had been kept a sufficient time to have attained their permanent magnetic state, and had been examined from time to time to prove that they had done so. The correction for temperature should be ascertained for each needle, and given with it; as well as the time of vibration (or whatever else constituted the measure of intensity,—as, for example, the angle of deflection in Mr. Lloyd's statical needles,)—observed at the spot which should be selected as most suitable for a point of general comparison; and the observations should be repeated at the same spot on the return of the needle. The want of such an establishment has long been greatly felt; and opportunities, where nothing was wanting but proper instruments, have been lost in consequence, where determinations of great value might have been obtained, in parts of the world of the highest magnetic interest, and where such opportunities are of rare occurrence.

The corrections necessary to render the times of vibration at the different stations strictly comparable with each other, are as follows.

1st, For the rate of the chronometer.

2d, For the temperature of the needle.

3d, For the arc of vibration.

4th, For any change in the magnetic condition of the cylinder.

In extensive voyages, the last-named correction, or that for the change in the cylinder itself, is the one which requires principal consideration. The corrections for temperature, and for the arc, on the first of which particularly much stress has sometimes been

© The Complete Work of Charles Darwin Online

laid, are important when extreme accuracy is sought; as for example, in comparing the force at stations which have served as the unities of different observers: their effect is, however, of little moment in observations which include great differences of the terrestrial intensity. But when the magnetic condition of the needle has varied, and interpolation becomes necessary, the instances are rare in which it can be done with entire satisfaction.

The time of vibration of this cylinder at Plymouth, with corrections applied for the chronometer's rate, the temperature, and the arc, was, in December 1831, 770,8 seconds, with a dip of 69° 27′,6, and in October 1836, 777,3 seconds with a dip of 69° 17′, 5. The difference in its magnetic state, at the two periods, is shown by the squares of the times of vibration multiplied by the cosine of the dip observed at the respective periods. This makes known what the time of vibration of the same cylinder would have been, had it been free to move in the direction of the dipping-needle, instead of being suspended horizontally; and, consequently, if it had been acted upon by the total magnetic intensity, instead of by the horizontal component only. It is here assumed that the total terrestrial intensity is constant at the same place. This is doubtless not strictly true; but the amount of the change must be too small to require consideration in the period occupied by Captain Fitz-Roy's observations. The horizontal component must, however, necessarily vary with the changes in the dip: and it is, therefore, from the time of vibration in the direction of the dipping-needle, and not from the time of horizontal vibration, that the change, or otherwise, in the magnetism of the needle is to be inferred. We find, then, the equivalent time of vibration of this cylinder in the direction of the dipping-needle to have been 456,4 seconds in December 1831, and 462,2 seconds in October 1836; showing a difference of 5,8 seconds in fifty-eight months. If we compare this amount with the far greater loss of intensity sustained by this cylinder in the preceding voyage, it seems a probable supposition that, at the commencement of Captain Fitz-Roy's voyage, the cylinder had nearly attained its permanent magnetic state; and that its further loss of magnetism, occasioning an increase of 5,8 seconds in the time of vibration, took place in the early part of the voyage: supposing the loss to have been progressive, and not sudden, as from accidents, of which the observations give no indications. Con-

© The Complete Work of Charles Darwin Online

sistently with this supposition, the loss has been distributed through the first half, or twenty-nine months, of this voyage, in the proportion of three-tenths of a second per month in the first ten months, commencing December 1st 1831; two-tenths per month in the next nine months; and one-tenth per month in the remaining nine months. In the last twenty-nine months of the voyage, the intensity of the cylinder is supposed to have been uniform, and the same which it was found to possess on the return to England in 1836.

It is satisfactory that, with this compensation, the observations at Port Praya, in January 1832, and in September 1836, assign almost identically the same relative magnetic intensity to that station.

The correction for temperature for this cylinder not having been previously examined, I received it from Captain Fitz-Roy for that purpose, and made with it the following observations. The cylinder, in its own apparatus, was placed in a large earthen jar, glazed at the top, and standing in a larger earthen vessel, into which warm water could be poured at pleasure, and the cylinder was then vibrated alternately in heated air and in air of the natural temperature. These experiments were made at Tortington, in Sussex.

	—	4 00 P.M.	15,45	774,00				
	—	4 22 P.M.	15,80	774,25	Mean,	4 22 P.M.	15,65	774,16 Natural Temperature.
	—	4 44 P.M.	15,70	774,23				
Exp. 2	June 13	10 49 A.M.	14,90	773,77				
	—	11 16 A.M.	15,10	773,37	Mean,	11 02 A.M.	15,0	773,57 Natural Temperature.
	—	0 20 P.M.	34,80	775,94				
	—	0 42 P.M.	36,55	775,89	Mean,	0 31 P.M.	35,7	775,92 Heated Air.
	—	1 30 P.M.	17,70	774,06				
	—	1 52 P.M.	15,90	774,11	Mean,	1 41 P.M.	16,8	774,08 Natural Temperature.

In the first Experiment, $T=777,09$; T' 774,74; $t=103°,4$ Faht.; and $t'=63°,1$ Faht.

In the second Experiment, $T=775,92$; T' 773,83; $t=112°,3$ Faht.; and $t'=67°,8$ Faht.

The first Experiment gives $$\frac{T-T'}{T\,(t-t')} = \frac{2{\cdot}35}{777,09\times 40,3} = {\cdot}000075.$$

The second Experiment gives $$\frac{T-T'}{T\,(t-t')} = \frac{2,09}{775,92\times 44,5} = {\cdot}000061.$$

© The Complete Work of Charles Darwin Online

Whence the formula $T'=T\,[1\times 0{\cdot}000068\ (60^\circ - t)]$, in which T is the time of vibration at any station, t, the temperature of the cylinder in degrees of Fahrenheit, and T′ is the equivalent time at a standard temperature of 60°. The thermometer was noted at the beginning and ending of every set of vibrations, and was always placed in the box with the cylinder.

At all Captain Fitz-Roy's stations the apparatus was placed for observation on a stand, which raised it from two to three feet above the ground, thereby rendering the cylinder somewhat less liable to be disturbed by local influences: it was not furnished with a means of examining the strict horizontality of the cylinder, that improvement having been introduced into M. Hansteen's apparatus at a later period. On this point Captain Fitz-Roy remarks: "A small leaden tripod was used as a stand, whose upper surface " was adjusted by a small spirit-level—or roughly by the trough " of an artificial horizon, filled with mercury. Upon the leaden " stand the box containing the needle was adjusted by its foot- " screws, so that the suspending fibre of silk hung centrally in " the wooden tube, the needle's centre being over that of the " graduated circle, and the needle itself near, but not touching, " the bottom of the box. The needle was not always strictly " parallel to the bottom of the box, nor strictly horizontal, be- " cause I would not move the brass stirrup in which it was sus- " pended, but its deviation from strict horizontality *never* exceeded " two degrees, and was seldom nearly so much."

The time of completing every tenth vibration was recorded. The time of performing 300 vibrations is deduced from a mean generally of seven partial results: *i. e.* from the 0th to the 300th; 10th to the 310th; and so on, to the 60th and 360th vibrations; the commencing vibration being always at an arc of 20°. In a very few instances the number of vibrations observed, after the commencing arc of 20°, was less than 360; in such cases the first vibration after the arc had become 20° has still been taken as the commencing one, though previous ones may have been recorded; it being kept strictly in view, to obtain the relative time of vibration in arcs as nearly the same as possible, and not exceeding 20° as the initial. The arc was reduced to 10° generally about the 100th vibration; and one thousandth of the time of vibration has been taken throughout the series as the correction to infinitely small arcs.

© The Complete Work of Charles Darwin Online

The object of noting the time of every tenth vibration is to check errors in the counting, which will sometimes occur in the course of the 360, particularly with the very short and quick-moving needles of M. Hansteen's very portable apparatus, and at stations of low dip, where the horizontal force is greatest, and the needle consequently moves most quickly. Several such mistakes evidently occurred. When the time of completing every supposed tenth vibration is observed with tolerable exactness, and the duration of each pair of vibrations decidedly exceeds any irregularity of probable occurrence, apart from miscounting the number of vibrations, such mistakes can be discovered with ease, and rectified with certainty. This has been done in every case where no doubt could exist of a mistake of the kind having occurred; such as when all the intervals are of nearly equal duration, with one or two exceptions, which differ as much as three or four seconds from the general body. There are two stations, however, Callao and Keeling Islands, where the rectification is not so clear, or the true result so obvious. At Callao there are three series of horizontal intensities, each of forty observed intervals, which should be of ten vibrations each. Several of these intervals are between 17,5 and 18,5 seconds, and several others between 20,5 and 21,5 seconds. These can hardly represent an equal number of vibrations, because the difference between them is greater than can easily be supposed due to any uncertainty in seizing the particular beat of the chronometer at which the vibration was completed; it is, moreover, about the time that would be occupied by two vibrations more or less. The question then arises, do the longer intervals represent 12, and the shorter 10 vibrations, or do the longer represent 10, and the shorter 8? In the former supposition the intensity at Callao would be about 1.01(Paris=1.348): in the latter about 0.75. The difference shews how great an error would be risked by either assumption. If we take a mean of all the intervals as they stand, the amount of error risked would be certainly lessened; but we should assuredly not have the true time of three hundred vibrations, except on one supposition: namely, that the irregularities in question are not errors in estimating the number of vibrations, but that each interval really represented an equal number, and that some unusual and accidental cause occasioned the needle to differ so greatly in successive intervals. But this

© The Complete Work of Charles Darwin Online

supposition would imply a disturbing cause vitiating the series as a measure of the magnetic intensity at the station. I have not ventured, therefore, to draw any conclusion from these observations, farther than to notice, as above, the limits within which, in either of the two first suppositions, the intensity would fall.

A nearly similar reasoning applies to the observations at Keeling Islands; of three series, one is decidedly so irregular, that no inference could be drawn from it; in the two other series the irregularities are neither so frequent, nor so large: my general impression (in the uncertainty created by the irregularity of the first series), is, that the majority of the intervals are of twelve vibrations, and not of ten: if of twelve, the intensity would be about 1,21; if of ten, about 0,85.

The inconvenience of the rapid motion of the needle, occasioned, at one part of the voyage, the practice to be discontinued of observing every tenth vibration, and every twentieth was substituted. This no doubt relieved the perplexity in which the observer occasionally found himself, in having to observe, and record, and be prepared again to observe, at every twenty seconds or less, and so far the change enabled him to observe better. But still, the disadvantage remains, in so quick moving a needle, that if a mistake of two vibrations is made, the difference of time occasioned is not of so marked and decided a character as to be at all times at once distinguished. It is of much more importance that there should be no miscount of the vibrations, than that the times should be recorded correctly to the fraction of a second. It is only the earlier and later times that are finally influential; but every undetected error in the number of vibrations falls with its whole weight upon the result.

The occasional discrepancies in the results of the same, or of different, observers, or on the same, or on different, days, which are seen in the subjoined table, are not, I believe, traceable to the source I have been discussing, nor apparently to any other than an actual difference in the time of the cylinder performing its vibration. A mean has been taken as the result at each station, except at St. Helena, where the discrepancy on the 11th and 13th of July was so considerable, that it has been thought more satisfactory to collect the observations of each day into separate results.

The subjoined table comprises the result of each observation,

© The Complete Work of Charles Darwin Online

and the general results deduced for each station. The column entitled "Time" is that of 300 vibrations; and the "Corrected Time" is the mean of these, corrected for the rate of the chronometer and the arc, and reduced to an average temperature of 60°. The dips are those observed by Captain Fitz-Roy; except at Port Famine, where, as Captain Fitz-Roy did not observe, it has been supplied from Captain King's observations; and at Coquimbo, where, for the purpose of computing the intensity, it has been supplied by estimation from the other geographic positions on this coast, at which Captain Fitz-Roy observed the dip. In the column showing the time of vibration as a dipping-needle at Plymouth corresponding to the periods of observation at the several stations, the compensations have been introduced for the variation in the intensity of the cylinder, agreeably to what has been said above on that subject. The two final columns exhibit the values of the total magnetic intensity at the different stations derived from these observations. In the first of the two columns, the values are given relatively to the force at Plymouth, considered as unity; and in the second column, relatively to the force at Plymouth, expressed by 1.375; for the purpose of exhibiting Captain Fitz-Roy's results in direct comparison with the determinations of continental observers, who have taken Paris as their basis, giving the force at Paris the arbitrary expression of 1.3482. I have taken the ratio of the force at Plymouth to that at Paris to be as 1.375 to 1.348, which I believe will prove a very near approximation; it is that which results from Captain Fitz-Roy's observations at Plymouth, in October 1836 (page 17), and mine, at Tortington, in Sussex, in June 1837 (page 10): the dip at Tortington, at the period in question being 68° 57′, and the intensity, compared with Paris, through the medium of London, 1.368.

3. *Captain King's Observations of Dip and Intensity.*

Captain King, having hitherto made known his observations with the same cylinder in the years 1826 to 1830 only by communicating them to M. Hansteen, from whom he received the apparatus, has now given permission to Captain Fitz-Roy to publish them with his own. I have already noticed the great loss of magnetism which took place in this cylinder during Captain King's voyage, and the care with which that officer availed himself of every opportunity of ascertaining, by direct observation, the proportion of the loss sustained in separate portions of the voyage. There are twelve stations of observation on the east and west coasts of South America, besides three stations in ports of the Atlantic on the outward voyage. By the practice of repeating observations at the same station at distant intervals, the South American stations are so linked together and connected, that by adopting a method similar to that used in determining longitudes by means of chronometers, we may compute the intensity at all the South American stations referred to and dependent on the force at Rio de Janeiro; regarding Rio in the same light as a first meridian is considered in determinations of longitude. We may then make Rio the means of connecting the whole series with Europe; for which it is remarkably well suited, the intensity there having been determined, independently of Captain King, by four observers of different nations, whose results are extremely accordant.

The dip observations of Captain King were communicated, in occasional correspondence during the voyage, to M. Hansteen, who computed them by Mayer's formula, and arranged them in a table, of which a copy was given by Captain King to Captain Fitz-Roy, and is printed in the next page. At some of the stations Captain Fitz-Roy also observed the dip in the subsequent voyage, and, as will be seen, the results of the two observers sometimes differ considerably. This may have been caused, either by instrumental or other error of observation, or by actual differences of dip existing in different localities at the same station.

© The Complete Work of Charles Darwin Online

At Rio de Janeiro, which was the first station observed at in South America, the cylinder was vibrated in August 1826, September 1827, and December 1828; in the intervals between these dates are comprised the greater part of the observations on the east side of South America. There is no direct observation at Rio subsequently to December 1828; but we are enabled to supply the time of vibration, which would have been observed had the cylinder been employed at Rio on June 1, 1830, in the following manner. We have seen that on the 15th September 1827 the time of vibration was observed at Rio; on the 18th December following it was observed at Monte Video. These observations give the intensity at Monte Video relatively to that at Rio, subject to whatever change of magnetism the cylinder may have undergone in the interval of three months. This comparison was repeated in the following year, on Captain King's return from Monte Video to Rio, the interval being nearly of the same duration, and the order of the experiment reversed, the passage being in this instance from Monte Video to Rio, it having been before from Rio to Monte Video. On the supposition of an uniform, or nearly uniform rate of change in the cylinder, the errors arising therefrom during the two passages would be of opposite kinds, and should compensate each other in a mean of the two comparisons. Calling the force at Rio unity, these comparisons give its value at Monte Video respectively as follows, namely,

September and December 1827 ...	1·197	} Mean 1·202.
October and December 1828 ...	1·207	

On the 1st of June 1830, being then on his return from the west coast of South America, and on the eve of sailing for England, Captain King again observed the time of vibration of the cylinder at Monte Video; whence, through the preceding comparison, we obtain the time of vibration at Rio, which should belong to the same date. We have thus a fourth date at Rio, which, added to those enumerated above, will include the whole of the South American stations; and we have only to distribute in each interval the loss of magnetism which the observations shew to have taken place from one date to the next, in the manner which may appear most suitable. There is no very obvious indication that the loss was other than gradual; and by considering it uniform in each separate

© The Complete Work of Charles Darwin Online

interval, the results are found extremely accordant at several other stations at which observations were repeated at distant intervals.

In the first of the subjoined tables are given the times of vibration at Rio at the four periods referred to; and the corresponding times as a dipping needle. In its three last columns are shewn,—the number of days comprised in each interval,—the increase in the time of vibration owing to the loss of magnetism,—and the resulting daily correction, on the supposition in each case of the loss having been uniform in the interval during which it occurred.

The second table contains the corrected times of horizontal vibration at each of the South American stations, at the dates respectively inserted,—the corresponding times as a dipping needle,—the times of vibration as a dipping needle at Rio de Janeiro at the same dates, derived from the observations in the first table,—and the resulting intensity at each station relatively to unity at Rio. Thus far the results are derived from Captain King's observations, unmixed with those of any other observer: but in order to bring Captain King's series into connexion with the general body of results of other observers, the values of his intensities are expressed in the final column in terms of the scale in common use, in which the force at Paris = 1,348, and at Rio de Janeiro 0,884; the latter being the mean of four independent determinations by the following observers, namely,

1817 and 1820	Freycinet	0,890	0,884
1827.....	Lütke	0,886	
1830.....	Erman	0,879	
1836.....	Fitz-Roy	0,878	

Port St. Elena is not included in this table, as no dip was observed there, and the total intensity consequently cannot be computed. The three stations, Madeira, Teneriffe, and Port Praya, at which the cylinder was vibrated in the outward voyage, are also without dips observed by Captain King. The deficiency at Port Praya has been supplied from Captain Fitz-Roy's observations and my own, both having been made at the same place at which Captain King's intensity was observed,—Captain Fitz-Roy's at a later, and mine at an earlier date. At Madeira also the dip has been supplied from my observations, which were made in the British consul's garden at Funchal, where Captain King's cylinder was vibrated. I have

© The Complete Work of Charles Darwin Online

deducted, from my determination of the dip, 12′ for the probable change between 1822 and 1826. At Teneriffe the dip has been frequently observed; but the values assigned by different observers vary so much as to indicate a more than usual frequency of local disturbance, which might also be expected from the geological character of that island. It would be unsafe therefore to employ any dip for that station but one which was certainly obtained at the same spot at which the horizontal intensity was observed.

The dates of the observations at these three stations fall between the observations at Greenwich in March 1826, and those at Rio de Janeiro in August of the same year. Having the intensity at Greenwich = 1,372 and at Rio = 0,884, and the dip at Greenwich 69° 52′, and at Rio 14° 00, we have the time of vibration of Captain King's cylinder as a dipping needle at Rio at the respective dates as follows, namely,

March 1826	536,2.
August 1826	537,0.

It appears therefore that but a very slight change took place in the magnetism of the cylinder during the outward voyage, and we may take 536,6 as the time of vibration at Rio, corresponding to the dates of the intermediate observations; and this is done in the table for Madeira and Port Praya.

General Remarks.

1. *Variation.*

Captain Fitz-Roy's observations are so well distributed over the southern hemisphere, that a good view of the changes which the variation is undergoing throughout its meridians may be obtained by comparing his determinations with those of earlier observers at the same stations. The following table has been formed for the purpose of exhibiting such a comparison at all those stations where materials for it exist; and I may here remark how much such comparisons are facilitated by the valuable collection of early observations contained in the Appendix to the Magnetismus der Erde.

Cape of Good Hope.

Observer.	Date.	Variation.
		° ′
Davis	1605	0. 30 E.
Keeling	1609	0. 12 W.
Leydecker ..	1675	8. 28 W.
Mathews ..	1724	16. 22 W.
La Caille ..	1752	19. 0 W.
Wales	1772	20. 26 W.
Wales	1775	21. 14 W.
Bligh	1788	23. 16 W.

Fitz-Roy	1836	11. 18W.

We may derive from the facts in the above table the following general and easily remembered conclusion in regard to the changes of the variation in the southern hemisphere; namely, that taking for our point of departure the meridian of 65° west in South America, we find that at all the stations east of that meridian to the Cape of Good Hope inclusive, the north pole of the needle has moved towards the west; and that all the stations west of the same meridian to Mauritius inclusive, the north pole of the needle has moved towards the east.

An almost equally simple generalization may be drawn in respect to the changes of situation of the lines of equal variation in the southern hemisphere: but here it must be supposed either that the reader is thoroughly familiar with the general arrangement of these lines, or that he has a map of them before him. He will find such a map of the variation lines in 1787 in the Fifth Report of the British Association; but any other map, corresponding to any epoch within the last hundred years, will equally serve the purpose. Referring to such a map, it will be seen that the lines of variation in the South Pacific, form a system of nearly concentric curves, of an oval, or pear-shaped form, the outside curves having a higher variation, which progressively diminishes to the centre. We may regard this system as comprehending the whole of the geographical space between the coast of South America and the meridian of New Zealand. Throughout this space the variation is easterly, and increases: we may consequently characterize the change in the situation of the lines of equal variation as a progressive closing-in

© The Complete Work of Charles Darwin Online

of the curves from all sides towards the centre, by which the areas severally comprehended by them become less; and the lower variations, as they successively reach the centre, disappear, and are replaced by the closing-in of those of next higher amount. The changes which have taken place at all Captain Fitz-Roy's stations comprised within the space referred to, are accordant with the systematic alteration thus described.

In all other parts of the hemisphere the lines of variation have a progressive westerly movement, and to this also Captain Fitz-Roy's observations correspond.

It follows, from what has been stated, that the lines on the western side of the concentric system in the South Pacific have an eastward movement, which presents an apparent anomaly to the general progress of the lines of variation in the southern hemisphere, which is from east to west.

Otaheite, and the Bay of Islands in New Zealand, present examples of changes in the variation corresponding to this apparent anomaly. The consistency, however, both of the movement and of the configuration of the lines of variation in this quarter, with those in other parts of the southern hemisphere, and with the general system of the magnetic phenomena, has been shewn by Mr. Hansteen in the Magnetismus der Erde, and in the Annalen der Physik, vol. xxi.

The annual amount of the change of the variation appears considerably greater at the Cape of Good Hope and Mauritius than at any other of Captain Fitz-Roy's stations, amounting to about eight minutes; shewing that the variation lines in that quarter are changing their position more rapidly than elsewhere. The north pole of the needle is moving to the west at the Cape, and to the east at Mauritius; but it will be seen, by a reference to the map, that these opposite movements are in perfect correspondence with the uniform westerly progression of the variation lines, and result from their configuration.

At the stations in the vicinity of the meridian of 65° west, the change appears to be very small.

[The variation at Ascension (13° 30′ W.) is correctly inserted in the tables: it is the only one of Captain Fitz-Roy's stations at which his observations are not accordant with those of other observers: the discordance may be occasioned by the great prevalence of local disturbances at Ascension.]

We may classify the changes which are taking place in the dip in the southern hemisphere in four divisions, characterised by an

© The Complete Work of Charles Darwin Online

alternate increase and decrease of dip. Commencing with the meridian of Greenwich, and proceeding eastwardly round the hemisphere, we may distinguish the divisions as follows, in the order of their geographical succession.

1st. South dip increasing.

		annually.			annually.
St. Helena	1754 to 1775	6,9′	Cape of Good Hope	1775 to 1836	6,6
Do.	1775 to 1836	6,5	Mauritius	1754 to 1824	1,3
Cape of Good Hope	1751 to 1775	7,2	Do.	1824 to 1836	0,8

To this division also belongs Ascension; but as the north end of the needle dips at that island, the change is *north dip diminishing*, instead of *south dip increasing*.

Ascension	1754 to 1775	..	6,3 annually.
Do.	1775 to 1836	..	7,2 ——

2d. South dip decreasing.

New Zealand	1824 to 1835	..	1,2 annually.*

3d. South dip increasing.

Otaheite	1775 to 1836	..	0,5 annually.

4th. South dip decreasing.

		annually.			annually.
Lima and Callao ..	1710 to 1799	0,4′	Tierra del Fuego	1774 to 1828	8,0
Do.	1799 to 1835	4,9	Falkland Islands	1820 to 1834	8,2
Valparaiso	1794 to 1835	10,0	St^{a} Catharina ..	1822 to 1827	8,4
Concepçion	1710 to 1786	3,7	Rio de Janeiro ..	1751 to 1817	4,8
Do.	1786 to 1835	8,3	Do.	1817 to 1832	4,3

In the 2d and 3d divisions the annual change is small; in the 1st and 4th considerably greater. It is greatest at the southern station in South America; the observations at Valparaiso, Concepçion, Tierra del Fuego, and the Falkland Islands, concur in shewing it to exceed 8′. The observations at Ascension, St. Helena, and the Cape of Good Hope, concur in shewing an annual change in that quarter of the 1st division exceeding 6′.

As the south dip decreases in South America, and increases in Africa, it is obvious that somewhere intermediately the dip must be stationary. Between Africa and New Zealand, for the same reason, there must be a second locality so characterised. Between New Zealand and Otaheite, a third; and between Otaheite and the west coast of South America, a fourth. Captain Fitz-Roy has

* This is derived from the observations of Captains Duperrey and Fitz-Roy at the Bay of Islands, in Lat. 35°. 16′. The interval is short; but the indication receives confirmation from the observations of Captains Cook and Vancouver at Dusky Bay, New Zealand, in Lat. 45°. 47′.

Cook	1773	..	70°. 06′	1′.4 annual decrease.
Vancouver ..	1791	..	69. 43	

© The Complete Work of Charles Darwin Online

stations in the second of these localities only, between Africa and New Zealand. At Hobart Town, Sydney, and King George Sound, there appears to have been little or no change in the dip since the commencement of the present century.

The arrangement of the changes of dip in the southern hemisphere in four divisions, characterised by an alternate increase and decrease of dip, is in correspondence with the *double flexure* of the lines of dip; and is a consequence of the western motion of the two southern magnetic poles.

Careful observations made at St. Petersburgh, have shewn that the annual change of the dip in the northern hemisphere takes place altogether between the months of May and December; there being in fact a small movement in an opposite direction between December and May. This fact is of great interest in its bearing on the study of the causes of the magnetic phenomena. We have as yet no corresponding knowledge in regard to the southern hemisphere. The magnitude of the annual change which Captain Fitz-Roy's observations show is now taking place at the Cape of Good Hope, is deserving of attention in this respect. A large amount of annual change is obviously highly favourable for a determination of all the circumstances belonging to it; and its existence at the Cape, where there is already a fixed observatory, points to that station as most eligible for this investigation.

The observations at Ascension shew that the epoch is fast approaching when the needle will pass from north to south dip at that island: it is extremely desirable that the period at which this change takes place should be determined with as much precision as possible.

III. *Intensity.*

I have discussed in the Seventh Report of the British Association, the very important inferences in regard to the general distribution of magnetism in the southern hemisphere, afforded by Captains King and Fitz-Roy's most valuable series of intensity observations; but no inferences in regard to the *changes* which this phenomenon may be supposed to undergo can be drawn, as has been done in the cases of the variation and dip, because we possess no observations of the intensity made at a sufficiently early period to afford good materials for such a comparison.

EDWARD SABINE.

© The Complete Work of Charles Darwin Online

Catalogue of the more interesting Specimens of Natural History that were collected during the voyage.

MAMMALIA.

1. Mustela Zorilla. Desm:*

The skunk. This animal was found abundantly on the coast of Patagonia, between Monte Video and Cape Gregory, at the eastern entrance of the Strait of Magalhaens. It appeared to be the same species throughout the whole extent of the coast.—Mus. Zool. Soc.

2. Mustela lutris.—Lin.

Lutra marina, Steller. Erxleb. Harlau; *Enhydra marina*, Fleming.

The sea otter exists, but not very plentifully, on the coast of Tierra del Fuego; we saw very few. The Fuegian Indians hunt them with dogs which are trained for the purpose.—Museum Zool. Soc.

3. Canis.

The dogs belonging to the Fuegian Indians are certainly of the domesticated kind, originally obtained, probably, from the Spanish settlements at Buenos Ayres; generally they resemble the Esquimaux breed, but are much more diminutive in size.

4. Canis Vulpes.

Two if not three distinct species of the fox were brought home; one, of a small size, was thought to be a novelty; the other, perhaps, was only remarkable for its large size. Mr. Vigors thought the small one was quite new; the last is perhaps *C. cinereo argenteus*. —Museum of Zool. Soc.

5. Felis puma.

Several were seen: a skeleton was found on the shores of the Strait, supposed to be one of the above species.

* Or *Mephitis Americana?*

© The Complete Work of Charles Darwin Online

6. Felis pajeros.—Desm. E. M. p. 231.

Chat pampa, D'Azara, 1. 179.

A variety of this species was given to me, by the Patagonian Indians, that had been recently killed; the skin was preserved, and is now in the museum of the Zoological Society. The following is the description of my specimen:—

The prevailing colour is a yellowish grey, deeper above, and gradually blending into the colour of the belly, chin, neck, inner part of the legs, the region of the anus, and below the root of the tail, which are white; the under part of the neck and belly also are spotted with black, disposed in transverse bands; the fore arms have three similar transverse bands, and the thighs four encircling the legs; ears white inside and tipped black; eyes dark blue, eyelids whitish, corner of the eyes black, particularly at the anterior or inner angle; claws whitish, and paws black; whiskers white, and some long white hairs over the eyes; the canine teeth are very acute, and have the longitudinal grooves or angles deeply marked.

	Inches.
Length of the body from the extremity of the nose to the root of the tail	29
Length of tail	$11\frac{3}{4}$
Ditto head	6
Breadth of head between the ears	$2\frac{7}{8}$
Height at the shoulder	12

7. Otaria jubata.—Desm. E. M. No. 380.

The sea lion of Anson and other voyagers; numerous in the eastern entrance of the Strait, and particularly at Port San Julian and the neighbourhood of Port Desire.

8. Otaria flavescens.—Desm: E. M. 250.

A young male was found on the beach, near Port Famine, that had been recently wounded by the Indians, and had crawled on shore to die.

9. Ctenomys Magellanicus. n. s.—Bennet.

This little animal possesses fur as soft as the chinchilla. It abounds in the neighbourhood of Cape Gregory, at the eastern entrance of the Strait of Magalhaens, and burrows under the

© The Complete Work of Charles Darwin Online

ground, which is so much undermined by them that it gives way at almost every step. It is a timid little fellow, feeds upon grass, and is eaten by the Patagonian Indians.—See Bennet in the Proceedings of the Zool. Soc. Dec. 22, 1835. A specimen is preserved in the Museum.

10. KERODA KINGII. n. s.

See Bennet ut supra, in Museum of Zool. Soc.

11. CAVIA CUTLERI, n. s. nob.—See Bennet ut supra.

This specimen is in the collection of the Society. It was known in the voyage by the name of the Peruvian cavy: it was presented to one of the officers of the Beagle by an American sailing master, Mr. Cutler, of Stonington, U.S., a very intelligent person, to whom we are much indebted for information. The name which I have proposed for it is in recollection of the benefit we derived from his experience and knowledge of the intricate navigation of the south-western coast of Patagonia, which was freely imparted to us on several occasions.—See Bennet in Proceedings of Zool. Soc. ut supra.

12. DASYPROCTA PATACHONICA.—Desm. E. M. 358.

I regret very much that the only specimen obtained was not preserved. Desmaret seems to suspect that it differs sufficiently in its dentition from the agouti to constitute a new genus, for which he has proposed the name *Dolichotis*.—See E. M. 359.

13. DASYPUS MINUTUS.—Desm.

Procured at Port S^{ta} Elena, and corresponds exactly with the description of the above species. It is the Tatou pichiy, or Tatou septième of D'Azara.

14. AUCHENIA GLAMA.—Desm. E. M. 655.

A living female guanaco was brought home in the Adventure, and placed in the garden of the Zoological Society. The guanaco inhabits Patagonia from Buenos Ayres to the Strait of Magalhaens: we also found it on King Charles Foreland, the eastern island of Tierra del Fuego, and on Navarin Island, at the north side of Nassau Bay, in the vicinity of Cape Horn.

3. Polyborus vulgaris.—*Falco Brasiliensis.* Latham.
Caraçara Eagle.
Strait of Magalhaens.

4. Miloago ochrocephala.—Spix. Young birds.
Strait of Magalhaens.

5. Haliætus erythronotus.—Nob. in Zool. Journal, iii. 424.

Hal. capite alisque fusco-griseis; dorso scapularibusque rufis, corpore caudáque subtus albis, fasciis fuscis gracilibus leviter notatis, hâc fasciâ latâ prope apicem nigrâ.

The total length of the bird from the *apex* of the bill to the extremity of the tail is 2 feet; of the bill from the *rictus* to the *apex* 2 inches; from the cere 1 inch; of the wing, from the end of the carpal joint to the end of the third quill feather, 18 inches; of the tail 10½ inches; of the *tarsus* three inches.
Strait of Magalhaens.

6. Falco sparoerius.—Latham.
Strait of Magalhaens.

7. Falco peregrinus?
Strait of Magalhaens.

8. Polyborus Brasiliensis.
Polyborus Novæ Zealandiæ.
Falco Novæ Zealandiæ of Latham.

9. Circus histrionicus.—Nob. in Zool. Journal, iii. 425.
Falco histrionicus, Quoy and Gaimard.

Circo cineraceus uropygio corporeque subtus albis: hoc fasciis frequentibus rufis notato.

The length from the *apex* of the bill to that of the tail is 18

© The Complete Work of Charles Darwin Online

inches; bill 1 inch; wing, from the carpal joint to the end of the third quill feather, 13½ inches; tail 9 inches; *tarsus* 2½ inches.

Strait of Magalhaens.

10. STRIX RUFIPES.—Nob. in Zool. Journ., iii. 426.

Str. saturate brunnea, albido fulvoque maculata fasciataque femorum tarsorumque plumis rufis.

The total length is 15½ inches; that of the bill 1 inch; of the wing, from the *carpus* to the end of the fourth quill feather, 11 inches; of the tail 7½ inches; of the *tarsi* 2⅜.

11. STRIX NANA.—Nob. in Zoological Journal iii. 427.

Str. fusco brunnea, fronte nuchâ alisque albo-notatis, gulâ albâ, caudâ fasciis frequentibus rufis notatâ.

The total length is 5⅘ inches; of the bill ½ inch; of the wing, from the *carpal* joint to the extremity of the fourth quill feather, 3¾ inches; of the tail 2¾ inches; of the *tarsi* ⅞.

N.B.—Three other species of this genus *Spix* are in the collection which appear to be new.

12. HIRUNDO.—Sp.*

13. HIRUNDO.—Sp.*

14. HIRUNDO.—Sp.*

* Three distinct species of swallow, very much resembling the British species,—Hir. *rustica, urbica*, and *riparia*.

Strait of Magalhaens.

15. TURDUS MAGELLANICUS.—Nob. in Proceedings of Zool. Soc.

Turd. corpore supra grisescenti olivaceo, subtus pallidè rufescenti, capite supra, remigibus, caudâque fusco-atris gulâ-alba, fusco-atro lineatâ.

Strait of Magalhaens.

16. SYNALLAXIS ANTHOIDES.—Nob. in Proceedings of Zool. Soc.

Syn. supra brunnea plumis in medio fusco latè striatis, tectricibus alarum superioribus rufo tinctis subtus pallidè cinerea; rectricibus lateralibus ad marginem externum, fasciâque alarum, rufis. Statura. Syn. Spinicaudæ.

Strait of Magalhaens.

17. SILVIA SPINICAUDÆ.—Latham.

© The Complete Work of Charles Darwin Online

18. SILVIA DORSALIS.—Nob. in Zool. Journ. iii. 428.

Syl. nigra, dorso scapularibusque rufis, remigibus rectricibusque fuscis.

The length from the end of the bill to that of the tail is $4\frac{1}{2}$ inches.

19. SILVIA OBSCURA.—Nob. in Zool. Journ. iii. 429.

Syl. corpore unicolore fusco-nigro, alis brevibus rotundatis caudâ brevi, pedibus elongatis, fortibus pallidis.

The length from the *apex* of the bill to that of the tail is $4\frac{1}{4}$ inches; of the wing, from the carpal joint to the end of the fourth quill feather, $1\frac{7}{8}$; of the tail $1\frac{1}{4}$; of the *tarsi* $\frac{3}{4}$.

20. TROGLODYTES. Fursa, Veillot.

21. FRINGILLA.—(Several species, probably new.)

22. STURNUS MILITARIS.—Lin.
MOTACILLA PATACHONICA.—Lin.
Patagonian warbler of Dixon's voyage.

23. STURNUS.—Sp. (black)? Leistes sp. Vigors.

24. DENDROCOLAPTES ALBO-GULARIS.
Nob. in Proceedings of Zool. Soc.

Dend. corpore supra, abdominisque lateribus, rufo brunneis; remigibus secundariis, dorso imo, caudâque rufis; mandibulâ inferiori ad basim, gulâ, jugulo, pectore, abdomineque medio, albis, hujus plumis brunneo ad apicem marginatis; rostro sursum recurvo.

Length $6\frac{4}{10}$ inches.—Strait of Magalhaens.

25. PSITTACUS SMARAGDIMIS.—Gmel.

26. PSITTACARA LEPTORHYNCA.
Nob. in Proceedings of Zool. Soc.

Psitt. viridis: fronte, strigâ per oculos, caudâque rufis: capite nigro, abdomine imo rufo, variegatis; mandibulâ superiori elongatâ, gracillimâ.

Staturâ.—*Psitt. Lichtensteinii æqualis.*
Habitat in insulâ Chiloe.

27. PICUS MAGELLANICUS.—Nob. in Zool. Journ. iii. 430.

Pic. niger, capite cristato colloque coccineis, remigibus albo notatis.
Fœm. *Capite cristato nigro, fronte mentoque coccineis.*

© The Complete Work of Charles Darwin Online

The length of the bird from the tip of the bill to the extremity of the tail is 17 inches; of the bill $2\frac{1}{2}$; of the wing, from the carpal joint to the fourth quill feather, $8\frac{3}{4}$; of the tail $7\frac{1}{2}$; of the *tarsi* $1\frac{1}{8}$; of the external hind toe, the nail included, 2.

Strait of Magalhaens.

28. Picus melanocephalus.—Nob. in Proceedings of Zool. Soc.

Pic. capite corporeque supra nigris, hoc albo maculato; pectore abdomineque albis, illo albo lineato, hoc albo fasciato.

Length 6 or 7 inches.—Strait of Magalhaens and Chiloe.

29. Mellisuga Kingii.—Vigors in Zool. Journal, iii. 432.

Ornismya sephanoides.—Lesson et Garn.

Mell. supra metallicè viridis, infra alba viridi variegata, vertice splendide rubeo, rectricibus acuminatis.

This bird was found in the Strait of Magalhaens, so late in the year as the month of May, when it was seen flying in a snow-squall. It seemed regardless of the cold, and so long as the *fuchsia* and *veronica* were in blossom, so long did this hitherto supposed to be delicate little bird, remain to cull their sweets, or rather to prey upon the insects which buried themselves in the flowers; for, innocent as it seems, it is insectivorous. The bird was long known to naturalists, but was not described until November 1827, when Mr. Vigors described it, from a specimen transmitted by me to the Museum of the Zoological Society. It was found by MM. Lesson and Garnot, on the coast of Chile, where we also subsequently found it. M. Lesson described it in his useful little Manuel d'Ornithologie, ii. p. 80, as above, and has given a detailed account. Had not Mr. Vigors previously described it, I should have had pleasure in referring it to their description, and their excellent plate, in Lesson's Monograph upon the Trochilidæ.

30. Trochilus Fernandensis.—Nob. in Proceedings Zool. Soc.

Troch. ferrugineo-rufus; capitis vertice splendenti-coccineo; remigibus fuscis.

Length, 5 inches.

Island of Juan Fernandez, South Pacific.

31. Trochilus Stokesii.—Nob. in Proceedings of Zool. Soc.

Troch. corpore supra viridi-splendente, subtus albo viridi-guttato; capite supra, guttisque confertis gulæ lazulino-splendentibus;

© The Complete Work of Charles Darwin Online

remigibus fusco-atris ; remigum omnium, mediis exceptis, pogoniis internis albis.

Length 5 inches.

Island of Juan Fernandez.

HYLACTES.—*Novum genus. Megapodio affine.*

Characteres Generici.

Rostrum subelongatum, subtenue, apice subemarginato: naribus basalibus, longitudinalibus, membraná subtumescenti pilisque per mediam longitudinem tectâ.

Alæ, brevissimæ, rotundatæ ; remige 5ta longissimâ.

Cauda, subelongata, gradata.

Pedes, fortes : tarsis subelongatis, in fronte scutellatis ; digitis unguibusque elongatis, hic fortioribus subcompressis ; halluce fortissimo, incumbente.

This genus appears to have some resemblance to MM. Quoy and Gaimard's genus *Megapodius :* but no specimen of it being in this country, and my bird differing in essential points from its generic characters, particularly in the length and form of the wings, which in my bird are rounded, and so short as not to reach beyond the base of the tail, I have formed it into a new genus, for which the term Hylactes (from its note, which very much resembles the sharp bark of a dog) has been selected.

32. HYLACTES TARNII.—Nob. in Proceedings of Zool. Soc.

Hyl. saturate fusco-brunneus ; fronte, dorso, abdomineque rufis, hoc fusco fasciato.

At Chiloé and Port Otway, in the Gulf of Peñas.

The specific name I have selected is in compliment to Mr. John Tarn, surgeon of the Adventure, to whose attention, in procuring and preserving numerous specimens in ornithology, I am greatly indebted.

33. STRUTHEO RHEA.—Lin. (223.)

The American ostrich. Maldonado.

34. COLUMBA FITZ ROYII.—Nob. in Proceedings of Zool. Soc.

Col. rinacea ; alis, dorso imo, caudâque plumbeis, hujus fasciâ remigibusque atris : nuchæ plumis viridi-splendentibus ; fascia occipitali albâ.

In the woods of Chiloé.

Dedicated to Captain Robert Fitz Roy, who succeeded to the command of H.M.S. Beagle upon the death of Captain Stokes.

© The Complete Work of Charles Darwin Online

35. COLUMBA MERIDIONALIS.—Nob. in Zool. Journal, iv. 92.

Col. brunnescenti-plumbea, subtus rufescens; colli lateribus purpureo nitore splendentibus, genis pennisque secundariis nigro maculatis, rectricibus apice griseo fasciâque sub-apicali nigrâ.

Length, 9½ inches.

36. ARDEA.—Sp. One of the night bitterns.

37. ARDEA MAJOR.—Bonat., E. M. 1148.

Port Otway, Gulf of Peñas.

38. IBIS MELANOPIS.—Bonat., E. M. 1148.

Port San Julian.

In the Ency. Méth. the length of the bird is stated to be 21 inches, but in the Dict. d'Histoire Naturelle 27 inches is given, which is correct.

39. TOTAMUS FUSCUS?

40. SCOLOPAX MAGELLANICUS.—Nob. in Zool. Jour. iv. 93.

Scol. supra brunneus, rufo fulvo nigroque maculatus undulatusque; abdomine medio albo; pectore brunneo rufoque sparso; tarsis brevibus.

The length of the bird from the front to the end of the tail is 8½ inches; of the beak 2½; of the wing, from the carpal joint to the end of the quill feather, 5; of the tail 2½; and of the *tarsi* $1\frac{1}{16}$.

Strait of Magalhaens.

41. RHYNCHÆA OCCIDENTALIS.—Nob. in Zool. Jour. iv. 94.

Rhync. supra brunnea, capite summo pectore alisque saturatioribus, fulvo undulata strigataque; abdomine, maculâ utrinque pectorali, maculisque alarum, albis, stringâ frontali brunneâ.

The length of the bird from the forehead to the end of the tail is seven inches; of the bill $1\frac{3}{8}$; of the wing from the carpal joint to the extremity of the first quill feather, 4¼; of the *tarsus* $1\frac{5}{16}$; of the tail 1¾.

Strait of Magalhaens.

This bird may be considered as one of the most interesting acquisitions made in our voyage. The singular and strongly marked genus has been hitherto considered peculiar to the Old World; and two species only having been discovered, an additional species from the New World is an important accession to science. The form of our Magellanic bird accords accurately with that of the Old World species, the bill being distinguished chiefly by its infe-

© The Complete Work of Charles Darwin Online

rior length. The general appearance of the plumage also is similar, although it possesses sufficiently distinctive characters to authorize this species being separated from the other.

42. Rallus Setosus.—Nob. in Zool. Journ. iv. 94.

Rall. supra brunneus, dorso alisque nigro notatis, subtas plumbeus; remigibus primariis rectricibusque fuscis, his saturatioribus; fronte setoso.

The length of the bird from the forehead to the extremity of the tail is 10 inches; of the bill $1\frac{5}{16}$; of the wing, from the carpal joint to the end of the second quill feather, $4\frac{7}{8}$; of the tail 3; of the *tarsus* $1\frac{5}{8}$.

43. Rallus antarcticus. Nob. in Zool. Jour. iv. 95.

Rall. supra brunneus, nigro strigatus; subtus plumbeus, femorum tectricibus crissoque atris, albo-fasciatis.

The length of the body is $7\frac{1}{2}$ inches; of the bill $1\frac{1}{4}$; of the wing, from the carpal joint to the end of the second quill feather, $3\frac{3}{4}$; of the tail, $1\frac{3}{4}$; of the *tarsus* $1\frac{5}{16}$.

44. Fulica chloropoïdes.—Nob. in Zool. Journ. iv. 95.

Ful. capite, coll. superiore, caudâque atris; corpore reliquo atro-fusco, crisso albo.

The length of the body is 15 inches; of the bill $1\frac{1}{4}$; of the wing, from the carpal joint to the extremity of the second quill feather, $6\frac{1}{2}$; of the tail 3; of the *tarsi* 2.

45. Fulica gallinuloïdes.—Nob. in Zool. Jour. iv. 96.

Ful. atro-fusca; dorso saturatiore, capite atro, gulâ albo-notatâ crisso albo, rostro angusto, in frontem parum extendente.

44. Chionis alba.—Forster.

Seen at Cape Horn, and at sea, four hundred miles from the nearest land. Captain Foster, of H.M.S. Chanticleer, saw some at South Shetland.

47. Hœmatgpus palliatus.—Temminck.

Strait of Magalhaens.

48. Hœmatopus leucopus.—Gam.

Strait of Magalhaens.

The above two species of Hœmatopus were frequently seen on

the shores of the Strait; the latter appears to answer the description of M. Bougainville. See Lesson, Manuel d'Ornithologie, ii. 30.

49. CHARADRIUS PLUVIALIS.—Var.

Not to be distinguished from the golden plover.

50. CHARADRIUS RUBECOLA.—Nob. in Zool. Jour. iv. 96.

Char. capite summo, dorso, alis, caudâque supra grisescenti-fuscis, thorace nuchâque pallide griseis; pectore rufo, collari subpectorali nigro; fronte, striga superciliari, abdomine, crisso, rectricibusque lateralibus albis.

The length of the body is $8\frac{2}{3}$ inches; of the bill $\frac{3}{4}$; of the wing, from the carpal joint to the end of the first quill feather, $5\frac{5}{8}$; of the tail 3; of the *tarsi* $1\frac{1}{4}$.

Mountains of the Strait of Magalhaens 2,000 feet above the level of the sea.

51. VANELLUS CAYANENSIS.—Ency. Méth. 1073. pl. 57, fig. 2.

Maldonado, River Plate.

52. PODICEPS.—Sp.

Very much resembling P. minor.

53. PODICEPS.—Sp.

54. PODICEPS LEUCOPTERUS.—Nob. in Zool. Jour. iv. 101.

Pod. capite colloque superioribus nigris, gulâ grisco-albidâ, collo inferiore rufo; dorso fusco-atro; abdomine strigâque latâ alarum albis.

The length of the body is 20 inches; of the bill 3; of the wing, from the carpal joint to the *apex* of the second quill feather, $7\frac{1}{4}$; of the *tarsi* 2.

55. APTENODYTES MAGELLANICA.—E. Méth.

56. APTENODYTES CHRYSOCOME. ?—A young bird.

57. PHALACROCORAX NIGER.—Nob. in Zool. Journal, iv. 101.

Phal. intensè niger, circulo angusto ab oculis descendente, mandibulasque circumcingente, paucisque genarum capitisque plumis albis.

The length of the bird is 31 inches; of the bill $3\frac{3}{8}$; of the wing, from the carpal joint to the extremity of the third quill fea-

© The Complete Work of Charles Darwin Online

ther, 11; of the tail $7\frac{1}{2}$; of the *tarsi* 2. The irides a bright blue green; the pupils black.

This bird is probably D'Azara's black Zaramagullon (No. 432 of his Birds of Paraguay), but it has not hitherto been described.

58. PHALACROCORAX ATRICEPS.—Nob. in Zool. Journal, iv. 102.

Phal. capite supra corporeque superiore atris, inferiore albo; rostro pedibusque flavescentibus, rectricibus duodecim.

The dimensions are nearly the same as those of the last bird, except those of the bill, which is a quarter of an inch longer.

59. PHALACROCORAX CIRRIGER.

Phal. supra fusco-griseus, subtus albidus; gulâ, cirroque longitudinali per collum utrinque descendente, albis; rostro pedibusque rubris; rectricibus quatuordecim.

The length of the body is 26 inches; of the bill $3\frac{3}{16}$; of the wing, from the carpal joint to the extremity of third quill feather, 10; of the tail 6; of the *tarsi* $1\frac{3}{4}$.

60. PHALACROCORAX IMPERIALIS.—Nob. in Proceedings of Zoological Society.

Phal. capite cristato, collo posteriori, corporeque supra intense purpureis; alis scapularibusque viridi atris; remigibus rectricibusque duodecim fusco-atris; corpore subtus, fasciâ alarum, maculâque dorsi medii sericeo-albis; rostro nigro; pedibus flavescentibus.

Statura.—Phal. carbonis.

Hab.—Interior Sounds of Western Patagonia.

61. PHALACROCORAX SARMIENTONUS.

Phal. capite, collo, dorsoque imo atro-purpureis; pectore abdomineque albis; dorso superiori, scapularibus, alisque viridi-atris; remigibus rectricibusque duodecim atris; gulâ, genis, femorumque tectricibus superioribus albo-notatis; rostro nigro; pedibus flavescentibus.

remigibus, rectricibus duodecim, rostroque sub-brevi atris: pedibus flavescentibus.

Staturâ paulo minor præcedentibus duobus.

63. LARUS HÆMATORHYNCHUS.—Nob. in Zool. Journ. iv. 103.

Lar. corpore plumbeo-griseo, dorso medio alisque nigris, his albo notatis; rostro pedibusque sanguineis.

The length of the bird is 18 inches; of the bill 2; of the wing, from the carpal joint to the end of the first quill feather, 13; of the tail 6; of the *tarsi* 2. Irides green silvery colour, pupil dark.

64. LARUS FUSCUS?

65. LARUS RIDIBUNDUS?

66. LESTRIS CATARRHOCTES?

67. PROCELLARIA GIGANTEA. A young bird.

68. PROCELLARIA CAPENSIS.

This beautiful, but well-known petrel, was, of course, our constant companion on all occasions of our being at sea, and was particularly numerous off the entrance to the river Plata, feeding probably upon the exuviæ that drift out with the current. One being taken with the hook, was killed, and in its entrails several small fragments of granite were found mixed with the half-digested food. A remarkable instance of the natural habits of this bird has lately come to my knowledge, which deserves to be recorded. The late Mr. George Fairfowl, surgeon R.N., on his return from New South Wales, in the year 1831, caught one of these birds, and let it go, with a ribbon tied round the body, by which it was easily distinguished; the bird was thereby observed to follow the ship, from day to day, for the space of 5,000 miles.

69. PROCELLARIA BERARDI.

70. PROCELLARIA WILSONII.—Prince of Musignano.
Thalassidroma Wilsonnii—Vigors.

71. DIOMEDEA EXULANS.

72. CYGNUS ANATOÏDES.

Cygn. albus, remigibus primariis ad apicem nigris; rostro pedibusque rubris, illo lato, subdepresso, tuberculo nullo.

© The Complete Work of Charles Darwin Online

Interior Sounds on the west coast of Patagonia.

Molina describes a Chilian duck, *anas coscoroba*, thus: *A. rostro extremo dilatato rotundato; corpore albo;* but I do not think it can be the same as mine, or he would have noticed its red feet and bill. It certainly is not *A. candidus*, of Viellot; the *ganso blanco* of D'Azara, which the author of the article in the Dict. d'Hist. Nat. xxiii. supposes to be the one and the same with *A. coscoroba*. Molina gives but a short description of that bird.

73. Anser inornatus.—Nob. in Proceedings of Zool. Society.

Mas. Ans. albus: dorso inferiori, caudâ, fasciis nuchæ dorsique superioris femorumque tectricum, pteromatibus, remigibusque atris: rostro nigro, pedibus flavescentibus. Fœm. *Capite colloque canis; dorso superiori corporeque inferiori albis, nigro confertim fasciatis; dorso imo remigibus, rectricibusque nigris; ptilis speculoque albis; tarsis subelongatis.*

Strait of Magalhaens.

SHELLS.

Description of the CIRRHIPEDA, CONCHIFERA, and MOLLUSCA, in a Collection formed by the Officers of H.M.S. Adventure and Beagle, employed between the years 1826 and 1830 in surveying the Southern Coasts of South America, including the Strait of Magalhaens and the coast of Tierra del Fuego. By Captain Phillip P. King, R.N., F.R.S., &c., assisted by W. J. Broderip, Esq., F.R.S., &c. (From the Zoological Journal.)

The testacea, of which the following paper is a descriptive list, were principally collected upon the coast of South America; and, upon my arrival in England, were submitted to the examination of Mr. George Sowerby; who very obligingly selected the undescribed species from the collection which had been formed under my superintendence by the Officers of H.M.S. Adventure and Beagle, employed under my command in surveying the southern coast of South America.

To these gentlemen I am greatly indebted for the unwearied assiduity which they at all times displayed, and for the extent of the collection in this, as well as in other departments of Natural History.

In the description of the species I have had the benefit of the advice and assistance of my friend Mr. Broderip; and to his knowledge of the subject, and the attention which he has devoted to my collection, I owe in a great measure the paper which I have now the satisfaction of presenting to the public through the medium of the Zoological Journal.

Upon examining my specimens, Mr. George Sowerby found that he possessed several species not in my collection. These had been obtained during the voyage, and had been purchased from some of the crew by Mr. Sowerby, who handsomely put his acquisitions into my hands for description.

---

1. BALANUS PSITTACUS.

Syn. Lepas Psittacus. Molina, 1., 223.

profundè sulcato, lineis elevatis creberrimè plicatis ; valvis posticis valdè productis, acuminatis.

Habitat ad oras Concepçionis et insulam Chiloé. *Mus. Brit., nost., Broderip, &c.*

This cirrhiped which, at Concepçion de Chile, is frequently found of a larger size than 5½ inches long and 3½ in diameter, forms a very common and highly esteemed food of the natives, by whom it is called *Pico*, from the acuminated processes of the two posterior opercular valves. The anterior and posterior opercular valves, when in contact, present some resemblance to a parrot's beak, whence Molina's name. It is also found very abundantly at Valdivia and at Calbuco, near the north end of the island of Chiloé. It occurs in large bunches, and presents somewhat of a cactus-like appearance. The parent is covered by its progeny, so that large branches are found composed of from fifty to one hundred distinct individuals, each of which becomes in its turn the foundation of another colony. One specimen in the possession of my friend W. J. Broderip, Esq., consists of a numerous group based on two large individuals. They are collected by being chopped off with a hatchet. At Concepçion, where they are found of larger size than to the southward, they are principally procured at the Island of Quiriquina, which lies across the entrance of the bay; whence they are exported in large quantities to Valparaiso and Santiago de Chile, where they are considered as a great delicacy, and indeed with some justice, for the flesh equals in richness and delicacy that of the crab, which, when boiled and eaten cold, it very much resembles.

2. Elminius Leachii.*

E. testâ albidâ, truncatâ, longitudinaliter striatâ, radiis creberrimè longitudinaliter substriatis ; operculo ad basin transversim striato, quadripartito ; long. ⅝ *; lat.* ⅜ *; poll.*

Habitat. In Museo Geo. Sowerby et nost.

3. Scalpellum papillosum.

S. pedunculo creberrimè papilloso ; testâ lævi valdè compressâ ; long. omnino 11/16 *;* 4/16 *pedunculi ; lat.* 5/16*, poll.*

* *Elminius Kingii*, Gray in Zool. Miscell. from a specimen collected during the voyage.—Ed.

© The Complete Work of Charles Darwin Online

Habitat in mare alto circa oras Patagonicas. Mus. nost., G. Sowerby.

Taken by a dredge in 40 fathom water, off the coast of South America, in latitude 44½° south, and found adhering to a Terebella.

4. Pholas Chiloensis. Molina.

P. testâ elongatâ posticè ovato-rotundatâ, costis posticis dentato-muricatis; anticè attenuatâ striis transversis posticè undato-muricatis, anticè muticis; lat. 5 : *long.* 2 ; *poll.*

Habitat ad insulam Chiloei. Mus. Brit., nost., Brod., Stokes.

Some doubt has been thrown upon the existence of this shell, notwithstanding the description of Molina. A species very nearly approaching it, if not identical, was found at Rio de Janeiro ; but as only single valves were obtained, and these were in a very imperfect state, I have not ventured to characterise it.

The soft parts of *Pholas Chiloensis* are considered very delicate by the inhabitants of the Island of Chiloé, by whom the animal is called "*Co-mes.*" They are found in great abundance at low water imbedded in the rocks near Sandy Point, at San Carlos de Chiloé.

5. Solen scalprum.

S. testâ lineari subrectâ extremitatibus subrotundatis ; cardine bidentato; long. $\frac{13}{16}$; *lat.* $3\frac{1}{16}$; *poll.*

Habitat ad Patagoniæ oras Orientales (Sea Bear Bay). *Mus. nost.*

6. Anatina elliptica.

A. testâ ellipticâ, subtenui, transversim striatâ, anticè sub-truncatâ, epidermide fuscâ, tenui ; long. $1\frac{3}{8}$; *lat.* $2\frac{3}{8}$; *poll.*

Habitat ad oras Antarcticas (New South Shetland). *Mus. Brit., nost.*

This shell was found at New South Shetland, by Lieutenant Kendall, of his Majesty's sloop, Chanticleer, by whom it was presented to me.

7. Mactra edulis.

M. testâ subtrigonâ, tumidâ, sublævi, fulvo-squalidâ, intus albâ, dentibus lateralibus prominentibus ; long. 2 ; *lat.* $2\frac{4}{8}$; *poll.*

Habitat in freto Magellanico (Port Famine). *Mus. Brit., nost., Brod.*

This shell was found in great abundance on the flat of sandy mud, which fronts the west shore of Port Famine, and proved a

© The Complete Work of Charles Darwin Online

valuable article of food to the ship's company, particularly during the winter months, when sea-birds and game were not to be procured, and the fish had deserted us. I have named it, in allusion to its affording us a grateful, as well as seasonable, supply of fresh food.

8. ERYCINA SOLENOIDES.

E. testâ subellipticâ, transversim creberrimè substriatâ, albidâ, epidermide fusco-griseâ; long. 1 *paulo minus; lat.* 2; *poll.*

Habitat in freto Magellanico (sandy mud flats of Port Famine). *Mus. Brit., nost., Brod.*

9. TELLINIDES ROSACEA.

T. testâ subtrigonâ, planulatâ, striis concentricis creberrimis; long. $\frac{6}{8}$; *lat.* $1\frac{5}{16}$; *poll.*

Habitat ad littora Brasiliæ (Santos). *Mus. nost.*

10. VENUS INFLATA.

V. testârotundatâ, concentricè substriatâ, albente, intus albâ, lunulâ obsoletâ; long. $1\frac{9}{16}$; *lat.* $1\frac{5}{8}$; *poll.*

Habitat in freto Magellanico (Port Famine). *Mus. nost.*

11. VENUS ANTIQUA.

V. testâ sub-ovali, convexiusculâ, creberrimè cancellatâ, sub-fuscâ, intus albidâ; lunulâ cordatâ; long. $2\frac{5}{8}$; *lat.* 3; *poll.*

Obs. in junioribus, striis transversis concentricis elevatis, acutis.

Habitat ad littora occidentalia Patagoniæ (Gulf of Peñas and its vicinity). *Mus. Brit., nost., Brod.*

12. ARCA ANGULATA.

A. testâ transversâ, subcordato-quadratâ, intus fusco-violascente; latere antico producto, elevato, undulatim lamellato, postico rotundato; umbonibus valdè remotis, areâ cardinali maximâ, striatâ; margine hiante; long. $1\frac{1}{8}$; *lat.* $1\frac{7}{8}$; *poll.*

Habitat ad Juan Fernandez. *Mus. nost.*

This shell was dredged up from 80 fathoms water in the offing of Cumberland Bay, at Juan Fernandez; it was attached to a branch of coral.

The hinge is broad and smooth, with distinct markings; the gape is rather wide, and the anterior part of the shell rises rather elegantly, like the stern of some Indian canoes, and in all the specimens but one, terminates in a point. The one above

© The Complete Work of Charles Darwin Online

described has a rounded form; the bows or front being rather elegantly and finely lamellated in a wavy form; the colour of the hinge is red, and the inside is generally of a brownish purple; in some it has a more yellow tinge.

13. Arca pectinoides.

A. testâ auriculatâ, cordatâ, ventricosâ, multi-costatâ, transversim striatâ, albâ, epidermide rufo nigricante, pilosâ; umbonibus sub-approximatis, incurvatis, margine crenulato; long. 1; *lat.* $1\frac{9}{8}$; *poll.*

Habitat ad Rio de Janeiro. *Mus. Brit., nost., Brod.*

14. Nucula striata.

N. testâ striatâ, subtumidâ, crassâ, sub-trigonâ, albâ; latere antico productiori, sub-rostrato; long. $\frac{9}{32}$; *lat.* $\frac{3}{8}$; *poll.*

Habitat in mari alto circa oras Patagonicas. Mus. nost.

Taken by a dredge in 40 fathoms water, 20 miles from the coast of South America, in the neighbourhood of Port Sta Elena.

15. Modiola sinuosa.

M. testâ ventricosâ, subovatâ, longitudinaliter striatâ; intus irides-cente, margine sinuoso, epidermide fuscâ; long. $\frac{7}{16}$; *lat.* $\frac{14}{16}$ *fere; poll.*

Habitat ad littora Brasiliæ (Santos). *Mus. nost.*

16. Pecten Patachonicus.

P. testâ sub-æquivalvi, brunneâ, longitudinaliter creberrimè elevato-radiatâ; intus albidâ, longitudinaliter sub-radiatâ; long. $2\frac{4}{8}$; *lat.* $2\frac{4}{8}$; *poll.*

Obs. auribus inæqualibus.

Habitat in freto Magellanico passim. Mus. nost.

17. Pecten vitreus.

P. testâ subæquivalvi, translucente, longitudinaliter multi-sulcatâ; sulcis convexis flavidulis, valvâ inferiore pallidiori; long. $1\frac{9}{16}$; *lat.* $1\frac{4}{8}$; *poll.*

Obs. Auribus inæqualibus.

Habitat in freto Magellanico passim. Mus. nost.

This shell is found attached to the leaves of the *Fucus giganteus*, and, with other *Mollusca*, is the food of the Steamer or Race-horse Duck (*Micropterus brachyptera and M. Patachonica*).

© The Complete Work of Charles Darwin Online

18. TEREBRATULA FLEXUOSA.

T. testâ rotundato-cordatâ, gibbâ, sub-fuscâ, longitudinaliter creberrimè sulcatâ; margine valdè flexuoso; long. $1\frac{3}{8}$; *lat.* $1\frac{4}{8}$ *paulo minus; poll.*

Habitat in freto Magellanico (Port Famine). *Mus. Brit., nost., Brod.*

This shell, which was dredged up from deep water in the bay of Port Famine, attached to stones, is not a common shell in the Strait.

19. TEREBRATULA SOWERBII.

T. testâ subrotundâ, planiusculâ, subfuscâ, longitudinaliter radiatim transversim substriatâ, medio supernè depressâ, infra convexâ, subglabrâ; margine utrinque crenulato, medio glabro; long. $1\frac{7}{16}$; *lat.* $\frac{7}{16}$ *paulo plus; alt.* $\frac{11}{16}$ *poll.*

Habitat in freto Magellanico. Mus. nost., Geo. Sowerby.

20. CHITON SETIGER.

C. testâ ovali, anticè subattenuatâ; valvis subdentatis, tenuiter concentricè striatis, anticâ 10-*radiatâ, posticâ lævi, parvulâ; areis lateralibus striis duabus elevatis marginalibus; ligamento marginali lævigato, setigero; long.* $2\frac{3}{8}$; *lat.* $1\frac{3}{8}$; *poll.*

Habitat ad oras insulæ Tierra del Fuego *et in freto Magellanico. Mus. Brit., nost., Brod.*

Shell ovate, rather attenuated towards the anterior end, generally of a light blue-green colour, variegated with markings of dark slate. Valves slightly beaked with minute concentric striæ, the lateral compartments with two marginal ridges, which in some specimens are granulose, in others smooth. The anterior valve has eight, besides two marginal, ridges of the same character; the posterior valve is very small and smooth. Border coriaceous, and set with bristles produced from three rows of tufts or pores. In some of the specimens in my possession the bristles are rubbed off.

The shell is found in all parts of the shores of Tierra del Fuego, particularly on its seaward coast, and the western parts of the Strait of Magalhaens.

21. CHITON BOWENII.

C. testâ oblongo-ovatâ, castaneo-rufâ; dorso elevato; valvis subdentatis, sublævibus concentricè tenuiter striatis; areis lateralibus radiatim sulcatis; ligamento marginali granuloso, nigro; long. $3\frac{2}{8}$; *lat.* $1\frac{1}{2}$; *poll.*

© The Complete Work of Charles Darwin Online

Habitat ad oras insulæ Tierra del Fuego *et in freto Magellanico. Mus. Brit., nost., Brod.*

Shell oblong-ovate, and generally of a chestnut red, and the granulose ligament black; the colour of the younger specimens is more brilliant, and sometimes interspersed with yellow. Middle valves slightly toothed, and very delicately lineated, the lines forming an obtuse angle in the direction of the axis of the shell; the lateral compartments are marked with deeper striæa or grooves, radiating from the upper angle to the base, which, crossing the transverse markings of the valve, have a reticulated appearance: the anterior and posterior valves are radiated with fine lines.

This Chiton was discovered by Mr. Bowen, surgeon of the Beagle, by whom it was presented to me. The specimen was sent home among a collection of Natural History, transmitted in the year 1827.

22. Fissurella coarctata.

F. testâ ovatâ, anticè attenuatâ, elevatâ; radiis frequentibus elevatis; internè virescenti; foraminis margine externo juxta medium coarctato, subdentato; long $2\frac{5}{16}$; *lat.* $1\frac{13}{16}$; *alt.* $\frac{14}{16}$; *poll.*

Habitat ad Portum Praya. *Mus. Brit., nost.*

23. Helix translucens.

H. testâ subglobosâ, translucente, levissimè transversim striatâ; anfractu basali lineâ longitudinali castaneâ sub-mediâ ornato; long. $\frac{11}{32}$; *lat.* $\frac{9}{16}$; *poll.*

Habitat ad Rio de Janeiro, *Mus. Brit., nost., Brod.*

24. Helix pusio.

H. testâ rotundo-complanatâ, creberrimè striatâ, translucente, maculis castaneo-rufis ornatâ; long. $\frac{1}{16}$; *lat.* $\frac{3}{16}$; *poll.*

Habitat ad Juan Fernandez. *Mus. Brit., nost., Brod.*

25. Helicina sordida.

H. testâ globoso-conoideâ; anfractibus rotundatis longitudinaliter striatis; operculo castaneo; long. $\frac{8}{8}$ *paulo plus; lat* $\frac{5}{16}$ *paulo plus; poll.*

Habitat ad Rio de Janeiro. *Mus. Brit., nost.*

The colour of this shell is of a dirty yellowish white, with a slight tinge of diaphanous violet within the margin of the lip.

26. Pupa subdiaphana.—No. 194. MSS.

P. testâ cylindraceâ, albâ, subdiaphanâ, transversim creberrimè substriatâ; long. $\frac{4}{8}$ *paulo minus; lat.* $\frac{3}{16}$ *paulo minus; poll.*

© The Complete Work of Charles Darwin Online

Habitat ad Portum Praya. (Cape Verd Islands.) *Mus. Brit., nost.*

27. Bulinus Gravesii.

B. testâ subventricosâ, longitudinaliter subrugosâ, sub-albidâ, fusco-maculatâ, spirâ longitudinaliter striatâ; long. $1\frac{1}{8}$; *lat.* $\frac{13}{16}$ *paulo minus; poll.*

Habitat ad Valparaiso. *Mus. nost.*

I have named the shell after my shipmate and friend, Lieutenant Thomas Graves, whose zeal and assiduity in assisting and increasing my collections of Natural History was as unwearied as the alacrity and ability which he displayed in the primary and more important objects of the voyage, of which, in his Majesty's ship Adventure, he filled the appointment of assistant surveyor. To Lieutenant Graves I am principally indebted for my land-shells, and I therefore take the opportunity of recording the valuable assistance he rendered me during the whole period of his serving under my command.

28. Bulinus Gravesii, var.

B. testâ subpyramidali, scabrâ, albidâ, aliquando lineolis raris; epidermide lutescente; long. $1\frac{9}{16}$; *lat.* $\frac{11}{16}$ *paulo plus. poll.*

Habitat ad Valparaiso. *Mus. Brit., nost., Brod.*

This is certainly a variety of No. 27, Bulinus Gravesii.

29. Bulinus dentatus.

B. testâ cylindraceâ, punctatâ, sub-diaphanâ, fusco maculatâ; aperturâ dentatâ, clausiliam mentiente; long. $\frac{15}{16}$; *lat.* $\frac{5}{16}$; *poll.*

Habitat ad oras Brasiliæ (St. Catherine). *Mus. Brit., nost.*

30. Bulinus lutescens.—No. 140. MSS.

B. testâ obovatâ, ventricosâ, subscabrâ, lutescente; long. $1\frac{1}{8}$; *lat.* $\frac{11}{16}$; *poll.*

Habitat ad Maldonado (Gorriti). *Mus. Brit., nost., Brod.*

31. Bulinus corrugatus.—No. 941 MSS.

B. testâ subalbidâ, transversim et longitudinaliter rugoso-striatâ, maculis fuscis, obsoletis; aperturâ purpurascente; columellâ nigricante purpureâ; long. $1\frac{6}{8}$ *paulo plus; lat.* $\frac{13}{16}$; *poll.*

Habitat ad Concepcion. *Mus. Brit., nost., Brod.*

The body-whorl of the older specimens of this shell is rather roughly striated or wrinkled, the last but one slightly so, and the remaining whorls are quite smooth. The colour is whitish, with

© The Complete Work of Charles Darwin Online

purple spots more or less obsolete: the old specimens are sometimes of a dull yellowish white. A specimen is deposited in the British Museum.

The young shells of this species are of a whitish brown, with darker coloured *striæ*. They are very fragile and semi-transparent.

32. BULINUS SORDIDUS.—No. 803 MSS.

B. testâ pyramidali, transversim striatâ, fuscâ; anfractu basali ad suturam subalbido, lineâ subcentricâ pallidâ; labii vix reflexi margine albo; long. $1\frac{5}{16}$; *lat.* $\frac{7}{8}$ *poll.*

Habitat ad Brasiliam (Rio de Janeiro). *Mus. nost.*

33. BULINUS MULTICOLOR.*—No. 791 MSS.

B. testâ ovato-pyramidali, longitudinaliter et transversim creberrimè substriatâ, luteo-fuscâ maculis albis et purpureo-atris fucatâ; labio roseo subreflexo; columellâ subalbidâ, aperturâ intus subatro-purpureâ; long. $1\frac{5}{16}$; *lat.* $\frac{9}{16}$; *poll.*

Habitat ad Brasiliam. Mus. nost., Geo. Sowerby.

33.* BULINUS ROSACEUS.

B. testâ ovato-oblongâ, scabriusculâ; apice et anfractibus primis, rosaceis, cæteris viridi-fuscis; labro albo; suturis crenulatis seu plicatis; long. $2\frac{1}{8}$; *lat.* 1; *poll.*

Habitat ad oras Americæ meridionalis (Chile). *Mus. Brit., nost., Brod., Geo. Sowerby, &c.*

Soon after the return of the expedition, my friend Mr. Broderip, to whose inspection Lieutenant Graves had submitted his collection, observing symptoms of life in some of the shells of this species, took means for reviving the inhabitants from their dormant state, and succeeded. After they had protruded their bodies, they were placed upon some green leaves, which they fastened upon and ate greedily. These animals had been in this state for seventeen or eighteen months, and five months subsequently another was found alive in my collection, so that this last had been nearly two years

* Whilst this sheet was printing, the September number of the Annales des Sciences made its appearance in England, containing a description of the above shell by M. Sander Rang, accompanied by an excellent figure (Annales des Sciences Naturelles, September 1831, p. 55, pl. 3, f. 1). It is there named *Helix multicolor*. In my description I have considered it to be a *Bulinus*, but its specific name has been altered to that given to it by M. Rang.

© The Complete Work of Charles Darwin Online

dormant. The shells were all sent to Mr. Loddige's nursery, where they lived for eight months, when they unfortunately all died within a few days of each other. Soon after the shells were first deposited at Mr. Loddige's, one got away, and escaped detection for several months, until it was at last discovered in a state of hybernation; it was removed to the place where the others were kept, when it died also. The upper surface of the animal when in health is variegated with ruddy spots and streaks on an ash-coloured ground.

34. PARTULA FLAVESCENS.

P. testâ subfusiformi, pallide flavâ, interdum castaneâ vel flavo et castaneo variâ; long. $\frac{1}{16}$; *lat.* $\frac{5}{16}$ *paulo plus; poll.*

Habitat ad oras Americæ meridionalis (Valparaiso). *Mus. Brit., nost., Brod.*

This shell varies in its colour almost as much as *Bulinus citrinus*.

35. ACHATINA DONELLII.—No. 413 MSS.

A. testâ subalbidâ, transversim substriatâ, anfractu basali ventricosâ; long. $\frac{7}{16}$ *paulo plus; lat.* $\frac{2}{8}$; *poll.*

Habitat ad Lima. *Must. nost.*

36. ACHATINA DIAPHANA.

A. testâ subcylindraceâ, diaphanâ, transversim striatâ; long. $\frac{5}{16}$; *lat.* $\frac{5}{32}$; *poll.*

Habitat ad insulam Juan Fernandez, *in montibus. Mus. Brit., nost., Brod.*

37. ACHATINA STRIGATA.—No. 462 MSS.

A. testâ diaphanâ, subalbidâ, creberrimè transversim substriatâ, strigis longitudinalibus castaneis raris; anfractu basali subangulato; long. $\frac{1}{16}$ *paulo plus; lat.* $\frac{6}{16}$ *paulo minus; poll.*

Habitat in paludibus Brasiliæ (Santo Paulo). *Mus. nost.*

38. ACHATINA SORDIDA.—No. 798 MSS.

A. testâ subdiaphanâ, subconicâ, anfractu basali ventricoso; long. $\frac{6}{8}$ *paulo plus; lat.* $\frac{3}{8}$ *paulo plus; poll.*

Habitat ad Brasiliam (Rio de Janeiro). *Mus. nost.*

39. ACHATINA SELLOVII.

A. testâ cylindraceâ transversim striatâ subdiaphanâ; long. $\frac{5}{16}$; *lat.* $\frac{2}{16}$; *poll.*

Habitat ad Brasiliam (St. Catherine). *Mus. Brit., nost., Brod.*

This shell, which I found at the city of Nossa Sen^{a}. de Estero,

© The Complete Work of Charles Darwin Online

I have dedicated to my friend, Dr. Sellow, whose researches in Natural History for several years past in the interior of Brazil, are well known to the scientific world.

40. Succinea fragilis.

S. testâ ovato-acutâ, diaphanâ, ventricosâ, transversim striatâ, obliquè subrugosâ; spirâ brevi; long. $\frac{9}{16}$ *paulo minus; lat.* $\frac{6}{16}$; *poll.*

Habitat ad insulam Juan Fernandez. *Mus. Brit., nost., Brod.*

41. Succinea patula.

S. testâ diaphanâ, ovato-rotundatâ, ventricosissimâ, transversim creberrimè striatâ; spirâ brevissimâ; aperturâ patulâ; long. $\frac{4}{8}$ *paulo plus; lat.* $\frac{3}{8}$ *paulo plus; poll.*

Habitat ad insulam Juan Fernandez.

Marinula. *Nov. Genus.*

Character Genericus.

Testâ ovato-productâ, sub-solidâ; aperturâ ovatâ, integrâ; columellâ bidentatâ, et basin versus uniplicatâ; dentibus magnis subremotis conniventibus, superiore maximo; operculum nullum.

42. Marinula pepita.

M. testâ ovato-productâ, viridi-fuscâ; anfractibus sub-tumidis; spirâ brevi; aperturâ nigricante; dentibus plicâque albidis; long. $\frac{7}{16}$; *lat.* $\frac{4}{16}$; *poll.*

Habitat ad insulam Chilóe. *Mus. Brit., nost., Brod., G. Sowerby.*

This animal, which I have thought it necessary to assign to a new genus, appears to have for its nearest neighbours the genera *Auricula* and *Pedipes*. It was found on the wooden piles which support the mole in the Bay of San Carlos, in Chilóe, below the wash of the high water. The mole stands out into the sea, and there is no fresh water near it, save a very little rill, which discharges its tiny stream more than fifty yards off.

43. Lymnæa diaphana.—No. 349 MSS.

L. testâ turritâ, transversim substriatâ, anfractibus ventricosis; long. $\frac{11}{16}$; *paulo plus; lat.* $\frac{5}{16}$; *poll.*

Habitat ad fretum Magellanicum (Cape Gregory). *Mus. Brit., nost., Brod.*

This shell was found in the fresh-water ponds in the neighbourhood of Cape Gregory, which is on the continental side of the eastern end of the Strait of Magalhaens.

© The Complete Work of Charles Darwin Online

44. AMPULLARIA CUMINGII.

A. testâ globosâ, transversim striatâ, subalbidâ, longitudinaliter castaneo-lineatâ et fasciatâ, epidermide virescente; umbilico parvo; lat. $1\frac{7}{16}$; *long.* $1\frac{6}{16}$; *poll.*

Habitat in Sinu Panamæ (island of Saboga, in a small hill-stream). *Mus. Brit. nost., Brod.*

From Mr. Cuming's collection. I have named this shell after Mr. Cuming, from whom I received it.

45. NATICA GLOBOSA.

N. testâ globosâ, tenui, ventricosissimâ, corneâ, vel subalbidâ, subtilissimè striatâ; spirâ brevi; umbilico parvo; operculo valdè tenui; long. $\frac{15}{16}$ *paulo plus; lat.* $\frac{7}{8}$; *poll.*

Habitat ad fretum Magellanicum (Cape Gregory). *Mus. Brit., nost., Brod.*

46. NATICA CASTANEA.

N. testâ ovato-acutâ castaneâ, albo-lineatâ; aperturâ mediocri; columellâ valdè callosâ; umbilico mediocri; long. $\frac{13}{16}$; *lat.* $\frac{21}{32}$; *poll.*

Habitat ad Brasiliæ oras, circa Santos. *Mus. nost.*

47. TURBO LUGUBRIS.

T. testâ nigricante, striatâ; aperturâ argenteâ; labri margine nigrâ, subcrenulatâ; operculo valdè lapidoso, albo; long. $2\frac{1}{8}$; *lat.* $2\frac{2}{8}$ *fere; poll.*

Habitat ad Sinum Peñas. *Mus. Brit., nost., Brod.*

48. ODONTIS SUBPLICATA.

O. testâ granuloso-striatâ, viridi-fuscâ, nigro maculatâ; umbilico mediocri; labri margine sub-plicato; long. $\frac{10}{16}$; *lat.* $\frac{13}{16}$ *paulo plus; poll.*

Habitat ad Brasiliam (Rio de Janeiro). *Mus. Brit., nost.*

49. LITTORINA FLAVA.

L. testâ longitudinaliter striatâ, sub-flavâ; spirâ brevi; anfractu basali ventricoso; columellæ purpurascentis margine et aperturâ sub-flavâ; operculo nigricante; long. $\frac{5}{8}$ *paulo plus; lat.* $\frac{7}{16}$ *poll.*

Habitat ad Brasiliam (Rio de Janeiro). *Mus. Brit., nost.*

In young shells there are a few obscure reddish brown streaks crossing the striæ.

50. LITTORINA PERDIX.

L. testâ striis elevatis balteatâ, albidâ, fusco-maculatâ, striis interstitialibus minus elevatis, ambabus sub-cancellatis; aperturâ albâ,

© The Complete Work of Charles Darwin Online

labri margine tenui, castaneo-maculatâ; long. $\frac{13}{16}$; *lat.* $\frac{17}{32}$; *poll.*
Habitat? *Mus. nost.*

51. LITTORINA STRIATA.

L. testâ ovato-conicâ, fuscâ, striis elevatis scabrâ; spirâ brevi; anfractu basali tumido; aperturâ nigricante, basin versus strigâ luteo-albâ ornatâ; labri margine crenulato albo-fulvido; operculo nigro; long. $\frac{4}{8}$ *paulo plus; lat.* $\frac{7}{16}$ *ferè; poll.*
Habitat in Mari Atlantico boreali (Port Praya). *Mus. Brit., nost.*

52. MARGARITA FASCIATA, n. s.

M. testâ albidâ, creberrimè striatâ, purpureo fasciatâ, aperturâ argenteâ; long. $\frac{4}{16}$; *lat.* $\frac{5}{16}$ *ferè; poll.*
Habitat in Mari Pacifico. Mus. nost.
Portions of the striated surface are elevated into belts, which are of a purple colour.

53. MARGARITA VIOLACEA.

M. testâ sub-ovatâ, violaceâ, spirâ brevi; anfractibus tumidis; aperturâ iridescente; long. $\frac{7}{16}$; *lat.* $\frac{8}{16}$ *fere; poll.*
Habitat ad fretum Magellanicum. Mus. Brit., nost., Brod.
Of this shell the Indians make their necklaces; it is found adhering to the leaves of the *Fucus giganteus*, and is the principal food of the Steamer or Racehorse Duck (*Micropterus Patachonicus*, nob. in Proceedings of the Zoological Society, December 14, 1830, page 15).

54. MARGARITA CŒRULESCENS.

M. testâ sub-complanatâ, cæruleâ, striatâ, albido-lineatâ, aperturâ iridescente; lat. $\frac{13}{16}$ *ferè; long.* $\frac{15}{16}$; *poll.*
Habitat ad fretum Magellanicum (Cape Gregory). *Mus. Brit., nost., Brod.*

55. TURRITELLA TRICARINATA.

T. testâ turritâ, anfractibus tricarinatis; carinis nodulosis; long. $1\frac{5}{8}$; *lat.* $\frac{9}{16}$ *paulo minus; poll.*
Habitat ad oras Americæ meridionalis (Valparaiso). *Mus. Brit., nost., Brod.*
The *Carinæ* are nodulous, or twisted like the strands of a rope; the twists of the upper *carina* are in the direction of a water-laid,

© The Complete Work of Charles Darwin Online

or right-handed rope, and those of the two lower *carinæ* are in the opposite direction, or like what is termed a hawser-laid rope. Between these nodulous *carinæ* are elevated lines, and the base is very strongly striated. Found in deep water in the Bay of Valparaiso. Dead shells of this species are occasionally found thrown upon the beach, near the Almendral.

56.—TURRITELLA NODULOSA.

T. testâ elongato-turritâ; anfractibus striatis; striis duabus maximis subnodulosis; long. $1\frac{11}{16}$; *lat.* $\frac{7}{16}$ *fere; poll.*

Habitat? *Mus. Brit., nost.*

The two large *striæ*, which are remarkable for the nodules, are not far from the middle of each whorl, and generally are nearer the upper suture: of these the lowest is the largest.

57. MUREX SALEBROSUS.

M. testâ elongato-ovatâ, subalbidâ, fasciis fuscis, epidermide cinereâ; spirâ brevi; anfractibus angulatis, nodulosis; aperturâ oblongâ ad basin angustâ, castaneâ, intus albâ; labro internè denticulato, dentibus obtusis albis; columellâ rectâ, lævi; canali brevi; long. $3\frac{7}{16}$; *lat.* 2; *poll.*

Habitat? *Mus. nost., Geo. Sowerby.*

This species approaches *Murex vitulinus* very nearly; the body-whorl is very much elongated, and the nodules which mark the angles of the whorl are formed of the more elevated parts of what may be termed coarse longitudinal plaits.

58. MUREX RHODOCHEILUS.

M. testâ ventricosâ, albâ, fasciis elevatis striatis; septemfariam varicosâ, varicibus roseis denticulatis; aperturâ rotundatâ, roseâ, intus albidâ; labri margine asperrimè denticulato; caudâ mediocri, sub-recurvâ; long. $3\frac{13}{16}$; *lat.* $2\frac{7}{16}$; *poll.*

Habitat? *Mus. nost.*

59. TRITON RANELLIFORMIS.

T. testâ ovato-fusiformi, subdepressâ, albidâ fusco fasciatâ, costatâ; costis granulosis, interstitiis striatis; aperturâ subrotundâ, albidâ; columellâ subrugosâ; labro internè obtusè denticulato; margine undulato; epidermide viridi-fuscâ, scabrâ; long. $3\frac{3}{16}$; *lat.* $1\frac{6}{8}$; *poll.*

Habitat ad Sinum Peñas *et oram occidentalem Americæ meridionalis.* *Mus. Brit., nost., Brod.*

© The Complete Work of Charles Darwin Online

The denticules of the outer lip are ranged in pairs, at regular and somewhat distant intervals.

60. TRITON SCABER.

T. testâ ovato-acutâ, cancellatâ; spirâ elongatâ; epidermide fuscâ, setosâ; aperturâ albâ granulosâ; labro interne obtusè denticulato; long. ; lat. ; poll.

Habitat ad oras Americæ meridionalis (Valparaiso). *Mus. nost.*

The denticules of the inner lip are more elevated than those of the last (T. ranelliformis), and are equidistant. It was fished up with the anchor in Valparaiso Bay.

61. MONOCEROS FUSOIDES.

M. testâ ventricosâ, spirâ mediocri, anfractibus bicarinatis; anfractu basali lineis elevatis admodum distantibus cincto; aperturâ patulâ; dente labiali brevi, lato, obtuso; canali producto, recto, integro; operculo corneo; long. $2\frac{3}{4}$; *lat.* $1\frac{5}{8}$; *poll.*

Habitat ad oras Americæ meridionalis (Concepcion). *Mus. Brit., nost., Brod.*

Approaching *Fusus* in its elongated and entire canal, while its exterior lip has the labial tooth which distinguishes *Monoceros*. The columella is not straight, as in all the other species, but curved, so as to make an angle in some specimens at the commencement of the canal, and in all it becomes very broad at the point where it is opposite to the tooth. The shell is of a reddish colour, ventricose, and girt with elevated lines, about a quarter of an inch apart. The spire has only two of these lines on each whorl, and has a bicarinated appearance. The aperture is wide, the outer lip sinuous, its tooth short, broad, and obtuse, and the operculum horny. The shell is seldom found in a perfect state, the beak being generally broken off, and the surface is, in all the specimens that I have seen, covered with a calcareous encrustation, entirely concealing the colours.

62. BUCCINUM MURICIFORME.

B. testâ ovato-fusiformi, cinereâ; anfractibus tumidis, costellatis, costellis cancellatis; aperturâ castaneo-nigricante; labri margine crenulato. Muricem mentiens; long. 1; *lat.* $\frac{9}{16}$; *poll.*

Habitat ad fretum Magellanicum. Mus. Brit., nost., Brod.

The eggs of this species were found, and are preserved in spirits.

© The Complete Work of Charles Darwin Online

63. BUCCINUM SQUALIDUM.

B. testâ conico-fusiformi, fuscâ; anfractu basali ventricoso; spirâ mediocri; aperturâ fuscâ, lutescenti, patulâ; long. $1\frac{15}{16}$; *lat.* $1\frac{1}{8}$; *poll.*

Habitat? *Mus. Brit., nost., Brod.*

64. BUCCINUM DEFORME.

B. testâ ovatâ, subponderosâ, subalbidâ, fasciis duabus fuscis obscuris; spirâ brevi; anfractu basali subdepresso, suturam versus crasso; columellâ valdè callosâ; long. $1\frac{9}{16}$; *lat.* 1 *paulo plus; poll.*

Habitat ad flumen Plata (Gorriti). *Mus. Brit., nost.*

The eggs of this shell, contained in a transparent orbicular nidus, the size of a turtle's egg, were found thrown up on the sea-beach of the island. In the month of January they were observed in all stages of growth. A series was preserved in spirits, and presented to the College of Surgeons.

65. COLUMBELLA MITRIFORMIS.

C. testâ fusiformi, luteo-rufescente, fasciis nigro-castaneis, maculis albis tessellatâ; long. $\frac{7}{16}$; *lat.* $\frac{3}{16}$; *poll.*

Habitat? *Mus. Brit., nost., Brod.*

66. MITRA PUSILLA.

M. testâ ovato-acutâ, ventricosâ, fulvâ, creberrimè costatâ; costis interstitiisque striatis, basi granulosâ; spirâ brevi, anfractibus suturam supereminentibus; columellâ quinque-plicatâ; long. $\frac{5}{8}$; *lat.* $\frac{5}{16}$ *paulo plus; poll.*

Habitat? *Mus. nost.*

The denticules of the outer lip are arranged in pairs, at regular, and somewhat distant, intervals.

67. VOLUTA.

A fragment of a turbinated shell, bearing marks more assignable to *Voluta* than to any other genus, was found on the sea-beach in the neighbourhood of Cape Fairweather, on the east coast of Patagonia, in latitude $51\frac{1}{2}°$ south. The remains appear to differ from *Voluta Ancilla* and *V. Brasiliana*.

COPIES OF ORDERS.

His Majesty's surveying vessel Adventure, Sea Bear Bay.

SIR; 27th March 1829.

It is my direction, that when finally parting company from me, you proceed to the execution of the following orders, in company with the Adelaide schooner, the commander of which, upon our meeting him, will receive instructions to put himself under your command.

You will, as soon as possible, make the best of your way to Port Famine, stopping at Pecket Harbour to communicate with the Indians, should they be there, for the purpose of securing a supply of guanaco meat for the ship's company.

At Port Famine you will immediately detach Lieutenant Skyring, with a boat and boat's crew, in the Adelaide, to co-operate with Lieutenant Graves in surveying the Magdalen Channel and its communication with the sea; after which you will direct him to rejoin you, by the Barbara Channel, at Port Gallant, whither you will proceed, after completing your water at Port Famine; on your way to which, if you should have an opportunity, the following bays, on the south side of the Strait, might be planned, *viz.* Lyell Bay, Cascade Bay, San Pedro Bay, and Freshwater Bay (or Cove). The coast also to the west of the Barbara Channel, behind the islands of Charles and Ulloa, should be examined; and of the northern arm of the Jerome Channel, called in the chart, Indian Sound, we know nothing.

If, after the return of the Adelaide, you should find the weather so favourable as to permit your extending your exploration of those parts of the Strait which are yet unknown to us, you will remain for that purpose; but, at all events, you are to leave the Strait by the middle of June, or the first of July at latest, and repair with the Adelaide to San Carlos, at the north end of Chiloe, where you will find or hear of me, by the 10th of August.

© The Complete Work of Charles Darwin Online

In performing the above orders you will act as you may consider best for their most effectual execution, keeping in mind that the most desirable part is the survey of the Magdalen Channel.

From our experience, last year, of the weather during the months of April and May, I am in hopes of your being able to work during those months, with success; but should you meet with bad weather, you will be most careful in not exposing your people unnecessarily to the severity of the climate.

Upon detaching the Adelaide you will appoint Lieutenant Skyring to the superintendence of the service upon which she is sent, giving Lieutenant Graves instructions to that effect accordingly.

I have, &c.

(Signed) PHILLIP PARKER KING,
Commander and Senior Officer.

His Majesty's surveying sloop Beagle, Port Famine.

SIR; April 19, 1829.

In obedience to the orders I have received from Commander Phillip Parker King, senior officer of the Expedition for the survey of a part of South America, it is my direction that you proceed immediately, in the Adelaide schooner, to survey as much of the Magdalen Channel and the Strait or Channel of Santa Barbara as you find practicable at this season of the year.

If, in the execution of this service, you should find the season too much advanced to proceed without much risk to the vessel, or exposing yourself and the men to much bad weather, you will give up the design, and hasten to Port Gallant.

Should the Beagle not be in Port Gallant at your return, and no letter left for you in a bottle, you will wait there one week, and then return to Port Famine. At all events, you will endeavour to rejoin the Beagle before the first week in June has ended.

I have, &c.

(Signed) ROBERT FITZ-ROY,
Commander.

To Lieut. Wm. Geo. Skyring,
His Majesty's sloop Beagle.

© The Complete Work of Charles Darwin Online

SIR; Beagle, Port Famine, 19th April 1829.

In obedience to the orders I have received from Captain King, it is my direction that you put yourself under the orders of Lieut. Skyring, and proceed with him as he may think best for the execution of the service upon which he is ordered, and in which you will give him every assistance that you can afford.

Mr. Kirke, with a boat and boat's crew, will be sent to assist you.

I have, &c.

(Signed) ROBERT FITZ-ROY,
Commander.

To Lieut. Thos. Graves,
Commanding His Majesty's schooner Adelaide.

SIR; Beagle, Port Gallant, 19th June 1829.

It is my direction that you put yourself under the orders of Lieutenant Skyring, and co-operate with him in the execution of the service on which he is about to be employed.

Mr. Kirke, with a boat and five men, will be sent to assist.

I have, &c.

(Signed) ROBERT FITZ-ROY.
Commander.

To Lieut. Thos. Graves,
His Majesty's schooner Adelaide.

SIR; Beagle, Port Gallant, June 19th 1829.

It is my direction that as soon as you consider the rates of the chronometer on board the Adelaide sufficiently settled, you proceed in her to search for, and, if practicable at this season of the year, survey such part of the passage which is supposed to lead from the vicinity of Cape Tamar to Concepcion Strait and the Gulf of Trinidad, as your time and provisions will allow.

Your chief object will be to open a passage from Cape Three Points to Cape Tamar, between the mass of islands which lie between those capes.

© The Complete Work of Charles Darwin Online

When to the northward of Cape Tamar, and before reaching as far north as Oracion Bay, or the latitude of 52° 6′, should you notice an opening to the eastward, with a current or stream of tide setting through it, and an appearance of its joining another body of water, of considerable extent, you will endeavour to ascertain whether it communicates with the Skyring Water, provided that in so doing you do not turn from your chief object more than a few days.

In the execution of the above orders you will act as you may consider best for the service of his Majesty; and if, at any time before its completion, you find your provisions getting short, the climate too severe, or yourself, or those under your orders, in bad health, you will immediately make the best of your way to Chilóe.

You will endeavour to be at San Carlos, in the island of Chilóe, before the 20th of September, and will let nothing that can be avoided detain you beyond that time.

I have, &c.

(Signed) Robert Fitz-Roy,
Commander.

To Lieutenant Wm. Geo. Skyring,
His Majesty's sloop Beagle.

By Phillip Parker King, Esq., Commander of His Majesty's surveying vessel Adventure, and Senior Officer of an Expedition for the survey of a part of South America.

As soon as you shall have completed the rates of your chronometers and be otherwise ready, it is my direction that you proceed to sea in His Majesty's sloop under your command, to survey the sea-coast of Tierra del Fuego, from Cape Pillar to the east entrance of the Strait of Magellan, in the progressive examination of which you will be guided by the state of the weather, and other circumstances, keeping in view that the most interesting part of the coast is that portion between Christmas Sound and the Strait Le Maire, particularly the openings of New Year Sound and Nassau Bay, and the openings to the eastward of the latter as far as New Island; as there is reason to believe that there is a considerable body of water to the eastward of the termination of Admiralty

© The Complete Work of Charles Darwin Online

Sound, communicating with the sea by some one if not many openings in the neighbourhood of Nassau Bay, and with an outlet on the N.E. coast (St. Sebastian Channel); and as the existence of such a strait would be of the greatest importance to small vessels bound to the westward round Cape Horn, you will see it fitting not to spend so much time to the westward of Cape Noir as may in the least impede the determination of the question, or prevent it being completely explored. It is my intention to be at Port Famine by the 1st of April, and at Rio de Janeiro by the 1st June, calling in my way at Monte Video, or Gorriti, for chronometrical observations; and if I can, conveniently, I shall also go to Port Desire for the same purpose. But as it is at present uncertain what orders I may find for me at Valparaiso, you are to act according to your own discretion, so that you arrive at Rio by the 20th of June to rejoin me.

Given under my hand, on board the Adventure, at St. Carlos de Chiloe, November 18th, 1829.

PHILLIP P. KING, Commander.

To Robert Fitz-Roy, Esq.,
Commander of H.M.S. Beagle.

By Phillip Parker King, Esq., Commander of His Majesty's surveying vessel Adventure, and Senior Officer of an Expedition for the survey of a part of South America.

As soon as the Adelaide Tender is ready, you will proceed to sea, in the execution of the following orders:—

As your principal object will be to trace the main-land from the peninsula of Tres Montes to the southward, by penetrating into all the openings that lead easterly, you will commence at the Channel Mouths, and explore them to their termination.

In the event of their affording a communication with the Gulf of Trinidad, and your having time, you will examine the channels that you have reported to exist in the neighbourhood of Neesham Bay, so as to complete the Fallos Channel, which separates Campana from the land within it.

Should the Channel Mouths not afford the expected termination, you will proceed through the Mesier or Fallos Channels, in

© The Complete Work of Charles Darwin Online

which, and in the channels more to the southward, you will explore all openings leading into the interior, and, if possible, not lose sight of the main-land until you reach the Strait of Magellan; by doing which it is expected, from the results of your last survey, that you will pass through the Skyring and Otway Waters, and enter the Strait by the Jerome Channel. The above being the principal object of your operations, you will take every opportunity of examining all other interesting parts of the coast, in the vicinity of your anchorages, among which the following seem to be of most interest:—

The Guaianeco Islands, and the probable place of the Wager's wreck, which would seem to be to the southward of, and not far from the Dundee Rock of your former survey.

If time afforded, it would be interesting to lay down the shores of Concepcion Strait; also to examine the deep opening on the west side of St. Estevan Channel, in the latitude of 51° 8′.

Lord Nelson Strait is also of much interest, and any extension of our knowledge of the land that bounds the western side of Smyth Channel.

But in these you will be guided by your own discretion, keeping in mind the principal object of the present survey, that of tracing the shores of the main-land.

The Adventure will be at Port Famine by the 1st of April, if nothing occurs to prevent it; and at Rio de Janeiro by the 1st of June, where you will rejoin me; but you are at liberty to call at Monte Video, on your way, for any supplies which you may require.

(Signed) PHILLIP P. KING.

7th Dec. 1829. San Carlos de Chiloe.

To Lieutenant W. G. Skyring,
commanding H.M. schooner Adelaide,
Tender to H.M.S. Adventure.

© The Complete Work of Charles Darwin Online

Some Observations relating to the Southern Extremity of South America, Tierra del Fuego, and the Strait of Magalhaens; made during the Survey of those Coasts in his Majesty's ships Adventure and Beagle, between the years 1826 and 1830. By Captain Phillip Parker King, F.R.S., Commander of the Expedition.

[The original paper, from which the following observations have been extracted, was read before the Geographical Society of London on the 25th of April and 9th of May 1831; and was printed in the Journal of that Society for the same year.

It is here reprinted, with a few omissions and very slight alterations, in order that this volume may contain all that the Author has yet published respecting South America; excepting particular Sailing Directions.]

Considering the vast extent of the sea-coast of the southern extremity of America, it is not a little surprising that it should have been so frequently passed by, during the last century, without having been more explored. Within the last twenty years, however, it has been very much resorted to by English and American vessels in the seal trade, and to the observing portion of their enterprising crews many of its intricacies are well known; but as the knowledge they have derived from their experience has only in one instance, that of Mr. Weddell's voyage, been published to the world, our charts cannot be said to have been much improved for the last fifty years.

The eastern coast of Patagonia, by which name the country between the River Plata and the Strait of Magalhaens* is known,

* There has existed much difference of opinion as to the correct mode of spelling the name of this celebrated navigator. The French and English usually write it Magellan, and the Spaniards Magallanes; but by the Portuguese, (and he was a native of Portugal,) it is universally written Magalhaens. Admiral Burney and Mr. Dalrymple spell it Magalhanes, which mode I have elsewhere adopted: but I have since convinced myself of the propriety of following the Portuguese orthography for a name, which to this day is very common both in Portugal and Brazil.

© The Complete Work of Charles Darwin Online

was coasted, as well as the north-eastern side of Tierra del Fuego, by Malaspina; and the charts of his voyage not only vie with any contemporaneous production for accuracy and detail, but are even now quite sufficient for the general purposes of navigation.

The Strait of Magalhaens has been explored by several navigators; but, among the numerous plans of it extant, those of Sir John Narborough and Cordova are the most correct. The first is particularly noticed in the late Admiral Burney's very useful work, and the result of the last has been published in the Spanish language, and is entitled "Ultimo Viage al Estrecho de Magallanes." A second voyage was also made by Cordova to the Strait, the proceedings of which form an appendix to the above work. It is furnished with a good general chart of the coast, another of the Strait, and many plans of the anchorages within it. Byron, Wallis, Carteret, and Bougainville, had already made considerable additions to Narborough's plan, from which a chart had been compiled that answered all the purposes of general geographical information, and might even have been sufficient for navigation: for the latter purpose, however, Cordova's chart was much superior; but, being published in Spain only, and its existence little known in England, I found great difficulty in procuring a copy before I sailed, for my own use.

The southern coast of Tierra del Fuego, between Cape Good Success, the southern limit of Strait le Maire, and Cape Pillar at the western end of the Strait of Magalhaens, was very little known. Cook's voyage affords several useful notices of the coast between Cape Deseado and Christmas Sound, and the Dutch fleet under Hermite partially explored the neighbourhood of Cape Horn: a confused chart of this coast, however, was the best that could be put together; and although Mr. Weddell has more recently published an account of the harbours and anchorages near Cape Horn and New Year Sound, yet little available benefit was derived from it, because these different navigators having confined their examinations to small portions of the coast, it was difficult to connect their respective plans, even on so small a scale as that of the general chart.

The western coast of South America, which is very intricate, extending from Cape Victory (the north-west entrance of the

© The Complete Work of Charles Darwin Online

Strait of Magalhaens) to the island of Chiloé, may be said to have been wholly unknown; for since the time of Sarmiento de Gamboa nothing in the least descriptive of it had been published, with the exception of the brief notices of two missionary voyages in piraguas, from Chiloé to the Guiateca and Guaianeco islands.

Every person conversant with South American geography, must be acquainted with the voyage of Sarmiento. From the determined perseverance shown by that excellent and skilful navigator, through difficulties of no ordinary nature, we are possessed of the details of a voyage down the western coast, and through the Strait of Magalhaens, that has never been surpassed. His journal has furnished us with the description of a coast more difficult and dangerous to explore than any which could readily be selected—for it was at that time perfectly unknown, and is exposed to a climate of perpetual storms and rain: yet the account is written with such minute care and correctness, that we have been enabled to detect upon our charts almost every place described in the Gulf of Trinidad, and the channels to the south of it, particularly their termination at his Ancon sin Salida.

It would be irrelevant to enter here into the history of Sarmiento's voyage, or indeed of any other connected with these coasts. Modern surveys are made so much more in detail than those of former years, that little use can be made of the charts and plans that have been hitherto formed; but the accounts of the voyages connected with them are replete with interesting and useful matter, and much amusement as well as information may be derived from their perusal, particularly Sir John Narborough's journal, and Byron's romantic and pathetic narrative of the loss of the Wager.

The Cordillera of the Andes, which is known to extend from the northern part of the continent almost to its southern extremity, decreases in elevation near the higher southern latitudes. In the neighbourhood of Quito, Chimborazo and Pinchincha rear their summits to the height of nearly twenty-two thousand feet above the level of the sea; near Santiago de Chile the highest land is supposed to be fourteen thousand feet; farther south, near Concepcion, it is lower; and near Chiloé there are few parts of the range exceeding seven thousand feet. Between Chiloé and the

© The Complete Work of Charles Darwin Online

Strait of Magalhaens the average height may be taken at three thousand feet; though there are some mountains which may be between six and seven thousand feet high.

By a reference to the chart it will be seen that about the parallel of 40° the coast begins to assume, and retains to its furthest extremity, a very different appearance from that which it exhibits to the northward, where the sea, which is kept at a distance from the Cordillera by a belt of comparatively low land for continuous intervals of some hundred miles, washes a long unbroken shore, affording neither shelter for vessels nor landing for boats; but, to the southward of that parallel, its waters reach to the very base of the great chain of the Andes, and, flowing as it were into the deep ravines that wind through its ramifications, form numerous channels, sounds, and gulfs, and, in many instances, insulate large portions of land. In fact, the whole of this space is fronted by large islands and extensive archipelagoes, of which the most conspicuous are the great island of Chiloé, Wellington Island, the Archipelago of Madre de Dios, Hanover Island, and Queen Adelaide Archipelago. The last forms the western entrance of the Strait on its north side. The land of Tres Montes, however, is an exception: it is a peninsula, and is the only part of the continent within the above limits that is exposed to the ocean's swell. It forms the northern part of the Gulf of Peñas, and is joined to the main by the narrow isthmus of Ofqui, over which the Indians, in travelling along the coast, carry their canoes, to avoid the extreme danger of passing round the peninsula. It was here that Byron and his shipwrecked companions crossed over with their Indian guides: but it is a route that is not much frequented; for this part of the coast is very thinly inhabited, and the trouble of pulling to pieces and reconstructing the canoes,* an operation absolutely necessary to be performed, is so great, that I imagine it is only done on occasions of importance. In this way the piraguas which conveyed the missionary voyagers to the Guaianeco Islands were transported

* During our examination of this part, our boats ascended the river San Tadeo, and endeavoured in vain to find any traces of the road; an almost impenetrable jungle of reeds and underwood lined the banks of the river, and time was too valuable to admit of further delay, in search of an object comparatively of minor importance.

© The Complete Work of Charles Darwin Online

over the isthmus; the particulars of which are fully detailed in their journals.*

The river San Tadeo, although of small size, being navigable only for eleven miles, is the largest river of the coast south of the archipelago of Chiloe, and therefore merits a particular description. At seven miles from the mouth it is fed by two streams or torrents, the currents of which are so strong that a fast-pulling boat can hardly make way against it. One of these streams takes its rise in a mountainous range, over which perhaps the communicating road passes; and the other is the drain of an extensive glacier or plain of ice of fifteen miles in extent. The river falls into the Gulf of St. Estevan over a shallow bar, upon which there is scarcely two feet water, and at low tide is probably dry.

At the head of St. Estevan Gulf is St. Quintin Sound; both were examined and found to afford excellent anchorage, and they are both of easy access should a ship, passing up the coast, find herself upon a lee shore and not able to weather the land, as was the case with the ill-fated Wager.†

The Guaianeco islands form the southern head of the Gulf of Peñas; then follows Wellington Island, separated from the main by the Mesier Channel, which had not been previously explored, its mouth only being laid down in the charts, compiled from the information of Machado, a pilot who was sent in 1769 by the Viceroy of Peru to examine the coast from Chiloe to the Strait

* Agüeros, Descripcion Historial de la Provincia y Archipielago de Chiloe, 1791, p. 229.

† The precise situation of the wreck of this vessel had hitherto been very vaguely marked on our charts: a careful perusal, however, of Byron's narrative, and of Agüeros' account of the Missionary Voyages in 1779, sufficiently points out the place within a few miles. It is on the north side, near the west end of the easternmost of the Guaianeco islands, which we named, in consequence, Wager Island. At Port Santa Barbara, seventeen miles to the southward of this group, a very old worm-eaten beam of a vessel was found, which there is reason to think may be a relic of that unfortunate ship. It was of English oak, and was found thrown up above the high-water mark upon the rocks at the entrance of the port. No other vestige was detected by us;—the missionaries, however, found broken glass bottles, and other evident traces of the wreck. At Chiloe I saw a man who had formed one of this enterprising party, and obtained from him a curious and interesting account of those voyages.

© The Complete Work of Charles Darwin Online

of Magalhaens.* This channel is also noticed in one of the two missionary voyages above mentioned; but the object of these expeditions being for the purpose of converting the Indians to Christianity,† and not for the extension of geographical knowledge, little information of that nature could be obtained from their journal: the entrance of the Mesier, however, is described by them; and on one occasion they were obliged to take refuge in it for fifteen days.‡ With this exception I cannot find that it had ever been entered before our visit.

The length of the channel is one hundred and sixty miles, and it joins the Concepcion Strait behind the Madre de Dios archipelago, at the Brazo Ancho of Sarmiento. Lieutenant Skyring, who superintended this particular part of the survey, called the land which it insulates, Wellington Island; the seaward coast of which is fronted by several islands. Fallos Channel, which separates the Campaña and Wellington Islands, was examined, from its northern entrance, for thirty-three miles, and was conjectured, after communicating with the sea at Dynely Sound, to extend to the southward, and fall into the Gulf of Trinidad by one of the deep sounds which were noticed on the north shore.

About thirty miles within the Mesier Channel, from the northern extremity, the west side appears to be formed by a succession of large islands, many of which are separated by wide channels leading to the south-west, and probably communicating with the Fallos Channel. On the eastern shore the openings were found to be either narrow inlets or abruptly terminating sounds.

On both sides of the channel the coast is hilly, but not very high, and in many places there is much low and generally thickly wooded land. This character distinguishes the Mesier from other channels in these regions.

The trees here are nearly of the same description as those which are found in all parts between Cape Tres Montes and the Strait of Magalhaens. Of these the most common are an evergreen beech (*Fagus betuloides*), a birch-like beech (*Fagus antarctica*), the Winter's bark (*Winterana aromatica*§), and a tree with all the appearance and habit of a cypress, of which the Indians make their

* Agüeros, p. 205, et seq. † Ibid. p. 181, et seq. ‡ Ibid. p. 237.

§ Living plants of the above trees, and other vegetable productions from the Strait of Magalhaens, were introduced into England upon the return of the expedition, and have since thriven exceedingly well.

© The Complete Work of Charles Darwin Online

spears. Among others there is one, the wood of which being extremely hard and weighty, answers better than the rest for fuel: the sealers call it 'the red wood,' from its colour. From the great quantity of timber which grows here it would be naturally supposed probably that spars for masts could be easily obtained, or at least wood useful for less important purposes; but although many trees were found that were sufficiently large at the base, they grew to no great height; and, in consequence of the moisture of the climate, and the crowded state of the forests preventing the admission of the sun's rays, the wood generally proved to be decayed in the heart; besides being very apt, even after a long seasoning, to warp and split when exposed to a dry air.

Ten miles beyond White-kelp Cove, which is fifty miles within the entrance, the character of the Mesier Channel changes entirely; the shore on either side being formed of mountainous and precipitous ridges rising abruptly from the water. After this, at Halt Bay, twenty-three miles beyond White-kelp Cove, the channel narrows for a considerable distance, and in three particular places is not more than four hundred yards wide. This part of the channel is called in the chart the English Narrow. It is long and intricate, with many islands strewed throughout; and preserves its tortuous and frequently narrow course to its junction with the Wide Channel, in which the breadth increases to two miles and a half; and then, running thirty-four miles with a direct and unimpeded course, falls into the Concepcion Strait as above stated.

At the point where the Mesier and the Wide Channels unite, a deep sound extends to the N.N.E. for forty-six miles. It was named Sir George Eyre Sound. An extensive glacier sloping into the sea from the summit of a range of high snowy mountains, that are visible from many parts of the Mesier Channel, terminates this sound; and near the head of it several large icebergs, containing no inconsiderable blocks of granite, were found aground.*

* Near Falcon Inlet, seven miles up the eastern side of Sir George Eyre Sound, are some large 'rookeries,' or breeding-haunts, of fur-seal. Many thousands of these animals were congregated together, which probably had been driven from the sea-coast by the activity of the seal-fishers; and perhaps, for many years, if not ages, have been breeding undisturbed in this hitherto unknown, and therefore safe and quiet recess. Two seals that were killed appeared to be of the same description as the species which frequents the sea-coasts.

Of the archipelago of Madre de Dios we know very little. It has probably many deep openings on its seaward face, and is fronted by islands and rocks. Its character is rocky and mountainous, and by no means agreeable. The wide and safe channel of Concepcion Strait separates it from the main land, which in this part is much intersected by deep sounds, the principal of which, the Canal of San Andres, extends to the base of the snowy range of the Cordillera, and there Lieutenant Skyring describes it to be suddenly closed by immense glaciers.

Behind Hanover Island, which is separated from Madre de Dios by the Concepcion Strait, the main-land is very much intersected by sounds like the San Andres Channel, extending to the base of the Andes.

South of Hanover Island is Queen Adelaide Archipelago, through which are several channels that communicate with the Strait of Magalhaens; of which the principal, Smyth Channel, falls into the Strait at Cape Tamar.

In the winter of 1829, Captain Robert Fitz-Roy, then commanding the Beagle, in examining the Jerome Channel, which communicates with the Strait in that part called Crooked Reach, discovered 'Otway Water,' an inland sea fifty miles long, trending to the N.E., and separated from the eastern entrance of the Strait by a narrow isthmus; the actual width of which was not ascertained, for in the attempt the boats were nearly lost. The south-eastern shore is high and rocky, and generally precipitous, but the northern is formed by low undulating grassy plains, free from trees, and precisely like the country about the eastern entrance of the Strait. At the north-west corner of the water a passage was found leading in a north-west direction for twelve miles, when it opened into another extent of water, about thirty-four miles long and twenty wide. This he called the Skyring Water. Its southern and western sides are bounded by mountainous land, but the northern shore is low, apparently formed of undulating downs and grassy plains, and in some places watered by rivulets. At the western extremity of the water two openings were observed, separated by a remarkable castellated mountain which was called Dynevor Castle. Beyond the southernmost opening there was no land visible, not even a distant mountain, which induced Captain Fitz-Roy to suppose that it was a channel communicating with the

© The Complete Work of Charles Darwin Online

western coast; but from what we now know, it is not probable that it can lead to anything of consequence. It is, perhaps, backed by low marshy land reaching to the hills at the bottom of Glacier Bay, which, from the distance being seventy miles, were not visible above the horizon. The northern opening probably passes Dynevor Castle, and, perhaps, nearly reaches the bottom of Obstruction Sound. The Skyring Water was not further explored; partly from want of a sufficient quantity of provisions to undertake it with any prospect of succeeding, and partly from a strong south-westerly gale, from which there was no shelter for the open boats in which this examination was performed. The remainder, therefore, of Captain Fitz-Roy's time was spent in completing what he had commenced; and, after an absence of thirty-two days, he rejoined his ship at Port Gallant.

At the western end of the passage, which unites the waters, the shore is well clothed on the north side with luxuriant grass and trefoil, with here and there a sprinkling of brushwood, but is entirely destitute of trees. The soil, although dry, is light, and tolerably good; but the ground is perforated everywhere by some burrowing animal, probably skunks, or *cavias*. The tracks of horses were noticed in many places, and the bones of guanacoes were scattered about. Water was not very plentiful, but several small brooks and springs in the sides of the hills were observed, sufficient for all useful purposes.

On the south side of the passage the land is low, but wooded: the banks are from five to forty feet high, sloping to the water, and covered with grass. In the entrance the tide ran five or six knots at the neaps, but inside with only half that rapidity. On the north side, at the distance of a mile and a-half, there is a ridge of hills, to the summit of which Captain Fitz-Roy made an excursion, which is described in the Narrative.

In consequence of the supposed communication of the Skyring Water with some part of the western coast, a careful examination was made of every opening trending into the interior behind the islands and archipelagoes that line the western coast; the result of which has proved that the hypothesis so naturally formed was not confirmed by fact. A reference to the chart will show how carefully the search was carried on, and with what want of success it was concluded. The deep opening discovered by Sarmiento, and

© The Complete Work of Charles Darwin Online

named by him, 'Ancon sin salida,' was found, upon examination, to extend so far into the interior, and in the direction of the Skyring Water, that the most strict investigation of the numerous sounds and canals was made, in the perfect conviction of finding the desired communication. But after a patient, laborious, and minute examination, particularly of those openings which led to the southward, among which Obstruction Sound held the most flattering appearance, Lieutenant Skyring, who performed this service, was obliged to give up the search and return. At one part, near the south-eastern end of the sound, he entered an opening, which at first had an appearance that was favourable to the desired communication, but it terminated in low, woody land. There was, however, a hill near the shore, which he ascended with the hope of obtaining a view of the country; but the sides and summit of the hill were so thickly wooded as to obstruct his view, and with the exception of some distant high land in the south-east quarter, and a sheet of water about six miles off in the same bearing, nothing was discerned to repay him for the fatigue and trouble of the ascent. Whether the water is a lagoon, or a part of the Skyring Water, or whether it communicates with the opening trending round the north side of Dynevor Castle, yet remains to be ascertained.

Being foiled in this attempt, Lieutenant Skyring proceeded onward in a S.S.W. direction, and after a pull of ten miles came to the bottom of the sound, which was terminated by high, precipitous land encircling every part. Neither wigwams nor traces of Indians were seen, another proof, were one required, of the sound not communicating with the Skyring Water; for the Indians very rarely visit these deep inlets, but are always to be found in narrow straits or communicating channels, where, from the strength of the tide, seals and porpoises, which constitute the principal food of the Fuegian Indians, abound. Sarmiento's name, therefore, of 'Ancon sin salida,' which we had hoped to have expunged from the chart, must now remain, a lasting memorial of his enterprising character, and of a voyage deservedly one of the most celebrated, as well as most useful, of the age in which it was performed.

The termination of Obstruction Sound is one of the most remarkable features in the geography of this part of South America.

In this examination the southern extremity of the Cordillera was

© The Complete Work of Charles Darwin Online

ascertained. The eastern shores of the interior channels were found to be low plains, with no hills or mountains visible in the distance; and such being characteristic also of the northern shores of the Otway and Skyring Waters, it is probable that all the country to the east of the sounds is a continued plain.

Recent traces of Indians were seen in some places; but at the time our party was there, they were either absent or had concealed themselves. I should not think that these interior sounds are much frequented by them; a family was, however, met in the passage between the Otway and the Skyring Water, clothed with guanaco skins, like the Patagonian tribes, but in manners and disposition resembling the wandering inhabitants of the Strait and Tierra del Fuego; and they had canoes, which the Patagonians do not use. They had probably come thus far for the purpose of communicating with the latter tribes, with whom they frequently have friendly intercourse. No guanacoes were seen either on the shores of the inland waters or of the sounds within the 'Ancon sin salida,' although the country, being open and covered with luxuriant grass, was peculiarly suited to their habits; but as several large herds of deer were observed feeding near the sea-shore of Obstruction Sound, and the neighbouring country, the presence of these latter animals may probably be the cause; for on the eastern coast, where the guanacoes are every where abundant, the deer do not make their appearance. Sea-otters were the only other animals that we met with; but they were only occasionally noticed, swimming about the kelp. The shores of the sounds were in many places crowded with the black-necked swan (*Anas nigricollis*, Linn.), and there were a few seen, but only one captured, whose plumage, excepting the tips of the wings, which were black, was of a dazzling white colour. I have described it in the first part of the Proceedings of the Zoological Society as a new species (*Cygnus anatoïdes.*)

The Strait of Magalhaens, being a transverse section of the continent, exhibits a view of its geological structure. The Strait may be divided into three portions; the western, the central, and the eastern. The western and central are of primitive character, rugged and very mountainous; but the eastern portion is of recent formation and low. The western tract is composed of a succession of stratified rocks, a difference at once distinguishable by the form

© The Complete Work of Charles Darwin Online

and nature of the ranges, and the direction of the shores: the hills are irregularly heaped together; the sounds are intricate and tortuous in their course, and the shores are formed by deep sinuosities and prominently projecting headlands: the channels, also, are studded with innumerable islands and rocks extremely dangerous for navigation. In this portion the rock is, for the most part, granite and greenstone.

Near the centre of the Strait, the rock being clay-slate, the mountains are higher, and more precipitous and rugged in their outline; and consequently not easily to be ascended. They are in general three thousand feet, but some are found to be four thousand feet, in height; and one, Mount Sarmiento, is upwards of six thousand feet high, and is covered throughout the year with snow. The line of perpetual snow in the Strait seems to be about three thousand five hundred feet above the sea: the mountains, whose height does not exceed three thousand, are, during the summer, frequently free from any, excepting in holes, where a large quantity is accumulated by drifting, and protected from the sun. The Strait here is quite free from islands, and it is a remarkable fact, that where the greenstone formation terminates, there the islands cease to appear.

The slate formation continues as far as Freshwater Bay, where the stratified rocks leave the coast and extend in a north-west direction. The soil then becomes apparently a mixture of decomposed slate and clay; the slate gradually disappearing on approaching to Cape Negro, where the rock partakes of the character of the east coast. Here again we observe, along with the change of geological character, the re-appearance of islands, the soil of which is clayey, but with masses of granite, hornblende rock and clay slate protruding in many places through the superficial soil, which, although it yields a poor grass, is entirely destitute of trees.

In that portion of the Strait to the eastward of Cape Negro the hills are remarkable for the regularity and parallelism of their direction, and their general resemblance to each other. On the north shore, near Cape Gregory, a range of high land commences suddenly, with rather a precipitous ascent, and extends for forty miles to the north-east, where it terminates in detached rocky hills. The south-western end of the range is a ridge of flat-topped

© The Complete Work of Charles Darwin Online

land covered with soil, but with here and there a protruding mass of primitive rock: one of these appeared to be of sienite or granite. The north-eastern end of this range is perhaps more bare of soil, and, therefore, exposes the rock, which shows itself in detached hills. Precisely similar in appearance and direction is a range on the south shore, about fifty miles in length, commencing at Cape Monmouth and terminating in detached hills in the vicinity of the south side of the First Narrow. The courses, also, of both the First and Second Narrow, which are just within the eastern entrance of the Strait, are nearly parallel with these hills; and the smaller ranges of eminences, Elizabeth Island and the cliffy land of Cape Negro, where the clay formation commences, all trend to the N.N.E., preserving a general resemblance of form and character to the two ranges above mentioned.

The irregularity of the topographic features of the western portion of the Strait, combined with its confused assemblage and immense number of islands and rocks;—the regularity of the strata —the coinciding parallelism of all the bays, channels, and sounds, —and the total absence of islands in the central portion or slate formation;—together with the remarkable similarity of the direction of the hills and coast line, and the stratification of the north-eastern tract, which is very different from that of the centre;— are very striking facts, and, geologically considered, are of great interest.

No less remarkable, however, and equally interesting, is the character of the vegetation; not so much in the variety of plants, as in their stunted growth to the westward, their luxuriance in the centre, and the total absence of trees to the eastward. For this modification the following reasons seem to me to account sufficiently. To the westward the decomposition of granite, and the other primitive rocks which are found there, forms but a poor, unproductive soil; so that, although the land is thickly covered with shrubs, they are all small and stunted: the torrents of water also that pour down the steep sides of the hills, wash away the partial accumulations of soil that are occasionally deposited; consequently, few trees are to be found, excepting in clefts and recesses of the rock, where decomposed vegetable matter collects and nourishes their growth; but even there they are low and stunted, for the most luxuriant seldom attain a larger diameter than nine or ten inches.

© The Complete Work of Charles Darwin Online

From the regularity of the direction of the strata in the slate districts the vallies are very extensive, and, being bounded on either side by precipitous mountains much intersected by deep ravines, receive large streams of water, which, uniting together in their course to the sea, form no inconsiderable rivers. During the winter months these rivers become swollen and overflow their banks, and deposit a quantity of alluvium, which, blending with the fallen leaves and other putrescent substances, produces a good superficial soil, in which trees grow to a large size, and the shrubs and smaller plants become particularly luxuriant and productive.

At Port Famine, and in its neighbourhood, the evergreen beech (*Fagus betuloides*) grows in the greatest abundance, and reaches a very large size. Trees of this species, of three feet in diameter, are abundant; of four feet, there are many; and there is one tree (perhaps the very same noticed by Commodore Byron*), which measures seven feet in diameter for seventeen feet above the roots, and then divides into three large branches, each of which is three feet through. This venerable tree seemed to be sound, but from our experience of several others that were cut down, might be expected to prove rotten in the centre. This tendency to decaying in the heart may be attributed to the coldness of the schistose sub-soil upon which the trees are rooted, as well as to the perpetual moisture of the climate above alluded to.

The slate formation ceases at Port St. Mary, but there is no decided change in the vegetation until we come to Cape Negro, where the clay commences; and from thence onwards there is not a tree to be found. The nature of the soil is not favourable to plants which take a deep root, and, therefore, only shrubs and grasses are found: the former are thinly scattered over the extensive plains which characterise this country; but the grasses are abundant, and although of a harsh and dry appearance, must be nourishing, for they form the chosen food of numerous and large herds of guanacoes.

Besides the evergreen beech above-mentioned, there are but few other trees in the Strait that can be considered as timber trees. Such an appellation only belongs to two other species of beech and the Winter's bark. The last, which is also an evergreen, is to be found mixed with the first, in all parts of the Strait; so that

* Hawkesworth, Voyages, i. 38.

© The Complete Work of Charles Darwin Online

the country and hills, from the height of two thousand feet above the sea, to the very verge of the high-water mark, are covered with a perpetual verdure which is remarkably striking, particularly in those places where the glaciers descend into the sea; the sudden contrast in such cases presenting to the view a scene as agreeable as it seems to be anomalous. I have myself seen vegetation thriving most luxuriantly, and large woody-stemmed trees of Fuchsia and Veronica* (in England considered and treated as tender plants), in full flower, within a very short distance of the base of a mountain, covered for two-thirds down with snow, and with the temperature at 36°. The Fuchsia certainly was rarely found except in sheltered spots, but not so the Veronica; for the beaches of the bays on the west side of San Juan Island at Port San Antonio are lined with trees of the latter, growing even in the very wash of the sea. There is no part of the Strait more exposed to the wind than this, for it faces the reach to the west of Cape Froward, down which the wind constantly blows, and brings with it a succession of rain, sleet, or snow; and in the winter months, from April to August, the ground is covered with a layer of snow, from six inches to two or three feet in depth.

There must be, therefore, some peculiar quality in the atmosphere of this otherwise rigorous climate which favours vegetation; for if not, these comparatively delicate plants could not live and flourish through the long and severe winters of this region.

In the summer, the temperature at night was frequently as low as 29° of Fahrenheit, and yet I never noticed the following morning any blight or injury sustained by these plants, even in the slightest degree.

I have occasionally, during the summer, been up the greater part of the night at my observatory, with the internal as well as the external thermometers as low as freezing point, without being particularly warmly clad, and yet not feeling the least cold; and in the winter, the thermometer, on similar occasions, has been at 24° and 26°, without my suffering the slightest inconvenience. This I attributed at the time to the peculiar stillness of the air, although, within a short distance in the offing and overhead, the wind was high.

Whilst upon this subject, there are two facts which may be

* The stems of both from six to seven inches in diameter.

© The Complete Work of Charles Darwin Online

mentioned as illustrative of the mildness of the climate, notwithstanding the lowness of the temperature. One is the comparative warmth of the sea near its surface, between which and the air, I have in the month of June, the middle of the winter season, observed a difference of 30°, upon which occasion the sea was covered with a cloud of steam. The other is, that parrots and humming-birds, generally the inhabitants of warm regions, are very numerous in the southern and western parts of the Strait—the former feeding upon the seeds of the Winter's bark, and the latter having been seen by us chirping and sipping the sweets of the Fuchsia and other flowers, after two or three days of constant rain, snow, and sleet, during which the thermometer had been at freezing point. We saw them also in the month of May upon the wing, during a snow shower: and they are found in all parts of the south-west and west coasts as far as Valparaiso. I have since been informed that this species is also an inhabitant of Peru; so that it has a range of more than 41° of latitude, the southern limit being 53½° south.*

Tierra del Fuego is divided by several channels; a principal one of which is opposite to Cape Froward, and another fronts Port Gallant. The easternmost, called Magdalen, trends in a due south direction for nineteen miles, and separates the clay slate from the more crystalline rocks, which seem to predominate in Clarence Island, and are chiefly of greenstone; though, at the eastern end, there is much mica slate. At the bottom of Magdalen Sound the channel turns sharply to the westward; and, after a course of about forty miles, meets the Barbara Channel, which, as above-mentioned, communicates with the Strait opposite to Port Gallant, and both fall into the sea together. Magdalen Sound and its continuation, Cockburn Channel, are almost free from islands and rocks; but the Barbara Channel, which separates

* This bird, although not rare in several English collections had never been noticed until I forwarded it to England in the early part of the year 1827, when my friend Mr. Vigors described it in the Zoological Journal for the month of November 1827 (vol. iii. p. 432), under the name of *Mellisuga Kingii*. Shortly afterwards, M. Lesson published it in his Manuel d'Ornithologie (vol. ii. p. 80), as *Ornismya sephaniodes*, as a discovery belonging to the Coquille's voyage, in the illustrations of which it is figured at plate 31.

© The Complete Work of Charles Darwin Online

the granite from the greenstone and mica slate districts, is throughout thickly strewed with islands, which reduce the channel in some parts to a mile, and, in one place, to not more than fifty yards in width. Here, of course, the tide sets with great strength. Several vessels, however, have passed through it under sail; and one ship, a whaler belonging to Messrs. Enderby, working through the Strait, and finding much difficulty in passing to the westward, bore up, and, the wind being fair and the distance to sea only fifty miles, ran through it without accident. The land to the westward of the Barbara Channel is high and rugged; and although in the vallies, ravines, and sheltered nooks, there is no want of vegetation, yet, in comparison with the eastern part of the Strait, it has a very dismal and uninviting appearance. It was called by Sarmiento, 'Santa Ines Island';* but Narborough called it, 'South Desolation; it being,' as he says, 'so desolate land to behold.'†

Clarence Island, which is fifty-two miles long and twenty-three broad, although equally rocky, is much more verdant in appearance. The uniform direction of the headlands of the north shore of the island is remarkable. Upon taking a set of angles with the theodolite placed upon the extremity of the west end of Bell Bay, opposite to Cape Holland, the most prominent points to the south-east, as far as could be seen, were all visible in the field of the telescope at the same bearing. The same thing occurred on the opposite shore of the Strait, where the projections of Cape Gallant, Cape Holland, and Cape Froward, are in the same line of bearing; so that a parallel ruler placed on the map upon the projecting points of the south shore, extended across, will also touch the headlands of the opposite coast.

The eastern island, which had been previously called, and of course retains on our chart the name of King Charles South Land, extends from the entrance of the Strait to the outlet of the Barbara and Cockburn Channels, at Cape Schomberg. The northern part partakes of the geological character of the eastern portion of the Strait. The centre is a continuation of the slate formation, which is evident at a glance, from the uniformity of the direction of the shores of Admiralty Sound, the Gabriel Channel, and all the bays and mountain ranges of Dawson Island. The south shore, or seaward coast line, is principally of greenstone,

* Sarmiento, p. 180. † Narborough's Voyage, p. 78

© The Complete Work of Charles Darwin Online

excepting the shores of the Beagle Channel, which extends from Christmas Sound to Cape San Pio, a distance of a hundred and twenty miles, with a course so direct that no points of the opposite shores cross and intercept a free view through; although its average breadth, which also is very parallel, is not much above a mile, and in some places is but a third of a mile across. The south shores of Hoste and Navarin Islands are of horn-blende rock, which is also the principal component of the islands in the neighbourhood, as well as of the island itself of Cape Horn. The eastern part of King Charles South Land is low, with plains like the Patagonian coast; but the range of high land interrupted at Port Famine extends down the north side of Admiralty Sound, and perhaps, with some few intervals, continues to the south-east extremity of the land, near Cape Good Success, which is the south cape of the west side of Strait Le Maire, and there terminates in lofty mountains covered with snow, one of which, called in the charts 'The Sugar Loaf,' is probably four thousand feet high.

The eastern shore of King Charles South Land, towards the south part, is lofty, but near the northern part is very low. The interior is also low, with extensive plains, abounding with guanacoes, some of which also were found, and shot by the officers of the Beagle, within fifty miles of Cape Horn.

The eastern coast of Patagonia, from the entrance of the Strait of Magalhaens to the River Plata, is comparatively low. From Cape Virgins to Port St. Julian, where porphyritic claystone commences, the coast is formed of clay cliffs, horizontally stratified, and the country is undulating, with extensive plains, or pampas, covered with grass, but without trees. At Port St. Julian, the country becomes hilly, and continues so as far to the northward as latitude 44°, the rock being porphyritic. The clay formation to the southward has been likened to the appearance of the coast of Kent, and at a short distance it bears certainly a very great resemblance to it; but the cliffs, instead of being of chalk, are composed of a soft marly clay, without any gravel or impressions of organic remains, excepting at Port St. Julian, where fossil shells, both bivalves and univalves, are found imbedded in clay cliffs; and on the surface are lying, strewed about, large oyster-shells.

In the clay formation there are two rivers: the Gallegos, in lat. 51° 38′; and Port Santa Cruz, in lat. 50° 7′. The Gallegos, at

© The Complete Work of Charles Darwin Online

high water, may be easily entered, but at low water the banks are dry to a great extent; a channel, however, is left on its south side, of sufficient depth for a small vessel: the tide rises forty-six feet, and the stream is very strong.

Port Desire, in 47° 45′ south latitude, has a narrow entrance with strong tides; but affords in the offing very good anchorage as well as shelter from the prevailing winds, which are off shore, or westerly. The inlet extends up the country, nearly in a west direction, for eighteen miles; but the land is dry and parched, and very unsuitable for the establishment which the Spanish government formed there not many years since, and of which evident traces remain to this day.

St. George's Gulf, called in the old charts 'Bahia sin Fondo,' or Deep-Sea Gulf, was formerly considered to be a deep sinuosity of the coast, into which a river emptied its waters after winding through a large tract of country; for, until the Descubierta and Atrevida's voyage of discovery, very vague accounts had been given of this, or indeed of any other part of the coast. The Gulf, upon that examination, was found to possess no river or creek in any part excepting on the north side, where there are several deep bays and coves, which are, and have been frequented by our sealing vessels. The country about is dry and parched, although partially covered with small shrubs, and a wiry grass on which large herds of guanacoes feed.

According to Falkner (the Jesuit missionary, who resided many years among the Indian tribes inhabiting the country about Buenos Ayres), the eastern coast between the latitudes of 41° and 51° is frequented by the natives for the purpose only of burying the dead: they have, however, been occasionally met with travelling along the coast, apparently without any particular object in view. Near Port Desire I have seen the graves of the Indians on the summit of the hills, but the bodies had been removed, probably by the Indians themselves; for we are informed by Falkner, that, after the dead have been interred twelve months, the graves are visited by the tribe, for the purpose of collecting the bones and conveying them to their family sepulchres, where they are set up and adorned with all the beads and ornaments the friends and family of the deceased can collect for the occasion. The ceremony

© The Complete Work of Charles Darwin Online

is performed by certain women of the tribe whose peculiar office it is to attend to these rites.

In the year 1828, from the commencement of January to the middle of August, the Adventure (the ship I commanded) was at anchor at Port Famine, in the Strait of Magalhaens, in latitude 53° 38¼′ south, and longitude 70° 54′ west of Greenwich; and during the whole of that time a careful meteorological journal was kept. The temperature was registered from a very good thermometer of Fahrenheit's scale, suspended within a copper cylindrical case of nine inches diameter, and perforated above and below with holes, to admit a free current of air. The cylinder was fixed to the roof of a shed, thatched with dried leaves to shelter it from the sun, while the sides were open. The barometer (a mountain barometer made by Newman, with an iron cylinder) was hung up in the observatory, five feet above the high-water mark, and both instruments were examined carefully and regularly at the following hours, namely: six and nine o'clock in the morning, at noon, and at three and six o'clock in the evening. The state of the atmosphere was observed daily, by Daniel's hygrometer, at three o'clock in the afternoon. The maximum and minimum temperatures were also observed twice in twenty-four hours, from a Six's thermometer, namely: at nine o'clock in the morning, and at nine in the evening. From this journal the following abstract has been drawn up:—

From the preceding tables it will be seen that the mean temperature for the autumnal period (the months of February, March, and April) was 47°·2; the maximum and minimum were respectively 68° and 28°. For the brumal period, the three following months, the mean temperature was 34°·5, and the maximum and minimum 49° 5 and 12°·6. During the former, or autumnal period, the barometer ranged between 30·099 and 28·768 inches, and for the latter it was between 30·5 and 28·274 inches. The range for the first being 1·331 inches, and for the last 2·226 inches.

INDEX.

Adelaide (Tender) granted, 107—proceedings, 108, 110, 111—goes to look for San Sebastian Channel, 122-124—return to Port Famine, 140 — sent to Cayetano Island, loses boat, 142-143 — in Bougainville Harbour, 145 — further proceedings, 149, 151, 182, 183—suffers from gale in River Plata, 191 — detention, 192-196 — goes to Magdalen Channel, 197, 212, 213, 217, 241, 248—proceedings, 251-257 —at Chiloé, 258—proceedings, 258-268—repaired, 300—sails to Gulf of Peñas, 301—arrives at Port Famine, 321—sails with Adventure to Monte Video and Rio de Janeiro, 322—particulars of her last cruise, 323-358 —left as tender to flag-ship, 462.

Adventure, leaves River Plata, 1—at Sta. Elena, 2-6 — anchors near Cape Fairweather, 7—enters Strait of Magalhaens, 12 — passes First Narrow, 15 — in Gregory Bay, 16 — passes Second Narrow, 20—in Freshwater Bay, 22—at Port Famine, 25-84—in Laredo Bay, 85—in Gregory Bay, 85-104—at Rio de Janeiro, 105—goes to Santos, Sta. Catharina, Monte Video, thence to southward, 106, 107 —re-enters Strait, in Possession Bay, 109—in Gregory Bay, 111—in Port Famine, 117—scurvy on board, 144 —leaves Port Famine, 182—enters River Plata, Brazilian squadron, 186, 187—at Rio de Janeiro, 188—in pampero, 189, 190—at Port Desire, 192—in Sea-Bear Bay, 193—goes to Staten Land, 197—St. Martin Cove, 198—at Valparaiso Bay, 207—at Chiloé, 210—at Valparaiso, goes to Juan Fernandez, 302—at Concepcion, 308 —enters Strait of Magalhaens, 311—in Playa Parda, 312—Fortescue Bay, 313—reaches Port Famine, 315—departs finally, 321—at Rio de Janeiro, 322—arrival in England, 462.

Admiralty Sound, glaciers, weather, Indians, passages, description of shores, 56-59.

Agnes Islands, rocks, dangers, 380.

Agüeros, boundaries of Chiloé, 271—description of Piraguas, 285—quoted on climate, 294, 295—account of missionary voyages, 327-329.

Ainsworth, Mr., goes to survey Port San Antonio, drowned, burial-place, 63-64.

Aldunate, takes Chiloé, Yntendente of the province, 299—anecdote, 300, —goes in Adventure to Valparaiso, 302.

Alerse, good qualities of wood, difficult to obtain, 282-283.

Anas specularis, 117.

Ancon Sin Salida (of Sarmiento), 262—Adelaide there, weather, traced, 347.

Andres San, canal (of Sarmiento), disappointment, 339.

Anser Nigricollis, 352.

Anson,—Juan Fernandez, 307.

Antonio San, Port, Cordova's account, vegetation, 126 — humming-birds,

© The Complete Work of Charles Darwin Online

weather, 127, 128 — detention there, 133-135.

Apterodytes Magellanica, 5.

Araucanian Indians, dress, 309—meeting, 310, 311.

Araucaria imbricata, 311.

Argonauta tuberculosa, found in maw of dolphin, containing *Octopus Ocythöe*, 106, 107.

Ariel Rocks, supposed, search for, meeting of currents gave rise to false report of their existence, 460, 461.

Asses' ears, 12.

Aymond Mount, 12.

Barbara Channel, islands, rocks, tides, 256.

Barbara Santa, Port, 164 — oak-beam, supposed Wager's, found, 165—mountains, island, productions, wigwams, weather, 166, 167.

Barnevelt Islands, 436.

Barometer, 41—observations for height of Mount Tarn, 42, 43—for weather, 144, 149—before pampero, 189, 191—observations, 202, 203, 210 — for height of Mountain de la Cruz, 244—attention to, 371 — changes, 426, 427, 429, 465, 466, 467.

Beagle, leaves Monte Video, 1—at Sta. Elena, 7 — approaches Strait of Magalhaens, 13 — passes First Narrow, 15—at Gregory Bay, 16 — at Port Famine, 25—prepared to go to West part of Straits, and sails, 26, 28 — anxiety for, arrival, 65— proceedings, currents, squalls, doubles Cape Froward, leaves Port Gallant, Cape Tamar, danger, difficulties, dangerous service, 68-80 — sails from Port Famine for Monte Video, 85 — goes thence to Rio de Janeiro, 105 — ordered to Port Desire, 108 — protracted absence, arrival at Port Famine, 119 — sails again, 129 — return, 151 — proceedings during absence, dangers off Parallel Peak, sufferings of crew, at Port Santa Barbara, Port Henry, Port Otway, perilous situation in Channel's mouth, sufferings of crew, at Port Otway for recovery, 154-181 — injured during pampero in River Plata, 190 — sails thence, 191 — at Port Desire, 192 — in Sea-Bear Bay, 195 — proceedings from, 212—to, arrival at Chiloé, 250 —sails for Tierra del Fuego, 300—at Rio de Janeiro, 322 — proceedings during absence, weather, anchorage, gales, boat stolen, critical accident, in Good Success Bay, at Monte Video, returns to England, 360-462.

Bell Cape, tide-race, rocks, 448, 456.

Bellaco Rock, unsuccessful search for, 109—found and examined, 120.

Black River, branch of San Tadeo River, 328 — rapid currents, obstructions, shores, glaciers, 329.

Blanco Cape, shoals off, 108.

Boat upset, lives lost, 63, 64 — boat stolen, 142, 143 — yawl lost, 180 — another boat lost, 193—boats in danger, 231 — whale-boat stolen near Cape Desolation, 391 — basket-like substitute described, 392—boat building, 407—finished, 423.

Borja Bay, weather, williwaws, 247, 312.

Bougainville, 10, 35, 39, 69—memorial, 70, 71—on Patagonians, 99, 101.

Bougainville Harbour, 122, 145, 146.

Breaker Bay, 373, 374.

Buckland Mount, 51.

Bueno Port, its excellence, productions, 340, 341.

Burney Mount, 260.

Bynoe, Mr., excursion, 214—volunteer in Adelaide, 217, 241—meets Indians, 255 — volunteers again in Adelaide, 301, 359.

Byron, Commodore, notice of Sedger River, 38 — of Patagonians, 99 — of cave near Port Otway, 323 — endeavour to trace steps of his party after loss of Wager, account of circumstances connected with it, 324-329 — his description of Montrose Island, 325.

Bowen, Mr., ascends Mountain de la Cruz, 69.

Campana Island, bad weather, danger of Beagle, 161, 163.

Candish, arrival in the Strait, 33—conduct to settlers, gives the name of Port Famine, 34.

Canqueña, or Cagge, 288, 289. (Note.)

© The Complete Work of Charles Darwin Online

Carlos San, de Chilóe, 249—anchorage, position, 274 — buildings, woods, 275—piraguas, 284-286.

Cascade Bay, 219.

Cavia, by some called hare, 5.

Centurion, 303, 304, 307.

Chama, 306.

Channel's mouth, anchorage, weather, surf, 178 — desolate scene, perils, squalls, 179—inlets near, gales, tides, 330.

Chanticleer at Monte Video, 187 — at St. Martin Cove, 198 — sails thence, 205.

Charadrius rubecola, 41.

Charles Islands, surveyed, 315.

Chilóe, position, extent, population, 271, 272—government, troops, 273—cultivation, peasantry, 276 — manners, morals, 277—schools, language, produce, 278 — manufactures, exports, imports, 279—varieties of wood, 280, 281—log roads, 283—ploughs, 286—soil, 287—forced contributions, birds, 288—shell-fish, 290—mode of cooking, 291 — anecdote, 293 — climate, 294-296 — struggles against Chile, 298.

Cholgua (*Mytilus Magellanicus*, Lamarck), 290.

Choro (*Mytilus choras*, Molina), 290.

Cockburn Channel, 254.

Coleoptera, a few species at Sta Elena, 6.

Concholepas Peruviana, used as drinking cups, 167.

Condor, size, accounts of Molina and Humboldt, 185.

Crepidula, one species at Sta Elena, 6.

Cruz, de la, mountain, ascended, 69 — memorials found, 70, 71 — ascended again, 243, 244—its height, 314.

Cygnus Anatodoides, 359.

Dasyprocta (agouti), 5.

Dasypus Minutus, of D'Azara, 5.

Deer, on Point Sta. Anna, 48 — track near Obstruction Sound, 353 — many more observed, 354 — supposed of a novel species, 355.

Desire, Port, examined, 120, 192, 195, 349—quince found there, tides, 460.

Diego Ramirez Islets, 434 — climate, 435.

Diego San, Cape, strong tide, 453 — coast near, 456.

Dislocation Harbour, 364.

Dogs, 46, 52, 62, 76, 89, 137—fine one (Fuegian), 148, 216 — small-sized, 238 — at Juan Fernandez, 304 — fine Fuegian dog, 444 — one like young lion, 448.

Doris Cove, weather, 406.

Dungeness Point, 12.

Eagle Bay, 35, 37, 48.

Easter Bay, 348, 349.

Elena, Sta. Port, arrival there, coast, 2—bad weather, fossil oyster-shells, 4 — animals and birds, 5 — scarcity of fish, trees, traces of natives, departure, 6.

Englefield Island, 225.

Estevan San, channel of, tides, 265.

Evangelists, or Isles of Direction, 156.

Eyre, Sir George, Sound, glaciers, whales, seal, icebergs, 337.

Fairweather, Cape, gale near, singular error, 7—abundance of fish, 8, 9—departure from, 9, 120.

Falkner, the Jesuit, description of Patagonians, 86, 87—funeral ceremonies, 113—graves, 156.

Famine, Port, 26 — former Spanish colony, 29, 30, 31, 32, 33—named by Candish, 34 — shells, 37 — animals, birds, 38—fishing, 39 — preparations and departure, 84—re-visited, 117—events there during absence, 118 — weather, 119 — winter, 142 — floods, lightning, 144 — scurvy, 145—effects of weather, 149, 150 — Beagle there, 216—Adventure there, 315 — finally quitted, 321.

Felipe, San, Spanish settlement under Sarmiento, Viedma, 31, 32 — abandoned, now Port Famine, 34.

Felis pajaros, 117.

Fire, at Port Sta Elena, 3 — at Port Famine, 83—boat and sheds destroyed by Fuegians, 118, at Port Desire, 193, 194—in Gregory Bay, 213 — traces of near Level Bay, 336.

BALFOUR LIBRARY CAMBRIDGE

ceedings, 45, 46, 47—surveys Lomas Bay, 63—sails again in Hope, 65—returns, 80—appointed to Adelaide tender, 107—in Gregory Bay, 110, 111—in Port Gallant, 134, 136—detached, 142—loss of boat, 142, 143—at Bougainville Harbour, 145, 146—with Patagonians, 149, 151—at Port Gallant, 241—honourable trait, 242—journal, 251-257—near Cape Upright, 258—goes to Chiloe, 268.

Gregory Bay, Beagle joins Adventure there, 16—gales, mirage, Patagonians, 85—scenery, productions, fires, 111—natives, 183.

Guanacoes, 3, 4, 5—near Cape Orange, 15—in Gregory Bay, 111—bezoar-stone, 117—mode of hunting them, 151—unusual chase, 193—near Sea-Bear Bay, 194—very large ones seen near Windhond Bay, 439—numerous near Aguirre Bay, 446.

Guayaneco Islands, 167, 331.

Guyot Duclos, 10, 22—notice of natives, 99—skirmish with natives, 320.

Henry, Port, 159—productions, scenery, 160, 161.

Hermite Island, remarkable peaks, survey, 207.

Hope, Mount, 56, 57, 58.

Hope, decked boat, 26—crew, sails on survey, 28—proceedings, meets Fuegians in Brenton Sound, 45, 46—passage back to Port Famine, 47—repaired, 48—goes to Eagle Bay, into Gabriel Channel, 49—further proceedings, 50-63—sails again, 65—goes with Captain King, 80—further proceedings, 82.

Horn, Cape, ascent of highest point, memorial left, 432—weather, 433.

Horn Island, 432.

Hymenoptera, at Port St.ª Elena, 6.

Icebergs, field of ice, 175, 337, 442.

Icy Sound, glaciers, avalanches, 140.

Ildefonsos, 424.

Indian Channel, bivouac, weather, 223.

Island Harbour, 333—weather, 334.

Jerome Channel, 221—scenery, 222.

Jesuit Sound, explored, 329.

Juan Fernandez, 302—establishment, productions, 303—dogs, goats, fish, buccaneers, 304—botany, trees, fruits, 305, 306—shells, coral, anchorage, 306—animals, seals, birds, 307—excursions, thermometer, 308.

Kater Peak, ascended, 200, 201, 202—again, 433, 434.

Kelp, or sea-weed, its great use, 13—immense growth, 363.

Kelp fish, excellent food, 199.

Kelly Harbour, 175.

Kempe, Lieut., excursions, 214, 409—in chase of Fuegians, 412, 413—promptness, 423, 432—left in charge of Beagle, 437—vigilance, 445, 449.

Kempe Harbour, 218.

Kirke, Mr., goes in Adelaide, 217, 241, 242—ascends Mount Skyring, 253—near Cape Tamar, 258—sails again in Adelaide, 301—examines the Channel's Mouth, 330—zealous exertion, 333—examines Sir George Eyre Sound, 337—further proceedings, 338, 339—traces Canal of the Mountains, 347, 348—Worsley Sound, 349—disappointments, 350, 359—further examinations, 354-357.

Latitude Bay, 368—advantages, 370.

Laura Basin, 375.

Leeward Bay, 347.

Lennox Harbour, 437—natives, 449.

Lepidoptera, a few species at Port St.ª Elena, 6.

Liévre pampa, of D'Azara, 5.

Lizards, 6.

Lobos, Port, 2.

Lomas Bay, 63.

Loyasa's voyage quoted, 96.

Lucia Santa, Cape, coast near, 157.

Lyndsey, Serjeant, death of, 176—burial, 177.

Magalhaens, Strait of, voyage to explore, under Don Antonio de Cordova, 9—account of bad weather, confirmed by Wallis and Carteret, 10—difference in spelling name, 11, vegetation of Strait, 22—animals, 23—scenery, 51—

© The Complete Work of Charles Darwin Online

whales, &c., 131—climate, 141—repassed, 186 — entered again, 311 — finally quitted, 322.

Magdalen Channel, 60 — anchorage, scenery, 61 — examined, 251—directions, 252.

Magnetic influence, unusual, 199, 200, 204, 382, 383, 384, 385.

Maire Le, Strait, tides in, 455, 456.

Malaspina, at Port Stª Elena in 1798, 2.

March Harbour, 408, 424.

Maria, a Patagonian, first interview with, 18—at Gregory Bay, 85, 86—visits ships, 88—obtains guanaco meat for them, interview with on shore, 89—acts as priestess, 90—cupidity, 92—'toldo,' 93—disappointment, 104—cordial meeting with, presents, 114—importunity, anecdote, 115—scene in toldo, 116—re-visited, 183.

Marian Cove, 71.

Martin St. Cove, 198—weather, ascent of Kater Peak, 200, 201, 202 — gales and williwaws, 203.

Maxwell, Port, 199.

Mesier Channel, entrance to, 331 — entered by Adelaide, 333 — anchorages, shores, trees, 334 — scarcity of inhabitants, 345.

Millar, Alexander Mr., death of, 321.

Misery Mount, 234.

Mitchell, Lieut., activity, 301, 317, 319.

Montes Tres, Cape, 167, 168, 169, 322.

Morton Island, 420 — tide between it and Gold-dust Isle, 421.

Mountains, canal of the, 347.

Morrion El, 238.

Muræna, near Cape Fairweather, 9.

Murray, Mr., accident, 364 — goes to E. end of Landfall Islands, 368 — in distress, 369 — goes to Euston Bay, 375-378 — goes to Cape Desolation, bad weather, 390—severe gales, return anxiously looked for, sends coxswain back in basket-like canoe, 391 — loss of whale-boat, 393 — search for her, 401, 402, 403—goes away again, 407 — penetrates into channels leading from Christmas Sound, 417—goes to head of Nassau Bay, 427—discovers Beagle Channel, 429—natives, 430—goes towards Cape Good Success, 437 — extract from journal, natives near Cape Graham, difficulties, 446, 447, 448.

Muscle Bay, 332.

Murex at Port Stª Elena, 6 — (*Magellanicus*) brought up by lead, 13—found in Eagle Bay, 37.

Mytilus, at Port Stª Elena, 6—at Port Gallant, 133.

Mytilus choras, at Chiloé, 290.

Mytilus Magellanicus, at Chiloé, 290.

Narborough, Sir John, quoted, 4, 5, 25, 76 — notice of Patagonians, 99, 123, 192.

Narrow, English, described, 335, 336.

Narrow, First, passage attempted, 14—cleared, tides, 15—passed again, 110, 111—tide-race before entering, 322.

Narrow, Guia, tides, 265 — passed by Adelaide, 340.

Narrow, Kirke, 347 — prospect after leaving it, 348 — tides, errors, wider channel, 349—plan of Narrow, singular eddies, 356, 357.

Narrow, Murray, tides, shores, natives, woods, 439, 440 — channels near, mountains, anecdote, wigwam, 441—tides, glaciers, 442 — disadvantages, 443.

Narrow, Second, passed, 20, 85.

Narrow, Shag, 139.

Narrow of San Benito, 264.

Narrow, White, intricate, 347 — agreeable prospect, 348.

Nassau Bay, 425 — master passes through it, 429—formerly Bay of St. Francis, errors in charts, 433—further examined, 438.

Nautical remarks, gales on the eastern coast of Patagonia, entrance of Strait of Magalhaens, 463 — Staten Island, New Year Islands, 464 — passage round Cape Horn, barometer, 465—barometer off Cape Horn, 466, 467—directions for passage through Strait, 468—anchorages, 469, 470 — advantage of passing Strait from Pacific to Atlantic, 471, 472—further directions, 473, 474, 475.

Neesham Bay, Indians near, 267.

Negro Cape, 21, 22, 24, 215.

© The Complete Work of Charles Darwin Online

New Year Sound, 419, 420.

Nodales, voyage of the, 7, 99 — Bellaco Rock, 109—San Sebastian Channel, 122, 123 — discovered Sea-Bear Bay, 193.

Noir Island, roadstead, penguins, 387—Tower Rocks, 388.

North Cove, 382.

Obstruction Sound, tides, 352 — remarks, 352.

Oidemia Patachonica, 35.

Oliver Islands, 351.

Ophidium, near Cape Fairweather, 8.

Orange Bay, 426, 427—anchorage, productions, 430.

Orthoceratite, fossil resembling an, Rocky Bay, 321.

Osorio Pedro, at Chiloe, Byron, 'Desecho,' 327.

Ostrea Edulis, at Chiloe, 291.

Ostrea, fossil at Port Sta. Elena, 4.

Otway, Port, 169—weather, woods, 170—trees, soil, birds, 323.

Otway Water, 224.

Pampero, 189, 190.

Parallel Peak, 163, 164.

Patagonians, near Gregory Bay, 16 — size, friendliness, dress, weapons, three go in Adventure to Cape Negro, native names, 20 — appearance described, 21 — met again in Gregory Bay, animals with them, 85—account of various tribes, 86, 87—go on board ships, intoxication, 88 — trade, 89—religious ceremony, 90, 91 — toldos, 92—utensils, 93—tomb, father's grief, women, occupations, 94 — parental affection, anecdotes, 95 — their size, 96 — former accounts compared, 97, 98, 99, 100, 101, 102—character, 103—contempt for Fuegians, 104—fires, 110—tomb in Gregory Bay re-visited, 112 — natives arrive, traffic, 113 — cordial meeting, 114 — natives on board, 116 — in Pecket Harbour, hunting, 151, 152—seen again, toldos, 183 — Portuguese sailors living with them, native language, 184—observed again in passing Gregory Bay, 321.

Patagonian Cavy, 5.

Patella deaurata, at Port Sta. Elena, 6.

Patella trochi-formis, 13.

Paul's, St., dome of, 169.

Pecheray, Fuegian expression, anecdotes, 313, 314, 315 — mentioned again, 320.

Pecket Harbour, 151, 183, 184, 213.

Pecten vitreus, in Eagle Bay, 37.

Penguins, 387—mode of feeding young, 388.

Phalacrocorax Imperialis, 359.

Phoca Jubata, food of Fuegians, 24.

Pico, 292.

Pillar, Cape, 79, 311, 361 — mountains near, 375—tide, 455.

Pinoleo, Araucanian Cacique, account of meeting near Concepcion, daughters, their dress, ornaments, reception from him, his appearance, 309—followers, intoxication, 310.

Pinto, General, Director of Chile, 209.

Piure, remarkable appearance, 292.

Plata, River, Brazilian Squadron, confusion, mistake, 186 — severe 'pampero,' effects, 189, 190—gales, 191—currents, 461.

Playa Parda, 312.

Polyborus Novæ Zealandiæ, 143.

Possession, Cape, 12—tides, 13, 15 — detention, 109—weather, 110.

Psittacus smaragdinus, near Port Famine, 39.

Quintin San, Sound, 174, 175 — Adelaide there, 324.

Quod, Cape, 247.

Roldan Campana de, 27.

Rundle Passage, 322.

Rupert Island, rocks, weather, 246.

Saddle Island, magnetic needle much affected, scenery, whales, kelp-fish, 199.

Santiago, journey to, 207, 208—weather, 210.

Sarmiento, 26 — sent to look for Sir Francis Drake, enters Strait, 29 — sails to form establishments, 30 —

© The Complete Work of Charles Darwin Online

marks out city, colonists' sufferings, goes to Rio de Janeiro, 31—disappointments, taken to England, 32 — his account of natives near Useless Bay, 125 — Campana de Roldan, 130 — discovery of Gulf of Trinidad, 158, 159—his 'Abra' opposite Playa Parda, 312—quoted, 340..

Sarmiento channel, passed, 341 — discoveries, 342—course followed, 346.

——— Mount, first appearance, 26 —height, 27, 28—seen again, 130, 147, 252.

Saxe Cobourg, Prince of, wrecked in Fury Harbour, 66—crew's sufferings, saved by Beagle, 67.

Sea-Bear Bay, 6—described by Nodales, 193—animals, birds, 195.

Seal, teaching their young to swim, 422.

Sebastian San, Channel supposed, noticed by Nodales, 122—various voyagers' opinions, 123—vain search, 458.

Sedger River, mouth changes, remarks, 37—trees, 38.

Shags (corvorants), nests on trees in Courtenay Sound, 404.

Sholl, Robert Lieut., interview with natives, 23, 24, 65—death of, 121.

Skyring, Lieut., 77, 78, 165—takes command of Beagle, 182 — superseded, 188 — takes command of Adelaide, goes to survey Magdalen, Cockburn, and Barbara Channels, reaches Port Gallant, 241 — part company near Cape Upright, 249—meets Indians, 256 — near Cape Upright, 258 — searches for 'Ancon Sin Salida' of Sarmiento, 261 — natives, 262 — tides, 263—weather, 264—his journal, 266 —sails for gulf of Peñas, 301—journal of proceedings, 323—examines River San Tadeo, 327—proceedings, 328—returns to Adelaide, 329—illness, 333 —officers' proceedings, 346—resumes duty, 347 — disappointments, 350, 351 —excellence of charts, 386.

Skyring Mount, ascent, memorial, 253, 254—described, strong local attraction, effect on compasses, 382, 383—view from it, 383.

Skyring Water, 228—tides, land, birds, 229.

Skunk, or Zorillo, 184, 185.

Smyth Channel, 259—fish, 260—survey, 261.

Snakes at Port Sta Elena, 6.

Snowy Sound, 237.

Speedwell Bay, abundance of wild-fowl, crabs, potatoes, trees, 332.

Spencer Cape, 431, 435.

Steamer-Duck, or Race-Horse, 35, 36.

Stewart Harbour described, its advantages, 406.

Stokes, Pringle Captain, commands Beagle, 2, 18, 26, 28 — rescues crew of shipwrecked vessel, 65—journal, 67 to 80—dangerous cruise, 73—skill and daring, 77—rides to Patagonian toldos, 92—ordered to Port Desire, 108—arrival at Port Famine, 119—proceedings during absence, 121—sails again, 124—describes Bougainville Harbour, 146—returns to Port Famine, sufferings, illness, 150, 151—death, 153—unfinished journal, 154-181.

Stokes, Mr. goes to explore Jerome Channel, 221, 225—narrow escape, 232, 233—examines Hope Harbour, 382—Fury Harbour, 384, 445.

Success Good, Cape, 445, 448—shores, anchorage in bay, swell, 450—gales, 451.

Tadeo San, River, 323, 327, 328.

Tamar Cape, weather off, 72—Beagle in Bay of, 73—returns three times, 74.

Tarn, Mr., 4—excursion to Eagle Bay, 35 — ascends Mount Tarn, 40, 42 — interview with natives, 61 —summit of Table Land, 111—Laredo Bay, 117 — in Adelaide, 143, 149—with Patagonians, 151—signal-fire, guanacoes, 194.

Tarn Mount, ascent of, 40—temperature, observations, descent, 42, 43.

Teal found at Port Sta Elena, 5.

Tower Rock near Port Desire, remarkable, Narborough's description, 192.

Tower Rocks, off Noir Island, 388.

Tower, rock like, near Aguirre Bay, 447.

Trinidad Sanctisima, Golfo de la, 158.

Tres Puntas Cape, 158, 161.

© The Complete Work of Charles Darwin Online

Trochilus at Juan Fernandez, 307.

Ulloa, Don J. Juan, y Don A. de, their account of the anchorage at Juan Fernandez, 306.

'Ultimo Viage al estrecho de Magallanes,' quoted, 10, 27, 57, 101.

Upright, Cape, 71—bay, 155—weather, 258.

Useless Bay, 124—natives near, 125.

Valdivia de, Don Pedro, founds cities, 269—Indians destroy them, settlers migrate, 270.

Valentyn Bay, natives, 448.

Valparaiso, 207, 210.

Vicente San, Bay, 453.

Viedma Andres de, at San Felipe, 32—wrecked, return, distresses, 33, 34.

Video Monte, departure from, 1—return to, and sail from, 105—revisited, meeting with Captain Foster at, 187 gales in leaving, 191—return there, 322—finally quitted, 462.

Virgins Cape, 12, 105, 109.

Wager, loss of, 324 to 327, 331.

Warrington cove, 135—geology, 136—productions, 139.

Waterfall Bay, weather, tides, 334.

Waterfall, Port, 51-52.

Weddell's Leading Hill, 418, 421.

Whales, dead, mistaken for rocks, 107, 380.

White Kelp Cove, fish, birds, 335.

William, Cape, 158.

Wickham Lieut., takes command of Hope, 28—meets Indians, 45—returns to Port Famine, 47—in Gregory Bay, 111—obtains curious birds, 117—at Port Famine, 141—goes to Patagonians, 149—ill, 152—goes overland to Port Desire, 195—at Santiago, 207, 210.

Williwaws, 50, 203.

Wilson, Mr., goes to Landfall Island, 368, 369, 376—good drawings, 383—natives, 409, 413—sketches of coast, 436.

Woodcock Mount, 139-140.

Wreck found in Port Sta Elena, 2—in Fury Harbour (of Saxe Cobourg), 66, 67.

Xavier San Island, 176—examined further, 329.

Xavier Port, woods, water, birds, 176.

Xaultegua, Gulf of, curious islet, frost and snow, 247.

York-Minster of Cook, noticed, 407—mark for March Harbour, 408, 411.

'Yungue' (Juan Fernandez), height, woods, squalls, 302, 303.

Zorillo, 184, 185.

SURVEYING VOYAGES

OF

THE BEAGLE.

1831—1836.

CHAPTER I.

Explanation—Natives of Tierra del Fuego, or Fuegians—Passages across the Equator (Atlantic)—Letters—Small-pox—Hospital—Boat Memory—Fuegians in London—At Walthamstow—At St. James's—Beagle recommissioned—Correspondence with Mr. Wilson—Fuegians re-embark.

As the following narrative of the Beagle's second voyage to South America is a sequel to the "Surveying Voyages of the Adventure and the Beagle," which are related in the preceding volume, it may be advisable that this chapter should contain a sketch of some few incidents intimately connected with the origin and plan of the second Expedition.

Captain King has already mentioned that the two ships under his orders sailed from Rio de Janeiro, on their homeward passage, early in August 1830.

During the time which elapsed before we reached England, I had time to see much of my Fuegian companions; and daily became more interested about them as I attained a further acquaintance with their abilities and natural inclinations. Far,

DARWIN LIBRARY CAMBRIDGE

28

© The Complete Work of Charles Darwin Online

very far indeed, were three of the number from deserving to be called savages—even at this early period of their residence among civilized people — though the other, named York Minster, was certainly a displeasing specimen of uncivilized human nature.

The acts of cannibalism occasionally committed by their countrymen, were explained to me in such terms, and with such signs, that I could not possibly misunderstand them ; and a still more revolting account was given, though in a less explicit manner, respecting the horrible fate of the eldest women of their own tribes, when there is an unusual scarcity of food.

This half-understood story I did not then notice much, for I could not believe it ; but as, since that time, a familiarity with our language has enabled the Fuegians to tell other persons, as well as myself, of this strange and diabolical atrocity ; and as Mr. Low (of whom mention will often be made in the following pages) was satisfied of the fact, from the concurrent testimony of other Fuegians who had, at different times, passed months on board his vessel, I no longer hesitate to state my firm belief in the most debasing trait of their character which will be found in these pages.

At the sea-ports which the Beagle visited in her way from Tierra del Fuego to England, animals, ships, and boats seemed to engage the notice of our copper-coloured friends far more than human beings or houses. When any thing excited their attention particularly, they would appear, at the time, almost stupid and unobservant ; but that they were not so in reality was shown by their eager chattering to one another at the very first subsequent opportunity, and by the sensible remarks made by them a long time afterwards, when we fancied they had altogether forgotten unimportant occurrences which took place during the first few months of their sojourn among us.

A large ox, with unusually long horns, excited their wonder remarkably ; but in no instance was outward emotion noticed, to any great degree, excepting when they saw a steam-vessel going into Falmouth Harbour. What extraordinary monster it was, they could not imagine. Whether it was a

© The Complete Work of Charles Darwin Online

huge fish, a land animal, or the devil (of whom they have a notion in their country), they could not decide; neither could they understand the attempted explanations of our sailors, who tried to make them comprehend its nature: but, indeed, I think that no one who remembers standing, for the first time, near a railway, and witnessing the rapid approach of a steam-engine, with its attached train of carriages, as it dashed along, smoking and snorting, will be surprised at the effect which a large steam-ship, passing at full speed near the Beagle, in a dark night, must have had on these ignorant, though rather intelligent barbarians.

Before relating occurrences subsequent to our arrival in England, I must ask permission to make the first of a few nautical remarks that will be found in this volume, some of which, I hope, may be useful to young sailors.

Our passage across the Atlantic, from Rio de Janeiro to Falmouth, was unusually long. In order to sail within sight of the Cape Verd Islands, for a particular purpose, we steered eastward from the coast of Brazil, and crossed the equator far east. This course, unavoidable in our case, carried us into that tract of ocean, between the trade-winds, which in August and September is subject to westerly winds—sometimes extremely strong—and we encountered a very heavy gale, although so near the equator. Afterwards, when close to our own shores, we were unfortunate enough to be delayed by what seamen call a hard-hearted easterly wind; and not until the middle of October were we moored in a British port.

As a remarkable contrast, a Falmouth packet, which sailed from Rio de Janeiro some time after our departure, steered northward, as soon as she had cleared the coast of Brazil, crossed the line far to the west, and arrived in England a fortnight before us.

My own humble opinion, with respect to crossing the equator, is, that an outward-bound ship ought to cross near twenty-five—and that one homeward-bound may go even beyond thirty degrees of west longitude—but should not attempt to pass eastward of twenty-five. Ships crossing the line between

© The Complete Work of Charles Darwin Online

twenty-five and thirty degrees west, are, I believe, far less subject to detention—taking the year through—than those which adopt easterly courses.

Cape St. Roque, St. Paul Rocks, Fernando Noronha, and the Roccas, ought not to be thought of too lightly; but in avoiding them, and the lee current near St. Roque, many ships have encountered the tedious calms, extremely hot weather, frequent torrents of rain, and violent squalls, which are more or less prevalent between the longitudes of twenty and ten degrees west.

To return to the Fuegians. While on our passage home I addressed the following letter to my commanding officer and kind friend, Captain King.

" Sir, Beagle, at sea, Sept. 12, 1830.

" I have the honour of reporting to you that there are now on board of his Majesty's sloop, under my command, four natives of Tierra del Fuego.

" Their names and estimated ages are,

York Minster	26
Boat Memory	20
James Button	14
Fuegia Basket (a girl)	9

" I have maintained them entirely at my own expense, and hold myself responsible for their comfort while away from, and for their safe return to their own country: and I have now to request that, as senior officer of the Expedition, you will consider of the possibility of some public advantage being derived from this circumstance; and of the propriety of offering them, with that view, to his Majesty's Government.

" If you think it proper to make the offer, I will keep them in readiness to be removed according to your directions.

" I am now to account for my having these Fuegians on board, and to explain my future views with respect to them.

" In February last, the Beagle being moored in ' Townshend Harbour,' on the south-west coast of Tierra del Fuego, I sent Mr. Matthew Murray (master), with six men, in a whale-boat, to Cape Desolation; the projecting part of a small,

© The Complete Work of Charles Darwin Online

but high and rugged island, detached from the main land, and twelve miles distant from Townshend Harbour.

"Mr. Murray reached the place, and secured his party and the boat in a cove near the cape: but during a very dark night, some Fuegians, whose vicinity was not at all suspected, approached with the dexterous cunning peculiar to savages and stole the boat.

"Thus deprived of the means of returning to the Beagle, and unable to make their situation known, Mr. Murray and his party formed a sort of canoe, or rather basket, with the branches of trees and part of their canvas tent, and in this machine three men made their way back to the Beagle, by his directions: yet, although favoured by the only fine day that occurred during the three weeks which the Beagle passed in Townshend Harbour, this basket was twenty hours on its passage.

"Assistance was immediately given to the master and the other men, and a chase for our lost boat was begun, which lasted many days, but was unsuccessful in its object, although much of the lost boat's gear was found, and the women and children of the families from whom it was recovered, were brought on board as hostages. The men, excepting one of them, escaped from us, or were absent in our missing boat.

"At the end of February the Beagle anchored in Christmas Sound; but before this time all our prisoners had escaped, except three little girls, two of whom we restored to their own tribe, near 'Whale-boat Sound,' and the other is now on board.

"From the first canoe seen in Christmas Sound, one man was taken as a hostage for the recovery of our boat, and to become an interpreter and guide. He came to us with little reluctance, and appeared unconcerned.

"A few days afterwards, traces of our boat were found at some wigwams on an island in Christmas Sound, and from the families inhabiting those wigwams I took another young man, for the same purpose as that above-mentioned. No useful information respecting our lost boat was, however, gained from them, before we were obliged to leave that coast, and she remained the prize of their companions.

© The Complete Work of Charles Darwin Online

"Afterwards, when in Nassau Bay, our captives informed us that the natives of that part of the coast, and all to the eastward, were their enemies, and that they spoke a different language. This intelligence was extremely disappointing, and made me anxious to persuade one of this eastern tribe to come on board and stay with us; but I had then no hopes of doing so, and gave up the idea: however, some time afterwards, accidentally meeting three canoes, when away in my boat exploring the Beagle Channel, I prevailed on their occupants to put one of the party, a stout boy, into my boat, and in return I gave them beads, buttons, and other trifles. Whether they intended that he should remain with us permanently, I do not know; but they seemed contented with the singular bargain, and paddled again towards the cove from which they had approached my boat. We pulled on along shore, attended by other canoes, which had been endeavouring to barter with us whenever we stopped; but at dusk they ceased following, us and went ashore.

"When about to depart from the Fuegian coast, I decided to keep these four natives on board, for they appeared to be quite cheerful and contented with their situation; and I thought that many good effects might be the consequence of their living a short time in England. They have lived, and have been clothed like the seamen, and are now, and have been always, in excellent health and very happy. They understand why they were taken, and look forward with pleasure to seeing our country, as well as to returning to their own.

"Should not his Majesty's Government direct otherwise, I shall procure for these people a suitable education, and, after two or three years, shall send or take them back to their country, with as large a stock as I can collect of those articles most useful to them, and most likely to improve the condition of their countrymen, who are now scarcely superior to the brute creation.

"I have, &c.
ROBERT FITZ-ROY,
Commander."

"Phillip Parker King, Esq.
Commander H.M.S. Adventure,
Senior officer of the Expedition."

© The Complete Work of Charles Darwin Online

This letter was forwarded to the Admiralty by Captain King, as soon as he arrived in England; and a few days afterwards the following answer was received.

"Sir, Admiralty Office, 19th Oct. 1830.

"Having laid before my Lords Commissioners of the Admiralty your letter and its enclosure from Commander Fitz-Roy, of the Beagle, relative to the four Indians whom he has brought from Tierra del Fuego under the circumstances therein stated; I am commanded to acquaint you that their Lordships will not interfere with Commander Fitz-Roy's personal superintendence of, or benevolent intentions towards these four people, but they will afford him any facilities towards maintaining and educating them in England, and will give them a passage home again.

"I am, &c.

"To Commander King, (Signed) JOHN BARROW."
H.M.S.V. Adventure."

I was, of course, anxious to protect the Fuegians, as far as possible, from the contagion of any of those disorders, sometimes prevalent, and which unhappily have so often proved fatal to the aboriginal natives of distant countries when brought to Europe; and, immediately after our arrival in England, they landed with me, after dark, and were taken to comfortable, airy lodgings, where, next day, they were vaccinated, for the second time.

Two days afterwards they were carried a few miles into the country, to a quiet farm-house, where I hoped they would enjoy more freedom and fresh air, and, at the same time, incur less risk of contagion than in a populous sea-port town, where curiosity would be excited.

Meanwhile, the Beagle was stripped and cleared out; and the Adventure went to Woolwich for a similar purpose, preparatory to being paid off. On the 27th of October, the Beagle's pendant was hauled down; and on the 15th of November, the Adventure was put out of commission.

© The Complete Work of Charles Darwin Online

Both vessels' crews were dispersed, as usual, unfortunately; and of those who had passed so many rough hours together, but few were likely to meet again. I much regretted the separation from my tried and esteemed shipmates, and from our excellent little vessel.

Soon afterwards, Captain King and Lieutenant Skyring were promoted: a gratifying proof of the good opinion of their exertions and conduct, which was entertained by the Lords Commissioners of the Admiralty.

Early in November I received the sad intelligence that the young man, called Boat Memory, was taken ill; and that the symptoms of his disorder were like those of the small-pox. Dr. Armstrong, of the Royal Hospital at Plymouth, whose advice I solicited, suggested that he and the other three Fuegians should be received immediately into the hospital, with the view of preventing further infection, and ensuring the best treatment for the poor sufferer. Dr. Armstrong applied to the physician, Dr. Dickson (now Sir David Dickson), as well as Sir James Gordon, the superintendent, and by their advice and permission the Fuegians were removed into the hospital without delay; and an application was made to the Admiralty, of which the following is a copy.

"Sir, "Devonport, 7th Nov. 1830.

"I have the honour of addressing you to request that the four Fuegians, whom I brought to England in the Beagle, may be received into the Royal Naval Hospital.

"The Lords Commissioners of the Admiralty have stated in a letter to Commander King, dated 19th Oct. 1830, that 'their Lordships will not interfere with Commander Fitz-Roy's personal superintendance of, or benevolent intentions towards these four people, but they will afford him any assistance in maintaining and educating them in England, and will give them a passage home again.'

"In consequence of this assurance, I now beg that you will draw their Lordships' attention to the circumstance of an eruption having broken out upon one of the Fuegian men, since he

© The Complete Work of Charles Darwin Online

was vaccinated, which is supposed, by the medical officers of the hospital, to be the small-pox.

"As the other three individuals have been always in company with him, it is to be feared that they also are affected; and as the vaccination has not yet taken a proper effect, it is the opinion of the medical officers that it would be safer to receive them into the hospital, until the present critical period is passed, than to allow them to remain in private care.

"I have further to request, that my late coxswain, James Bennett, may be permitted to accompany, and remain with the Fuegians, in order to attend upon them, in the event of their Lordships allowing them to be admitted into the hospital; and I hope, Sir, that the peculiar nature of the case may be thought to justify this application.

"I have, &c.

"The Secretary of the Admiralty. ROBERT FITZ-ROY, Commander."

"Sir, Admiralty-Office, 10th Nov. 1830.

"I am commanded by my Lords Commissioners of the Admiralty to acquaint you, in answer to your letter of this day's date, that directions have been given for the admission of the four Fuegians therein alluded to, into the Naval Hospital at Plymouth, and that James Bennett be allowed to attend them, agreeably with your request.

"I am, Sir, &c.

"Commander Fitz-Roy. (Signed) "JOHN BARROW."

The Admiralty having thus sanctioned the admission of the Fuegians into one of the best hospitals, and assured that they could not be under better treatment than that of the well-known gentlemen whom I have mentioned, I felt less anxiety in leaving them for a time, as I was obliged to do, in order to attend to duties connected with the survey; but I had hardly reached London, when a letter from Dr. Dickson informed me of the untimely fate of Boat Memory. He had been vaccinated four different times; but the three first opera-

© The Complete Work of Charles Darwin Online

tions had failed, and the last had just taken effect, when the disease showed itself. It was thought that the fatal contagion must have attacked him previously.

This poor fellow was a very great favourite with all who knew him, as well as with myself. He had a good disposition, very good abilities, and though born a savage, had a pleasing, intelligent appearance. He was quite an exception to the general character of the Fuegians, having good features and a well-proportioned frame. It may readily be supposed that this was a severe blow to me, for I was deeply sensible of the responsibility which had been incurred; and, however unintentionally, could not but feel how much I was implicated in shortening his existence. Neither of the others were attacked, the last vaccination having taken full effect; but they were allowed to remain in the hospital for some time longer, until I could make satisfactory arrangements for them. While they were under Dr. Dickson's care, in the hospital, his own children had the measles; and thinking that it would be a good opportunity to carry the little Fuegian girl through that illness, he prepared her for it, and then took her into his house, among his own children; where she had a very favourable attack, and recovered thoroughly.

Of course, I was anxious that no time should be lost in arranging a plan for their education and maintenance; and deeming the Church Missionary Society to be in some measure interested about the project I had in view, I applied to their secretary, through whose kindness I became acquainted with the Rev. Joseph Wigram; to whom I am under great obligations for the friendly interest taken at that time in my wishes with respect to the Fuegians, and for introducing them and myself to the notice of the Rev. William Wilson, of Walthamstow. Mr. Wilson at once relieved my mind from a load of uncertainty and anxiety, by saying that they should be received into his parish, and that he would talk to the master of the Infant School about taking them into his house, as boarders and pupils. In a short time, it was arranged that the school-

© The Complete Work of Charles Darwin Online

master should receive, and take entire charge of them, while they remained in England, and should be paid by me for their board and lodging, for his own trouble, and for all contingent expenses.

Mr. Wilson proposed to keep a watchful eye over them himself, and give advice from time to time to their guardian and instructor. Mr. Wigram also lived at Walthamstow, and as he would have frequent opportunities of offering a useful caution, in case that the numerous calls upon Mr. Wilson's attention should at any time render additional thoughts for the Fuegians an unfair or unpleasant trouble to him—I did indeed think that no plan could be devised offering a better prospect; and immediately made arrangements for conveying them to London.

The inside of a stage-coach was taken, and under the guidance of Mr. Murray (the Beagle's late master), attended by James Bennett, they arrived in Piccadilly, and were immediately carried to Walthamstow, without attracting any notice. Mr. Murray told me that they seemed to enjoy their journey in the coach, and were very much struck by the repeated changing of horses.

I took them myself from the coach-office to Walthamstow; they were glad to see me, but seemed bewildered by the multitude of new objects. Passing Charing Cross, there was a start and exclamation of astonishment from York. 'Look!' he said, fixing his eyes on the lion upon Northumberland House, which he certainly thought alive, and walking there. I never saw him show such sudden emotion at any other time. They were much pleased with the rooms prepared for them at Walthamstow; and the schoolmaster and his wife were equally pleased to find the future inmates of their house very well disposed, quiet, and cleanly people; instead of fierce and dirty savages.

At Walthamstow they remained from December 1830 till October 1831; and during all that time were treated with the utmost kindness by the benevolent men whose names I have mentioned; by their families, and by many others in the

© The Complete Work of Charles Darwin Online

neighbourhood, as well as casual visitors, who became much interested in their welfare, and from time to time gave them several valuable presents.

The attention of their instructor was directed to teaching them English, and the plainer truths of Christianity, as the first object; and the use of common tools, a slight acquaintance with husbandry, gardening, and mechanism, as the second. Considerable progress was made by the boy and girl; but the man was hard to teach, except mechanically. He took interest in smith's or carpenter's work, and paid attention to what he saw and heard about animals; but he reluctantly assisted in garden work, and had a great dislike to learning to read. By degrees, a good many words of their own languages were collected (the boy's differed from that of the man and the girl), and some interesting information was acquired, respecting their own native habits and ideas. They gave no particular trouble; were very healthy; and the two younger ones became great favourites wherever they were known. Sometimes I took them with me to see a friend or relation of my own, who was anxious to question them, and contribute something to the increasing stock of serviceable articles which I was collecting for their use, when they should return to Tierra del Fuego. My sister was a frequent benefactress; and they often talked, both then and afterwards, of going to see 'Cappen Sisser.'

During the summer of 1831, his late Majesty expressed to Colonel Wood a wish to see the Fuegians, and they were taken to St. James's. His Majesty asked a great deal about their country, as well as themselves; and I hope I may be permitted to remark that, during an equal space of time, no person ever asked me so many sensible and thoroughly pertinent questions respecting the Fuegians and their country also relating to the survey in which I had myself been engaged, as did his Majesty. Her Majesty Queen Adelaide also honoured the Fuegians by her presence, and by acts of genuine kindness which they could appreciate, and never forgot. She left the room, in which they were, for a minute, and returned with one

© The Complete Work of Charles Darwin Online

of her own bonnets, which she put upon the girl's head. Her Majesty then put one of her rings upon the girl's finger, and gave her a sum of money to buy an outfit of clothes when she should leave England to return to her own country.

I must now revert to matters more immediately connected with the Beagle's second voyage.

My own official duties, relating to the survey, were completed in March 1831; when my late commanding officer, Captain King, addressed a letter to the Lords Commissioners of the Admiralty expressive of his approbation of the part I had taken, under his direction, and recommending me to their Lordships.*

From various conversations which I had with Captain King, during the earlier period of my service under him, I had been led to suppose that the survey of the southern coasts of South America would be continued; and to some ship, ordered upon such a service, I had looked for an opportunity of restoring the Fuegians to their native land.

Finding, however, to my great disappointment, that an entire change had taken place in the views of the Lords of the Admiralty, and that there was no intention to prosecute the survey, I naturally became anxious about the Fuegians; and, in June, having no hopes of a man-of-war being sent to Tierra del Fuego, and feeling too much bound to these natives to trust them in any other kind of vessel, unless with myself—because of the risk that would attend their being landed anywhere, excepting on the territories of their own tribes—I made an agreement† with the owner of a small merchant-vessel, the John of London, to carry me and five other persons to such places in South America as I wished to visit, and eventually to land me at Valparaiso.

My arrangements were all made, and James Bennett, who was to accompany me, had already purchased a number of goats, with which I purposed stocking some of the islands of Tierra del Fuego—when a kind uncle, to whom I mentioned

* Appendix. † Ibid.

© The Complete Work of Charles Darwin Online

my plan, went to the Admiralty, and soon afterwards told me that I should be appointed to the command of the Chanticleer, to go to Tierra del Fuego.

My agreement with the owner of the John was, however, in full force, and I could not alter it without paying a large proportion of the whole sum agreed on for the voyage.

The Chanticleer was not, upon examination, found quite fit for service; and, instead of her, I was again appointed to my well-tried little vessel, the Beagle. My commission was dated the 27th of June, and on the same day two of my most esteemed friends, Lieutenants Wickham and Sulivan, were also appointed.

While the Beagle was fitting out at Devonport, I received the following letter from Mr. Wilson.

" Sir, Walthamstow, 5th Aug. 1831.

" I am informed that the Fuegians who have been lately resident in this place are shortly to return to their native country under your care. Will you permit me to ask whether, if two individuals should volunteer to accompany and remain with them, in order to attempt to teach them such useful arts as may be thought suited to their gradual civilization, you will give them a passage in the Beagle? and whether, upon your arrival on the coast of Tierra del Fuego, you will be able to give them some assistance in establishing a friendly intercourse with, and settlement amongst the natives of that country? Would these individuals be required to pay you for their passage, and maintenance on board? or would his Majesty's Government allow them to be maintained on board at the public expense? Do you think that you would be able to visit them, after their first settlement, supposing so desirable an object should be attained, in order to give them some encouragement, and perhaps assistance; or to remove them if they should find it impracticable to continue their residence among the natives?

© The Complete Work of Charles Darwin Online

"A subscription has been set on foot by gentlemen who are extremely desirous that this opportunity of extending the benefits of civilization should not be lost; and, in consequence of their united wishes, I now take the liberty of asking these questions.

"I am, &c.

(Signed) "WILLIAM WILSON."

"To Captain Fitz-Roy, R.N."

After reading this communication, I wrote to the Secretary of the Admiralty, and enclosed a copy of Mr. Wilson's letter. The answer is subjoined.

"Sir, Admiralty Office, 10th Aug. 1831.

"Having laid before my Lords Commissioners of the Admiralty your letter of yesterday's date, with the letter which accompanied it, from the Rev. William Wilson, respecting the natives of Tierra del Fuego who were brought to England in his Majesty's ship Beagle; I am commanded to acquaint you that their Lordships will give the necessary orders for the passage of these individuals, and of the two persons who are to accompany them; and that your request to be allowed to visit these people, after their arrival, will be taken into consideration in preparing your instructions.

"I am, &c.

(Signed) "JOHN BARROW."

"To Commander Fitz-Roy,

"H.M.S. Beagle."

In consequence of this reply, it was wished that two persons should accompany the Fuegians, and endeavour to pass some time in their country: but it was not easy to find individuals sufficiently qualified, and in whom confidence could be placed, who would willingly undertake such an enterprise. One young man was selected by Mr. Wilson, but a companion for him could not be found in time to embark on board the Beagle.

In October the party from Walthamstow arrived, in a

© The Complete Work of Charles Darwin Online

steam-vessel, at Plymouth, and not a few boats were required to transport to our ship the large cargo of clothes, tools, crockery-ware, books, and various things which the families at Walthamstow and other kind-hearted persons had given. In the small hold of the Beagle, it was not easy to find places for the stowage of so many extra stores; and when dividing the contents of large chests, in order to pack them differently, some very fair jokes were enjoyed by the seamen, at the expense of those who had ordered complete sets of crockery-ware, without desiring that any selection of articles should be made.

Instructions were given, by the Secretary of the Church Missionary Society, to the young man who wished to accompany the Fuegians, which will be found in the Appendix; and although he was rather too young, and less experienced than might have been wished, his character and conduct had been such as to give very fair grounds for anticipating that he would, at least, sincerely endeavour to do his utmost in a situation so difficult and trying as that for which he volunteered.

CHAPTER II.

Hydrographer's Opinion—Continuation of Survey—Chain of Meridian Distances—Efficient Arrangements—Repair and raise Deck—Outfit—Boats—Lightning-Conductors—Rudder—Stove—Windlass—Chronometers—Mr. Darwin—Persons on board—Changes—List of those who returned—Supplies—Admiralty Instructions—Memorandum—Hydrographer's Memorandum.

When it was decided that a small vessel should be sent to Tierra del Fuego, the Hydrographer of the Admiralty was referred to for his opinion, as to what addition she might make to the yet incomplete surveys of that country, and other places which she might visit.

Captain Beaufort embraced the opportunity of expressing his anxiety for the continuance of the South American Surveys, and mentioning such objects, attainable by the Beagle, as he thought most desirable: and it was soon after intimated to me that the voyage might occupy several years. Desirous of adding as much as possible to a work in which I had a strong interest, and entertaining the hope that a chain of meridian distances might be carried round the world if we returned to England across the Pacific, and by the Cape of Good Hope; I resolved to spare neither expense nor trouble in making our little Expedition as complete, with respect to material and preparation, as my means and exertions would allow, when supported by the considerate and satisfactory arrangements of the Admiralty: which were carried into effect (at that time) by the Navy Board, the Victualling Board, and the Dockyard officers at Devonport.

The Beagle was commissioned on the 4th of July 1831, and was immediately taken into dock to be thoroughly examined, and prepared for a long period of foreign service. As she required a new deck, and a good deal of repair about the upper works, I obtained permission to have the upper-deck

BALFOUR LIBRARY
CAMBRIDGE

raised considerably,* which afterwards proved to be of the greatest advantage to her as a sea boat, besides adding so materially to the comfort of all on board. While in dock, a sheathing of two-inch fir plank was nailed on the vessel's bottom, over which was a coating of felt, and then new copper. This sheathing added about fifteen tons to her displacement, and nearly seven to her actual measurement. Therefore, instead of 235 tons, she might be considered about 242 tons burthen. The rudder was fitted according to the plan of Captain Lihou: a patent windlass supplied the place of a capstan: one of Frazer's stoves, with an oven attached, was taken instead of a common 'galley' fire-place; and the lightning-conductors, invented by Mr. Harris, were fixed in all the masts, the bowsprit, and even in the flying jib-boom. The arrangements made in the fittings, both inside and outside, by the officers of the Dock-yard, left nothing to be desired. Our ropes, sails, and spars, were the best that could be procured; and to complete our excellent outfit, six superior boats† (two of them private property) were built expressly for us, and so contrived and stowed that they could all be carried in any weather.

Considering the limited disposable space in so very small a ship, we contrived to carry more instruments and books than one would readily suppose could be stowed away in dry and secure places; and in a part of my own cabin twenty-two chronometers were carefully placed.

Anxious that no opportunity of collecting useful information, during the voyage, should be lost; I proposed to the Hydrographer that some well-educated and scientific person should be sought for who would willingly share such accommodations as I had to offer, in order to profit by the opportunity of visiting distant countries yet little known. Captain Beaufort approved of the suggestion, and wrote to Professor Peacock, of Cambridge, who consulted with a friend, Professor Henslow, and he named Mr. Charles Darwin, grandson of Dr. Darwin the poet, as a young man of promising ability,

* Eight inches abaft and twelve forward.

† Besides a dinghy carried astern.

© The Complete Work of Charles Darwin Online

extremely fond of geology, and indeed all branches of natural history. In consequence an offer was made to Mr. Darwin to be my guest on board, which he accepted conditionally; permission was obtained for his embarkation, and an order given by the Admiralty that he should be borne on the ship's books for provisions. The conditions asked by Mr. Darwin were, that he should be at liberty to leave the Beagle and retire from the Expedition when he thought proper, and that he should pay a fair share of the expenses of my table.

Knowing well that no one actively engaged in the surveying duties on which we were going to be employed, would have time—even if he had ability—to make much use of the pencil, I engaged an artist, Mr. Augustus Earle, to go out in a private capacity; though not without the sanction of the Admiralty, who authorized him also to be victualled. And in order to secure the constant, yet to a certain degree mechanical attendance required by a large number of chronometers, and to be enabled to repair our instruments and keep them in order, I engaged the services of Mr. George James Stebbing, eldest son of the mathematical instrument-maker at Portsmouth, as a private assistant.

The established complement of officers and men (including marines and boys) was sixty-five: but, with the supernumeraries I have mentioned, we had on board, when the Beagle sailed from England, seventy-four persons, namely :—

Robert Fitz-Roy	Commander and Surveyor.
John Clements Wickham.....	Lieutenant.
Bartholomew James Sulivan	Lieutenant.
Edward Main Chaffers..,.....	Master.
Robert Mac-Cormick	Surgeon.
George Rowlett	Purser.
Alexander Derbishire	Mate.
Peter Benson Stewart	Mate.
John Lort Stokes.....	Mate and Assistant Surveyor.
Benjamin Bynoe	Assistant Surgeon.
Arthur Mellersh	Midshipman.
Philip Gidley King	Midshipman.

© The Complete Work of Charles Darwin Online

Alexander Burns Usborne ..... Master's Assistant.
Charles Musters ..... Volunteer 1st Class.
Jonathan May ..... Carpenter.
Edward H. Hellyer ..... Clerk.
Acting boatswain : sergeant of marines and seven privates : thirty-four seamen and six boys.

On the List of supernumeraries were—
Charles Darwin ..... Naturalist.
Augustus Earle ..... Draughtsman.
George James Stebbing ..... Instrument Maker.
Richard Matthews and three Fuegians : my own steward : and Mr. Darwin's servant.

Some changes occurred in the course of the five years' voyage, which it may be well to mention in this place.

In April 1832, Mr. Mac-Cormick and Mr. Derbishire returned to England. Mr. Bynoe was appointed to act as Surgeon. Mr. Mellersh received a Mate's warrant; and Mr. Johnson joined the Beagle as Midshipman. In May Mr. Musters fell a victim to fever, caught in the harbour of Rio de Janeiro:—Mr. Forsyth took his place.

Mr. Earle suffered so much from continual ill health, that he could not remain on board the Beagle after August 1832; but he lived at Monte Video several months previously to his return to England. The disappointment caused by losing his services was diminished by meeting Mr Martens at Monte Video, and engaging him to embark with me as my draughtsman.

In March 1833, Mr. Hellyer was drowned at the Falkland Islands, in attempting to get a bird he had shot. In September 1833, Mr. Kent joined as Assistant Surgeon. In June 1834, Mr. Rowlett died, at sea, of a complaint under which he had laboured for years: and the vacancy caused by his lamented decease was filled by Mr. Dring.

Mr. Martens left me, at Valparasio, in 1834; and Mr. King remained with his father, at Sydney, in Australia, in February 1836. After these changes, and at our return to England in October 1836, the list stood thus—

© The Complete Work of Charles Darwin Online

Robert Fitz-Roy	Captain and Surveyor.
John Clements Wickham	Lieutenant.
Bartholomew James Sulivan	Lieutenant.
Edward Main Chaffers	Master.
Benjamin Bynoe	Surgeon (Acting.)
John Edward Dring	Purser (Acting.)
Peter Benson Stewart	Mate.
John Lort Stokes	Mate and Assistant Surveyor.
Arthur Mellersh	Mate.
Charles Richardson Johnson	Mate.
William Kent	Assistant Surgeon.
Charles Forsyth	Midshipman.
Alexander Burns Usborne	Master's Assistant.
Thomas Sorrell	Boatswain (Acting.)
Jonathan May	Carpenter.

And on the List of supernumeraries were Mr. Darwin: George J. Stebbing: my steward: and Mr. Darwin's servant.

Our complement of seamen, marines, and boys was complete at our return, and generally during the voyage; because, although many changes happened, we had always a choice of volunteers to fill vacant places.

Many of the crew had sailed with me in the previous voyage of the Beagle; and there were a few officers, as well as some marines and seamen, who had served in the Beagle, or Adventure, during the whole of the former voyage. These determined admirers of Tierra del Fuego were, Lieutenant Wickham, Mr. Bynoe, Mr. Stokes, Mr. Mellersh, and Mr. King; the boatswain, carpenter, and sergeant; four private marines, my coxswain, and some seamen.

I must not omit to mention that among our provisions were various antiscorbutics—such as pickles, dried apples, and lemon juice—of the best quality, and in as great abundance as we could stow away; we had also on board a very large quantity of Kilner and Moorsom's preserved meat, vegetables, and soup: and from the Medical Department we received an ample supply of antiseptics, and articles useful for preserving specimens of natural history.

Not only the heads of departments exerted themselves for

© The Complete Work of Charles Darwin Online

the sake of our health and safety, but the officers subordinate to them appeared to take a personal interest in the Beagle; for which I and those with me felt, and must always feel, most grateful.

Perhaps no vessel ever quitted her own country with a better or more ample supply (in proportion to her probable necessities) of every kind of useful provision and stores than the little ship of whose wanderings I am now about to give a brief and very imperfect narrative; and, therefore, if she succeeded in effecting any of the objects of her mission, with comparative ease and expedition, let the complete manner in which she was prepared for her voyage, by the Dock-yard at Devonport, be fully remembered.

On the 15th of November I received my instructions from the Lords Commissioners of the Admiralty.

INSTRUCTIONS

By the Commissioners for executing the office of Lord High Admiral of the United Kingdom of Great Britain and Ireland, &c.

"You are hereby required and directed to put to sea, in the vessel you command, so soon as she shall be in every respect ready, and to proceed in her, with all convenient expedition, successively to Madeira or Teneriffe; the Cape de Verde Islands; Fernando Noronha; and the South American station; to perform the operations, and execute the surveys, pointed out in the accompanying memorandum, which has been drawn up under our direction by the Hydrographer of this office; observing and following, in the prosecution of the said surveys, and in your other operations, the directions and suggestions contained in the said memorandum.

"You are to consider yourself under the command of Rear-Admiral Sir Thomas Baker, Commander-in-chief of his Majesty's ships on the South American station, whilst you are within the limits of that station, in execution of the services

© The Complete Work of Charles Darwin Online

above-mentioned; and in addition to the directions conveyed to you in the memorandum, on the subject of your supplies of provisions, we have signified to the Rear-Admiral our desire that, whenever the occasion offers, you should receive from him and the officers of his squadron, any assistance, in stores and provisions, of which you may stand in need.

"But during the whole time of your continuing on the above duties, you are (notwithstanding the 16th article of the 4th section of the 6th chapter, page 78, of the General Printed Instructions) to send reports, by every opportunity, to our Secretary, of your proceedings, and of the progress you make.

"Having completed the surveys which you are directed to execute on the South American station, you are to proceed to perform the several further operations set forth in the Hydrographer's memorandum, in the course therein pointed out; and having so done, you are to return, in the vessel you command, to Spithead, and report your arrival to our Secretary, for our information and further directions.

"In the event of any unfortunate accident happening to yourself, the officer on whom the command of the Beagle may in consequence devolve, is hereby required and directed to complete, as far as in him lies, that part of the survey on which the vessel may be then engaged, but not to proceed to a new step in the voyage; as, for instance, if at that time carrying on the coast survey on the western side of South America, he is not to cross the Pacific, but to return to England by Rio de Janeiro and the Atlantic.

"Given under our hands, the 11th of November 1831.

(Signed) "T. M. HARDY,

"G. BARRINGTON."

"To Robert Fitz-Roy, Esq.,
Commander of his Majesty's surveying vessel
'Beagle,' at Plymouth."

"By command of their Lordships,

(Signed) "GEO. ELLIOT."

© The Complete Work of Charles Darwin Online

" Sir ; Admiralty Office, 11th November 1831.

" With reference to the order which my Lords Commissioners of the Admiralty have this day addressed to you, I am commanded by their lordships to transmit to you a memorandum, to be shown by you to any senior officer who may fall in with you, while you are employed on the duties pointed out in the above order.

" I am, Sir, &c.

(Signed) " Geo. Elliot."

" To Commander Fitz-Roy,
' Beagle' surveying vessel, Plymouth."

" Admiralty Office, 11th November 1831.

" Memorandum.

" My Lords Commissioners of the Admiralty having ordered Commander Fitz-Roy, of his Majesty's surveying vessel the ' Beagle,' to make surveys of various parts of the South American station, it is their lordships' direction that no senior officer who may fall in with Commander Fitz-Roy, while he is employed in the above important duties, do divert him therefrom, or in any way interfere with him, or take from him, on any account, any of his instruments or chronometers.

(Signed) " Geo. Elliot."

" Memorandum.

" A considerable difference still exists in the longitude of Rio de Janeiro, as determined by Captains King, Beechey, and Foster, on the one hand, and Captain W. F. Owen, Baron Roussin, and the Portuguese astronomers, on the other; and as all our meridian distances in South America are measured from thence, it becomes a matter of importance to decide between these conflicting authorities. Few vessels will have ever left this country with a better set of chronometers, both public and private, than the Beagle; and if her voyage be made in short stages, in order to detect the changes which take place in all chronometers during a continuous increase of temperature, it will probably enable us to reduce that difference within limits too small to be of much import in our future conclusions.

© The Complete Work of Charles Darwin Online

"With this view, the run to Rio de Janeiro may be conveniently divided into four parts:—

"1st. Touching at Madeira, the exact position of which has been admitted by all parties. Having obtained a four days' rate there, or, if the weather and the exposed anchorage will not permit, at Teneriffe, the Beagle should, 2dly, proceed with the least possible delay to Port Praya, in the Cape de Verde Islands, not only to establish a fresh four days' rate; but that point being the pivot on which all Captain Owen's longitudes turn, no pains should be spared in verifying the position he has assumed for it. From thence, 3dly, she should make the best of her way across the Line to Fernando Noronha. This island, indeed, lies somewhat to the westward of her track, and may retard her progress a little; yet a series of chronometric observations there is essential to the object in view, because it forms the third nearly equal division of the whole run, and because it was the point of junction of Commander Foster's double line of longitudes. If two or three days' delay at either of these two last stations will enable him to obtain satisfactory occultations, and moon culminating observations, which are likely to be seen in this country, the increased certainty of the results will well atone for that loss of time. The Commander will, of course, be careful to adopt, in all those stations, the precise spot of the former observations, with which his are to be compared. The Governor of Fernando Noronha was peculiarly obliging to Commander Foster, and gave up part of his own house for the pendulum experiments. There will be no occasion now for trespassing so heavily on his kindness; but the difference of longitude between that station and Commander Fitz-Roy's must be well measured.

"However desirable it may be that the Beagle should reach Rio de Janeiro as soon as possible, yet the great importance of knowing the true position of the Abrolhos Banks, and the certainty that they extend much further out than the limits assigned to them by Baron Roussin, will warrant the sacrifice of a few days, if other circumstances should enable her to beat down about the meridian of 36° W. from the latitude of

© The Complete Work of Charles Darwin Online

16° S. The deep sea-line should be kept in motion; and if soundings be obtained, the bank should be pursued both ways, out to the edge, and in to that part already known.

" Its actual extent to the eastward, and its connection with the shoals being thus ascertained, its further investigation may be left to more convenient opportunities.

" At Rio de Janeiro, the time necessary for watering, &c. will, no doubt, be employed by the commander in every species of observation that can assist in deciding the longitude of Villegagnon Island.

" It is understood that a French Expedition is now engaged in the examination of the coast between St. Catherine's and the Rio de la Plata; it would therefore be a waste of means to interfere with that interval; and Commander Fitz-Roy should be directed to proceed to Monte Video, and to rate his chronometers in the same situation occupied by Captain King.

" To the southward of the Rio de la Plata, the real work of the survey will begin. Of that great extent of coast which reaches from Cape St. Antonio to St. George's bay, we only know that it is inaccurately placed, and that it contains some large rivers, which rise at the other side of the continent, and some good harbours, which are undoubtedly worth a minute examination. Much of it, however, from the casual accounts of the Spaniards, seems to offer but little interest either to navigation or commerce, and will scarcely require more than to have its direction laid down correctly, and its prominent points fixed. It should nevertheless be borne in mind there, and in other places, that the more hopeless and forbidding any long line of coast may be, the more precious becomes the discovery of a port which affords safe anchorage and wholesome refreshments.

" The portions of the coast which seem to require particular examination are—

" 1st. From Monte Hermoso to the Rio Colorado, including the large inlet of Bahia Blanco, of which there are three manuscripts in this office that differ in every thing but in name.

© The Complete Work of Charles Darwin Online

"2dly. The gulf of Todos los Santos, which is studded in the Spanish charts with innumerable islands and shoals. It is said to have an excellent harbour on its southern side, which should be verified; but a minute survey of such an Archipelago would be a useless consumption of time, and it will therefore be found sufficient to give the outer line of the dangers, and to connect that line with the regular soundings in the offing.

"3dly. The Rio Negro is stated to be a river of large capacity, with settlements fifty miles from its mouth, and ought to be partially reconnoitred as far as it is navigable.

"4thly. The gulf of San Matias should be examined, especially its two harbours, San Antonio and San José, and a narrow inlet on the eastern side of the peninsula, which, if easy of access, appears to be admirably situated: and—

"5thly. From the Bahia Nueva to Cape Blanco, including the Gulf of St. George, the coast is of various degrees of interest, and will accordingly require to have more or less time bestowed on its different parts. The position of Cape Blanco should be determined, as there appears to be an error of some miles in its latitude, as well as much doubt about the places of two shoals which are marked near it in the Spanish charts.

"From Cape Blanco to the Strait of Magalhaens, the coast has been partially corrected by Captain King; and Port Desire, having been carefully placed by him, will afford a good place for rating the chronometers, and an opportunity for exploring the river.

"Port San Julian, with its bar and wide river, should be surveyed, as well as any parts of that interval which were not visited in the last expedition.

"The above are the principal points of research between the Rio de la Plata and the Strait. They have been consecutively mentioned in order to bring them into one point of view; but that part of this service would perhaps be advantageously postponed till after the Beagle's first return from the southward; and, generally speaking, it would be unwise to lay down here a specific route from which no deviation

© The Complete Work of Charles Darwin Online

would be permitted. Where so many unforeseen circumstances may disturb the best-concerted arrangements, and where so much depends on climates and seasons with which we are not yet intimately acquainted, the most that can be safely done is to state the various objects of the voyage, and to rely on the Commander's known zeal and prudence to effect them in the most convenient order.

"Applying this principle to what is yet to be done in the Strait, and in the intricate group of islands which forms the Tierra del Fuego, the following list will show our chief desiderata.

"Captain King, in his directions, alludes to a reef of half a mile in length, off Cape Virgins, and in his chart he makes a seven fathoms' channel outside that reef; and still further out, five fathoms with overfalls. Sarmiento places fifty fathoms at ten miles E.S.E. from that Cape; thirteen fathoms at nineteen miles; and, at twenty-one miles in the same direction, only four fathoms, besides a very extensive bank projecting from Tierra del Fuego, between which and the above shoals Malaspina passed in thirteen fathoms. In short, there is conclusive evidence of there being more banks than one that obstruct the entrance to the Strait, and undoubtedly their thorough examination ought to be one of the most important objects of the Expedition; inasmuch, as a safe approach to either straits or harbours is of more consequence to determine than the details inside.

"None of the above authors describe the nature of these shoals, whether rock or sand; it will be interesting to note with accuracy the slope, or regularity, of the depths, in their different faces, the quality of their various materials, and the disposition of the coarse or fine parts, as well as of what species of rock in the neighbourhood they seem to be the detritus; for it is probable that the place of their deposition is connected with the very singular tides which seem to circulate in the eastern end of the Strait.

"Beginning at Cape Orange, the whole north-eastern coast of Tierra del Fuego as far as Cape San Diego should be sur-

© The Complete Work of Charles Darwin Online

veyed, including the outer edge of the extensive shoals that project from its northern extreme, and setting at rest the question of the Sebastian Channel.

"On the southern side of this great collection of islands, the Beagle Channel and Whale-boat Sound should be finished, and any other places which the Commander's local knowledge may point out as being requisite to complete his former survey, and sufficiently interesting in themselves to warrant the time they will cost; such as some apparently useful ports to the westward of Cape False, and the north side of Wakefield Channel, all of which are said to be frequented by the sealers.

"In the north-western part it is possible that other breaks may be found interrupting the continuity of S^ta^ Ines Island, and communicating from the Southern Ocean with the Strait; these should be fully or cursorily examined, according to their appearance and promise; and though it would be a very useless waste of time to pursue in detail the infinite number of bays, openings, and roads, that teem on the western side of that island, yet no good harbour should be omitted. It cannot be repeated too often that the more inhospitable the region, the more valuable is a known port of refuge.

"In the western division of the Strait, from Cape Pillar to Cape Froward, there are a few openings which may perhaps be further explored, on the chance of their leading out to sea; a few positions which may require to be reviewed; and a few ports which were only slightly looked into during Captain King's laborious and excellent survey, and which may now be completed, if likely to augment the resources of ships occupied in those dreary regions.

"In the eastern division of the Strait there is rather more work to be done, as the Fuegian shore from Admiralty Sound to Cape Orange has not been touched. Along with this part of the service, the Islands of Saints Martha and Magdalena, and the channel to the eastward of Elizabeth Island, will come in for examination; and there is no part of the Strait which requires to be more accurately laid down and distinctly described, from the narrowness of the channels and the trans-

© The Complete Work of Charles Darwin Online

verse direction of the tides. Sweepstakes Foreland may prove to be an Island; if so, there may be found an useful outlet to the long lee-shore that extends from Cape Monmouth; and if not, perhaps some safe ports might be discovered in that interval for vessels caught there in strong westerly gales.

"It is not likely that, for the purposes of either war or commerce, a much more detailed account will be necessary of those two singular inland seas, Otway and Skyring Waters, unless they should be found to communicate with one of the sounds on the western coast, or with the western part of the Strait. The general opinion in the former Expedition was certainly against such a communication, and the phenomena of the tides is also against it; still the thing is possible, and it becomes an interesting geographical question, which a detached boat in fine weather will readily solve.

"These several operations may probably be completed in the summer of 1833-34, including two trips to Monte Video for refreshments; but before we finally quit the eastern coast of South America, it is necessary to advert to our present ignorance of the Falkland Islands, however often they have been visited. The time that would be occupied by a rigorous survey of this group of islands would be very disproportionate to its value; but as they are the frequent resort of whalers, and as it is of immense consequence to a vessel that has lost her masts, anchors, or a large part of her crew, to have a precise knowledge of the port to which she is obliged to fly, it would well deserve some sacrifice of time to have the most advantageous harbours and their approaches well laid down, and connected by a general sketch or running survey. Clear directions for recognizing and entering these ports should accompany these plans; and as most contradictory statements have been made of the refreshments to be obtained at the east and west great islands, an authentic report on that subject by the Commander will be of real utility.

"There is reason to believe that deep soundings may be traced from these islands to the main, and if regular they would be of great service in rectifying a ship's place.

© The Complete Work of Charles Darwin Online

"Having now stated all that is most urgent to be done on this side of the South American Continent as well as in the circuit of Tierra del Fuego, the next step of the voyage will be Concepçion, or Valparaiso, to one of which places the Beagle will have to proceed for provisions, and where Captain King satisfactorily determined the meridian distances.

"The interval of coast between Valparaiso and the western entrance of the Strait has been partly surveyed, as well as most of the deep and narrow channels formed by the islands of Hanover, Wellington, and Madre de Dios; but of the sea face of that great chain of islands which stretches from Queen Adelaide Archipelago to Campana Island, little has yet been done. It presents a most uninviting appearance, can probably afford but little benefit to the navigator, and the chief object in urging its partial examination, is to remove a blank from this great survey, which was undertaken by Great Britain from such disinterested motives, and which was executed by Captains King and Fitz-Roy with so much skill and zeal.

"The experience gained by the latter in that climate will enable him to accomplish all that is now required in much less time than it would have occupied in the beginning of the former expedition.

"At the Gulf of Peñas the last survey terminated. Of the peninsula de Tres Montes, and of the islands between that and Chiloé, a Spanish manuscript has been procured from Don Felipe Bauzá, which may greatly abridge the examination of that interval.

"From thence to Valdivia, Concepçion, and Valparaiso, the shore is straight, and nearly in the direction of the meridian, so that it will require no great expenditure of time to correct the outline, and to fix the positions of all the salient points. Mocha Island is supposed to be erroneously placed: and the depth, breadth, and safety of its channel are not known.

"To the south of Valparaiso the port of Topocalmo and the large shoal in the offing on which an American ship was wrecked, require special examination; and according to Captain Burgess, of the Alert, the coast and islands near Coquimbo

© The Complete Work of Charles Darwin Online

are very imperfectly laid down. Indeed of the whole of this coast, the only general knowledge we have is from the Spanish charts, which seem, with the exception of certain ports, to have been merely the result of a running view of the shore. Of this kind of half-knowledge we have had too much: the present state of science, which affords such ample means, seems to demand that whatever is now done should be finally done; and that coasts, which are constantly visited by English vessels, should no longer have the motley appearance of alternate error and accuracy. If, therefore, the local Governments make no objections, the survey should be continued to Coquimbo, and indefinitely to the northward, till that period arrives when the Commander must determine on quitting the shores of South America altogether. That period will depend on the time that has been already consumed, and on the previous management of his resources, reserving sufficient to ensure his obtaining a series of well-selected meridian distances in traversing the Pacific Ocean.

"The track he should pursue in executing this important duty cannot well be prescribed here, without foreseeing to what part of the coast he may have pushed the survey, and at what place he may find it convenient to take in his last supplies. If he should reach Guayaquil, or even Callao, it would be desirable he should run for the Galapagos, and, if the season permits, survey that knot of islands. Felix Island, the London bank seen by the brig Cannon, in 1827, in 27° 6′ S. 92° 16′ W., even with the water's edge, and half a mile in length; some coral islands, supposed to be 5° or 6° south of Pitcairn Island, and other spots, which have crept into the charts on doubtful authority, would all be useful objects of research if the Beagle's route should fall in their vicinity. But whatever route may be adopted, it should conduct her to Tahiti, in order to verify the chronometers at Point Venus, a point which may be considered as indisputably fixed by Captain Cook's and by many concurrent observations. Except in this case, she ought to avoid as much as possible the ground examined by Captain Beechey.

© The Complete Work of Charles Darwin Online

"From Tahiti the Beagle should proceed to Port Jackson touching at some of the intervening islands, in order to divide the run into judicious chronometer stages; for the observatory at Paramatta (Port Jackson) being absolutely determined in longitude, all those intervening islands will become standard points to which future casual voyagers will be able to refer their discoveries or correct their chronometers.

"From Port Jackson her course will depend on the time of the year. If it be made by the southward, she might touch at Hobart Town, King George Sound, and Swan River, to determine the difference of longitude from thence to the Mauritius, avoiding the hurricane months; to Table or Simon's Bay, according to the season; to St. Helena, Ascension, and home.

"If she should have to quit Port Jackson about the middle of the year, her passage must be made through Torres Strait. In her way thither, if the in-shore route be adopted, there are several places whose positions it will be advantageous to determine:—Moreton Bay, Port Bowen, Cape Flinders, and one of the Prince of Wales Islands; and in pursuing her way towards the Indian Ocean, unless the wind should hang to the southward, Cape Valsche or the south-west extreme of New Guinea, one of the Serwatty Chain, Coupang, or the extreme of Timor, Rotte Island, and one of the extremes of Sandalwood Island, may be easily determined without much loss of time. And, perhaps, in crossing the ocean, if circumstances are favourable, she might look at the Keeling Islands, and settle their position.

"Having now enumerated the principal places at which the Beagle should be directed to touch in her circuit of the globe, and described the leading operations which it would be desirable to effect, it remains to make some general remarks on the conduct of the whole survey.

"In such multiplied employments as must fall to the share of each officer, there will be no time to waste on elaborate drawings. Plain, distinct roughs, every where accompanied by explanatory notes, and on a sufficiently large scale to show the

© The Complete Work of Charles Darwin Online

minutiæ of whatever knowledge has been acquired, will be documents of far greater value in this office, to be reduced or referred to, than highly finished plans, where accuracy is often sacrificed to beauty.

" This applies particularly to the hills, which in general cost so much labour, and are so often put in from fancy or from memory after the lapse of months, if not of years, instead of being projected while fresh in the mind, or while any inconsistencies or errors may be rectified on the spot. A few strokes of a pen will denote the extent and direction of the several slopes much more distinctly than the brush, and if not worked up to make a picture, will really cost as little or less time. The in-shore sides of the hills, which cannot be seen from any of the stations, must always be mere guess-work, and should not be shown at all.

" It should be considered an essential branch of a nautical survey, to give the perpendicular height of all remarkable hills and headlands. It requires but a single angle at each station, adds much to our geographical knowledge, materially assists the draftsman, and by tables which are now printing it will afford to the seaman a ready and exact means of knowing his distance.

" All charts and plans should be accompanied by views of the land ; those which are to be attached to the former should be taken at such a distance as will enable a stranger to recognize the land, or to steer for a certain point ; and those best suited for the plan of a port should show the marks for avoiding dangers, for taking a leading course, or choosing an advantageous berth. In all cases the angular distances and the angular altitudes of the principal objects should be inserted in degrees and minutes on each of the views, by which means they can be projected by scale, so as to correct any want of precision in the eye of the draftsman. Such views cannot be too numerous; they cost but a few moments, and are extremely satisfactory to all navigators.

" Trifling as it may appear, the love of giving a multiplicity of new and unmeaning names tends to confuse our geogra-

© The Complete Work of Charles Darwin Online

phical knowledge. The name stamped upon a place by the first discoverer should be held sacred by the common consent of all nations; and in new discoveries it would be far more beneficial to make the name convey some idea of the nature of the place; or if it be inhabited, to adopt the native appellation, than to exhaust the catalogue of public characters or private friends at home. The officers and crews, indeed, have some claim on such distinction, which, slight as it is, helps to excite an interest in the voyage.

"Constant observations on the tides, including their set, force, and duration, the distance to which they carry salt water up the rivers, their rise at the different periods of the lunation, and the extent to which they are influenced by the periodic winds, by the sea currents, or by the river freshes, form so prominent a part of every surveyor's duty, that no specific directions on this subject can be necessary. Nor is there any occasion to insist here on the equally important subject of currents; for it is only by a great accumulation of data that we can ever hope to reduce them to regular systems, or that we can detect the mode in which they are affected by change of seasons, or influenced by distant winds.

"The periods and limits of the monsoons and trade-winds will naturally be a continual object of the Commander's observation and study. It is true that he can only witness what occurs during his voyage; but besides collecting facts on this and the last subject, on which others can hereafter reason, it will be of immense advantage that he should endeavour to digest them with the remarks of former voyagers when on the spot.

"On the western coast of South America, for instance, some skill is required in making passages at different periods, and much scattered experience has been gained by seamen who have been long occupied there; but this information has not yet been presented to the public in an intelligible form; and it seems to be the peculiar province of an officer expressly employed on a scientific mission like this, to combine that information with his own, and to render it accessible to every navigator.

© The Complete Work of Charles Darwin Online

"The local attraction of the Beagle will of course have been ascertained before she leaves England; but when favourable opportunities occur, it will be satisfactory to swing her again in different latitudes, and under large differences of variation.

"No day should pass at sea without a series of azimuths, and no port should be quitted without having ascertained not only the magnetic angle, but the dip, intensity, and diurnal variation. If these observations should have been well made in the same places before, we shall at once obtain the annual change; and by multiplying them in new places, we shall have the means of inferring the magnetic curves.

"The Commander has been so accustomed to the management of chronometers, that there is no doubt, with proper precautions and with proper formulæ for determining their rates, that he will succeed in obtaining good results in reasonably short intervals of time and in gradual changes of temperature; but after long periods, and sudden changes of heat and cold, it will be absolutely necessary to check them by astronomical means.

"Eclipses, occultations, lunar distances, and moon-culminating stars, will furnish those means in abundance: of all these, the last can be obtained with the greatest regularity and certainty; they have become part of the current business at the establishments of the Cape of Good Hope, Paramatta, and St. Helena, in the southern hemisphere; probably at Madras, and in many of the European observatories, and it will therefore be scarcely possible that there should not be corresponding observations for all such as he may have made.

"The eclipses of Jupiter's third and fourth satellites should also be sedulously observed whenever both immersion and emersion can be seen, as the different powers of the telescopes employed by the observers do not in that case affect the results.

"There are also some remarkable phenomena, which will be announced in the Nautical Almanacks, and which will occur during the Beagle's voyage. Some of these will be highly

© The Complete Work of Charles Darwin Online

interesting to astronomers, and if it would not much derange her operations, she should be taken to some convenient anchorage for the purpose of landing the instruments.

"If a comet should be discovered while the Beagle is in port, its position should be determined every night by observing its transit over the meridian, always accompanied by the transits of the nearest known stars, and by circum-meridional altitudes, or by measuring its angular distance from three well-situated stars by a sextant. This latter process can be effected even at sea, and the mean of several observations may give very near approximations to its real position.

"Meteorological Registers may be of use in a variety of ways; but then they must be steadily and accurately kept. The barometer should be read off to the third place of decimals, and recorded at regular periods of the day; nine o'clock and four o'clock may be recommended as the best, as being the usual hours of its maximum and minimum. The temperature should be marked at the same time, and the extremes of the self-registering thermometer should be daily recorded; care being taken that no reflected heat should act on any of these instruments. The temperature of the sea at the surface ought to be frequently observed and compared with that of the air. An officer cruizing on the east coast of South America, between the parallels of 20° and 35°, was enabled by these means to predict with singular precision the direction and strength of the current.

"In this register the state of the wind and weather will, of course, be inserted; but some intelligible scale should be assumed, to indicate the force of the former, instead of the ambiguous terms 'fresh,' 'moderate,' &c., in using which no two people agree; and some concise method should also be employed for expressing the state of the weather. The suggestions contained in the annexed printed paper are recommended for the above purposes, and if adopted, a copy should be pasted on the first page of every volume of the log-book; and the officer of the watch should be directed to use the same terms in the columns of the log-board.

© The Complete Work of Charles Darwin Online

"The circularly-formed Coral Islands in the Pacific occasionally afford excellent land-locked harbours, with a sufficient entrance, and would be well adapted to any nice astronomical observations which might require to be carried on in undisturbed tranquillity. While these are quietly proceeding, and the chronometers rating, a very interesting inquiry might be instituted respecting the formation of these coral reefs.

"An exact geological map of the whole island should be constructed, showing its form, the greatest height to which the solid coral has risen, as well as that to which the fragments appear to have been forced. The slope of its sides should be carefully measured in different places, and particularly on the external face, by a series of soundings, at very short distances from each other, and carried out to the greatest possible depths, at times when no tide or current can affect the perpendicularity of the line. A modern and very plausible theory has been put forward, that these wonderful formations, instead of ascending from the bottom of the sea, have been raised from the summits of extinct volcanoes; and therefore the nature of the bottom at each of these soundings should be noted, and every means exerted that ingenuity can devise of discovering at what depth the coral formation begins, and of what materials the substratum on which it rests is composed. The shape, slope, and elevation of the coral knolls in the lagoon would also help the investigation; and no circumstances should be neglected which can render an account of the general structure clear and perspicuous.

"A set of observations connected with the theory of the tides might likewise be carried on with peculiar propriety in one of these coral basins, provided the openings should be sufficiently wide and deep to admit the flux and reflux without material impediment. The island selected for such a purpose should be nearly midway in the ocean, and not very far from the equator. There the tidal wave, uninfluenced by the interrupting barrier of one continent, and equally far from the reaction of the other, might be measured with very beneficial results. Delicate tide-gauges should be prepared beforehand,

© The Complete Work of Charles Darwin Online

and immediately fixed in some snug nook, where the undulation of the sea could not reach. The rise and fall of the tide should be registered every hour, during the stay of the Beagle, as well as the moments (stated whether in apparent or mean time) of high and low water, as nearly as they can be obtained; and the periods at which the sea and land breezes spring up and fail should likewise be noted, with their effects on the tide, if they can be detected. A boat should be detached, on each tide, to some distance from the island, in order to ascertain the strength and direction of the stream; and all these operations should be continued, if possible, through a whole lunation.

"Compiling general and particular instructions, for the navigation of all the places which he may visit, will of course be an essential part of the Commander's duty; but he will also have innumerable opportunities of collecting a variety of auxiliary information, which, when judiciously combined with the above instructions, of a purely nautical character, will much enhance their utility to all classes of vessels. Such as the general resources on which ships may depend in different places: the chief productions that can be obtained, and the objects most anxiously desired in return: the effect of seasons, of climate, and of peculiar articles of food on the health of the crew, and many others which will readily occur to his mind, and which become of great value to a stranger.

"On all the subjects touched on in these memoranda, Commander Fitz-Roy should be directed to draw up specific reports, and to transmit them from time to time, through their Lordship's Secretary, to the Hydrographic Office, so that if any disaster should happen to the Beagle, the fruits of the expedition may not be altogether lost. Besides such reports, and with the same object in view, he should keep up a detailed correspondence by every opportunity with the Hydrographer.

"The narrative of every voyage in the Pacific Ocean abounds with proofs of the necessity of being unremittingly on guard against the petty treacheries or more daring attacks of the natives. It should be recollected that they are no longer the timid and unarmed creatures of former times, but that many of

© The Complete Work of Charles Darwin Online

them now possess fire-arms and ammunition, and are skilful in the use of them. Temper and vigilance will be the best preservatives against trivial offences and misunderstandings, which too often end in fatal quarrels; and true firmness will abandon objects of small importance, where perseverance must entail the necessity of violence; for it would be a subject of deep regret that an expedition devoted to the noblest purpose, the acquisition of knowledge, should be stained by a single act of hostility.

(Signed) "F. BEAUFORT."

"Hydrographical Office, 11th November 1831."

LETTERS

TO DENOTE THE STATE OF THE WEATHER.

b Blue Sky; (whether clear, or hazy, atmosphere).
c Clouds; (detached passing clouds).
d Drizzling Rain.
f Foggy——f Thick fog.
g Gloomy (dark weather).
h Hail.
l Lightning.
m Misty (hazy atmosphere).
o Overcast (or the whole sky covered with thick clouds).
p Passing (temporary showers).
q Squally.
r Rain (continued rain).
s Snow.
t Thunder.
u Ugly (threatening appearances).
v Visible (clear atmosphere).
w Wet Dew.
. Under any letter, indicates an extraordinary degree.

By the combination of these letters, all the ordinary phenomena of the weather may be expressed with facility and brevity.

Examples :—Bcm, Blue sky, with passing clouds, and a hazy atmosphere.

Gv, Gloomy dark weather, but distant objects remarkably visible.

Qpdlt, Very hard squalls, with passing showers of drizzle, and accompanied by lightning with very heavy thunder.

CHAPTER III.

Ready for sea—Detained—Sail from England—Well provided—Bay of Biscay — Compasses — Local attraction — Eight Stones—Madeira—Deception—Squall—Teneriffe — Santa Cruz—Quarantine—Squalls—Cape Verd Islands—Port Praya—Produce—Archilla—Bad season—St. Paul Rocks — Cross Equator — Fernando Noronha — Bahia — Slavery—Abrolhos—Cape Frio.

In November, the Beagle was ready for sea, but a succession of hard gales from the westward prevented her leaving England until the end of December. Twice she sailed, and went a few leagues; yet was obliged to return in order to avoid the risk of being damaged, or losing a boat, at the very beginning of her voyage. At last the westerly gales seemed exhausted, a dead calm succeeded, and, warned by the appearances so peculiar to easterly winds, we unmoored at daylight on the 27th, and, as soon as the tide would allow, for there was still no breeze, we warped from our sheltered and picturesque retreat in Barn-pool, under that beautiful place Mount Edgecumbe.

Vessels in the offing, and distant land 'looming' much; a few mottled, hard-edged clouds appearing in the east; streaks (mare's tails) across the sky, spreading from the same quarter; a high barometer (30.3); and the smoke from chimneys rising high into the air, and then going westward; were the signs which assured us of a favourable wind. A light 'cat's paw' rippled the water, we made all sail, the breeze increased, and at noon our little vessel was outside the Breakwater, with a fresh easterly wind.

Of the bitter feelings experienced by most of us when every sail was trimmed, and the land sinking fast from our view, I will say nothing: yet there were enlivening hopes, and all were glad to be freed from the tiresome uncertainty of the past month, all were anxious to enter upon a voyage which, though

© The Complete Work of Charles Darwin Online

likely to be very long, promised much that would interest, and excite, and perhaps reward.

To the executive officers of a ship it is always a most satisfactory feeling, independent of other thoughts, to be fairly at sea, and away from the scenes of irregularity which so often take place in ports. Those scenes, however, are now much less offensive, and the sailor is far less heedless than he was formerly, if we may take Fielding's description as authority. That humorous sensible author says, in one of the most entertaining accounts of a voyage ever written, "To say the truth, from what I observed in the behaviour of the sailors in this voyage, and comparing it with what I have formerly seen of them, at sea, and on shore, I am convinced that on land there is nothing more idle and dissolute; but, in their own element, there are no persons, near the level of their degree, who live in the constant practice of half so many good qualities."

Never, I believe, did a vessel leave England better provided, or fitted for the service she was destined to perform, and for the health and comfort of her crew, than the Beagle. If we did want any thing which could have been carried, it was our own fault; for all that was asked for, from the Dockyard, Victualling Department, Navy Board, or Admiralty, was granted.

To mention the names of those to whom my shipmates and myself felt most grateful for attention to requests, and for a kind foresight of our future wants, may be unnecessary, some may think improper; yet, at the risk of offending, I must try to express the gratitude that I, and those who sailed with me in the Beagle, owe to Sir James Graham, Sir Thomas Hardy, Captain Beaufort, Commissioner (now Admiral) Ross, Sir Robert Seppings, Sir James Gordon, the late Sir Manley Dixon, and Sir William Burnett: less I cannot say, more might be displeasing.

The wind increased, and drove us onwards into the Atlantic as fast as a heavily laden small vessel, with her 'scuppers' in the water, could be forced. We steered as southerly a course as was safe, in hopes of keeping the east wind longer, and the

© The Complete Work of Charles Darwin Online

result proved that we were right; for although the Beagle had a fair wind all the way to the Canary Islands, vessels which sailed from England only one day after her, and steered more westerly, lost the east wind very soon, and were retarded by another succession of strong and contrary gales, similar to those which had detained us a whole month.

Individual misconduct, arising out of harbour irregularities, obliged me to have recourse to harsh measures before we had been two days at sea; but every naval officer knows the absolute necessity of a certain degree of what inexperienced persons might think unnecessary coercion, when a ship is recently commissioned. Hating, abhorring corporal punishment, I am nevertheless fully aware that there are too many coarse natures which cannot be restrained without it, (to the degree required on board a ship,) not to have a thorough conviction that it could only be dispensed with, by sacrificing a great deal of discipline and consequent efficiency. "Certainty of punishment, without severity," was a maxim of the humane and wise Beccaria; which, with our own adage about a timely 'stitch,' is extremely applicable to the conduct of affairs on board a ship, where so much often depends upon immediate decision, upon instant and implicit obedience.

We crossed the Bay of Biscay without a gale; though the heavy rolling of a vessel so deep in the water, running before a strong wind, was almost as disagreeable as the effects of one would have been. After witnessing high seas and storms in various parts of the world, I can call to mind only two or three that exceeded what I have myself experienced, or what I have heard described, as having been sometimes encountered in this famed bay.

Why should the sea be higher, or more dangerous, in the bay of Biscay, than it is in the middle of the Atlantic, or elsewhere?—Is it really so?—are questions often asked.

I believe that there is a shorter, higher, and consequently worse sea, in and near the Bay of Biscay, than is often found in other places, and attribute it to the effect of immense Atlantic waves, rolling into a deep bight, or bay, where

© The Complete Work of Charles Darwin Online

they close upon each other and receive vibratory undulations from each shore; augmented perhaps by the peculiar formation of the bottom of that bay, the variation in depth, and the effects of currents, which, when running over uneven ground, or against the wind, alone cause a heavy swell; a striking exemplification of which may be seen on the bank of Lagullas, near the Cape of Good Hope.

Though so deep in the water, our little vessel's movements were uncommonly easy, and all our best timekeepers being hung in particularly good jimbals, I had no fear of their rates being altered, except by the effect of a change of temperature. This was a point about which I was especially anxious, as so much would depend upon the going of our chronometers, and I did not then think that the motions of a ship affected those instruments so little: as I have since proved to be the case by trying them frequently in boats, or small craft of only a few tons burthen. In her previous voyage the Beagle was as easy a sea-boat as could be desired; but, having raised her upper deck, altered her stowage and trim, loaded her more heavily, and sheathed her with two-inch plank, preparatory to this second expedition, I had abundant cause to feel anxious until the practical effects of such material changes were ascertained.

A little alteration was required near the compasses, for owing to some ill-placed iron-work they did not quite agree; but, after this change was made, we were gratified by finding four first-rate compasses, three fixed for steering, and one for bearings, agree precisely. Another source of satisfaction, connected with the compasses, was the knowledge that they were not affected, unless in a very trifling degree, by local attraction: for while lying in Barn-pool we swung the vessel in order to ascertain its quantity, but were agreeably surprised to find that none could be detected amounting even to one degree. This was attributed to her having only brass guns; and to some very large iron davits for the quarter boats, which were placed rather closely abaft and above the compasses, and perhaps counteracted the effect of iron in the hold, which was so much more distant.

© The Complete Work of Charles Darwin Online

On the 3d of January we were occupied in looking for the "Eight Stones;" but nothing was seen to indicate either rocks, or shoals, or even shallow water. The sun was shining brightly on a deep blue sea, of one uniform colour: no soundings could be obtained; and had there been a shoal or rock within seven miles of us at any hour of that day, it could not have been passed unnoticed. So many vessels have searched, in vain, for this alleged group of rocks, that their existence can now hardly be thought possible.

At day-light, on the 4th, the rocky high islet of Porto Santo was seen looming through haze and clouds which hung around it. We steered between Porto Santo and the Desertas, intending to anchor in Funchal Roads; but the wind drew round to south-west, with such strong squalls, that I abandoned my intention, and at once steered for Teneriffe. The roadstead I have just mentioned is well known to be unsafe in south-west gales; and there can be no doubt that the most prudent plan is to keep at sea while they last: but I have been told by old traders to Madeira, that ships sometimes remain at anchor, about half a mile from the Loo rock, and ride out south-west gales without difficulty: the 'under-tow' being so considerable that their cables are little strained.

In fine weather, and it is fine at Madeira nine months in the year, the view of this steep and lofty island,* covered with bright verdure, and enlivened by numerous scattered houses, as white as snow, is very striking to a stranger who arrives from the low, and tame-looking shores of the south coast of England.

Seamen are often deceived, when about to anchor in Funchal Roads, in consequence of the sudden transition which they have probably made from a low shelving coast to an abrupt and high mountain-side: for the bottom of the anchorage slopes away as suddenly as the heights overlooking it, and the anchor must indeed be let go upon the side of a mountain. Hence ships seldom go close enough, unless guided by a person who knows the place; and many a chain cable ran out to the clinch, when chains were first used, owing to an incorrect estimate of

* About five thousand feet high.

the vessel's distance from the shore, and not taking time to sound accurately.

Closing the land quickly after passing some time at sea—approaching high cliffs, or hilly shores, after being, for a time, accustomed to low coasts—or nearing a flat shore, after the eye has been used to precipices and mountains—almost always is a cause of error in estimating distance, however experienced a seaman may be.

While passing at a few leagues from the land, a violent squall came from the west, which was near doing damage: after one puff there was a short calm, with heavy rain, and then a sudden blast struck the ship so violently that we were obliged to take in all sail and run before it during the few minutes it lasted. This squall was one of very many which have reminded me of the old doggrel lines—

> When rain comes before the wind,
> Halyards, sheets, and braces mind:
> But if wind comes before rain,
> Set and trim your sails again.

At daylight the next morning we saw the Salvages, and at sunset thought we could distinguish the Peak of Teneriffe.

Early on the 6th we saw part of the island, and soon afterwards the upper clouds dispersed, and we enjoyed a magnificent view of the monarch of the Atlantic: the snow-covered peak glittering in the rays of the morning sun. Yet as our ideas are very dependent upon comparison, I suppose that persons who have seen the Himalaya Mountains, or the Andes, in all their grandeur, would not dwell much upon the view of Teneriffe, had it not become classical by its historical associations, and by the descriptions of Humboldt and many distinguished travellers.

Although some geographers adopted the Peak of Teneriffe as a zero point from which to reckon longitude, I am free to say, that a less satisfactory one could hardly have been selected; because there are no means of connecting the position of the peak with that of the observer, whether on the shore of the

© The Complete Work of Charles Darwin Online

island, or on board a ship in the offing, except by a trigonometrical process, always open to errors. Indeed the summit of the peak is not visible from the east, on account of intervening land, until the observer is at some distance from the shore. Hence all meridian distances measured from Teneriffe must depend upon the degree of accuracy with which the position of the actual starting-point, with respect to the Peak, was determined.

How many errors have been caused in ascertaining the longitudes of distant places, by a mistake in the longitude of the position from which a ship, or an observer, actually departed! How many discrepancies between the measurements of different nations would vanish, if the precise points from which each observer set out were known; and if the positions of those points, with respect to one another, were accurately verified!

About noon we approached the sun-burned, uninviting town of Santa Cruz. Lying upon a level, arid space, at the foot of hills, that rise slowly to a considerable height, so as to shut out the more elevated part of the island; hardly a tree to be seen, and no appearance of cultivation; guarded by a rocky shore, on which there is always a disagreeable—often a dangerous surf; it offers indeed little to tempt delay. But notwithstanding this unpromising exterior, and a port so exposed that Spanish ships of war were ordered by their Government to moor there with four anchors, there is much to be found in the higher and interior parts of Teneriffe which amply repays the labour of ascending to and exploring those regions. In one of the churches in Santa Cruz is still hanging the remains of a flag, taken from the English, or left behind, when Nelson lost his arm.

Our anchor had just touched the ground, when a boat from the Health Office approached nearly along-side, conveying the British vice-consul and some quarantine officers, who told us, after hearing whence we came, that it would be impossible to grant permission for any person to land; and that until we should have performed a strict quarantine of twelve days' duration, no personal communication could be expected. This

© The Complete Work of Charles Darwin Online

regulation was adopted on account of the reports which had reached them respecting the cholera in England.

Observations on shore being indispensable for our purpose, and finding, after some discussion, that there was no chance of attaining our object in a manner that would at all compensate for the delay caused by anchoring and performing quarantine, we weighed without further loss of time, and made sail for the Cape Verd Islands.

This was a great disappointment to Mr. Darwin, who had cherished a hope of visiting the Peak. To see it—to anchor and be on the point of landing, yet be obliged to turn away without the slightest prospect of beholding Teneriffe again—was indeed to him a real calamity.

During the whole of the 7th, the Peak was visible; but on the following day no land was in sight, and we made rapid progress. A very long swell from the north-west, which we felt until the 10th, was probably caused by a gale in the northern Atlantic; and, judging from its size and velocity, I should think that it could not have subsided before traversing many, perhaps ten more, degrees of latitude; which would be to about 10° north. It is interesting to notice how far the undulatory movement of water reaches: in this case it extended through at least ten degrees of latitude where the wind was from different quarters, and probably much farther.

An unusual appearance was observed on the 12th. A cloud like a dense fog-bank approached; and as it drew near, the lower and darker part became arched, and rose rapidly, while under it was a white glare, which looked very suspicious. Sail was immediately reduced—we expected a violent squall; but the cloud dispersed suddenly, and only a common fresh breeze came from the foreboding quarter. Neither the sympiesometer nor the barometer had altered at all; but the cloud was so threatening that I put no trust in their indications, not being then so firm a believer in their prophetic movements as I am at present. Nevertheless, I would by no means advocate the neglect of any precaution suggested by appearances of the

© The Complete Work of Charles Darwin Online

weather, although no change should be foretold by the glasses. A mistake may be made by the observer, or a variation in the height of the column may have passed unheeded; while it is seldom that a practised eye can be deceived by the visible signs of an approaching squall or gale of wind.

Undoubtedly the worst wind, next to a hurricane, which a vessel can encounter, is a violent 'white squall,' so called because it is accompanied by no cloud or peculiar appearance in the sky, and because of its tearing up the surface of the sea, and sweeping it along so as to make a wide sheet of foam. By squalls of this description, frequent in the West-Indies, and occasionally felt in other parts of the world, no notice will be given much above the horizon; but by consulting a good barometer or sympiesometer, and frequently watching the surface of the sea itself, even a white squall may be guarded against in sufficient time.

Squalls accompanied by clouds are so common, and at sea every one is so much accustomed to look out for them, that I may cause a smile by these notices; yet as there is often much doubt in a young officer's mind, whether an approaching cloud will be accompanied by wind or rain, or by both, and many persons are unable to distinguish, by the mere appearance of a cloud, what is likely to come with or from it, I will venture to mention that when they look hard, or hard-edged (like Indian ink rubbed upon an oily plate), they indicate wind, and perhaps rain; but before the rain falls, those clouds will assume a softer appearance. When they are undefined, and look soft, rain will follow, but probably not much wind.

Dark clouds, hard mixed with soft, and inky fragments in rapid motion beneath them, accompanied perhaps by lightning and distant thunder, are the fore-runners of a heavy squall. Soft, shapeless clouds, in which it is impossible to point out a definite edge, usually bring rain, but not wind: and, generally speaking, the more distinctly defined the edges of clouds are, the more wind they foretell. A little attention

© The Complete Work of Charles Darwin Online

to these simple observations, so familar to persons who have been some time at sea, may save young officers unnecessary anxiety in one case, and prompt them to shorten sail at a proper time in the other.*

In again trying for soundings with three hundred fathoms of line, near the Island of St. Jago, we became fully convinced of the utility of a reel, which Captain Beaufort had advised me to procure, and of which Captain Vidal had spoken to him in very favourable terms. Two men were able to take in the deep sea line, by this machine, without interfering with any part of the deck, except the place near the stern, where the reel was firmly secured. Throughout our voyage this simple contrivance answered its object extremely well, and saved the crew a great deal of harassing work.

15th. In consequence of a thick haze, very prevalent about the Cape Verd Islands, land was not distinctly seen until we were within three miles of it, and we then found ourselves rather too far westward, owing to a current setting towards the west, at the rate of two knots an hour; this was close to the north point of St. Jago. Next day we anchored in Port Praya.

The wind being always from the north or east during this season of the year (from December to June), a ship can moor as close to the weather shore as may be convenient; but during July, August, September and October, no vessel should deem the bay secure, or anchor near the shore, because southerly gales sometimes blow with much strength, and the rollers, or heavy swell sent in by them, are dangerous to ships which have bad ground tackle, or are lying near the land. As I have myself experienced the force of these gales in the vicinity of the Cape Verd Islands, and witnessed the sea raised by them, I can confidently warn those who are inclined to be incredulous about a gale of wind being found in fifteen degrees of north latitude, beyond the limits of the hurricane regions.

* In the Appendix are a few remarks on clouds.

© The Complete Work of Charles Darwin Online

Strong gusts come over the land into the bay during the fine season, when the breeze is fresh; therefore a ship entering, with intent to anchor, ought to have a reef in her top-sails, and be ready to clew up the top-gallant sails at a moment's warning.

The vicinity of Port Praya offers little that is agreeable to the eye of an ordinary visitor, though interesting enough to a geologist. A desolate and hilly country, sun-burned and stony, with but few trees even in the vallies, and those only the withering, spectre-like trunks of old palms, surrounds the harbour. The distant and higher parts of the island, however, present a striking outline; and in the interior there is more to be seen, as the following extract from a few notes made by Mr. Rowlett will show.

"We procured some indifferent horses and rode to Ribeira Grande, the remains of an old town, about nine miles west of Port Praya, which was formerly the residence of the Portuguese governor of the Cape Verd Islands; but in consequence of the anchorage becoming blocked up,* the seat of government was shifted to the small straggling town, or rather village, which stands upon a height overlooking the port of Praya. We passed through the fertile and beautiful vallies of Achao and San Martin, and enjoyed drinking some of the finest water we had ever tasted. On a commanding height stood the ruins of a very large fortress, and within the limits of the old town were remains of a cathedral, a bishop's palace, and a college; besides a modern church, in tolerable repair, an inhabited convent, and a hospital supported by charity. In the convent we saw some good paintings from scriptural subjects; and there were some curious old tombs, on one of which, said to be that of a bishop, was the date 1571, and on another we thought the almost obliterated figures were 1497.

"No person who has only visited the port of Praya can form the slightest idea of the beauty of the interior country; it exceeded any thing I had seen, either in Brazil or in the West Indies.

* Perhaps by an earthquake?

© The Complete Work of Charles Darwin Online

"Fruit was abundant; there were oranges, grapes, plantains, bananas, sour-sops, mammee apples, pomegranates, guavas, quinces, sapodillas, papaw apples, pines, citrons, medlars, figs, and occasionally apples."

Notwithstanding its unfavourable exterior, its small and dirty town, and its black or brown population, I am inclined to think Port Praya of more consequence to shipping than is usually supposed. Water may be procured by rafting the casks, placing a pump in the well, and hiring a few of the natives to do the more laborious work of filling and rolling. The local authorities are attentive and obliging: it is indeed their interest to be so, because much of their trade, and even many of the necessaries of life, depend upon the visits of shipping. Fowls, turkeys, and pigs, are very plentiful, but it is better to procure them by barter than with money. Clothes, new or old, are eagerly sought for, and their full value may be obtained in the produce of the island.

The population is said to be about thirty thousand, a few of whom are Portuguese by birth, and many are descended from Portuguese parents, but the greater number are negroes.

I could hear no decided account of any earthquake having happened; but being so near Fogo, now an active volcano, one may suppose that St. Jago is not exempted from an occasional shock.

The exports of the Cape Verd Islands are small quantities of sugar, cotton, and coffee. Hides of small bullocks, sheep and goat-skins, are likewise exported; and horses, mules, and asses, of an inferior description, are sometimes sent to the West-Indies. The Archilla weed, so much used in dyeing, is however the staple commodity, and, under proper management, might be made highly profitable. At the time of our visit, the yearly revenue arising out of the government monopoly of this article amounted to fifty thousand dollars; and in some years it has been as much as three hundred thousand dollars. This weed grows like a kind of moss upon the cliffs, and is collected by men who climb up or are let down by ropes, like the samphire gatherers.

© The Complete Work of Charles Darwin Online

The natural dye is blue, approaching to purple; but by using metallic and other solutions, it may be turned to purple, crimson, or scarlet.

Money having been slowly remitted of late years from the mother-country, a great part of the archilla has been applied to the payment of the authorities, the clergy, and the troops (such as they are). A story is told of the last governor having caused a sham mutiny, in order that he might have a good reason for selling the archilla gathered that year, and with the produce paying the troops—and himself. He was brought out with a rope round his neck into the street, and there obliged to promise that he would sell the archilla, then in the government storehouse, to the best bidder.

A kind of castor-oil plant is found, from which a small quantity of oil is obtained, and a sort of soap. Yams are very scarce, being grown only at one part of the island. Mandioca is common, but it degenerates rapidly, and will not produce even a second crop. Vegetables of various kinds are abundant in their seasons.

From August to October is the rainy and sickly season. In September, a south-west gale is usually experienced; but from five to ten hours before its commencement, a dark bank of clouds is seen in the southern horizon, which is a sure forerunner of the gale. Should a vessel be at anchor in the port at such a time, she ought to weigh and put to sea, until the storm has ceased and the swell subsided. In the month of September preceding our visit, an American merchant-brig and a Portuguese slaver were at anchor in Port Praya. A bank of clouds was seen during the day in the S.W., and the American went to sea; but the slaver remained at anchor. A storm arose at night, drove the slave-vessel ashore, and dashed her to pieces in less than half an hour, yet did the American no damage whatever, and the next day she anchored again in the port.

In a valley near the town is a very remarkable tree, of the Baobab kind, supposed to be more than a thousand years old; but I am not aware of the grounds upon which this

© The Complete Work of Charles Darwin Online

assertion is made. Wild guinea-fowls are found in flocks, and there are wild-cats in the unfrequented parts of the island; but if induced to take a gun in pursuit of the guinea-fowls, I would advise a stranger not to overheat himself, or sleep on shore at night; for fatal fevers have been contracted by Europeans, who were unguarded as to their health, while passing a few days in this hot climate, after being for some time accustomed to the cold weather of a high northern latitude.

Except during the rainy season, the wind is always north-easterly, and then the sky is clear and the sun very powerful; but a dry haze hangs over the island in a peculiar manner, and a quantity of fine dust, quite an impalpable powder, frequently settles on every exposed surface, even on the sails and rigging of a vessel, when passing near the islands.

On the 8th of February our instruments were re-embarked, and, after swinging the ship to ascertain the amount of local attraction, we weighed anchor and sailed. By the compass fixed upon a stanchion in front of the poop, not twenty minutes difference of bearing could be detected, in any position of the vessel: the object observed being the highest point of a sharp peak, distant eleven miles.

On the 10th we spoke the Lyra packet, going from England to Rio de Janeiro, and received a box from her, containing six of Massey's sounding-leads, those excellent contrivances which we frequently found so useful. These machines, as formerly made, did not answer for a much greater depth than one hundred fathoms; because their hollow cylinder yielded to the pressure of the water: but Mr. Massey has since remedied that defect in their construction.

On the 13th a very confused swell seemed to presage a change of weather. Hitherto the wind had been steady from the north-east, and the sky clear; but on this day large soft clouds, light variable breezes, rain, and sometimes a short calm, showed us that we had passed the limits of the north-east trade wind. 14th. Similar weather, with a good deal of rain, but still breeze enough to keep us moving on our course.

On the 15th, the wind was steady from east south-east,

© The Complete Work of Charles Darwin Online

and the sky free from heavy threatening clouds. We had then entered the south-east trade wind, without having had two hours calm.

St. Paul Rocks, or Peñedo de San Pedro, were seen on the horizon at sunset of the 15th. They appeared extremely small, being about eight miles distant; and had we not been looking out for them, I doubt whether they would have attracted attention. Excepting "Las Hormigas," on the coast of Peru, I never saw such mere rocks at so great a distance from any land.

At daylight next morning, two boats were sent to land upon, and examine them; while the Beagle sailed round this "sunk mountain top," sounding, and taking angles. Good observations were made during the day, as the sky was clear, and the water smooth.

When our party had effected a landing through the surf, and had a moment's leisure to look about them, they were astonished at the multitudes of birds which covered the rocks, and absolutely darkened the sky. Mr. Darwin afterwards said, that till then he had never believed the stories of men knocking down birds with sticks; but there they might be kicked, before they would move out of the way.

The first impulse of our invaders of this bird-covered rock, was to lay about them like schoolboys; even the geological hammer at last became a missile. "Lend me the hammer?" asked one. "No, no," replied the owner, "you'll break the handle;" but hardly had he said so, when, overcome by the novelty of the scene, and the example of those around him, away went the hammer, with all the force of his own right-arm.

While our party were scrambling over the rock, a determined struggle was going on in the water, between the boats' crews and sharks. Numbers of fine fish, like the groupars (or garoupas) of the Bermuda Islands, bit eagerly at baited hooks put overboard by the men; but as soon as a fish was caught, a rush of voracious sharks was made at him, and notwithstanding blows of oars and boat hooks, the ravenous monsters could not be deterred from seizing and taking away more than half the fish that were hooked.

CROSSING THE LINE.

© The Complete Work of Charles Darwin Online

© The Complete Work of Charles Darwin Online

© The Complete Work of Charles Darwin Online

At short intervals the men beat the water with their oars all round the boats, in order to drive away the sharks; and for a few minutes afterwards the groupars swarmed about the baited hooks, and were caught as fast as the lines could be hauled up—then another rush of sharks drove them away—those just caught were snatched off the hooks; and again the men were obliged to beat the water. When the boats returned they were deeply laden with birds and fish, both welcome to those who had been living on salt provisions.

From the highest point of the rock,* no discoloured water, nor any breaking of the sea, could be discerned, apart from the place itself; and from the soundings taken in the boats, as well as on board the ship, I conclude that it is unconnected with any shoal, being merely the summit of a steep-sided mountain rising from the bottom of the ocean.

There was a slight current setting to the westward, not amounting to a mile an hour.

At sunset that day we were out of sight of St. Paul (or St. Peter), and soon after dark were hailed by the gruff voice of a pseudo-Neptune. A few credulous novices ran upon the forecastle to see Neptune and his car, and were received with the watery honours which it is customary to bestow, on such occasions.

Next morning we crossed the Equator, and the usual ceremonies were performed.

> Deep was the bath, to wash away all ill;
> Notched was the razor—of bitter taste the pill.
> Most ruffianly the barber looked—his comb was trebly nailed—
> And water, dashed from every side, the neophyte assailed.

The disagreeable practice alluded to has been permitted in most ships, because sanctioned by time; and though many condemn it as an absurd and dangerous piece of folly, it has also many advocates. Perhaps it is one of those amusements, of which the omission might be regretted. Its effects on the minds of those engaged in preparing for its mummeries, who enjoy it

* Sixty-four feet above the sea.

© The Complete Work of Charles Darwin Online

at the time, and talk of it long afterwards, cannot easily be judged of without being an eye-witness.

During the early ages of navigation, before the invention of the compass, somewhat similar, though really ceremonious rites were observed in Spanish, Portuguese, and Italian vessels, when they passed the more remarkable promontories then known. A modern voyager, Kotzebue, notices this subject in a manner which appears to me so sensible, that I shall quote his words without affecting to add another remark.

"On the 11th of October we crossed the Equator, at twenty-five degrees west longitude, reckoning from Greenwich. Having saluted the southern hemisphere by the firing of guns, our crew proceeded to enact the usual ceremonies. A sailor, who took pride in having frequently passed the line, directed the performance with much solemnity and decorum. He appeared as Neptune, attired in a manner that was meant to be terribly imposing, accompanied by his consort, seated on a gun-carriage instead of a shell, drawn by negroes, as substitutes for tritons. In the evening the sailors represented, amidst general applause, a comedy of their own composition.

"These sports, while they serve to keep up the spirits of the men, and make them forget the difficulties they have to go through, produce also the most beneficial influence upon their health; a cheerful man being much more capable of resisting a fit of sickness than a melancholy one. It is the duty of commanders to use every innocent means of maintaining this temper in their crews; for, in long voyages, when they are several months together wandering on an element not destined by nature for the residence of man, without enjoying even occasionally the recreations of the land, the mind naturally tends to melancholy, which of itself lays the foundation of many diseases, and sometimes even of insanity. Diversion is often the best medicine, and used as a preservative, seldom fails of its effect."—(Kotzebue's Voyage, 1823-26.)

Before sunset on the 19th we saw the island of Fernando Noronha, with its singular peak towering aloft, and at midnight anchored in the roadstead.

© The Complete Work of Charles Darwin Online

Next morning I landed with difficulty for observations, the surf being so high that any common boat would have been swamped. By taking great care, our broad and well-built whale-boats landed the instruments and a small party, and re-embarked them afterwards, without accident.

We landed in a small bay under the (so called) citadel, but there is a safer and in every way preferable landing-place about a mile to the northward. My object being chiefly to take sights of the sun, for time, and compare the chronometers used on shore as soon as possible with those on board, I preferred landing as near as I could to the place where the lamented Captain Foster observed:—but it was difficult to ascertain the house in which his pendulum observations were made. Not even the governor could tell me, for he had arrived since Captain Foster's departure; and most of the inhabitants of the island had changed their dwellings frequently, being all exiles from Brazil.

The governor was a major in the Brazilian service, born at Pernambuco, and under his command were two hundred black troops, and about eight hundred human beings, only thirty of whom were women, and a very few children.

We obtained some fire-wood from one of the islets northward of the principal island; but it was full of centipedes and other noxious insects, from which it was not easy to free it even by charring and washing. Water we did not try to get, because of the heavy surf, but there is no scarcity of it on the island. Neither live-stock nor vegetables could be procured from the apathetic inhabitants.

This place is rather picturesque; and the lofty barren peak, already mentioned, is conspicuous from every point of view. Near the summit is a station from which a look-out is kept, not only over all the island, but over many leagues of the surrounding sea; so that neither ship nor boat can approach or depart, during daylight, without being noticed.

No boats are allowed to be kept on the island, and no intercourse is held with shipping without permission and the strictest inspection.

We sailed from Fernando Noronha the same evening, passed

© The Complete Work of Charles Darwin Online

round the north-east extremity of the island, and steered for Bahia de Todos Santos. Having remained only one day at anchor, in consequence of information that no better landing could be expected for many days; and wishing to ascertain the rates of the chronometers, as well as to procure a supply of water, I decided to go to Bahia, as the nearest port convenient for both purposes. From the 23d to the 27th we found a current setting us southward, between twenty and thirty miles each day. This was quite unexpected by me, for I thought that we should have been set westward. At daylight on the 28th we made the land about Bahia, and before noon were at anchor in the port.

As we sailed in rapidly from the monotonous sea, and passed close along the steep but luxuriantly wooded north shore, we were much struck by the pleasing view. After the light-house was passed, those by whom the scene was unexpected were agreeably surprised by a mass of wood, clinging to a steep bank, which rose abruptly from the dark-blue sea, showing every tint of green, enlivened by bright sunshine, and contrasted by deep shadow: and the general charm was heightened by turretted churches and convents, whose white walls appeared above the waving palm trees; by numerous shipping at anchor or under sail; by the delicate airy sails of innumerable canoes; and by the city itself, rising like an amphitheatre from the water-side to the crest of the heights.

We found ourselves in the middle of the rainy season, and although favoured by a fine day at arriving, cloudy weather and frequent rain succeeded it, and during the short stay we made, much embarrassed our observations.

Bahia has declined ever since its separation from Portugal: unsettled, weak governments, occupied too constantly by party strife to be able to attend to the real improvement of their country, have successively misruled it. Revolutions, and risings of the negro population, interrupting trade, have repeatedly harassed that rich and beautiful country, and are still impending.

Were property secure, and industry encouraged, the trade from Bahia might be very extensive, particularly in sugar and

© The Complete Work of Charles Darwin Online

cotton: but who will embark much capital upon so insecure a foundation as is there offered?

The immense extent and increase of the slave population is an evil long foreseen and now severely felt. Humanely as the Brazilians in general treat their slaves, no one can suppose that any benevolence will eradicate feelings excited by the situation of those human beings. Hitherto the obstacles to combinations and general revolt among the negroes, have been ignorance, mutual distrust, and the fact of their being natives of various countries, speaking different languages, and in many cases hostile to each other, to a degree that hardly their hatred of white men can cause them to conquer, even for their immediate advantage.

The slave trade has already entailed some of its lamentable consequences upon the Brazilians, in demoralizing them by extreme indolence, and its sure accompaniment, gross sensuality; but there are in store afflictions hitherto unfelt, occasioned by the growing hordes of enemies who are yearly causing more perplexity and dread in the territories of Brazil.

Could the Brazilians see clearly their own position, unanimously condemn and prevent the selfish conduct of individuals, emancipate the slaves now in their country, and decidedly prevent the introduction of more, Brazil would commence a career of prosperity, and her population would increase in an unlimited degree. In that immense and most fertile country, distress cannot be caused by numerous inhabitants; food is abundant, and the slight clothing required in so warm a climate is easily procured.

The chief, if not the only cause of the slave trade in Brazil, is want of population—want of an industrious population, able as well as willing to clear away primeval forests, and render the soil fit for culture—able to work in the open fields under a hot sun, to cultivate the sugar cane, cotton plants, mandioca, and other productions of tropical climates.

While this extensive and most powerful cause exists, selfish, unprincipled owners of immense territories in Brazil, and elsewhere, will not refrain from importing hundreds, even thou-

© The Complete Work of Charles Darwin Online

sands of unhappy wretches, who, once landed, become the helpless instruments of immense gain to their owners: neither can any reasonable number of shipping efficiently blockade the coasts of two great continents.

If I am right in these assertions, it appears that there is no method by which the slave trade can be totally suppressed, except by destroying the cause of so abominable a traffic: and that, to this end, a native population should be encouraged in hot climates, who, being gradually inured to work on their native soil, for remuneration from their employers, and a prospect of future comfort for themselves and their offspring, would totally supersede the demand for constrained labour. Of course, the only way by which such a result could be obtained—I should say, perhaps, the first step towards so satisfactory a result, would be, that the government of a slave-importing country should declare that trade piratical: and proclaim every human being free; bound to no man, free to do any thing not contrary to religion, or law, from the moment he or she embarked on board a vessel belonging to that country, or placed a foot upon its soil; which might then indeed be termed, in common with our happy land, a sacred soil. By such a plan as this, individuals would suffer for a time, but the mass of society would be gainers incalculably.

Well-known authors have already said so much of Bahia, its spacious harbour, and delightful environs, that it would be impertinent in the writer of a mere narrative to add his hasty remarks to the calmly considered information which their works contain. But I will venture to notice that however pleased a stranger to Bahia may be at the sensations conveyed through his eyes, previous to landing, he will be miserably disappointed when he finds himself in the dirty, narrow, crowded, and hot 'lower town;' and that the sooner he gets into a sedan* chair, and desires the almost naked bearers to make the best of their way to the 'upper town,' where he will enjoy

* An arm-chair, with a high back, a foot-board, and curtains to draw round, hung to a pole which rests on the shoulders of two men.

fresh air, a pleasing view, and freedom from annoyances, the less his organs will be offended, and his temper tried.

We sailed from Bahia on the 18th. The bank which projects from the light-house point had been minutely examined by us, during the Beagle's stay in port; on one day, indeed, she went out and anchored at the outer end of the shoal, in order to determine its extent, and assist the boats in sounding; therefore I did not hesitate to stand across it; but there is not water enough over the shallower parts for any ship drawing more than fourteen feet, especially if there is a swell. The shoalest spot is near the outer end; ships of any size may pass between the inner extremity and the point of land adjacent to it.

There are rocks and dangerous shallows southward of the port, which it is extremely necessary to guard against in approaching it from sea, because the current generally sets towards the south, and ships have got ashore on those shoals in consequence. The land northward of Bahia should be made, and some white sandy patches, looking like linen hung out to dry, should be seen before a ship steers more southerly.

After losing sight of the land, our course was shaped to the south-east, towards the eastern limit of the great bank of soundings which extends so far to seaward of the Abrolhos islets. Having reached the parallel of the islands, and being to the eastward of the easternmost soundings laid down in any chart, without finding any ground with three hundred fathoms of line, I began to steer westward—sounding continually, and keeping a sharp look-out at the mast-head. At two in the afternoon of the 26th, we had no bottom, with three hundred fathoms of line; and at the next cast, about an hour afterwards, found only thirty fathoms, without there being the slightest change in the colour of the water, or in its temperature, or any other indication of so sudden a change in the depth. We hauled to the wind directly, worked to the eastward in order to ascertain the precise limit of the bank, and lost soundings as suddenly as we had previously struck them. A grapnel was then put overboard, with two hundred fathoms of line, and we

© The Complete Work of Charles Darwin Online

again steered westward, till a heavy pull upon the line, and a sudden jerk, showed that we had hooked the bank.

The ship was hove-to, and the necessary observations made on the spot. The grapnel, when hauled up, was found to be straightened, a proof, in addition to that afforded by the lead, that the bottom was rocky. Our soundings at this time were thirty-eight fathoms, and thence to the Abrolhos islets we carried a line of soundings, no where exceeding that depth, but extremely irregular, between thirty-six and four fathoms.

As far as we had time to examine, the chart of these islands, by the Baron Roussin, appeared to be satisfactory; but the soundings are so very irregular in the vicinity of the Abrolhos, that little dependence could be placed on the lead. More than once we had four or five fathoms under one side of the vessel, and from fifteen to twenty under the other. These sudden and startling changes, called by the French, 'Sauts de sonde,' are very unpleasant and perplexing.

The tide, or rather current, which we found when lying at anchor near the islets, set continually to the southward, varying in strength from half a mile to a mile and a half an hour; but we had only three days' experience.

I had imagined, from what I had heard, that the rock of which these islets were chiefly composed was coral; but was surprized to find only coralline growing upon gneiss or sandstone.

While sounding near the Abrolhos we made a great number of experiments with Massey's lead, in order to verify its qualities; and found it agree remarkably well with the common lead, while in less than forty fathoms, but differ from it frequently when the depth of water exceeded seventy fathoms; and wholly fail when used in upwards of one hundred and twenty fathoms. The failure, in great depths, was in consequence of the small hollow cylinder, to which the vanes were attached, bursting, or rather, being compressed by the weight of water. Some more remarks upon this instrument will be found in the Appendix.

We anchored near the islets, at dusk, on the 28th, after being in frequent anxiety, owing to sudden changes in the

© The Complete Work of Charles Darwin Online

depth of water; and next morning, moved to a better berth at the west side, very near them. They are rather low, but covered with grass, and there is a little scattered brushwood. The highest point rises to about a hundred feet above the sea. Their geological formation, Mr. Darwin told me, is of gneiss and sandstone, in horizontal strata. When our boats landed, immense flights of birds rose simultaneously, and darkened the air. It was the breeding and moulting season; nests full of eggs, or young unfledged birds, absolutely covered the ground, and in a very short time our boats were laden with their contents.

A large black bird, with a pouch like that of a pelican, but of a bright red colour, was very remarkable, as it hovered, or darted among the bright verdure, and at a distance looked handsome; but when seen close, it at once descended to the level of a carrion-eating cormorant or buzzard.

Turtle are to be found at times: we observed the shell and skeleton of an extremely large one lying on a sandy spot at the north side of the northern islet. Some very fine fish, of the cod kind, were caught; one was so large, that, until hauled on board, it was supposed to be a shark. The anchorage is good, and easy of access: all swell is stopped by the shallow places, and by the islets themselves. There is no fresh water.

If a general reader should honour these pages by his perusal, and find such details about wood, water, fish, birds, &c., at places about which few know, and still fewer care—extremely tiresome, he will of course pass them over; but, in my own exculpation, I must beg to be permitted to remind him that the Beagle was employed by Government, to obtain practical information likely to be useful to shipping; and that I might neglect my duty by omitting to mention such matters, when speaking of places which are seldom visited, and hitherto but slightly known.

By those employed in the coasting trade, the Abrolhos are said to be particularly subject to squalls. If this be true, what is the reason? Have the extensive shallows in their

© The Complete Work of Charles Darwin Online

vicinity any connection with the fact? Thinking myself that they have, I would beg the reader to bear this idea in mind, when, at another part of this narrative, the squalls so frequent in the dangerous archipelago of the low islands are mentioned.*

March 30th. We sailed and sounded in various directions, but such irregular depths I never found elsewhere. Sudden jumps, from thirty to ten, sometimes even to four fathoms, in successive casts of the hand-lead, gave us frequent alarm; but by keeping a boat a-head, and two leads going briskly, we avoided danger, and giving up exploring, regained before dark the safe channel which runs north and south between the Abrolhos and the main land, and steered to pass near Cape San Tomè, or St. Thomas. Next day we were off that cape, but saw none of the breakers which have been so frequently reported to lie at a dangerous distance from the neighbouring shore; although we looked out for them, and steered so as to pass the places where I was informed they would be seen.

On the 3d of April, we passed Cape Frio. I wished to visit the cove in which the Lightning and Algerine lay, while recovering the treasure sunk in the unfortunate Thetis, but circumstances were unfavourable.

* The Bermuda Islands ("still vexed Bermoothes") may also be thought of, as being similarly circumstanced.

CHAPTER IV.

Loss of the Thetis—Causes of her wreck—Approach to Rio de Janeiro—Owen Glendower—Disturbance in Rio Harbour—Observations—Chronometers—Return to Bahia—Deaths—Macacu—Malaria—Return to Rio de Janeiro—Meridian Distances—Regatta—Fuegians—Lightning—Leave Rio—Equipment—Santa Martha—Weather—Santa Catharina—Santos—River Plata—Pamperoes—Gales off Buenos Ayres—Monte Video—Point Piedras—Cape San Antonio—River Plata—Currents—Tides—Barometer—Absence of trees—Cattle.

Among the shipwrecks which have taken place during late years, perhaps none excited so much astonishment, or caused so much trouble and discussion, as the loss of that fine frigate the Thetis.

Had any seaman been asked, on what frequented shore there was least probability of a wreck, I almost think he would have answered on that of Cape Frio. Yet, against the high cliffs of that bold and well-known coast did she run 'stem on,' going nine knots. One may conceive the shock and general consternation as she crashed against the rocky cliff, and all her masts fell inboard.

As some who turn over these pages may not have read the proceedings of the Court-martial held after the return of her officers to England, I will insert a short account, derived chiefly from those of old friends and shipmates, who were on board her at the awful time of her wreck.

The Thetis sailed from Rio de Janeiro on the 4th of December 1830, and worked to the southward all day, against a southerly wind and thick foggy weather. At 1h. 30m. A.M. on the 5th, she saw Raza Island for the last time, bearing N.W. by W., and distant eight or nine miles. The weather was still hazy, indeed at times very thick, and the wind south-east. She stood off on the larboard tack until seven A.M., and then the wind having increased, and a cross sea getting up, she wore to the eastward. Soon afterwards the wind drew to SS.E., and the ship was kept by the wind on the

© The Complete Work of Charles Darwin Online

starboard tack until 1h. 30m. P.M., when it was considered that Cape Frio bore about N. 40° E., distant thirty-eight miles. The position at noon, by dead reckoning, gave the Cape bearing N. 43. E., distant forty-one miles; all the calculations giving results between that and N. 51. E., fifty-three miles; but by dead reckoning only, as neither sun, moon, or stars had been seen. At 1h. 30m. the wind being scant, the ship was steered E. by N., and at two, a cross sea checking her way through the water, the course was altered to E.N. E. At two, when the course was thus changed, she had run nineteen miles since noon, and at four, twenty more miles had been made on the E.N.E. course; at which time, four P.M. (under the idea that she was almost abreast of Cape Frio, supposed to be then distant about twenty-four miles), seeing a large ship, 'courses down,' in-shore of her, steering west or W. by N., with all sail set; and the weather clearing, for an interval, without any land being seen; it was concluded that the Thetis was still further from the shore than had been estimated, and her course was altered to N.E. by E. At five, the crew was mustered at quarters, after which the reefs were mended, and the fore top-gallant sail, jibs, spanker, and reefed fore top-mast studding-sail were set. From four o'clock to six she ran, by log, twenty-one miles; after six the weather became very thick and rainy: and when the look-out men were relieved at eight o'clock, it was so dark, and rained so fast, that nothing could be distinguished half a ship's length distant. Soon after eight one of the look-out men, named Robinson, said to another man on the forecastle,* "Look how fast that squall is coming" (this was the cliff looming indistinctly through the rain and darkness), and next moment, "Land a-head," "Hard a-port," rung in the ears of the startled crew, and were echoed terribly by the crashing bowsprit, and thundering fall of the ponderous masts.

The hull did not then strike the rocks, having answered the helm so fast as to be turning off shore when the bowsprit

* Borsworthick. Both these men afterwards sailed with me in the Beagle.

© The Complete Work of Charles Darwin Online

broke; but the lee yard-arm irons (boom-irons) actually struck fire from the rocky precipice as they grated harshly against it, the boom ends snapping off like icicles.

All three masts fell aft and inward, strewing the deck with killed and wounded men. An immense black barrier impended horribly, against which heavy breakers were dashing with an ominous sound; but the ship's hull was still uninjured. Sentries were placed over the spirit-room; a sail was hoisted upon the stump of the main-mast; the winches were manned; guns fired; rockets sent up, and blue-lights burned; the quarter-boats were cleared away to be ready for lowering; and an anchor was let go; but the water was so deep, that before she brought up, her stern drifted upon a more shelving part of the rock. Several men then tried to land; but, in jumping ashore, many slipped, and were drowned in the surf, or crushed against the rocks. The stern and lee quarter boats were dashed to pieces, as the surf hove the ship against the cliff, and no boat was then available; for the others were either stove, or so covered with wreck, that they could not be used. Finding that the anchor, which had been let go, did no good, but seemed to keep her tailing upon the rocks, the cable was slipped, after which her head fell off to the westward. It was then found that the water was gaining, and the winches were worked. Successive waves threw her starboard quarter upon the rocks; and the effects of repeatedly striking were soon but too apparent, as the water burst open the spirit-room hatches.

At this moment a small opening appeared, into which the ship providentially drove. It was at first thought that this was the opening into Cape Frio Harbour; but it proved to be only a very small cove, or indentation of the rocky cliffs. While drifting close along the rocks into this cove, a hawser was passed ashore, by which afterwards several persons landed. The ship struck heavily in the cove, gave some tremendous yawns, and sunk. As she then lay upon the rocky bottom, each succeeding wave broke over and just covered her. By a violent surge, the rock to which the hawser above-mentioned had been made fast, was torn away; and, for a short time, all

© The Complete Work of Charles Darwin Online

hope of further communication with the land was suspended. Every effort that could be made to convey a rope to the shore was attempted in vain, until Mr. Geach, the boatswain, went out on the stump of the bowsprit, and by the help of two belaying-pins, succeeded in throwing the end of a small rope to the rocks, by which a large one was immediately hauled ashore, and then kept as much stretched as the strength of the men who had landed would allow. On this larger rope each man was slung, in his turn, and hauled by the small one through the surf to a rough craggy rock. Mr. Geach and John Langley, the captain of the forecastle, were among the last to leave the ship, having almost exhausted themselves in slinging their shipmates.

As day-light broke, the last man was hauled ashore. Many were terribly bruised and lacerated by the fall of the masts, or during these struggles for life, and twenty-five persons perished. Some of the officers made their way to a small village near Cape Frio, and obtained horses, and a guide who conducted them to Rio de Janeiro, where the melancholy news was communicated to the commander-in-chief. The captain, the other officers, and the crew, remained near the place of the wreck, waiting for assistance.

An adequate cause for so great an error in the reckoning of only nineteen hours as that which occasioned the loss of this fine ship and twenty-five souls, besides the personal property of those on board, and a large freight of treasure, is not difficult to find, even without supposing the compasses to have been in error, or affected by local attraction, which, by the way, would in this case have operated in the ship's favour.

The vicinity of Cape Frio, one of the most salient promontories on the coast of Brazil, cannot be supposed exempt from currents; set in motion either by temporary causes, such as strong or lasting winds; or by the varying pressure of the atmosphere upon different portions of the ocean:—or from tidal streams, more or less strong.

© The Complete Work of Charles Darwin Online

Presuming that the Thetis was carried out of her supposed position, by the former cause, about twenty-four miles; surely rather more than a mile an hour is no surprising current during nineteen hours. But if a stream of tide also affected her, in that time she would have had one whole tide either in her favour or against her.

There was no reason to suspect the existence of much current near Cape Frio, when the Thetis was lost, except on such general grounds as those just mentioned, because no pilot, as far as I know, was aware of such a fact. With strong southerly winds ships of large size do not often leave Rio de Janeiro—coasting vessels never—therefore few persons could have experienced its effect when sailing from the port; and when approaching Rio in similar weather, vessels sail before a fair wind, steer by sight of the land, and take little notice of the log: besides which, they then employ but three or four hours in passing through that space of sea where the Thetis was detained nineteen.

In all probability, such a current as that which drove the Thetis on the rocks is only to be found during southerly winds, and in the summer season of that climate, when the general set of the current is along the coast, towards the south and west.

If a man of war is accidentally lost, a degree of astonishment is expressed at the unexpected fate of a fine ship, well found, well manned, and well officered; and blame is imputed to some one: but before admitting a hastily-formed opinion as fact, much inquiry is necessary. As in the case of the Thetis, an English man-of-war may incur risk in consequence of a praiseworthy zeal to avoid delaying in port, as a merchant-ship would probably be obliged to do, from her being unable to beat out against an adverse wind, and, like that frigate, may be the first to prove the existence of an unsuspected danger.

Those who never run any risk; who sail only when the wind is fair; who heave to when approaching land, though perhaps a day's sail distant; and who even delay the performance of urgent duties until they can be done easily and quite safely; are,

© The Complete Work of Charles Darwin Online

doubtless, extremely prudent persons: — but rather unlike those officers whose names will never be forgotten while England has a navy.

Of the measures taken for recovering the treasure sunk in the Thetis, much has appeared in print; therefore I will not add a word to that subject of controversy.

Weather such as that which caused the loss of the Thetis, is only at times met with off Capé Frio; a clear sky, with a hot sun, and but little wind, is more usual; and as my first approach to Rio de Janeiro, on board H.M.S. Owen Glendower, in 1819, made much impression upon me, I will endeavour to describe it's circumstances.

High blue mountains were seen in the west, just after the sun had set, and with a fair wind we approached the land rapidly. The sea was quite smooth, but a freshening breeze upon our quarter carried us on, nearly thirteen knots an hour. Though dark as any cloudy tropical night, when neither moon nor star relieves the intense blackness—astern of us was a long and perfectly straight line of sparkling light, caused by the ship's rapid way through the water; and around the bows, as far forward as the bowsprit end, was dazzling foam, by whose light I read a page of common print. Sheet lightning played incessantly near the western horizon: and sometimes the whole surface of the sea seemed to be illuminated. As the moon rose, and the breeze decreased, the contrasts of light and darkness, of swift change of place and apparent tranquillity, lost their effect. Next morning we had a dead calm: high land towered over the fog-banks, which were slowly drawn upwards and dispersed by the heat of a powerful sun; and the sea was smooth as a lake. Numbers of that beautiful fish, the dorado, often called a dolphin, were caught; and the vivid, various colours displayed, as they lay upon our deck, exceeded description. Well I remember too the trouble we middies had with the sun at noon on that day; not with the sun above our heads, but with its image reflected by our quadrants. As he was almost vertical over us, we were dispersed round the ship, each thinking he had brought the reflected image down

© The Complete Work of Charles Darwin Online

to the proper point of the horizon, until, startled by hearing 'twelve o'clock,' reported by the master, we found too late, and much to our annoyance, that it would have been wiser to have looked at the compass before observing the altitude.

Soon after mid-day black curling ripples stole along the hitherto glassy surface; sail was made, the sea-breeze freshened, and we steered towards the entrance of that magnificent harbour, Rio de Janeiro.

Often as it has been visited and described, I cannot expect any one to require another sketch, but will merely remark that I know no port equal to it in situation, security, capacity, convenience, and abundant supply of every necessary, as well as in picturesque beauty. A day or two after the Owen Glendower anchored, a party of her midshipmen were allowed to take a boat and enjoy a day's excursion in the beautiful harbour, or rather gulf. We landed on an island, which seemed to me like an immense hot-bed, so luxuriant and aromatic were the shrubs, and so exotical the appearance of every tree and flower. Years since elapsed have not in the least diminished my recollection of the novelty and charm of that first view of tropical vegetation.

To return to the Beagle. On the 3d we were near Raza Island, but detained by calms. The light-house lately erected there showed a bright revolving, or rather intermitting light. On the following day, when the sea-breeze set in, we steered for the harbour. The sun shone brightly, and there were enough passing clouds to throw frequent shadows over the wooded heights and across vallies, where, at other times, the brightest tints of varied green were conspicuous: yet I did not think the place half so beautiful as formerly. The charm of novelty being gone, and having anticipated too much, were perhaps the causes; and it is possible that so much wood has been cleared away in late years, as to have diminished sensibly the rich and picturesque appearance which it certainly once possessed.

As we shortened sail under the stern of our flag-ship, I was surprised by finding Sir Thomas Baker, the Commander-in-

© The Complete Work of Charles Darwin Online

chief, giving directions for the positions to be taken forthwith by the ships of his squadron then present, and orders for the boats to be prepared for landing marines. This was in consequence of one of those disturbances almost usual in South America, especially in Brazil. Some outrages had been committed in the town, and a mutiny had broken out among the troops. Under old and established governments, revolt and mutiny are events which so seldom occur that their shock is not only felt at the time, but transmits vibrations through succeeding ages. In these unsettled states, however, they recur so frequently, that even on the spot they cause little sensation, and excepting by those personally concerned, are scarcely remembered afterwards.

Few strangers visit the metropolis of Brazil without being disappointed, if not disgusted. Numbers of almost naked negroes, hastening along narrow streets—offensive sights and smells, an uncivil and ill-looking native population — indispose one to be pleased, even with novelty; but impressions such as these soon wear off. In the environs of the city are many good houses, in beautiful situations; and while enjoying delightful rides amidst the richest and most varied scenery, or resting in the shade of a veranda, refreshed by the sea-breeze, and overlooking a prospect hardly to be surpassed in the world, the annoyances and the nuisances of the town are forgotten.

With respect to astronomical observations, I was extremely unfortunate at Rio de Janeiro, except in those simple ones for time and latitude, which depend upon sextants and artificial horizons. Being the rainy season, but few nights were favourable for observing the transits of stars with the moon, and those few were too near the full moon to be available. But had the weather been otherwise, I doubt whether I should have obtained satisfactory results, because the transit instrument employed was of an inferior construction, and still more, because I was unaccustomed to its use. So much time was employed, to the prejudice of other duties, in adjusting and re-adjusting this imperfect instrument, and ineffectually watching for intervals of clear sky, that I resolved to set up the transit

© The Complete Work of Charles Darwin Online

no more, until I had an interval of leisure, and a prospect of some cloudless nights.

Having so many good chronometers on board; being practised in observations such as they require; and placing great confidence in their results; I felt inclined to give attention and time to them rather than to perplex myself, and cause much delay in moving from place to place, by attempting series of observations which would give occupation to an astronomer, and could not be undertaken by me, while actively engaged in coast-survey, without interfering with other duties.

In the Appendix it may be seen how far results obtained by the chronometers agree with those of a higher class, especially with the recent ones of Captain Beechey, to whose determinations, resulting from moon-culminating observations, I conclude that a high value will be attached, because he is a well-practised and able observer.

As I found that a difference, exceeding four miles of longitude, existed between the meridian distance from Bahia to Rio, determined by the French expedition under Baron Roussin, and that measured by the Beagle; yet was unable to detect any mistake or oversight on my part; I resolved to return to Bahia, and ascertain whether the Beagle's measurement was incorrect. Such a step was not warranted by my instructions; but I trusted to the Hydrographer for appreciating my motives, and explaining them to the Lords of the Admiralty. In a letter to Captain Beaufort, I said, "I have not the least doubt of our measurement from Bahia; but do not think that any other person would rely on this one measure only, differing widely, as it does, from that of a high authority—the Baron Roussin. By repeating it, if it should be verified, more weight will be given to other measures made by the same instruments and observers."

We sailed with the ebb-tide and sea-breeze, cleared the port before the land-wind rose, and when it sprung up steered along the coast towards Cape Frio. Most persons prefer sailing from Rio early in the morning, with the land-wind; but to any well-manned vessel, there is no difficulty whatever in working

© The Complete Work of Charles Darwin Online

out of the port during a fresh sea-breeze, unless the flood-tide should be running in strongly.

On this passage one of our seamen died of a fever, contracted when absent from the Beagle with several of her officers, on an excursion to the interior part of the extensive harbour of Rio de Janeiro. One of the ship's boys, who was in the same party, lay dangerously ill, and young Musters seemed destined to be another victim to this deadly fever.

It was while the interior of the Beagle was being painted, and no duty going on except at the little observatory on Villegagnon Island, that those officers who could be spared made this excursion to various parts of the harbour. Among other places they were in the river Macacu, and passed a night there. No effect was visible at the time; the party returned in apparent health, and in high spirits; but two days had not elapsed when the seaman, named Morgan, complained of headach and fever.

The boy Jones and Mr. Musters were taken ill, soon afterwards, in a similar manner; but no serious consequences were then apprehended, and it was thought that a change of air would restore them to health. Vain idea! they gradually became worse; the boy died the day after our arrival in Bahia; and, on the 19th of May, my poor little friend Charles Musters, who had been entrusted by his father to my care, and was a favourite with every one, ended his short career.

My chief object in now mentioning these melancholy facts is to warn the few who are not more experienced than I was at that time, how very dangerous the vicinity of rivers may be in hot climates. Upon making more inquiry respecting those streams which run into the great basin of Rio de Janeiro, I found that the Macacu was notorious among the natives as being often the site of pestilential malaria, fatal even to themselves. How the rest of our party escaped, I know not; for they were eleven or twelve in number, and occupied a day and night in the river. When they left the ship it was not intended that they should go up any river; the object of their excursion being to visit some of the beautiful islets which stud the harbour. None of us were aware, however, that there was so

© The Complete Work of Charles Darwin Online

dangerous a place as the fatal Macacu within reach. I questioned every one of the party, especially the second lieutenant and master, as to what the three who perished had done different from the rest; and discovered that it was believed they had bathed during the heat of the day, against positive orders, and unseen by their companions; and that Morgan had slept in the open air, outside the tent, the night they passed on the bank of the Macacu.

As far as I am aware, the risk, in cases such as these, is chiefly encountered by sleeping on shore, exposed to the air on or near the low banks of rivers, in woody or marshy places subject to great solar heat. Those who sleep in boats, or under tents, suffer less than persons sleeping on shore and exposed; but they are not always exempt, as the murderous mortalities on the coast of Africa prove. Whether the cause of disease is a vapour, or gas, formed at night in such situations, or only a check to perspiration when the body is peculiarly affected by the heat of the climate, are questions not easy to answer, if I may judge from the difficulty I have found in obtaining any satisfactory information on the subject. One or two remarks may be made here, perhaps.—The danger appears to be incurred while sleeping; or when over-heated; not while awake and moderately cool; therefore we may infer that a check to the perspiration which takes place at those times is to be guarded against, rather than the breathing of any peculiar gas, or air, rising from the rivers or hanging over the land, which might have as much effect upon a person awake, as upon a sleeper. Also, to prevent being chilled by night damp, and cold, as well as to purify the air, if vapour or gas should indeed be the cause of fever, it is advisable to keep a large fire burning while the sun is below the horizon. But the subject of malaria has been so fully discussed by medical men, that even this short digression is unnecessary.

To return to the narrative. Mr. Bynoe consulted with the best medical advisers at Bahia, and afterwards at Rio de Janeiro, and he and I had the melancholy satisfaction of knowing that the best had been done for his patients.

© The Complete Work of Charles Darwin Online

The affectionate kindness of Mr. Bynoe on this, and indeed every occasion where his skill and attention were required, will never be forgotten by any of his shipmates.

In our passage from Rio de Janeiro to Bahia, we passed between the Abrolhos Islands and the main land, having a fresh southerly wind, and cloudy weather, with frequent rain. Of course there was some anxiety until we saw the islands, and it was necessary to keep the lead constantly going; but we got into no difficulty, and, assisted by Massey's log, as well as Massey's lead, we made a short passage, without an hour's delay or scant wind. This was favourable for the chronometer measurement, and I was deeply gratified by finding, soon after our arrival, that the measure from Rio to Bahia confirmed that previously made, even to a second of time.

On the 23d of May, we sailed the second time from Bahia, and steered to pass as near as possible to the eastern side of the Abrolhos; but, owing to unfavourable winds, could not approach nearer to them than in fourteen fathoms water.

When examining many of the cases of preserved meat* with which the Admiralty had ordered us to be provided, we found that several had burst and caused a most disagreeable smell. This was not the fault of the tin cases, but an unavoidable accident consequent upon their being stowed where salt water had occasional access, and corroded the tin. In so small and so crammed a hold as ours, it was not easy to make stowage for every thing that ought to be kept dry, particularly with a hatch-deck, while rolling about in the Bay of Biscay; but being warned by this first appearance of decay, our internal arrangement was partly changed, and some of the hatches on the lower deck temporarily caulked down.

Delayed by southerly winds and a long heavy swell from the southward, we made rather a tedious passage back to Rio, and did not anchor until the night of the 3d of June.

Next day (4th) the usual sets of equal altitudes were observed; and after the chronometer rates were ascertained, I

* Prepared by Kilner and Moorsom.

© The Complete Work of Charles Darwin Online

had the satisfaction of finding that this third meridian distance agreed exactly with the first and second. Upon further examination, it was seen that the Abrolhos Islands were laid down correctly in the French chart, with respect to Bahia; but that the meridian distance between those islands and Rio de Janeiro differed more than four miles from that resulting from three measures made by our twenty chronometers.

A few weeks afterwards all the data and results of these measurements were given to the French Commander-in-chief on the station, who promised to forward them to the Baron Roussin; but I have heard nothing of their having been received. Even those who are disposed to place little reliance on the performance of chronometers, and who doubt the accuracy of distances measured by the transport of time, might be interested by a glance at the particulars of these meridian distances, which are given in the Appendix. They much increased my own confidence in that simple method of ascertaining differences of longitude, and tended to determine my dependence upon a connected chain of meridian distances, in preference to any other mode of finding the precise longitude.

While watering, and rating the chronometers, a few comparatively leisure days afforded a seasonable opportunity for trying the qualities of boats, and exciting fair emulation among their crews. With the Commander-in-chief's permission, and the encouragement of the officers of his squadron, then in the port, some good boat-races were arranged; and knowing how much might afterwards depend upon the qualities of the Beagle's boats, it was very gratifying to find them excellent. Four of the set were built by Mr. Johns, the well-known boat-builder in Plymouth Dock-yard, and the other two by Mr. May, our carpenter. Captain Talbot, of the Warspite, and Captain Waldegrave, of the Seringapatam, tried their best boats and best men on two successive days, to the encouragement of the boats' crews and boat-sailers of the squadron, and much to the surprise of the Brazilians, who had never witnessed any thing like a regatta.

From our first arrival at Rio de Janeiro, until we were

© The Complete Work of Charles Darwin Online

ready to leave, finally, in July, little Fuegia was staying on shore, at the house of an Englishwoman, near Botafogo bay; and it is worth noticing, that while there, she was supposed by strangers to be one of the aboriginal natives of Brazil: and that I went with York and Jemmy to see a person (who had been many years resident in the interior of Brazil) who remarked, directly he saw them, "they are extremely like the Brazilian aborigines!"

At this time of year (July) the climate of Rio is comparatively cool and pleasant. Cloudy skies, southerly winds, and rain, are frequent; but there is less thunder and lightning than in summer, when not only thunder-storms occur often, but every night there is a continual flashing or reflection of lightning over the distant Organ mountains.

Many ships and buildings have been struck, during late years, still there are but a very few protected by lightning conductors. I was a lieutenant on board the Thetis, when her foremast was shattered by lightning, in Rio Harbour, and shall not easily forget the sensation. Some of the officers were sitting in the gun-room, one very dark evening, while the heavens were absolutely black, and the air hot and close, to an oppressive degree, but not a drop of rain falling, when a rattling crash shook the ship. Some thought several guns had been fired together—others, that an explosion of powder had taken place; but one said—"The ship is struck by lightning!" and that was the case. The top-gallant masts were not aloft; but the fore-topmast was shivered into a mere collection of splinters; the hoops on the foremast were burst, and the interior, as well as outside of the mast, irreparably injured. From the foremast the electric fluid seemed to have escaped by some conductor, without doing further damage; yet it filled the fore part of the ship with a sulphureous smell, and the men who were there thought something full of gunpowder was blown up.

No person received injury: the foremast was taken out afterwards, and replaced by another, purchased from the Brazilian government at a great expense, and made by the carpen-

© The Complete Work of Charles Darwin Online

ters of the Thetis. I should say that the electric fluid shook rather than shattered the fore-topmast, for it did not fall, but resembled a bundle of long splinters, almost like reeds. It twisted round the head of the foremast, instead of descending by the shortest line, went into the centre of the spar, and then out again to the hoops, every one of which, above the deck, was burst asunder. The Thetis was to have sailed in a few days, but was detained by this accident almost two months. She had no conductor in use.

Only two or three flashes of lightning were seen afterwards; they were accompanied by loud peals of thunder, and then heavy rain poured down. Just before the rain began, St. Elmo's fire was seen at each yard-arm, and at the mast-head. Those who have not seen this light, always a favourite with sailors, because they say it only appears when the worst part of the storm is over, may excuse my saying that it resembles the light of a piece of phosphorus—not being so bright, or so small, as that of a glow-worm, nor yet so large as the flame of a small candle. I was curious enough to go out to a yard-arm and put my hand on a luminous spot; but, of course, could feel nothing, and when I moved my hand the spot re-appeared. About the same time of the year in which this happened, the Heron corvette was struck by lightning, and damaged, while lying at anchor off Buenos Ayres, in the river Plata, a locality extremely subject to vivid lightning, yet different in every respect from that of Rio de Janeiro: one being a flat, open country, near a fresh water river, and in latitude 34°; the other a mountainous and woody region, near the sea, and within the tropic of Capricorn.

On the 5th of July we sailed from Rio de Janeiro, honoured by a salute, not of guns, but of hearty cheers from H.M.S. Warspite. Strict etiquette might have been offended at such a compliment to a little ten-gun brig, or, indeed, to any vessel unless she were going out to meet an enemy, or were returning into port victorious: but although not about to encounter a foe, our lonely vessel was going to undertake a task laborious, and often dangerous, to the zealous execution

© The Complete Work of Charles Darwin Online

of which the encouragement of our brother-seamen was no trifling inducement.

While in harbour, a few alterations had been made in the disposition of our guns and stores, as well as some slight changes in the sails and rigging; and as the Beagle's equipment afterwards remained unaltered, I will here briefly describe it. She was rigged as a bark; her masts were strongly supported by squarer cross-trees and tops, and by larger rigging than usual in vessels of her tonnage.* Chains were used where found to answer, and in no place was a block or a sheave allowed which did not admit the proper rope or chain freely. There were large trysails between the masts, made of stout canvas, with several reefs, and very useful we found them. On the forecastle was a six-pound boat-carronade: before the chestree were two brass six-pound guns: close to the bulwark on each side of the waist were the 'booms;' and amidships two boats, on the diagonal principle, one stowed inside the other, and as close to the deck as possible; being secured by iron cranks, or supports. Abaft the main-mast were four brass guns, two nine-pound, and two six-pound: the skylights were large; there was no capstan; over the wheel the poop-deck projected, and under it were cabins, extremely small, certainly, though filled in inverse proportion to their size. Below the upper deck her accommodations were similar to, though rather better than those of vessels of her class. Over the quarter-deck, upon skids, two whale-boats, eight-and-twenty feet long, were carried; upon each quarter was a whale-boat twenty-five feet in length, and astern was a dinghy.

A few leagues southward of the port is a good situation for enjoying a general view of the picturesque mountains in its vicinity. When near the shore one only sees those of an inferior order; and it is not until an offing is gained that the bold and varied outlines of the distant Organ Mountains,† the sharp

* Two hundred and forty-two tons.

† So called because they have a number of pinnacles, somewhat like the pipes of an organ.

© The Complete Work of Charles Darwin Online

peak of the Corcovado, and the singular heights over Tijuca, can be seen at once. Whimsical allusion has been made to the first Lord Hood in the name by which one of these heights is called by English sailors; and in their general outline is a fancied resemblance to a huge giant lying on his back.

Off Santa Martha, a sort of Cape Spartivento, near which one rarely passes without having a change of wind, if not a storm, we were detained by strong southerly gales, which raised a high sea. This extreme movement and delay I regretted much at the time, on account of the chronometers; but the sequel shewed that such motion did not affect them materially, and that alterations of their rates were caused chiefly, if not entirely, by changes of temperature.

Gales in the latitude of Santa Martha generally commence with north-westerly winds, thick cloudy weather, rain, and lightning. When at their height, the barometer begins to rise (having previously fallen considerably), soon after which the wind flies round, by the west, to south-west, and from that quarter usually blows very hard for several hours. But these, which are the ordinary gales, blow from, or along the land, and do not often raise such a sea as is sometimes found off this coast during a south-east storm.

After a tiresome continuance of south-west winds, I became anxious to make Santa Catharina, but before we could reach it the wind changed, and enabled us to steer along the coast towards the south. Having mentioned Santa Catharina, I may as well add a few words to the many lavished in its praise by voyagers of all nations; for it is, excepting Rio de Janeiro, and perhaps Bahia, the best trading port on the east coast of South America; and, considering its situation, capabilities, and productions, is a place in which seamen must always have an interest. It enjoys the advantages of a temperate climate; an extensive and accessible harbour; a most fertile country, abounding in the necessaries of life; and a mercantile position of much importance. The people are more inclined to exert themselves than those in northern Brazil; a difference arising partly, no doubt, from effect of climate;

© The Complete Work of Charles Darwin Online

but chiefly from their having descended from active and enterprising, though lawless settlers, who were ejected from other places; and from a few respectable colonists induced to emigrate from the Azores. Before I quit the neighbourhood of frequented ports on this coast, one possessing peculiar interest, Santos, ought to be mentioned; to remind seamen that they may there also obtain any refreshments, and secure their ships in a sheltered creek, quite easy of access. For several leagues round Santos there is an extensive flat, covered with thick woods, but intersected by rivers and salt water inlets, whose banks are lined with thickets of mangrove trees. Inland a mountain range abruptly rises to the height of two or three thousand feet, every where clothed with almost impenetrable forests. The climate is, however, unhealthy in December, January, and February; and during the whole year there is a great deal of rain.

Returning to the coast southward of Santa Catharina, I may mention that Cape Santa Martha, and the shores extending northward of it, are high and woody, like the greater part of the coast of Brazil; but that on the south side of the promontory there is a complete change of character: lofty ranges of mountains sinking into low treeless shores, whose outline is as tame and unvarying as that of the former is bold and picturesque.

While sailing along the level uninteresting coast just mentioned, with a fresh breeze off the land, we found it bitterly cold, though the thermometer never was below 40°. Faht: so much does our perception of heat or cold depend upon comparison. Some of our exaggerated opinions as to the coldness of the southern hemisphere may have arisen from the circumstances under which voyagers usually visit high southern latitudes, immediately after enduring the heat of the tropics, and without staying long enough to ascertain the real average temperature during a whole year.

On the 22d of July we were near the river Plata, and as the weather, after sunset, became very dark, with thunder and lightning, though with but little wind, we anchored in the

© The Complete Work of Charles Darwin Online

vicinity of Cape Sta Maria to avoid being drifted about by irregular currents. For upwards of an hour St. Elmo fires were seen at each mast-head, and at some of the yard-arms: the mast-head vane also, fixed horizontally, and framed with copper, had an illuminated border round it. Heavy rain, much thunder, and a fresh southerly wind followed; but as we were prepared for bad weather, and the sea did not rise much, we maintained our position till daylight next morning, notwithstanding an officer of the watch startling me by reporting that we must be very near the land, because he heard bullocks bellowing.*

On the 23d we entered the great estuary of this shallow though wide river, a hundred and twenty miles across at this part, yet averaging less than ten fathoms in depth; and above fifty miles wide between Monte Video and the opposite point, called Piedras, where the average depth is not more than three fathoms. Very great care is required by vessels navigating the Plata, because of its exceedingly dangerous shoals, its strong and irregular currents, and the sudden tempests to which it is subject. The shoals and currents may be guarded against by a very careful attention to the lead, and a ground-log; but the fury of a violent pampero† must be endured. The land on each side of the Plata is so low, and those extraordinary plains called pampas, hundreds of miles in extent, are so perfectly free from a single obstacle which might offer any check to the storm, that a pampero sweeps over land and water with the weight of a rushing hurricane. Captain King has already described one, by which the Beagle suffered severely, in 1829;‡ but having, to my sorrow, been more immediately concerned, I will endeavour to give a brief account of that disastrous affair, as a warning to others.

On the 30th of January 1829, the Beagle was standing in,

* These noises must have been the discordant 'braying' of the bird called by seamen 'jack-ass penguin.'

† So called because it appears to come from the vast plains called 'pampas.'

‡ Vol. i. pp. 189, 190, 191.

© The Complete Work of Charles Darwin Online

from sea, towards the harbour of Maldonado. Before mid-day the breeze was fresh from N.N.W., but after noon it became moderate, and there was a gloominess, and a close sultry feeling, which seemed to presage thunder and rain. I should mention that during three preceding nights banks of clouds had been noticed near the south-west horizon, over which there was a frequent reflection of very distant lightning.

The barometer had been falling since the 25th, slowly, but steadily, and on the 30th, at noon, it was at 29.4, and the thermometer 78°. I, and those with me, thought little about the fall of the mercury, and still less about the threatening aspect of the south-west horizon. "Heavy rain," I thought, "at night, will not signify when we are moored in Maldonado:" and there was then every prospect of our reaching that port before night.

Having been often in the river Plata, and once for eight months successively, I had acquired a familiarity with the place, and a disregard for pamperoes, which was not surprising in a young man who had witnessed many, but certainly, as it happened, not one of so serious a nature as to cause any particular impression on his mind. I had not then learned never to despise an enemy.

At about three o'clock the wind was light, and veering about from north-west to north-east. There was a heavy bank of clouds in the south-west, and occasionally lightning was visible even in daylight. Myriads of insects, such as butterflies, dragon-flies, and moths, came off from the land; driven, as it appeared, by gusts of heated wind. At four the breeze freshened up from N.N.W., and obliged us to take in all light sails. Maldonado Tower then bore west, and Lobos Island (centre) S.W.b.S. The weather became more unsettled and threatening, though still we had no expectation of any material change before night: but soon after five it became so dark towards the south-west, and the lightning increased so much, that we shortened sail to the reefed topsails and foresail; still hoping to reach our destination before the pampero began. Shortly before six the upper clouds in the south-west quarter

© The Complete Work of Charles Darwin Online

assumed a singularly hard, and rolled or tufted appearance, like great bales of black cotton, and altered their forms so rapidly, that I ordered sail to be shortened, and the topsails to be furled, leaving set only a small new foresail. The water was smooth, and, not being deep, there was none of that agitated swell usually noticed before a storm in the great ocean.

Gusts of hot wind came off the nearest land, at intervals of about a minute. The fore-topsail was just furled, and the men down from aloft, the main-topsail in the gaskets, but the men still on the yard, when a furious blast from the north-west struck the ship. The helm was put up, and she paid off fast; yet the wind changed still more quickly, and blew so heavily from south-west, that the foresail split to ribands, and the ship was thrown almost on her beam-ends, and no longer answered her helm. The main-topsail was instantly blown loose out of the men's hands, whose lives were in imminent danger; the fore-topsail blew adrift out of the gaskets; the mainsail blew away out of the gear; the lee hammock-netting was under water; and the vessel apparently capsizing, when topmasts and jib-boom went, close to the caps, and she righted considerably. Both anchors were cut away (for the land was under our lee), and a cable veered upon each, which brought her head to wind, and upright. The heaviest rush of wind had then passed, but it was still blowing a hard gale, and the Beagle was pitching her forecastle into the short high waves which had risen. As the depth of water was small, and the ground tenacious clay, both anchors held firmly, and our utmost exertions were immediately directed towards clearing the wreck, and saving the remains of our broken spars and tattered sails. Had we suffered in no other way, I should have felt joy at having escaped so well, instead of the deep regret occasioned by the loss of two seamen, whose lives, it seemed, might have been spared to this day had I anchored and struck topmasts, instead of keeping under sail in hopes of entering Maldonado before the pampero began.

When the main-topsail blew away from the men, who strug-

© The Complete Work of Charles Darwin Online

gled hard to keep it fast, they could scarcely hold on, or get off the yard, and one young man fell from the lee yard-arm into the sea. Poor fellow, he swam well, but in vain: the ship was unmanageable, almost overset, the weather quarter boat stove, and the lee one under water: a grating was thrown to him, and the life-buoy let go, but he was seen no more. Another man was supposed to have been carried overboard with the main-topmast, as he was last seen on the cap.

The starboard quarter boat was stove by the force of the wind; and the other was washed away: and so loud was the sound of the tempest, that I did not hear the masts break, though standing, or rather holding, by the mizen rigging. Never before or since that time have I witnessed such strength, or, I may say, weight of wind: thunder, lightning, hail, and rain, came with it, but they were hardly noticed in the presence of so formidable an accompaniment.

After seven the clouds had almost all passed away; the wind settled into a steady south-west gale, with a clear sky; the barometer rose to 29.8, and the thermometer fell to 46°. Lobos Island was set S.E., bearing distant two miles.

In this pampero the masts of a vessel, at anchor off Monte Video, were carried away; and the upper cabin bulkhead of a Brazilian corvette was blown in while lying at anchor, head to wind, with her masts struck. But Maldonado seemed to feel its utmost violence; and there it certainly commenced like a whirlwind. A small boat, belonging to a poor man who carried fruit and vegetables to ships in the bay, was hauled ashore, just above high-water mark, and fastened, by a strong rope, to a large stone. After the storm it was found far from the beach, shattered to pieces, but still fast to the stone, which it had dragged along. Not many days after our disaster, while lying in Maldonado bay, repairing damages, another pampero assailed the Beagle; but though it did her no injury, it blew the boat, stove by its predecessor, away from the place on shore where she was being repaired, and left no trace of her behind.

© The Complete Work of Charles Darwin Online

Singular fluctuations occur in the river Plata before and after these pamperoes.* For some days previously the river rises, and it is always higher than usual when the south-west wind begins: but, after a few hours, the water falls rapidly, and vessels are left aground: indeed instances have been known of the upper parts of the river, near Buenos Ayres, being so much emptied by strong south-westerly, or westerly winds, that men have rode several miles into its bed, to places where ships usually anchor. I have myself known the water fall, in the outer road, off Buenos Ayres, from six to two fathoms, in less than twelve hours, in a place where the usual depth was four fathoms. Such a change as this would not be thought remarkable where tides usually rise several fathoms; but in the river Plata, where there is very little, if any, tide, where the width of the channel is so great in proportion to its depth, and the confining boundaries are so low, and in many places easily overflowed, a variation of four fathoms cannot take place without causing great difficulties and destruction. In this particular instance,† a heavy gale from the eastward dammed up the river for some days; and then changing, by the south, to the westward, emptied it again proportionably. Small craft were left literally scattered about the low country bordering on the river near Buenos Ayres, and many vessels never floated again. By that gale, which blew directly up the river, and raised a heavy sea, every vessel was driven ashore from the inner road of Buenos Ayres, except a schooner. Fourteen English merchant vessels lay high and dry upon the shore next day, most of them totally lost. The Owen Glendower, bearing the broad pendant of Sir Thomas Hardy, the Icarus brig, and two or three merchant vessels, anchored in the outer road, weathered it out with topmasts struck; but all drove considerably, except the frigate, and she brought both anchors ahead, backed by

* Although generally considered by strangers to refer solely to a squall, or storm, the term pampero is applied by the natives of the country to every south-westerly wind, whether moderate or a hurricane.

† In the year 1820.

© The Complete Work of Charles Darwin Online

stream anchors with half a cable on each, and riding with a whole cable on each bower, in four fathoms water, over very soft tenacious ground. Part of her forecastle netting was washed away by the sea, though she was an excellent roadster, and at that time drawing a foot less water than usual. She also lost a boat in a manner so likely to be of future occurrence, that I will yet digress, in hopes of being useful, by relating the incident.

Her barge, ably managed by an experienced seaman,* had tried to beat off from the town to the ship, during the commencement of the gale, but could get no farther than the leewardmost merchantman in the outer road. Astern of that vessel she was made fast by a strong hawser, and there rode out the gale admirably until the current began to set out of the river: when the boat was carried against the vessel, and knocked to pieces before any thing could be done to save her, as the sea was running high, and the wind still blowing a gale. The Druid frigate, when lying there,† would have lost a boat in the same way, had it not been one of those excellent diagonal boats, built by Mr. Johns; for it was taken, by the strong weather current, under the ship's bottom, and kept striking there long enough to have broken any ordinary boat into a thousand pieces; but nevertheless she appeared again with only her gunwales injured, the bottom being still perfectly sound.

The Plata has been called by the Spaniards 'El Infierno de los marineros;' sufficient stress has not however been laid on the redeeming qualities which it possesses in having anchoring ground every where, and in soundings, whose nature tells whether you are approaching danger; as on and near the banks the bottom is hard; while in the deeper water it is very soft.

I have remarked that before a continuance of southerly winds the water rises considerably in this river; and I may

* The first who took a steam-vessel to the West-Indies.

† In 1832.

© The Complete Work of Charles Darwin Online

add, that the reverse takes place under opposite circumstances. Some persons attribute this change of level to the horizontal action of wind; but I am inclined to think it occasioned chiefly by vertical pressure of the atmosphere, increased, doubtless, during strong winds by their driving force.

Before a pampero, the barometer continues to fall during several days, and invariably the water then rises. The gale commences, the barometer ceases falling and begins to rise, and very soon afterwards the level of the river is found to be sinking. For many following days the glass remains high, but the water continues to fall, and, generally speaking, the river is low while the mercury is steady and above the average height, which I should consider to be 29·9 inches. In the Plata I never saw the barometer higher than 30·3, nor lower than 29·4.* I will not delay here to speak of corresponding elevations or depressions of the ocean at other parts of the South American coast, and attempt to trace out the effects of gales in high latitudes, the space through which those winds extend, and whether they reach or affect places in a low or even middle latitude; but leaving such inquiries for another place, take a few more glances at the vicinity of the Plata, and then continue the narrative.

Having already noticed the width and average shallowness of this immense river, and the lowness of its adjacent shores, I need only add, that on the northern side there is a sprinkling of hills, of a granitic structure, scattered amidst extensive plains, while on the south, or right bank, there is neither a hill, a rock, or even a stone.† So low is the land between Point Piedras and Cape San Antonio, that around the great bay, called Sanborombon, it is extremely difficult to say where the water ends, or the coast line begins. Each difference, of

* In estimating weather, or force of wind, by the height of the mercurial column, due regard should be had to the goodness of the instrument, as some barometers, used in ships, differ from others even tenths of an inch.

† Which has not been carried there by man, or by running water.

© The Complete Work of Charles Darwin Online

even a foot, in the height of the water, makes a change of cables' lengths, if not of miles, in the position of the limiting line between water and land. In consequence it is very dangerous for ships to approach that shore; and, although the bottom is in many places soft, often extremely deep mud, there are other spaces in which hard lumps of tosca* are found, almost as injurious to a ship's bottom as actual rock. I am not aware that there is any granite on the south side of the river Plata, near the shore; and although the name 'Piedras' would incline one to suppose there are rocks or stones near it, I could only find tosca. But towards the northern shore rocks are found, and the dangerous shoal called 'Banco Yngles,' is said to have a granitic foundation. The ridge, of which the English Bank is the north-west extremity, extends eastward, inclining to the south, considerably beyond a line drawn from Cape Santa Maria to Cape San Antonio, and less than ten fathoms water may be found upon it out of sight of land. Northward of the ridge the depth of water varies from ten to thirty fathoms over a very soft bottom of bluish mud; and to the southward of it there are from twelve to three fathoms (diminishing as you approach San Antonio) over a softish bottom of brown or yellow muddy sand.† When it is considered that three very large rivers, besides a host of smaller streams, enter the ocean by the estuary whose more remarkable features we are noticing, that two of those rivers are flooded periodically by tropical rains,‡ and that very heavy gales assist in emptying or filling the shallow wide gulf, in which floods of fresh water contend against the volume of a powerful ocean; not only will frequent

* Tosca is a kind of hardened earth, rather than soft stone, about the consistence of slightly baked clay: it is of a dark brown colour, and varies in hardness from that which is almost stony, to the texture of a sound old cheese.

† Near Cape San Antonio and Point Tuyu there is very soft mud.

‡ The Paraguay rises so far northward, that (excepting a portage of three miles) a canoe may go from Monte Video to the mouth of the Amazon.

© The Complete Work of Charles Darwin Online

variations in depth be expected, as a natural consequence, but also strong and varying currents. Little or no tide has been hitherto noticed with any degree of accuracy in the estuary of the Plata; but this anomaly may be more apparent than real: for where the depth of water is so fluctuating, and the currents are so variable, it is difficult to distinguish the precise effects of tides, except by a series of observations far longer than has yet been made.

To say much of Maldonado village, the town of Monte Video, or the city of Buenos Ayres, would be to repeat an 'oft-told tale.' The views attached to this volume will give a tolerably clear idea of a few striking peculiarities which are immediately noticed by the eye of a stranger; and of the inhabitants themselves I will only venture to say, upon my slight acquaintance with them, that although prejudiced by their erroneous ideas of freedom, and deficient in high principles, they are courteous and agreeable as mere acquaintances, kind to strangers, and extremely hospitable.

It is well known that there are very few trees* on either bank of the Plata near its mouth, or on those immense plains, called pampas, excepting here and there an 'ombu,'† or some which have been planted near houses; or a few copses of small trees (mostly peach) planted for fuel: but I have not heard any sufficient reason given for this scarcity of wood, in a country covered with a great depth of alluvial soil, and adjoining districts in which trees are abundant. The only second causes for such a peculiarity, which I can imagine, are the following: the nature of the soil, which may be unsuited to most trees, although very productive of grass and gigantic thistles: the furious storms which sweep along the level expanse, and would demolish tender, unprotected young trees: the general want of water, which in some years is so great as to become a severe drought: and the numerous herds of wild cattle which range

* The exceptions are so few, that one might almost say there are no trees which have not been planted.

† A kind of elder.

© The Complete Work of Charles Darwin Online

over the plains, and eat up every leaf which retains any moisture during the dry heats of summer. Before there were herds of cattle, guanacoes ranged over the country, in great numbers, as they now do to the southward of the river Negro, where I have seen them grazing in large companies, like flocks of sheep. During the droughts above-mentioned vast numbers of cattle die for want of water, and perhaps this may be the principal reason why so few trees grow there naturally; but it cannot be the only one, because they grow where planted, and partially sheltered, though not watered.

Most people are aware of the scale upon which the cattle farms of the 'Banda Oriental' and 'Republica Argentina' were carried on: but the civil wars which have succeeded the steady government of Spain have broken up and ruined many of the largest establishments, where from one hundred to two hundred thousand head of cattle were owned by one man—where the annual increase was about thirty per cent—and where the animals were, generally speaking, slaughtered for their hides alone. What must be the natural fertility of a country, which, without the slightest assistance from man, can nourish such enormous multitudes of cattle, besides immense droves of horses and flocks of sheep, and yet, except near its few towns, appear almost destitute of inhabitants.

To return to our little vessel—entering the Plata in 1832. Unfavourable winds, and currents setting out of the river, delayed our progress, and obliged us to anchor frequently. We arrived at Monte Video on the 26th, and lost no time in making observations for our chronometers, and preparing for surveying the coasts southward of Cape San Antonio: but as I found that it would be advisable to visit Buenos Ayres, in order to communicate with the Government, and obtain information, we sailed from Monte Video on the 31st, and two days afterwards anchored off Buenos Ayres. There, however, we did not remain an hour; for the misconduct of a Buenos Ayrean officer on board a vessel under their colours, and a vexatious regulation with respect to quarantine, decided my

© The Complete Work of Charles Darwin Online

returning forthwith to Monte Video; and commissioning a capable person to procure for me copies of some original charts, which I thought would be exceedingly useful, and which could only be obtained from the remains of hydrographical information, collected by Spain, but kept in the archives of Buenos Ayres. The Beagle anchored again off Monte Video, on the 3d of August, and as soon as the circumstances which occasioned her return were made known to Captain G. W. Hamilton, commanding the Druid frigate, that ship sailed for Buenos Ayres.

Scarcely had the Druid disappeared beneath the horizon, when the chief of the Monte Video police and the captain of the port came on board the Beagle to request assistance in preserving order in the town, and in preventing the aggressions of some mutinous negro soldiers. I was also requested by the Consul-general to afford the British residents any protection in my power; and understanding that their lives, as well as property, were endangered by the turbulent mutineers, who were more than a match for the few well-disposed soldiers left in the town, I landed with fifty well-armed men, and remained on shore, garrisoning the principal fort, and thus holding the mutineers in check, until more troops were brought in from the neighbouring country, by whom they were surrounded and reduced to subordination. The Beagle's crew were not on shore more than twenty-four hours, and were not called upon to act in any way; but I was told by the principal persons whose lives and property were threatened, that the presence of those seamen certainly prevented bloodshed.

Some days after this little interruption to our usual avocations, we sailed across the river to Point Piedras, anchored there for some hours to determine its position, then went to Cape San Antonio, and from that point (rather than cape) began our survey of the outer coast. To relate many details of so slow and monotonous an occupation as examining any shore, of which the more interesting features have long been known, could answer no good purpose, and would be very tiresome to

© The Complete Work of Charles Darwin Online

a general reader; therefore I shall hasten from one place to another, dwelling only, in my way, upon the few incidents, or reflections, which may have interest enough to warrant their being noticed in this abridged narrative, or are absolutely necessary for carrying on the thread of the story.

Aug. 22. From Cape San Antonio (which, though so called, is only a low point) to rather more than half-way towards Cape Corrientes, the sea-coast is sandy and low. Behind the beach are sand-hills, and farther inshore are thickets affording shelter to numbers of jaguars. In sailing along, even with both leads going, we were, for a few minutes, in imminent danger of grounding upon a bank, or ledge, which extends six miles E.S.E. from Point Medanos. The water shoaled so suddenly, and so irregularly, that I could not tell which way to steer; and as we had been running directly before the wind, it was impossible to retreat by the safest track (that which we had made in approaching): however, by persevering in pushing eastward, away from the land, steering one way or another as the water deepened, we at last got clear. We then stood out to gain an offing, rounded the bank, and hauled close inshore again nearly opposite to a large salt lagoon, called Mar-chiquito, which approaches the sea so closely as to have occasioned an idea that, by cutting through the narrow strip of land which separates them, a fine port might be formed.

Some persons assert that there is always a communication between the lagoon and the sea; that cattle cannot pass along the isthmus on account of that opening; and that a boat might swim from one to the other. If this is the case, we were much deceived on board the Beagle; for when she passed so near the spot that the lagoon was overlooked by the officers at her mast-

© The Complete Work of Charles Darwin Online

heads, nothing like an opening could be detected, though the beach was scrutinized with good glasses, as well from the deck as by those who looked down upon it from aloft as we sailed by. I suspect that there has been some confusion of ideas respecting the little river San Pablo, and a supposed entrance to the lagoon: but, be this as it may, very great difficulty would be found in attempting to form a large and permanent communication at a spot so exposed to heavy south-east gales.

At Port Valdez (in latitude 42° S.) the entrance is sometimes completely blocked up by shingle and sand, during and after a strong south-east gale; and I think it probable that such an effect would be caused here, at times, whether there were a natural or an artificial opening; and as there is no great rise and fall of tide, I much doubt whether the opening would be again cleared, as at Port Valdez, by the mere ebb and flow of water.

In the vicinity of Mar-chiquito, the country (campo) is very fertile, and well watered. Sheltered to the south by a range of down-like hills, whence numerous small brooks originate, it gives abundant pasturage to many thousands of cattle, and is considered by the Buenos Ayreans to be the finest district of their territory. This range of hills extends in a west north-west direction for more than fifty leagues, and varies in name at different places. That part next to Cape Corrientes is called Sierra Vuūlcan;* twenty leagues inland is the ridge named Tandil, and at the western extreme is a height called Cayru. Between Tandil and Cayru there are many hills known by particular names, but they are all part of the range above-mentioned; and it is a remarkable fact, that not only this range, that nearer to Buenos Ayres called Cerrillada, and that of which the Sierra Ventana forms a part, extend nearly in an east-south-east and west-north-west direction; but that most of the ranges of high land, most of the rivers, and the greater number of inlets, between the Plata and Cape Horn, have a similar direction, not varying from it above one point, or at most two points of the compass. After we became aware

* An Indian word, which means 'opening,' or 'having openings.'

© The Complete Work of Charles Darwin Online

of this peculiarity, it was far easier to avoid shoals, as they all lay in a similar direction.

On a round-topped hill, near Mar-chiquito, we saw an immense herd of cattle, collected together in one dark-coloured mass, which covered many acres of ground. A few men, on horseback, were watching them, who, seeing us anchor, drove the whole multitude away at a gallop, and in a few minutes not one was left behind. Probably they suspected us of marauding inclinations.

Cape Corrientes is a bold, cliffy promontory; off which, notwithstanding the name, I could not distinguish any remarkable current. It is said to be hazardous for a boat to go alongshore, near the high cliffs of that cape, because there are rocks under water which sometimes cause sudden and extremely dangerous 'blind breakers.' More than one boat's crew has been lost there, in pursuit of seals, which are numerous among the rocks and caves at the foot of those cliffs. Hence to Bahia Blanco is a long and dreary line of coast, without an opening fit to receive the smallest sailing vessel, without a remarkable feature, and without a river whose mouth is not fordable. Even the plan of it, on paper, has such a regular figure, that an eye accustomed to charts may doubt its accuracy; so rarely does the outline of an exposed sea-coast extend so far without a break. A heavy swell always sets upon it; there is no safe anchorage near the shore; and, as if to complete its uninviting qualities, in the interior, but verging on this shore, is a desert tract, avoided even by the Indians, and called, in their language, Huecuvu-mapu (country of the Devil). In exploring this exposed coast, southerly winds sometimes obliged us to struggle for an offing; and we lost several anchors in consequence of letting them go upon ground which we thought was hard sand lying over clay, but which turned out to be tosca, slightly covered with sand, and full of holes. The lead indicated a sandy, though hard bottom; but we found it every where so perforated and so tough, that, drop an anchor where we might, it was sure to hook a rock-like lump of tosca, which sometimes was torn away, but at others broke the anchor.

© The Complete Work of Charles Darwin Online

Finding this to be the case, I had a stout hawser 'bent' to the 'crown' of the anchor, and after shortening in cable, tripped the anchor by the hawser, and then weighed it, uninjured, without much difficulty.

Along this extent of sea-coast, half way between the currents in the vicinity of the Plata, and those occasioned by strong tides near Blanco Bay and the river Negro, we found no current. Whether there was a rise of tide it was not easy to ascertain by the lead-line, when at anchor, from the bottom being so uneven; and to land was impossible, on account of a furious surf.

Several kinds of fish were caught at our temporary anchorages, and noticed carefully by Mr. Darwin. Anchorage is not a word I should use in this case (where the anchor was only let go for a short time while the ship's position could be fixed with accuracy, and our triangulation carried on in a satisfactory manner), as it might deceive a stranger to the coast: stopping-place would be better.

While examining the positions nearest to Blanco Bay, we had occasional alarms—such as the wind shifting and blowing strong directly towards the land; our soundings shoaling suddenly to three, or less than three fathoms; or thick weather coming on while a boat was away sounding;—but these are every-day events in a surveying vessel actively employed.

Near Blanco Bay we found the water greatly discoloured, and the soundings were not such as to tempt us onwards; however, it was necessary to proceed. We steered towards a little hill, which I fancied must be Mount Hermoso,* and soon after sun-set, on the 5th, anchored in what we afterwards found to be the roadstead near that hillock, at the head of Blanco Bay, close to the entrance of Port Belgrano, but divided from it by a bank.

As the bad apologies for charts of this place, which we possessed at our first visit, left us as much at a loss as if we had

* Mount Hermoso is but 140 feet above the sea; yet, on this low coast, it is somewhat remarkable, as being the only peaked hill close to the water; and having under it a low cliffy point, the only one thereabouts.

© The Complete Work of Charles Darwin Online

none, I set out with the boats next morning to seek for a passage into Port Belgrano.*

Our boats were soon stopped by shoal water, and I found, to my vexation, that the Beagle was anchored at the head of an inlet, between the shore and a large bank extending far towards the south-east, and that before going farther west she must retreat eastward, and look for another passage. This was an unexpected dilemma; but our prospect was improved by the appearance of a small schooner running towards us, from Port Belgrano, with a Buenos Ayrean (or Argentine) flag flying.

Very soon she came near enough for our boat to reach her, and an Englishman came on board, who offered to pilot the Beagle to a safe anchorage within the port. This was Mr. Harris, owner of the little schooner in which he sailed, (a resident at Del Carmen, on the river Negro, and trading thence along the coast), with whom we had much satisfactory intercourse during the next twelvemonth.

By his advice we weighed anchor, stood across the great north bank, in very little more water than we drew, until we got into a channel where there was water enough for any ship, and a soft muddy bottom: there we hauled up west-north-west,† by his direction, and with a fresh wind sailed rapidly into the extensive and excellent, though then little known harbour, called Port Belgrano; and at dusk anchored near the wells under Anchorstock Hill (or Point Johnson).

To give an idea of the general appearance, or almost disappearance, of the very low land around this spacious port, I will mention, that when the Beagle had crossed the north bank, and hauled up in the fair way, Mount Hermoso was nearly beneath the horizon; some bushes on the flat land southward

* Often erroneously called Bahia Blanco; a name originally given to the outer bay, in compliment to General Blanco.

† So constantly did Mr. Harris give this course, on subsequent occasions, that it became quite a joke; but it is nevertheless a strong corroboration of what I stated respecting the general direction of the inlets, and ridges, or ranges of hills.

© The Complete Work of Charles Darwin Online

of us (Zuraita Island) could be just distinguished; and ahead in the north-west quarter, no land could be made out, except the distant Ventana mountain, which we saw for the first time on that day.

In consequence of this extent of water being intersected by banks, and having so few marks, it is very difficult of access; and no place can offer less that is agreeable to the eye, especially when the tide is out, and much of the banks shows above water. A more disagreeable place to survey, or one that would occupy more time, we were not likely to find, I thought, as I looked around from the mast-head; but upon questioning Mr. Harris, I learned that a succession of similar inlets indented a half-drowned coast, extending hence almost to the Negro; and that, although the dangers were numerous, tides strong, banks muddy, and the shores every where low, the intervening ports were so safe, and so likely to be useful, that it was absolutely necessary to examine them.

Sept. 7. Messrs. Darwin, Rowlett, and Harris set out with me to visit the Buenos Ayrean settlement, called Argentina. Mr. Harris undertook to be our guide, but after two hours' sailing and pulling we found ourselves near the head of a creek, between two soft mud banks, where we could neither row nor turn the boat. We could not land because the mud was too soft to bear our weight, so there we staid till the tide flowed. About two hours after this stoppage there was water enough for us to cross a large bank, and gain the right channel, from which we had deviated, and then, with a flowing tide, we made rapid progress, until the 'Guardia' was announced to us. This was a small hut near the water side, but to reach it we had to wind along a tortuous canal, between banks of soft mud: and when we arrived at the landing-place seven hours had been passed among rushy mud banks, surrounded by which we were often prevented from seeing any solid land. The water was every where salt, the tide running strongly, and the boat often aground.

Waiting to meet us was an assemblage of grotesque figures, which I shall not easily forget—a painter would have been

© The Complete Work of Charles Darwin Online

charmed with them. A dark visaged Quixotic character, partly in uniform, mounted on a large lean horse, and attended by several wild looking, but gaily dressed gauchos,* was nearest to us. Behind him, a little on one side, were a few irregular soldiers, variously armed, and no two dressed alike, but well mounted, and desperate-looking fellows; while on the other side, a group of almost naked Indian prisoners sat devouring the remains of a half roasted horse; and as they scowled at us savagely, still holding the large bones they had been gnawing, with their rough hair and scanty substitutes for clothing blown about by the wind, I thought I had never beheld a more singular group.

The tall man in uniform was the Commandant of the settlement, or fortress, called Argentina: he and his soldiers had arrived to welcome us, supposing that we were bringing supplies from Buenos Ayres for the needy colony. The Indian prisoners had been brought to work, and assist in carrying the supplies which were expected. Finding that we were neither Buenos Ayreans, nor traders from any other place, it was supposed that we must be spies sent to reconnoitre the place previous to a hostile attack. Neither the explanations nor assertions of Mr. Harris had any weight, for as he was our countryman, they naturally concluded he was in league with us; yet, as the commandant had some idea that we might, by possibility, be what we maintained we were, he disregarded the whispers and suggestions of his people, and offered to carry us to the settlement for a night's lodging.

Leaving the boat's crew to bivouac, as usual, I accepted a horse offered to me, and took the purser up behind; Mr. Darwin and Harris being also mounted behind two gaucho soldiers, away we went across a flat plain to the settlement. Mr. Darwin was carried off before the rest of the party, to be cross-questioned by an old major, who seemed to be considered the wisest man of the detachment, and he, poor old soul,

* Countrymen, employed in keeping and killing cattle, breeding and training horses, hunting, war, &c.

© The Complete Work of Charles Darwin Online

thought we were very suspicious characters, especially Mr. Darwin, whose objects seemed most mysterious.

In consequence, we were watched, though otherwise most hospitably treated; and when I proposed to return, next morning, to the boat, trifling excuses were made about the want of horses and fear of Indians arriving, by which I saw that the commandant wished to detain us, but was unwilling to do so forcibly; telling him, therefore, I should walk back, and setting out to do so, I elicited an order for horses, maugre the fears and advice of his major, who gave him all sorts of warnings about us. However, he sent an escort with us, and a troop of gaucho soldiers were that very morning posted upon the rising grounds nearest to the Beagle, to keep a watch on our movements.

We afterwards heard, that the old major's suspicions had been very much increased by Harris's explanation of Mr. Darwin's occupation. 'Un naturalista' was a term unheard of by any person in the settlement, and being unluckily explained by Harris as meaning 'a man that knows every thing,' any further attempt to quiet anxiety was useless.

As this small settlement has seldom been visited by strangers, I will describe its primitive state. In the midst of a level country, watered by several brooks, and much of it thickly covered with a kind of trefoil, stands a mud-walled erection, dignified with the sounding appellation of 'La fortaleza protectora Argentina.' It is a polygon, 282 yards in diameter, having about twenty-four sides, and surrounded by a narrow ditch. In some places the walls are almost twenty feet high, but in others I was reminded of the brothers' quarrel at the building of ancient Rome, for there is a mere ditch, over which a man could jump. It is, however, said by the gauchos, that a ditch six feet wide will stop a mounted Indian, and that their houses require no further defence from attacks of the aborigines. How, or why it is that such excellent horsemen do not teach their horses to leap, I cannot understand.

Within, and outside the fort, were huts (ranchos) and a few

© The Complete Work of Charles Darwin Online

small houses:—more were not required for the inhabitants, who, including the garrison, only amounted to four hundred souls. Some half-dozen brass guns were in a serviceable condition; and two or three other pieces occupied old carriages, but did not seem to be trustworthy.

The fort was commenced in April 1828, by a French engineer, named Parchappe. The first commandant was Estomba: his successor, Morel, was killed, with ninety followers, by a party of Indians under Chenil, in 1829. Valle and Rojas succeeded, and the latter was followed by Rodriguez. Placed in the first instance as an advanced post, at which to watch and check the Indians, rather than as a colony likely to increase rapidly, Argentina has scarcely made any progress since its establishment, though it is the beginning of what may hereafter be a considerable place. Situated favourably for communicating with Concepcion—by way of the pass through the Cordillera, near Tucapel—it is also the only port, between 25° S. and Cape Horn, capable of receiving in security any number of the largest ships.

There is pasture for cattle near the streams which descend from the 'Sierra Ventana:' large salinas (spaces covered with salt) lie within an easy distance of the settlement: of brushwood for fuel there is plenty, though there are no large trees: and report says that there are valuable minerals, including coal and iron,* in the Ventana† mountain.

The most serious objection to the locality, as an agricultural, or even as a mere grazing district, is the want of rain. Two or three years sometimes pass without more than a slight shower; and during summer the heat is great. In winter, there are sharp frosts, sometimes snow; but neither ice nor snow ever lasts through the day.

Good fresh water may be generally obtained, independent of the few running streams, by digging wells between four and

* I believe there is no good foundation for this report. Mr. Darwin's opinion is against the supposition.

† The name 'Ventana' was given because of an opening, at the south side, resembling a window.

© The Complete Work of Charles Darwin Online

ten feet deep: and in this way we found no difficulty in obtaining an ample supply.

Three months before our visit to Argentina, a number of Indians had been surprised and taken prisoners by Rodriguez; and among them was the famous old cacique, Toriano, whose mere name was a terror to the frontier settlers. The commandant attacked their 'tolderia' (encampment) just before sunrise—when the young men were absent on an expedition—and made prisoners of the old men, women, and children. Toriano was shot in cold blood; with another cacique, and several Indians of inferior note: and his head was afterwards cut off, and preserved for some time at the fort, in order to convince his adherents of his death. Toriano was a noble Araucanian, upwards of seventy years old when surprised asleep and taken prisoner by his merciless enemies. So high was his acknowledged character as a warrior, that his followers supposed him invincible; and until convinced by the melancholy spectacle seen by their spies, they would not believe him gone.

Perhaps it is not generally known, that many of the most desperate incursions upon the Buenos Ayrean colonists have been made by flying troops, or hordes of Indians, whose head-quarters are in the Cordillera of the Andes, or even on the west coast, between Concepcion and Valdivia. Mounted upon excellent horses, and acquainted with every mile of the country, they think lightly of a predatory or hostile excursion against a place many hundred miles distant.

We returned to the Beagle without another delay among the mud-banks, and found the rising grounds (heights they could not be called), nearest the ship, occupied by the troop of gaucho soldiers. As they did not interfere with us, our surveying operations were begun, and carried on as usual. Mr. Darwin, and those who could be spared from duties afloat, roamed about the country; and a brisk trade was opened with the soldiers for ostriches and their eggs, for deer, cavies, and armadilloes.

My friend's attention was soon attracted to some low cliffs near Point Alta, where he found some of those huge fossil

© The Complete Work of Charles Darwin Online

bones, described in his work; and notwithstanding our smiles at the cargoes of apparent rubbish which he frequently brought on board, he and his servant used their pick-axes in earnest, and brought away what have since proved to be most interesting and valuable remains of extinct animals.

The soldiers appointed to watch our movements soon relaxed so far as to spend nearly all their time in hunting animals for us. Besides those already mentioned, they one day brought a fine living puma, in hopes I should offer a good price, and embark it alive; but having no wish for so troublesome a companion in our crowded little vessel, I only bargained for its skin. The soldiers made a hearty meal of the flesh, and asserted that it was good, though inferior to that of a horse, which I had seen them eating a day or two previously.

Four kinds of armadilloes were described to us by these men, of which we saw but two: the quiriquincha, with nine bands; the mataca-bola, which rolls up into a ball; the peludo, which is large and hairy; and the molito, of which I heard only the name. Mr. Rowlett saw a black fox, and he was told that there are wolves in the neighbourhood. Two small burrowing animals are also found: the zorillo, or skunk; and the tucu-tucu. While speaking of animals, I should say that the commandant (Rodriguez) told me, that he had once seen, in Paraguay, a 'gran bestia,' not many months old, but which then stood about four feet high. It was very fierce, and secured by a chain. Its shape resembled that of a hog, but it had talons on its feet instead of hoofs; the snout was like a hog's, but much longer. When half-grown, he was told that it would be capable of seizing and carrying away a horse or a bullock. I concluded that he must have seen a tapir or anta; yet as he persisted in asserting that the animal he saw was a beast of prey,* and that it was extremely rare,* I here repeat what he said. (See extract from Falkner.—Appendix—No. 11.)

Abundance—I may well say shoals of fish were caught by our men, whenever we hauled the nets at a proper time (the beginning of the flood-tide); and as they were chiefly un-

* Neither of which remarks apply to the Anta.

© The Complete Work of Charles Darwin Online

known to naturalists, Mr. Earle made careful drawings of them, and Mr. Darwin preserved many in spirits. We procured plenty of good fresh water from wells near the beach, and small wood for fuel in their immediate neighbourhood. The climate is delightful, and healthy to the utmost degree, notwithstanding such extensive flats, half-covered with water, and so many large mud-banks. Perhaps the tides, which rise from eight to twelve feet, and run two or three knots an hour, tend to purify the air; indeed, as the whole inlet is of salt water, there may be no cause for such effects as would be expected in similar situations near fresh water.

In our rambles over the country, near Port Belgrano, we every where found small pieces of pumice-stone; and till Mr. Darwin examined the Ventana, supposed they had been thrown thence: he has, however, ascertained that it is not volcanic; and, I believe, concludes that these fragments came from the Cordillera of the Andes.—(See Vol. III. by Mr. Darwin.)

Falkner, in whose accounts of what he himself saw I have full faith, has a curious passage illustrative of this supposition; and it is not impossible—nor even, I think, improbable—that some of the pumice we saw fell at the time mentioned in the following extract:—" Being in the Vuūlcan, below Cape St. Anthony, I was witness to a vast cloud of ashes being carried by the winds, and darkening the whole sky. It spread over great part of the jurisdiction of Buenos Ayres, passed the river of Plata, and scattered its contents on both sides of the river, insomuch that the grass was covered with ashes. This was caused by the eruption of a volcano near Mendoza, the winds carrying the light ashes to the incredible distance of three hundred leagues or more."—Falkner, p. 51.

As an indisputable, and very recent instance of the distance to which volcanic substances are sometimes carried, I might mention the fact of H.M.S. Conway having passed through quantities of pumice-stone and ashes, in latitude 7° north, and longitude 105° west, being more than seven hundred miles from the nearest land, and eleven hundred from the volcano near Realejo, whence it is supposed that they proceeded; but as it is

© The Complete Work of Charles Darwin Online

possible that those substances might have been thrown out of a volcano in the Galapagos Islands, and drifted on the surface of the sea by currents, which near there run from twenty to eighty miles in twenty-four hours, towards the north-west, one cannot, with certainty, rely upon that fact as evidence of a distance to which pumice has been carried by wind.

Captain Eden informed me, that the Conway was surrounded by ashes and pumice-stone for a day and a half (on the 5th and 6th of May 1835), and that they were supposed to have been ejected from a volcano near Realejo, at the time of the great earthquake; and an eruption which darkened the air during three days.

The aborigines of these regions attach considerable importance to the Ventana,* chiefly on account of its use as a landmark; for, rising abruptly to the height of 3,340 feet in a flat country, where there is not another hill of consequence, it is of no small use to them in their wanderings. I was told by Mr. Darwin, that he found it to be chiefly of quartz formation; but I need not risk causing a mistake, by repeating here the information which he gave me, when it is given fully in his own words in the accompanying volume.

After a few days' examination of Port Belgrano, and making inquiries of Harris, as well as those persons at Argentina who knew something of the neighbouring waters and shores, I was convinced that the Beagle alone could not explore them, so far as to make her survey of any real use, unless she were to sacrifice a great deal more time than would be admissible, considering the other objects of her expedition. What then was to be done? Open boats could not explore the seaward limits of those numerous shoals which lie between Blanco Bay and the river Negro, because there are dangerous 'races,'† and often heavy seas. The Beagle herself, no doubt, could do so, and her boats might explore the inlets; but, the time that such a proceeding would occupy was

* The Puel Indians called the Ventana Casu-hati (high hill); and the Molu-che, Vuta-calel (great bulk.)—Falkner, p. 74.

† Tide-races, or ripples.

© The Complete Work of Charles Darwin Online

alarming to contemplate. I might run along the outer line of danger in the Beagle, and connect it with the soundings in the offing; but how could an English ship surveying a frequented coast overlook six large ports,* only because their examination required time, and was dangerous? At last, after much anxious deliberation, I decided to hire two small schooners —or rather decked boats, schooner-rigged—from Mr. Harris, and employ them in assisting the Beagle and her boats. Mr. Harris was to be in the larger, as pilot to Lieutenant Wickham—and his friend Mr. Roberts, also settled at Del Carmen, on the river Negro, was to be Mr. Stokes's pilot in the smaller vessel. These small craft, of fifteen and nine tons respectively, guided by their owners, who had for years frequented this complication of banks, harbours, and tides, seemed to me capable of fulfilling the desired object—under command of such steady and able heads as the officers mentioned—with this great advantage; that, while the Beagle might be procuring supplies at Monte Video, going with the Fuegians on her first trip to the southward, and visiting the Falkland islands, the survey of all those intricacies between Blanco Bay and San Blas might be carried on steadily during the finest time of year. One serious difficulty, that of my not being authorized to hire or purchase assistance on account of the Government, I did not then dwell upon, for I was anxious and eager, and, it has proved, too sanguine. I made an agreement with Mr. Harris,† on my own individual responsibility, for such payment as seemed to be fair compensation for his stipulated services, and I did hope that if the results of these arrangements should turn out well, I should stand excused for having presumed to act so freely, and should be reimbursed for the sum laid out, which I could so ill spare. However, I foresaw and was willing to run the risk, and now console myself for this, and other subsequent mortifications, by the reflection that the service entrusted to me did not suffer.

* Blanco Bay and Port Belgrano, False Bay, Green Bay, Brightman Inlet, Union Bay, and San Blas Bay.

† See Appendix.

© The Complete Work of Charles Darwin Online

The formal agreement with Mr. Harris being duly signed, I despatched him forthwith to the river Negro, in search of his vessels, and sent the purser with him to ascertain the state of things at Del Carmen, especially with a view to future supplies.

They went in a small coasting vessel, belonging to another Englishman (H. Elsegood), settled at Del Carmen; for the schooner, from which Mr. Harris came to us near to Mount Hermoso, did not delay, but continued her course towards the river Negro.

Our boats were constantly employed while these arrangements were pending, and directly they were finished, the Beagle got under sail to examine the entrance and outer parts of the port. For several days she was thus engaged, anchoring always at night. In a week the schooners arrived, bringing our purser and their owners. The Paz, of about fifteen tons burthen, was as ugly and ill-built a craft as I ever saw, covered with dirt, and soaked with rancid oil. The Liebre, of about nine tons burthen, was a frigate's barge,* raised and decked—oily like the other; but as both had done their owners good service in procuring seal and sea-elephant oil, I saw no reason to doubt our being able to make them answer our purpose. Yet the prospect for those who had so handsomely volunteered to go in any thing, with or without a deck, could not be otherwise than extremely unpleasant; for they did not then foresee how soon a thorough cleansing and complete outfit would be given to both vessels, and how different they would afterwards appear.

Lieutenant Wickham, with the sailmaker, armourer, cooper, and a small party, were immediately established under tents, on the banks of a small creek (Arroyo Pareja). The little schooners were hauled ashore for examination and a thorough refit; and then, having left them the stores and other necessaries which they would require, I went with the Beagle towards Blanco Bay; completed the examination of a narrow though deep channel, by which any ship may

* She had been the barge of the Brazilian frigate Piranga.

© The Complete Work of Charles Darwin Online

enter Port Belgrano, passed round the great north bank, and again anchored under Mount Hermoso. While some officers and men were on shore there, building a sea-mark on the mount, and otherwise employed for the survey, a gale of wind came on from S.E., which soon sent so heavy a sea into the road-stead near the mount, that the Beagle was obliged to strike topmasts and veer a long scope of cable upon two anchors, besides having another under foot. Unluckily, our party on shore had only one day's provisions, so while the gale lasted their situation was sufficiently disagreeable; the keen air and hard exercise sharpening their appetites, while they had nothing to eat after the first day; and having no guns, they had no prospect of procuring anything. Mr. Darwin was also on shore, having been searching for fossils, and he found this trial of hunger quite long enough to satisfy even his love of adventure. Directly it was possible to put a boat on the water, one was sent, with provisions secured in a cask which was thrown overboard at the back of the surf, and soon drifted ashore to the famishing party. This gale lasted several days, and proved to us not only how heavy a sea is thrown into this bight (rincon, Sp.), by a south-east gale; but also, that the holding-ground is sufficiently good to enable a ship to withstand its effects.

One of our party on shore (who is not likely to forget building a mark on Mount Hermoso) discovered many curious fossils in some low cliffs under the mount; and judging from what Mr. Darwin then found, future collectors may reap a rich harvest there, as well as at Point Alta.

We next returned to the Wells, and while some assisted the outfit of Lieutenant Wickham's little vessels, others explored the upper parts of the port, quite to its end, and Mr. Darwin took advantage of the opportunity to make some of those interesting excursions which he describes in his volume. At this time there were no soldiers to watch us, neither was there any longer a suspicion of our character; for it appeared that an express had been sent off to Buenos Ayres, at our first arrival, giving an exaggerated and rather ludicrous account of

© The Complete Work of Charles Darwin Online

our officers, instruments and guns—to which an answer had been immediately returned, desiring the commandant to afford us every facility in his power, and checking the old major rather sharply for his officious and unnecessary caution. Had we not been hastily treated in the roads of Buenos Ayres, when I went there to communicate with the Government, and obtain information, I should doubtless have carried with me orders, or a letter, to this commandant, which would have prevented a moment's suspicion: but, as it happened, no real delay was occasioned, and no person was much disturbed except the major, who fancied that our brass guns were disguised field-pieces, our instruments lately invented engines of extraordinary power, our numerous boats intended expressly for disembarking troops; and an assertion of mine, that any number of line-of-battle ships might enter the port, a sure indication that the Beagle was sent to find a passage for large ships: which would soon appear, and take possession of the country. Such was the substance of his communication to the Government at Buenos Ayres, and as he acted as secretary—(Rodriguez being a man of action rather than words)—he had free scope for his disturbed imagination. I shall not easily forget his countenance, when I first told him—thinking he would be glad to hear it—that there was a deep channel leading from Blanco Bay to the Guardia near Argentina, and that a line-of-battle ship could approach within gunshot of the place where I first met the commandant. He certainly thought himself almost taken prisoner; and I really believe that if he had been commanding officer, we should have been sent in chains to Buenos Ayres, or perhaps still worse treated. Fortunately, Rodriguez the commandant, being a brave man, and a gentleman, contemplated no such measures.

CHAPTER VI.

Beagle sails with Paz and Liebre—Part company—Beagle visits Buenos Ayres—Nautical remarks on the Plata—Sail from Monte Video for San Blas—Lieut. Wickham and tenders—Butterflies—Sail for Tierra del Fuego—White-water—Icebergs—Rocks—Cape San Sebastian—Oens-men—Cape San Diego—Good Success Bay—Natives—Guanacoes—Cape Horn—St. Martin Cove—Gales—Heavy Seas—Nassau Bay—Goree Road—Prepare to land Matthews and the Fuegians.

18th October. No person who had only seen the Paz and Liebre in their former wretched condition, would easily have recognised them after being refitted, and having indeed almost a new equipment. Spars altered, and improved rigging, well-cut sails, fresh paint,* and thorough cleanliness, had transformed the dirty sealing craft into smart little cock-boats: and as they sailed out of Port Belgrano with the Beagle, their appearance and behaviour were by no means discouraging.

At dusk, Lieutenant Wickham and his small party of venturous associates separated from us, and steered into False Bay.† The Beagle anchored for the night, and next day pursued her route towards Monte Video, where she arrived on the 26th.

Desirous of communicating with the Government at Buenos Ayres, and measuring the difference of meridians between that city and Monte Video, we weighed anchor on the 31st, proceeded up the river, and remained in the outer roadstead, off Buenos Ayres, until the 10th of November. We then employed three days in verifying the positions of some banks,‡ as laid down in Heywood's and other charts, and returned to Monte Video on the 14th.

* Or rather red-ochre, coal-tar, and white-wash.

† See orders to Lieut. Wickham, in the Appendix.

‡ Ortiz, Chico, and Ensenada.

© The Complete Work of Charles Darwin Online

It is not prudent for any vessel drawing more than ten feet water to remain under sail in this part of the river, while it is dark, unless a good pilot is on board; and even the best practical experience is not always a sure guide, so uncertain and fluctuating are the currents and depths of water. There are a few simple precautions, useful in such circumstances, of which I may be excused for reminding young sailors. A ground-log ought to be hove frequently, and compared with a common log; there should be a leadsman in each chains, one, at least, of whom should sound constantly: the deep-sea lead* ought to be used now and then, even in shallow water, as a check upon the hand-lead: from the vessel's draught of water to two fathoms more than that depth, the hand-line should be marked to feet, by alternate marks of dark-coloured hair and small line: strong lanterns should be suspended under the chain-wales, near the water, but close to the ship's side; while a careful person ought to superintend the leadsman, and occasionally take a line into his own hand, so that by 'plumbing' the bottom himself he may ascertain how far reliance is to be placed upon the leadsman's opinion.

In the Plata, as well as in many other pilot-waters, to feel the ground thus is often more useful than knowing the precise depth of water, or even the colour, or nature, of the bottom.

27th Nov. Our arrangements and observations being satisfactorily completed, a sufficient quantity of provision on board to last eight months, at full allowance, and an extra supply of iron and coals for the forge, in case of any serious accident, the Beagle sailed from Monte Video; and, after filling water near Cape Jesu Maria,† hastened to look after her little assistants, left near Bahia Blanco.

In this trip we benefitted by the assistance of Mr. Robert N. Hamond, an early and much esteemed friend of mine, who was lent to the Beagle from H.M.S. Druid, of which he was then a mate.

* Massey's is preferable.

† Above Monte Video, on the north shore.

© The Complete Work of Charles Darwin Online

December 3d. Soon after daylight we saw the very low islands, just to the northward of San Blas. I wished to have made Point Rubia, but was set twenty miles northward, during the night, by the flood tide. We stood directly towards the shore, but when eight miles from it found a wide breadth of discoloured water, and the depth shoaled suddenly from ten to three fathoms in a few casts of the lead. Hauling off, we steered southward, with the ebb tide. There was no ripple on the banks, but the water was quite yellow, and at the time we altered our course, in consequence of such shallow water, the nearest land was, at least, eight miles distant.

While tracing the outer edge of this bank we descried our cock-boats coming out to meet us, and soon afterwards Mr. Wickham came on board. He gave us gratifying news with little drawback; but had he been half-roasted his own appearance could hardly have been more changed. Notwithstanding the protection of a huge beard, every part of his face was so scorched and blistered by the sun that he could hardly speak, much less join in the irresistible laugh at his own expense. His companions were similarly sun-burned, though not to such a degree. They had been much occupied in sounding extensive banks and harbours, under a hot sun, and while a fresh wind kept them constantly wet with spray. But this inconvenience was trifling; one of more importance was excessive sea-sickness, in consequence of the short and violent movements of such small craft under sail among the tide-races and eddies so numerous on that coast.

In other respects all had prospered so well, that I determined to give Mr. Wickham fresh orders,* enlarging considerably his share of surveying operations. He was desired to continue exploring the coast, even as far as Port Desire, until the Beagle's return from her visit to Tierra del Fuego and the Falkland Islands.

As the weather promised well, an anchor was dropped where we were, outside the banks, but the schooners sought shelter in the harbour of San Blas. Next day they came out and anchored

* See Appendix.

© The Complete Work of Charles Darwin Online

close to us, in order to receive stores and various supplies which we had brought for them from Buenos Ayres and Monte Video. I was a little uneasy when I saw that the pilot of the Liebre, Mr. Roberts, was one of the largest of men, and that his little vessel looked, by comparison, no bigger than a coffin; but Mr. Wickham allayed my doubts by assuring me that his moveable weight answered admirably in trimming the craft; and that, when she got a-ground, Mr. Roberts stepped overboard, and heaved her afloat. "Certainly," said Mr. Wickham, "he did harm on one day, by going up to look-out, and breaking the mast."

In the afternoon of this day (4th) we weighed anchor and parted company from the Paz and Liebre. They returned to San Blas, and the Beagle steered southward. Secure and capacious as is the port just mentioned, it is one of the most difficult and dangerous to enter on this coast. The best, indeed only approach to it, is called by those sealers and sea-elephant fishers who have hitherto frequented it,—'Hell-gate.'

At about four the weather was very hot, the sky cloudless, and varying flaws of wind drove quantities of gossamer, and numbers of insects off from the land. The horizon was strangely distorted by refraction, and I anticipated some violent change. Suddenly myriads of white butterflies surrounded the ship, in such multitudes, that the men exclaimed, "it is snowing butterflies." They were driven before a gust from the north-west, which soon increased to a double-reefed topsail breeze, and were as numerous as flakes of snow in the thickest shower. The space they occupied could not have been less than two hundred yards in height, a mile in width, and several miles in length.

Our next object was to visit Tierra del Fuego, examine some portions of that country—yet unexplored—and restore the Fuegians to their native places; but in our passage, strong southerly winds, severe squalls, and cold weather, though it was near midsummer in that hemisphere, caused delay and discomfort, as they must always in a small and deeply-laden vessel, where little can be done except in fine weather.

© The Complete Work of Charles Darwin Online

We passed through a space of sea,* many miles in extent, where the water was of a very much lighter colour than usual; not of a light-green or muddy hue, such as one sees near land, but of a milky white tint. Being in soundings, one naturally attributed such a change of colour to some peculiarity in the ground; but I have since thought differently, and am now inclined to believe that the light-coloured water came from a distance, in one of those great, though slow-moving currents, which sweep past the Falkland Islands, and thence northwards: but to what cause its unusual whiteness is to be attributed, I know not. The dissolution of a huge iceberg, or of many icebergs, might alter the colour, and certainly would change the temperature of a considerable body of water; but in this case, a thermometer immersed in the sea did not indicate a degree lower than that of the previous or following day. During the three days, our soundings varied only from fifty to sixty fathoms. The lead certainly brought up fine grey sand while the water was light-coloured, and dark sand at other times; but I can hardly think that so decided a change—different from any I noticed elsewhere—could have been caused in fifty fathoms water by so small an alteration in the quality of the bottom.

Icebergs have been seen in latitude 40° S., and near the longitude of 50° W.; perhaps they are sometimes carried nearer the coast, in which case they would ground, and melt away.

I suspect that some of the rocks, so often, yet so fruitlessly, sought for—and instead of which many persons have supposed dead whales, wrecks, or large trees, were seen—may have been icebergs, against and upon which sea-weed, drift-wood, or other substances, may have lodged temporarily, causing a rock-like appearance. In this way, perhaps, arose the report of a rock said to have been seen by Lieutenant Burdwood; of the Aigle and Ariel rocks—and even of those islets sought for ineffectually by Weddell, a few degrees eastward of the Falkland Islands.†

* Lat. 46° S. Long. 63° W.

† On this subject there are a few more remarks, under the head—Currents of the ocean,—in the last chapter but one.

© The Complete Work of Charles Darwin Online

In the first volume some notice was taken of the supposed Ariel Rocks, and I will avail myself of this opportunity to say that at various times the Beagle passed over and near their asserted position; and that she likewise searched for the reported Aigle shoal or rock, without ever finding the slightest indication of either.

On the 15th, we saw the land off Tierra del Fuego, near Cape San Sebastian, and next day closed the shore about Cape Sunday, ran along it past Cape Peñas, and anchored off Santa Inez. A group of Indians was collected near Cape Peñas, who watched our motions attentively. They were too far off for us to make out more than that they were tall men, on foot, nearly naked, and accompanied by several large dogs. To those who had never seen man in his savage state—one of the most painfully interesting sights to his civilized brother—even this distant glimpse of the aborigines was deeply engaging; but York Minster and Jemmy Button asked me to fire at them, saying that they were "Oens-men—very bad men."

Our Fuegian companions seemed to be much elated at the certainty of being so near their own country; and the boy was never tired of telling us how excellent his land was—how glad his friends would be to see him—and how well they would treat us in return for our kindness to him.

We remained but a few hours at anchor under Cape Santa Inez, for so heavy a swell set in, directly towards the shore, caused probably by a northerly gale at a distance, that our situation was dangerous as well as disagreeable. Our only chance of saving the anchor and chain was by weighing immediately; yet if we did so, there would be a risk of drifting ashore: however, we did weigh, and drifted some distance, rolling our nettings in; but a breeze sprung up, freshened rapidly, and soon carried us out of danger. This happened at three in the morning, so my hopes of observations and angles were frustrated, and I had no choice but to run for the strait of Le Maire.

At noon, very high breakers were reported by the mast-head man, off Cape San Diego; at that time the flood-tide was set-

© The Complete Work of Charles Darwin Online

ting strongly against a northerly wind and high swell; but when the tide was slack, at one, the breakers disappeared; and when we passed close to the cape, at two, the water was comparatively smooth.

There is a ledge extending from Cape San Diego, over which the flood-tide, coming from the southward, sometimes breaks with such violence, that a small vessel might be swamped by the 'bore' which it occasions.

As we sailed into Good Success Bay, a Fuegian yell echoed among the woody heights, and shout after shout succeeded from a party of natives, posted on a projecting woody eminence, at the north head of the bay, who were seen waving skins, and beckoning to us with extreme eagerness. Finding that we did not notice them, they lighted a fire, which instantly sent up a volume of thick white smoke. I have often been astonished at the rapidity with which the Fuegians produce this effect (meant by them as a signal) in their wet climate, where I have been, at times, more than two hours attempting to kindle a fire.

Scarcely was our ship secured, when the wind shifted to south-west, and blew strongly, bringing much rain with it; and we had indeed reason to rejoice at having attained so secure an anchorage. During the night, heavy squalls (williwaws) disturbed our rest very often, but did no injury, the water being quite smooth.

18th. Mr. Darwin, Mr. Hamond and others, went with me to the natives who had so vociferously greeted our arrival; and deeply indeed was I interested by witnessing the effect caused in their minds by this first meeting with man in such a totally savage state.

There were five or six stout men, half-clothed in guanaco-skins, almost like the Patagonians in aspect and stature, being near six feet high, and confident in demeanour. They scarcely bore resemblance to the Fuegians, except in colour and class of features. I can never forget Mr. Hamond's earnest expression, "What a pity such fine fellows should be left in such a barbarous state!" It told me that a desire to benefit these igno-

rant, though by no means contemptible human beings, was a natural emotion, and not the effect of individual caprice or erroneous enthusiasm; and that his feelings were exactly in unison with those I had experienced on former occasions, which had led to my undertaking the heavy charge of those Fuegians whom I brought to England.

Disagreeable, indeed painful, as is even the mental contemplation of a savage, and unwilling as we may be to consider ourselves even remotely descended from human beings in such a state, the reflection that Cæsar found the Britons painted and clothed in skins, like these Fuegians, cannot fail to augment an interest excited by their childish ignorance of matters familiar to civilized man, and by their healthy, independent state of existence. One of these men was just six feet high, and stout in proportion; the others were rather shorter: their legs were straight and well formed, not cramped and misshapen, like those of the natives who go about in canoes; and their bodies were rounded and smooth. They expressed satisfaction or good-will by rubbing or patting their own, and then our bodies; and were highly pleased by the antics of a man belonging to the boat's crew, who danced well and was a good mimic. One of the Fuegians was so like York Minster, that he might well have passed for his brother. He asked eagerly for "cuchillo." About his eyes were circles of white paint, and his upper lip was daubed with red ochre and oil. Another man was rubbed over with black. They were (apparently) very good-humoured, talked and played with the younger ones of our party, danced, stood up back to back with our tallest men to compare heights, and began to try their strength in wrestling—but this I stopped. It was amusing and interesting to see their meeting with York and Jemmy, who would not acknowledge them as countrymen, but laughed at and mocked them. It was evident that both of our Fuegians understood much of the language in which the others talked; but they would not try to interpret, alleging that they did not know enough. York betrayed this by bursting into an immoderate fit of laughter at something the oldest man told him, which

© The Complete Work of Charles Darwin Online

he could not resist telling us was, that the old man said he was dirty, and ought to pull out his beard. Now, if their language differed much from that of York Minster, or was indeed other than a dialect of the same original, it is not probable that York could have understood the old man's meaning so readily when he spoke quietly, without signs.

Richard Matthews was with us, but did not appear to be at all discouraged by a close inspection of these natives. He remarked to me, that "they were no worse than he had supposed them to be."

20th. Soon after day-light this morning, some very large guanacoes were seen near the top of Banks Hill.* They walked slowly and heavily, and their tails hung down to their hocks. To me their size seemed double that of the guanacoes about Port Desire. Mr. Darwin and a party set off to ascend the heights, anxious to get a shot at the guanacoes and obtain an extended view, besides making observations. They reached the summit, and saw several large animals, whose long woolly coats and tails added to their real bulk, and gave them an appearance quite distinct from that of the Patagonian animal; but they could not succeed in shooting one.

21st. Sailed from Good Success Bay. On the 22d we saw Cape Horn, and being favoured with northerly winds, passed close to the southward of it before three o'clock. The wind then shifted to north-west, and began to blow strong. Squalls came over the heights of Hermite Island, and a very violent one, with thick weather, decided my standing out to sea for the night under close-reefed topsails. The weather continued bad and very cold during that night and next day.

On the morning of the 24th, being off Cape Spencer, with threatening weather, a high sea, the barometer low, and great heavy-looking white clouds rising in the south-west, indicative of a gale from that quarter, I determined to seek for an anchorage, and stood into (the so-called†) St. Francis Bay. In

* So named in remembrance of Sir Joseph Banks's excursion.

† In the first volume doubts are expressed (in a note to page 199) respecting the place named by D'Arquistade, St. Francis Bay; or rather, I said'

© The Complete Work of Charles Darwin Online

passing Cape Spencer we were assailed by such a furious hail-squall, that for many minutes it was quite impossible to look to windward, or even to see what was a-head of us. We could not venture to wear round, or even heave to, for fear of getting so far to leeward as to lose our chance of obtaining an anchorage; however, we stood on at hazard, and the squall passed away soon enough to admit of our anchoring in seventeen-fathoms water, quite close to a steep promontory at the south side of St. Martin Cove.

After being for some time accustomed to the low barren shores and shallow harbours of the Pampa and Patagonian coasts, our position almost under this black precipice was singularly striking. The decided contrast of abrupt, high, and woody mountains, rising from deep water, had been much remarked in Good Success Bay; but here it was so great that I could hardly persuade myself that the ship was in security —sufficiently far from the cliff.*

25th. Notwithstanding violent squalls, and cold damp weather, we kept our Christmas merrily; certainly, not the less so, in consequence of feeling that we were in a secure position, instead of being exposed to the effects of a high sea and heavy gale.

I said, that "I do not think the bay adjacent to Cape Horn is that which was named by D'Arquistade, 'St. Francis,' and, if my supposition is correct, Port Maxwell is not the place which was called 'St. Bernard's Cove.'"

If the modern chart be compared with that issued by the Admiralty a few years ago, published by Faden in 1818, it will be seen that the particular plan of St. Francis Bay, given in Faden's chart, agrees much better with the west side of Nassau Bay than with any other place; and that the "remarkable island, like a castle," noticed in the plan, is evidently "Packsaddle Island," of the modern chart. The rough sketch of land towards the north and east, as far as Cape Horn, on that plan, I take to be the random outline of land seen at a distance by the person who drew the plan, and the name "Cape Horn," affixed to the southernmost land then in sight; which must have been Cape Spencer. But it is now too late to remedy the mistake, which is indeed of no consequence.

* As the shores of Tierra del Fuego are so much spoken of in other places, I say no more of them here.

© The Complete Work of Charles Darwin Online

At sun-set, there was a reddish appearance all over the sky —clouds shot over the summits of the mountains in ragged detached masses—and there was a lurid haze around, which showed a coming storm as surely as a fall of the barometer. The gale increased, and at midnight such furious squalls came down from the heights, that the water was swept up, and clouds of foam were driven along the sea. Although we were close to a weather shore, with our top-gallant masts down and yards braced sharp up, we hardly thought ourselves in security with three anchors down and plenty of chain cable out.*

Dec. 31. Tired and impatient at the delay caused by bad weather, we put to sea again the first day there was a hope of not being driven eastward; and during a fortnight we tried hard to work our way towards Christmas Sound. My purpose was to land York Minster and Fuegia Basket among their own people, near March Harbour, and return eastward through the Beagle Channel, landing Jemmy Button also with his tribe, the Tekeenica. Part of Whale-boat Sound and the western arms of the Beagle Channel were to be surveyed: and by this scheme I proposed to combine both objects.

Jan. 2d. We were rather too near the Diego Ramirez Islands, during a fresh gale of wind, with much sea; but by carrying a heavy press of sail, our good little ship weathered them cleverly, going from seven and a half to eight knots an hour, under close-reefed topsails and double-reefed courses—the top-gallant-masts being on deck.

On the 5th, the same islands were again under our lee—a sufficient evidence that we did not make westing. In fact, no sooner did we get a few reefs out, than we began taking them

* During such sudden, and at times tremendous squalls as these, it is absolutely necessary to have a long scope of cable out, although the vessel may be in smooth water, in order that the first fury of the blast may be over before the cable is strained tight; for otherwise, the chain or anchor might snap. When the violence of the squall is past, the weight of a chain cable sinking down, draws the ship a-head, so far as to admit of her recoiling again at the next williwaw; thus, a kind of elasticity may be given to a chain, in some degree equivalent to that always possessed by a hemp cable.

© The Complete Work of Charles Darwin Online

in again; and although every change of wind was turned to account, as far as possible, but little ground was gained.

On the 11th we saw that wild-looking height, called York Minster, 'looming' among driving clouds, and I flattered myself we should reach an anchorage; but after tearing through heavy seas, under all the sail we could carry, darkness and a succession of violent squalls, accompanied by hail and rain, obliged me to stand to seaward, after being within a mile of our port. All the next day we were lying-to in a heavy gale—wearing occasionally.

At three in the morning of the 13th, the vessel lurched so deeply, and the main-mast bent and quivered so much, that I reluctantly took in the main-topsail (small as it was when close-reefed), leaving set only the storm-trysails (close-reefed) and fore-staysail.* At ten, there was so continued and heavy a rush of wind, that even the diminutive trysails oppressed the vessel too much, and they were still farther reduced. Soon after one, the sea had risen to a great height, and I was anxiously watching the successive waves, when three huge rollers approached, whose size and steepness at once told me that our sea-boat, good as she was, would be sorely tried. Having steerage way, the vessel met and rose over the first unharmed, but, of course, her way was checked; the second deadened her way completely, throwing her off the wind; and the third great sea, taking her right a-beam, turned her so far over, that all the lee bulwark, from the cat-head to the stern davit, was two or three feet under water.

For a moment, our position was critical; but, like a cask, she rolled back again, though with some feet of water over the whole deck. Had another sea then struck her, the little ship might have been numbered among the many of her class which have disappeared: but the crisis was past—she shook the sea off her through the ports, and was none the worse—excepting

* I have always succeeded in carrying a close-reefed main-topsail (five reefs) in the Beagle, excepting on this and two other occasions; but were I again under similar circumstances, I think I should try to carry it—even then—for some time longer.

© The Complete Work of Charles Darwin Online

the loss of a lee-quarter boat, which, although carried three feet higher than in the former voyage (1826-1830), was dipped under water, and torn away.*

From that time the wind abated, and the sea became less high.† The main-topsail was again set, though with difficulty, and at four o'clock the fore-topsail and double-reefed foresail were helping us towards False Cape Horn, my intention being to anchor in Nassau Bay. When the quarter-boat was torn away, we were between the Ildefonsos and Diego Ramirez: the wind varying from W.S.W. to S.W.

This gale was severely felt on all parts of the coast, south of 48°, as I afterwards ascertained from sealing-vessels: and at the Falkland Islands, a French whaler, called Le Magellan, was driven from her anchors and totally wrecked in that land-locked and excellent port, Berkeley Sound.

Some persons are disposed to form a very premature opinion of the wind or weather to be met with in particular regions, judging only from what they may themselves have experienced. Happily, extreme cases are not often met with; but one cannot help regretting the haste with which some men (who have sailed round Cape Horn with royals set) incline to cavil at and doubt the description of Anson and other navigators, who were not only far less fortunate as to weather, but had to deal with crazy ships, inefficient crews, and unknown shores; besides hunger, thirst, and disease.

Before midnight we anchored under shelter of the land

* It was well that all our hatchways were thoroughly secured, and that nothing heavy could break a-drift. But little water found its way to the lower deck, though Mr. Darwin's collections, in the poop and forecastle cabins on deck, were much injured. Next to keeping a sharp look-out upon the sky, the water, and the barometer, we were always anxious to batten down our hatches in time—especially at night, during a gale, or in very squally weather.

† The roller which hove us almost on our beam ends, was the highest and most hollow that I have seen, excepting one in the Bay of Biscay, and one in the Southern Atlantic; yet so easy was our little vessel that nothing was injured besides the boat, the netting (washed away), and one chronometer.

© The Complete Work of Charles Darwin Online

near False Cape Horn; and next morning (14th) crossed Nassau Bay in search of a convenient harbour near the Beagle Channel. Having found so much difficulty in getting to the westward by the open sea, I decided to employ boats in the interior passages, and leave the Beagle at a secure anchorage.

Furious squalls prevented our effecting this purpose; and we anchored for the night in Windhond Bay.* The following day (15th) we again tried to get to the head or north-west corner of Nassau Bay, but ineffectually, for repeated squalls opposed us, and at last obliged me to bear up for Goree Road; one of the most spacious, accessible, and safe anchorages in these regions. Here, to my surprise, York Minster told me that he would rather live with Jemmy Button in the Tekeenica country than go to his own people. This was a complete change in his ideas, and I was very glad of it; because it might be far better that the three, York, Jemmy, and Fuegia, should settle together. I little thought how deep a scheme master York had in contemplation.

18th. Having moored the Beagle in security, and made arrangements for the occupation of those who were to remain on board, I set out with four boats (yawl and three whale-boats), carrying Matthews and the Fuegians, with all the stock of useful things which had been given to them in England.† A temporary deck having been put upon the yawl, she carried a large cargo, and was towed by the other boats when the wind was adverse. Matthews showed no sign of hesitation or reluctance; on the contrary, he was eager to begin the trial to which he had been so long looking forward. Messrs. Darwin, Bynoe, Hamond, Stewart, and Johnson, with twenty-four seamen and marines, completed the party.

My intention was to go round the north-east part of Navarin Island, along the eastern arm of the Beagle Channel, through Murray Narrow, to the spot which Jemmy called his country:

* So named by the Dutch in 1624, after one of their ships, the Windhond.

† By far the larger part of their property, including Matthews's outfit, was sent by Mr. Coates, Secretary of the Church Missionary Society.

© The Complete Work of Charles Darwin Online

there establish the Fuegians, with Matthews:—leave them for a time, while I continued my route westward to explore the western arms of the channel, and part of Whaleboat Sound: and at my return thence decide whether Matthews should be left among the natives for a longer period, or return with me to the Beagle.

But before I briefly relate this attempt to form a temporary settlement among the Fuegians, it may be advisable to give a general sketch of the aborigines who thinly people the southernmost regions of South America: including not only the various tribes of Fuegians (as far as we know them), but the Patagonians, and those natives of Western Patagonia who are supposed to be a remnant of the tribe called Chonos.

© The Complete Work of Charles Darwin Online

CHAPTER VII.

SOUTHERN ABORIGINES OF SOUTH AMERICA.

Of the tribes which scantily people Patagonia and Tierra del Fuego, far less is yet known than might generally be expected. Although frequently seen by white men, and often holding intercourse with them, probably no person even moderately educated, excepting Falkner, has staid among them long enough to become acquainted with, and describe their peculiarities.

His description of the aboriginal natives who, in his time (1740–80), roamed over the fertile 'Pampas' of Buenos Ayres, or the sterile plains of Patagonia; of the western mountaineers; and of those unconquerable tribes which repulsed the Peruvian Yncas, opposed Spanish conquerors, and are still independent, is so decidedly corroborated by Molina, by many Spanish authors, and by modern testimony, that in attempting to describe the Patagonians, I shall try to unite his account (bearing in mind the time elapsed, and consequent changes) to the information which has been obtained during late years.

Of the Fuegians, a few notices are to be found in narratives of various voyagers; but the imperfect description here given is principally derived from the natives who went to England in the Beagle; and from Mr. Low, who has seen more of them in their own country than any other person.

About the middle of the last century, the aboriginal inhabitants of that portion of South America which lies between the parallels of thirty and forty, formed two principal divisions, more or less separated by the only real barrier existing in that extent of country, the Cordillera of the Andes. Those who lived eastward of the Andes were called 'Puel-che,' signifying

© The Complete Work of Charles Darwin Online

east people; and those on the other side were known by the term 'Molu-che,' which signifies war people, or warriors: and these terms are still in habitual use.

Numerous subdivisions have perplexed all whose attention has been attracted to the aboriginal population of Southern America. Falkner's account is the least confused, in every way the most probable, and agrees the best with what is now found to be the condition of that portion of uncivilized man. For our present purpose, I believe, it will be sufficient to remark, that the Puel-che and Molu-che called the tribes who lived towards the south, 'Tehuel-het'* and 'Huilli-che,' both of which terms signify people of the south. The Huilliche were again divided into Pichi Huilli-che and Vuta Huilliche; 'pichi,' meaning little; and 'vuta,' great. Both the Tehuel-het and the Vuta Huilli-che lived to the southward of forty degrees of latitude. A branch or tribe of the Tehuel-het who lived farthest towards the south, on the eastern side, had no horses, and that tribe was called 'Yacana-kunny,'† (foot people). Westward of those people, separated from them by a ridge of mountains, was a tribe called Key-uhue, Key-yus, or Key-es; and northward, the Sehuau-kunny‡.

Falkner, in his account, rather confuses the habits of the Yacana-kunny with those of the Key-uhue, which is not to be wondered at, as he described those tribes solely from the accounts of others. The Key-uhue have neither 'bowls,' or balls (bolas), nor 'ostriches,' (see Falkner, p. 111), in their rugged tempestuous islands: neither do the Yacana-kunny 'live chiefly on fish.' The former live on fish, while the latter kill guanacoes, birds, and seals.

Between the Key-uhue and the Chonos tribe were the Poy-yus, or Pey-es, living on the sea-coast. The Chonos inhabited the Archipelago so called, and part of Chilóe.

These three last-mentioned tribes—Key-uhue, Poy-yus, and Chonos—were called 'Vuta Huilli-che.'

* Called by themselves 'Tehuel-kunny.'

† 'Che,' 'het,' and 'kunny,' signify people, in different dialects.

‡ The Sehuau-kunny are a part of the Tehuel-het.

© The Complete Work of Charles Darwin Online

Rather than occupy time in attempting to give an account of the past state of these ever-varying tribes,—whose numbers have been so much altered, and whose locations may be now changed,—I will endeavour to give some idea of the present condition, distribution, and probable numbers of the people called Patagonians; of the natives of Tierra del Fuego, or Fuegians, and of the western tribe called Chonos. By those who have frequented the Strait of Magalhaens or its vicinity, the latter are often called 'Canoe Indians;' and the Patagonians, 'Horse Indians.'

The Patagonians (Tehuel-het) travel on horseback over the country between the River Negro and the Strait of Magalhaens; from the Atlantic to the Cordillera of the Andes. They have no boats or canoes of any kind; and their disposition, habits, and language are very different from those of the Fuegians (Yacana-kunny, Key-uhue, and Poy-yus). Those who live in the north-eastern part of Tierra del Fuego have neither canoes nor horses. The natives of the southern and western islands, and of the shores of Otway and Skyring waters, also the people who live upon the western islands and coast of Patagonia, have canoes, but no horses.

The Patagonians are now divided into four parties, each of which has a separate though ill-defined territory. Each of these parties has a leader, or cacique; but they speak one language, and are evidently subdivisions of one tribe. When mutually convenient, they all assemble in one place: but if food becomes scarce, or quarrels happen, each party withdraws to its own territory. At such times one body will encroach upon the hunting grounds of another, and a battle is the consequence. About four hundred adults, and a rather large proportion of children, are in each of these parties: the number of women being to that of the men as three to one. Near the Strait of Magalhaens about fourteen hundred Patagonians have been lately seen encamped together for a short time; but usually there is only one horde, of about four hundred grown people, in that neighbourhood.

Less is known of the Yacana-kunny than of any other tribe,

© The Complete Work of Charles Darwin Online

or portion of a tribe. It may consist of about six hundred men and women, besides children.

Beyond a range of high mountains to the southward of the Yacana, is the tribe formerly called Key-uhue, now probably the Tekeenica. These are the smallest, and apparently the most wretched of the Fuegians. They inhabit the shores and neighbourhood of the Beagle Channel. The number of adults in this tribe may be about five hundred. (Note 1.)

To the westward, between the western part of the Beagle Channel and the Strait of Magalhaens, is a tribe now called Alikhoolip (which may be the Poy-yus), whose numbers amount perhaps to four hundred.

About the central parts of Magalhaens Strait is a small and very miserable horde, whose name I do not know. Their usual exclamation is 'Pecheray!' 'Pecheray!' whence Bougainville and others called them the Pecherais. For want of a more correct term I shall here use the same word. The number of adults among them is about two hundred.

Near Otway and Skyring waters is a tribe, or fraction of a tribe, whose name I could not learn; for the present I shall call them 'Huemul'—because they have many skins of a kind of roebuck, which is said to be the animal described by Molina as the 'Huemul' *. Their number may be one hundred, or thereabouts. I am inclined to think that these Huemul Indians are a branch of the Yacana people, whom Falkner describes as living on both sides of the Strait.

On the western coast of Patagonia, between the Strait of Magalhaens and the Chonos Archipelago, there is now but one tribe, in which there are not above four hundred grown people.

Each of the tribes here specified speaks a language differing from that of any other, though, as I believe, not radically different from the aboriginal Chilian. Some words are common to two or more tribes; as may be seen by reference to the fragment of a vocabulary in the Appendix; and differences must increase because neighbouring tribes are seldom at peace.

The numbers above stated are mere estimations. The diffi-

* See Note 2, at the end of this chapter.

© The Complete Work of Charles Darwin Online

culty of obtaining either language or information from the Fuegians can only be well appreciated by those who have had intercourse with them, or with the New Hollanders; whose mimickry of what one says is as perplexing as the same trick is when speaking to the Fuegians.

Allowing that the Tehuel-het or Patagonians amount to	1,600
Yacana	600
Tekeenica	500
Alikhoolip	400
Pecheray	200
Huemul	100, and
Chonos	400
the total will be	3,800,

which I do not think is five hundred in error: and I should say, in round numbers, that there are about four thousand adults south of the latitude of forty degrees, exclusive of Chiloé.

By Patagonia is meant that part of South America which lies between the River Negro and the Strait of Magalhaens.

Eastern Patagonia is the portion of this district which lies eastward of the Cordillera; and Western Patagonia, the part lying between the summits of the Andes and the Pacific Ocean.

Tierra del Fuego takes in all the islands southward of the Strait of Magalhaens (including Staten Land), as far as the Diego Ramirez islets.

Before entering into a more detailed account of these aborigines, I will try to give a slight general idea of their personal appearance; of their horses and canoes; of their houses and country; in short, an outline sketch of that which is observed at the first glance of a stranger's eye. The minuter details, which will follow, may be tedious to many readers.

Magalhaens first gave the name of Patagones to the natives whom he saw at Port San Julian in 1520. They were of very large (gigantic) stature, and their feet, being wrapped in rough guanaco skin, by way of shoes, were remarked particularly. Probably their footsteps in the sand were noticed, and excited

© The Complete Work of Charles Darwin Online

some such exclamation as 'que patagones!' (what great feet!) patagon meaning a very large foot.—(See note 3.)

Tierra del Fuego was also named by Magalhaens, because many fires were seen, in the night, upon that land.

The aboriginal natives of Eastern Patagonia are a tall and extremely stout race of men. Their bodies are bulky, their heads and features large, yet their hands and feet are comparatively small. Their limbs are neither so muscular nor so large boned as their height and apparent bulk would induce one to suppose: they are also rounder and smoother than those of white men. Their colour is a rich reddish-brown, between that of rusty iron and clean copper, rather darker than copper, yet not so dark as good old mahogany.* But every shade of colour between that just mentioned and the lighter hue of a copper kettle, may be seen among individuals of various ages. Excepting among old or sickly people, I did not notice a tinge of yellow: some of the women are lighter coloured—about the tint of pale copper—but none are fair, according to our ideas.

Nothing is worn upon the head except their rough, lank, and coarse black hair, which is tied above the temples with a fillet of platted or twisted sinews. A large mantle, made of skins sewed together, loosely gathered about them, hanging from the shoulders to their ankles, adds so much to the bulkiness of their appearance, that one ought not to wonder at their having been called 'gigantic.' I am not aware that a Patagonian has appeared, during late years, exceeding in height six feet and some inches; but I see no reason to disbelieve Falkner's account of the Cacique Cangapol, whose height, he says, was seven feet and some inches. When Falkner stood on tiptoe he could not reach the top of Cangapol's head. It is rather curious, that Byron could only just touch the top of the tallest man's head

* The colour of these aborigines is extremely like that of the Devonshire breed of cattle. From the window of a room in which I am sitting, I see some oxen of that breed passing through the outskirts of a wood, and the partial glimpses caught of them remind me strongly of the South American red men.

© The Complete Work of Charles Darwin Online

whom he saw. Ever restless and wandering, as were the Tehuel-het, of which tribes that cacique was chief, might not Byron have measured Cangapol?* Who disbelieves that the Roman Emperor, Maximinus, by birth a Thracian, was more than eight feet in height? yet who, in consequence, expects all Thracians to be giants? At present, among two or three hundred natives of Patagonia, scarcely half-a-dozen men are seen whose height is under five feet nine or ten; and the women are tall in proportion.

I have nowhere met an assemblage of men and women whose average height and apparent bulk approached to that of the Patagonians. Tall and athletic as are many of the natives of Otaheite, and other islands in the Pacific Ocean, there are also many among them who are slight, and of low stature. The Patagonians seem high-shouldered—owing perhaps to the habit of folding their arms in their mantles across the chest, and thus increasing their apparent height and bulk, as the mantles hang loosely, and almost touch the ground. Until actually measured, I could not believe that they were not much taller than was found to be the fact.

But little hair shews itself on their faces or bodies. From the former it is studiously removed by two shells, or some kind of pincers. Although they do not augment the coarseness of their features by piercing either nose or lips, they disfigure themselves not a little by red,† black,‡ or white§ paint, with which they make grotesque ornaments, such as circles around their eyes, or great daubs across their faces. Upon particular occasions, all the upper part of their body, from the waist upwards, is strangely decorated (or disfigured) by paint, awkwardly laid on with very little design. On their feet and legs are boots made out of the skins of horses' legs. Wooden spurs, if they cannot get iron; sets of balls (bolas), and a long tapering lance of bamboo, pointed with iron, complete their equipment. These lances are seldom seen near the Strait of Magalhaens, but the natives are not always without them.

The women are dressed and booted like the men, with the

* Byron's voyage, 1765.—Falkner, 1740-80.

† Ochre. ‡ Charcoal and oil. § Felspathic earth and oil.

© The Complete Work of Charles Darwin Online

addition of a half petticoat, made of skins, if they cannot procure foreign coarse cloth. They clean their hair, and divide it into two tails, which are platted, and hang down, one on each side. Ornaments of beads, bits of brass, or silver, or any similar trifles, are much prized, and worn in necklaces, or as bracelets; sometimes also as ear-rings, or round their ankles. Mounted upon horses of an inferior size, averaging only about fourteen hands and a half in height, though rather well-bred, the Patagonians seem to be carried no better than the full-accoutred dragoons, who rode eighteen stone upon horses equal to twelve; yet those horses, so slight in comparison with their masters, carry them at full speed in chase of ostriches or guanacoes; and we all know what our dragoon horses have done under their heavily-weighted, but determined riders. With bridles of hide tied to the lower jaw, when there is not a Spanish bit, and a light saddle of wood, covered with some skins and placed upon others, a Patagonian rides hard when there is occasion—but frequently changes his horse. Many large dogs, of a rough, lurcher-like breed, assist them in hunting, and keep an excellent watch at night. (Note at end of Chapter VIII.)

The toldos (huts) of these wanderers are in shape not unlike gipsy tents. Poles are stuck in the ground, to which others are fastened, and skins of animals, sewed together, form the covering, so that an irregular tilt-shaped hut is thus made. Three sides and the top are covered; but the front, turned towards the east, is open. These toldos are about seven feet high, and ten or twelve feet square; they are lower at the back, or western side, than in front, by several feet. These are their ordinary dwellings; of other rather larger constructions a description will be given hereafter.

The country inhabited by these Patagonians is open and, generally speaking, rather level, but with occasional hills and some extensive ranges of level-topped heights (steppes). There are very few trees, and water is scarce. The eye wanders over an apparently boundless extent of parched, yellow-looking semi-desert, where rain* seldom falls, and the sky is almost

* Except during a few days in each year, or perhaps at intervals of two or three years, when it pours down in torrents.

PATAGONIANS.

© The Complete Work of Charles Darwin Online

HEREFORD PERMANENT LIBRARY

© The Complete Work of Charles Darwin Online

always clear. The heats of summer are very great; but in winter, though the days are not cold, the frosts at night are severe; and at all times of the year, in the day-time, strong winds sweep over the plains.

The Yacana-kunny, natives of the north-eastern part of Tierra del Fuego, resemble the Patagonians in colour, stature, and clothing.* They seem to be now much in the condition in which the Patagonians must have been before they had horses.† With their dogs, with bows and arrows, balls (bolas), slings, lances, and clubs, they kill guanacoes, ostriches, birds, and seals.

The north-eastern portion of Tierra del Fuego is a better country than Patagonia. The woody mountains of the south-western islands are succeeded, towards this north-east district, by hills of moderate height, partially wooded; northward of which are level expanses, almost free from wood, but covered with herbage adapted to the pasturage of cattle.

The climate is a mean between the extremes of wetness and drought, which are so much felt by the neighbouring regions; and when a settlement is made, at some future day, in that part of the world, San Sebastian Bay, in the Yacana country, called by Narborough, King Charles South Land, would be an advantageous position for its site.‡

The Tekeenica, natives of the south-eastern portion of Tierra del Fuego, are low in stature, ill-looking, and badly proportioned. Their colour is that of very old mahogany, or rather between dark copper, and bronze. The trunk of the body is large, in proportion to their cramped and rather crooked limbs. Their rough, coarse, and extremely dirty black hair half hides yet heightens a villanous expression of the worst description of savage features.

Passing so much time in low wigwams, or cramped in small

* Excepting boots.

† See Magalhaens' first interview. Burney, vol. i. p. 34.

‡ Falkner says (p. 93, speaking of this country), "It is evident that this place has the conveniences of wood, water, and soil; and, if there could be found a tolerable harbour, it would be much more convenient for a colony, and have a better command of the passage to the South Sea than Falkland's Islands."

© The Complete Work of Charles Darwin Online

canoes, injures the shape and size of their legs, and causes them to move about in a stooping manner, with the knees much bent; yet they are very nimble, and rather strong.

They suffer very little hair to grow, excepting on their heads. Even their eyebrows are almost eradicated—two muscle-shells serving for pincers. This aversion to the smaller tufts of hair does not extend to the thatch-like covering of their ugly heads, which is lank, covered with dirt, hanging about their ears, and almost over their faces. Just above their eyes it is jagged away by a broken shell, if they have not a piece of iron hoop for a knife, the pieces cut off being scrupulously burned. In height varying from four feet ten to five feet six, yet in the size of their bodies equalling men of six feet, of course they look clumsy and ill-proportioned; but their hands and feet are rather small with respect to the size of their bodies, though not so in proportion to their limbs and joints, which, excepting the knees, are small. Their knees are all strained, and their legs injured in shape, by the habit of squatting upon their heels. Awkward and difficult as such a posture appears to us, it is to them a position of easy rest.

Sometimes these satires upon mankind wear a part of the skin of a guanaco or a seal-skin upon their backs, and perhaps the skin of a penguin or a bit of hide hangs in front; but often there is nothing, either to hide their nakedness or to preserve warmth, excepting a scrap of hide, which is tied to the side or back of the body, by a string round the waist. Even this is only for a pocket, in which they may carry stones for their slings, and hide what they pick up or pilfer. A man always carries his sling around his neck or waist, wherever he goes.

Women wear rather more clothing, that is, they have nearly a whole skin of a guanaco, or seal, wrapped about them, and usually a diminutive apron. The upper part of the wrapper, above a string which is tied around the waist, serves to carry an infant. Neither men nor women have any substitute for shoes.

No ornaments are worn in the nose, ears, or lips, nor on the fingers; but of necklaces, and bracelets, such as they are, the women are very fond. With small shells, or pieces of the bones

© The Complete Work of Charles Darwin Online

of birds, strung upon lines made of sinews, these necklaces and bracelets are made, when nothing preferable is to be found; but beads, buttons, pieces of broken glass, or bits of fractured crockery-ware are most highly esteemed.

The hair of the women is longer, less coarse, and certainly cleaner than that of the men. It is combed with the jaw of a porpoise, but neither platted nor tied; and none is cut away, excepting from over their eyes. They are short, with bodies largely out of proportion to their height; their features, especially those of the old, are scarcely less disagreeable than the repulsive ones of the men. About four feet and some inches is the stature of these she-Fuegians—by courtesy called women. They never walk upright: a stooping posture, and awkward movement, is their natural gait. They may be fit mates for such uncouth men; but to civilized people their appearance is disgusting. Very few exceptions were noticed.

The colour of the women is similar to that of the men. As they are just as much exposed, and do harder work, this is a natural consequence: besides, while children, they run about quite naked, picking up shell-fish, carrying wood, or bringing water. In the colour of the older people there is a tinge of yellow, which is not noticed in the middle-aged or young.

Both sexes oil themselves, or rub their bodies with grease; and daub their faces and bodies with red, black, or white. A fillet is often worn round the head, which upon ordinary occasions is simply a string, made of sinews; but if going to war, or dressed for show, the fillet is ornamented with white down, white feathers, or pieces of cloth, if they have obtained any from shipping. Small lances, headed with wood; others, pointed with bone; bows, and arrows headed with obsidian, agate, or jasper; clubs; and slings; are the weapons used by the Tekeenica.

The smoke of wood fires, confined in small wigwams, hurts their eyes so much, that they are red and watery; the effects of their oiling, or greasing themselves, and then rubbing ochre, clay, or charcoal, over their bodies; of their often feeding upon the most offensive substances, sometimes in a

© The Complete Work of Charles Darwin Online

state of putridity; and of other vile habits, may readily be imagined.

As a Tekeenica is seldom out of sight of his canoe or a wigwam, a slight idea of these—his only constructions—should be given with this sketch.

The canoe is made of several large pieces of bark, sewed together; its shape is nearly that which would be taken by the strong bark of the trunk of a tree (twelve to twenty feet in length, and a foot, or two feet, in diameter), separated from the solid wood, in one piece. If this piece of bark were drawn together at the ends, and kept open by sticks in the middle, it would look rather like a Fuegian canoe.

A Tekeenica wigwam is of a conical form, made of a number of large poles, or young trees, placed touching one another in a circle, with the small ends meeting. Sometimes, bunches of grass or pieces of bark are thrown upon the side which is exposed to the prevailing winds. No Fuegians, except the Tekeenica, make their huts in this manner.

The country of this people may be briefly described by saying that deep but narrow arms of the sea intersect high mountainous islands, many of whose summits are covered with snow, while the lee or eastern sides of their steep and rocky shores are more than partially covered with evergreen woods.

Between projecting rocky points are sandy or stony beaches, fronting very small spaces of level land, on which the huts of the natives are generally placed. Almost throughout the year, cloudy weather, rain, and much wind prevail; indeed, really fine days are very rare. Being so near the level of that great climate agent, the ocean, frost and snow are far less frequent than might be expected in a high latitude, among snow-covered mountains, of which the sight alone inclines one to shiver.

The men of the Alikhoolip tribe are the stoutest and hardiest, and the women the least ill-looking of the Fuegians. Though not very dissimilar, they are superior to the Tekeenica; but they are inferior to the Yacana, and far below the natives of Patagonia. Their canoes are rather better than those of the Tekeenica, made, however, in the same manner.

The wigwams of the Alikhoolip, and indeed of all the Fuegians, except the Tekeenica (and perhaps some of the Yacana, whom we have not seen), are shaped like bee-hives. Their height is not above four or five feet above the ground; but an excavation is usually made within, which gives another foot, making about five feet and a-half of height, inside, and they are two, three, or four yards in diameter. Branches of trees stuck in the ground, bent together towards the top, form the structure, upon which skins, pieces of bark, and bunches of coarse grass are roughly fastened. Of course, neither these nor the Tekeenica wigwams are wind or water tight, neither does the smoke need a chimney.

The country and climate of the Alikhoolip are similar to the Tekeenica, though wetter, more windy, and more disagreeable. Both men and women are better covered with seal or otter skins than the Tekeenica and Pecheray tribes. When surprised, or sure that they would not be plundered, the women of this tribe were always seen wrapped in large otter or seal skins.

The natives of the central parts of Magalhaens Strait appear to be almost as miserable a race as the Tekeenica. As in nothing but language, and the construction of their wigwams, is there any difference which has yet been found out (though probably existing), I shall say no more of them in this place.

Their climate is nearly the same as that of the Alikhoolip; and the country is similar, though more wooded in many places, because more sheltered.

Those whom I have hitherto called Huemul, who live near the Otway and Skyring Waters, seem to be a mixed breed, rather resembling the Yacana, of which tribe they are probably a branch. In habits, as well as in appearance, they partake of some of the peculiarities of Patagonians as well as Fuegians. Their country is like the Yacana—Tierra del Fuego blending or sinking into Patagonia, sharing the qualities of each region, and therefore preferable to either. They have very few canoes; and no horses: but large dogs are used by them in hunting the huemul and guanaco.

© The Complete Work of Charles Darwin Online

The tribe mentioned in a following page, which was met by Mr. Low at the north side of Fitz-Roy Passage, must have been chiefly composed of slaves (zapallos). The Huemul tribe is not numerous, and having plenty of land, with abundance of food, would hardly quit their own territory to submit to a Patagonian Cacique. These natives are neither inclined to serve a master, nor to learn new habits: besides, being separated from the Horse Indians by a little channel, they could not easily be caught, and obliged to remain with the Patagonians, as some persons have supposed.

The Chonos, who live on the western shores and islands of Patagonia, are rather like the Alikhoolip, but not quite so stout or so daring. In general they are less savage than the Fuegians; and though their habits of life are similar, traces are visible of former intercourse with the Spaniards, which doubtless has tended to improve their character.

Prior to the Spanish conquest, the Chonos Indians inhabited Chiloé and the Chonos Archipelago; but that now they are all south of Cape Tres Montes, there is good reason to suppose, though certainly no positive proof. The canoes of these Chonos Indians are made of planks, sewed together; and they are rowed with oars. Generally there is a cross at one end of the canoe, or rather boat. Their wigwams are like those already mentioned of the bee-hive form.

The climate of Western Patagonia is so disagreeable that the country is almost uninhabitable. Clouds, wind, and rain are continual in their annoyance. Perhaps there are not ten days in the year on which rain does not fall; and not thirty on which the wind does not blow strongly; yet the air is mild, and the temperature surprisingly uniform throughout the year. The country is like the worst part of Tierra del Fuego—a range of mountains, half sunk in ocean; barren to seaward, impenetrably wooded towards the mainland, and always drenched with the waters of frequent rain, which are never dried up by evaporation before fresh showers fall.

Having thus endeavoured to give a slight general idea of the more obvious peculiarities of these, the most southern abori-

© The Complete Work of Charles Darwin Online

gines on the globe, I will enter into rather more detail, even at the risk of being prolix. As there is much similarity in the habits of all the tribes above-mentioned who use canoes, and we know little of the Yacana, I shall speak of the Horse Indians, generally, in the first place; and of the Canoe Indians, as one body, in the second.

NOTE 1.—There is so much difficulty in deciding upon the orthography of words whose sounds are variously given by individuals even of the same tribe, and which, caught by ears of varying acuteness, are written down according to the pronunciation of different languages, that one may trace some connexion between the names Key-es, Key-yus; Keyuhues, or Keyuhue; Kekenica, or Tekeenica, and Kenneka. This last term is taken from Van Noort. (Burney, vol ii. p. 215.) Perhaps the country there called 'Coin' may be that inhabited by Jemmy Button's Oens-men.

2. Molina's description of the Huemul is said by naturalists to be unsatisfactory and inconclusive; therefore, whether it is an animal hitherto unnoticed (except by him), or the 'kind of roebuck,' mentioned in page 132, remains to be decided. See Molina, vol. i. p. 364.

3. Pennant, in his 'Literary Life,' quotes Cavendish's as well as Brouwer's measurement of footsteps eighteen inches long! As Pennant was personally acquainted with Falkner, and collected much information respecting the Patagonians from other sources likewise, I have inserted a short extract from his work in the Appendix to this volume. The original book is now becoming scarce, and some of the notices contained in it are very interesting in connexion with this subject.

While I was revising my manuscript journal, Sir Woodbine Parish had the kindness to lend me 'Viedma's Diary,' with permission to make use of it: and, finding some interesting notices of the Patagonians which were quite new to me, I have added to the appendix of this volume a verbatim extract from Viedma, which I think will repay the curious reader, especially where their ideas of the transmigration of souls are mentioned.

CHAPTER VIII.

HORSE INDIANS OF PATAGONIA.

Head — Physiognomy — Stature — Wanderings — Clothing — Armour — Arms — Food — Chase — Property — Huts — Wizards — Marriage — Children — Health — Illness — Death — Burial — War — Horsemanship — Gambling — Caciques — Superstitions — Warfare — Morality — Disposition — Chups — Zapallos.

The head of a Patagonian is rather broad, but not high; and, except in a few instances, the forehead is small and low. His hair hangs loosely: it is black, coarse, and very dirty. A fillet which is worn around the top of the head may be intended as an ornament, for it is certainly of no use. The brow is prominent: the eyes are rather small, black, and ever restless. Deficiency of eyebrow adds to the peculiar expression of their eyes; and a mixture of simplicity and shrewdness, daring and timidity, with that singular wild look which is never seen in civilized man, is very conspicuous in the Patagonians. Its immediate effect is to remind one of the necessity of being always on guard while within reach: yet of all savage nations, perhaps the Patagonians are least inclined to attack or deceive strangers.

In general, the women's stature, physiognomy, and dress, so much resemble those of the men, that, except by their hair, it is difficult for a stranger to distinguish them.

By nature they have but little hair on either face or body, and that little they try to eradicate. Their faces are roundish, and the width or projection of the cheek-bones makes them look unusually wide. The nose is a little depressed, narrow between the eyes, but broad and fleshy about the nostrils, which are rather large. The mouth is large and coarsely formed, with thick lips. Their teeth are often very good, though rather large; and those in front have the peculiarity, which will be discussed when speaking of the Fuegians, of being flattened, solid, and shewing an inner substance. The chin is

© The Complete Work of Charles Darwin Online

usually broad and prominent: all the features, indeed, are large, excepting the eyes. The expression of their countenances is open and honest (compared with other savages), and their intrepid, contented look is rather prepossessing. The unhesitating manner in which, unarmed, they trust themselves among strangers whom they never before saw, or venture on board ship, even under sail in the offing (if they can obtain a passage in the boat), and go voluntarily from place to place with their white acquaintances, is very remarkable.

Of the stature and bulk of these Indians I have already spoken. It appears to me that those who now live on the northern side of Magalhaens' Strait are descendants of the Patagonians whose size excited so much surprise and discussion; and that, occasionally, individuals have exceeded the common height. Speaking of Cangapol, whose chief resort was the vicinity of the river Negro, though he and his tribe were restless wanderers, Falkner says—"This chief, who was called by the Spaniards the 'Cacique bravo,' was very tall and well proportioned. He must have been seven feet and some inches in height, because, on tiptoe, I could not reach to the top of his head. I was very well acquainted with him, and went some journeys in his company. I do not recollect ever to have seen an Indian that was above an inch or two taller than Cangapol. His brother, Sausimian, was but about six feet high. The Patagonians are a large-bodied people; but I never heard of that gigantic race which others have mentioned, though I have seen persons of all the different tribes of southern Indians." In another place he says, "there is not a part of all this extremity of the continent that some of these wandering nations do not travel over frequently." Of their wanderings, many persons besides myself and those with me can bear witness. Patagonians, who were personally known by officers of the Beagle, were seen by them at the Spanish (now the Buenos Ayrean) settlement, Del Carmen, near the mouth of the river Negro, in September 1832; and by Mr. Low, at their usual abode, near the Strait of Magalhaens, in February 1833. The individual who was then most noticed, a half-breed Indian woman, named

© The Complete Work of Charles Darwin Online

Maria,* once persuaded some of her companions to go with her to the Falkland islands, in a vessel commanded by Mr. Matthew Brisbane. They went, staid there some weeks, and returned in the same vessel, highly delighted by all the novelties, excepting sea-sickness. The chief wizard of the tribe was one of the party. Maria was then a person of much consequence, being almost their only interpreter, and the wife of a principal person. Her own history must be curious: she was born at Asuncion, in Paraguay; and has a son who is a cacique.

The mantles are curiously painted, usually on one side only, but some have had the hair rubbed off and are painted on both sides. They are very neatly sewed together with thread made out of the split sinews of ostriches, which is the strongest and most durable material they can procure. Making mantles is one of the occupations of the women. The paint used is found on the hills: it is an earthy substance, of various colours. Moistened with water, and made into the shape of crayons, pieces of this substance are dried in the sun; and when used, one end of the crayon is dipped in water and rubbed on the part to be coloured. These mantles are tied about the neck, and usually round the middle, by sinew cords. Often the upper part is dropped, and the body left quite exposed above the waist, and while in active exercise on horseback, this is usually the case, if the mantle is not then entirely discarded. This substantial substitute for clothing is made with skins of the animals of their country; and among those of guanaco, puma, fox, skunk (a kind of weasel or polecat), cavy, dog, otter, seal, and colt, the most esteemed are the small grey fox skins. A kind of 'maro' is sometimes worn by the men; and their boots, I have already said, are made out of the hock part of the skins of mares' and colts' legs. After being cleaned from fat, or membranous substances, dried, and then made pliable with grease, these ready-shaped boots require neither sewing nor soles. Wooden substitutes for spurs are worn, if iron cannot be procured.

For warlike purposes the men clothe themselves in three of

* Frequently mentioned by Captain King in vol. i.

© The Complete Work of Charles Darwin Online

their thickest mantles: the two outer ones have no hair, but are gaily painted: all three are worn like ponchos. On their heads they then wear conical caps, made of hide; and surmounted by a tuft of ostrich feathers. Another kind of armour, worn by those who can get it, is a broad-brimmed hat, or helmet, made of a doubled bull's hide: and a tunic, or frock, with a high collar, and short sleeves, made of several hides sewed together; sometimes of anta skins, but always of the thickest and most solid they can procure. It is very heavy, strong enough to resist arrows or lances, and to deaden the blow of a stone ball (bola perdida); but it will not turn the bullet fired from a musket. Some say that it will do so, but that which I saw had been pierced through, in the thickest part, by the musket-ball which killed the wearer. When obliged to fight on foot, they use a shield made of hides sewed together (clypeus septemplex).

Their arms are balls (bolas), lances, bows and arrows, clubs, and swords when they can get them. But in hasty, unforeseen skirmishes, they engage in as light order as the more northern Indians, without head-cover or mantle, stripped to their spurs, and armed only with lances and balls; which latter they are never without.

The balls, bowls, or bolas, called by themselves 'sōmai,' are two or three round stones, lumps of earth hardened, iron or copper ore, or lead. If made of earth or clay, the material is enclosed in small bags of green (fresh) hide, which, placed in the sun, contract so much, that they become like stones in hardness; but these clay balls are not used by the Patagonians so much as by the Pampa Indians, in whose country stones or metals are so scarce that there probably the last-mentioned balls were invented. Two balls, connected by a thong of hide, two, three, or four yards in length, are called 'sōmai.' Three such balls, connected by thongs, equal to one another in length, with their inner ends united, are called 'achico.' Taking one ball in the right hand, the other two are whirled around several times, and the whole then thrown at the object to be entangled. There are also balls of less weight and size, made of marble,

© The Complete Work of Charles Darwin Online

lead, or metallic ore, with shorter cords or thongs, which are for small animals.

Sometimes two small balls, each of which has a cord about a yard in length, are fastened to the thong of the larger set. This is to entangle the victim more effectually. They do not try to strike objects with these balls, but endeavour to throw them so that the thong shall hit a prominent part; and then, of course, the balls swing around in different directions, and the thongs become so 'laid up' (or twisted), that struggling only makes the captive more secure. They can throw them so dexterously, as to fasten a man to his horse, or catch a horse without bruising him. If an animal is to be caught without being thrown down suddenly—an inevitable consequence of these balls swinging round his legs while at full speed—a sōmai is thrown at his neck. The two balls hang down, and perplex him so much by dangling about his fore-legs, that his speed is much checked; and another set of balls, or a lasso, may be used, to secure, without throwing him down. The lasso is not much used, so adroit are they with the balls. A formidable missile weapon is the single ball, called by the Spaniards 'bola perdida.' This is similar to the other in size and substance, but attached to a slighter rope, about a yard long. Whirling this ball, about a pound in weight, with the utmost swiftness around their heads, they dash it at their adversary with almost the force of a shot. At close quarters, it is used, with a shorter scope of cord, as an efficient head-breaker.

Several of these original, and not trifling offensive weapons, are kept in readiness by each individual; and many a Spaniard, armed with steel and gunpowder, has acknowledged their effect.

The lance (chuza) is a long bamboo cane, from twelve to twenty-four feet long, headed with iron or steel. The great length and tapering slightness of these spears makes them formidable to any adversaries, but often fatal to those who are unskilful or timorous, because their vibration, artfully increased to the utmost by the holders, makes it extremely difficult to parry the advance of their point; but, once parried they are

© The Complete Work of Charles Darwin Online

useless—perhaps become encumbrances to their owners, who, if they do not turn and dash off at full speed, have recourse to their balls or to swords. Some have swords obtained from white men; others fasten long blades (knife-blades, perhaps, or pieces of iron hoop, straightened and sharpened) to handles three or four feet in length. Their bows are three or four feet long; and the arrows, about two feet in length, are headed with small triangular pieces of agate, jasper, obsidian, or even bone. But bows, arrows, shields, clubs, and heavy armour are daily less used; and may we not infer, that arms and armour, suited to foot encounters—such as arrows, heavy clubs or maces, shields, and many-fold tunics—have been laid aside by degrees, as horses have multiplied in the country? Fighting on foot is now seldom practised, except in personal quarrels. Falkner says, they used to envenom the points of their arrows with a species of poison, which destroyed so slowly, that the wounded person lingered for two or three months, till, reduced to a skeleton, he at last expired; but I have not heard of such a practice among the southern aborigines in these days.

Those Indians who have felt the effects of fire-arms, and own abundance of horses, the men of Araucania, who are the terror of the Pampa tribes, have long abolished armour and the arms of former wars—wars so well sung by Ercilla, in which they gained unfading honour in maintaining the freedom of their country. Naked on their horses, armed with lances, swords, and balls, those men now rush like the whirlwind—destroy—and are gone!

The women of Patagonia wear nothing on their heads; their hair, parted before and behind, is gathered into two large tresses, one on each side. Ear-ornaments, necklaces, bracelets, and anklets, made of beads, pieces of brass, silver, or gold, are much esteemed. Their mantles are similar to those of the men; but they are pinned across the breast by a wooden skewer, or a metal pin, and are gathered about the waist, hanging loosely almost to their ankles. A short apron, or half-petticoat, made with skins of small animals, or coarse cloth, is tied about their waist, under the mantle. It only covers them in front, and reaches to the knee. Boots, similar to those

© The Complete Work of Charles Darwin Online

of the men, and additional clothes, are worn when they ride distances; sitting astride, upon a heap of skins, which serve at night for bedding.

The principal subsistence of these Indians is the flesh of mares, ostriches, cavies, or guanacoes; but though they are not particular, and eat almost anything that they catch, the flesh of young mares is preferred to any other. They broil their meat, and eat it with a lump of fat, and salt. The fat of mares and that of ostriches are boiled together and put into bladders; but the fat of guanacoes is eaten raw, being preferred in that state. There are two roots which they eat, one called tus, the other chālăs. The tus is a bulbous root, growing wild, which when cleaned and baked, or rather roasted, becomes mealy, like a yam. They use it sometimes with their meat, but not often. The chālăs is a long, white root, about the size of a goose-quill. It is either roasted in the embers or put into broth, which they make for women and sick people. When on the sea-coast, limpets and muscles are gathered by the women and children; but fish or seals are seldom obtained. Dogs are not eaten, neither are horses, unless disabled by an accident.

Cattle are yet scarce in the southern regions, because pasture-land is rather deficient; but about the lately-discovered river, Chupat, (lat. 43.21. S.) which, though small, is supposed to cross the continent, they are rather numerous, but their flesh is not thought equal to that of mares.

The only prepared drink which they use, besides the decoction of chālăs, is the juice of barberries, mixed with water, and drank in its natural state. They have no fermented liquor.

Hunting is both amusing and necessary to the men. They go out to the chase in parties, more or less numerous, according to the strength of the tribe, the scarcity of food, and the supply of horses. An extent of country is enclosed by the horsemen; then drawing together, they drive before them all the animals; till, when tolerably collected together, the cacique, or leading man of the party rides at an animal and throws it down with his balls. All then set to work, and ball away in every direction. They do not stop because one animal falls,

© The Complete Work of Charles Darwin Online

since not one in a hundred escapes by his own exertions when once entangled; but another and another become the victims of a good hunter, before the collection escapes out of his reach. All their sets of balls being employed, and the game dispersed, they begin to kill and divide. Each animal is knocked on the head with a ball, skinned, and cut into pieces, where it fell, and the pieces are then carried on horseback to their huts.

After reaching their settlement, the produce of the chase is brought together, and divided among the different families, in proportion to their respective numbers. If one family has eaten its share sooner than others, some one of that hungry house goes to any party which has meat left, and cuts off what is wanted, without a question.

A number of large dogs assist in the hunt: whether they scent the game I know not, but probably they run by eye, as so many animals are a-foot at once. Each regular hunter has a spare horse at hand; the best horses being carefully reserved for war and the chase. Upon others they travel, place the women and children, and their property.

The method of hunting abovementioned is that employed on set occasions; but if only a few men are together, they surprise and chase, as they can. Sometimes they ride together, and chase whatever they see, whether ostrich, skunk, guanaco, fox, or puma.

The wealth of these Indians consists chiefly in horses and dogs, the richer individuals having forty or fifty horses, and a large number of dogs; the poorer, only one or two horses, and but one dog.

The tents or huts called by themselves 'cow,' and by the Spaniards and their descendants, toldos (tolderia is the place of toldos, or Indian village, in Spanish), have already been partly described. Made of skins, sewed together and supported by poles, a tilt-like construction, open towards the east, is their hastily-formed dwelling. The top slopes towards the west side, which is not above two feet in height. The front is about six or seven feet high; and the inside space about twelve feet by nine. Both poles and skins are carried with them when

© The Complete Work of Charles Darwin Online

they migrate from place to place. Water does not lodge on the hide covering, neither does wind penetrate; and as east winds are very rare in Patagonia, a temporary screen, such as a few skins, suffices for protection against them.

Two or three families sleep in one hut, unless it is the dwelling of a cacique, or person who has many wives. Poor people have but one wife. Those who are rich, and able to maintain them, have several wives—three, four, five, or even more.

In places where some of the tribe stay constantly, and which are considered the head-quarters, or central rendezvous of a tribe, there are larger huts, almost deserving the name of houses. Some of these are for the cacique and his wives; others are for the wizards, who, in their three-fold capacity of priests, magicians and doctors, have great influence over the superstitious minds of their countrymen. These larger dwellings are made with poles and skins, put together so as to form an oblong shed, with a sloping roof, shaped like a small cottage. The substitutes for walls are about five feet in height, and the roof is in the middle about eight feet from the ground. Some of these houses are four or five yards in width, and eight, ten, or twelve in length. I have never seen one myself; but those who gave me other information, which I found true, said that there were such houses in the interior, and described them minutely to me.

At night, skins are spread upon the ground to sleep on; two or three rolled up, along the length of the back part of the tent or hut, form a pillow for the whole party, on which each family has its place, and the dogs lie at their feet.

The children have a little square place to themselves, in one corner. Infants in the cradle (a piece of hide with a thong fast to its four corners, by which it is suspended from the roof of the dwelling), are placed near their mother.

Marriages are made by sale more frequently than by mutual agreement. Instead of receiving a dowry with his wife, a man pays a large price to her nearest relations. Sometimes girls are betrothed while very young, and a part of the stipulated price paid to the relations. Mutual inclination may sometimes determine the choice; but payment must in every case be

© The Complete Work of Charles Darwin Online

made, in proportion to the supposed value of the damsel, and the property of her purchaser. If a girl dislikes a match made for her, she resists, and although dragged forcibly to the hut of her lawful owner, plagues him so much by her contumacy, that he at last turns her away, or sells her to the person on whom she has fixed her affections; but he seldom beats her, or treats her ill. Perhaps she does not wait to be so disposed of, but elopes and takes her choice of a protector; who, if more powerful than the husband, obliges him to submit to the double loss, unless a cacique, or a powerful friend of the losing party, forces the gallant to restore her, or compromise the matter, and these affairs are in general easy to settle. It has been already mentioned that each man who possesses any property has usually more than one wife; and that some few men, who have forty or fifty horses, and other riches in proportion, maintain four or five wives.

"Women who have accepted their husbands with good-will are in general very faithful and laborious," says Falkner; "their lives are but one continued scene of labour; for, besides nursing and bringing up children, they are obliged to do much drudgery." Except hunting, providing food, and fighting, all work is done by the women. Indeed they sometimes aid in battle. Some families have slaves who do household work; but if they should have no slaves, not even the wives of a cacique are exempt from every-day labour.

Men do not marry before they are about twenty years of age. Girls are married earlier: from fourteen or fifteen they are considered to be marketable commodities. Falkner says, "When once the parties are agreed, and have children, they seldom forsake each other, even in extreme old age. The husband protects his wife from all injuries, and always takes her part, even if she is in the wrong, which occasions frequent quarrels and bloodshed; but this partiality does not prevent him from reprimanding her, in private, for engaging him in these disputes.

"He very seldom beats her; if she is found unfaithful he lays blame on the gallant, and, if able, punishes him severely;

© The Complete Work of Charles Darwin Online

unless the delinquent atones by some valuable gift. Sometimes, at the command of a wizard, a man orders his wife to go to an appointed place, usually a wood, and abandon herself to the first person she meets. Yet there are women who refuse to comply with such orders."

When it does happen that a man and his wife quarrel, the woman is sometimes punished by having her two tails rather savagely pulled. I have been told that the husband scarcely ever beats her, except in the height of passion.

Children are left to take care of themselves soon after they can walk. With sets of little balls (bolas) they annoy the dogs not a little, practising their future occupation. While very young they climb upon old, or quiet, horses' backs. If a young guanaco is caught and tamed, or a bird with its wings clipped hops about the tolderia, the little ones have fine sport. While infants are suckling, the mothers use frames or cradles in which their charges are carried about: they are made of flat pieces of wood, with a few semi-circular guards of lath, or thin branches, whose ends are fixed into holes in the wood. In such frames, between pieces of guanaco skin, the babies are placed; and while travelling, these cradles are hung at the mothers' saddle-bows. The children are much indulged. Falkner says, "The old people frequently change their habitations to humour the caprices of their children. If an Indian, even a cacique, wish to change his abode, and the tribe with whom he is living do not choose to part with him, it is customary to take one of his children, and pretend such a fondness for it, that they cannot part with the little favourite. The father, fond of his child, and pleased that it is so much liked, is induced to remain."

Yet with all this apparent goodness of disposition, in moments of passion, these Indians have been seen to be like other savages, disgraced by the worst barbarity. Neither man, woman, wife, nor even a smiling innocent child, is safe from that tiger in human shape—a savage in a rage. "Nunca, nunca fiarse de los Indios," is a Spanish maxim, as well founded as it is common.

© The Complete Work of Charles Darwin Online

Education, and the beneficial effects of the opinions of others, an influence fully felt only in civilized society, have so tamed and diminished the naturally strong passion of anger, with its sequel, immediate violence, or hatred and revenge, that imagination must be called to the assistance of those who, happily, have never seen a furious savage.

Who can read that instance of child murder, related so well by Byron, in his narrative of the Wager's wreck, without a shudder? yet the man who, in a moment of passion, dashed his own child against the rocks, would, at any other time, have been the most daring, the most enduring, and the most self-devoted in its support and defence! (Appendix No. 14.)

Generally speaking, the Patagonians are extremely healthy. Their constitutions are so good that wounds heal rapidly: but they are not ignorant of the healing properties of some herbs; nor of the purgative qualities of others. They know the effect of bleeding, and can adroitly open a vein with a sharp piece of shell or flinty stone.

When sick, the chālăs root, pounded and mixed with water, is a favourite specific. Should this, or the few other remedies which they think they know, fail, the wizard (who is also doctor) performs some absurd ceremonies, and then rattles together two pieces of dry bladder, in which are some loose stones, in order to frighten away the 'Valichu,' or evil spirits, who are opposing their art, and tormenting the unlucky patient. The diabolical noise caused by rattling these dried bladders, is continued until the disease takes a favourable turn, or the sufferer dies. If death ends the scene, the body is wrapped in the best mantle of the deceased, placed on his favourite horse, and carried to the burying-place of the tribe. The wizard rattles, and the other people howl over the corpse as it is carried to the sepulchre. In a square pit, about six feet deep, and two or three feet wide, where many others have been deposited, the corpse is placed in a sitting posture, adorned with mantles, plumes of feathers, and beads. The spurs, sword, balls, and other such property belonging to the deceased, are laid beside him; and the pit is then covered over with branches of

© The Complete Work of Charles Darwin Online

trees, upon which earth is laid. His favourite horse is afterwards killed. It is held at the grave while a man knocks it on the head with one of the balls of the deceased. When dead, it is skinned and stuffed, then, supported by sticks (or set up) upon its legs, with the head propped up, as if looking at the grave. Sometimes more horses than one are killed. At the funeral of a cacique four horses are sacrificed, and one is set up at each corner of the burial place. The clothes and other effects belonging to the deceased are burned: and to finish all, a feast is made of the horses' flesh.

But there are also other modes of disposing of dead bodies: and as I am certain that at least two of them are practised by the Patagonians of the present day, and we are assured by Falkner that other methods, one of which was carrying them into the desert by the sea-coast, were customary in his time, I shall here repeat what he says on the subject (p. 118).

"The burial of the dead and the superstitious reverence paid to their memory, are attended with great ceremony. When an Indian dies, one of the most distinguished women among them is immediately chosen to make a skeleton of his body; which is done by cutting out the entrails, which they burn to ashes, dissecting the flesh from the bones as clean as possible, and then burying them under ground till the remaining flesh is entirely rotted off, or till they are removed (which must be within a year after the interment, but is sometimes within two months) to the proper burial-place of their ancestors.

"This custom is strictly observed by the Molu-che, Taluhet, and Diuihet,* but the Chechehet and Tehuelhet, or Patagonians, place the bones on high, upon canes or twigs woven together, to dry and whiten with the sun and rain.

"During the time that the ceremony of making the skeleton lasts, the Indians, covered with long mantles of skins, and their faces blackened with soot, walk round the tent, with long poles or lances in their hands, singing in a mournful tone of voice, and striking the ground, to frighten away the Valichus,

* The Taluhet, Chechehet, and Diuihet, were tribes of Puel-che.

© The Complete Work of Charles Darwin Online

or evil spirits. Some go to visit and console the widow, or widows, and other relations of the dead, that is, if there is any thing to be got; for nothing is done but with a view of interest. During this visit of condolence they cry, howl, and sing in the most dismal manner; straining out tears, and pricking their arms and thighs with sharp thorns, to make them bleed. For this shew of grief they are paid with glass beads, brass cascabels and such like baubles, which are in high estimation among them. The horses of the dead are also immediately killed, that he may have wherewithal to ride upon in the 'alhue mapu,' or country of the dead, reserving only a few to grace the last funeral pomp, and to carry the relics to their proper sepulchres.

"When they remove the bones of their dead, they pack them up together in a hide, and place them upon one of the deceased's favourite horses, kept alive for that purpose, which they adorn after their best fashion, with mantles, feathers, &c., and travel in this manner, though it be to the distance of three hundred leagues, till they arrive at the proper burial-place, where they perform the last ceremony.

"The Molu-che, Taluhet, and Diuihet, bury their dead in large square pits, about a fathom deep. The bones are put together, and secured by tying each in its proper place, then clothed with all the best robes they can get, adorned with beads, plumes, &c., all of which they cleanse or change once a year. They are placed in a row, sitting, with the sword, lance, bow and arrows, bowls, and whatever else the deceased had while alive. These pits are covered over with trees, canes, or branches woven together, upon which they put earth. An old matron is chosen out of each tribe, to take care of these graves, and on account of her employment is held in great veneration. Her office is to open every year these dreary habitations, and to clothe and clean the skeletons. Besides all this they every year pour upon these graves some bowls of their first-made chicha, and drink some of it themselves to the good health of the dead. (N. B. Not the Tehuelhet.)

"These burying places are, in general, not far distant from

© The Complete Work of Charles Darwin Online

their ordinary habitations; and they place, all around, the bodies of their dead horses, raised upon their feet and supported with sticks.

"The Tehuelhet, or more southern Patagonians, differ in some respects from the other Indians. After having dried the bones of their dead, they carry them to a great distance from their habitations, into the desert by the sea-coast; and after placing them in their proper form, and adorning them in the manner before described, they set them in order above ground, under a hut or tent erected for that purpose, with the skeletons of their dead horses placed around them.

"In the expedition of the year 1746, some Spanish soldiers, with one of the missionaries, travelling about thirty leagues within land, to the west of Port San Julian, found one of these Indian sepulchres, containing three skeletons, and having as many dead horses propped up around it."

In the expeditions of the Adventure and Beagle, between 1826 and 1834, a few burial places of another kind were examined. These were piles of stones, upon the summits of the highest hills, on the eastern sea-coast. Some had been thrown down and ransacked; probably by the crews of sealing vessels: others there was no opportunity of visiting: only one untouched pile was found: and that one was examined by Lieutenant Wickham. It was on a height, near Cape Dos Bahias, in latitude forty-five south. Only bones were found, in a much decayed state, under a pile of stones about four feet high; and from the remains of the bones Mr. Bynoe ascertained that they had belonged to a woman of the ordinary stature. A pile of stones on a neighbouring height had been pulled down by the crew of a sealing vessel: under it were fragments of decayed bones, which were thought too much injured by time and weather to be worth removing; indeed they crumbled to the touch. Under similar heaps of stones the 'gigantic skeletons' which some voyagers have described, were said to have been found.

Doubtless these several methods of disposing of the dead are not those of one horde only, but of various tribes. But I prefer mentioning all that is yet known of the subject, as

© The Complete Work of Charles Darwin Online

far as I am aware,* and leaving it for better-informed persons to decide upon the particular habits of each subdivision. Would any one tribe bury each of the five following persons in a similar manner, and in the same place? A powerful cacique—a wizard—a woman—an ordinary man—a child?

"The widow or widows of the dead are obliged to mourn and fast for a whole year after the death of their husband. This consists in keeping themselves close shut up in their huts, without having communication with any one, or stirring out, except for the common necessaries of life; in not washing their faces or hands, but being blackened with soot, and having their garments of a mournful appearance; in abstaining from horse's and cow's flesh, and, within land where they are plenty, from the flesh of ostriches and guanacoes; but they may eat any thing else. During the year of mourning, they are forbidden to marry, and if, within this time, a widow is discovered to have had any communication with a man, the relations of her dead husband will kill them both, unless it appears that there has been violence. But I did not discover that the men were obliged to any such kind of mourning on the death of their wives." (Falkner, p. 119.)

Manslaughter is not infrequent. When quarrels arise, the parties draw their knives, or take such weapons as are at hand, and fight, if not parted, till one is killed. War often occurs between the smaller tribes, but does not last long. When the small tribes unite against another nation, such as the Molu-che, or the Puel-che of the north, their preparations are more serious, and their hostilities of far longer duration.

When at war, or expecting an attack, the Patagonians exercise on horseback, in their armour, every other evening. Frequently the occasion of hostility is an encroachment upon the territories of a neighbouring tribe, either for hunting or plunder. War is, in such case, instantly declared by the insulted

* Except about the tomb which is described by Captain King in the first volume.

© The Complete Work of Charles Darwin Online

party. In armour, and upon their best horses, they sally forth to meet the intruders. Having met, they ask why their land has been invaded, and desire the strangers to return to the place whence they came. The non-compliance of the intruders is a signal for action; they close—fight—and one party, being vanquished, loses all its property. The manner of fighting has already been mentioned.

The horsemanship of the Patagonians is not equal to that of the northern Indians: yet it is not indifferent. From their weight, and the openness of their country, they do not habitually ride so hard, or practise so many manœuvres as the Araucanian,* who can hang at the side of his horse while at speed, directing him by voice and rein; or even while going through a wood can cling quite beneath his belly for a short time, still urging on and directing him; but such feats, performed by naked men, who are almost centaurs, surpass the powers, or rather the dexterity, of the bulky, well-fed, and heavily-clothed Patagonian.

The Patagonians are very fond of racing. At almost every leisure hour either horses or play engage their attention, for they are also great gamblers. Race-courses are regularly marked out, but they are very short, not a quarter of a mile in length. These short bursts at the utmost speed seem absurd, till one considers that in hunting wild animals, attacking or escaping from the sudden attack of an adversary, such short starts are of the utmost importance. They bet upon the horses, and sometimes stake even their wives and their children. Payment is faithfully made, even to the uttermost. The cards with which they play are pieces of skin, with figures

* The Araucanian hangs at one side of his horse to shelter himself from the lances, balls, or shot of his adversaries, or to avoid trees. At a distance, a troop of these Indians advancing irregularly, might seem to an inexperienced eye merely loose horses, of which so many are seen in the Pampas; but to another Indian, or to a trained gaucho, the attempt to conceal themselves would avail them nothing, because the horses' action, and manner of going, would, at a glance, show him that they were guided by riders.

© The Complete Work of Charles Darwin Online

painted upon them: perhaps rough imitations of the cards used by the Spaniards; but this may be doubted.

According to Falkner, the native of Patagonia is a superstitious polytheist. I cannot add to, nor have I reason to doubt his account; and shall therefore repeat what he says on this subject, abridging it slightly.

"The Indians imagine that there is a multiplicity of deities, some good, others evil. At the head of the good deities is Guayara-kunny, or the lord of the dead. The chief evil agent is called Atskannakanatz, or Valichu. This latter name is applied to every evil demon.*

"They think that the good deities have habitations in vast caverns under the earth, and that when an Indian dies his soul goes to live with the deity who presides over his particular family.

"They believe that their good deities made the world, and that they first created the Indians in the subterranean caverns above mentioned; gave them the lance, the bow and arrows, and the balls, to fight and hunt with, and then turned them out to shift for themselves. They imagine that the deities of the Spaniards created them in a similar manner, but that, instead of lances, bows, &c., they gave them guns and swords. They say that when the beasts, birds, and lesser animals were created, those of the more nimble kind came immediately out of the caverns; but that the bulls and cows being the last, the Indians were so frightened at the sight of their horns, that they stopped the entrances of their caves with great stones. This is the grave reason they give why they had no black cattle in their country, till the Spaniards brought them over; who, more wisely, had let them out of their caves.

* The Patagonians call the good deity the Creator of all things, but consider him as one who afterwards has no concern about them. He is styled by some Soucha, or chief in the land of strong drink; by others, Guayara-kunny, or lord of the dead. The evil principle is called Huecovoe, or the wanderer without. Other spirits are supposed to take care of particular people—protect their own and injure others: they are called Valichu.—Pennant, p. 61.

© The Complete Work of Charles Darwin Online

"Some say that the stars are old Indians; that the milky way is the field where the old Indians hunt ostriches, and that the Magellan clouds are the feathers of the ostriches which they kill. They have an opinion that the creation is not yet exhausted; nor all of it yet come out to the daylight of this upper world. The wizards, beating their drums, and rattling their hide-bags full of shells, or stones, pretend to see into other regions under the earth. Each wizard is supposed to have familiar spirits in attendance, who give supernatural information, and execute the conjuror's will. They believe that the souls of their wizards, after death, are of the number of these demons, called Valichu, to whom every evil, or unpleasant event is attributed.

"Their religious worship is entirely directed to the powers of evil; except in some particular ceremonies made use of in reverence to the dead.

"To perform their worship they assemble together in the tent of the wizard, who is shut up from the sight of the rest in a corner. In this seclusion he has a small drum, one or two round calabashes or bags of dry hide, with small sea shells in them, and some square bags of painted hide in which he keeps his spells. He begins the ceremony by making a strange noise with his drum and rattle-bags; after which he feigns a fit, or struggle with the evil spirit, who it is then supposed has entered into him; keeps his eyes turned up, distorts his face, foams at the mouth, screws up his joints, and, after many violent and distorting motions, remains stiff and motionless, resembling a man seized with an epilepsy. After some time he comes to himself, as having overcome the demon's influence; next he feigns, behind his screen, a faint, shrill, mournful voice, as of the evil spirit, who, by this dismal cry, is supposed to acknowledge himself subdued; and then the wizard, from a kind of tripod, answers all questions that are put to him.

"Whether his answers are true or false, is of very little consequence; because, if his intelligence should prove false, it is the fault of the demon, or Valichu. On all these occasions the wizard is well paid.

© The Complete Work of Charles Darwin Online

"The profession of the wizards is very dangerous, notwithstanding the respect that is sometimes paid to them; for it often happens, when an Indian chief dies, that some of the wizards are killed; especially if they had any dispute with the deceased just before his death; the Indians, in this case, attributing the loss of their cacique to the wizards and their demons. In cases also of pestilence and epidemic disorders, when great numbers are carried off, the wizards often suffer.

"On account of the small-pox, which almost destroyed the Chechehet tribe, Cangapol ordered all the wizards to be killed, to see, if by such means, the distemper would cease.

"There are wizards and witches. The former are obliged to dress in female apparel, and are not allowed to marry. The latter are not restricted. Wizards are generally chosen when children; and a preference is always shewn to those who, at that time of life, discover an effeminate disposition. They are clothed very early in female attire, and presented with the drum and rattles belonging to the profession which they are to follow. Those who are seized with fits of the falling sickness, or the 'Chorea Sancti Viti' (St. Vitus's dance), are immediately chosen for this employment, as selected by the demons themselves; whom they suppose to possess them, and to cause all those convulsions and distortions common in epileptic paroxysms."

The Patagonians, and indeed all the South-American aborigines, have faith in witchcraft. They all believe that the wizards or witches can injure whom they choose, even to deprivation of life, if they can possess themselves of some part of their intended victim's body, or that which has proceeded thence—such as hair, pieces of nails, &c.; and this superstition is the more curious from its exact accordance with that so prevalent in Polynesia.

The tribe, or subdivision of the Tehuelhet who generally live near Magalhaens' Strait, have learned to pay a sort of homage (perhaps it may be termed worship) to an image of wood, cut into the figure of a man's head and body, and called Cristo; this image they rarely produce to strangers, or even amongst

© The Complete Work of Charles Darwin Online

themselves, except at deaths, or on very particular occasions. This attempt at an outward demonstration of faith in customs of the Romish church, appears to have been caused by a Captain Pelippa, who visited the Strait of Magalhaens some time before the Adventure and Beagle. Who or what he was, I could not discover.

There is a particular kind of tree, which is esteemed sacred, and never burned. It is like a thorn; a resinous gum issues from the knotty, close-grained stem, which has a pleăsant aromatic smell, if put into the fire.

Regular government, or any forms and rules approaching to what may be called a civil constitution, no one would expect to find among tribes of wandering savages; but amongst the Araucanian tribes of Moluche, who do not wander, and have advanced towards civilization, there are regular laws, supporting a settled form of government; and their ideas have been communicated to the southern tribes, and have slightly influenced them. Thus, in many cases, offenders are tried by an assembly of the older people, and their sentence pronounced, after mature deliberation, instead of being at once dealt with as the cacique may, at first thought, deem expedient.

The caciques or chiefs are hereditary. Those who possess much property and have many followers are highly respected; but their authority, though absolute in some instances, is little exerted in the common occurrences of life. When meetings are held for the purpose of deciding upon any question, the cacique presides—that is, he is considered the principal person present; certainly he looks the most solemn, and is the least active. He gives orders to hunting parties, or to those who exercise for war: and if men quarrel, he sometimes causes them to be parted. In time of war he leads his tribe, and in proportion to his enterprise and success is his actual authority while the war lasts. Each person has a particular name, implying a quality or some peculiarity; sometimes a particular place.

"All the sons of a cacique," says Falkner, "have a right to assume the dignity, if they can get any persons to follow them;

© The Complete Work of Charles Darwin Online

but, on account of the small utility of the rank of cacique, it is often resigned."

Falkner's account of the caciques ought to be, and is, no doubt, one of the best; it is as follows:—

"The cacique has the power of protecting as many as apply to him; of composing or silencing any difference; or delivering over the offending party to be punished with death, without being accountable for it. In these respects, his will is the law. He is generally too apt to take bribes, delivering up his vassals, and even his relations, when well paid for it. According to his orders, the Indians encamp, march, or travel from one place to another, to hunt or make war. He frequently summons them to his tent, and harangues them upon their behaviour; the exigencies of the time; the injuries they have received; the measures to be taken, &c. In these harangues, he always extols his own prowess and personal merit. When eloquent, he is greatly esteemed; and when a cacique is not endowed with that accomplishment, he generally has an orator, who supplies his place" (as in Polynesia).

"In cases of importance he calls a council of the principal Indians and wizards, with whom he consults about the measures to be taken, to defend himself or attack his enemies. In a general war, when many nations unite against a common enemy, as in the great alliances against the Spaniards, they choose a commander-in-chief, called Apo (or Toqui), from among the oldest or most celebrated caciques; but this honour though properly elective, has for many years been hereditary in the family of Cangapol. (Written in 1780.)

"The caciques have not the power to raise taxes, or to take away any thing from their vassals; nor can they oblige them to serve in the least employment, without paying them. They are obliged to treat their vassals with great humanity and mildness, and oftentimes to relieve their wants, or they will seek the protection of some other chief. For this reason, many of those who are born caciques refuse to have any vassals, as they cost them dear, and yield but little profit. No Indian, or body of Indians, can live without the protection of

© The Complete Work of Charles Darwin Online

some cacique, according to their law of nations; and if any of them attempted to do so, they would undoubtedly be killed, or carried away as slaves, as soon as they were discovered.

"In case of any injury, notwithstanding the authority of the cacique, the party aggrieved often endeavours to do himself justice to the best of his power. They know of no punishment or satisfaction, but that of paying or redeeming the injury or damage done with something of value. If the offence is not very great, and the offender is poor, the injured party perhaps beats him with his balls on the back and ribs; but, in general, they do not chastise, except by death. When the offender is too powerful, they let him alone; unless the cacique interferes, and obliges him to make satisfaction."

A curious plant is found in Patagonia (and at the Falkland Islands), somewhat like a very large and very solid cauliflower. It is greenish, or yellowish-green, tough, and very abundant. It grows upon and close to the ground, forming a lump like a large ant-hill overgrown with moss and grass. From the succulent stalks of this plant a balsamic juice or sap exudes, which is particularly good for healing wounds.

Battles between tribes are carried on similarly to their wars against a nation; but, of course, on a smaller scale. The attacking party halts at a great distance from the enemy, and sends out scouts to reconnoitre. These emissaries hide during the day, but at night examine every detail most minutely, and return to the camp with a full account of their opponent's strength and position. When the moon is near, or a little past the full, showing good light for their work, they advance to the attack. A few hours after midnight they make the assault, kill all the men who resist, and carry away the women and children for slaves.

Sometimes the Indian women follow their husbands, and share in the booty. Laden with plunder, they all retreat as hastily as possible, resting neither night nor day, till they are at a great distance, and out of the reach of their enemies. Sometimes they ride more than a hundred leagues from the place of attack before stopping to rest, and divide the booty.

© The Complete Work of Charles Darwin Online

On such occasions, if fearful of pursuit, or hard pressed by pursuers, they stop very little by the way—light no fire—eat but little food, and that raw—and some are even able to change horses without checking their speed, or touching the ground. A troop of loose horses is always driven along before the party: and when an Indian, at such a time, wants to change, he rides along-side of a loose horse, jumps on his back, bridle in hand, and in an instant, the bit is transferred from one to the other. Saddle they care not for, when thus pressed.

In guiding and managing their horses, the Indians use the voice with very good effect. The best of those animals are exceedingly well trained; and the owners are as reluctant to part with them as Arabs are to sell their steeds.

The natives of Patagonia breed their own horses as well as dogs: but their constant practice of killing the horses of men who die tends to prevent their being numerous. Upon such occasions, all, excepting the few which had been assigned to his children (generally one or two to each child at its birth), are killed. Dogs have a similar fate. With such laws, a man need not fear being put out of the way for the sake of his property; nor, while the women are enjoined to go through such a mourning ordeal, is it likely they would enter into or favour any combination made against their husbands, however harshly they might be treated by them.

Excepting that of the caciques, I believe there is no superiority of one person over another among the Patagonians. Those who have more property than others, or who are related to the chief, have influence over the rest, but are not considered by them to be their superiors.

The moral restraints of these people seem to be very slight. Each man is at liberty to do very much as he feels inclined; and, if he does not injure or offend his neighbour, is not interfered with by others. Their social habits are those handed down by their ancestors, and adapted to the life they are compelled to lead. Ideas of improvement do not trouble them. Contented with their fine climate—plenty of wholesome food, and an extensive range of country—they rather pity white

© The Complete Work of Charles Darwin Online

people, who seem to them always in want of provisions, and tossed about at sea. These natives have a great dislike to the motion of a ship; yet, for novelty, they will go afloat when opportunity offers.

In landing at Gregory Bay, Mr. Low has had much trouble in preventing the natives from crowding into his boat, all being anxious to see the vessel. Once, when many strange Indians (of another tribe) were present, he was obliged to affect to quarrel with them; and afterwards they behaved better and were quite civil, but he never allowed his boat to be grounded. Having left a Dutchman as boat-keeper, the natives teased him into a quarrel, and then dragged him out of the water, boat and all, with their lassoes, leaving him among the bushes, frightened and spluttering, while they galloped off, laughing heartily. The Dutchman hastened to Mr. Low; but while he was gone, the boat was put into the water by the authors of the trick, who then dashed off at full speed, highly amused at their feat. Mr. Low gave one of the women a gay gown: it was the first she had seen; and wishing to suckle her infant, she put it under the skirt of the gown, and, with some difficulty, forced the little thing upwards to her breast.

When the Patagonians meet white men, their inclinations are almost always friendly; but if they find themselves able to dictate to the strangers, a tribute of tobacco, bread, muskets, powder, ball, or such articles as they see and fancy, is often imposed.

A trading schooner called at Gregory Bay (in the Strait of Magalhaens) in 1834. Her mate landed, and was asked for various things which he could not or did not wish to give. The natives detained him as a prisoner; sent his boat away; and kept him till his ransom (tobacco and bread) was sent ashore.

Considerable traffic for knives, swords, muskets, ammunition, tobacco, bread, and, latterly, spirits, has been kept up between the southern Patagonians and the vessels which have touched on their shores (especially at Gregory Bay) in going through the Strait. Their returns have been mantles, skins, and fresh guanaco meat.

© The Complete Work of Charles Darwin Online

During late years, several persons, run-away seamen and others, have passed many months—some, indeed, have passed years—in their company,—living as they live.

In 1833-34, one of the most influential individuals among them was a Chilian, named San Leon, who had been carried to Patagonia by Mr. Brisbane, for the purpose of trading with the Indians for horses. He ran away from the vessel (1830-32), and has since lived with the tribe who are generally found near Gregory Bay. His wife is the daughter of an old native who possesses much property (according to their ideas); she speaks a little Spanish, and interprets for strangers better than her husband, whose knowledge of the Indian language is very slight. Bred in Chile, San Leon is a good horseman, and considered by the Indians to be an excellent hunter.

Mr. Low thinks that the natives would encourage and be friendly to a settlement of white people, made in Patagonia. They profess to like white men, and to wish some to live with them: when old Maria (the woman previously mentioned) was at the Falkland Islands, Mr. Low told her that he intended to build a house at Gregory Bay, and carry white people with him to live there, at which she and her party (including the wizard) seemed to be much pleased.

Mr. Low considers that those natives who live eastward and northward of the First Narrow are not of the same tribe as those who are generally about Gregory Bay, with whom, he says, they are frequently at war. He also thinks that those who live farther westward, near Otway and Skyring Waters, form another subdivision. The following notices, written from his dictation, will show that what I have already stated respecting these minor tribes, considered as subdivisions of one large body or nation, cannot be very far wrong:—

During the stay of the Unicorn (Mr. Low's vessel) in the channel between Otway and Skyring Waters, a fire was made, as a signal to the Indians. They soon began to arrive in small detached parties, some of whom were known to Mr. Low, whose acquaintance with them had been formed at Gregory Bay. They travelled in small parties, therefore were not,

© The Complete Work of Charles Darwin Online

in all probability, on bad terms with their neighbours at that time.

Those who first arrived were invited on board; but declined going, because their chief was expected: and with the last party came a boy, about nine years' old, fantastically decked with ornaments of copper and brass, with beads, and with a new mantle. A tall, fine-looking man, of the Gregory Bay tribe, accompanied this young cacique, and made him known to Mr. Low, by the name of 'Capitan Chups.'

These natives have adopted the word 'capitan,' and now always use it when addressing white men who they suppose have authority. When some Patagonians of the Gregory Bay party came on board the Beagle, in 1834, seeing a larger number of officers than is usual in small vessels, one of the first questions asked, in broken Spanish, was, "Quanto capitanes abordo?"

Little Capitan Chups seemed to have no small idea of his own consequence, and tried to affect much dignity. He willingly went on board the Unicorn; but not a native would enter the boat until the young chief was seated, when there was a most inconsistent scramble, which nearly swamped it. However, after pushing out a few of the intruders, the party reached the vessel in safety. On board her was a Patagonian boy, who had been four months with Mr. Low, and had been clothed at Monte Video. He had recognized Capitan Chups at a distance, said who he was, and showed by his manner that he considered him a person of high distinction. The little cacique called this boy, asked him many questions, and examined every part of his dress. Afterwards the boy joined some of his own family, who were present. He had before refused to go to the party at Gregory Bay, while there in the vessel, alleging that they were not his people.

Mr. Low said, that the tribe on the banks of this channel were mixed, being partly horse and partly canoe Indians. They were entirely under the dominion of the Gregory Bay party, who appointed their chiefs. Maria's son, called 'Capitan Chico,' was their ruler, until the arrival of Capitan Chups.

FUEGIANS GOING TO TRADE IN ZAPALLOS WITH THE PATAGONIANS.

Published by Henry Colburn, Great Marlborough Street, 1839.

© The Complete Work of Charles Darwin Online

Yet Mr. Low did not think that the little capitan belonged to any of the families residing near Gregory Bay, but to some part of the same tribe who live far inland. Maria's son, Chico, was subsequently cacique, or acting as cacique of the Gregory Bay party. Had this western tribe been under the dominion of the Gregory Bay party, would the successor to Chico have been taken from a tribe who live far inland?

The apparent mixture of horse and canoe Indians appears to me to have been an accidental consequence of the fire made as a signal, which called to the spot horsemen from the north and canoes from the south. The novelty of a vessel anchoring in a place never before disturbed by such a visitor, might well suspend hostilities between neighbouring tribes, even had they been at war; but there is every reason to conclude that the canoe men of the south side of those waters have frequent and even amicable intercourse with the horsemen of Patagonia. A part though of that amicable intercourse consists in selling their children to the Patagonians for slaves. The following incident led to the discovery of this slave-trade: Mr. Low heard Maria talking of 'zapallos,'* and asked her if she could get some for him—and how many? He thought she meant pumpkins (for which zapallos is Spanish); Maria replied, "two boat loads," and to show of what, pointed to a young slave, lately purchased from the Fuegians. When there are more zapallos among them than are wanted for slaves, or than suits their convenience, what becomes of them? While young, they may be more useful than when they grow old; and a wandering people, subsisting by hunting, would not in all probability take the trouble of providing for useless slaves, who might maintain themselves. The Patagonians are not so barbarous as to kill them; then what becomes of those zapallos? If they are not sent to the borders of the Skyring and Otway Waters, there to shift for themselves, with perhaps a few old horses, and even some young men who help them to hunt, the employment of their later years is unexplained.

* 'Zapallos,' or some word of similar sound.

© The Complete Work of Charles Darwin Online

The canoe Indians are in reality despised by the Patagonians; but, for the sake of trade, are generally kept upon half-friendly terms. For dogs, old horses, guanaco meat, and old mantles, the former give pieces of iron pyrites (used for striking fire), their captives, or their children.

Patagonians have a great antipathy to negroes. As soon as they see a black man, they shout, hoot, hiss, and make faces at him.

No signs of hieroglyphics or writing have been noticed among the Patagonians. They can reckon as far as thousands. Time is counted by years and moons, days and nights. There are particular words denoting the various phases of the moon, the seasons of the year, and the times of day and night. In counting, the fingers and toes are used, as well as words expressing numbers, especially when trying to make their meaning clear to strangers. Once, when Mr. Low was leaving Gregory Bay, he gave Maria to understand that he would return again in four moons, and asked her to have some guanaco meat ready for him when he should arrive. He returned a fortnight before his time. No meat was ready. Maria said he was too soon, explaining herself by holding three fingers up, and the fourth bent half down. The few words of their language which have been collected by me are mentioned in the Appendix.

The Patagonians pay respect to old people, taking great care of them; they seldom move about on ordinary occasions, but remain near the tolderia (village or encampment) with the herds of mares.

It has been mentioned that the Patagonians have lately taken a liking to spirits. When intoxicated, they are very noisy, but not quarrelsome. They are very fond of tobacco; and use some sort of pipe, frequently ornamented with brass and tassels: it is passed round from one to the other. They neither work, nor use any metal but what is obtained from white men. There is no kind of pottery made by them: wooden vessels, or bladders, being used for containing water. Many of them now have iron kettles, in which meat is sometimes boiled, but their usual mode of cookery is roasting; a

© The Complete Work of Charles Darwin Online

piece of meat being put upon a wooden skewer, which is stuck into the ground near their fire.

The conduct of the women does not correspond to their character drawn by Falkner; but their ideas of propriety may have been altered by the visits of licentious strangers. Both at Gregory Bay (on the north shore of Magalhaens Strait), and at the River Negro, the Patagonian women are now thought to be unfaithful to their husbands, and to care little about chastity. The men appear to give themselves no anxiety on the subject. Spirits, provisions, and (to them) valuable articles of hardware, or clothing which they receive, occupy much more of their attention.

These Indians do not appear very sensible of heat or cold, if one may judge from their habits of life, and from their clothing; in the latter, the only difference made during the coldest part of winter is wearing horse-hide boots more constantly. In summer, their feet and legs are generally naked. Both men and women wash themselves occasionally, neither regularly nor often; but the women are rather less uncleanly than the men. I have elsewhere mentioned that they comb their hair with the jawbone of a porpoise (obtained from the zapallos). They have also a small brush, made of coarse grass, twigs, or rushes, with which their toilet is assisted.

When Mr. Low was returning from Monte Video, with the boy on board who has been spoken of as recognizing Capitan Chups, some natives were seen on Elizabeth Island (Strait of Magalhaens). A boat was sent, with the boy in her, to trade with them for skins. When near enough to distinguish persons, he seemed extremely frightened—clung to the thwarts of the boat—and begged not to be landed. These were canoe Indians, but of what tribe was not ascertained: he said they would certainly kill him. Some time after this boy had rejoined his family, Mr. Low was informed, by the Gregory Bay people, that he had collected seal-skins for 'Capitan Low,' which he would not part with to any other person, as he knew they were the object of his friend's trading voyages. This instance of gratitude for kind treatment speaks well for both

© The Complete Work of Charles Darwin Online

parties: but, indeed, every white man who has passed any time among the Patagonian Indians agrees in giving a favourable account of the treatment experienced. The 'Basket-maker,' however, would fare better than the 'Scholar,' I fancy, with these, as well as with most other tribes of savages, until ideas could be communicated clearly.*

The dogs now found in the southern part of Patagonia have a wolfish appearance—their size, colour, hair, ears, nose, tail, and form being in general much like those of a wolf; though some black or spotted dogs are also seen. The roof of the mouth is black: the ears are always erect, and the nose sharp-pointed. I should say that their usual height is about that of a large fox-hound. Generally the coat is harsh or wiry, and rather short; but there are some dogs among them which have thick woolly coats, like those of Newfoundland or large shepherd's dogs, which some resemble; others being more like lurchers; but all have a wild wolf-like look, not at all prepossessing. I had a fine dog of this kind, rather like a Newfoundland, except in physiognomy, but his habits were so savage that he came to an untimely end. These dogs hunt by sight, without giving tongue; but they growl or bark loudly at the approach of strangers. As to attachment to their masters, the dogs we had could hardly give fair testimony, having been taken (bought) from them; but to strangers they were always snappish.

* With reference to what has been already mentioned about their migratory inclinations, I will here annex an omitted date:—Maria and her companions were at Gregory Bay in November 1831: at the River Negro in September 1832: and again at Gregory Bay, in the Strait of Magalhaens, in March 1833.

CHAPTER IX.

Features—Form—Paint—Disposition—Food—Doctor—Religious ideas Superstitions — Marriage — Death—Burial—Cannibalism—Weapons —Women's occupation—Training—Obtaining food—Fire—Language —Sagacity and local knowledge—Battles — Ceremony — Natives in Trinidad Gulf—Obstruction Sound—Potatoes—Dogs.

The most remarkable traits in the countenance of a Fuegian are his extremely small, low forehead; his prominent brow; small eyes (suffering from smoke); wide cheek-bones; wide and open nostrils; large mouth, and thick lips. Their eyes are small, sunken, black, and as restless as those of savages in general. Their eyelids are made red and watery by the wood smoke in their wigwams. The chin varies much; that of a Tekeenica is smaller and less prominent than that of an Alikhoolip, in whom it is large and rather projecting, but there is much variety. The nose is always narrow between the eyes, and, except in a few curious instances, is hollow, in profile outline, or almost flat. The mouth is coarsely formed (I speak of them in their savage state, and not of those who were in England, whose features were much improved by altered habits, and by education); their teeth are very peculiar: no canine, or eye-teeth, project beyond the rest, or appear more pointed than those; the front teeth are solid, and often flat-topped like those of a horse eight years old, and enamelled only at the sides: the interior substance of each tooth is then seen as plainly, in proportion to its size, as in that of a horse. Their hair is black, coarse, and lank, excepting the few instances mentioned in the next page. It grows by single hairs, not by piles, or by little bunches like very small camel-hair pencils. It does not fall off, nor does it turn gray until they are very old. Little, if any, hair is seen on the eye-brow. They would have a straggling beard, but scrupulously pull out every hair with tweezers made of muscle-shells.

© The Complete Work of Charles Darwin Online

As exceptions to the general appearance of these people, it ought to be said that, among the Fuegians, I have seen several individuals, both men and women, with curly or frizzled hair (like that of some of the Polynesians or Malays), with rather high foreheads, straight or aquiline noses; and in other features allied to the natives of New Zealand rather than to their countrymen of Tierra del Fuego. I was much struck by those exceptions, and, at the time, conjectured that they might be descendants of the Spanish colonists at Port Famine: but since then, having seen the Polynesians, I have been led to think otherwise; as will be mentioned in a future page relating to New Zealand.

Phrenological remarks on the forms of their heads are added in the Appendix: some were made on the spot by Mr. Wilson, the former surgeon of the Beagle, and others by a person in London. Mr. Wilson's paper also contains anatomical remarks and measurements. In this place it will be sufficient to remark that their heads are remarkably low, but wide; and full from the ears backward. The neck of a Fuegian is short and strong. His shoulders are square, but high; his chest and body are very large. The trunk is long, compared to the limbs and head. His arms and legs are rounder, and less sinewy, than those of Europeans; his joints are smaller, and his extremities are likewise comparatively less. The hands are shaped like those of Europeans, but the feet, from always going barefooted, are square at the toes, and would, by some persons, be considered of the Papua form. Most of them are rather bow-legged, and they turn their feet a little inwards in walking. The knee is strained by the custom of sitting so long on their heels, so that, when straightened, there are considerable folds or wrinkles of loose skin above and below the joint. The muscles of their thighs are large, but those of the legs, small. Little children are nearly of the same hue as their parents' skin is when cleaned; but infants are, for a few days, rather lighter coloured.

As I have already said, a small fillet is all that is worn around the head. Usually this is a mere string, made of the

© The Complete Work of Charles Darwin Online

sinews of birds or animals; but, to make a show, they sometimes stick feathers, bits of cloth, or any trash given to them, into these head-bands. White feathers, or white down, on the fillet, is a sign of hostility, or of being prepared for war. Red is the favourite colour, denoting peace, or friendly intentions, and much admired as ornamental. Red paint, made with ochre, is profusely used. Their white* paint is added to the red when preparing for war; but the marks made are mere daubs, of the rudest, if of any design. Black is the mourning colour. After the death of a friend, or near relation, they blacken themselves with charcoal, and oil or grease. Any sort of clay is used, if their paint is scarce, to preserve warmth rather than as an improvement to their appearance.

When discovered by strangers, the instant impulse of a Fuegian family is to run off into the wood with their children, and such things as they can carry with them. After a short time, if nothing hostile is attempted by the intruders, and if they are not too numerous, the men return cautiously, making friendly signs, waving pieces of skins, rubbing and patting their bellies, and shouting. If all goes on quietly, the women frequently return, bringing with them the children; but they always leave the most valuable skins hidden in the bushes. This hasty concealment of seal or otter skins is the result of visits from sealers, who frequently robbed Fuegian families of every skin in their possession, before the natives understood the motives of their expeditions in boats into the interior waters of Tierra del Fuego. Sometimes nothing will induce a single individual of the family to appear; men, women, and children hide in the thick woods, where it would be almost impossible to find them, and do not show themselves again until the strangers are gone: but during the whole time of their concealment a watchful look-out is kept by them upon the motions of their unwelcome visitors.

Scarcity of food, and the facility with which they move from one place to another in their canoes, are, no doubt, the reasons

* Aluminous earth, indurated pipe clay, or decomposed feldspar.

© The Complete Work of Charles Darwin Online

why the Fuegians are always so dispersed among the islands in small family parties, why they never remain long in one place, and why a large number are not seen many days in society. They never attempt to make use of the soil by any kind of culture; seals, birds, fish, and particularly shell-fish, being their principal subsistence; any one place, therefore, soon ceases to supply the wants of even one family; hence they are always migratory.

In a few places, where the meeting of tides causes a constant supply of fish, especially porpoises, and where the land is broken into multitudes of irregular islets and rocks, whose shores afford an almost inexhaustible quantity of shell-fish, a few families may be found at one time, numbering altogether among them from twenty to forty souls; but even those approaches towards association are rare, and those very families are so migratory by nature, that they do not remain many months in such a spot, however productive it may be, but go wandering away among the numerous secluded inlets or sounds of their country, or repair to the outer sea-coast in search of seals, a dead whale, or fragments of some wrecked ship. During the summer they prefer the coast, as they then obtain a great quantity of eggs and young birds, besides seal, which come ashore to breed at that season; and in the winter they retire more into the interior waters in search of shell-fish, and the small but numerous and excellent fish which they catch among the sea-weed (kelp).

The substitutes for clothing, the arms, canoes, and dwellings of the Fuegians have been so often described already, that I will not tire the reader by a repetition. Some of their customs, hitherto not related, may be more interesting.

There is no superiority of one over another, among the Fuegians, except that acquired gradually by age, sagacity, and daring conduct; but the 'doctor-wizard' of each party has much influence over his companions. Being one of the most cunning, as well as the most deceitful of his tribe, it was not surprising that we should always have found the 'doctor' concerned in all mischief and every trouble arising out of our intercourse

© The Complete Work of Charles Darwin Online

with these natives. It became a saying among us, that such a person was as troublesome as a Fuegian doctor.

In each family the word of an old man is accepted as law by the young people; they never dispute his authority. Warfare, though nearly continual, is so desultory, and on so small a scale among them, that the restraint and direction of their elders, advised as they are by the doctors, is sufficient.

Ideas of a spiritual existence—of beneficent and evil powers—they certainly have; but I never witnessed or heard of any act of a decidedly religious nature, neither could I satisfy myself of their having any idea of the immortality of the soul. The fact of their believing that the evil spirit torments them in this world, if they do wrong, by storms, hail, snow, &c., is one reason why I am inclined to think that they have no thought of a future retribution. The only act I have heard of which could be supposed devotional, is the following. When Matthews was left alone with them for several days, he sometimes heard a great howling, or lamentation, about sun-rise in the morning; and upon asking Jemmy Button what occasioned this outcry, he could obtain no satisfactory answer; the boy only saying, "people very sad, cry very much." Upon one occasion, when some canoes were alongside the Beagle, at a subsequent visit to the Beagle Channel (in 1834), a sudden howl from one of the Fuegians aroused several others who were near, and at the opposite side of the vessel, when a general howl of lamentation took place, which was ended by a low growling noise. By this, as well as by pulling their hair, and beating their breasts, while tears streamed down their faces, they evinced their sorrow for the fate of some friends who had perished, some days before the Beagle's arrival, by the upsetting of a loaded canoe.* There was no regular weeping, nor any thing at all like the downright cry of a civilized being; it was a noise which seemed to be peculiar to a savage. This howling was mostly among the men, only one young woman was similarly affected. Now whether the noises heard by

* The bottom of a Fuegian canoe is full of mud, or clay, for the fireplace.

© The Complete Work of Charles Darwin Online

Matthews were occasioned by similar feelings, or by those of a devotional nature, I cannot pretend to say.

The natives whom I carried to England often amused us by their superstitious ideas, which showed, nevertheless, that their ideas were not limited by the visible world. If any thing was said or done that was wrong, in their opinion it was certain to cause bad weather. Even shooting young birds, before they were able to fly, was thought a heinous offence. I remember York Minster saying one day to Mr. Bynoe, when he had shot some young ducks with the old bird—'Oh, Mr. Bynoe, very bad to shoot little duck—come wind—come rain—blow—very much blow."

A great black man is supposed to be always wandering about the woods and mountains, who is certain of knowing every word and every action; who cannot be escaped, and who influences the weather according to men's conduct. York related a curious story of his own brother, who had committed a murder. "In woods of my country," said he, "some men go about alone; very wild men—have no belly (meaning probably that they were very thin), live by stealing from other men." He then went on to say, that his brother had been getting birds out of a cliff, and, on coming down, hid them among some long rushes, and went away. Soon afterwards he returned, and, seeing feathers blown away by the wind from the spot, suspected what was going on; so taking a large stone in his hand, he crept stealthily towards the place, and there saw one of these wild men plucking a bird which he had got out of the cliff. Without saying a word, he dashed the stone at the wild man's head, and killed him on the spot. Afterwards York's brother was very sorry for what he had done, particularly when it began to blow very hard. York said, in telling the story, "rain come down—snow come down—hail come down—wind blow—blow—very much blow. Very bad to kill man. Big man in woods no like it, he very angry." At the word 'blow,' York imitated the sound of a strong wind; and he told the whole story in a very low tone of voice, and with a mysterious manner; considering it an extremely serious affair.

© The Complete Work of Charles Darwin Online

Jemmy Button was also very superstitious, and a great believer in omens and dreams. He would not talk of a dead person, saying, with a grave shake of the head, "no good, no good talk; my country never talk of dead man." While at sea, on board the Beagle, about the middle of the year 1832, he said one morning to Mr. Bynoe, that in the night some man came to the side of his hammock, and whispered in his ear that his father was dead. Mr. Bynoe tried to laugh him out of the idea, but ineffectually. He fully believed that such was the case, and maintained his opinion up to the time of finding his relations in the Beagle Channel, when, I regret to say, he found that his father had died some months previously. He did not forget to remind Mr. Bynoe (his most confidential friend) of their former conversation, and, with a significant shake of the head said, it was "bad—very bad." Yet those simple words, as Mr. Bynoe remarked, seemed to express the extent of his sorrow, for after that time he said no more about his father. This subsequent silence, however, might have been caused by the habit already noticed, of never mentioning the dead.

When a person dies, his family wrap the body in skins, and carry it a long way into the woods; there they place it upon broken boughs, or pieces of solid wood, and then pile a great quantity of branches over the corpse. This is the case among the Tekeenica and Alikhoolip tribes, as well as the Pecheray; but how the others dispose of their dead, I know not, excepting that, on the west coast, some large caves have been found, in which were many human bodies in a dried state. One of these caves is mentioned in Byron's narrative of the wreck of the Wager: and another was seen by Mr. Low, which will be spoken of in describing the natives of the western coast of Patagonia (the Chonos Indians), who from their intercourse with the Spaniards may be supposed to have acquired ideas somewhat more enlarged than those of the southernmost regions —the Alikhoolip and Tekeenica. I prefer relating all that I know of these tribes, in consequence of the intercourse carried on with them by the Beagle's officers and myself, and the visit

© The Complete Work of Charles Darwin Online

of York, Jemmy, and Fuegia to England, before any of Mr. Low's account is given; because, as his intercourse was chiefly with the Chonos tribe, and was quite unconnected with the Beagle's visit, it will be more satisfactory to the reader to be enabled to compare accounts from different sources, which in some points are so strikingly similar, that their agreement gives great weight to the whole.

The Fuegians marry young. As soon as a youth is able to maintain a wife, by his exertions in fishing or bird-catching, he obtains the consent of her relations, and does some piece of work, such as helping to make a canoe, or prepare seal-skins, &c. for her parents. Having built or stolen a canoe for himself, he watches for an opportunity, and carries off his bride. If she is unwilling, she hides herself in the woods until her admirer is heartily tired of looking for her, and gives up the pursuit; but this seldom happens. Although this is undoubtedly the custom among many of them, we had some reason to think there were parties who lived in a promiscuous manner—a few women being with many men. It is, however, hardly fair to judge from what we saw during our short visit, when the ordinary habits of their life were certainly much altered. We observed, while at Woollya, a disproportionately small number of females; but it ought to be remembered, that the people whom we then saw came to look at us from a distance, and that the greater part of their women and children were probably left in security at various places, as were the women and children of those who stole our boat in the former voyage (vol. i. p. 394) whom we found in a retired nook, far out of ordinary observation.

Jemmy Button often talked of his father, mother, brothers, and sisters, also of uncles* and aunts, after he knew enough of our language to understand distinctly the relationship. Now this could not have been the case had not his father and mother lived together permanently as man and wife, according to the clear account which he himself always gave of their custom in this respect.

* It was an uncle who gave him to me for some buttons.

© The Complete Work of Charles Darwin Online

From the concurring testimony of the three Fuegians above-mentioned, obtained from them at various times and by many different persons, it is proved that they eat human flesh upon particular occasions, namely, when excited by revenge or extremely pressed by hunger. Almost always at war with adjoining tribes, they seldom meet but a hostile encounter is the result; and then those who are vanquished and taken, if not already dead, are killed and eaten by the conquerors. The arms and breast are eaten by the women; the men eat the legs; and the trunk is thrown into the sea. During a severe winter, when hard frost and deep snow prevent their obtaining food as usual, and famine is staring them in the face, extreme hunger impels them to lay violent hands on the oldest woman of their party, hold her head over a thick smoke, made by burning green wood, and pinching her throat, choke her. They then devour every particle of the flesh, not excepting the trunk, as in the former case. Jemmy Button, in telling this horrible story as a great secret, seemed to be much ashamed of his countrymen, and said, he never would do so—he would rather eat his own hands. When asked why the dogs were not eaten, he said "Dog catch iappo" (iappo means otter). York told me that they always eat enemies whom they killed in battle; and I have no doubt that he told me the truth.

When the Dutch fleet were in Nassau Bay (1624), a boat's crew were attacked by the natives, murdered and partly eaten. But previous to this (in 1599), Oliver Van Noort had attacked some Fuegians in a cave near a cape, then called Nassau, where he killed several men, and took four boys and two girls prisoners.

Jemmy Button told me that there are two tribes of Tekeenica, differing only in situation, who go to war sometimes with one another, though usually at peace; they live east and west, respectively, of some islets in the Beagle Channel, a short distance north-eastward of Woollya. With these two tribes or subdivisions of the Tekeenica there is constant war made by the Yacana, called by Jemmy 'Oens-men;' but they (the Tekeenica) are sometimes at peace with the Alikhoolip.

© The Complete Work of Charles Darwin Online

The food of the Fuegians has been mentioned so often in the preceding pages of this or the former volume, that I will only add here a few remarks which have not hitherto been made. When there is time, the natives roast their shell-fish, and half-roast any other food that is of a solid nature; but when in haste, they eat fish, as well as meat, in a raw state. A seal is considered to be a grand prize; for, besides the flesh, they feast on the oil; and a porpoise is much valued, for a similar reason. Seal are often killed on the rocks, by striking them on the nose with a club, or large stick: and rather than let a seal go, which has been intercepted by getting between it and the water, they will risk having a severe bite by attacking it with a stone in hand. Both seal and porpoises are speared by them from their canoes. When struck, the fish usually run into the kelp, with the spear floating on the water, being attached by a short line to a moveable barb; and there the men follow with their canoe, seize the spear, and tow by it till the fish is dead. To them, the taking of a seal or porpoise is a matter of as much consequence as the capture of a whale is to our countrymen. On moonlight nights, birds are caught when roosting, not only by the men but by their dogs, which are sent out to seize them while asleep upon the rocks or beach; and so well are these dogs trained, that they bring all they catch safely to their masters, without making any noise, and then return for another mouthful. Birds are also frequently killed with arrows,* or by stones slung at them with unerring aim. Eggs are eagerly sought for by the natives; indeed, I may say that they eat any thing and every thing that is eatable, without being particular as to its state of freshness, or as to its having been near the fire. Penguins are much prized; the otter is also valued, excepting the body part, which they seldom

* These arrows are of hard wood, well polished, and quite straight. They are about two feet in length, and in a notch at the point have a sharp triangular piece of agate, obsidian, or broken glass; which is not permanently fixed, and therefore remains in a wound, though the shaft may be drawn out. The bow is from three to four feet long, quite plain, with a string made of twisted sinews.

© The Complete Work of Charles Darwin Online

eat unless hard pressed by hunger. Sometimes they spear fine fish, like cod-fish—fifteen or twenty pounds in weight. Small fish are caught in abundance by the method formerly described,* and they are the staple article of food among the Tekeenica. The fins of a dead whale are esteemed; but if other food is to be had, they do not eat the blubber.

In the Tekeenica country, near the Beagle Channel, there are many small animals, about the size of a cat, which they sometimes take and eat. These, I think, are nutria; for, on one occasion, a fresh nutria skin was obtained from them, the only sign I ever found of a small animal in that neighbourhood.

Of vegetable food they have very little: a few berries, cranberries, and those which grow on the arbutus, and a kind of fungus, which is found on the birch-tree, being the only sorts used. This fungus is very plentiful in some places: it grows upon the birch-tree much as the oak-apple upon an oak-tree. Mr. Darwin describes it fully in his journal (vol. iii). There is also another much larger kind of fungus, which is sometimes eaten. On what tree it grows, I know not, but it was mentioned to me as being about two feet in circumference. The Fuegians drink only pure water, but often, and in large quantities. The women or children fetch it in small buckets, made of birch-bark; and two or three times in the course of a night they wake to eat and drink. In the day-time also they eat and drink very frequently.

The men procure food of the larger kind, such as seal, otter, porpoises, &c.; they break or cut wood and bark for fuel, as well as for building the wigwams and canoes. They go out at night to get birds; they train the dogs, and of course undertake all hunting or warlike excursions.

The women nurse their children, attend the fire (feeding it with dead wood, rather than green, on account of the smoke), make baskets and water-buckets, fishing-lines and necklaces,† go out to catch small fish in their canoes, gather shell-fish, dive for sea-eggs, take care of the canoes, upon ordinary occasions paddle their masters about while they sit idle;—and do any other drudgery.

* See vol. i. p. 428. † See note at end of chapter.

© The Complete Work of Charles Darwin Online

Swimming is a favourite amusement of the Fuegians during summer; but the unfortunate women are obliged to go out into rather deep water, and dive for sea-eggs in the depth of winter as often as in summer. Men, women, and children are excellent swimmers; but they all swim like dogs. Directly they come out of the water they run to the fire, and rub their bodies all over with oil or grease and ochreous earth, to keep out the cold. Swinging between branches of trees, as our children do, is also a favourite pastime, the ropes being made of strips of seal-skin. Frequently the men are lowered down by such ropes over the faces of high cliffs in search of eggs and young birds, or to attack the seal which herd in caves washed by the surf, and inaccessible to man from seaward.

When ill, however seriously, they know of no remedies but rubbing the body with oil, drinking cold water, and causing perspiration by lying near the fire, wrapped up in skins.

Both men and women are remarkably fond of the little children, and were always much pleased at any notice taken of them by our parties, when they felt sufficient confidence in us to bring the children forward. Much respect is said to be paid to age; yet we never saw either man or woman who appeared to be very old—certainly no one was decrepit.

It is rather curious that usually each of these natives is trained to a particular pursuit: thus, one becomes an adept with the spear; another with the sling; another with a bow and arrows; but this excellence in one line does not hinder their attaining a considerable proficiency in all the others.*

Hostilities are usually carried on with slings and stones rather than by close encounters; yet occasional surprises happen, especially when the Oens-men make an attack, and then there is savage work with clubs, stones in the hand, and spears.

In the winter, when snow lies deep on the ground, the Tekeenica people assemble to hunt the guanaco, which then comes down from the high lands to seek for pasture near the sea. The long legs of the animal stick deeply into the snow and soft boggy ground, disabling him from escape, while the

* Mr. Low has seen Fuegians with balls (bolas) in the northern part of their country.

© The Complete Work of Charles Darwin Online

Fuegians and their dogs hem him in on every side, and quickly make him their prey.

Jemmy Button's division of the Tekeenica, living westward of Murray Narrow, never obtain guanacoes; but the other division, who live eastward of that small passage, often kill them in winter; and at other times of the year they sometimes get them by lying in wait, and shooting them with arrows, or by getting into a tree near their track, and spearing them as they pass beneath the branches. An arrow was shewn to Low, which was marked with blood two-thirds of its length in wounding a guanaco, afterwards caught by dogs. Low held out his jacket, making signs that the arrow would not penetrate it: upon which the native pointed to his eye.

Some of the families of this eastern division of the Tekeenica have no canoes, living entirely at a distance from the shore, and subsisting upon berries, birch-fungus, guanacoes, and birds. The bows and arrows of those men are longer and better, and they have some very fine dogs, which are trained to search for and bring home food. These dogs often surprise the larger birds, while feeding on the ground, as well as when they are at roost, so quietly do they steal upon their prey. Byron mentions that the Chonos Indians send their dogs away to fish, and that they assist their owners in fishing, by swimming about, and driving the fish into a corner. This I have not witnessed or heard of among the Fuegians; but their dogs assist in a similar manner when in pursuit of an otter, by swimming and diving after it with the utmost eagerness.

Fire, that essential necessary to man in every state and every climate, is always kept alive by these savages wherever they go, either in their canoes, in their wigwams, or even in their hand, by a piece of burning wood; but they are at no loss to rekindle it, should any accident happen. With two stones (usually iron pyrites) they procure a spark, which received among tinder, and then whisked round in the air, soon kindles into a flame. The tinder used is the inner down of birds, well dried; very fine dry moss; or a dry kind of fungus found on the under side of half-rotten trees. Where the pyrites is

© The Complete Work of Charles Darwin Online

usually obtained, I do not know; but it cannot be plentiful in the Tekeenica country, since every woman keeps small pieces by her, in the basket which holds their paint and ornaments, and will not easily be prevailed upon to part with them. Some of the sealers have fancied these pieces of pyrites were silver or gold ore, and have eagerly sought for the mines whence they came. One person finding a large quantity in a rock somewhere near the Gulf of Trinidad, employed his crew and himself for many days in loading his ship with it, being quite sure it was gold.

Of the Fuegian language we know but little, although three of the natives were so many months with us. I found great difficulty in obtaining words, excepting names for things which could be shown to them, and which they had in their own country; however, the few which I have collected are given in the Appendix to this volume, and I can assure the reader that the utmost pains were taken to spell each word so as to ensure having the correct sound when pronounced by other persons; and to place the marks of accent, as well as quantity, with precision. All the Fuegian sounds are imitable by using our letters, excepting one, a curious sort of 'cluck,' meaning 'no.' Many of their words are exceedingly guttural in their pronunciation, yet I have twice heard their women sing, and not disagreeably. Weddell, in his narrative (p. 173), gives some Fuegian words, and endeavours to trace a similarity to the Hebrew language. Molina also, in his vocabulary of the Araucanian language, which appears to be related to the Fuegian, traces some singular correspondences.

Mr. Low, who has had more intercourse with the Fuegians than perhaps any other individual, gave me much information about them. He says that, generally speaking, they appear to be friendly when meeting strangers, but that their subsequent conduct depends entirely upon their relative numbers. They ought never to be trusted, however, as they have hasty tempers, and are extremely revengeful. They show much hardiness and daring, being always ready to defend their own property, or resent any ill treatment; and they are enterprising thieves.

© The Complete Work of Charles Darwin Online

When the intentions of the natives are hostile, the women and children are kept out of the way; the men are quite naked, their bodies painted more than usual, and the leader of the party has a band of white feathers around his head.

Mr. Low had a Fuegian boy on board the Adeona, who learned to speak English very tolerably, during eighteen months that he staid on board as a pilot and interpreter. This boy, whose name, among the sealers, was Bob, was one of the Chonos tribe, and had never been south of Magalhaens Strait before he embarked with Mr. Low. He said, that in cases of extreme distress, caused by hunger, human flesh was eaten, and that when they had recourse to such food, the oldest women invariably suffered. The poor creatures escaped to the woods, if possible, at such a time, but were soon found and brought back by force. They were killed by suffocation, their heads being held over the thick smoke of a fire made of green wood, and their throats squeezed by the merciless hands of their own relations. This boy imitated the piercing cries of the miserable victims whom he had seen sacrificed. He also mentioned that the breasts, belly, hands, and feet, were most liked. When first questioned on this subject, he showed no reluctance in answering any questions about it; but after a time, perceiving how much shocked his English companions were at the story, and how much disgust it excited among the crew of the vessel, he refused to talk of it again.

The different tribes of canoe Indians are generally upon hostile terms with each other, as well as with the horse Indians. This may be more particularly noticed about the western entrance of Magalhaens Strait, where the tribes which inhabit opposite sides* are particularly inveterate in their hostility.

On the west coast of Patagonia, from the Strait of Magalhaens to Cape Tres Montes, Mr. Low found that the natives seemed to be of one tribe, and upon friendly terms with one another. A man, whose native name was Niqueaccas, was taken on board Mr. Low's vessel, near Cape Victory, as a pilot,

* Chonos and Alikhoolip.

© The Complete Work of Charles Darwin Online

and he afterwards proved to be acquainted with all the natives met with along the coast as far north as the parallel of 47°. He was always glad to see the various parties of Indians whom they met, and was invariably well received by them. Perfectly acquainted with every part of the coast, he was able to point out excellent harbours, as well as the best seal 'rookeries.' Niqueaccas and the boy Bob were of the same tribe; but whenever he was spoken to about eating people, he became sullen, and not a word could be obtained from him. He spoke English very fairly before leaving the vessel in his own country, after being with Mr. Low fourteen months.

The people of this tribe* are by no means without ideas of a superior Being. They have great faith in a good spirit, whom they call Yerri Yuppon, and consider to be the author of all good: him they invoke in time of distress or danger. They also believe in an evil spirit, called Yaccy-ma, who they think is able to do all kinds of mischief, cause bad weather, famine, illness, &c.: he is supposed to be like an immense black man. After being hard pressed for food, and then obtaining a good quantity, much form is observed in distributing the first supplies. Mr. Low witnessed a ceremony of this kind, during which the greatest order prevailed. The whole tribe was seated round a fire, and the oldest man gave each individual a share, repeatedly muttering a short prayer, and looking upwards. Not one of the party, although nearly starved, attempted to touch the food, a large seal, until this ceremony was ended: one share was offered to Mr. Low. At another time, on Madre de Dios Island, after having been detained in port upwards of three months, owing to very bad weather, during which time the natives were almost famished, being unable to reach the outer rocks in quest of food, Mr. Low went with his boats and procured a few seals, taking an Indian in each boat. At his return the carcasses of the seals were sent ashore, but not one of the natives, ravenous as they were, attempted to touch a morsel until all was landed, till the

* Chonos. See page 194.

© The Complete Work of Charles Darwin Online

ceremony above-mentioned had been duly performed, and till the natives who had been in the boats had chosen what they pleased for their share.

This tribe appears to have regular places for depositing their dead; as on a small out-lying island, a little southward of Madre de Dios, Mr. Low found a cave which had been used for such a purpose: it was strewed with human bones, and the body of a native child was found in a state of putrefaction. The bodies seemed to have been placed in shallow graves, about a foot deep, which had been dug along the sides of the cave, and covered with twigs and leaves. Slips of a peculiar plant, resembling box, had been carefully planted along the outer sides of each grave, and those near the mouth of the cave had taken root and were growing, but all those in the interior had decayed.

One evening, while at sea, Mr. Low called the boy to him, and said, "Bob, look at the sun; it is going to be drowned." The boy shook his head, saying, "No, no drown; to-morrow morning get up again. Sun go round earth; come again to-morrow."

The natives of this tribe* suppose that all white people originally came from the moon; they call them "cubba;" and often make use of an expression with reference to them which means "White men of the Moon." These Indians, in common with those of the other southern tribes, are exceedingly superstitious, implicitly believing omens, signs, and dreams, as well as the 'wise men' among them, who are thought infallible as prophets, doctors, and magicians. Once, when Mr. Low was detained about three weeks by contrary winds and bad weather, his crew became discontented, and attributed their ill-luck to a native who was detained on board against his will. To pacify those who were, in this instance, every bit as superstitious as the aborigines themselves, a fire was made on shore, to invite the Indians to approach; and when they came he delivered their countryman to them, explaining at the same

* Chonos.

© The Complete Work of Charles Darwin Online

time that he would depart as soon as the wind became fair. An old Indian, then, in a very ceremonious and mysterious manner, gave Low what he understood to be a charm, with strict injunctions not to look at it until next morning; when, at sunrise, there would be a fair wind, and the vessel might sail. Notwithstanding the old man's orders, he was no sooner out of sight than Low opened the mysterious packet, which appeared to contain human hair, mixed with the scrapings of the shaft of an arrow.

Next morning, however, at sunrise, a fair (easterly) wind sprung up, and the vessel sailed. How the old man foreknew the change—whether he judged by the sky, the tides, or other indications, did not transpire; but this was by no means a singular instance of extraordinary accuracy shown by the natives in foretelling changes of weather.

The sagacity and extensive local knowledge of these people is very surprising; Niqueaccas was so well acquainted with all the coast between 47° and the Strait of Magalhaens, that, upon being taken to a high hill, immediately after landing from a cruise, in which they had been far out of sight of land, he pointed out the best harbours and places for seal then visible; and in one direction, a long way off (pointing towards Eyre Sound, then far out of sight), he said there were great numbers of fur seals. The boy Bob also described that same place, when he was with Mr. Low at the Galapagos Islands. On a calm day, while there was nothing going on, he made a chart with chalk upon the vessel's deck, reaching from the windlass to the taff-rail, and Mr. Low has since felt quite certain that the boy meant Eyre Sound, though at that time these interior waters on the west coast of Patagonia had not been explored by any white man.

Niqueaccas was always anxious and timid about taking the Adeona through a passage where he knew danger existed, and proportionably pleased when the dangers were safely passed, and the vessel anchored in a safe position.

The boy Bob, when only ten years old, was on board the Adeona at sea. As the vessel approached land, Low asked

© The Complete Work of Charles Darwin Online

him where a harbour could be found? As soon as he understood what was meant, which was an affair of some difficulty, for he then could speak but very little English, he got up on the vessel's bulwark, and looked anxiously around. After some hesitation, he pointed to a place where the ship might go, and then went to the lead-line, and made signs to Mr. Low that he must sound as he approached the land. The cove was found to have a shoal and narrow entrance, but was safe and sufficiently spacious within. Such knowledge at so early an age is an extraordinary proof of the degree in which the perceptive and retentive faculties are enjoyed by these savages. Whenever the advice of Niqueaccas or any of his tribe was rejected, much sullenness and displeasure were shown. Upon one occasion his services were refused, and a harbour tried against his advice, which proved to be a bad one; it was left to seek for that which he had previously recommended, and his sullenness suddenly changed into delight; but when his harbour was pronounced excellent, and he was duly praised, his joy knew no bounds.

Generally speaking, both Niqueaccas and the boy Bob were well-behaved and good-tempered; but the boy was sometimes inclined to be mischievous, and would hide the people's clothes, or put salt into their mouths while asleep. When much annoyed, he would use both teeth and nails, and attack any one, however superior to himself in size and strength.

Battles between parties of the same tribe seem to occur occasionally, as this boy showed Mr. Low two spots where quarrels had been decided. Both were open spaces, clear of trees, and near them were the remains of wigwams. One of those battles occurred in consequence of one party wishing to take some seal-skins away from the other; but it did not distinctly appear from the boy's account whether these encounters were between parties of his tribe, or whether an encroachment upon their territory, with a view to plunder, had been made by some other tribe. That parties occasionally cross overland from Skyring Water to Obstruction Sound is evident from Mr. Bynoe's account (page 198), and that people of the

© The Complete Work of Charles Darwin Online

tribe to which Niqueaccas belonged either make excursions themselves southward of the Strait of Magalhaens, or that the Alikhoolip invade their territory and take away canoes, is evident from the fact of plank canoes* having been seen in and about the Barbara Channel. The arms used are similar to those of the Alikhoolip already described.

A method of declaring war, ascertained by the following circumstance, is rather curious. The boy Bob had been taken on board the Adeona, in consequence of some dispute with the natives, who had stolen things from the vessel. Mr. Low intended to keep him as a hostage until the missing property should be restored; but the tribe decamped, and as Low was obliged to sail, he carried the boy away with him. At the return of the vessel, about eight months afterwards, the boy saw something on shore, at the entrance of the harbour, which he looked at for some time very earnestly, and then gave Mr. Low to understand that the natives had declared war against him and his ship, and intended to attack her at her return. No natives being visible, Low went ashore with the boy, to see what it was that had attracted his attention, and found a number of spears, arrows, and clubs, roughly cut out of wood, painted red, and stuck into the ground, across a point of the island, and having in the middle a large block of wood, roughly carved into a strange figure (said by the boy to be that of their evil spirit) curiously painted, with long red teeth, and having a short halter of hide (seal-skin) round the part intended to represent a neck. Notwithstanding this outward demonstration of anger and intent to revenge, not a native was seen in the neighbourhood during the many months which Low passed there, and in consequence he had no opportunity of restoring the boy to his own tribe; but he was afterwards kindly received, and treated as Low's son, among the Patagonians of Gregory Bay.

The natives of Niqueaccas' tribe (Chonos) are less dishonest and deceitful than those of the southernmost islands. Mr. Low

* Plank canoes are used on the west coast. See page 142.

© The Complete Work of Charles Darwin Online

has sometimes left his vessel, while he was away sealing, with only two men on board; and although in one instance, at Madre de Dios, there were about a hundred and fifty natives assembled, no hostile or predatory attempt whatever was made by them in his absence: indeed so careful were they to prevent any cause for misunderstanding, that in no instance did more than two of their party go on board the vessel during the absence of the boats; though, after their return with Low, they went to her as usual in great numbers. This tribe was in extreme distress for want of food; the whole party looked thin and miserable. Continual gales had prevented the rocks from being uncovered at low water, and no canoe could be launched on account of the surf, therefore they could get neither shell-fish nor seal. A small party were observed going away, as if on an excursion, and the others who remained explained to Low, by signs, that in four sleeps they would return with food. On the fifth day they were met by Low, returning, but almost dead with fatigue, each man having two or three great pieces of whale-blubber, shaped like a poncho with a hole in the middle, on his shoulders. The blubber was half putrid, and looked as if it had been buried under ground. When they entered the largest wigwam, an old man cut very thin slices off one piece, broiled each successively, and distributed to the party in rotation; but before doing so, he muttered a few words over each piece in a mysterious manner, while strict silence was kept by the by-standers. One slice was offered to Low. The boy Bob once noticed marks where a whale had been cast ashore; taking a sharp stick, he probed the sand in several places, and found many large pieces of blubber, which were taken on board and boiled down for oil. One of the men of this tribe, seeing two long powder-horns on board the Adeona, placed them to his head and made a noise like the bellowing of cattle; but he and his tribe were much frightened by sheep and pigs. They would not land on a small island where some pigs were turned loose, and when talking of them, made signs that they had very big noses which alarmed them. When a pig was killed by the crew

© The Complete Work of Charles Darwin Online

and part of it cooked, the natives refused even to taste the meat. One day several of these people had gone on board the Adeona with some old axes and pieces of iron, which they wished to have ground at her grindstone (a favour which had often been granted); but in consequence of something having gone wrong in the vessel, which had ruffled Low's temper, he rather roughly refused to let them stay on board. They went away quietly, but left their axes, &c. behind; and while returning were met by the mate of the vessel, who asked if they had ground them; they replied negatively, and gave the mate to understand that the captain's face was too long, but that they would come again when it was shorter. This occurred before either Niqueaccas or the boy had been taken on board the Adeona.

Mr. Low remarked to me that the conduct of these Indians on this occasion of his harshly refusing to comply with a slight request, was quite different from that which the Fuegians would have shown under similar circumstances: they would have been angry, and in all probability have returned his ill-temper with a display of their own, evinced by a shower of stones. Once, when Low was in the Magdalen Channel, he desired some Fuegians who were on board to leave the vessel while his men were below at dinner. They refused to comply, and offered resistance; but being obliged to go, went in their canoes to a short distance a-head, and there remained slinging large stones on board, which broke several windows. To drive them away muskets were used, though without injuring any of their party. Next day the hardy fellows came alongside again, as unconcernedly as ever.

When the Fuegians are inclined to attack an enemy with stones, they generally try to raise a breastwork of boughs or logs; but no such preparation was ever noticed among the natives of the western coast of Patagonia.

While the Adelaide tender was examining the inner passages and sounds of the western shores of Patagonia, under Lieutenant Skyring, some interesting remarks were made by

© The Complete Work of Charles Darwin Online

Mr. Bynoe, which do not appear in the narrative of that cruise given in the preceding volume. I shall here insert them in his own words :—

"We entered the Gulf of Trinidad, and while surveying thereabouts met two large canoes, which were thought to be whale-boats when first seen at a distance; but as we concluded that some sealing vessel was in the neighbourhood, and that these were her boats, little notice was taken of them until they had approached very near, when, to our astonishment they proved to be large plank canoes, pulled with oars, and full of fine stout Indians. Just within hail they stopped, lay on their oars, halloed to us most vociferously, and waved skins above their heads. One man was very conspicuous, having on his head a tall leathern cap, tapering to a point, which was ornamented with feathers of various gaudy colours; and around the brim of this high conical hat there was also a fringe of feathers. This singular character was painted black all over from head to foot, except a circle of white round each eye, and a few white dots upon his cheeks. By signs we succeeded in tempting them to come alongside the schooner, and were then still more struck by their appearance: they were far superior to any Fuegians I had seen, being a taller race, more upright, and better proportioned; their limbs were better formed, more muscular, rounder, and fuller than those of any canoe Indians of the Strait of Magalhaens or Barbara Channel; and their skins were cleaner as well as clearer, which was probably the reason why we thought them lighter coloured than the others whom we had seen. The length of back, so remarkable in a Fuegian, was not very discernible in these people, neither were they by any means so ugly as the former; indeed a rather pleasing smile was sometimes noticed on the younger faces. None among them were much smoke-dried, nor did their eyes look red and watery. There did not appear to be one of the party above a middle age, and most of them were young. Three of the men had lost each an upper incisor tooth, and one had a long though not deep scar upon the breast. We all pronounced these people to belong to a finer race than we had

© The Complete Work of Charles Darwin Online

seen on the water, and the size of their canoes was quite beyond anything hitherto noticed: they were near thirty feet in length and seven feet broad, with proportionate depth, being made of planks sewn together with strips of twisted bark and rushes: the bow and stern were flat, and nearly upright. Six round pieces of wood formed the thwarts, which were fastened to the gunwale by ropes of twisted rushes; and there were six short oars on each side. These oars were about seven feet long, the blade being a flat piece of wood about sixteen inches in length, fastened to the handle by rush rope passed through two holes in the blade. Of such burthen were these boats (rather than canoes), that two men standing on one gunwale did not bring it down to the water. Each was steered by an old woman, who sat silently abaft with a paddle. All the party were quite naked excepting the old women.

"From one of the old women a small bag was obtained, in exchange for a shirt and some woollen stuff, which proved to contain white dust, feathers, parrots' heads, hawks' feet, white earth, and red ochre. One of the men had an old hatchet, and made signs that he wanted to sharpen it at our grindstone: of course we complied with his request, and allowed a man and a young lad to come on board for that purpose. The lad turned the stone, while the man held the axe; and extremely well it was sharpened. The spears and slings were similar to those seen in other places.

"Although these natives seemed to be remarkably well disposed, it was not quite pleasant to see thirty of them looking over the schooner's bulwark, while our boats were away and only five or six men left on board: however, they made no attempt to do any thing improper, and before sunset left us peaceably, striking up a song as they paddled away."

Mr. Bynoe remarked, that in the neighbourhood of Easter Bay (Obstruction Sound), the country had much the appearance of English park scenery; large clumps of trees growing straight and tall, with intervening spaces of clear ground covered with long grass. In this place he found great numbers of wigwams and deserted canoes. Some of the former were of

© The Complete Work of Charles Darwin Online

large dimensions, and various shapes: two were like inverted whale-boats, each of which might hold forty or fifty people; and in the long ones (six feet high), Mr. Bynoe could walk upright. All of them were built of slight materials, such as branches of trees covered with long grass. Five or six large wigwams stood together in each place; and near them canoes had evidently been built, for many trees had been felled and barked close by. The traces of fire were visible, which had been trained around the roots of the trees; and many large pieces of bark were lying about, partly sewed together. Four good canoes were found in one place, one of the four being quite new: and there were many old or broken ones. They also saw on nearly every sandy point a neatly-constructed small wigwam, about two feet high, at the entrance of which was a platted rush noose, intended as a snare to catch swans probably, which were numerous about the adjoining grounds, and generally roost on those sandy points. Many deer, like a kind of roebuck, were seen by Mr. Bynoe, but he did not suceeed in shooting one. Horse tracks were seen near the upper part of Obstruction Sound; showing that the eastern Patagonians occasionally visit this part of the western coast. Mr. Bynoe suggested the possibility of the natives of Skyring Water travelling overland, building canoes, and then going northward along the west coast; but I do not myself think it so likely as that the Chonos Indians should select such a spot, abounding in food, to pass their winter in, or to stay at for a considerable time while building canoes. Probably, when Mr. Bynoe was there (being summer-time) the tribe, whose winter quarters it had been, were dispersed along the sea-coast in search of seal, eggs, and young birds. In support of his idea Mr. Bynoe says, "I only met one canoe, and that of the bark kind, in the Mesier Channel: whence could that one have come? None of the bark canoes have been seen by us on the west coast, excepting in that instance, and in Obstruction Sound. The distance from Skyring Water to the head of Obstruction Sound is small, though sufficiently difficult to traverse to prevent transporting canoes, because of low prickly brushwood.

© The Complete Work of Charles Darwin Online

How can we account for the numerous canoes stranded in Obstruction Sound, excepting by a supposition that the natives, after using them in a north-westerly excursion, left them behind at their return, as they may have left others on the shores of Skyring Water? These canoes were all of bark, and rather smaller than those usually made by the southern Fuegians." Should this be the case, there can no longer be any doubt of the non-existence of a direct passage between Skyring Water and the Smyth Channel (leading northwards from Magalhaens Strait). Perhaps the horse Indians sometimes stay in the neighbourhood of Obstruction Sound, and oblige their slaves (zapallos) to build canoes and swan-traps, to fish for them, and even make excursions for seal.

Mr. Bynoe saw many nutria among the islands of Western Patagonia, and a great number of otters. Brant-geese, swans, ducks, and rock-geese were also plentiful in particular places, but not generally. Besides the wild potato, found on the Guaianaco islands (mentioned in the first volume), Mr. Bynoe noticed, in the Gulf of Peñas, an abundance of the plant called 'pangue,' which grows also in Chilóe, and is so much liked by the Chilotes.

Mr. Low said that natives whom he met in the Gulf of Trinidad relished potatoes which he gave them, and asked for more. They pointed towards the north and used the word 'aquinas,' which he recognized as being the term used for potatoes by the aborigines at the south of Chilóe.

A native who was on board the Adeona in one of her excursions among the western islands of Patagonia induced Low to take long walks in search of potatoes, which never were found; and afterwards, in the Mesier Channel, he persuaded him to go about in quest of seals, until an opportunity offered for escaping to a small party of his own tribe whom he met there. When taxed by the crew with deceiving Mr. Low about the potatoes, he fell into (or affected) a violent passion, and sprung at the nearest man, grappling him in a most determined and malicious manner.

Having now mentioned all that I know respecting the Canoe

© The Complete Work of Charles Darwin Online

Indians (excepting some facts related by Capt. King in vol. i.), I will add a few words about their constant and faithful companion, the dog: and then continue the narrative.

The dog of a Fuegian or Chonos Indian is small, active, and wiry, like a terrier with a cross of fox. His hair is usually rough, and dusky, or dark-coloured; but there are many dogs among the Fuegians almost white, or prettily spotted, some of which have fine smooth hair. All that were examined had the roof of their mouth black, the ears erect, large, and pointed; the nose sharp, like that of a fox; the tail drooping, and rather inclined to be bushy. They are exceedingly vigilant and faithful. Their sagacity is shown in many ways, some of which I have already noticed; and not least, in their providing for themselves, each low-water, by cunningly detaching limpets from the rocks, or by breaking muscle and other shells, and then eating the fish.

These dogs bark at strangers with much fury: and they give tongue eagerly when hunting the otter.*

* Byron says they do so likewise when driving fish into corners.

NOTE to page 185.—The Fuegian necklaces show some ingenuity in those who make them, being composed of small shells, perforated very neatly, and fastened together on strings of sinews or gut, so finely divided and platted, that one is, at first, inclined to doubt their being the manufacture of such uncouth savages.

CHAPTER X.

Set out to land Matthews and the Fuegians—Their meeting with Natives —Supposed Volcano—Dream—Oens-men—Scene—Arrival at Woollya —Encampment—Concourse of Natives—Jemmy's Family—Wigwams —Gardens—Distrust—Experiment—Westward Exploration—Remove Matthews—Revisit Woollya—Gale—Sail for the Falkland Islands.

At the end of Chapter VI., I described our preparations for landing the Fuegians, who had been in England, among their own countrymen; and now, having attempted to give a fuller idea of those people, the narrative of our proceedings shall be continued.

Jan. 19, 1833. The yawl, being heavily laden, was towed by the other three boats, and, while her sails were set, went almost as fast as they did; but after passing Cape Rees, and altering our course to the westward, we were obliged to drag her along by strength of arm against wind and current. The first day no natives were seen, though we passed along thirty miles of coast, and reached Cutfinger Cove. (This name was given because one of our party, Robinson by name, almost deprived himself of two fingers by an axe slipping with which he was cutting wood.) At this place, or rather from a hill above it, the view was striking. Close to us was a mass of very lofty heights, shutting out the cold southerly winds, and collecting a few rays of sunshine which contrived to struggle through the frequent clouds of Tierra del Fuego. Opposite, beyond a deep arm of the sea, five miles wide, appeared an extensive range of mountains, whose extremes the eye could not trace; and to the westward we saw an immense canal, looking like a work of gigantic art, extending between parallel ranges of mountains, of which the summits were capped with snow, though their sides were covered by endless forests. This singular canal-like passage is almost straight and of nearly an

© The Complete Work of Charles Darwin Online

uniform width (overlooking minute details) for one hundred and twenty miles.

20th. We passed the clay cliffs, spoken of in the former volume, first visited by Mr. Murray. They narrow the channel to less than a mile, but, being low, were beneath the horizon of our eye at Cutfinger Cove:—westward of them the channel widens again to its usual breadth of two miles. Several natives were seen in this day's pull; but as Jemmy told us they were not his friends, and often made war upon his people, we held very little intercourse with them. York laughed heartily at the first we saw, calling them large monkeys; and Jemmy assured us they were not at all like his people, who were very good and very clean. Fuegia was shocked and ashamed; she hid herself, and would not look at them a second time. It was interesting to observe the change which three years only had made in their ideas, and to notice how completely they had forgotten the appearance and habits of their former associates; for it turned out that Jemmy's own tribe was as inferior in every way as the worst of those whom he and York called "monkeys—dirty—fools—not men."

We gave these 'Yapoos,' as York called them, some presents, and crossed over to the north side of the channel to be free from their importunities; but they followed us speedily, and obliged us to go on further westward than was at all agreeable, considering the labour required to make way against a breeze and a tide of a mile an hour. When we at last landed to pass the night, we found that the forests on the sides of the mountains had been burned for many leagues; and as we were not far from the place where a volcano was supposed to exist, in consequence of flames having been seen by a ship passing Cape Horn, it occurred to me that some conflagration, like that of which we found the signs, might have caused appearances resembling the eruption of a distant volcano: and I have since been confirmed in this idea, from having witnessed a volcano in eruption; and, not long afterwards, a conflagration, devouring many miles of mountain forest; both of which, at a distance, shewed lines of fire, fitful flashes, and sudden gleams.

© The Complete Work of Charles Darwin Online

Persons who have witnessed a forest burning on the side of a mountain, will easily perceive how, when seen from a distance, it may resemble the eruption of a volcano; but to those who have not seen fire on such a scale, I may remark that each gust of wind, or temporary calm; each thick wood, or comparatively barren space; augments or deadens the flames so suddenly, as the fire sweeps along the mountain side, that, at a distance of fifty miles or more, the deception may be complete.

22d. Favoured by beautiful weather, we passed along a tract of country where no natives were seen. Jemmy told us it was "land between bad people and his friends;" (neutral-ground probably). This evening we reached a cove near the Murray Narrow; and from a small party of Tekeenica natives, Jemmy's friends, whom we found there, he heard of his mother and brothers, but found that his father was dead. Poor Jemmy looked very grave and mysterious at the news, but showed no other symptom of sorrow. He reminded Bennett* of the dream (related in the previous chapter), and then went for some green branches, which he burned, watching them with a solemn look: after which he talked and laughed as usual, never once, of his own accord, recurring to the subject of his father's decease. The language of this small party, who were the first of Jemmy's own tribe whom we met, seemed softer and less guttural than those of the "bad men" whom we had passed near the clay cliffs; and the people themselves seemed much better disposed, though as abject and degraded in outward appearance as any Fuegians I had ever seen. There were three men and two women: when first we were seen they all ran away, but upon two of our party landing and advancing quietly, the men returned and were soon at their ease. Jemmy and York then tried to speak to them; but to our surprise, and much to my sorrow, we found that Jemmy had almost forgotten his native language, and that, of the two, York, although belonging to another tribe, was rather the best interpreter. In a few minutes the natives comprehended that we should do them no harm; and they then called back their women, who were hiding in the

* My coxswain.

© The Complete Work of Charles Darwin Online

woods, and established themselves, very confidently, in a wigwam within a hundred yards of our tents. During this and the preceding day, we found the weather, by comparison, so mild, even warm, that several of our party bathed; yet the thermometer ranged only to 53° in the shade, and at night fell to 40°. The temperature of the sea was 48°.

Being within a few hours' pull (row) of Jemmy's 'own land,' which he called Woollÿa, we all felt eager, though anxious, and I was much gratified by seeing that Matthews still looked at his hazardous undertaking as steadily as ever, betraying no symptom of hesitation. The attentions which York paid to his intended wife, Fuegia, afforded much amusement to our party. He had long shewn himself attached to her, and had gradually become excessively jealous of her good-will. If any one spoke to her, he watched every word; if he was not sitting by her side, he grumbled sulkily; but if he was accidentally separated, and obliged to go in a different boat, his behaviour became sullen and morose. This evening he was quizzed so much about her that he became seriously angry, and I was obliged to interpose to prevent a quarrel between him and one of his steadiest friends.

On this and previous evenings, as we sat round the blazing piles, which our men seemed to think could never be large enough, we heard many long stories from Jemmy about the Oens, or Coin men, who live beyond the mountains at the north side of the Beagle Channel, and almost every year make desperate inroads upon the Tekeenica tribe, carrying off women and children, dogs, arrows, spears, and canoes; and killing the men whom they succeed in making prisoners. He told us that these Oens-men made their annual excursions at the time of 'red leaf;' that is in April or May, when the leaves of deciduous trees are changing colour and beginning to fall; just the time of year also when the mountains are least difficult to pass.

At that period these invaders sometimes come down to the shores of the Beagle Channel in parties of from fifty to a hundred; seize upon canoes belonging to the Yapoo division of

© The Complete Work of Charles Darwin Online

the Tekeenica tribe, cross over to Navarin Island, and thence sometimes to others, driving the smaller and much inferior Tekeenica people before them in every direction. By Jemmy's own account, however, there are hard battles sometimes, and the Oens tribe lose men; but as they always contrive to carry away their dead, it seems that the advantage of strength is on their side.

These periodical invasions of a tribe whose abode is in the north-eastern quarter of Tierra del Fuego are not to be confounded with the frequent disputes and skirmishes which take place between the two Tekeenica tribes; and it is interesting to compare what we thus heard with the account obtained by Oliver Van Noort in 1589: who learnt that the people lived in caves dug in the earth, * and that there were five tribes—four of ordinary stature and one of gigantic size. These giants, called Tiremenen, lived in 'Coin.' The other tribes were called Enoo, Kemenites, Karaike, and Kenneka.

23d. While embarking our tents and cooking utensils, several natives came running over the hills towards us, breathless with haste, perspiring violently, and bleeding at the nose. Startled at their appearance, we thought they had been fighting; but it appeared in a few moments, that having heard of our arrival, they lost not a moment in hurrying across the hills from a place near Woollȳa, and that the bloody noses which had surprised us were caused by the exertion of running. This effect has been noticed among the New Hollanders, I believe the islanders of the Pacific Ocean, as well as the Esquimaux, and probably others; but to our party it was then a novelty, and rather alarming.

Scarcely had we stowed the boats and embarked, before canoes began to appear in every direction, in each of which was a stentor hailing us at the top of his voice. Faint sounds of deep voices were heard in the distance, and around us echoes to the shouts of our nearer friends began to reverberate, and warned me to hasten away before our movements should be-

* The ground within a wigwam is scooped out considerably.

© The Complete Work of Charles Darwin Online

come impeded by the number of canoes which I knew would soon throng around us. Although now among natives who seemed to be friendly, and to whom Jemmy and York contrived to explain the motives of our visit, it was still highly necessary to be on our guard. Of those men and boys who ran over the hills to us, all were of Jemmy's tribe excepting one man, whom he called an Oens-man; but it was evident, from his own description, that the man belonged to the Yapoo, or eastern Tekeenica tribe, and was living in safety among his usual enemies, as a hostage for the security of a man belonging to Jemmy's tribe who was staying among the eastern people.

As we steered out of the cove in which our boats had been sheltered, a striking scene opened: beyond a lake-like expanse of deep blue water, mountains rose abruptly to a great height, and on their icy summits the sun's early rays glittered as if on a mirror. Immediately round us were mountainous eminences, and dark cliffy precipices which cast a very deep shadow over the still water beneath them. In the distant west, an opening appeared where no land could be seen; and to the south was a cheerful sunny woodland, sloping gradually down to the Murray Narrow, at that moment almost undistinguishable. As our boats became visible to the natives, who were eagerly paddling towards the cove from every direction, hoarse shouts arose, and, echoed about by the cliffs, seemed to be a continual cheer. In a very short time there were thirty or forty canoes in our train, each full of natives, each with a column of blue smoke rising from the fire amidships, and almost all the men in them shouting at the full power of their deep sonorous voices. As we pursued a winding course around the bases of high rocks or between islets covered with wood, continual additions were made to our attendants; and the day being very fine, without a breeze to ruffle the water, it was a scene which carried one's thoughts to the South Sea Islands, but in Tierra del Fuego almost appeared like a dream. After a few hours (pulling hard to keep a-head of our train) we reached Woollȳa, and selected a clear space favourably situated for our encampment, landed, marked a boundary-line,

© The Complete Work of Charles Darwin Online

placed sentries, and made the various arrangements necessary for receiving the anticipated visits of some hundred natives. We had time to do all this quietly, as our boats had distanced their pursuers several miles, while running from the Murray Narrow before a favourable breeze which sprung up, and, to our joy, filled every sail.

We were much pleased by the situation of Woollȳa, and Jemmy was very proud of the praises bestowed upon his land. Rising gently from the water-side, there are considerable spaces of clear pasture land, well watered by brooks, and backed by hills of moderate height, where we afterwards found woods of the finest timber trees in the country. Rich grass and some beautiful flowers, which none of us had ever seen, pleased us when we landed, and augured well for the growth of our garden seeds.

At our first approach, only a few natives appeared, who were not of Jemmy's family. The women ran away and hid themselves, but Jemmy and York contrived (with difficulty) to make the men comprehend the reason of our visit; and their awkward explanation, helped by a few presents, gradually put them at ease. They soon understood our meaning when we pointed to the boundary-line which they were not to pass. This line was on the shore between our tents and the grass-land; immediately behind the tents was a good landing-place, always sheltered, where our boats were kept in readiness in case of any sudden necessity.

Soon after our arrangements were made, the canoes which had been following us began to arrive; but, much to my satisfaction, the natives landed in coves at some distance from us, where the women remained with the canoes while the men and boys came overland to our little camp. This was very favourable for us, because it divided their numbers and left our boats undisturbed. We had only to guard our front, instead of being obliged to look out all round, as I had expected; and really it would have been no trifling affair to watch the pilfering hands and feet of some hundred natives, while many of our own party (altogether only thirty in num-

ber) were occupied at a distance, cutting wood, digging ground for a garden, or making wigwams for Matthews, York, and Jemmy.

As the natives thronged to our boundary-line (a mere mark made with a spade on the ground), it was at first difficult to keep them back without using force; but by good temper on the part of our men, by distributing several presents, and by the broken Fuegian explanations of our dark-coloured shipmates, we succeeded in getting the natives squatted on their hams around the line, and obtaining influence enough over them to prevent their encroaching.

Canoes continued to arrive; their owners hauled them ashore on the beach, sent the women and children to old wigwams at a little distance, and hastened themselves to see the strangers. While I was engaged in watching the proceedings at our encampment, and poor Jemmy was getting out of temper at the quizzing he had to endure on account of his countrymen, whom he had extolled so highly until in sight, a deep voice was heard shouting from a canoe more than a mile distant: up started Jemmy from a bag full of nails and tools which he was distributing, leaving them to be scrambled for by those nearest, and, upon a repetition of the shout, exclaimed "My brother!" He then told me that it was his eldest brother's voice, and perched himself on a large stone to watch the canoe, which approached slowly, being small and loaded with several people. When it arrived, instead of an eager meeting, there was a cautious circumspection which astonished us. Jemmy walked slowly to meet the party, consisting of his mother, two sisters, and four brothers. The old woman hardly looked at him before she hastened away to secure her canoe and hide her property, all she possessed—a basket containing tinder, firestone, paint, &c., and a bundle of fish. The girls ran off with her without even looking at Jemmy; and the brothers (a man and three boys) stood still, stared, walked up to Jemmy, and all round him, without uttering a word. Animals when they meet show far more animation and anxiety than was displayed at this meeting. Jemmy was evidently much morti-

© The Complete Work of Charles Darwin Online

fied, and to add to his confusion and disappointment, as well as my own, he was unable to talk to his brothers, except by broken sentences, in which English predominated. After a few minutes had elapsed, his elder brother began to talk to him; but although Jemmy understood what was said, he could not reply. York and Fuegia were able to understand some words, but could not or did not choose to speak.

This first evening of our stay at Woollȳa was rather an anxious one; for although the natives seemed inclined to be quite friendly, and they all left us at sunset, according to their invariable practice, it was hard to say what mischief might not be planned by so numerous a party, fancying, as they probably would, that we were inferior to them in strength, because so few in number. Jemmy passed the evening with his mother and brothers, in their wigwam, but returned to us to sleep. York, also, and Fuegia were going about among the natives at their wigwams, and the good effect of their intercourse and explanations, such as they were, was visible next day (24th) in the confident, familiar manner of the throng which surrounded us while we began to dig ground for gardens, as well as cut wood for large wigwams, in which Matthews and his party were to be established. Canoes still arrived, but their owners seemed as well-disposed as the rest of the natives, many of whom assisted us in carrying wood, and bringing bundles of grass or rushes to thatch the wigwams which they saw we were making, in a pleasant sheltered spot, near a brook of excellent water. One wigwam was for Matthews, another for Jemmy, and a third for York and Fuegia. York told me that Jemmy's brother was "very much friend," that the country was "very good land," and that he wished to stay with Jemmy and Matthews.

A small plot of ground was selected near the wigwams, and, during our stay, dug, planted and sowed with potatoes, carrots, turnips, beans, peas, lettuce, onions, leeks, and cabbages. Jemmy soon clothed his mother and brothers, by the assistance of his friends. For a garment which I sent the old woman she returned me a large quantity of fish, all she had to offer;

© The Complete Work of Charles Darwin Online

and when she was dressed, Jemmy brought her to see me. His brothers speedily became rich in old clothes, nails and tools, and the eldest were soon known among the seamen as Tommy Button and Harry Button, but the younger ones usually staid at their wigwams, which were about a quarter of a mile distant. So quietly did affairs proceed, that the following day (25th) a few of our people went on the hills in search of guanacoes: many were seen, but they were too wild to approach. An old man arrived, who was said to be Jemmy's uncle, his father's brother; and many strangers came, who seemed to belong to the Yapoo Tekeenica tribe. Jemmy did not like their visit; he said they were bad people, 'no friends.'

26th. While some of my party were washing in a stream, stripped to the waist, several natives collected round, and were much amused at the white skins, as well as at the act of washing, so new probably to them. One of them ran to the nearest wigwams, and a troop of curious gazers collected, whose hands, however, were soon so actively employed in abstracting the handkerchiefs, shoes, &c., which had been laid on the bank, that a stop was put to the ablutions.

We discovered that Jemmy's eldest brother was a 'doctor,' and though young for his occupation of conjuring and pretending to cure illness, he was held in high estimation among his own tribe. I never could distinctly ascertain whether the eldest man, or the doctor of a tribe had the most influence; but from what little I could learn, it appeared to me that the elder of a family or tribe had a sort of executive authority, while the doctor gave advice, not only in domestic affairs, but with respect to most transactions. In all savage nations, I believe there is a person of this description—a pretended prophet—conjuror—and, to a certain degree,—doctor.

This evening our party were employed for a short time in firing at a mark, with the three-fold object of keeping our arms in order—exercising the men—and aweing, without frightening, the natives. While this was going on, the Fuegians sat about on their hams, watching our proceedings, and often eagerly talking to each other, as successful shots were made at the target,

© The Complete Work of Charles Darwin Online

which was intentionally placed so that they could see the effect of the balls. At sunset they went away as usual, but looking very grave, and talking earnestly. About an hour after dark, the sentry saw something moving along the ground near our tents, within the boundary line, which he thought was a wild animal, and had just levelled his musket to fire at it, when he discovered it was a man, who instantly darted off, and was lost in the darkness. Some native had doubtless stolen to the tents, to see what we were doing; perhaps with a view to surprise us, if asleep, perhaps only to steal.

27th. While a few of our party were completing the thatch of the last wigwam, and others were digging in the garden which was made, I was much surprised to see that all the natives were preparing to depart; and very soon afterwards every canoe was set in motion,—not half a dozen natives remaining. Even Jemmy's own family, his mother and brothers, left us; and as he could give no explanation of this sudden departure, I was in much doubt as to the cause. Whether an attack was meditated, and they were removing the women and children, previous to a general assembly of the men, or whether they had been frightened by our display on the preceding evening, and feared that we intended to attack them, I could not ascertain; but deeming the latter by far the most probable, I decided to take the opportunity of their departure to give Matthews his first trial of passing a night at the new wigwams.

Some among us thought that the natives intended to make a secret attack, on account of the great temptation our property offered; and in consequence of serious offence which had been taken by two or three old men, who tried to force themselves into our encampment, while I was at a little distance; one of whom, when resisted by the sentry, spit in his face; and went off in a violent passion, muttering to himself, and every now and then turning round to make faces and angry gestures at the man who had very quietly, though firmly, prevented his encroachment.

In consequence of this incident, and other symptoms of a

© The Complete Work of Charles Darwin Online

disposition to try their strength, having more than three hundred men, while we were but thirty, I had thought it advisable, as I mentioned, to give them some idea of the weapons we had at command, if obliged to use them, by firing at a mark. Probably two-thirds of the natives around us at that time had never seen a gun fired, being strangers, coming from the Beagle Channel and its neighbourhood, where no vessel had been; and although our exercise might have frightened them more than I wished, so much, indeed, as to have induced them to leave the place, it is not improbable that, without some such demonstration, they might have obliged us to fire at them instead of the target. So many strangers had arrived during the few days we remained, I mean strangers to Jemmy's family —men of the eastern tribe, which he called Yapoo—that his brothers and mother had no longer any influence over the majority, who cared for them as little as they did for us, and were intent only upon plunder. Finding this the case, I conclude that Jemmy's friends thought it wise to retreat to a neighbouring island before any attack commenced; but why they did not tell Jemmy their reasons for going, I know not, neither could he tell me more than that they said they were going to fish, and would return at night. This, however, they did not do.

In the evening, Matthews and his party—Jemmy, York, and Fuegia—went to their abode in the three new wigwams. In that made for Matthews, Jemmy also took up his quarters at first: it was high and roomy for such a construction; the space overhead was divided by a floor of boards, brought from the ship, and there most of Matthews' stores were placed; but the most valuable articles were deposited in a box, which was hid in the ground underneath the wigwam, where fire could not reach.

Matthews was steady, and as willing as ever; neither York nor Jemmy had the slightest doubt of their being all well-treated; so trusting that Matthews, in his honest intention to do good, would obtain that assistance in which he confided, I decided to leave him for a few days. The absence of the

© The Complete Work of Charles Darwin Online

natives, every one of whom had decamped at this time, gave a good opportunity for landing the larger tools belonging to Matthews and our Fuegians, and placing them within or beneath his wigwam, unseen by any one except ourselves; and at dusk, all that we could do for them being completed, we left the place and sailed some miles to the southward.

During the four days in which we had so many natives about us, of course some thefts were committed, but nothing of consequence was stolen. I saw one man talking to Jemmy Button, while another picked his pocket of a knife, and even the wary York lost something, but from Fuegia they did not take a single article; on the contrary, their kindness to her was remarkable, and among the women she was quite a pet.

Our people lost a few trifles, in consequence of their own carelessness. Had they themselves been left among gold and diamonds, would they all have refrained from indulging their acquisitive inclinations?

Notwithstanding the decision into which I had reasoned myself respecting the natives, I could not help being exceedingly anxious about Matthews, and early next morning our boats were again steered towards Woollÿa. My own anxiety was increased by hearing the remarks made from time to time by the rest of the party, some of whom thought we should not again see him alive; and it was with no slight joy that I caught sight of him, as my boat rounded a point of land, carrying a kettle to the fire near his wigwam. We landed and ascertained that nothing had occurred to damp his spirits, or in any way check his inclination to make a fair trial. Some natives had returned to the place, among them one of Jemmy's brothers; but so far were they from showing the slightest ill-will, that nothing could be more friendly than their behaviour.

Jemmy told us that these people, who arrived at daylight that morning were his friends, that his own family would come in the course of the day, and that the 'bad men,' the strangers, were all gone away to their own country.

A further trial was now determined upon. The yawl, with one whale-boat, was sent back to the Beagle, and I set out on

© The Complete Work of Charles Darwin Online

a westward excursion, accompanied by Messrs. Darwin and Hamond, in the other two boats: my intention being to complete the exploration of Whale-boat Sound, and the north-west arm of the Beagle Channel; then revisit Woollȳa, either leave or remove Matthews, as might appear advisable, and repair to our ship in Goree Road. With a fair and fresh wind my boat and Mr. Hamond's passed the Murray Narrow, and sailed far along the channel towards the west, favoured, unusually, by an easterly breeze. Just as we had landed, and set up our tent for the night, some canoes were seen approaching; so rather than be obliged to watch their movements all night, we at once embarked our tent and half-cooked supper, and pulled along the shore some miles further, knowing that they would not willingly follow us in the dark. About midnight we landed and slept undisturbed. Next day we made little progress, the wind having changed, and landed, earlier than usual, on the north side of the channel, at Shingle Point. Some natives soon appeared, and though few in number, were inclined to give trouble. It was evident they did not know the effect of fire-arms; for if a musket were pointed at them, and threatening gestures used, they only made faces at us, and mocked whatever we did. Finding them more and more insolent and troublesome, I preferred leaving them to risking a struggle, in which it might become necessary to fire, at the hazard of destroying life. Twelve armed men, therefore, gave way to six unarmed, naked savages, and went on to another cove, where these annoying, because ignorant natives could not see us.

On the 29th we reached Devil Island, and found the large wigwam still standing, which in 1830 my boat's crew called the 'Parliament House.' Never, in any part of Tierra del Fuego, have I noticed the remains of a wigwam which seemed to have been burned or pulled down; probably there is some feeling on the subject, and in consequence the natives allow them to decay naturally, but never wilfully destroy them. We enjoyed a grand view of the lofty mountain, now called Darwin, with its immense glaciers extending far and wide. Whether

© The Complete Work of Charles Darwin Online

this mountain is equal to Sarmiento in height, I am not certain, as the measurements obtained did not rest upon satisfactory data; but the result of those measures gave 6,800 feet for its elevation above the sea. This, as an abstract height, is small, but taking into consideration that it rises abruptly from the sea, which washes its base, and that only a short space intervenes between the salt water and the lofty frozen summit, the effect upon an observer's eye is extremely grand, and equal, probably, to that of far higher mountains which are situated at a distance inland, and generally rise from an elevated district.

We stopped to cook and eat our hasty meal upon a low point of land, immediately in front of a noble precipice of solid ice; the cliffy face of a huge glacier, which seemed to cover the side of a mountain, and completely filled a valley several leagues in extent.

Wherever these enormous glaciers were seen, we remarked the most beautiful light blue or sea green tints in portions of the solid ice, caused by varied transmission, or reflection of light. Blue was the prevailing colour, and the contrast which its extremely delicate hue, with the dazzling white of other ice, afforded to the dark green foliage, the almost black precipices, and the deep, indigo blue water, was very remarkable.

Miniature icebergs surrounded us; fragments of the cliff, which from time to time fall into a deep and gloomy basin beneath the precipice, and are floated out into the channel by a slow tidal stream. In the first volume the frequent falling of these masses of ice is noticed by Captain King in the Strait of Magalhaens, and in the narrative of my first exploring visit to this arm of the Beagle Channel; therefore I will add no further remark upon the subject.

Our boats were hauled up out of the water upon the sandy point, and we were sitting round a fire about two hundred yards from them, when a thundering crash shook us—down came the whole front of the icy cliff—and the sea surged up in a vast heap of foam. Reverberating echoes sounded in every direction, from the lofty mountains which hemmed us in; but our whole attention was immediately called to great rolling waves

© The Complete Work of Charles Darwin Online

which came so rapidly that there was scarcely time for the most active of our party to run and seize the boats before they were tossed along the beach like empty calabashes. By the exertions of those who grappled them or seized their ropes, they were hauled up again out of reach of a second and third roller; and indeed we had good reason to rejoice that they were just saved in time; for had not Mr. Darwin, and two or three of the men, run to them instantly, they would have been swept away from us irrecoverably. Wind and tide would soon have drifted them beyond the distance a man could swim; and then, what prizes they would have been for the Fuegians, even if we had escaped by possessing ourselves of canoes. At the extremity of the sandy point on which we stood, there were many large blocks of stone, which seemed to have been transported from the adjacent mountains, either upon masses of ice, or by the force of waves such as those which we witnessed. Had our boats struck those blocks, instead of soft sand, our dilemma would not have been much less than if they had been at once swept away.

Embarking, we proceeded along a narrow passage, more like a river than an arm of the sea, till the setting sun warned us to seek a resting-place for the night; when, selecting a beach very far from any glacier, we again hauled our boats on shore. Long after the sun had disappeared from our view, his setting rays shone so brightly upon the gilded icy sides of the summits above us, that twilight lasted an unusual time, and a fine clear evening enabled us to watch every varying tint till even the highest peak became like a dark shadow, whose outline only could be distinguished. No doubt such scenes are familiar to many, but to us, surrounded even as we so often were by their materials, they were rare; because clouds continually hang over the heights, or obscure the little sunshine which falls to the lot of Tierra del Fuego.

The following day (30th) we passed into a large expanse of water, which I named Darwin Sound—after my messmate, who so willingly encountered the discomfort and risk of a long cruise in a small loaded boat. Desirous of finding an opening

© The Complete Work of Charles Darwin Online

northwards, I traced the northern shore of this sound, mile by mile, leaving all islands to the southward until we entered Whale-boat Sound, and I recognized Cape Desolation in the distance, as well as a number of minor points which had become familiar to me during the search after our lost boat in the former voyage (1830).

Feb. 2. Having done what was necessary and attainable for the purposes of the survey, we traversed Whale-boat Sound, and stopped for a time at an old bivouac, used by me twice before, on an islet near the east extremity of the largest Stewart Island. While the boat's crew were occupied in preparing our meal, I went to Stewart Island, and from a small eminence saw Mount Sarmiento quite distinctly. We next steered eastward, along the north side of the Londonderry Islands, and passed the night in a narrow passage. On the 3d we got to the open sea at the south side of Darwin Sound, and entered the south-west arm of the Beagle Channel rather too late, for it had become so dark we could distinguish no place fit to receive us; however, after much scrutiny and anxious sounding, to ascertain if our boats could approach without danger of being stove, we were guided by the sound of a cascade to a sheltered cove, where the beach was smooth. Excepting for the novelty and excitement of exploring unknown places, however uninteresting they may be, there was little in this trip worthy of general notice, considering how much has already been said of these unprofitable regions. Even to a professed naturalist, there was scarcely anything to repay the time and trouble, as it was impossible to delay long enough in any one place to give time for more than a most cursory examination.

I need hardly say that the survey of such places as were visited in this hasty manner is little more than an eye-sketch, corrected by frequent bearings, occasional latitudes by sun, moon, or stars, and meridian distances, measured by two chronometers, which were always kept in a large box and treated very carefully. To have attempted more, to have hoped for such an accurate delineation of these shores, at present almost useless to civilized man, as is absolutely necessary where ship-

© The Complete Work of Charles Darwin Online

ping may resort, would have been wrong, while so many other objects demanded immediate attention.

4th. We sailed along the passage very rapidly, a fresh wind and strong tide favouring us. The flood-tide stream set two or three knots an hour through this south-west arm of the Beagle Channel, but the ebb was scarcely noticed: certainly its strength did not, even in the narrowest places, exceed one knot an hour. A few Alikhoolip Fuegians were seen in a cove on the south shore, ten miles west of Point Divide; the only natives, except a very small party in Darwin Sound, that had been met in the excursion since we left the Tekeenica people.

Near Point Divide we saw a large fire, and approached the spot guardedly, supposing that a number of Fuegians must be there. No one appeared; but still the fire burned brightly, and we began to think there might be an ambush, or that the natives who had been there had fled, but were still in the neighbourhood. Approaching nearer, we found that the fire was in a large tree, whose trunk it had almost consumed. Judging from the slow rate at which the tree burned while we were present, I should say it had been on fire two or three days, and that the frequent heavy rain had prevented the flames from making head. Had the weather been some time dry, the adjoining woodland would have blazed, and, as the mountain side is steep and covered with trees, the conflagration would have been immense. At Point Divide the slate rock seemed to be of excellent quality, fit for roofing; but when will roofing slates be required in Tierra del Fuego? Perhaps though sooner than we suppose; for the accidental discovery of a valuable mine might effect great changes.

On the south shore, nearly opposite to Shingle Point, we met a large party of natives, among whom those who disturbed us at that place as we passed westward were recognized. All of them appeared in full dress, being bedaubed with red and white paint, and ornamented, after their fashion, with feathers and the down of geese. One of their women was noticed by several among us as being far from ill-looking: her features were regular, and, excepting a deficiency of hair on the eyebrow,

© The Complete Work of Charles Darwin Online

and rather thick lips, the contour of her face was sufficiently good to have been mistaken for that of a handsome gipsy. What her figure might be, a loose linen garment, evidently one that had belonged to Fuegia Basket, prevented our noticing. The sight of this piece of linen, several bits of ribbon, and some scraps of red cloth, apparently quite recently obtained, made me feel very anxious about Matthews and his party: there was also an air of almost defiance among these people, which looked as if they knew that harm had been done, and that they were ready to stand on the defensive if any such attack as they expected were put into execution. Passing therefore hastily on, we went as far as the light admitted, and at daybreak next morning (6th) were again hastening towards Woollÿa. As we shot through the Murray Narrow several parties of natives were seen, who were ornamented with strips of tartan cloth or white linen, which we well knew were obtained from our poor friends. No questions were asked; we thought our progress slow, though wind and tide favoured us: but, hurrying on, at noon reached Woollÿa. Several canoes were on the beach, and as many natives seemed to be assembled as were there two days before we left the place. All were much painted, and ornamented with rags of English clothing, which we concluded to be the last remnants of our friends' stock. Our boats touched the shore; the natives came hallooing and jumping about us, and then, to my extreme relief, Matthews appeared, dressed and looking as usual. After him came Jemmy and York, also dressed and looking well: Fuegia, they said, was in a wigwam.

Taking Matthews into my boat, we pushed out a short distance to be free from interruption, and remained till I had heard the principal parts of his story: the other boat took Jemmy on board, and York waited on the beach. Nearly all the Fuegians squatted down on their hams to watch our proceedings, reminding me of a pack of hounds waiting for a fox to be unearthed.

Matthews gave a bad account of the prospect which he saw before him, and told me, that he did not think himself

© The Complete Work of Charles Darwin Online

safe among such a set of utter savages as he found them to be, notwithstanding Jemmy's assurances to the contrary. No violence had been committed beyond holding down his head by force, as if in contempt of his strength; but he had been harshly threatened by several men, and from the signs used by them, he felt convinced they would take his life. During the last few days, his time had been altogether occupied in watching his property. At first there were only a few quiet natives about him, who were inoffensive; but three days after our departure several canoes full of strangers to Jemmy's family arrived, and from that time Matthews had had no peace by day, and very little rest at night. Some of them were always on the look-out for an opportunity to snatch up and run off with some tool or article of clothing, and others spent the greater part of each day in his wigwam, asking for every thing they saw, and often threatening him when he refused to comply with their wishes. More than one man went out in a rage, and returned immediately with a large stone in his hand, making signs that he would kill Matthews if he did not give him what was demanded. Sometimes a party of them gathered round Matthews, and, if he had nothing to give them, teased him by pulling the hair of his face, pushing him about, and making mouths at him. His only partizans were the women; now and then he left Jemmy to guard the hut, and went to the natives' wigwams, where the women always received him kindly, making room for him by their fire, and giving him a share of whatever food they had, without asking for any thing in return. The men never took the trouble of going with him on these visits (which, however, ceased when so many strangers arrived), their attention being engrossed by the tools, clothes, and crockeryware at our shipmate's quarters. Fortunately, the most valuable part of Matthews' own things were underground, in a cave unsuspected by the natives, and other large tools were hidden overhead in the roof of his hut. York and Fuegia fared very well; they lost nothing; but Jemmy was sadly plundered, even by his own family. Our garden, upon which much labour had been bestowed, had been trampled

© The Complete Work of Charles Darwin Online

over repeatedly, although Jemmy had done his best to explain its object and prevent people from walking there. When questioned about it, he looked very sorrowful, and, with a slow shake of the head, said, "My people very bad; great fool; know nothing at all; very great fool." It was soon decided that Matthews should not remain. I considered that he had already undergone a severe trial, and ought not to be again exposed to such savages, however willing he might be to try them farther if I thought it right. The next difficulty was how to get Matthews' chest and the remainder of his property safely into our boats, in the face of a hundred Fuegians, who would of course understand our object, and be much more than a match for us on land; but the less hesitation shown, the less time they would have to think of what we were about; so, dividing our party, and spreading about a little to create confidence—at a favourable moment the wigwam was quickly cleared, the cave emptied, and the contents safely placed in our boats. As I stood watching the proceedings, a few anxious moments passed, for any kind of skirmish would have been so detrimental to the three who were still to remain. When the last man was embarked, I distributed several useful articles, such as axes, saws, gimblets, knives and nails, among the natives, then bade Jemmy and York farewell, promising to see them again in a few days, and departed from the wondering throng assembled on the beach.

When fairly out of sight of Woollȳa, sailing with a fair wind towards the Beagle, Matthews must have felt almost like a man reprieved, excepting that he enjoyed the feelings always sure to reward those who try to do their duty, in addition to those excited by a sudden certainty of his life being out of jeopardy. We slept that night in a cove under Webley Head; sailed early the following morning (7th) along the north side of Nassau Bay, and about an hour after dark reached the Beagle—found all well, the surveying work about Goree Road done, the ship refitted, and quite ready for her next trip.

A day or two was required for observations and arrangements, after which (10th) we beat to windward across Nassau

© The Complete Work of Charles Darwin Online

Bay, and on the 11th anchored in Scotchwell Bay. A rough night was passed under sail between Wollaston and Navarin Islands, in which we pretty well proved the clearness of that passage, as it blew fresh and we made a great many boards.

Next day I set out to examine the western part of Ponsonby Sound and revisit Woollÿa. In my absence one party was to go westward, overland, to look at the outer coast between False Cape and Cape Weddell, and another was to examine and make a plan of the bay or harbour in which the Beagle lay. In 1830, Mr. Stokes had laid down its shores with accuracy on a small scale, but there was not then time to take many soundings; and as I conceived that Orange Bay and this harbour were likely to be useful ports, it was worth making a particular plan of each.

12th. With one boat I crossed Tekeenica Sound, and explored the western part of Ponsonby Sound. Natives were seen here and there, but we had little intercourse with them. Some curious effects of volcanic action were obsevred, besides masses of conglomerate, such as I had not noticed in any other part of Tierra del Fuego. On one islet I was placed in an awkward predicament for half an hour; it was a very steep, precipitous hill, which I had ascended by climbing or creeping through ravines and among trees; but, wishing to return to the boat's crew, after taking a few angles and bearings from its summit, I could find no place by which it appeared possible to descend. The ravine up which I crawled was hidden by wood, and night was at hand. I went to and fro, like a dog on a wall, unable to descend, till one of the boat's crew who was wandering about heard me call, and, ascending at the only accessible place, showed me where to plunge into the wood with a prospect of emerging again in a proper direction. This night we had dry beautiful weather, the leaves and sticks on the ground crackling under our feet as we walked, while at the ship, only sixty miles distant, rain poured down incessantly.

The night of the 13th was passed on Button Island. This

© The Complete Work of Charles Darwin Online

also was quite fine, without a drop of rain, while at the ship, in Packsaddle Bay, it rained frequently. I mention these instances to show how different the climate may be even in places so near one another as Packsaddle Bay and Woollȳa.

14th. With considerable anxiety I crossed over from Button Island to Woollȳa. Several canoes were out fishing, women only being in them, who did not cease their occupation as we passed: this augured well; and in a few minutes after we saw Jemmy, York, and Fuegia, in their usual dress. But few natives were about them, and those few seemed quiet and well disposed. Jemmy complained that the people had stolen many of his things, but York and Fuegia had contrived to take better care of theirs. I went to their wigwams and found very little change. Fuegia looked clean and tidily dressed, and by her wigwam was a canoe, which York was building out of planks left for him by our party. The garden was uninjured, and some of the vegetables already sprouting.

Jemmy told us that strangers had been there, with whom he and his people had 'very much jaw,' that they fought, threw 'great many stone,' and stole two women (in exchange for whom Jemmy's party stole one), but were obliged to retreat. Jemmy's mother came down to the boat to see us; she was decently clothed, by her son's care. He said that his brothers were all friendly, and that he should get on very well now that the 'strange men' were driven away. I advised Jemmy to take his mother and younger brother to his own wigwam, which he promised to do, and then, finding that they were all quite contented and apparently very happy, I left the place, with rather sanguine hopes of their effecting among their countrymen some change for the better. Jemmy's occupation was hollowing out the trunk of a large tree, in order to make such a canoe as he had seen at Rio de Janeiro.

I hoped that through their means our motives in taking them to England would become understood and appreciated among their associates, and that a future visit might find them so favourably disposed towards us, that Matthews might then

© The Complete Work of Charles Darwin Online

undertake, with a far better prospect of success, that enterprise which circumstances had obliged him to defer, though not to abandon altogether.

Having completed our work in Packsaddle Bay on the 18th, the Beagle went to the inlet originally called Windhond Bay, a deep place full of islets: thence, on the 19th, she moved to Gretton Bay, on the north side of Wollaston Island, and to Middle Cove. On the 20th, it was blowing a gale of wind from the south-west, but we pushed across before it to Goree Road, knowing that we should there find secure anchorage, and be unmolested by the furious williwaws which whirled over the high peaks of Wollaston Island.

We weighed from Goree Road on the 21st, and ran under close-reefed topsails to Good Success Bay, where our anchors were dropped in the evening. The night of the 22d was one of the most stormy I ever witnessed. Although close to a weather shore in a snug cove, upon good holding ground, with masts struck and yards braced as sharp as possible, the wind was so furious that both bowers were brought a-head with a cable on each, and the sheet anchor (having been let go early) had half a cable on it, the depth of water being only ten fathoms. During some of the blasts, our fore-yard bent so much that I watched it with anxiety, thinking it would be sprung. The storm being from the westward, threw no sea into the cove, but I several times expected to be driven out of our place of refuge, if not shelter. During part of the time we waited in Good Success Bay for an interval of tolerable weather, in which we might cross to the Falkland Islands without being molested by a gale, there was so much surf on the shore that our boats could not land, even while the wind was moderate in the bay.

While we were prisoners on board, some fish were caught, among which was a skate, four feet in length and three feet wide. Several fine cod-fish, of the same kind as those off Cape Fairweather, were also hooked, and much relished.

On the 26th we sailed, passed through a most disagreeable swell off Cape San Diego, and ran before a fresh gale towards

© The Complete Work of Charles Darwin Online

the Falkland Islands. Towards evening we rounded to for soundings, but the sea was so high and short, that a man* at the jib-boom-end was pitched more than a fathom under water. He held on manfully, both to the boom and the lead-line, and as he rose above the wave, blowing and dripping, hove the lead forward as steadily as ever.† My own feelings at seeing him disappear may be imagined:—it was some time before we sounded again. This heavy though short sea seemed to be caused by the flood tide, coming from the southward, and meeting waves raised by strong north-west winds. The stream of tide set us a mile each hour north-eastward.

At eight the wind and sea were too much for us to run with; therefore, watching an opportunity, we rounded to ‡ under close-reefed main-topsail, trysails, and fore-staysail. Next morning (27th) we bore up, though the sea was still heavy, and steered to pass south of the Falklands. Our observations at noon showed that since leaving Good Success Bay we had been set more than thirty miles to the north-east. This effect, whether caused by the flood tide-stream, or by a current independent of the tide, would be dangerous to ships endeavouring to pass westward of the Falklands during bad weather, and in all probability caused the embayment of H.M.S. Eden, Captain W. F. W. Owen, when she was saved by his skill: also of a French storeship, the Durance; and of several other vessels. At noon, on the 28th, we found that the current or stream of tide had set us more towards the east than to the northward, during the preceding twenty-four hours, while we were at the south side of the islands.

At daylight on the 1st of March (having passed the preceding night standing off and on under easy sail), we made Cape Pembroke, at the eastern extremity of the Falklands. The weather was very cold and raw, with frequent hail-squalls,

* Nicholas White.

† Two men in the staysail netting were also dipped under water, at a second plunge, from which White escaped.

‡ The barometer was below 29 inches. See Meteorological Journal in Appendix.

© The Complete Work of Charles Darwin Online

although in the month corresponding to September of our hemisphere; and while working to windward into Berkeley Sound, the gusts of wind were sometimes strong enough to oblige us to shorten all sail. I did not then know of Port William—so close to us, and so easy of access.

The aspect of the Falklands rather surprised me: instead of a low, level, barren country, like Patagonia, or a high woody region, like Tierra del Fuego, we saw ridges of rocky hills, about a thousand feet in height, traversing extensive tracts of sombre-looking moorland, unenlivened by a tree. A black, low, and rocky coast, on which the surf raged violently, and the strong wind against which we were contending, did not tend to improve our first impressions of those unfortunate islands—scene of feud and assassination, and the cause of angry discussion among nations.

In a cove (called Johnson Harbour) at the north side of Berkeley Sound, was a wrecked ship, with her masts standing, and in other places were the remains of two more wrecks. We anchored near the beach on which Freycinet ran the Uranie, after she struck on a rock off Volunteer Point, at the entrance of Berkeley Sound; and from a French boat which came alongside learned that the Magellan, French whaler, had been driven from her anchors during the tremendous storm of January 12-13; that her crew were living on shore under tents, having saved every thing; that tnere were only a few colonists left at the almost ruined settlement of Port Louis; and that the British flag had been re-hoisted on the islands by H.M.S. Tyne and Clio.

CHAPTER XI.

HISTORICAL SKETCH OF THE FALKLAND ISLANDS.

THE Falkland Islands, lying between the parallels of 51° and 53° S., and extending from near 57° almost to 62° W., are in number about two hundred, but only two are of considerable size. Between these latter, called East, and West Falkland, is the channel to which our countryman, Strong, gave the name of Falkland Sound, he himself calling the adjacent country Hawkins' Land.

Plausible assertions have been made by parties anxious to disprove the claim of Great Britain to these islands, and so few persons, excepting those immediately concerned, have inclination to refer to original documents, that I may be pardoned for recalling to the recollection of those to whom the subject is still interesting, a few well-known facts, which, if fairly considered, place the question above dispute.

It has been asserted, that Americus Vespucius saw these islands in 1502,* but if the account of Americus himself is authentic,† he could not have explored farther south than the right bank of La Plata. In 1501-2 Americus Vespucius, then

* Il me paroît qu'on en peut attribuer la première découverte au célèbre Améric Vespuce, qui, dans son troisième voyage pour la découverte de l'Amérique, en parcourut la côte du nord au mois d'Avril 1502. Il ignoroit à la vérité si elle appartenoit à une île, ou si elle faisoit partie du continent; mais il est facile de conclure de la route qu'il avoit suivie, de la latitude à laquelle il étoit arrivé, de la description même qu'il donne de cette côte, que c'étoit celle des Malouines. J'assurerais, avec non moins de fondement, que Beauchesne Goüin, revenant de la mer du Sud en 1700, a mouillé dans la partie orientale des Malouines, croyant être aux Sebaldes.—Voyage de Bougainville, 2d édit. 1772, tom. i. p. 63.

† Letters of Americus Vespucius, in Ramusio's Collection, vol. i. fol. 128.

© The Complete Work of Charles Darwin Online

employed by the King of Portugal, sailed 600 leagues south and 150 leagues west from Cape San Agostinho (lat. 8° 20′ S.) along the coast of a country then named Terra Sancte Crucis.* His account of longitude may be very erroneous, but how could his latitude have erred thirteen degrees in this his southernmost voyage?

The south shore of the Plata is low, and appears to be woody, though it is not; the depth of water off it is moderate, and the currents are strong—all which peculiarities have been remarked on the northern coasts of the Falklands; therefore the 'description' alluded to by De Bougainville would apply equally well to the right bank of the Plata. The late Mr. Dalrymple published an extract from a chart printed at Rome, in 1508, in which it is said, that ships of Portugal discovered a continuation of land as far south as fifty degrees,† which did not there terminate. In that chart the name America is not to be found. Brazil is there called Terra‡ Sancte Crucis.

If the Portuguese or any other people actually traced or even discovered portions of coast south of the Plata before 1512, it appears strange that so remarkable an estuary, one hundred and twenty miles across, should have been overlooked; especially as soundings extend two hundred miles seaward of its entrance:—and that the world should have no clear record of its having been discovered prior to the voyage of Juan de Solis, in 1512. Vespucius has already robbed Columbus and his predecessor, Cabot, of the great honour of affixing their names to the New World—shall he also be tacitly permitted to claim

* The name America was not given before the year 1507. (Herrera, Dec. 1, 7, 5.)

† The Falklands are beyond fifty-one degrees of south latitude.

‡ In 1507 (the admiral Christopher Columbus being dead), Americus Vespucius was taken into the service of the King of Spain, with the title of 'Pilote mayor,' and was employed in making charts of the new discoveries, which gave him an opportunity to affix his own name to the land of South America. (Herrera, Dec. 1, 7, 5.)

© The Complete Work of Charles Darwin Online

even the trifling distinction of discovering the Falklands, when it is evident that he could not have seen them ? *

On the 14th of August 1592, John Davis, who sailed with Cavendish on his second voyage, but separated from him in May 1592, discovered the islands now called Falkland. In Mr. John Jane's relation of Davis's voyage (Hakluyt, vol. iii. p. 846), there is the following simple, but distinct account of this discovery: "Aug. 14, 1592. We were driven in among certain isles, never before discovered by any known relation, lying fifty leagues or better from the shore, east and northerly from the Strait" (of Magalhaens).

At this time Davis was striving to enter the Strait of Magalhaens, but had been long at sea, and driven far by tempests. His bearing is correct, though the distance (by estimation only) is too small.

In 1683-4, Dampier and Cowley saw three islands in lat. 51° to 51° 20′ S., which they (correctly) supposed to be those seen and named by Sebald de Weert. However, the editor of Cowley's narrative, one William Hack, published a different latitude for the land they saw, and called it Pepys Island, in compliment to the then Secretary of the Admiralty, intending that it should be supposed a new discovery. The false latitude given by Hack was 47° S.: in his drawing of the island he did not omit the insertion of an Admiralty Bay and a Secretary Point.

Hawkins sailed along the northern shores of these islands in 1594, and he, ignorant of Davis's discovery, named them Hawkins's Maiden Land. His account appearing first, and prominently, before the public, procured for them the name by which they were known until Strong, in 1690, sailed through and anchored in the channel which he named Falkland Sound. The Welfare's journal, written by Strong, is in the British Museum, together with Observations made during a South Sea Voyage, written by Richard Simson, who sailed in the

* Could the constructor of the chart, published at Rome in 1508, have been misinformed, owing to a mistake of 5 for 3 (50 for 30)? Such errors occur frequently in modern compilations.

© The Complete Work of Charles Darwin Online

same ship; but a few sentences in each are so relevant to the present subject, that I shall quote them verbatim:—"1690. Monday 27th January. We saw the land; when within three or four leagues, we had thirty-six fathoms. It is a large land, and lieth east and west nearest. There are several quays that lie among the shore. We sent our boat to one, and she brought on board abundance of penguins, and other fowls, and seals. We steered along shore E. by N., and at eight at night we saw the land run eastward as far as we could discern. Lat. 51° 3′ S.

"Tuesday 28th. This morning at four o'clock we saw a rock that lieth from the main island four or five leagues. It maketh like a sail.* At six, we stood into a sound that lies about twenty leagues from the westernmost land we had seen. The sound lieth south and north nearest. There is twenty-four fathoms depth at the entrance, which is four leagues wide. We came to an anchor six or seven leagues within, in fourteen fathoms water. Here are many good harbours. We found fresh water in plenty, and killed abundance of geese and ducks. As for wood, there is none.

"On the 31st we weighed from this harbour, with the wind at W.S.W. We sent our long-boat a-head of the ship, to sound before us. At eight o'clock in the evening, we anchored in nine fathoms. The next morning we weighed, and sent our boat before us. At ten, we were clear out of the sound. At twelve, we set the west cape bearing N.N.E., which we named Cape Farewell. This sound, Falkland Sound as I named it, is about seventeen leagues long; the first entrance lies S. by E., and afterwards S. by W."

How it happened that the name Falkland, originally given to the sound alone, obliterated Hawkins, and has never yielded to Davis, is now a matter of very trifling importance.

I may be permitted to remark particularly, that Hawkins and Strong not only saw both East and West Falkland, but that in 1690 Strong anchored repeatedly between them, and landed: and I do so, because stress has been laid upon the fact

* This rock was seen by Hawkins, and named by him 'White Conduit.' Now it is called Eddystone.

© The Complete Work of Charles Darwin Online

of Beauchesne Goüin having anchored in 1700 on their eastern coast.

In the year 1600, the islands now called Jasons, Salvages, or Sebaldines, at the north-west extremity of the Falklands, were seen and named by Sebald de Weert; and during the next two centuries many other navigators, sailing to or from the Pacific, saw the Falklands; but it does not appear that any further landing was effected, or even that any vessel anchored there, after Beauchesne, except the Saint Louis, of St. Malo, until M. de Bougainville landed to form his settlement, in February 1764.

Several ships of St. Malo passed near the Eastern Falklands between the years 1706 and 1714, from whose accounts M. Frezier compiled his chart, published in 1717; and in compliment to the owners of one of them (the Saint Louis), her commander, M. Fouquet, named the cluster of islets near which he anchored, the Anican Isles.

In consequence of the visits of these ships of St. Malo, the French named the islands Les Malouines; but this was not till after 1716, when Frezier compiled the chart in which he called them 'Isles Nouvelles,' although in his own narrative (p. 512, Amsterdam edition, 1717), he says, "Ces îsles sont sans doute les mêmes que celles que le Chevalier Richard Hawkins découvrit en 1593."

The Spaniards adopted the French name, slightly altered, by changing Malouines into Malvinas: even now the term 'Maloon,' a corruption of Malouine,* is sometimes used by English or Americans instead of island, in writing as well as in speaking.

During the early part of the last century, France maintained a lucrative commerce with Chile and Peru, by way of Cape Horn, and the advantages which might be derived from a port of refuge and supply at the eastern extremity of the Falklands did not escape her active discernment.

De Bougainville says, "Cependant leur position heureuse

* "Fortunately, it is on this maloon, or island, that bullocks and horses are found running wild."—(Weddell, p. 97.)

© The Complete Work of Charles Darwin Online

pour servir de relâche aux vaisseaux qui vont dans la mer du sud, et d'échelle pour la découverte des terres Australes, avoit frappé les navigateurs de toutes les nations. Au commencement de l'année 1763, la cour de France résolut de former un établissement dans ces îles. Je proposai au ministere de le commencer à mes frais, et secondé par MM. de Nerville et d'Arboulin, l'un mon cousin-germain et l'autre mon oncle, je fis sur le champ construire et armer à Saint Malo, par les soins de M. Duclos Guyot, aujourd'hui mon second, l'Aigle de vingt canons, et le Sphinx de douze, que je munis de tout ce qui étoit propre pour une pareille expédition. J'embarquai plusieurs familles Acadiennes, espèce d'hommes laborieuse, intelligente, et qui doit être chère à la France par l'inviolable attachement que lui ont prouvé ces honnêtes et infortunés citoyens.

" A' Monte Video nous prîmes beaucoup de chevaux, et de bêtes à corne,—nous atterrâmes sur les îles Sébaldes le 31 Janvier 1764.

" La même illusion qui avoit fait croire à Hawkins, à Woodes Rogers, et aux autres, que ces îles étoient couvertes de bois, agit aussi sur mes compagnons de voyage, et sur moi. Nous vîmes avec surprise, en débarquant, que ce que nous avions pris pour du bois en cinglant le long de la côte, n'étoit autre chose que des touffes de jonc fort élevées et fort rapprochées les unes des autres. Leur pied, en se desséchant reçoit la couleur d'herbe morte jusqu'à une toise environ de hauteur; et de là sort une touffe de joncs* d'un beau verd qui couronne ce pied; de sorte que, dans l'éloignement, les tiges réunies présentent l'aspect d'un bois de médiocre hauteur. Ces joncs ne croissent qu'au bord de la mer, et sur les petites îles; les montagnes de la grande terre sont, dans quelques endroits, couvertes entièrement de bruyères, qu'on prend aisément de loin pour du taillis."—(Voyage autour du Monde, 1766-69, séconde édition, 1772, tom. i. p. 66-69.)

On the 17th of March De Bougainville decided to place his

* Now called Tussac by the sealers and colonists.

© The Complete Work of Charles Darwin Online

establishment on the spot where the present settlement stands, and forthwith disembarked to commence the laborious undertaking of founding a colony.

In the year 1764, a squadron was sent to the South Seas by George III., in whose instructions, dated June 17th, 1764, it is said, "And whereas his Majesty's islands, called Pepys Island and Falkland Islands, lying within the said track," (the track between the Cape of Good Hope and the Strait of Magalhaens), "notwithstanding their having been first discovered and visited by British navigators, have never yet been so sufficiently surveyed, as that an accurate judgment may be formed of their coasts and product, his Majesty, taking the premises into consideration, and conceiving no junction so proper for enterprises of this nature as a time of profound peace, which his kingdoms at present happily enjoy, has thought fit that it should now be undertaken."

On the 23d January 1765, Commodore Byron went on shore at these islands, with the captains and principal officers of his squadron, "when the Union Jack being erected on a high staff, and spread, the commodore took possession of the harbour and all the neighbouring islands for his Majesty King George III., his heirs, and successors, by the name of Falkland Islands. When the colours were spread, a salute was fired from the ship."

In consequence of Byron's favourable report, Captain Macbride was sent out in H.M.S. Jason to begin their colonization. He arrived in January 1766.

Spain, hearing of the French settlement, immediately laid claim to the islands, as forming a part of her American possessions; and France, influenced by various considerations, agreed to deliver up to Spain her newly-formed colony, upon condition that the projectors and colonists should be indemnified for their losses: an agreement honourably fulfilled by Spain.

On the 1st of April 1767, De Bougainville gave up possession to the Spanish officer appointed to take charge; the standard of Spain was hoisted, and royal salutes fired by the ves-

© The Complete Work of Charles Darwin Online

sels present. Some of the French colonists remained, but the greater part preferred returning to France, and passages were given to them on board Spanish ships.

In 1770, a Spanish armament attacked the British colony at Port Egmont, and obliged its small garrison to surrender to an overpowering force, and quit the place. England, indignant at the insult, armed for war, and demanded satisfaction from Spain for the injury inflicted. At first Spain argued and temporized; but finding that Great Britain continued firm, and that the English people were even more disposed for action than their Government, she relinquished her views—disavowed the act of her officer—and restored Port Egmont. England was satisfied—or rather, the court party professed to be satisfied; but the opposers of government angrily declared that Spain had not done enough; and that, though compelled to make restitution, her insult was unatoned for.

In 1774, finding the establishment at the Falklands expensive, and almost useless,* England quietly withdrew it; but the marks and signals of possession and property were left upon the islands, and when the governor departed, the British flag remained flying, and various formalities were observed, intended to indicate the right of possession, as well as to show that the occupation of them might be resumed.

The reports made by officers employed at Port Egmont were of such a discouraging tendency, that no person at that time entertained the least wish to have any further concern with the islands—and for years they were unnoticed—though not forgotten by England. Spain, however, jealous of interference with her colonial possessions, and regarding the Falklands as a vantage-ground, from which those in the south might be suddenly or secretly invaded, maintained a small garrison at the eastern extremity of the Archipelago, where her ships occasionally touched, and from time to time reconnoitred the adjacent ports, in order to ascertain whether any visitors were there. At what precise time the Spaniards with-

* The fact was, it was injudiciously situated, and therefore seldom visited, except by a few fishermen.

© The Complete Work of Charles Darwin Online

drew this small garrison, and left the Falkland archipelago uninhabited by man, I am not certain; but it must have been early in this century, because from 1810 to 1820 there was no person upon those islands who claimed even a shadow of authority over any of them.

In 1820, a ship of war was sent from Buenos Ayres to Port Louis; her captain, Jewitt, hoisted the Argentine flag, and saluted it with twenty-one guns; notifying, at the same time, to the sealing and whaling vessels present, that he was "commissioned by the Supreme Government of the United Provinces of South America to take possession of these islands in the name of the country to which they naturally appertain."—(Weddell, p. 103.) This act of the Buenos Ayrean Government was scarcely known in Europe for many years; and not until 1829 was it noticed formally by Great Britain.

After reading this short statement of facts, one may pause to consider what nation is at this moment the legitimate owner of the Falklands. Do the discovery, prior occupation, and settlement of new and uninhabited countries give a right to possession? If so, Great Britain is the legal owner of those islands. Davis first discovered them; Hawkins first named them; Strong first landed on them; and (excepting the French), Byron first took formal possession of them; and (again excepting the French), Macbride first colonized them. Respecting the French claim, depending only upon first settlement, not discovering, naming, or landing; whatever validity any one may be disposed to allow it, that value must be destroyed, when it is remembered that Spain asserted her superior claim, and that France actually admitted it, resigning for ever her pretensions to those islands. Whatever France might have been induced to do for political reasons, of which the most apparent now is the continuance of the trade she then carried on with Chile and Peru, England never admitted that the Spanish claim was valid: and France having withdrawn, the question is solely between Spain and Great Britain. Spaniards neither discovered, landed upon, nor settled in the Falklands before Englishmen; and their only claim rests upon

© The Complete Work of Charles Darwin Online

the unstable foundation of a papal bull, by virtue of which Spain might just as well claim Otaheite, the Sandwich Islands, or New Zealand.

As to the pretensions of Buenos Ayres, I shall only remark, that in a paper transmitted by her government to Mr. Baylies, chargé-d'affaires of the United States of North America, on the 14th August 1832, the advocate of her claims asserts, that "it is a political absurdity to pretend that a colony which emancipates itself, inherits the other territories which the metropolis may possess. If that singular doctrine were to be found in the code of nations, the Low Countries, for example, on their independence being acknowledged, in 1648, would have succeeded to Spain in her rights to America; and in the same manner, the United States would have appropriated to themselves the British possessions in the East-Indies. Inheritance, indeed! the United States did not inherit the rights of England in Newfoundland, notwithstanding its contiguity; and are they to inherit those which she may have to the Malvinas, at the southern extremity of the continent, and in the opposite hemisphere."*

The writer of the preceding sentences, in his haste to attack the United States of America for an assertion made by one of their journalists, to the effect that the United States inherited from Great Britain a claim to fish around the Falklands, must have overlooked the simple fact, that his arguments were even more applicable to Buenos Ayres than they were to the United States of North America.

When Captain Jewitt arrived at the Falklands, he found more than thirty sail of vessels engaged there in the seal fishery, besides others which were recruiting the health of their crews after whaling or sealing voyages in the antarctic regions. By the crews of these ships numbers of cattle and pigs were killed, as well as horses, the wild descendants of those taken there by Bougainville and his successors.

* Papers relative to the origin and present state of the questions pending with the United States of America on the subject of the Malvinas (Falkland Islands). Translated and printed at Buenos Ayres in 1832.

© The Complete Work of Charles Darwin Online

In 1823, the Buenos Ayrean Government took another step, in the appointment of a 'comandante de las Malvinas;' and in the same year, Lewis Vernet, by birth a German, in concert with his friends at Buenos Ayres, "solicited and obtained from the Government the use of the fishery and of the cattle on the Eastern Malvina, and likewise tracts of land thereon, in order to provide for the subsistence of the settlement.* This undertaking did not prosper; but the next year Mr. Vernet prepared a second expedition, in which he himself sailed. His own words (translated) are: † "After many sacrifices, I was enabled to surmount great obstables; but still that which we expected to effect in one year was not realized before the expiration of five. My partners lost all hope, and sold me their shares. I bought successively three vessels, and lost them; I chartered five, one of which was lost. Each blow produced dismay in the colonists, who several times resolved to leave that ungrateful region, but were restrained by their affection for me, which I had known how to win, and by the example of constancy and patience which my family and myself held out to them."

In 1828, the Government of Buenos Ayres granted to Mr. Vernet (with certain exceptions) the right of property in the Falkland Islands—and in Staten Land! "It also conceded to the colony exemption from taxation for twenty years, and for the same period the exclusive right to the fishery in all the Malvinas, and on the coast of the continent to the southward of the Rio Negro, under the condition that within three years I (Vernet) should have established the colony." ‡

About this time merchant-vessels of all nations visited the Falkland Islands, both in their outward voyage and when returning from the Pacific; but advantageous as their visits were, those of numerous sealers had a very different effect: for, instead of frequenting the settlement, their crews killed the seal indiscriminately at all seasons, and slaughtered great numbers of wild cattle. "For this reason," says Vernet, "I

* See note in preceding page. † Idem. ‡ Idem.

© The Complete Work of Charles Darwin Online

requested the Government to furnish me with a vessel of war, to enable me to cause the rights of the colony to be respected. The Government was aware of the necessity of the measure; but not being then able to place a vessel at my disposal, it resolved to invest me with a public and official character, and for that purpose issued the two decrees of the 10th of June: the one re-establishing the governorship of the Malvinas and Tierra del Fuego; and the other nominating me to fulfil that office."*

In 1829, Vernet warned off some North American sealers; and in 1831, upon their repeating the sealing excursion of which he had complained, he detained them by force. This act, and various circumstances arising out of it, drew upon him and his unfortunate colony the hasty indignation of Captain Silas Duncan, of the United States corvette Lexington, who, on his own responsibility, without waiting to communicate with his Government, sailed from the Plata to the Falkland Islands, surprised, assaulted, and made prisoners of many unoffending people, and unwarrantably destroyed both property and buildings. Mr. Brisbane and several others were put into confinement, and carried away, on board the Lexington, to Buenos Ayres, where they were delivered up to the Buenos Ayrean Government, in February 1832. The United States supported their officer, and immediately despatched a chargé-d'affaires to Buenos Ayres, with instructions to demand compensation for the injury done to North American trade, and full reparation to all North American citizens for personal wrongs.

While the United States and Buenos Ayres were discussing the questions at issue, Great Britain, following up the solemn warnings she had given Buenos Ayres (especially in the protest addressed to that Government by Mr. Parish, in November 1829), issued orders to her Commander-in-chief on the South American station, to send a vessel of war to re-hoist the British flag upon the Falkland Islands; to assert her right of sovereignty, and to cause every thing belonging to the Buenos Ayrean Government to be embarked and sent away.

* See note, page 236.

© The Complete Work of Charles Darwin Online

On the 2d of January 1833, H.M.S. Clio anchored in Berkeley Sound, to carry these orders into effect; H.M.S. Tyne, about the same time, anchoring in Port Egmont. In each place the British colours were hoisted and saluted: the small Buenos Ayrean garrison at Port Louis quietly withdrew, and sailed for the Plata in an armed schooner, belonging to Buenos Ayres: and from that time those unhappy islands have been more ostensibly British, though but little has yet been done to draw forth the resources, and demonstrate the advantages which they unquestionably possess. When the Tyne and Clio sailed, after a very short stay at the islands, no authority was left there, but the colours were entrusted to an Irishman, who had been Mr. Vernet's storekeeper.*

In 1834, a lieutenant in the navy, with a boat's crew, was sent to reside at Port Louis, and since that time various small ships of war have succeeded each other in visiting and exploring the numerous islands and harbours of that archipelago.

Those who may wish for more historical information on this subject—for further details of former negociations between Spain and England, or of the late discussions between North America and Buenos Ayres—should refer to Dr. Johnson's "Thoughts respecting the Falkland Islands" (Johnson's Works, vol. viii. p. 96, Murphy's Edition, 1816); to Junius's 42d Letter; and to papers published at Buenos Ayres in 1832; in addition to general history.

* Not long before the Clio arrived, there had been a mutiny in the garrison, and the Buenos Ayrean commanding officer had been barbarously murdered. In the early part of 1834, Mr. Brisbane fell a victim to treachery. These fatal occurrences will be mentioned again in the course of my narrative.

CHAPTER XII.

First Appearance — Tides — Currents — Winds — Lightning — Seasons — Temperature — Rain — Health — Dangers — Cautions — View — Settlement — Animals — Foxes — Varieties — Seal — Whales — Fish and Fishery — Birds — Brushwood — Peat — Pasture — Potash — Orchilla — Grazing — Corn — Fruit — Vegetables — Trees — Plants — Land — Situation of principal Settlement — Prospective advantages — Suggestions — Vernet's Establishment — Reflections.

In the appearance of the Falkland Islands, there is very little either remarkable or interesting. About the greater part of the archipelago, barren hills, sloping towards low and broken ground, or rocky surf-beat shores, are the only objects which meet the eye. On the West Falkland, and some small islands near it, there are high precipitous cliffs in a few parts exposed to the western seas; but other places, and especially the southern portions of East Falkland, are so low that they cannot be seen from the deck of a vessel five miles distant. The average height of the western island is greater than that of the eastern, although the highest hills seem to be in the latter, where they rise to about thirteen hundred feet above the sea level.

Around the islands, especially toward the south-eastern and north-western extremes, there are numerous islets and rocks, whose distance from shores, where tides run strongly and winds are violent as well as sudden, makes them exceedingly dangerous; more particularly near the north-west extremity of the group: and as seamen require information on these matters before entering a port, I will notice the tides, winds, and climate previous to other subjects.

The tides differ much as to strength and direction in different parts of the archipelago, but the times of syzigial high water only vary from five to eight o'clock; and the rise of tide is almost similar every where, about four feet at neap, and eight

© The Complete Work of Charles Darwin Online

feet at spring tides. The principal swell of the ocean, which causes the tidal streams about these islands, comes from the south-east. Scarcely any stream is perceptible on the south-east coast of East Falkland; but along the north, south, and west shores it increases in strength, until among the Jason Islands it runs six miles an hour, causing heavy and dangerous races. Off Berkeley Sound, across the entrance, and near Cape Carysfort, the tide runs about two knots, at its greatest strength; and thence westward it increases gradually. Into Falkland Sound the tide flows from both openings, and meets near the Swan Islands; shewing, I apprehend, that the principal wave or swell impinges upon the coast considerably eastward of south.

The tidal currents are stronger along the northern shores of the archipelago than they are along the south coasts; and the stream of flood is stronger than the ebb. At Port William, the easternmost harbour, the time of high water at full moon is five; and thence westward, the times increase gradually to half-past eight, at New Island, which is nearly the westernmost of the group.

Generally speaking, the sea is much deeper near the southern and western shores than it is near those of the north; and to those local differences I attribute the varying velocity of the minor tide streams.

Besides these movements of the surrounding waters, there is a current setting past the islands from south-west to north-east: a current which continually brings drift wood to their southern coasts, and has brought Fuegian canoes. On all parts of the southern shores that are open to the south-west, the beaches or rocks are covered with trees, which have drifted from Staten Land or Tierra del Fuego. Great quantities of this driftwood may be found between Cape Orford and Cape Meredith; upon the Arch, Speedwell, George, and Barren Islands: indeed, there are few places between Cape Orford and Choiseul Bay where a vessel may not find a good supply of fuel. On Long Island, and in the bay behind the Sea-Lion Islands, portions of Fuegian canoes have often been found; one consisted of an entire side (pieces of bark sewed together), which

© The Complete Work of Charles Darwin Online

could not have been made many years. At sea, when north-eastward of the Falklands, great quantities of drift kelp* are seen, besides water-worn trunks and branches of trees, near which there are generally fish, and numbers of birds. These sure indications of a current from the south-west have been met with upwards of two hundred miles to the northward of Berkeley Sound. There is not, however, reason to think that this current ever runs more than two knots an hour, under any circumstances, and in all probability its usual set is even less than one knot.

Wind is the principal evil at the Falklands: a region more exposed to storms, both in summer and winter, it would be difficult to mention.

The winds are variable; seldom at rest, while the sun is above the horizon, and very violent at times; during the summer a calm day is an extraordinary event. Generally speaking, the nights are less windy than the days, but neither by night nor by day, nor at any season of the year, are these islands exempt from sudden and very severe squalls; or from gales which blow heavily, though they do not usually last many hours.

It has been stated by Bougainville and others that in summer the wind generally freshens as the sun rises, and dies away about sunset: also, that the nights are clear and starlight. The information I have received, with what I have myself witnessed, induces me to agree to the first of these statements in its most general sense, and to a certain degree I can admit the second; but, at the same time, it is true that there are many cloudy and very many windy nights in the course of each year, I might almost say month. The Magellan was driven from her anchors, though close to a weather shore in the narrowest part of Berkeley Sound, and totally wrecked in Johnson Harbour about midnight of the 12th of January† 1833.

The prevalent direction of the wind is westerly. Gales, in general, commence in the north-west, and draw or fly round to the south-west; and it may be remarked, that when rain

* Sea-weed detached from the rocks and drifting with the current.

† The month which, in that hemisphere, corresponds to July in ours.

© The Complete Work of Charles Darwin Online

accompanies a north-west wind it soon shifts into the south-west quarter, and blows hard.

Northerly winds bring cloudy weather; and when very light, they are often accompanied by a thick fog: it is also worth notice that they almost always occur about the full and change of the moon.

North-east and northerly winds bring gloomy overcast weather, with much rain; sometimes they blow hard and hang in the N.N.E., but it is more common for them to draw round to the westward. South-easterly winds also bring much rain, they are not frequent, but they blow hard, and as the gale increases it hauls southward. During winter the winds are chiefly from the north-west, and in summer they are more frequently south-west. Though fogs occur with light easterly or northerly winds, they do not often last through the day.

Gales of wind, as well as squalls, are more sudden, and blow more furiously from the southern quarter, between south-west and south-east, than from other directions.

Wind from the east is rarely lasting, or strong; it generally brings fine weather, and may be expected in April, May, June, and July, rather than at other times, but intervals of fine weather (short indeed), with light breezes from E.S.E. to E.N.E., occur occasionally throughout the year.

Neither lightning nor thunder are at all common, but when the former occurs easterly wind is expected to follow. If lightning should be seen in the south-east while the barometer is low,* a hard gale from that quarter may be expected. South-east and southerly gales last longer than those from the westward, and they throw a very heavy sea upon the southern shores. In the winter there is not, generally, so much wind as in the summer, and in the former season the weather, though colder, is more settled, and considerably drier.

* A seaman may naturally ask here, and at other passages where reference is made to the barometer, "What is considered low for that place?" and as a reply may be obtained more satisfactorily by consulting the Meteorological Journal, in the appendix, than by receiving an answer in figures (barometers and direction of wind varying so much), I will beg him to look at that Journal.

© The Complete Work of Charles Darwin Online

In different years seasons vary so much, that those who have been longest about the islands hardly venture to predict what weather will be found during any particular month. All they say is, that January, February, and March, though warmest, are the windiest months, and that May, June, and July, though cold, are much less stormy.*

I must here add one word in favour of the barometer, or sympiesometer. Every material change in the weather is foretold by these invaluable instruments, if their movements are tolerably understood by those who consult them, and if they are frequently observed. Mr. Low said to me, "The barometer is worth any thing in these countries" (alluding to Tierra del Fuego, as well as the Falklands); "some say they dislike it because it is always so low, and foretelling bad weather; but how often do we have any other?" They must, somehow, think the barometer ominous, and overlook the use of the omen.

The temperature may be considered equable; it is never hot, neither is it ever very cold; but the average is low, and in consequence of frequent rain and wind, a really moderate degree of cold is much more noticed than would probably be the case if the weather were dry and serene.

Since 1825 Fahrenheit's thermometer has only once been observed so low as 22° in the shade, at mid-day, and it has been but once above 80° in the shade. Its ordinary range is between 30° and 50° in the winter, and from 40° to 65° in the summer. Ice has not been known to exceed an inch in thickness; snow seldom lies upon the low lands, or at any period exceeds two inches in depth. Although rain is so frequent, it does not continue falling for any considerable time; and as evaporation is rapid, in consequence of so much wind, there are no unwholesome exhalations; indeed, the climate is exceedingly healthy, and no disease whatever has been hitherto contracted, in consequence of its influence, excepting ordinary colds and coughs, or rheumatic affections, brought on by unusual expo-

* Mr. Low scarcely ever found two succeeding years alike, as to wind and weather, during the corresponding seasons.

© The Complete Work of Charles Darwin Online

sure to weather. It is said by those who have had the most experience there, that the climate of West Falkland is milder than that of the Eastern large island. Probably the west winds are chilled in passing over the heights, and upon reaching Port Louis are several degrees colder than when they first strike upon the western islands. In Tierra del Fuego, and many other places, the case is similar, the western regions having a milder climate than is found about the central or eastern districts. Excellent harbours, easy of access, affording good shelter, with the very best holding ground, abound among these islands, and, with due care, offer ample protection from the frequent gales.

In approaching the land, and especially while entering a harbour, a careful look-out should be kept for 'fixed kelp,' the seaweed growing on every rock in those places, which is covered by the sea, and not very far beneath its surface. Lying upon the water, the upper leaves and stalks show, almost as well as a buoy, where there is a possibility of hidden danger. Long stems, with leaves, lying regularly along the surface of the sea, are generally attached to rocky places, or else to large stones. Occasionally a few straggling stalks of kelp are seen in deep water, even in thirty fathoms: many of which are attached to stones, and so firmly, that their long stems will sometimes weigh the stone adhering to their roots. Such scattered plants as these need not be minded by a ship; but in passing to windward of patches or beds of kelp, or rather in passing on that side from which the stems stream away with the current, care should be taken to give the place a wide berth, because the only part which shows, when the tide is strong, lies on one side of, not over the rocks. Where the stream of tide is very strong this kelp is quite 'run under,' or kept down out of sight, and can no longer be depended on as a warning. When a clear spot is seen in the middle of a thick patch of fixed kelp, one may expect to find there the least water.

Drift kelp, or that which is floating on the surface of the sea, unattached to any rock or stone, of course need not be

© The Complete Work of Charles Darwin Online

avoided; it may be known at a glance, by the irregular huddled look which it has. Off the south-east shores of the Falklands there are several rocky shallows, on which the sea breaks heavily during south-east gales, though not at other times: all those shallows are marked by kelp, and in one place, thus indicated, not more suspicious in appearance than others, a rock was found, almost 'awash' at low water.

Many wrecks have occurred, even on the land-locked shores of harbours themselves, and in 1833-4, some of their remains served as a warning to strangers to moor their ships securely: but with good ground tackle, properly disposed, and the usual precautions, a vessel will lie in absolute safety, as the holding-ground is excellent: indeed, in many places so tenacious, that it is exceedingly difficult to weigh an anchor which has been some time down. Particular directions for making the land, approaching and entering harbours, and taking advantageous berths, will be found in another place: generally speaking, the local pilotage is very simple.

The country is remarkably easy of access to persons on foot; but half-concealed rivulets and numerous bogs, oblige a mounted traveller to be very cautious. There are no trees any where, but a small bush is plentiful in many vallies. Scarcely any view can be more dismal than that from the heights: moor-land and black bog extend as far as eye can discern, intersected by innumerable streams, and pools of yellowish brown water. But this appearance is deceptive; much of what seems to be a barren moor, is solid sandy clay soil, covered by a thin layer of vegetable mould, on which grow shrubby bushes and a coarse grass, affording ample nourishment to cattle; besides which, one does not see into many of the vallies where there is good soil and pasture. Some tracts of land, especially those at the south of East Falkland, differ in character, being low, level, and abundantly productive of excellent herbage.

Mr. Darwin's volume will doubtless afford information as to the geological formation of the Eastern Falkland. He did not visit the western island, but obtained many notices of it from

© The Complete Work of Charles Darwin Online

those who were there. The more elevated parts of East Falkland are quartz rock; clay-slate prevails in the intermediate districts. Sandstone, in which are beautifully perfect impressions of shells, occurs in beds within the slate formation: and upon the slate is a layer of clay, fit for making bricks. Near the surface, where this clay is of a lighter quality, and mixed with vegetable remains, it is good soil, fit for cultivation. In some places, a great extent of clay is covered by a layer of very solid peat, varying in depth from two to ten feet. The solidity of this peat is surprising; it burns well, and is an excellent substitute for other fuel. To the clay and to the solid peat may be attributed the numerous bogs and pools of water, rather than to the total amount of rain. Is the peat now growing, or was the whole mass formed ages ago?

The settlement, now consisting only of a few huts, some cottages, and a ruinous house or two, occupies the place originally selected by Bougainville, close to Port Louis, at the head of Berkeley Sound. Standing in an exposed situation, scattered over half a mile of rising ground, without a tree or even a shrub near it, the unfortunate village has a bleak and desolate appearance, ominous of its sad history. Previous, however, to entering upon the affairs of the settlement, I will continue my sketch of the islands and their present produce, independent of the settlers now there.

By the French, and afterwards by the Spanish colonists, a number of black cattle, horses, pigs, and rabbits, were turned loose upon East Falkland; and, by considerate persons, engaged in whale or seal-fishery, both goats and pigs have been left upon smaller islands near West Falkland. These animals have multiplied exceedingly; and, although they have been killed indiscriminately by the crews of vessels, as well as by the settlers, there are still many thousand head of cattle, and some thousand horses, besides droves of pigs, perfectly wild, upon the eastern large island: while upon Carcass Island, Saunders Island, and others, there are numbers of goats and pigs. In 1834, the smallest estimate exceeded twelve thou-

sand cattle, and four thousand horses; but there were no means of ascertaining their number, except by comparing the accounts of the gaucho colonists, who were accustomed to pursue them, not only for ordinary food or for their hides, but even for their tongues alone, not taking the trouble to carry off more of the animal so wantonly slaughtered.* The wild cattle are very large and very fat, and the bulls are really formidable animals, perhaps among the largest and most savage of their race. At Buenos Ayres, the ordinary weight of a bull's hide is less than fifty pounds, but the weight of such hides in the East Falkland has exceeded eighty pounds. The horses look well while galloping about wild, but the gauchos say they are not of a good breed, and will not bear the fatigue of an ordinary day's work, such as a horse at Buenos Ayres will go through without difficulty. Perhaps their 'softness,' as it is there called, may be owing to the food they get, as well as to the breed. The wild pigs on East Falkland are of a long-legged, ugly kind; but some of those on Saunders Island and other places about West Falkland are derived from short-legged Chinese pigs. The only quadruped apparently indigenous is a large fox, and as about this animal there has been much discussion among naturalists, and the specimens now in the British Museum were deposited there by me, I am induced to make a few remarks upon it.

* "The settlers, when they abandoned the eastern island, left behind them several horses and horned cattle, which have increased so much, that, on going a few miles into the country, droves of both animals may be seen. I have taken several of the bullocks by shooting them. They are generally ferocious, and will attack a single person; and thus, those who hunt them are enabled to get within pistol-shot of them by the following stratagem. Four or five men advance in a line upon the animal, and, by appearing only as one person, it stands ready to attack, till within one hundred yards, when the hunters spread themselves, and fire, endeavouring to shoot the bullock either in the head or in the fore-shoulder. The horses will also attack a single person, and their mode of doing so is by forming a circle round him, and prancing upon him; but by means of a musquet they may be readily dispersed."—Weddell's Voyage, pp. 102, 103.

© The Complete Work of Charles Darwin Online

It has been said, that there are two varieties of this 'wolf-fox,' as it has been called,* one being rather the smaller, and of a redder brown; but the fact is, that no other difference exists between the two apparent varieties, and as the darker coloured larger animal is found on the East Falkland, while the other is confined to the western island, the darker colour and rather thicker furry coat may be attributed to the influence of a somewhat colder climate. The fox of West Falkland approaches nearer the large fox of Patagonia, both in colour and size, than its companion of East Falkland does; but allowing that there is one shade of difference between the foxes of East and West Falkland, there are but two, or at most three shades between the animal of West Falkland and the large fox of Port Famine. In Strong's voyage (1690), Simson describes these foxes as being twice as large as an English fox, but he does not say upon which island.†

* "Le loup-renard, ainsi nommé parce qu'il se creuse un terrier, et que sa queue est plus longue et plus fournie de poil que celle du loup, habite dans les dunes sur le bord de la mer. Il suit le gibier et se fait des routes avec intelligence, toujours par le plus court chemin d'une baie à l'autre; à notre première descente à terre, nous ne doutâmes point que ce ne fussent des sentiers d'habitans. Il y a apparence que cet animal jeûne une partie de l'année, tant il est maigre et rare. Il est de la taille d'un chien ordinaire dont il a aussi l'aboiement, mais foible. Comment a-t-il été transporté sur les îles?"—Voyage de Bougainville, seconde édition, tome i. p. 113.

† "They saw foxes on this land, which, Simson says, 'were twice as big as those in England. Having brought greyhounds with us, we caught a young fox alive, which we kept on board some months, but on the first firing our great guns in the South Sea, he was frighted overboard, as were also some St. Jago monkies. As to the antiquity of these foxes, as they cannot fly, and it is not likely they should swim so far as from America, nor again is it probable that any would be at the pains of bringing a breed of foxes so far as Hawkins' Island is from any other land, it will follow that there have either been two distinct creations, or that America and this land have been formerly the same continent.' There are means more within the common course of nature than those which occurred to Simson, by which foxes may have become inhabitants of this land. Islands of ice are met at sea in much lower southern latitudes,

© The Complete Work of Charles Darwin Online

All who have seen these animals alive have been struck by their eager ferocity and disregard of man's power. Byron says, "Four creatures of great fierceness, resembling wolves, ran up to their bellies in the water to attack the boat!" also, "When any of these creatures got sight of our people, though at ever so great a distance, they ran directly at them."—"They were always called wolves by the ship's company; but except in their size and the shape of the tail, I think they bore a greater resemblance to a fox. They are as big as a middle-sized mastiff, and their fangs are remarkably long and sharp." "They burrow in the ground, like a fox." The Beagle's officers, when employed in surveying the Falklands, were often annoyed, as well as amused, by the intrusion of these fearless animals. In size, the larger ones are about twice as bulky as an English fox, and they stand nearly twice as high upon their legs.* Their heads are coarser, and their fur is not only thicker as well as longer, but it is of a woolly nature.

Referring again to a resemblance between the Falkland and Patagonian foxes, I may remark, that there is as much difference in size, in coat, and in tail, between the guanaco of Port Desire and that of Navarin Island (near Cape Horn), as there is between the fox of West Falkland and that of Port Famine. What the Patagonian animal is which the Blanco Bay people called 'wolf,'† or to which Pigafetta alluded in his vocabulary of words used by the Patagonians at Port San Julian, as equivalent to 'ani,'‡ I cannot say: I was inclined to suspect an equivoque arising out of the word 'lobo,' which means seal as well as wolf; but Lieut. Wickham says he saw a wolf near the Colorado River. § The Falkland foxes feed upon birds, rab-

tudes, many of which, no doubt, are formed in the bays and rivers of the continent. Seals and sea-birds repose on the edge of the shore, whether it is ice or land, and foxes, or other animals, in search of prey, will frequently be carried away on the large pieces of ice which break off and are driven out to sea."—Burney, vol. iv, pp. 331-332.

* The country they range over being open, without trees, does not require them to steal along under branches, like the foxes of a woody country.

† Page 107 of this volume.

‡ Burney, vol. i. p. 37.

§ Page 296.

© The Complete Work of Charles Darwin Online

bits, rats and mice, eggs, seals, &c., and to their habits of attacking king-penguins, if not seal, while alive, I presume that a part of their unhesitating approach to man may be traced.

Naturalists say that these foxes are peculiar to this archipelago, and they find difficulty in accounting for their presence in that quarter only.* That they are now peculiar cannot be doubted; but how long they have been so is a very different question. As I know that three hairy sheep, brought to England from Sierra Leone in Africa, became woolly in a few years, and that woolly sheep soon become hairy in a hot country (besides that their outward form alters considerably after a few generations); and as I have both seen and heard of wild cats, known to have been born in a domestic state, whose size surpassed that of their parents so much as to be remarkable; whose coats had become long and rough; and whose physiognomies were quite different from those of their race who were still domestic; I can see nothing extraordinary in foxes carried from Tierra del Fuego to Falkland Island becoming longer-legged, more bulky, and differently coated. But how were they carried there? In this manner:—In page 242, the current was mentioned which always sets from Staten Land towards the southern shores of the Falklands—icebergs or trees

* Forster, as an exception, saw no difficulty in accounting for their involuntary migration. "M. Forster, Anglais, de la Société Royale, qui a fait à cet ouvrage l'honneur de le traduire, a accompagné sa traduction de plusieurs notes."—"Je dois dire que toutes ses notes ne sont pas également justes; par exemple, dans le chapître de l'Histoire Naturelle des Iles Malouines, il est surpris de ce que je le suis d'avoir trouvé sur ces îles un animal quadrupède, et de mon embarras sur la manière dont il a été transporté. Il ajoute qu'ayant passé comme je l'ai fait plusieurs années en Canada, j'aurois dû savoir que des quadrupèdes terrestres se trouvant sur de grandes glaces au moment où elles sont détachées des terres, sont emportées à la haute mer, et abordent à des côtes fort éloignées de leur pays natal, sur lesquelles ces masses de glace viennent échouer. Je sais ce fait; mais M. Forster ne sait pas que jamais les voyageurs n'ont rencontré de glaces flottantes dans les environs des îles Malouines, et que dans ces contrées il ne s'y en peut pas former, n'y ayant ni grand fleuve ni même aucune rivière un peu considérable.—Voyage de Bougainville, séconde édition, tom. i. pp. xiv. et xv. (note).

© The Complete Work of Charles Darwin Online

drifted by that current and westerly winds afford the means of transport; and I appeal to the quotations already made from Forster's and Bougainville's works for proof that animals may be so carried.

Because we do not know that there are foxes at this time upon Staten Land, it does not follow that there are none, or that they have never been there; and as guanacoes, pumas, and foxes are now found on Eastern Tierra del Fuego, why might not foxes have been carried to Staten Land and thence to the Falklands, or, which is still more probable, drifted from Eastern Tierra del Fuego direct. I have heard somewhere, though I cannot recollect the authority, that a man in North America hauled a large old tree to the bank of a river in which it was floating towards the sea, and proceeded to secure it on the bank, when to his astonishment, out of a hole in the tree jumped a fine fox. Clusters of trees are often found floating, which have fallen off a cliff, or have been carried out of a river; and once in the ocean, they are drifted along partly by currents and partly by wind acting upon their branches or exposed surfaces.

Rats and mice were probably taken to the Falklands by the earlier navigators who landed there, whose ships were often plagued with their numbers.* That they have varied from the original stock in sharpness of nose, length of tail, colour, or size, is to be expected, because we find that every animal varies more or less in outward form and appearance, in consequence of altered climate, food, or habits; and that when a certain

* In Viedma's Diary of an Expedition to Port San Julian in 1780, he says, "El Bergantin San Francisco de Paula entrò en el riachuelo para descargarlo y dar humazo a las ratas." (The brig San Francisco de Paulo went into the creek to be unloaded and smoked, to kill the rats (or mice, ratas signifying either). In Magalhaens' voyage (1520) "Juan (a Patagonian) seeing the Spaniards throwing mice into the sea, desired he might have them for food; and those that were afterwards taken being given to him, he carried them on shore."—Burney, vol. i. p. 34. Perhaps some of those mice reached land alive, as the ships lay close to the shore. Many other vessels, however, afterwards staid some time in Port San Julian, particularly those of Drake.

© The Complete Work of Charles Darwin Online

change, whatever it may be, is once effected, the race no longer varies while under similar circumstances; but to fancy that every kind of mouse which differs externally from the mouse of another country is a distinct species, is to me as difficult to believe as that every variety of dog and every variety of the human race constitute a distinct species. I think that naturalists who assert the contrary are bound to examine the comparative anatomy of all these varieties more fully, and to tell us how far they differ. My own opinion is, judging from what I have gathered on the subject from various sources, that their anatomical arrangement is as uniformly similar as that of the dogs and of the varieties of man.

On East Falkland there are numbers of rabbits, whose stock is derived from those carried there by Bougainville or the Spaniards. Among them were some black ones (when I was there), which had been pronounced indigenous, or, at all events, not brought from Europe. A specimen of these pseudo-indigenous animals has been carefully examined by those to whom a new species is a treasure, but it turns out to be a common rabbit.

Sea-elephant and seal (both hair and fur-seal) were abundant along the shores of the archipelago in former years, and by management they might soon be encouraged to frequent them again;* but now they are annually becoming scarcer, and if means are not taken to prevent indiscriminate slaughter, at any time of year, one of the most profitable sources of revenue at the Falklands will be destroyed.

Whales frequent the surrounding waters at particular seasons, and they are still to be found along the coasts of Patagonia and Tierra del Fuego (within easy reach from the Falklands), though their numbers are very much diminished by the annual attacks of so many whale-ships, both large and small, which have made the Falklands their head-quarters during the last twenty years.

A valuable source of daily supply, and by salting, of foreign

* On the little island 'Lobos,' in the river Plata, passed and therefore to a certain degree disturbed daily by shipping, seals are numerous; being preserved like game, and destroyed only at intervals.

© The Complete Work of Charles Darwin Online

export, is the inexhaustible quantity of fish which swarm in every harbour during the summer. The description which most abounds is a kind of bass, from two to three feet long, and six inches in depth: it takes salt well, and has been exported by cargoes to the river Plata* and to Rio de Janeiro; and there are delicious small fish in such shoals, that our boats' crews were sometimes obliged to let a large portion escape from the net before they could haul it ashore without tearing.†

Mr. Vernet said, "We have a great abundance of fish in all the bays, where they come at the beginning of spring to spawn. In the winter season they retire. They enter regularly twice in the twenty-four hours, at about half-flood. They are caught in such numbers, that ten or twelve men salted about sixty tons in less than a month. Generally, they are caught with a net, but they will also take the hook; they are of a species between the mullet and the salmon, and become very fat towards the end of the summer. They are very good eating, and when salted, some prefer them to the cod-fish."—Vernet, MS. 1831. In the fresh-water ponds, so numerous on the large islands, there is a very delicate fish, somewhat resembling a trout, which may be caught by angling. The shell-fish are chiefly muscles and clams, both of which are very abundant, and easily gathered at low water.

It may here be remarked that the cod-fishery off Patagonia and Tierra del Fuego might be turned to very good account by settlers at the Falklands.

Of the feathered tribe there are numbers, but not much variety has been found—a natural consequence of the absence of trees. Three or four kinds of geese,‡ two kinds of snipe, several varieties of the duck, occasionally wild swans of two

* Where fish, though plentiful, does not take salt well.

† Many tons have been taken at a haul.

‡ One kind of goose, that which has erroneously been called a bustard, arrives in a tame condition, about April or May, with easterly winds. Perhaps these birds come from Sandwich Land, or even Enderby Land. Their tameness may be a consequence of being ignorant of man, or of the half-tired state in which they arrive.

© The Complete Work of Charles Darwin Online

kinds, a sort of quail (like that of Tierra del Fuego), carrion-hawks or vultures, albatrosses, gulls, petrel, penguins, sea-hens, shags, rooks, curlew, sandpipers, rock-hoppers, and a very few land-birds, are found about most of the islands.*

Although there are no trees, a useful kind of brushwood grows abundantly in vallies, to the height of three or four feet, and thickly set together. Over level plains it is but thinly scattered. The settlers use this brushwood for lighting their peat-fires. There are three kinds of bushes: one grows straight, from two to five feet high, with a stem from half an inch to an inch and half in diameter: this kind is found abundantly in most of the vallies. Another is common about the southern parts of the islands, and has a crooked trunk, as thick as a man's arm, growing to about three feet in height. The third is smaller still, being little better than heather; it grows almost every where, though scantily.

Peat is inexhaustible; and, if properly managed, answers every common purpose of fuel, not only as a substitute, but pleasantly.† It will not, however, in its natural state, answer for a forge; but if dried and subjected to heavy pressure for some time before use, a much greater heat might be derived from it.

There is but little difference in the quality of the grass, either on high or low land; but in sheltered valleys it is longer, softer, and greener, than elsewhere. The whole face of the country is covered with it; and in some places, especially over a peaty soil, its growth becomes hard and rank. In the

* 'Birds' eggs are so numerous at the proper season, that "eight men gathered at one place alone, in four or five days, upwards of sixty thousand eggs, and might have collected twice that number had they remained a few days longer."—Vernet, MS. 1831.

† "The want of wood on these islands would be a great inconvenience, were it not that good peat is very abundant. I have burned many tons, and found it an excellent substitute for coal. In order to get it dry, it is necessary to pull it from the sides of the pit, not very deep; and as there are several peat-holes, by working them alternately, the material may be procured in a state fit for use."—Weddell's Voyage, p. 88.

© The Complete Work of Charles Darwin Online

southern half of East Falkland, where, as I mentioned, the soil is good, there is abundance of long, but brownish grass over all the country, and at the roots of it there are sweet tender shoots, sheltered from the wind, much liked by cattle. In that district there are several varieties of grass growing on fine dark-coloured earth, mixed with light white sand; and, although, from never being cut, it has a rugged and brown appearance, its nutritive properties must be considerable, as the finest cattle are found feeding there. Mr. Bynoe remarked to me, that wherever the surface of the ground had been broken by cattle, he found a very dark-coloured earth mixed with sand or clay, or else clay mixed with gravel and sand. That the clay is good for bricks has been mentioned; but I have not said that there is stone of two or three kinds suitable for building, and that any quantity of lime may be obtained by burning fossil shells brought from the coast of Patagonia, where the cliffs are full of them, or by collecting the shells scattered upon the Falkland shores. Another natural production, of more value than it has hitherto been considered, is the common sea-weed or kelp;* and I am told by Sir Woodbine Parish that the archil or orchilla weed was obtained there by the Spaniards.

It is to be remarked, that the soil of East Falkland has been very much improved in the neighbourhood of the settlement, as well as around the estancia, or farm, where the tame cattle are kept, in consequence of the treading and manuring it has

* The manner of extracting potash from sea-weed is as follows:—When a sufficient quantity of kelp has been collected, it is spread out in a place where it will be dried by the sun and wind, and when dry enough to burn, a hollow is dug in the ground three or four feet wide; round its margin are laid stones, on which the weed is placed and set on fire. Quantities of this fuel being continually heaped upon the circle, there is in the centre a constant flame, from which a liquid substance, like melted metal, drops into the hollow beneath. This substance is worked, or stirred, with iron rakes, and brought to an uniform consistence while in a state of fusion; and when cool, it consolidates into a heavy, dark-coloured alkaline substance, which undergoes in the glass-houses a second vitrification, and then assumes a perfect transparency.

© The Complete Work of Charles Darwin Online

received. The grass is there as short and as sweet as horses could desire; and does not this show, that by folding, on a large scale, any extent of pasture land might, by degrees, be brought to a similar condition? Why sheep have not been carried there in greater numbers I am not aware, but judging from the climate, and the fur of the foxes, I should suppose that the long-woolled sheep would do well, and perhaps improve the staple of its wool, as the merino sheep has done in an opposite manner—by transportation to Australia. Pigs have increased in great numbers on the small islands, where their young are safer from the foxes, and where there is abundance of the sedgy grass called tussac, the roots and stalks of which are much liked by them.

The size and fatness of the wild cattle is a clear proof that the country is adapted for grazing. Of twenty wild bulls which were killed during one excursion of the settlers, shortly before the Beagle's arrival, the average weight of each hide was above seventy, and a few weighed eighty pounds. Some of these animals are so fat and heavy, that the gauchos say they cannot drive them across the marshy grounds which are passed by the other cattle, as well as by men on horseback. It has been also ascertained that meat takes salt remarkably well in that climate; and as salt of excellent quality, as well as saltpetre, abounds on the coast of Patagonia, there is no reason why large quantities of salt meat and salt fish should not be prepared there, and exported to the Brazils, to the East, to Chile, and Peru, besides supplying a number of the ships which would touch there.

But there are alleged disadvantages to contend against, which must not be overlooked for a moment. It is very doubtful whether corn will ripen. Fruit, which requires much sun, certainly will not, and culinary vegetables have been said to run to stalk and become watery. Nevertheless, Mr. Brisbane assured me that wheat had been tried in Vernet's garden, and that there it grew well, producing a full ear and large grain. The garden was small, slightly manured, and defended from wind by high turf fences. Potatoes, he said,

© The Complete Work of Charles Darwin Online

grew large, though watery; but it was easy to see that justice had not been done to them, whole potatoes having been put into holes and left to take their chance, upon a soil by no means so suitable for them as might have been found. Planted even in this rough way, Mr. Bynoe collected three pounds weight of potatoes from one root. By proper management, I think that they, as well as turnips, carrots, cabbage, lettuce, and other esculent plants, might be brought to great perfection, particularly on sheltered banks sloping towards the north-east. The turnips which I saw and tasted were large and well-flavoured: the largest seen there weighed eight pounds and a-half. Flax has been tried in a garden, and succeeded. Mr. Bynoe saw some of it. Hemp has never yet been tried. Currant bushes (*ribes antartica*) have been transported from Tierra del Fuego, and tried near the settlement, but their fruit did not ripen properly. It ought, however, to be remembered that those currants are wild, a bad sort of black currant, and that when ripe in Tierra del Fuego they are scarcely eatable.

We read in Bougainville and Wallis, that thousands of young trees were taken up by the roots in the Strait of Magalhaens, and carried to the Falkland Islands; but no traces of them are now visible either at Port Egmont or Port Louis. Perhaps they were taken out of their native soil at an improper period, exposed to frost or salt water, while their roots were uncovered, and afterwards planted by men who knew more of the main brace than of gardening. Bougainville, however, had industrious 'familles Acadiennes' with him, under whose care the young trees ought to have fared better than under the charge of Wallis's boatswain. Mr. Brisbane told me that he had brought over some young trees from Tierra del Fuego for Mr. Vernet; that some had died, but others (which he showed me) were growing well in his garden. From the opinions I have collected on the subject, and from what has been effected on waste lands, downs, and exposed hills in England and Scotland, by planting thousands at once instead of tens, I have no doubt whatever that trees may be

© The Complete Work of Charles Darwin Online

grown upon either Falkland, and that the more are planted the better they would grow—assisting and sheltering each other. At first, young plants or trees should have banks of earth raised near them, to break the fury of south-west storms, and the most sheltered situations, with a north-east aspect, should be chosen for a beginning.

Anti-scorbutic plants are plentiful in a wild state, such as celery, scurvy-grass, sorrel, &c.; there are also cranberries,* and what the settlers call strawberries, a small red fruit, growing like the strawberry, but in appearance and taste more like a half-ripe blackberry. I must not omit the 'tea-plant,' made from which I have drank many cups of good tea,† and the settlers use it frequently. It has a peculiar effect at first upon some people, which is of no consequence, and soon goes off.‡ This little plant grows like a heath in many parts of the Falklands as well as in Tierra del Fuego, and has long been known and used by sealers.§ The large round gum plant (*Hydrocelice gummifere*), common in Patagonia and Tierra del Fuego, is abundantly found, and, when dried, is useful for kindling fires, being extremely combustible. The gum which exudes from its stalks when cut or broken, is called by the settlers 'balsam,' and they use it quite fresh for wounds; at the least it answers the purpose of sticking-plaister. In summer it may be collected in considerable quantities, without injuring the plants, as it then oozes out spontaneously; even while green, the whole plant is very inflammable. The gauchos, when in the interior of the islands, tear it asunder, set it on fire, and roast their beef before it. Within the stems of the tall sedgy grass, called tussac, is a white sweetish substance, something like the kernel of an unripe nut; this is often eaten by the set-

* One reason for the arrival of flights of geese during April and May may be, that the cranberries are then ripe, of which they are very fond.

† At my own table I have seen it drank by the officers without their detecting the difference: yet the only tea I used at other times was the best that could be obtained at Rio de Janeiro.

‡ U———m ciens.

§ It produces a small berry, of very pleasant taste, which when ripe is eaten as fruit.

© The Complete Work of Charles Darwin Online

tlers, and is so much relished by cattle, horses, and pigs, that the plant itself is greatly diminished in quantity, and now can only be found in its former luxuriance upon islands where cattle or hogs have not access. These flags or rushes are more than six feet high; they make good thatch and a soft bed. There is a shrub, or rather creeper, of which the French made a kind of beer, thought to be wholesome and anti-scorbutic; and there are other vegetable productions which are of little consequence, perhaps, except to botanists,* and as most of them were long ago well described by Bougainville, I may beg the reader to refer to his fourth chapter (Détails sur l'histoire naturelle des Iles Malouines) for a very faithful and well-written account, to every statement in which, as far as my own knowledge goes, I can bear testimony.

Having mentioned the principal productions, it remains to say what more may be effected and what improvements may be made by an industrious colony. Land, which is now in a state of nature, might be surprisingly improved by ploughing and manuring with burned peat or with kelp, which is so abundant on every part of the shore. Walls, or rather mounds of turf, a few feet in height, would assist the slopes of the ground in sheltering cultivated soil from south-west winds, and where stones, as well as turf, are so plentiful, it would be worth while to make a number of small enclosures for fields as well as gardens, taking care always to select the sides of hills, or rather sloping grounds which incline towards the north-east. Fresh water being abundant everywhere, and the islands being so much cut into by the sea, that water carriage could be obtained to within a very few miles of any place, there can be no great preference for one locality rather than another, with a view to agriculture alone; but of course the principal settlement must be near the eastern extremity of the archipelago, because that part is most accessible to shipping, and even now frequently visited. A colony planted near Port William, or at Port Louis, with a small establishment to supply the wants of ship-

* "On a spot, twelve feet square, chosen indiscriminately on the rising grounds in the interior, twenty-seven different plants were counted."—(Vernet, MS.)

© The Complete Work of Charles Darwin Online

ping at Port William, could not fail to prosper, if a free port were offered there to ships of all nations. Homeward-bound ships from our rapidly growing colonies in Australia, as well as those from Mexico, Peru, and Chile, are often in want of a port to which they can resort about the middle of their voyage. The River Plata is out of the way and dangerous; Santa Catharina is almost as much out of reach, and deficient in many articles of supply; Rio de Janeiro and Bahia are also out of the line and very expensive, though they are often resorted to; St. Helena is too far east, scantily supplied, and more expensive than the Brazils. But almost every one of those ships 'sight' the eastern end of the Falklands as they pass by, to correct or verify their longitude, and how very little delay then would they experience, if the course were shaped so as to pass a little nearer Port William, and there heave to under the lee of the land, or let go an anchor, as might be most suitable. Water and fresh provisions might be speedily procured, at a price now moderate, and if a colony were once well organized, in a short time as low as in any part of the world. A few small vessels should be attached to the colony, and two small men of war, one of which should be always about the chief harbour, and the other visiting the various ports of the archipelago. I have alluded more than once to the fact of excellent fresh water being plentiful every where, and I may here add, that if a sailing tank-vessel were kept at Port William in readiness to supply ships without delay, that one convenience only, when generally known, would ensure the visits of almost every Australian and Mexican trader, besides many others. No one making a long voyage hesitates to take in an additional supply of good water during his passage, if he can do so without delay (of consequence) and without danger. It is the natural unwillingness to get in with the land—to be delayed in port—to pay heavy port dues, and to risk losing men—that generally induces seamen in command of vessels to avoid every port excepting that to which they are bound; but if you could ensure to a ship loading at Sydney a safe 'half-way house' at the Falklands, she would hardly prefer carrying a quantity of

© The Complete Work of Charles Darwin Online

water, no longer necessary, to the proportion of cargo that might be stowed in its place.

Local circumstances, such as the relative position of the land, the set of the tides and currents, the prevailing winds, and the accessibility of Port William or Berkeley Sound, contribute to make the easternmost part of the Falklands safer and more easy to approach than almost any place that I am acquainted with.

With the supply of shipping, and the establishment of a frequented free port in view, as the first source of prosperity, colonists should augment the number of animals, birds, and vegetables, which they see thrive so well there, and take little thought about corn, except for home consumption (unless indeed oats should be found to grow well). They should assiduously increase their stock of cattle, sheep, pigs, and poultry, make butter and cheese, rear calves, and breed horses; they should salt meat and fish; bring wood and lime from Tierra del Fuego and Patagonia, and turn their thoughts to supplying ships with water, fuel (perhaps dried peat), and provisions, in the quickest and cheapest manner. Hides, pig-skins, goat-skins, sheep-skins, wool, foxes' fur, rabbit-skins, bird-skins and down, horns, salt meat, salt butter, cheese, potash, orchilla weed, potatoes, salt-fish, seal-skins, seal-oil, whale-oil, and whale-bone, would form no indifferent return cargo for vessels carrying there implements of husbandry, stores of various kinds, flour and biscuit, clothing, lumber, furniture, crockery-ware, glass, cutlery, and household utensils. North American vessels, laden with flour or lumber, might make very profitable voyages.

I have always thought the Falklands an admirable place for a penal establishment, a thorough convict colony. A healthy, temperate climate, far removed from civilized countries, and (if used for such a purpose only) incapable of being injured by the presence of bad characters, as our mixed settlements have been—fully supplied with necessaries, yet without any luxuries—sufficiently extensive to maintain a large population, though small enough to be kept under the strictest martial law, and inspected every where, by water as well as by land—

© The Complete Work of Charles Darwin Online

it seems to me the very best situation for locating those bad characters who are unfit to remain at home. But to whomsoever it may happen to colonize these islands, there can be no doubt that industry will be well rewarded, that health, safety, and a frequent communication with the mother country, will be as certain as in any other colony, and that the only drawbacks to be anticipated are those likely to be caused by wind and deficiency of solar heat.

Animals increase rapidly, and the quality of their hides or fur improves. Cows give a large quantity of excellent milk, from which good butter and cheese may be made. Not long since, a letter was received from the Hon. George Grey, Captain of H.M.S. Cleopatra, in which he said that the milk and butter at Howick was not superior to that which he tasted at the Falklands. In the event of steamers engaging in the navigation of those seas,* a port of supply and repair, in short, a maritime depôt would be required, in or near Tierra del Fuego; but no such establishment could easily be formed there without a military force, and occasional hostilities with the natives, whereas, at the Falklands, the only native opponents would be foxes, horses, and bulls.† This immense advantage over most habitable and fertile countries—the having no aboriginal population—should be duly considered by those who may contemplate planting a colony there. Weddell says, "A settlement at this point of the South Atlantic would evidently afford great facilities to navigation. The extensive tracts of ground, well clothed with grass, and the quantity of fine cattle running wild on the island, are sufficient proofs of its being a country that might be settled to advantage. The winters are mild, the temperature being seldom so low as the freezing point. Several of my crew, indeed, went without

* From Concepcion (37° S.) to Elizabeth Island, near the eastern entrance of Magalhaens Strait, there is every where abundance of wood fuel for steamers.

† It is very dangerous for persons on foot to approach the wild horses or cattle, especially the bulls, unless they are armed with rifles or balls (bolas); and even then, no one ought to venture alone.

© The Complete Work of Charles Darwin Online

stockings during the greater part of the winters we spent there. The south wind, however, is cold and stormy, but it is not frequent; the prevailing winds are between S.W. and N.W., which, blowing from the coast of Patagonia, are comfortably temperate. This climate appears to be in general much more temperate now than it was forty years ago, the cause of which may probably be, that immense bodies of ice were then annually found in the latitude of 50°; this ice, between the Falkland Islands and South Georgia, would necessarily lower the temperature of both air and water, and consequently an unfavourable opinion of the climate was produced."—Weddell's Voyage, pages 94-95.

For much of the produce of the islands, such as salt-meat and fish, potatoes, oil, butter, cheese, tallow, &c. a ready market would always be found on the coasts of South America, while other articles, previously mentioned, would have a free sale in Europe and North America. Should any accident happen to a vessel in doubling Cape Horn, obliging her to make for the nearest port at which she can obtain supplies, where can she now go? To the River Plata on one side, or to Chilóe on the other—either of which is twelve hundred miles from Cape Horn!

A great temptation to shipping would be, the certainty of supplies, and freedom from harbour dues as well as pilotage. Twenty years after the first establishment of a colony would be quite soon enough to think of any port charges, and till that time, every encouragement ought to be given to vessels, by piloting them gratis, and charging for nothing but the supplies which they may choose to purchase, and for those, upon the lowest possible terms. As to pilotage, indeed, I may say that none is required, if a stranger has the chart now published by the Admiralty, for there is no danger in any of the Falkland harbours that is not distinctly buoyed by kelp. A few rocks in the offing are indeed to be guarded against, such as the Uranie Rock, and those near the Jason Isles; but a ship must have passed all those before a pilot could board her, under ordinary circumstances, and afterwards there would be no

© The Complete Work of Charles Darwin Online

danger, if a vigilant look-out and common skill were exercised.

Berkeley Sound (besides many other ports) would contain a large fleet in security, while around it are coves and basins in which any repairs might be carried on.

Probably some intercourse might be opened with the Patagonians, and, by them, with other roving tribes on the continent, who would exchange guanacoes, horses, cattle, poultry, hides, horns, tallow, and hair, for hardware, clothing, cutlery, ornaments, saddles, spurs, bridles, &c.; and as the guanaco is so warmly clothed in the high southern latitudes, and is capable of being domesticated,* it might be found a valuable animal to encourage among sheep and cattle at the Falklands. Mr. Brisbane told me, that some wool, sent by Mr. Vernet from East Falkland to Liverpool, sold for nearly double the price of Buenos Ayres wool; and this was the produce of sheep which had only been a few years on the island, of the Buenos Ayrean stock, unmixed with any superior breed. To show how well the little colony, established by Mr. Vernet, was succeeding, prior to its harsh and unnecessary ruin by Captain Silas Duncan, I will give an extract of a letter received from a brother officer who visited Port Louis.

"The settlement is situated half round a small cove, which has a narrow entrance from the sound; this entrance, in the time of the Spaniards, was commanded by two forts, both now lying in ruins, the only use made of one being to confine the wild cattle in its circular wall when newly brought in from the interior. The governor, Louis Vernet, received me with cordiality. He possesses much information, and speaks several languages. His house is long and low, of one story, with very thick walls of stone. I found in it a good library, of Spanish, German, and English works. A lively conversation passed at dinner, the party consisting of Mr. Vernet and his wife, Mr.

Brisbane, and others; in the evening we had music and dancing. In the room was a grand piano-forte; Mrs. Vernet, a Buenos Ayrean lady, gave us some excellent singing, which sounded not a little strange at the Falkland Isles, where we expected to find only a few sealers.

"Mr. Vernet's establishment consisted of about fifteen slaves, bought by him from the Buenos Ayrean Government, on the condition of teaching them some useful employment, and having their services for a certain number of years, after which they were to be freed. They seemed generally to be from fifteen to twenty years of age, and appeared contented and happy.

"The total number of persons on the island consisted of about one hundred, including twenty-five gauchos and five Indians. There were two Dutch families (the women of which milked the cows and made butter); two or three Englishmen; a German family; and the remainder were Spaniards and Portuguese, pretending to follow some trade, but doing little or nothing. The gauchos were chiefly Buenos Ayreans; but their capataz or leader was a Frenchman."

Such was the state of Vernet's settlement a few months before the Lexington's visit; and there was then every reason for the settlers to anticipate success, as they, poor deluded people, never dreamed of having no business there without having obtained the permission of the British Government. They thought, naturally enough, that the Buenos Ayrean Government could not have sold the islands to Mr. Vernet, unless the state of La Plata had a right to them; they believed that the purchase-money had been paid;* but they were not aware that the British Government had protested formally against the pretended claim of Buenos Ayres, so quiet was that fact kept by the Argentine Government, although the solemn protest was made by Mr. Parish, the British consul-general, in November 1829.

* It is said that officers in the Buenos Ayrean army, relations of Mrs. Vernet, had claims upon their Government, which they agreed should be liquidated by receiving certain sums of money from Mr. Vernet; in consideration of which the Government made over to him their pretended right of property in the Falklands and Staten Land.

© The Complete Work of Charles Darwin Online

However unjustifiably Mr. Vernet may, in fact, have behaved towards vessels belonging to the United States of North America, it must be remembered that he had a commission from the Buenos Ayrean Government, empowering him to act as civil and military governor of the Falklands; that he believed the Buenos Ayrean authority valid; and had no doubt in his own mind that he was doing right. Mr. Vernet, therefore, was no robber—no pirate—as he was termed by Captain Duncan, because he tried to uphold his situation, and prevent his settlement being robbed by people who had no claim whatever upon any of the islands. However wrong Vernet's actions may have been, he was responsible to his Government for them; and those who acted under his order, he having a legal commission, certainly did not deserve to be seized as pirates, put into irons, and so carried to the Plata! Neither was it just (setting mercy quite aside) to destroy the infant colony, break open or tear down doors and windows, search houses, drawers, and chests, trample over gardens, break through fences, and ill-use the helpless, unarmed settlers to such a degree, that for many months afterwards whenever a man-of-war was seen approaching, the frightened inhabitants at once fled to the interior, not knowing how they might be treated. Poor Brisbane (of whom frequent mention has already been made, and of whom I have yet to speak), was taken, with others, in irons to Monte Video, where the British consul obtained his release; he had joined Vernet in a contract to take seal upon the Falklands, and was left in charge of the settlement at the period of Captain Duncan's hostility. At that time Vernet himself was absent, having gone with his family to Buenos Ayres, in order that he might attend at the ensuing trial of those sealing vessels which had been detained by him for repeatedly taking seal upon the Falkland Islands, after he had duly warned them off.

I have heard much of Mr. Vernet and his proceedings, from various quarters—from enemies as well as friends—and although I never met him, and therefore cannot be partial from friendship, I do sincerely pity his misfortunes; and it is my belief that he has been much misrepresented.

CHAPTER XIII.

Anchor in Berkeley Sound—Le Magellan—British flag hoisted—Ruined Settlement—Mr. Hellyer drowned—Burial—French Whalers—Unicorn—Adventure—Squall—Flashes—Fossils—Killing Wild Cattle—Sail from Falklands—River Negro—Maldonado—Constitucion—Heave down, copper and refit Adventure—Signs of weather—Sound banks—Los Cesares—Settle with Harris and part company—Blanco Bay—Return to Maldonado—Monte Video.

March 1. The Beagle anchored at the south side of Berkeley Sound (near the beach where Freycinet was obliged to run l'Uranie ashore, in 1820, after striking on the detached rock off Volunteer Point), and remained there till I had ascertained the state of affairs on shore: for seeing a French flag flying near some tents behind Johnson Cove or harbour, and knowing that, in 1831, the flag of Buenos Ayres was hoisted at a settlement in the sound, it was evident a change of some kind had occurred. Directly our anchor had dropped, a whale-boat belonging to the wrecked whale-ship, 'Le Magellan,' came alongside; and from her chief mate (who was also whaling-master), we learned that his ship had parted from her anchors during a tremendous squall on the night of the 12th of January, and was totally wrecked. He then informed me that the British colours had been hoisted on these islands by H.M.S. Clio; and that H.M.S. Tyne had since visited the port and saluted the flag; that the white flag was hoisted at the French tents only as a signal to us; and that he was sent by M. le Dilly, his captain, to entreat us to render them assistance. Two of our boats were forthwith manned; one was sent to the settlement at Port Louis, and in the other I went to the Frenchmen at Johnson Cove. I found them very comfortably established in large tents made from the sails of their lost ship; but they manifested extreme impatience to get away from the islands, even at the risk of abandoning the vessel and cargo. After due inquiry, I promised to carry as many of them as I

© The Complete Work of Charles Darwin Online

could to Monte Video, and to interest myself in procuring a passage for the rest.

Their ship was lying upon a sandy beach, one bilge stove in, and her hold full of sand and water; but as there was no surf, and at high spring-tide the sea rose only to her deck, all the stores and provisions, if not the ship herself, might have been saved by energetic application of proper means soon after she was stranded. When I saw her it was not too late, but I had too many urgent duties to fulfil to admit of my helping those who would not help themselves. Returning on board, I met Mr. Chaffers, who had been to Port Louis, and heard that there was no constituted authority whatever resident on the islands, but that the British flag had been left by Captain Onslow in charge of an Irishman, who had been Mr. Vernet's storekeeper. This man at first declined answering Mr. Chaffers's questions, because his uniform buttons were (as he thought) different from those of the Tyne's officers; however, being a simple character, he soon became more loquacious than was wished. He told Mr. Chaffers that he was ordered to 'hoist the flag up and *down*' when vessels arrived, and every Sunday: that there was 'plenty of beef,' and as for rabbits and geese, only the 'poor people eat them.'

2d. Weighed and shifted our berth to Johnson Cove. 3d. We got on board all the new rope, bread, salt meat, and small stores, which the Frenchmen had saved and wished us to embark for the benefit of their owners. Meanwhile, surveying operations were begun, and an officer despatched to the settlement, who informed me of the arrival of a merchant schooner (Rapid), fourteen days from Buenos Ayres, with Mr. Brisbane on board (as Vernet's agent as well as partner), who was delighted to meet our officer, finding in him one of those who helped to save his life when wrecked in the Saxe Cobourg in 1827.

No sooner had Mr. Brisbane landed than the master and crew of the Rapid hastened to make themselves drunk, as an indemnification for the fatigues of their exceedingly long and hazardous voyage: and in that state they were found by the

© The Complete Work of Charles Darwin Online

Beagle's officer. Next morning Brisbane came on board with his papers, and I was quite satisfied with their tenor, and the explanation which he gave me of his business. Some misapprehension having since arisen about his being authorized by Vernet to act in his stead, I may here mention again (though no longer of any material consequence), that Brisbane's instructions from Vernet authorized him to act as his private agent only, to look after the remains of his private property, and that they had not the slightest reference to civil or military authority. This settled, I went to Port Louis, but was indeed disappointed. Instead of the cheerful little village I once anticipated finding—a few half-ruined stone cottages; some straggling huts built of turf; two or three stove boats; some broken ground where gardens had been, and where a few cabbages or potatoes still grew; some sheep and goats; a few long-legged pigs; some horses and cows; with here and there a miserable-looking human being,—were scattered over the fore-ground of a view which had dark clouds, ragged-topped hills, and a wild waste of moorland to fill up the distance.

"How is this?" said I, in astonishment, to Mr. Brisbane; "I thought Mr. Vernet's colony was a thriving and happy settlement. Where are the inhabitants? the place seems deserted as well as ruined." "Indeed, Sir, it was flourishing," said he, "but the Lexington ruined it: Captain Duncan's men did such harm to the houses and gardens. I was myself treated as a pirate—rowed stern foremost on board the Lexington—abused on her quarter-deck most violently by Captain Duncan—treated by him more like a wild beast than a human being—and from that time guarded as a felon, until I was released by order of Commodore Rogers." "But," I said, "where are the rest of the settlers? I see but half a dozen, of whom two are old black women; where are the gauchos who kill the cattle?" "Sir, they are all in the country. They have been so much alarmed by what has occurred, and they dread the appearance of a ship of war so much, that they keep out of the way till they know what she is going to do." I afterwards interrogated an old German, while Brisbane was out of sight,

© The Complete Work of Charles Darwin Online

and after him a young native of Buenos Ayres, who both corroborated Brisbane's account.*

At my return on board, I was shocked by the sad information that Mr. Hellyer was drowned. He had walked about a mile along the shore of a creek near the ship, with one of the Frenchmen, who then left him† (having recollected that he would be wanted for a particular purpose). Mr. Hellyer, anxious to shoot some ducks of a kind he had not before seen, walked on with his gun, saying he would return in half an hour.

About an hour after this, the capataz of the gauchos, Jean Simon by name, riding towards the French tents to learn the news, saw clothes, a gun, and a watch, lying by the water side; but, as no person was in sight, he thought they must have belonged to some one in the boats which were surveying, so rode on quietly; and not until another hour had elapsed, did he even casually mention to the Frenchmen what he had seen. They, of course, were instantly alarmed and hastened to the spot, with those of our party who were within reach. Some rode or ran along the shore, while others pulled in whale-boats to the fatal spot, and there, after much searching, the body was discovered under water, but so entangled by kelp that it could not be extricated without cutting away the weed. Mr. Bynoe was one of those who found it, and every means that he and the French surgeon could devise for restoring animation was tried in vain. A duck was found dead in the kelp not far from the body, and his gun was lying on the beach, discharged, with which the bird had been shot.

To me this was as severe a blow as to his own messmates; for Mr. Hellyer had been much with me, both as my clerk and because I liked his company, being a gentlemanly, sensible young man. I also felt that the motive which urged him to strip and swim after the bird he had shot, was probably a

* The German told me, among other things, that he had collected rabbit-skins at his leisure hours, and had made, at different times, above two hundred dollars by them.

† It was a positive order on board the Beagle, that no one should make any excursion, in such places, alone.

© The Complete Work of Charles Darwin Online

desire to get it for my collection. Being alone and finding the water cold, he may have become alarmed, then accidentally entangling his legs in the sea-weed, lost his presence of mind, and by struggling hastily was only more confused. The rising tide must have considerably augmented his distress, and hastened the fatal result.

5th. This day we buried the body of our lamented young friend, on a rising ground near Johnson Cove, in sight of our ship. All the French attended the melancholy ceremony, as well as all our own party, excepting the very few who were obliged to stay on board.

6th. An agreement was brought about, and witnessed by me, between M. le Dilly and the master of the Rapid schooner, by which the latter bound himself to convey to Monte Video those of the Magellan's crew whom the Beagle could not carry: and next day another French whaler arrived (the fourth we had lately seen), belonging to the owners of the Magellan, so there was no longer any want of help for M. le Dilly.

A few days afterwards a sealing schooner, the Unicorn, arrived, Mr. William Low being sealing master and part owner; and, although considered to be the most enterprizing and intelligent sealer on those shores, perhaps anywhere, the weather had been so much against him that he returned from his six months' cruise a ruined man, with an empty ship. All his means had been employed to forward the purchase and outfit of the fine vessel in which he sailed; but having had, as he assured me, a continued succession of gales during sixty-seven days, and, taking it altogether, the worst season he had known during twenty years' experience, he had been prevented from taking seal, and was ruined. Passengers with him were the master and crew of a North American sealing schooner, the Transport, which had been wrecked on the south-west coast of Tierra del Fuego, in Hope Harbour; and he told me of two other wrecks, all occasioned by the gale of January 12-13th.

At this time I had become more fully convinced than ever that the Beagle could not execute her allotted task before she, and those in her, would be so much in need of repair and rest,

© The Complete Work of Charles Darwin Online

that the most interesting part of her voyage—the carrying a chain of meridian distances around the globe—must eventually be sacrificed to the tedious, although not less useful, details of coast surveying.

Our working ground lay so far from ports at which supplies could be obtained, that we were obliged to occupy whole months in making passages merely to get provisions, and then overload our little vessel to a most inconvenient degree, as may be supposed, when I say that eight months' provisions was our usual stock at starting, and that we sailed twice with ten months' supply on board.*

I had often anxiously longed for a consort, adapted for carrying cargoes, rigged so as to be easily worked with few hands, and able to keep company with the Beagle; but when I saw the Unicorn, and heard how well she had behaved as a sea-boat, my wish to purchase her was unconquerable. A fitter vessel I could hardly have met with, one hundred and seventy tons burthen, oak built, and copper fastened throughout, very roomy, a good sailer, extremely handy, and a first-rate sea-boat; her only deficiencies were such as I could supply, namely, a few sheets of copper, and an outfit of canvas and rope. A few days elapsed, in which she was surveyed very carefully by Mr. May, and my mind fully made up, before I decided to buy her, and I then agreed to give six thousand dollars (nearly £1,300) for immediate possession. Being part owner, and authorized by the other owners to do as he thought best with the vessel in case of failure, Mr. Low sold her to me, payment to be made into his partners' hands at Monte Video. Some of his crew being 'upon the lay,' that is, having agreed to be paid for their work by a small proportion of the cargo obtained, preferred remaining at the Falklands to seek for employment in other vessels, others procured a passage in the Rapid, and a few were engaged by me to serve in their own vessel which, to keep up old associations, I named 'Adventure.' Mr. Chaffers and others immediately volunteered to go

* Excepting water, of which we only carried six weeks.

© The Complete Work of Charles Darwin Online

in her temporarily (for I intended to place Mr. Wickham in her if he should be willing to undertake the responsibility), and no time was lost in cleaning her out thoroughly, loading her with stores purchased by me from M. le Dilly and from Mr. Bray (lately master of the Transport), and despatching her to Maldonado, to be prepared for her future employment.

This schooner was built at Rochester as a yacht for Mr. Perkins, and, as I have reason to believe, cost at least six thousand pounds in building and first outfit. Soon afterwards, she was armed and used by Lord Cochrane in the Mediterranean; then she was fitted out by a merchant to break the blockade of Buenos Ayres; but, taken by a Brazilian man-of-war, and carried into Monte Video, she was condemned as a prize and sold to Mr. Hood, the British Consul, who went to England and back again in her with his family; after which, she was fitted out for the sealing expedition I have mentioned. At the time of my purchase she was in want of a thorough refit, and her internal arrangements required alteration; but it happened that Mr. Bray and M. le Dilly had each saved enough from their respective vessels to enable me to load the Adventure on the spot with all that she would require; from the former I bought anchors, cables, and other stores, amounting to £216: and from M. le Dilly rope, canvas, and small spars, for which £187 were paid. Those who were conversant in such matters, the master, boatswain, and carpenter of the Beagle, as well as others, assured me that these articles were thus obtained for less than a third of their market prices in frequented ports.

While the Beagle lay in Johnson Cove, we witnessed a memorable instance of the strength with which squalls sometimes sweep across the Falklands. Our ship was moored with a cable each way in a land-locked cove, not a mile across, and to the south-westward of her, three cables' length distant, was a point of land which, under ordinary circumstances, would have protected her from sea, if not from wind. Our largest boat, the yawl, was moored near our eastern anchor, with a long scope of small chain. At six in the evening of a stormy

© The Complete Work of Charles Darwin Online

day (10th March), the wind increased suddenly from the strength of a fresh gale to that of a hurricane, and in a few minutes the Beagle brought both anchors ahead, and was pitching her forecastle into the sea. Topgallant-masts were on deck, and yards braced sharp up all day; but we were obliged to let go a third anchor, and even then had some anxiety for the result. Till this squall came, the water had been smooth, though of course covered with white crests ('horses'); but it was then changed into a short sea, such as I should have been slow to believe wind could have raised in that confined cove. The yawl, an excellent sea-boat, and quite light, was swamped at her moorings; but I think that the chief cause of her filling was a quantity of kelp which drifted athwart hawse and hindered her rising easily to the sea.

During the month we remained in Berkeley Sound, I had much trouble with the crews of whaling or small sealing vessels, as well as with the settlers, who all seemed to fancy that because the British flag was re-hoisted on the Falklands, they were at liberty to do what they pleased with Mr. Vernet's private property, as well as with the wild cattle and horses. The gauchos wished to leave the place, and return to the Plata, but as they were the only useful labourers on the islands, in fact, the only people on whom any dependance could be placed for a regular supply of fresh beef, I interested myself as much as possible to induce them to remain, and with partial success, for seven staid out of twelve.

While walking the deck after dark, I sometimes saw flashes of light on the distant hills, which it was difficult to account for as 'ignes fatui,' because they were seen only on the heights, and momentarily, long intervals intervening between each faint flash. I once remarked similar instantaneous glimpses of feeble light, like the flashing of a distant pistol, near Pecket Harbour, in Magalhaens Strait, during a rainy night, but on the hills, at the south side of Berkeley Sound, I witnessed such lights repeatedly. They were never bright or lasting—merely a faint sudden glimmer—exactly as I have said, like the flash of a pistol, fired at a great distance. It has

© The Complete Work of Charles Darwin Online

since occurred to me, that the phosphoric light spoken of by Bougainville in the following passage may be of a nature similar to that which I saw, and that those momentary flashes might have been caused by the occasional fall of stones among ravines, near the summits of hills. "Des voyages entrepris jusqu' au sommet des montagnes (pour chercher des calcaires), n'en (de pierre) ont fait voir que d'une nature de quartz et de grès non friable, produisant des étincelles, et même une lumière phosphorique, accompagnée d'une odeur sulphureuse." —(Bougainville, Voyage autour du Monde, 1766-69, tome I., p. 100).

The shattered state of most summits of mountains in these regions* has often struck me, many of them being mere heaps of rocks and stones, over which it is extremely difficult to climb. Mount Skyring may be cited as one remarkable instance; there, the stones gave out a very sulphureous smell when struck together, and were strongly magnetic.† Lightning, electricity, and magnetism being intimately related, one is led to think that, if the above conjecture is incorrect, there may be some connexion between these sudden glimpses of faint light and the transmission of the electric fluid. This much I am certain of, that they were not lights made by man, and that they were different from the will-o'-the-wisp, or ignis fatuus.

My own employment obliged me to remain near the ship, but some of the officers made excursions into the interior, and to them and Mr. Brisbane I am indebted for most of the following notices of these islands.

Some very large bones were seen a long way from the seashore, and some hundred feet above the level of high water, near St. Salvador Bay. How they got there had often puzzled Mr. Vernet, and Brisbane also, who had examined them with attention; Brisbane told me they were whale's bones.‡ The rocky summits of all the hills are amazingly broken up,

* Falklands and Tierra del Fuego. † Vol. I., p. 382.

‡ Bougainville says, "D'autres ossemens enormes, placés bien avant dans les terres, et que la fureur des flots n'a jamais été capable de porter si loin, prouvent que la mer a baissé, ou que les terres se sont elevées."—Vol. I., pp. 112-113.

© The Complete Work of Charles Darwin Online

like those of far higher elevations in Tierra del Fuego, and the fragments—some very large—have rolled down the nearest ravines, so that they look like the beds of dried-up torrents. The sand-stone, which is abundant, offers beautifully perfect impressions of shells, many of which were brought to England. In these fossils the minutest portions of delicate shells are preserved, as in a plaster of Paris cast, though the stone is now very hard. There are fine stalactites in some large caverns, but they are known only to a few sealers. The large muscles produce pearls of considerable size, though inferior quality, perhaps; Mr. Brisbane had a small bottle full. In one of the cottages I saw a heap of good whalebone, and was informed that some hundred pounds worth had been picked up on the coasts, and sold to whalers for a tenth part of its European value, in exchange for clothes, spirits, ammunition, and biscuit. On West Falkland there are beautiful pebbles, and on the heights fine crystals have been found.

Although the climate is so much colder than that of Buenos Ayres, the gauchos sleep in the open air, when in the interior, under their saddles, just as they do in the latitude of 35°. While idling at the settlement they gamble, quarrel, and fight with long knives, giving each other severe wounds. With their loose ponchos, slouched hats, long hair, dark complexions, and Indian eyes, they are characters fitter for the pencil of an artist than for the quiet hearth of an industrious settler. Besides these gauchos, we saw five Indians (p. 267), who had been taken by the Buenos Ayrean troops, or their allies, and allowed to leave prison on condition of going with Mr. Vernet to the Falklands. Including the crews of some thirty whale-ships, hovering about or at anchor among the islands; the men of several American vessels, all armed with rifles; the English sealers with their clubs, if not also provided with rifles; these cut-throat looking gauchos; the discontented, downcast Indian prisoners, and the crews of several French whalers—who could not or would not see why they had not as good a right to the islands as Englishmen—there was no lack of the elements of discord; and it was with a

© The Complete Work of Charles Darwin Online

heavy heart and gloomy forebodings that I looked forward to the months which might elapse without the presence of a man-of-war, or the semblance of any regular authority.

Our tender, the Adventure, sailed on the 4th of April, under the charge of Mr. Chaffers, who was desired to call off the River Negro, and thence go to Maldonado, moor his vessel close to Gorriti Island, land every thing, and commence her thorough refit.

About this time one of the officers went to see some wild cattle taken. After riding far beyond the hills seen from Port Louis, a black speck was discerned in the distance—instantly the three gauchos stopped, adjusted their saddle-gear, lassoes, and balls, and then cantered off in different directions. While stopping, my shipmate saw that the black spot moved and doubled its size. Directly afterwards, he perceived five other black things, and taking it for granted they were cattle, asked no questions of his taciturn, though eager, companions, but watched their movements and galloped on with the capataz (Jean Simon), the other two making a détour round some hills. Having got down wind of the herd, Simon slackened his pace, and, lying along his horse's back, gradually ascended a slight eminence, beyond which the cattle were feeding. For a moment he stopped to look round:—there was a monstrous bull within a hundred yards of him; three hundred yards further, were about twenty cows; and in a valley beyond, was a large herd of wild cattle. Just then the heads of the other two men were seen a quarter of a mile on one side, also to leeward of the cattle, which were still feeding unsuspiciously. With a sudden dash onwards, such as those horses are trained to make, Simon was within twenty yards of the overgrown, but far from unwieldy brute, before he could 'get way on.' Whirling the balls around his head, Simon hurled them so truly at the bull's fore-legs, that down he came, with a blow that made the earth tremble, and rolled over and over. Away went Simon at full gallop after a fine cow; and at the same time, each of the other men were in full chase of their animals. The herd galloped off almost as fast as horses; but in a few moments, another bull was bel-

© The Complete Work of Charles Darwin Online

lowing in impotent rage, and two cows were held tightly by lassoes—one being caught by Simon alone, and the other by his two companions. One of the men jumped off, and fastened his cow's legs together so securely, that she could only limp along a few inches at a time; his horse meanwhile keeping the second lasso tight, as effectually as if his master had been on his back. Both lassoes were then shaken off, and one thrown over Simon's cow, which had been trying in all kinds of ways to escape from or gore her active enemy, who—go which way she would—always kept the lasso tight; and often, by checking her suddenly, half overset and thoroughly frightened her. Leaving his horse as soon as the cow was secure, Simon hamstrung the bulls, and left them where they fell, roaring with pain and rage. He then remounted, and all four cantered back towards the 'estancia' (or farm), where the tame cattle are kept. Simon was asked to kill the poor brutes before he left them; but he shook his head, with a sneer, and remarked, that their hides would come off easier next day! At daybreak, the following morning, half-a-dozen tame cattle were driven out to the place of slaughter, and with them the frightened and already half-tamed cows (which had been left tied in a place where they had nothing to eat), were easily driven in to the farm. The two bulls were at last killed, skinned, cut up, and the best parts of their carcases carried to the settlement. The hides of those two animals weighed seventy-three and eighty-one pounds.

Speaking to Simon myself one day about the indiscriminate slaughter of cattle which I had heard took place occasionally, he told me that the gauchos used sometimes to kill them for their tongues only, and, perhaps, a steak or two, for 'asado' (meat roasted on a stick), without taking the trouble to skin them; being too great epicures in their way to feast twice upon the same animal.

In 1834, while surveying the sea-coast of these islands, in the Adventure, Lieutenant Wickham, Mr. Low, and Mr. Johnson had many a bull hunt; but though there was as much or more risk in their encounters, being on foot, with

© The Complete Work of Charles Darwin Online

rifles, assisted only by a good dog, their adventures were individually rather than generally interesting. They used to land in unfrequented harbours, very near herds of wild cattle or horses, creep quietly along behind tussac or bushes, till they got within rifle-shot, take good aim at the fattest, and after firing, do their best to kill the animal, in general only wounded by a first shot. They had an excellent dog, who always seized the creatures by the lower lip, and diverted their attention from Mr. Johnson or Low, who otherwise might have lost their lives, on more than two occasions.

The report of a gun usually alarmed the whole herd of cows, and off they went at a gallop; but the lordly bulls were not to be hurried, they would stand and face their enemies, often charge them; when a precipitate retreat behind a rock, or to the boat, or across a boggy place, which the bull would not try, was the only resource, if their hardy dog was not by, to seize the angry animal, and give time for a well-directed shot. In those excursions, also, while ashore at night in small tents, the foxes used to plague them continually, poking their unpleasant heads into the opening of the tent (while the man on watch was by the fire), stealing their provisions, and breaking their rest, after a fatiguing day's work. What with the foxes, the wild bulls, and the wild horses, it is thoroughly unsafe for a person to walk alone about the unfrequented parts of the Falkland Islands—even with the best weapons for self-defence against either man or beast. Several unfortunate people have been missed there, who wandered away from their parties.

April 6.—Having embarked M. le Dilly, with some of his officers and crew, and lumbered our little ship with the spars and stores purchased from him, we sailed from the Falklands. Our passage to within sight of the river Negro was short, though stormy, a south-east gale driving us before it, under a close-reefed fore-topsail. As the sea ran high, it might have been more prudent to have 'hove-to;' but time was precious, and our vessel's qualities as a sea-boat, scudding as well as 'by the wind,' were well known.

© The Complete Work of Charles Darwin Online

Early on the 12th, we were off the river Negro; but baffling winds and a heavy swell (raised by the late gale), prevented our anchoring near the bar, or sending in a boat.

Soon after noon on the 14th, while standing off and on, waiting for the swell to go down, and allow of a boat crossing the bar, a sail seen in the horizon was made out to be the Adventure. We steered for and spoke her, found all well, sent her on to Maldonado, and again stood towards the bar. Our tender, as I mentioned, sailed from Berkeley Sound on the 4th; but was obliged to heave-to during the gale in which we were able to scud.

Next day (15th), a decked boat, like the Paz, with some difficulty crossed the bar, and brought me letters from Lieutenant Wickham, by which I learned that he and his party had sailed from the river, intending to visit the Gulf of San Matias, only a few days before we arrived, having previously examined all the coast, from Port Desire to Valdes Creek.* I was sorry to hear that Corporal Williams, a very worthy man, in every sense of the words, had been drowned in the river Negro. Williams had been in two polar voyages, and under Captain King, in H.M.S. Adventure, from 1825 to 1830. The rest of the party were well, and making rapid progress with their task. Wind favouring, we made all sail for the Bay of San José, hoping to meet the little vessels under Lieutenant Wickham, but could not find them;† so concluding that they had run further south than was intended at their departure from the Negro, we steered out of the Gulf of San Matias, and made sail for the Plata.

At daylight on the 26th, land was seen near Maldonado, and at two, we anchored off Monte Video. In a few hours the French passengers were landed; next day our anchor was again weighed, and at noon on the 28th we moored the Beagle in Maldonado Bay, close to the little island of Gorriti. Our tender, the Adventure, had arrived on the 23d. My thoughts

* Or port, as it has been called, though improperly, because it is at times almost blocked up by a bar.

† They were in Port San Antonio.

© The Complete Work of Charles Darwin Online

were at this time occupied by arrangements connected with her, besides the usual routine observations. I was extremely anxious to fit the schooner properly, and to set her to work, but at the same time to keep all our other operations in active progress. A decked boat was lying in Maldonado, just built, which her owner, Don Francisco Aguilar, offered to lend me for two months, if I would rig her for him, and this proposal exactly suited my views, as it would enable me to send for Lieutenant Wickham, and supply his place by Mr. Usborne, leaving Mr. Stokes to continue the survey about San Blas and the Colorado. Accordingly, the Constitucion, as this little craft was named by her owner, was hauled alongside, and Mr. Usborne with a party, set to work in preparing her for a trip to the River Negro. On the 1st May Mr. Usborne sailed, having with him Mr. Forsyth and five men; he was to go to the River Negro, join and assist Mr. Stokes, and inform Lieutenant Wickham that he was wanted at Maldonado, to take charge of the Adventure. The Constitucion was about the size of the Liebre, a craft I should hardly have thought fit for such a voyage had I not heard so much from Mr. Harris and his companion, Roberts, of the capital weather those decked boats make in a gale. With their hatches secured, tiller unshipped, a storm try-sail—or no sail at all set, and nobody on deck, they tumble about like hollow casks, without caring for wind or sea.

Next day (2d) the Beagle returned to Monte Video, to procure carpenters, plank, and copper for the Adventure. I found that she was so fine a vessel, and so sound, that it was well worth while to copper her entirely afresh, with a view to her future operations among islands in the Pacific, where worms would soon eat through places on a vessel's bottom from which sheets of copper had been torn away. At this time the Adventure's copper was complete, but thin, and as the carpenters said it would not last above two years more with certainty, I determined to copper her forthwith, and make one substantial refit do for all. Here, to my great regret, Mr.

© The Complete Work of Charles Darwin Online

Hamond decided to return to England,* and we consequently lost a valuable member of our small society.

On the 17th, having engaged men and purchased plank, copper, provisions and other necessaries, we sailed from Monte Video, and next morning anchored in Maldonado. As soon as a part of our cargo was landed—all that was then wanted by the working party on Gorriti, under Mr. Chaffers—we proceeded up the river to fill water, anchored again off Monte Video for a short time, and returned to our future consort at Gorriti (24th). Preparations were then commenced for heaving the schooner down to copper her. We hauled her alongside, and on the 28th hove her 'keel out,' for a few hours, and righted her again at dark. While standing on her keel, examining the state of her copper and planking, I saw a sail in the offing, which was soon made out to be the Constitucion, and just after we righted the schooner Lieut. Wickham came alongside. He brought good tidings—without drawback—and those who know what it is to feel anxiety for the safety of friends whose lives are risked by their willingness to follow up the plans of their commanding officer—however critical those plans may be—will understand my sensations that night. The Constitucion anchored off the Negro on the 11th, entered it next day, found the Paz and Liebre there, and on the 17th sailed again. Six knots and a-half an hour was the most she could accomplish under any circumstances, yet her passages were very good, considering the distance. During June we remained in Maldonado, employed about the Adventure, and refitting as well as painting our own ship. Meanwhile Mr. Darwin was living on shore, sometimes at the village of Maldonado, sometimes making excursions into the country to a considerable distance; and my own time was fully occupied by calculations and chart-work, while the officers attended to heaving down the Adventure. This process, in a place partly exposed to south-west winds, was extremely tedious,

* Provided that the Commander-in-Chief approved of his doing so—a sanction which I had no doubt of his receiving.

© The Complete Work of Charles Darwin Online

and had it not been for the great advantages Maldonado and Gorriti offered in other respects, the situation might have been deemed exceedingly ill-chosen for such a purpose. Only when there was no swell could we haul her alongside and heave her down (an operation under any circumstances difficult, as she was one hundred and seventy tons in burthen, and we were but two hundred and thirty-five) and many days sometimes intervened on which no progress could be made. Every morning, at dawn of day, Lieut. Sulivan and I used to watch the sky most anxiously, in order to know whether it would be worth while unmooring, and warping the vessels together, and as the indications we looked for never deceived us, I will here mention them. Though familiar to all who lead a country or seafaring life, and often rise before the sun, they may be of use to others, whose attention has not been drawn to 'weather wisdom.'

When the first streak of light appeared close to the horizon, and the sun's rising was preceded by a glow of faint red, not extending far, a fine day succeeded, whether the sky were then overcast or clear; but if the first gleam of light appeared high above the horizon, behind clouds, and there was much red, not only near the sun, but visible on clouds even near the zenith, wind, if not rain, was sure to follow. Between the extremes of course there may be many varieties of appearance as well as of succeeding weather; but as I have found such signs followed by similar weather, in most parts of the world, and as I have often profited by them, with reference to making or shortening sail, &c.; I do not like to pass over this occasion for a hint to the inexperienced. I have always found that a high dawn (explained above) and a very red sky, foretold wind—usually a gale; that a low dawn and pale sun-rise indicated fine weather; that the sun setting behind a bank of clouds, with a yellow look, was a sign of wind, if not rain, and that the sun setting in a clear horizon, glowing with red, was an unfailing indication of a coming fine day. I have already said (page 50), that hard-edged, oily-looking clouds, foretell, if they do not accompany wind, and that soft clouds—clouds which have a watery rather than an oily look—are signs of

© The Complete Work of Charles Darwin Online

rain; and if ragged, or streaky, of wind also. Light foggy clouds, rising early, often called the 'pride of the morning,' are certain forerunners of a fine day.

On the 8th of July the Beagle sailed from Maldonado, and anchored off Monte Video for a few days, waiting for the arrival of a packet from England. Directly the letters were received she returned to Maldonado.

On the 18th, my survey work being finished, and our help no longer required at Gorriti, we sailed to sound eastward in the latitude of the English Bank, and then returned to make a few arrangements with Lieutenant Wickham, and obtain observations for the chronometers, previous to making an excursion towards the south.

On the 24th we sailed to Cape San Antonio, and thence along the coast, close by Cape Corrientes, and skirting the San Blas banks, till we anchored off the river Negro. There we found the Paz and Liebre just returned from their examination of those intricacies which surround the ports between Blanco Bay and San Blas. The Liebre came out to meet us with a satisfactory report of progress, as well as health; and, at her return, Mr. Darwin took the opportunity of going into the river, with the view of crossing overland to Buenos Ayres, by way of Argentina: after which, he proposed to make a long excursion from Buenos Ayres into the interior, while the Beagle would be employed in surveying operations along sea-coasts uninteresting to him. We then got under sail and began our next employment, which was sounding about the outer banks off San Blas and Union Bays, and examining those parts of Ports San Antonio and San José which the Paz and Liebre had been prevented doing by wind and sea; besides which, I wished to see them myself, for many reasons, more closely than hitherto. The accumulation of banks about San Blas, and near, though southward of the river Colorado, is an object of interest when viewed in connection with the present position of the mouth of that long, though not large, river, which traverses the continent from near Mendoza, and which may have contributed to their formation; at least, so think geologists.

© The Complete Work of Charles Darwin Online

Be this as it may, there is now a mass of banks extending far to seaward, which make the coast from Blanco Bay to San Blas extremely dangerous; more particularly, as the adjoining shore is almost a dead flat, and so low, that in many parts it can only be seen when the observer is among, or upon, the shoals. The space between Union Bay and San Blas was very appropriately named by the Spaniards Bahia Anegada (dried up bay), because it is so shallow, and the inner parts are rather drowned land than actual water, being only covered at half tide. Falkner says (p. 77), that a Spanish vessel was lost in this bay, the crew of which "saved themselves in one of the boats, and sailing up the river arrived at Mendoza." Whether this ship was called 'Los Cesares' I am not aware, but as there is an islet in the 'Bahia Anegada' named in the old Spanish charts, 'Isla de los Cesares,' I suspect that such was the fact, and incline to connect this story with the many rumours of a settlement, 'de los Cesares,' somewhere in the interior of Patagonia. Falkner says, that "the crew saved themselves in one of the boats;"* but there were few Spanish vessels about that coast in the early part of the eighteenth century whose whole crew could have been saved in one of their boats.† If the remainder had formed even a temporary encampment about San Blas, or near the river Negro, it would have been described, with much exaggeration, by Indians of the west, as well as by those of the East country. A few men might have been admitted into a tribe of Indians who improved their habits and dwellings, so far as to have given rise to the curious reports so much circulated in South America, during the last century and even in this—of a colony of white people, with houses and gardens, in the interior of the continent, somewhere about the latitude of forty degrees; according to some

* "In the year 1734, or thereabouts (within how many years after or before that time?), the masts and part of the hulk were seen," (Falkner, p. 77.) The so-called 'Isla de los Cesares' is closely attached to, if not a part of the main land at the west side of Anegada Bay.

† Reports of the Cesares began to be circulated in the early part of the eighteenth century.

© The Complete Work of Charles Darwin Online

between two ranges of the Cordillera; others said it was in the plains; but all appeared to think there was no doubt of the existence of such a settlement.

In Villarino's Diary of his Exploration of Anegada Bay, I find that he was much assisted by horses and mules, which he carried on board his vessels, and landed as often as he had occasion to make a journey by land. At the river Negro I heard that some of these animals became so tame, and accustomed to landing and embarkation, that they would leap quietly into or out of the boats, when required.*

On the 19th of August, we anchored near the bar of the Negro, to meet the Paz and Liebre, take our officers and men on board, and pay Mr. Harris the money to which he was entitled, not only by contract, but by the uniform attention, activity, and thorough kindness, which he and his partner had shown to their temporary companions; by their knowledge as pilots, and by the useful information which they had readily given, to the full extent of their abilities. The complete success of that enterprize was greatly owing to the conduct of those two worthy men. Before dark all was settled, our party was safely on board; we quitted Harris and Roberts, with their useful little craft, mutually satisfied; and made sail for Blanco Bay, where there was still work to be done; intending to add to our already numerous soundings, while following the seaward edges of the banks.

On the 24th, we moored off the Wells, in Port Belgrano.

Next day, Lieutenant Sulivan went with a party to explore the furthest extreme of the inlet, while others were occupied, as usual, in the various duties always necessary on board a ship, in addition to those of a survey.

Mr. Darwin was at Argentina, and hearing of our arrival, rode to the Wells. He had met General Rosas on the Colorado, who treated him very kindly; and he was enjoying his shore-roving without any annoyance, the old major being no longer afraid of a 'naturalista.'

* Viedma and other Spaniards were similarly assisted in their expeditions.

© The Complete Work of Charles Darwin Online

On the 7th of September, we finally left Blanco Bay;* but again sounded along the dangerous banks of Anegada Bay, determined to do our utmost to prevent vessels from getting ashore there in future, as many have done already, especially during the blockade of Buenos Ayres, when several prizes, which had been taken from the Brazilians, were wrecked and totally lost.

In these surveying trips along-shore we always anchored when we could, in order to preserve our station and connect triangles; but, of course, we were often obliged to weigh again at short notice, during the night; therefore every preparation was made for any change of wind or weather, and a careful look-out always kept upon the deep-sea lead (invariably attended throughout the night), as well as upon the sympiesometer, the sky, and the water. I mention the deep-sea lead particularly, because however shallow the water may be, mistakes are often made with the hand-lead, especially at night, when a tide or current is running, in consequence of the lead being drifted by the action of the water upon it and the line, and deceiving even a moderate leads-man; who sometimes thinks the water much deeper than it really is—sometimes the reverse; and never can tell exactly, under such circumstances, how a ship is moving over the ground, or whether she is dragging her anchors.

Off Starve Island we were obliged to weigh in a hurry, one night, owing to a gale coming on from the south-east, and during the 10th and 11th, we carried a press of sail, to get off the land; the wind then drew round by the south, and a succession of baffling weather ensued, which prevented our doing any thing on the coast, and also hindered our reaching the Plata until the 16th, on which day we ran up to Monte Video, and anchored.

On the 18th we weighed, hearing that H.M.S. Snake had brought stores and letters for us, and was at Maldonado, but had hardly lost sight of the town, when the Snake hove in

* Mr. Darwin had previously departed on his road to Buenos Ayres.

© The Complete Work of Charles Darwin Online

sight. Knowing her to be one of the new build, I altered course, to sail a few miles with her, and see how much she would beat us; but, to my surprize, she gained on us but little while running free with a fresh breeze, just carrying top-mast studding-sails; and I was afterwards told by her officers, that though she sailed uncommonly well on a wind, and worked to windward wonderfully, she did nothing remarkable with a flowing sheet. I did not like her upper works; they 'tumbled home' too much (like some old French corvettes); narrowing her upper deck, giving less spread to the rigging, and offering a bad form to the stroke of a heavy sea, whether when plunging her bow into it, or receiving it abeam. However good such a form may be for large ships, which carry two or three tier of guns, I cannot think it advantageous for flush-decked vessels or small frigates, and am quite certain that it is bad for boats. I here allude particularly to that 'tumbling home' of the upper works, which some persons approved of a few years ago. This is not the place, however, for a discussion upon naval architecture (even if I were qualified to deal with the subject, which assuredly I am not); but I cannot pass over an opportunity of adding my mite of praise to the genius and moral courage of Sir William Symonds and Captain Hayes, who, undeterred by opposition, and difficulties of every description, have succeeded in infusing (if the metaphor may be allowed) so large a portion of Arab blood into the somewhat heavy, though stalwart coursers of our native breed. Amidst the natural contention of eager candidates for an honourable position, to which they have been accustomed to aspire, and for which some are doubtless admirably qualified, it is not surprising that due credit has not always been given to that originality and justifiable daring, of which the merits are attested by the Vanguard and Inconstant. Neither has it always been recollected, however men may have differed in their opinions of this or that individual, as a naval architect, that the two best ships built of late years were constructed by naval officers, self-educated chiefly during the practice of their profession. I am quite aware, that some of those eminent architects who have con-

© The Complete Work of Charles Darwin Online

structed good ships since 1810—Sir Robert Seppings, Professor Inman, Mr. Roberts, and Mr. Fincham, were very much restricted as to dimensions allowed with respect to guns to be carried; and that, therefore, no one can pretend to say what degree of excellence the ships might have attained, had their architects been unshackled; but taking things as they are —not as they might have been—to Symonds and Hayes (if not chiefly to the former) belongs the merit of having improved our navy materially. We are so apt to forget, during the heat of controversy, that even an approach to perfection is unattainable, and the utmost any one can hope for is to have fewer faults than his rivals—that we should not hastily condemn, in any case, only because we can detect deficiencies or errors.

Many persons have remarked, that notwithstanding all the competition, all the trials of sailing, and all the reported improvements, which have taken place since the peace, our fastest ships have not excelled some of those built by France, England, or other countries, during the war. My own knowledge of those ships is only derived from the descriptions of persons who sailed in or chased them: but the conclusion I am led to draw from their accounts is that, with few exceptions,* those ships were very slightly built, often of unseasoned timber, and that their rapid rate of sailing only lasted so long as their frames would yield to the fluid, and were not water-sodden. Recently launched, light, and elastic, confined by few beams, knees, or riders, held together by trunnions more than by metal, and intended only to sail swiftly—for a short existence —those greyhound vessels were as different in their construction from the solid, heavy, durable ships of this day, as a light, active youth is from a well-set man trained to labour.

A man-of-war requires strength, solidity, capacity; great

* The Malta (Guillaume Tell), Norge, and a few others, were splendid exceptions, but even in the construction of those ships far less iron and copper were used than is now customary in vessels of their class. By substituting so much metal in place of wood, for knees, braces, and bolts, solidity, strength, and capacity are acquired in modern ships at the expense, in most instances, of elasticity, and swift sailing.

© The Complete Work of Charles Darwin Online

buoyancy for supporting her heavy metal, durability, and tenacity; besides easiness as a sea-boat, and superiority of sailing. Vessels may easily be built to excel in any of these qualifications; but to excel in all is the climax, only to be obtained by genius, aided by extraordinary study and experience.

After running a few miles with the Snake, and finding that she steered towards Buenos Ayres, we altered our course to resume our easterly route, and early next morning were anchored alongside the Adventure.

As it was evident that another month must elapse before the schooner would be ready for her work, notwithstanding the zealous exertions of Lieut. Wickham and his crew, I decided to finish myself the survey, which I had intended he should begin with, namely, of the south shore of the Plata and a reported bank off Cape Corrientes—and defer the second visit to Tierra del Fuego until December or January. Accordingly, the Beagle sailed on the 23d, and after a close examination of Cape San Antonio and the great mud-bank, called Tuyu, which lies within it, we went to the neighbourhood of Cape Corrientes, and there looked about and sounded in every direction, but could find no shoal. We then returned to the river, and sounded Sanborombon Bay, laying its shores down on the chart as accurately as we could, considering that the water was every where so shoal, that even a boat could not get within half a mile of the land, except at particular times, for which we could not wait. The distance at which the Beagle was obliged to keep, varied from four miles to three (seldom less), and then she was sailing in about a foot more water than she drew.*

On the 6th of October we returned to Maldonado; to prepare for a long excursion southward, and to hasten the equipment of the Adventure. By the 19th she was almost ready, so we weighed in company, ran up the river to water, and on the 21st moored off Monte Video, to take in our final supplies previous to quitting the River Plata for the last time. Here, to my surprise, I found people talking about the English having

* The Beagle's draught of water was eleven feet and a half forward, and thirteen feet aft, when in ordinary loaded trim.

© The Complete Work of Charles Darwin Online

taken possession of the island of Gorriti, and built houses upon it. This, I knew, must in some way have arisen out of the temporary encampment of the Adventure's crew; and enquiring further, I found that columns of the Monte Video newspapers had been filled with discussions on the subject.* The local authorities at Maldonado having been told (incorrectly) that the English had hoisted British colours upon the island—had repaired several old buildings—and had erected a house with glass windows, for the commanding officer's residence—became alarmed; and as stories seldom lose by repetition, the good people of Monte Video were soon in commotion. However, the affair was easily explained; but not without many a laugh at the absurdity of my little observatory (made of ninety small pieces of wood, so as to be stowed in a boat), having 'loomed' so large. Had our colours ever been displayed on shore, there might have been some foundation for their alarm; but it so happened that the only flag that was on the

"Monte Video, Octubre 22 de 1833.

*"El infrascripto Ministro Secretario de Estado en el departamento de Relaciones Exteriores, tiene órden del Gobierno para dirigirse al Sr. Cónsul General de S.M.B. y manifestarle, que á consecuencia de varios sucesos que han tenido lugar en la Isla de Gorriti, donde se halla la tripulacion de la Escuna de S.M. Adventure, los cuales constan de los documentos que en copia autorizada se acompañan; y deseoso el Gobierno de satisfacer la ansiedad publica que han producido aquellos sucesos, y quitar todo pretexto de interpretaciones, espera que el Sr. Cónsul tendrá á bien manifestarle los motivos que dieron mérito á que los individuos pertenecientes á aquel Buque pasasen á la Isla, como igualmente las causales de su permanencia en ella.

"El Ministro que subscribe reitera al Sr. Cónsul General de S.M.B. los sentimientos de su mayor consideracion y aprecio.

(Firmado) "Francisco Llambi."

"Monte Video, Octubre 28 de 1803.

"El abajo firmado Cónsul General de S.M.B. cerca de la República Oriental del Uruguay ha tenido el honor de transmitir al Sr. Fitz-Roy, comandante de la barca descubridora de S.M.B. Beagle, la comunicacion y copias

© The Complete Work of Charles Darwin Online

island, at any time while our party was there, was an old Monte Video (Banda Oriental) ensign, which belonged to the schooner when I bought her from Mr. Low. This incident, trifling as it is, may be worth notice, as showing how necessary it is to be more circumspect and explanatory in every dealing with a small State, than in similar transactions with the Authorities of old established governments.

The month of November was passed at Monte Video: laying down chart-work, computing observations, and writing; procuring and stowing provisions; painting the vessels outside and blacking their rigging; and occasionally giving the crews leave to go ashore. Mr. Darwin returned at the end of the month; and the first week in December both vessels sailed from the river: but before I go on with them to Tierra del Fuego and the Falklands, some pages shall be devoted to the proceedings of our enterprizing and hard-working labourers, who were employed so zealously during twelve months without intermission, in the little vessels Paz and Liebre.

y copias inclusas que S. E. el Sr. D. Francisco Llambi, Ministro Secretario de Negocios Extrangeros le hizó el honor de dirigirle en 22 del corriente; y el infrascripto se halla autorizado para decir que ni el 3 de Octubre, de 1833, ni otro dia alguno del presente año se ha enarbolado o desplegado en la Isla de Gorriti la Bandera de la nacion Britanica. El 3 de Octubre de 1833, y muchos días anteriores, la de este Estado fuè izada como un señal para D. Francisco Aguilar, avisándole que se iva á embiar un bote en busca de carne y comestibles. La casa de madera con vidriera que se dice ser habitada por el comandante, es un observatorio portatil hecho en Inglaterra, que ahora se halla en la Isla de Ratas de este Puerto; y ninguno de los edificios de la Isla de Gorriti, ha sido reparado por persona alguna bajo las órdenes del Comandante Fitz-Roy: lo que el abajo firmado comunica á S.E. saludándole con su particular consideracion y aprecio.

(Firmado) "Tomas Samuel Hood."

CHAPTER XIV.

Paz and Liebre begin work—Chronometers—Fish—Animals—San Blas—Wrecks—River Negro—Del Carmen—Inhabitants—Indians—Trade—Williams drowned—Port Desire—Gale—Salinas—Lightning—Bones in Tomb—Trees—Dangers—New Bay—Cattle—Seals—Soil—River Chupat—Drift Timber—Fertility—Wild Cattle—Valdes Creek—Imminent danger—Tide Races—Bar of the Negro—Hunting—Attack of Indians—Villarino—Falkner.

The Paz and Liebre parted company with the Beagle on the 18th of October 1832, and commenced their undertaking by a cursory examination of the entrance to False Bay, Green Bay, and Brightman Inlet. Lieut. Wickham and Mr. King, with Roberts and four men, were in the Liebre.* Messrs. Stokes, Mellersh, and Forsyth, with Harris and five men, were on board the Paz.† While they were northward of the Colorado, true bearings of the Ventana Mountain, and observed latitudes, made them independent of their five chronometers; but it was soon found that the rates of those useful machines were not injured even by the continual as well as sudden motions of so small a vessel. They were bedded in sawdust, wool, and sand,‡ within a large tub, which was secured to the deck under the cabin table of the Paz, not far from the centre of least motion.

In Brightman Inlet great quantities of fish were caught, by stopping up the mouths of small creeks with a net at high water, and when the tide ebbed many more were left ashore than were wanted. On Green Island they found good water by digging wells seven or eight feet deep. The island itself was overrun by deer and cavies: and on the main land the wild pig of the country (javali) was seen. On the 23d they entered the river Colorado, but had much trouble in warping to a safe berth, on account of the water being very shoal at the entrance which they had chosen. The principal mouth was a

* Nine tons burthen. † Fifteen tons.

‡ Sawdust alone would have been better.

© The Complete Work of Charles Darwin Online

quarter of a mile further south, the stream being there "broad and rapid," with two fathoms water when the tide was out; but beset, to seaward, by sandbanks, which shift with every south-east gale. Quantities of drift-wood, a kind of willow (sauci), lay about every where, indicating that the river sometimes overflowed its banks to a great distance, and brought down these trees from the interior country, as none grow within three leagues of the mouth. The river hereabouts is divided into many streams, forming a great number of small islands, which are nearly all of clay covered with rushes. From one of these streams or channels, the Cañada, there are creeks communicating at high-water with Union Bay. Here Lieut. Wickham's party saw a wolf.

On the 27th they met a whale-boat (at Creek Island in Anegada Bay) from the River Negro, in search of sea-elephants. Next day they reached a snug creek in San Blas Bay, where they heard that the Indians had lately driven off all the cattle from the San Blas Estancia, had destroyed the houses, dismounted the guns, and broken the carriages. They were accompanied by a number of desperate criminals who had fled from justice at Buenos Ayres, and idle gauchos, who preferred robbery to work, and were unquestionably the most savage of the troop. On the 29th the Liebre was hauled ashore, to extract a piece of sauci wood that had run through her bottom: and a party was afterwards employed in erecting a conspicuous mark upon Hog Island; a very difficult task, because the loose sand, of which that island wholly consists, flies in clouds at every gust, and nowhere affords a solid foundation. By the help of casks filled with it, and spare anchors, they at length succeeded in securing an old spar upright, which was large enough to be seen ten miles round, in that low half-drowned country.

Deer were very numerous on Javali Island; but on the place called Deer Island, there was not one, though they were so plentiful there a few years before. Some dogs had been left there by a whale-ship, which have increased very much in numbers and are very savage: these dogs have exterminated the deer.

© The Complete Work of Charles Darwin Online

Any quantity of fresh water may be obtained in San Blas Bay, by digging wells six or eight feet deep; and fish are abundant: but it is no place for a ship to enter unless under favourable circumstances of weather, wind, and tide; and decidedly dangerous with a south-easter, because there is then a sea on the banks outside which confuses the pilot's eye, and prevents his distinguishing the proper channel; besides which, thick weather, if not rain, is the general accompaniment to that wind.

On the 3d of December the Beagle anchored off San Blas (as formerly mentioned). Both schooners went out to her, and in returning at night into San Blas Bay, working to windward with a strong flood tide, they passed close to an unknown rock which would have made an end of their cruise had they touched it. The least water they had, however, was eight feet;* but both vessels were close to it, while the tide was running four or five knots. This rock is in the middle of the entrance to San Blas Bay. At midnight they reached their anchorage, without a dry article in either vessel.

On the 6th, Lieutenant Wickham remarked, while at anchor between San Blas and the River Negro, off Point Rasa, that the stream of tide began to set northward at half flood, and continued to run in that direction until half ebb, by the shore. "It is not at all uncommon on this coast," he says, "to see wrecks of vessels above high-water mark, and spars strewed along the beach where the sea does not touch them." These wrecks took place during south-east gales, when the sea was raised above its usual level in fine weather: and were the vessels spoken of in the previous chapter, as having been entrusted to ignorant or careless prize-masters, who ran for San Blas or the River Negro, not then knowing that so fine a port as Blanco Bay existed. Strong tides, shoals, a low coast, and bad weather would have perplexed professed seamen; but those difficulties were insurmountable to such unpractised craftsmen as those who were in charge of them, and most of the prizes were lost. One large ship of four or five hundred

* The Paz drew five feet and a half, the Liebre four feet.

© The Complete Work of Charles Darwin Online

tons was taken, by a wiser master, to Port Melo, and there her cargo was discharged into small craft, which landed it safely in the River Negro. Many of these ill-fated vessels were never afterwards heard of; but from the numerous wrecks seen along the coast between the Colorado and the Negro, it may be inferred that they and their unfortunate crews perished in the surf occasioned by south-east gales, or were capsized by sudden pamperoes.

Running up the River Negro (on the 7th December), Lieut. Wickham found the 'freshes'* strongly against him. The banks of the river afforded a pleasing contrast, by their verdure, to the arid desert around Anegada Bay. Most part of these banks was cultivated, and great quantities of fine corn was seen growing. Here and there were country houses (quintas) surrounded by gardens, in which apple, fig, walnut, cherry, quince, and peach trees, vines, and vegetables of most kinds were abundantly plentiful.

Although the banks of the river are so fit for cultivation, it is only in consequence of floods, which take place twice a-year—once during the rainy season of the interior, and once at the time when the snow melts on the Cordillera. These floods swell the river several feet above its banks, bringing a deposit of mud and decayed vegetable matter, which enriches the soil and keeps it moist even during the long droughts of that climate.

The plough used there is wooden, and generally worked by oxen, but it does not cut deeply. Manure is never used, the soil being so fattened by alluvial deposits.

The town of Nuestra Señora del Carmen, is about six leagues up the river, on its northern bank, upon a slightly-rising ground about forty feet above the water. It is irregularly built: the houses are small, one only having two stories; and glass windows are seldom seen: each house has a large oven. A square enclosure of some extent, formed by walls of unbaked bricks (adobes), is called the fort, and within it are the church, the

* Showing that this was the period of one of the two floods to which the Negro is annually subject.

© The Complete Work of Charles Darwin Online

governor's house, lodgings for the officers, and public stores. This fort commands the neighbourhood, as well as the houses (or cottages) surrounding it; and of the hundred buildings which compose the town of Carmen, exclusive of about thirty huts on the south bank of the river, the fort is the oldest. It was built about 1763. Some houses, forty years old, are as fresh in outward appearance, as if built only a few years ago. In a population of 1,400, there are about 500 negroes. Altogether there may be in the town about two thousand inhabitants, but many of the poorer families and negroes live in caves, which were dug out of cliffs on the river's bank by the first Spanish settlers. It is said that they served the Spaniards as a secure refuge from the Indians, who could only approach them by one path, easily secured. These caves, dug out of earthy clay, are not despicable dwellings, while there is a fire in them to expel damp.

About a league from the entrance of the river are the ruins of a large house, which was the "Estancia del Rey." In former days 100,000 head of cattle were attached to that establishment, now there is not even a calf.

Some of the first settlers were living at Carmen in 1833, staunch royalists, every one looking back with regret to former times. One of them belonged to the crew of the Spanish launch that first entered the river. He said, that the Indians were then living in detached tribes along both banks of the river, and were very friendly to the Spaniards. This same old man afterwards made one of the exploring party, under Villarino, in 1786, when the natives were not only inoffensive, but gave them assistance. How different from the present day! when if a Christian is seen by the natives, he is immediately hunted, and his safety depends upon the fleetness of his horse. It has sometimes happened, that persons riding along near this river, have been surprized by a marauding party of Indians, and obliged, as their only resource, to leap off the banks (barrancas), whether high or low, and swim across to the other side. The Indians have never followed; hence this, though requiring resolution, is a sure mode of escape.

© The Complete Work of Charles Darwin Online

Prior to the conclusion of the war between Brazil and Buenos Ayres (1828), the settlers at Carmen lived tranquilly—undisturbed by Indian aggression (retaliation?) but since that time, they have been kept in continual alarm. Prisoners are often brought to Carmen to be ransomed, whom the Indians have taken from other places. They are generally women or children; and as the Indians often find out who their prisoners are, the ransoms asked are proportionably exorbitant. Men are usually put to death, if they do not die of their wounds. There is a tribe of friendly Indians living near Carmen, at the outskirts of the town, who do much hard work for the inhabitants for very trifling remuneration; but they are shamefully abused, cheated in every way by shopkeepers and liquor-venders, and harshly treated by other persons, who seem to consider them inferior beings—unworthy of any kind or humane consideration. Should one of these poor creatures fall by the knife of a passionate white man, no notice is taken of it by the authorities; the murderer boasts of his deed, and the poor relations suffer patiently the loss and the insult, which they dare not avenge. Having quitted the free tribes, seduced by promises never fulfilled, they would not be received among them again; and their own numbers, originally small, are reduced daily by disease and abominable drugs, which the publicans sell them in what is said to be spirituous liquor (agua ardiente). Mr. Wickham saw a poor Indian woman, between forty and fifty years of age, almost killed by a blow on the head from an ox's skull (with the horns), given by a wretch, who had drawn his knife upon her husband for preventing his kissing a pretty girl, their daughter, who was walking with her. This scoundrel was seen by Mr. Wickham, a few days afterwards, betting at the race-course with the principal people of the place.

Thanks to the influence of Harris and Roberts, and their connections (both being married to daughters of Spanish settlers), our officers and men were exceedingly well treated. Every door was open to them; and the fruit in every garden was freely, as well as sincerely offered. Letters had been for-

© The Complete Work of Charles Darwin Online

warded to the commandant or governor, from Buenos Ayres, desiring that we might have every facility and freedom in our operations; but the disposition towards us was such, that those letters were not required.

From the remains of former buildings, and accounts of the old men, Lieutenant Wickham thought that the Spanish settlers must have been far more industrious and ingenious than their creole descendants, who are idle, indolent, and ignorant. The height of their ambition is to make a show at the Sunday races, where they deceive, drink, wrangle, gamble, and quarrel. These Sabbath occupations are always attended by the female part of the population, who take that opportunity of displaying their finery; and though seated upon handkerchiefs on the sandy ground, without any defence from sun, wind, dust, or rain, every damsel displays silk stockings and a gaudy dress upon these occasions. The men do not go near them, notwithstanding their attire: they can beat a poor woman almost to death, upon occasion; but they cannot defer a bet, or risk losing a dollar, for the sake of female society.

The climate is so healthy, that illness of any kind is scarcely known; and the inhabitants, in general, live to a good old age. There is a stirring trade carried on in small vessels, between Buenos Ayres and this place. Salt, of excellent quality, hides, peltry, seal or sea-elephant oil, and skins, are the principal exports, in return for which are received manufactures, sugar, spirits, tobacco, &c.

The Indians, who live at the outskirts of the town in 'toldos,' which are neither wind nor water-tight, load vessels with salt; but the price of their labour is usually spent in some kind of spirituous liquor, which is made and drugged expressly for them—the publicans often saying, "that it is a sin to give an Indian good spirits." When drunk, the howling of these poor wretches is quite frightful. Some of them are almost skeletons—the result, probably, of drinking.

Some leagues up the river coal is obtained, I was informed, but I did not see a specimen myself. Probably Mr. Darwin had an opportunity of examining its quality.

© The Complete Work of Charles Darwin Online

On the 12th, Lieutenant Wickham sailed for Blanco Bay, to deliver some letters from me (which I had received from Buenos Ayres) to the commandant Rodriguez.

13th. Off the banks in Anegada Bay there was too much sea (during a S.W. gale) for the Liebre to keep on her course any longer, having run as long as was prudent, and already shipped several seas. When hove-to, under a balance-reefed foresail, with the tiller unshipped, she was dry and easy, and lay about five points from the wind.

Mr. Wickham arrived at Argentina on the 16th, and left it on the following day. In sailing out of Blanco Bay, along the south shore, while it was dark, the Liebre grounded frequently; but her crew got overboard, and hauled her over the banks as often as she was stopped by them, and at midnight she was at sea. A south-east gale on the 18th drove her into the Colorado, where Lieutenant Wickham found a strong outset, owing to the 'freshes,' even during the flood-tide.

On the 22d, the Liebre entered the river again, and anchored near Carmen.

At daylight on the 24th, Corporal Williams was missed, supposed to have fallen overboard in the night, while asleep. He slept on deck sometimes, when tormented by musquitoes; and as the Liebre's weather-cloth rail was but a few inches above the deck, he might possibly have rolled overboard into the stream, which would immediately have carried him away. His body was found, about three miles down the river, at sun-set the next evening (Christmas day). The governor (though a Roman catholic) allowed the burial to take place in the consecrated ground of the church, and the curate himself was present.

While the Liebre was absent, Mr. Stokes, in the Paz, surveyed many miles of the river, as well as the bar. No vessel drawing more than eleven feet water can enter without much danger: if at a favourable time any person should be induced to risk crossing the bar with a ship of greater draught, he should bear in mind that it is much more difficult to get to sea than it is to enter, because wind which is fair for approach-

© The Complete Work of Charles Darwin Online

ing, raises the water; and the reverse. Although ships drawing fourteen feet have passed the bar, at unusually favourable times, others of only ten feet draught have been detained forty days in the river.

29th. Both our little vessels sailed, and on the 4th of January they anchored safely in Port Desire:—this was a bold stroke, but success attended it. They were thus placed at the southernmost point of the coast they were to survey, while the sun was farthest south; and as the days shortened, they would work along the coast northward. Recent traces of Indians were found; and the master of an American sealer told Mr. Wickham that they had been there in considerable numbers, about two months previously. The wells were all full; therefore much rain must have fallen during October, November, or December. I have mentioned elsewhere that although the eastern coast of Patagonia is usually an arid desert, there are periodical times, of short duration, at which rain falls abundantly.

11th. Having rated their chronometers, the little vessels stood out to sea, in company with the North American sealer; but they had not sailed many miles before the wind increased to a gale, and still becoming stronger, bringing clouds of dust and sand off the land, they were reduced to bare poles, and drifted fast off-shore, as well as northward. When the fury of the gale was over, their balance-reefed foresails were set, and with their tillers unshipped they made very good weather, until they were driven near the tide-races off Cape Blanco, where some anxious hours were passed, half-buried in foam, and the wind again almost a hurricane. Towards evening, the storm abated; our water-soaked explorers succeeded in regaining a position under shelter of the land; and anchored next morning under Cape Blanco, to dry themselves and take observations. In this severe gale, the North American schooner split two close-reefed foresails, lost a boat, and was otherwise damaged.

Lieutenant Wickham and Mr. Mellersh walked a long way

© The Complete Work of Charles Darwin Online

from Cape Blanco, to trace the coast, and look out for shoals in the offing; in doing which, they found numerous 'salinas' (extensive hollow places filled with salt), where the solid mass of very white and good salt was several feet in thickness. Guanacoes were numerous, but shy. On the rocks some fur-seal were seen; too few, however, to be worth a sealer's notice. The following week was passed in examining St. George Bay. Scarcely any stream of tide was found in its western part, though the rise amounted to nearly twenty feet. About Tilly road, where they landed, the mass or principal part of the soil, where visible in cliffs or ravines, is loose sandy clay (diluvium), with immense quantities of large fossil oyster shells imbedded in it. These shells were found every where, even on summits seven or eight hundred feet above the sea, and some of them weighed eight pounds.

A place honoured by the Spaniards with the name of Malaspina, and described as a port, was found to be a wretched cove, full of rocks, hardly safe even for the Liebre. While moored there, our party witnessed lightning set fire to bushes and grass. The flames spread rapidly, and for two days, the face of the country continued to blaze. Near Port Arredondo, Mr. Wickham went to the tops of several hills; he found the country unproductive, except of a few bushes, and yellow wiry grass. There were no traces of natives. Very heavy rain fell during the night of the 28th. I mention it thus particularly, because some persons have said that rain never falls on the east coast of Patagonia, in any quantity.

The cove called 'Oven' is a singular place, being a parting (as it were) in the solid rock, nearly a mile in length, but very narrow, with four fathoms water in it at low tide. Surrounded on all sides by precipitous hills, it is, indeed, an oven; and would injure a ship seriously, even more than other ports on this arid coast, if she were to lie long in it; as her seams would all be opened, and her planks split by the heat and drought. The water found here was so strongly impregnated with salt-petre, that it was not drinkable; but probably better

© The Complete Work of Charles Darwin Online

might have been procured had they dug fresh wells. On the summit of South Cape an Indian tomb was found. The stones had been displaced, and some bones were lying about, a few of which were taken on board, but none could be got in a perfect state. Mr. Bynoe afterwards examined them, and informed me that they had belonged to a female of small stature.*

Off Ship Island, and thence to Cape Dos Bahias, the tide-stream was again felt strongly, running two, three, or, in some places, four knots an hour. At a little creek, in Camarones Bay, near Cape Dos Bahias, abundance of small wood, fit for fuel, was found; and plenty of fresh water in hollows of the rocks. A guanaco was shot, which weighed upwards of two hundred pounds. Not only is small wood plentiful about Camarones Bay, but the country is sufficiently covered with grass of good quality. Several Indian tombs were seen on the hills, whence it may be inferred that natives at times frequent the neighbourhood, although no recent traces were met with by our party. Unfortunately, not one of these tombs, simply irregular piles of stones, was found in an undisturbed state, neither were any more bones discovered: they are all similarly situated upon the most conspicuous, smooth, and round-topped hills.

At Port Santa Elena many tons of excellent water were procured from hollows in the rocks. (7th Feb.) Approaches to trees were found at this place, which though stunted as to height, much like thorn-trees in exposed situations, were of respectable dimensions. One measured more than three feet round the trunk, but its fellow was not seen.

After dusk, on the 10th, while endeavouring to enter New Bay, with a fresh wind and strong flood-tide, the Liebre got into a 'race,' and was hustled within a fathom of a rock, over which the tide was boiling furiously. Fortunately, the Paz saw the Liebre alter course and make more sail, and by imme-

* I gave them to Sir Francis Chantrey, by whom they were shown to several persons.

© The Complete Work of Charles Darwin Online

diately following her example, avoided the danger. They then hauled off, and passed the night at sea.

Next day (11th), they stood towards the bay again, the wind increasing fast, till it blew a gale from W.S.W., which being against a flood-tide stream, running at the rate of four knots through the entrance, raised a short hollow sea, dangerous for small craft. Battening down the hatches securely, and close-reefing, the little vessels worked through gallantly, though frequently obliged to lower their sails in squalls, or as they dived into a sea heavier than usual. The tide soon swept them beyond the narrow part, and then they were comparatively in safety.

Part of the west shores of New Bay seemed to be fit for cultivation, being covered with a fine dark soil; and there is abundance of fire-wood. Some small ponds of excellent water were found, over a clayey bed, in which were tracks of cattle. A guanaco shot here was superior to any killed elsewhere, as to condition. Many thousand seals were seen on the rocks, which did not take to the water as soon as disturbed—therefore they could not have been much molested by man.

On the 24th, Lieutenant Wickham discovered the river Chupat, and after waiting for the tide, anchored half a mile within the entrance. Next day he went a few miles up it in a boat, and found that, though free from drift-timber, it was shoal and narrow, few places being deeper than six feet at low-water, or wider than a hundred yards. The stream ran down two or three knots an hour. Many tracks of cattle were seen, but none of natives. As the river seemed to be free from sunken trees, and to have but few banks in it, Mr. Wickham decided to move the Liebre as far up as he could, and then make another excursion in his little two-oared skiff. Between pulling* and sailing, the Liebre was moved twelve miles up in one day, and was moored in the middle of the stream, lest Indians should be near.

Next morning, Mr. Wickham went in his boat, about eight

* Both the vessels had oars.

© The Complete Work of Charles Darwin Online

miles further; but in a direct line he was then not more than twelve miles from the entrance. Along the banks on each side, as he had advanced, both he and those with him, were much struck by the richness of the alluvial land (caused doubtless by the river overflowing its low banks), and by the quantities of drift-timber, which actually looked like the stores in immense timber-yards. Among the drift-wood there were many large and sound trees left several hundred yards from the banks, therefore the periodical floods must be great.

At Mr. Wickham's westernmost point "the river and the country round had a beautiful appearance, as seen from a rising ground on the south side—an excellent position for a settlement." From this elevation the stream was traced to the westward, running with a very serpentine course, through level meadow land, covered with rich herbage. Several herds of wild cattle were seen, and their traces were observed every where in such numbers as to indicate a great abundance of animals.

Mr. Wickham returned on the 26th to the entrance, and found that a store of fish had been salted by the cook, while Mr. Stokes and others were going about, surveying the neighbourhood. These fish were a kind of bass, nearly as good as salmon.

I have no doubt that this is a river whose existence has been many years known by Spaniards, but of which the situation was intentionally concealed, on account of the lucrative trade some individuals hoped to carry on by means of hides and tallow obtained from the herds of wild cattle. The Spaniards used to anchor their vessels in Port San José, and thence ride in large parties to the Chupat; there they surrounded numbers of cattle, and drove them across the peninsula between San José and New Bay, where they slaughtered them at leisure. Numbers were probably killed nearer the river; but all that could be driven, had doubtless the privilege of conveying their own hides to the neighbourhood of their hunters' ships. There was still living at the River Negro (in 1833) an old man, who was one of the few individuals that escaped

© The Complete Work of Charles Darwin Online

during a dreadful massacre of Spanish settlers at Port San José. He said that the Indians were jealous of their encroachments, and seized an opportunity, while the Spaniards were attending the performance of mass, to fall upon them, and indiscriminately slay all, except three or four who were taken alive and kept as slaves.

That the Spaniards should have chosen San José for the place of their settlement instead of New Bay, or the Chupat itself, is easily accounted for, by mentioning that small vessels can generally run from the River Negro to Port San José without much risk and in a short time, whereas there are strong tides and dangerous 'races' off the peninsula of San José, and the entrance of the Chupat will not admit a vessel drawing more than seven feet: even this only at high-water. I think that the Chupat is the river alluded to by Falkner, as being in the "country of Chulilaw."* He was told that it traversed the continent as far as the Andes, and judging from the drift-timber, as well as volcanic scoriæ brought down by it, there is ground for thinking that the Chupat† rises in the Cordillera. There is also reason to suppose that the river described and placed variously by different geographers, under the name of Camarones, is this Chupat, chiefly because the Indians who frequent the country bordering upon the south bank of the Negro, say that there is no river of consequence between that and the Santa Cruz, excepting the Chupat.

With this river so near at hand, the west side of New Bay would be an excellent situation for a settlement. There ships of any burthen might anchor in safety, and a communication be carried on with the interior by means of flat-bottomed boats, or barges, so constructed as to admit of being towed, or tracked, in the river, and capable of running up to New Bay before a fair wind. In the River Negro similar boats go a long way up the river for salt; they are towed by horses or oxen; and such vessels, even of thirty tons burthen, might enter the Chupat, if constructed so as to draw but little water. I need not dwell upon the possible advantages to be derived from opening a

* Falkner, p. 87. † Chupat is the Indian name.

© The Complete Work of Charles Darwin Online

communication across the continent with Chiloé, which might be a means of diffusing Christianity, civilization, and commercial intercourse.

On the 3d, Lieut. Wickham and his party left the Chupat. Early on the 5th they entered Valdes Creek (by the Spaniards styled 'port'), with the flood tide running nearly six knots into the narrow entrance: and on its shores found heaps of horns and bones, besides the wreck of a vessel.* These were indications of one of the temporary settlements maintained on the peninsula of San José for the purpose of obtaining hides. The carcases of the animals were invariably left to decay; a few delicate portions only being selected for food.

Until the 12th our little vessels were unable to quit this singular place, for the ebb tide set so strongly against the swell outside, raised by a S.E. gale, that they could not attempt to cross the bar. Sometimes the very narrow entrance of Valdes Creek is almost stopped up for a time by shingle and sand, after a S.E. gale has been blowing for a few days, therefore at such a time no vessel ought to run for it.

During the war between Brazil and Buenos Ayres (1825-9), Mr. Adams, of Carmen, was master of a merchant vessel hired by Vernet to convey settlers to the Falkland Islands. In returning thence, short of water and provisions, he thought to put into Valdes Creek, knowing that some people were there employed in collecting hides. He ran in for the land, with a fresh S.E. wind, and did not discover, until almost too late, that the bar was not passable. When close in he perceived a heavy sea breaking at the entrance, where he expected smooth water, and directly hauled off; but it was only by carrying a heavy press of sail that he cleared the land; and at the expense of passing through 'races,' which tore off the vessel's bulwarks and otherwise damaged her materially. As our cock-boats crossed this bar, they had ten feet water, but on each side of it there were five fathoms. The Liebre, sharp built, plunged into each short swell; while the Paz, with her bluff bow, did not

* Of about two hundred tons burthen.

© The Complete Work of Charles Darwin Online

take in a single sea. The bar is a continuation of the long shingle spit, or bank, which forms the seaward side of the harbour; and is about nine miles long, though in some places not a hundred yards broad.

Towards noon the wind fell light, and the vessels were swept by a strong tide-stream towards a 'race,' whose noise might have appalled the crews of much larger and stouter barks. No bottom could be struck with the deep-sea lead, and no efforts of the crews at the oars had much effect in arresting their progress towards apparently inevitable destruction. Even at this awful time, habitual familiarity with danger, and zeal for the service, shewed their effects strongly in Mr. Stokes, who eagerly watched for the sun's meridian altitude, with his sextant to his eye, while every now and then he caught a hasty glimpse of the foaming and roaring race towards which the little craft were fast approaching. At this crisis a breeze sprung up which just enabled them to pass clear; but no one who was in those vessels can ever forget that day, neither do I think they attribute their preservation to blind chance. Sailors see too many of these 'chances' to think of or reflect upon them lightly, and those who have had experience are not wont to forget, that to direct and to preserve are among the least efforts of Omnipotence—so far, at least, as our limited intelligence enables us to discern.

At five that afternoon the Paz and Liebre were about eighteen miles off shore, out of soundings with their lead-lines, and yet were only a mile and half from the eastern part of the race; therefore they still stood to seaward, to get as far as possible from a neighbourhood so dangerous at any time, but especially so at night. For two hours they passed through a rippling, but could strike no soundings with sixty fathoms of line.

In 1830 Mr. Harris (owner of the Paz) sailed from the River Negro in a vessel of about ninety tons, with some horses on board, which he had engaged to convey to a party of gauchoes who were employed on the peninsula of San José, in killing cattle for their hides. Within the Bay of San Matias, about six

© The Complete Work of Charles Darwin Online

leagues N.W. of the port (San José), he got into one of these races,* and could not extricate his vessel. No soundings could be obtained: the sails were useless in consequence of the violent motion and want of wind, where the water was breaking so furiously, though elsewhere a fresh breeze was blowing; and nothing could be done. The crew took to the rigging, to avoid being washed overboard; and for almost three hours they were tossed about, like an empty bottle in a ripple, before the race abated, with the turn of tide, so as to admit of their sails acting enough to draw them a-head out of the commotion. The vessel, though a strong one, was so much shaken and damaged, the horses so much injured, and all hands so much 'scared,' as Harris honestly told me, that he steered back direct for the Negro, forfeited his agreement, and refused to go again.

On the 14th March the Paz and Liebre again crossed the bar of the River Negro, and next day they anchored a-breast of the town (Carmen). Lieut. Wickham found that an expedition had been sent from Buenos Ayres for the purpose of obliging the Indians to retire beyond (southward of) the Negro; and, if possible, deprive them of their horses. Bad weather and a heavy sea on the bar, caused by south-east gales, prevented the Paz and Liebre from sailing again until the 11th of April, when they went to Port San Antonio, and afterwards into Port San José. Plenty of firewood, and abundance of fish, were found at San Antonio; but no fresh water, except by digging wells. The tide-stream rushes into and out of Port San José in a violent manner, especially when opposed by wind; but after the narrow part of the entrance is passed, all agitation of the water ceases, except what may be caused by wind. It is a barren and desolate place, without wood or fresh water, and too large for a harbour. Our party saw proof of this assertion in the wreck of a small vessel at the north-east part of the port, which had been driven from her anchors and

* The tide-races within the bay are less formidable than those off Point Norte, near which our vessels were.

© The Complete Work of Charles Darwin Online

totally lost, though she was lying in a land-locked bay, or rather gulf.

On the 6th of May, while returning from San José to the River Negro, our little vessels got into a ripple, which did not break, but had almost the appearance of a whirlpool. There was a hollow short swell, and an irregular motion in every direction, exactly like the boiling of a pot, on a great scale. Here again they could touch no bottom with fifty fathoms of line and a heavy lead. These races and ripplings in such deep water, about the peninsula of San José, are very remarkable; chiefly because there are none such on any other part of the coast. They will be recurred to in a future page of this volume.

May 7th. The Paz and Liebre returned to the Negro, but could not reach an anchorage off Carmen until late the next day, owing to the 'freshes.'* The next occupation for our party was examining and sounding the entrance and bar of the Negro, a task purposely deferred, as being of minor consequence. The mouth of a rapid river like this, subject to floods, and disemboguing at a place exposed to the full force of such a heavy sea as is raised on that coast by a south-east gale, must be frequently changed, as to the detail of its shoals and channels; therefore no plan, however exact at one time, can be depended upon after the lapse of a few years; and no vessel larger than a boat would be justified in attempting to enter without a local pilot, if one can be obtained. In one spot, near Main Point, where a small battery stood in 1826, there were two fathoms water in 1833; and within the same period the deepest water for a few miles within the entrance, changed gradually from the south side to the north. Mr. Darwin was told that the river was called Negro after a cacique of that name; but Falkner asserts that it was so called by the Spaniards, because the aborigines knew it by the name of 'Cusu Leuvu,' which means black river.†

* There are two floods annually: one about December or January, caused by snow melted on the Cordillera; and the other about May or June, occasioned by heavy rains in the interior country. These inundations are very variable.

† Falkner, p. 79.

© The Complete Work of Charles Darwin Online

In May, June, July, and August, the neighbourhood of this river swarms with wild fowl, which migrate from the south, for the winter, and return there to breed about September. The old people foretell a severe winter when they arrive early, and in greater numbers than usual. In 1833-4 they formed the staple article of food for the inhabitants of Carmen during the winter, as the Indians had deprived them of their cattle; in the summer cavies and ostriches supplied their tables. Hunting is a favourite amusement of the Carmenites. They sally forth in large parties on horseback, attended by a motley crowd of dogs, inclose a large extent of country, contract the circle gradually,* and at last drive a great number of ostriches, wolves, cavies, deer, foxes, and pumas, into a comparatively small space, when the indiscriminate attack commences—balls and lassoes flying in every direction. Many accidents happen to the horses in these hunts, owing to the ground being so undermined, in some places, by the 'tucutucu,'† a little animal like a small rabbit; but the riders are so skilful, that they generally save themselves, however awkwardly their horses may fall. Pumas are an especial object of attack, not only for the risk attached to encountering them, but because they do so much damage to the young animals of all kinds: they have a peculiar method of instantly killing a young colt by breaking its neck with an adroit blow of one paw, while the poor creature is held fast between the other and a most formidably armed mouth. In 1779 there were numerous herds of cattle and horses near the town of Carmen, but incursions of the Indians have diminished them to but few.

During the time of the old Spaniards, after 1783, more than a thousand Indians attacked the settlement at one time. The inhabitants retreated to their caves,‡ where, defended by strong doors, with loop-holes for musketry, they were safe; but their

* As in eastern countries.

† This Indian name, gutturally pronounced, expresses the curious sound made by these creatures while under ground—a noise somewhat like the blow of a distant hammer.

‡ Mentioned in p. 299.

© The Complete Work of Charles Darwin Online

houses were ransacked and burned, and all their animals driven away. Since that time the frequent predatory excursions of minor parties of Indians have prevented the settlers from again attempting to collect animals in large numbers, seeing that they would assuredly tempt the aborigines to repeat their attacks on a greater scale than ever. The old man, who was one of Villarino's party,* gave Mr. Darwin some information about that expedition, which entirely corroborates the interesting account of Basilio Villarino himself, who made his way, by excellent management, and extreme perseverance, to the foot of the Cordillera, though surrounded by Indians suspicious of his intentions. He managed so dexterously as to make one tribe become his firm friends and assistants; and behaved so well himself, in his own enterprises, as well as in his conduct to those under him, as to have obtained their hearty co-operation during eight long months. But he was soon afterwards savagely murdered by the natives during another exploring expedition.† The old man said that Villarino was much guided by the account of an Englishman,‡ whose description of the river and Indian country was found to be very accurate. Mr. Darwin heard several anecdotes of the Indians, and their attacks upon the Christians (so they term all white men) which interested me very much; but as I suppose they will be found in his volume, it is unnecessary here to do more than allude to them.

On the 12th May Mr. Usborne, in the Constitucion, anchored in the river, and next day put himself under Mr. Stokes's orders; to whom Lieut. Wickham gave up the charge of this branch of the survey, and then went on board the Constitucion to hasten towards Maldonado. On the 17th all three little vessels sailed, Lieut. Wickham steering for the Plata, and Mr. Stokes for San Blas.

From this time till the Paz and Liebre were discharged, in

* Bowman of his boat (lancha).

† Sir Woodbine Parish has given an abridged translation of Villarino's Diary in the Journal of the R. Geogr. Society for 1836, vol. vi, part ii, pp. 136—167.

August,* Mr. Stokes and his party were most zealously occupied between the Negro and Blanco Bay; but time was too fully occupied in the uninteresting, though useful works, of sounding, measuring, observing, and chart-making, to admit of many notices of the country being obtained in addition to those already mentioned; indeed the nature of the coast, almost flat, uninhabited, without trees, and fronted by extensive sand-banks, precluded the possibility of acquiring much information not of a technical nature.

CHAPTER XV.

Beagle and Adventure sail from Monte Video—Port Desire—Bellaco Rock—Refraction—Port San Julian—Viedma—Drake—Magalhaens—Patagonians—Port Famine—San Sebastian Bay—Woollya—Jemmy—Story—Treachery—Oens-men—Improvement—Gratitude—Falklands—Events—Captain Seymour—Search for Murderers—Lieutenant Smith—Brisbane—Wreck—Sufferings—Lieutenant Clive—Sail from Falklands.

Dec. 6th, 1833. With a supply of provisions and coals,* sufficient for at least nine months, the Beagle and her tender sailed together from Monte Video.

We first touched at Port Desire (23d Dec.), and after passing a very cheerful Christmas-day,† and exploring the inlet to its extremity, the Adventure was left to complete some alterations in her masts and rigging, while the Beagle would survey the coast between Sea Bear Bay and Port San Julian.

The party who went up the inlet were much struck by the wildness and height‡ of the rocky cliffs which they saw on each side of what appeared to have been the bed of a former river; but could go no further with the yawl than I had been in 1829. This I had foreseen, and therefore Mr. Chaffers, who was in charge of the party, took with him a small dinghy, in which he went on after the yawl was stopped by the mud. Having proceeded two miles further, the prospect changed suddenly; instead of wild glens and precipitous heights of porphyritic rock, low flat banks were seen, covered with rushes near the water, and, further from the stream, with luxuriant pasture. It was almost high water when the dinghy reached this spot and entered a fresh water river about a hundred

* Wood and water being easily procured in the regions we were going to visit, we carried only a month's store of those essentials.

† After noon on the 25th, both crews amused themselves on shore in wrestling, racing, jumping, and various games.

‡ About three hundred feet.

yards wide, but so shallow that there was only three feet water in the middle. The river narrowed considerably as they ascended, till at the spot where Mr. Chaffers stopped to take sights of the sun, the stream was but forty yards across. In that place the deepest water was three feet at the top of high tide, over a gravelly bottom; but from the level space between the stream and the foot of the nearest hills, about three quarters of a mile, there was reason for supposing that during floods all the valley might be inundated. From a neighbouring hill, four hundred feet in height, the river could be traced several miles further, making a distance of about eight miles seen by our party, in which the water was quite fresh. It was lost to the westward, winding along an irregular break, or cliff-bounded valley, in the distant hills. The only living creature seen, of any size, was a lame horse, feeding near the river. There were no traces whatever of Indians. Having hastened back with the little boat before the river dried* (at half-ebb), Mr. Chaffers ascended another hill; but saw little more excepting an appearance of water to the southward, about which he could not clearly distinguish whether it was a lake, part of a river, or a salt-pond. I have no doubt, that during particular seasons a large body of fresh water is brought down this valley, but I do not think the river rises near the Andes, because there is no drift-wood on its banks, and the Indians say nothing of it when enumerating the rivers which cross the continent.

Jan. 4th, 1834. In working out of Port Desire, the Beagle struck her fore-foot heavily against a rock, so as to shake her fore and aft; but on she went with the tide, and as she made no water, I did not think it worth while returning into port. I was instantly convinced that we had hit the very rock on which the Beagle struck in 1829, in the night—a danger we never again could find by daylight till this day, when I was, rather imprudently, going out with the last quarter-ebb.

* The tide fell more than fourteen feet perpendicularly; but a small brook remained, perhaps a foot deep, winding its course between the uncovered banks.

© The Complete Work of Charles Darwin Online

At low-water there are but eight feet on this rock, which is not far from mid-channel, just without the entrance.

We anchored near Watchman Cape, and in other places along the coast, before reaching Port San Julian, and some time was devoted to an examination of the Bellaco Rock and its vicinity, as there is a dangerous reef extending from Watchman Cape towards, but not quite out to the Bellaco.

In my own notes I find this rock mentioned as "almost covered at times, but occasionally showing above water as high as the hull of a ship!" In Mr. Stokes's journal, left with me, it is mentioned in these words: "Passed between the Bellaco Rocks, close to the eastern one, nearly a-wash;" and in the diary of the Nodales' voyage (in 1619), it is spoken of as "una baxa que lababa la mar en ella," which means, a rock a-wash. The rise of tide there is about twenty feet, which explains the various appearances it had to my eye; for at high water I saw it almost covered, or a-wash; and as the Nodales described it similarly in 1619, there can have been extremely little, if any, change in the relative heights of sea and land in this place during the last two hundred and fifteen years.* Some time ago I thought differently, having formed a hasty opinion upon the fact of my having seen the rock as high out of water as a ship's hull. I did not then consider how much the tide falls, nor did I recollect, till I referred to notes, that I had also seen it a-wash (the top almost level with the water), at times during the many days we were in the neighbourhood.

On the day that Mr. Stokes and myself made our respective notes on the Bellaco (without any communication of opinion), an extraordinary effect of refraction was remarked. The meridian altitude of the sun (then far south) observed at opposite horizons, differed no less than sixteen miles! Similar effects had been noticed before, especially on the Patagonian coast, therefore we generally observed both ways; but to nearly

* As the larger and eastern rock is about a hundred yards long and eighty wide, with kelp growing on most parts of it, I do not think the top can wear away while so protected by sea-weed.

© The Complete Work of Charles Darwin Online

such an extent as this we never either before or afterwards witnessed an error arising wholly from the state of the atmosphere near the horizon; causing the visible water-line to be apparently raised several minutes of a degree. On these occasions we always used the mean of the two results, which agreed closely with the latitude resulting from triangular connection with points on the shore, whose latitude we knew by observations made with the artificial horizon.*

7th. Mr. Stokes and I landed some leagues northward of Port San Julian, near Cape Look-out, and ascended a level-topped range of hills about 300 feet above the sea. The view we obtained was similar to those so tiresomely common in eastern Patagonia. Level, arid, desert-like plains extended to the horizon: a few irregular hills were seen in the distance; some guanacoes and a few ostriches were here and there discerned; a fox crossed our path, and a condor wheeled overhead; nothing more was noticed.

We returned to the low ground near the sea, and there we found plenty of small wood, stunted shrubby trees, fit for fuel; as well as several ponds of fresh-water. The rise of tide on the shore was considerably more than twenty feet, but we had not time to ascertain it accurately.

9th. Mount Wood,† that excellent land-mark for Port San Julian, was seen at daylight: and about noon the Beagle anchored off the bar of the harbour. Mr. Stokes went with me to examine the passage, and before evening our ship was safely moored in the port. This was one, among numerous instances I could mention, where the good qualities of the Beagle, as to sailing and working, saved us days of delay, trouble, and anxiety. All hands immediately set-to about the plan of the port, and such efficient officers as were with me made short work of it. One day Mr. Darwin and I undertook an excursion in search of fresh-water, to the head of the inlet, and towards a place marked in an old Spanish plan,

* Bellaco rocks are the same as Estevan shoal. There are at least two distinct masses of rock. A ship may pass between them.

† Nine hundred and fifty feet high.

" pozos de agua dulce ;" but after a very fatiguing walk not a drop of water could be found. I lay down on the top of a hill, too tired and thirsty to move farther, seeing two lakes of water, as we thought, about two miles off, but unable to reach them. Mr. Darwin, more accustomed than the men, or myself, to long excursions on shore, thought he could get to the lakes, and went to try. We watched him anxiously from the top of the hill,* saw him stoop down at the lake, but immediately leave it and go on to another, that also he quitted without delay, and we knew by his slow returning pace that the apparent lakes were 'salinas.' We then had no alternative but to return, if we could, so descending to meet him at one side of the height, we all turned eastward and trudged along heavily enough. The day had been so hot that our little stock of water was soon exhausted, and we were all more or less laden with instruments, ammunition, or weapons. About dusk I could move no farther, having foolishly carried a heavy double-barrelled gun all day besides instruments, so, choosing a place which could be found again, I sent the party on and lay down to sleep ; one man, the most tired next to myself, staying with me. A glass of water would have made me quite fresh, but it was not to be had. After some hours, two of my boat's crew returned with water, and we were very soon revived. Towards morning we all got on board, and no one suffered afterwards from the over-fatigue, except Mr. Darwin, who had had no rest during the whole of that thirsty day—now a matter of amusement, but at the time a very serious affair.

Sir Woodbine Parish intends to publish a description of the Spanish settlements on these shores, in which no doubt Viedma's, at Port San Julian, will have place. A full account of it, in the original language, may be found in the diary of Antonio de Viedma, published at Buenos Ayres, in 1837, by Don Pedro de Angelis. Finding no water near the harbour except after rain, which is there rare, Viedma pitched

* Named in the plan 'Thirsty Hill.'

his tents some leagues inland, near a spring frequented by the Indians, but their doubtful friendship, the progress of scurvy among his own people, their discontent at such a situation, and other reasons, inclined the Spanish viceroy to withdraw the settlement. This dreary port, difficult of access and inhospitable even when the stranger is within its entrance, is well known to readers of early voyages as the place where Magalhaens so summarily quelled a serious mutiny, and conspiracy against his own life, by causing the two principal offenders, captains of ships in the squadron, to be put to death:* and as the scene of the unfortunate Doughtie's mock trial and unjust execution.† That two such remarkable expeditions as those of Magalhaens and Drake should have wintered at Port San Julian, and that two such tragedies should have occurred there is remarkable. In the plan of that port we now see Execution Island, Isle of True Justice, (injustice?) and Tomb Point: the two former being names given by Drake.‡ One naturally asks how their ships obtained water, and the answers occurring to me are,—that they were there in the winter season, when the rain which falls is not soon dried up; and that they may have dug wells, which we did not think it worth while to do, having no time to spare.

15th. A French whaler came in over the bar, at high water, without having sounded it, or knowing what depth she would find. The only instance of similar folly I have witnessed was that of a sealing schooner which I met near Port Famine, whose master had taken her through Possession Bay and both Narrows, without knowing that the tide rose and fell there more than six or seven feet, and without a chart of the Strait. When I told this man that the tide rose six or seven fathoms at the First Narrow, he certainly did not believe me. The bar of San Julian is shingle (or gravel), and often altered in form by south-east gales or unusual tides. Under ordinary circumstances the tide rises thirty feet at full moon.

‡ And the latter a memento of Lieut. Sholl, of the Beagle, (vol. I.)

© The Complete Work of Charles Darwin Online

19th. Sailed, and, for once during our experience of these shores, found a heavy swell setting in from the east.*

On the 20th we anchored again in Port Desire, and our first employment was to look for the rock whose top (Mr. May assured me with a grave face) we had knocked off with our keel.

22d. Both vessels sailed, and at sunset the Adventure parted company, steering for New Island in the Falklands. Lieutenant Wickham was to make a connected survey of the coast of that archipelago, while the Beagle was in other places.† After giving some time to sounding and examining portions of ground in the neighbourhood of Cape Virgins and the eastern entrance of Magalhaens Strait, we passed the First Narrow and anchored in Gregory Bay. There, of course, we had an interview with old Maria and her party. They received us kindly, but with some form, being assembled and seated on the ground near our landing place, with two men standing up in the midst of them, who looked immoveably grave and stupidly dignified. These men were acting as caciques, Maria said, the real chiefs being absent. They were stripped to the waist, and the upper parts of their bodies spotted with white paint.‡ The rest of the people were dressed as usual. An active barter commenced, but the portly actors in the middle did not take part in it, they remained in their solemnity till we left them.
