# About the Editors

---

**John M. Levine** is a professor of psychology and senior scientist in the Learning Research and Development Center at the University of Pittsburgh and Honorary Professor of Social Psychology at the University of Kent in the United Kingdom. He did his undergraduate work at Northwestern University and received his PhD in psychology from the University of Wisconsin. Levine's research focuses on small group processes, including innovation in work teams, group reaction to deviance and disloyalty, majority and minority influence, and group socialization. He has published widely on these and related topics. Levine has served as associate editor of the *Journal of Research in Personality*, both associate editor and editor of the *Journal of Experimental Social Psychology*, and executive committee chair of the Society of Experimental Social Psychology. He is a fellow of the Society of Experimental Social Psychology, the Society for Personality and Social Psychology, the American Psychological Society, and the Midwestern Psychological Association.

**Michael A. Hogg** is professor of social psychology at Claremont Graduate University in Los Angeles and an honorary professor of social psychology at the University of Kent in the United

Kingdom and at the University of Queensland in Australia. He is a fellow of the Society for Personality and Social Psychology, the Society of Experimental Social Psychology, the Society for the Psychological Study of Social Issues, the Western Psychological Association, and the Academy of the Social Sciences in Australia. He received his PhD from Bristol University and has taught at Bristol University, Macquarie University, the University of Melbourne, the University of Queensland, and Princeton University, and he has been a visiting professor at the University of California in Los Angeles, Santa Cruz, and Santa Barbara and at City University, Hong Kong. His research on group processes, intergroup relations, social identity, and self-conception is closely associated with the development of social identity theory. He has published extensively on these and related topics. A former associate editor of the *Journal of Experimental Social Psychology*, he is foundation coeditor with Dominic Abrams of the journal *Group Processes and Intergroup Relations* and senior consultant editor for the Sage Social Psychology Program. Current research foci include leadership, deviance, uncertainty reduction, extremism, and subgroup relations.

# Introduction

---

Scarcely anyone would quarrel with the assertion that humans are social animals or with the corollary assumption that, in order to understand people's thoughts, feelings, and behaviors, it is necessary to understand the role that *groups* play in human affairs. We all are members of large social categories based on such criteria as race, gender, ethnicity, and nationality, and most of us also belong to a range of groups and organizations (e.g., families, friendship cliques, work teams, religious congregations, political parties). These various social aggregates (which will be collectively referred to as "groups") profoundly affect our well-being and life trajectory through their impact on such basic needs as physical survival, belongingness and intimacy, accurate knowledge about the world, and sense of self and identity. The groups that people belong to vary on several dimensions, including size, voluntariness of membership, composition (the types of people who belong), structure (e.g., norms, roles, status systems), collective goals, level of conflict, rewardingness, relations with outgroups, and so on. Notwithstanding this diversity, groups matter, and matter a great deal, to their members.

Before discussing the goals and organization of this encyclopedia, two definitional issues need to be considered. First, what do we mean by a group? As suggested above, groups can vary in many ways, and so providing a succinct definition is no easy task. In fact, some observers have suggested, only partly in jest, that there are as many definitions of groups as there are researchers who study them. Rather than adding our imprimatur to one of these definitions, we will mention some of the major criteria that group researchers have emphasized in defining groups (all of which are used, either explicitly or implicitly, by some authors in this encyclopedia). These criteria include the presence

of particular structural features (e.g., norms or roles); group members' agreement on shared goals; patterns of interaction between members (e.g., communication, reciprocal influence, coordinated action); members' emotional bonds to the group as a whole and/or one another (cohesiveness); and members' identification with the group. Which criterion, then, is the most important? As suggested by the eminent group theorist Joseph McGrath, this question assumes that the goal is to distinguish groups from all other social aggregates (non-groups), which may be a futile exercise. He argues, and we agree, that it is more productive to construe groupness as a continuum, such that a given social aggregate is more or less "groupy" depending on how many of the above criteria it satisfies.

The second definitional issue is raised by the title of the encyclopedia. What do we mean by "group processes" and "intergroup relations"? In general, the term group processes refers to what happens *within* groups, that is to how members of a group think, feel, and act toward others who belong to the *same* group. Topics that are typically subsumed under the heading of group processes include the impact of member diversity on team performance, the development and operation of group norms, the conditions under which numerical minorities can produce innovation, the characteristics of effective leaders, the factors that influence whether negotiators reach mutually acceptable agreements, the conditions under which team members fail to work hard on collective tasks, and the causes of poor decision making in groups that are under stress. Defining intergroup relations is more complex. In most cases, this term refers to what happens *between* groups, that is to how members of a group think, feel, and act toward others who belong to a *different* group. Topics that are typically subsumed under the heading of intergroup

relations include the role of categorization in stereotyping and prejudice, the impact of social roles on gender stereotypes, the function that language serves in maintaining stereotypes, the conditions under which members of stigmatized groups engage in collective action against those who discriminate against them, the circumstances under which intergroup contact does and does not reduce prejudice, and the justifications that dominant groups use to rationalize discrimination against subordinate groups. However, the term intergroup relations is not restricted solely to what happens between groups. It can also apply to what happens within groups (i.e., to how members of a group think, feel, and act toward others who belong to the same group) *as long as* these responses are influenced by the broader context of intergroup relations. An example is the black sheep effect, in which group members respond more negatively toward ingroup members who deviate from group norms (and more positively toward ingroup members who conform to these norms) when the ingroup feels threatened by an outgroup than when it does not. Moreover, the term intergroup relations can also apply to some forms of *self-directed* thought, feeling, and action. An example is the phenomenon of stereotype threat, in which group members who are reminded that outgroups hold negative stereotypes of their ability in certain domains then perform poorly in these domains.

### Development of the Encyclopedia

Over the past 75 years, there has been a tremendous amount of theoretical and empirical work on group processes and intergroup relations by scholars from various disciplines. Until recently, these two lines of work were quite distinct, and few efforts were made to bring them together in a single volume (or, as in the present case, pair of volumes). This situation began to change in the 1980s due in large part to the influence of the social identity approach to groups championed by Henri Tajfel and John Turner. A major indicator of and impetus for the integration of group processes and intergroup relations was the establishment of a journal by this name in 1998, co-founded by Dominic Abrams and Michael Hogg. In an important sense, then, this encyclopedia is a reflection of the growing (though still far from complete) integration of

what were formerly two distinct perspectives on groups.

When we (John Levine and Michael Hogg) were approached by Michael Carmichael of Sage with the idea of editing an *Encyclopedia of Group Processes and Intergroup Relations*, we were initially reluctant to take on a task of this magnitude. Nevertheless, a combination of M. Carmichael's persistence and charm and our propensity to overcommit ourselves eventually led to a round of handshakes and then a contract. We knew that the only way to make the venture a success was to convince other overcommitted colleagues to help. We had three criteria for choosing associate editors—disciplinary background (we wanted people from the three key disciplines of social psychology, sociology, and organizational behavior), substantial expertise and visibility in their respective fields, and excellent judgment. With only a little arm twisting, we were able to assemble a Dream Team of associate editors, which included Linda Argote, Marilynn Brewer, Jack Dovidio, Norb Kerr, Dick Moreland, and Cecilia Ridgeway. With their help and guidance, we developed a set of approximately 300 topics for inclusion in the encyclopedia and then selected experts to write the relevant entries. Almost all of these people accepted our invitations, and those who did produced excellent entries. Either we or one of the associate editors evaluated each entry and provided feedback to the author(s). Many entries were revised to increase their accessibility to the general reader. The invitation and reviewing process was orchestrated by our superb managing editor, Danielle (Dani) Blaylock, who was a PhD student at Claremont Graduate University and is now a postdoctoral fellow at Queens University in Belfast, Ireland.

### Intended Audience

In choosing topics for inclusion, selecting authors, and editing entries, we were mindful that the encyclopedia is *not* intended for professionals or experts with extensive knowledge of social psychology, sociology, or organizational behavior. Instead, it is intended for general readers who want state-of-the-art information about group processes and intergroup relations that is presented in a clear and accessible manner. Our instructions to authors were designed to achieve these goals.

We stated that, “The main target audience is undergraduate students in various disciplines (e.g., psychology, sociology, business, political science, education), but the encyclopedia should also prove useful to graduate students and faculty as well as high school students . . . entries must accurately convey what behavioral scientists know about how people think, feel, and act toward ingroup and outgroup members . . . entries must be written so that readers with little or no behavioral science background can understand what is being said.” Thanks to the hard work of the authors and the editorial team, we believe that these goals were accomplished.

### Organization of the Entries

The entries are listed in alphabetical order, beginning with Action Research and ending with Xenophobia. The lengths of the entries reflect our judgment regarding topic breadth and importance. The longest entries are approximately 4,000 words, and the shortest are about 1,500 words. Many of the shorter entries provide detailed discussions of topics that are only briefly covered in the longer entries. To help readers locate the topics in which they are most interested, we prepared a Reader’s Guide (see below) that organizes the entries into 12 general categories. Note that many entries appear in more than one category. At the end of each entry, readers will find cross-references to other entries and a short list of Further Readings.

#### *Reader’s Guide Headings*

Cognitions and Feelings  
 Conflict and Cooperation Within Groups  
 Group Decision Making  
 Group Performance and Problem Solving  
 Group Structure

 Types of Groups and Subgroups

### Acknowledgments

We owe a great debt to the people at Sage who encouraged and assisted us at each stage of the project. We thank Michael Carmichael for his enthusiastic support at the beginning and Rolf Janke for clearing obstacles that arose as we went along. Diana Axelsen did an excellent job of keeping our feet to the fire when progress lagged, Kate Schroeder was extremely patient during the copyediting phase (as were our two fine copy editors—Bonnie Freeman and Jamie Robinson), and Carole Maurer made the “end game” as pleasant as possible. Finally, Leticia Gutierrez and Laura Notton were very helpful with the Sage Reference Tracking system, which greatly facilitated our work.

We also want to thank the people who worked most closely with us during the process of editing the encyclopedia. They include our associate editors—Linda, Marilyn, Jack, Norb, Dick, and Cecilia—who devoted a great deal of time to the project, and our managing editor—Dani—who was efficient and good humored even when we were not. Finally, we want to express our gratitude to the authors of the entries. They met or exceeded our expectations for both the quality and clarity of their entries, and we appreciate their efforts.

Last but not least, we thank Jan and Alison for their patience and support as we worked on the encyclopedia.

*John M. Levine  
 Michael A. Hogg*

## ACTION RESEARCH

---

*Action research* is a process of participatory inquiry aimed at generating knowledge to guide action in pursuit of the participants' goals. It can be compared with traditional scientific research, which seeks to find the "truth" through methods that are highly controlled by the researcher. Action research, in contrast, seeks to generate knowledge that solves specific problems and enables the actors in the situation to achieve their goals. It is carried out collaboratively by these actors, including researchers, who engage in a mutual inquiry process that takes into account the perspectives, knowledge, and purposes of all involved. Thus the conduct of action research is heavily dependent on the process through which the various people involved in the action research project interact to create new ways of understanding their situation and new paths forward. Action research may include traditional, scientific data-gathering and analysis approaches. But it is more generally characterized by inquiry approaches that build on and create the knowledge of practice. It employs different knowledge-generating approaches—approaches that place practitioners and their knowledge front and center. The ultimate test of the knowledge that is generated through action research is whether the action taken because of the knowledge accomplishes the purposes of the participants.

This entry provides a short history that illustrates the varieties of action research and discusses

the role of the researcher. It also shows how action research differs from traditional scientific research, exploring the common elements and core processes of action research as well as the nature of the knowledge that is created and applied.

### History and Forms of Action Research

Action researchers trace their philosophical roots to Aristotle's notion of goal-directed action (*praxis*) as one of the key activities of human beings, distinct from theorizing (*theoria*), and crafting things (*poiesis*). They also refer to his notion of practical wisdom (*phronesis*), that is, the ability to reflect and determine the appropriate ends to which to direct one's life. This combination of reflecting on appropriate purposes and learning how to achieve them is central to all forms of action research. Action research involves groups, or communities, of individuals reflecting and learning for action. Individuals represented in the action research group may have different perspectives and goals, thus, effective action research requires group processes for reflection, learning, and consensus building.

The modern philosophical roots of action research may be traced to John Dewey's early 20th-century discussions of learning through a cycle of reflective thinking about problems, formulating hypotheses about what might solve them, and testing them through practical action. The term *action research* as an approach to social science research is often traced to the field research tradition begun by Kurt Lewin during the Second World War. In this approach, people in various

real-life settings such as work organizations participate in research to discover better ways to accomplish their goals. This action research tradition emphasizes the formulation of theory that can be tested and refined through experiments whose results have an impact on practice—so that the requirements of practice are met and systematic knowledge is furthered. Lewin’s belief that the best way to understand something is to change it has been echoed by action researchers ever since.

Lewin’s approach sponsored the development of the *sociotechnical systems* (STS) tradition for improving work systems. Early STS research discovered that productivity is enhanced by leadership styles and work systems that empower employees to be actively involved in making decisions about how to run their own work units. These core STS ideas were expanded and refined through many action research projects in which the participants in a work setting such as a factory or a mine collaboratively designed their own work setting to be technically and socially effective. Researchers involved in this stream of action research provide theoretical input and a process for design and planning. They study the group processes through which the diverse members of the setting—managers, supervisors, and workers—develop a new way of working together, the choices they make about how to organize themselves, and the outcomes of putting these choices into action.

Since the 1980s, the Norwegian democratic dialogue approach has emphasized the gathering of various stakeholders (including management, the workforce, government, and unions) in conferences in which they can speak with each other as equals about how to move forward on issues such as work organization. The underlying principle is to move from traditional adversarial approaches to cooperation through democratic dialogue, and the purpose is to build relationships and establish a new way of making decisions that take the interests of all parties into account. At about the same time, throughout the world, social justice has become the focus of action research activities that emphasize gender and race issues, and of emancipatory work in poor nations that is based on empowering ordinary people by helping them develop the capabilities to generate their own knowledge as a basis for action.

### Differences From Traditional Social Science Research

There are several ways in which action research differs from more traditional research. These include the purpose of the research—whether the researcher is out to discover scientific “truth,” or whether the researcher aims to help people accomplish their purposes. Other differences concern where the research is conducted, and the methodologies that are used. These differences have implications for the relationship between the researcher and the people in the real-life settings being studied.

#### *Purposes*

Traditional social science research is based on a search for the “truth” about the phenomena being investigated—whether they are aspects of the physical world, investigated by hard scientists, or aspects of the social world, investigated by social scientists. Scientific truths, as scientists have been able to discover them, are embodied in theories that yield predictions for further investigations to confirm and expand theoretical understanding. In traditional social science research, the quest is to find the truth about the social behavior of individuals, groups, organizations, and societal institutions. The social entities being studied are treated as the objects of the research and it is considered poor form to engage with them, as the scientist is expected to remain disinterested in outcomes and purposes and to retain objectivity in explaining behavior.

Purposes are central to action research, as the quest of action research is to create knowledge that can help participants accomplish their purposes. Various traditions of action research differ in the extent to which they emphasize the use of academic theoretical knowledge in the processes through which purposes are defined and action is crafted. At one extreme are action researchers who believe there is no generalizable truth, and that all knowledge is created in specific situations. Their purpose is not to discover truth, but to introduce frameworks for interaction that enable participants to gather information, make choices, and take action to accomplish their purposes. This is the position of the Norwegian democratic dialogue advocates. The action researcher’s role in the conversation is as a member of the group who brings

knowledge of how to set up dialogues, reflection, and learning. Yet even these action researchers are guided by their own values and purposes, such as achieving democratic dialogue or emancipation.

Other action researchers, such as STS researchers, have as their purpose contributing to knowledge that is generalizable across settings, in addition to helping participants in an action setting learn how to generate actionable knowledge. These researchers bring relevant theoretical constructs and the cumulative knowledge of the social sciences—sometimes called *content knowledge*—to bear in the processes by which participants define and solve problems. The researchers' knowledge of theory and the participants' knowledge of practice are combined to yield solutions to problems and designs for action. Through the action research, the practical knowledge of the participants and the theoretical knowledge of the social sciences are both expanded. These action researchers bring expertise to diagnose problems and to intervene in a way that helps participants solve them. They may train, educate, and facilitate the group, thus assuming a central position in the group.

#### *Research Conducted In Situ*

Traditional researchers carrying out studies in the field try to avoid focusing on only one organization. They seek random selection of the populations being studied—sometimes into treatment and control groups—in order to randomly distribute external factors that might otherwise distort the findings. Action research, in contrast, always is situated in and generates knowledge about a particular social system that has expressed interest in engaging in action research—for example, a work unit, an industry, a community, or a subpopulation. It focuses on creating the knowledge-generating and action-taking capability in that particular system. An action research project enables researchers to learn about one system, and to test and expand theory in only that system. Action researchers who are interested in building widely applicable knowledge do so through a succession of action research projects in different settings. For example, STS researchers created cumulative knowledge about the participative design of manufacturing systems for high performance through a succession of action research interventions in different factories. Each

successive setting presented different challenges and different opportunities for learning. The participants in each setting were interested in creating their own solutions, yet the action researcher brought useful experience and knowledge from previous research. For the action researcher in a new setting to establish enough trust for the other participants to learn from this previous work, he or she has to be open to the uniqueness of each setting and of the group of participants engaged in the participative design process—and open to different design choices and resulting action. Only in this way can the research be truly participative and the researcher learn how the unique factors of the setting contribute to general knowledge.

#### *Research Methodologies*

Beyond differences concerning randomization versus in situ focus, action research methodologies differ from traditional social science research in other ways, including the amount of control the researcher has over the research and the data-gathering methods. Traditional researchers conduct research in a carefully controlled manner to eliminate alternative explanations for the results that they find. This generally means that the objects of the research are unaware of the purpose of the research, the research questions, and the hypotheses being tested. This is believed to be necessary so that they do not behave in a manner that distorts the findings—either by trying to act in a manner that fits the expectations of the researcher or by trying to prove the opposite. Highly controlled approaches fit a model where the researcher is seen as having a privileged knowledge-creating role in society and is given permission to study others. People and organizations may agree to be part of such research to further science, but often do not believe that it will yield knowledge useful to their personal purposes.

The members of the action research community are, in contrast, co-investigators. Purposes are transparent and they are codetermined by the action researcher and other participants. The research questions are often co-defined by the participants, because these questions have to do with their real-life situation. If there are hypotheses guiding the research, these also will be formulated and influenced both by the researchers' knowledge

from theory and the other participants' knowledge from practice. Finding common purposes and hypotheses to guide the inquiry and action planning process entails finding a process to come to agreement despite differing experience bases, knowledge, and preferences.

The action researcher is one of the participants in this community of co-investigators. Like all participants in any group, action researchers face challenges in defining and achieving perceived legitimacy for their role in the group. The group members are being guided to behave in ways they may not be used to—putting aside rank and biases and listening to and building on the perspectives of all. The members of the group may only appreciate the power of a truly participative inquiry process after experiencing it. Only then may they understand collaboration and appreciate the researcher's contribution.

The action researcher who claims to have content expertise relevant to the group's purpose, and who aims to further that knowledge through the action research, faces the additional challenge of achieving legitimacy and trust for that expert role within the group. Theoretical knowledge is likely to be rejected unless the researcher engages with the group, and accepts the importance of combining theoretical knowledge with the group members' knowledge of practice, to yield an approach that is tailored to the situation and purposes at hand.

Traditional social science research is often characterized by data-gathering methods such as surveys, questionnaires, and structured observations that are coded, counted, and analyzed statistically to discover patterns of relationships between variables predetermined by the researchers. For example, researchers may be interested in whether the purposes of low-status group members are less likely to be voiced and achieved in an action planning process; they may measure the status of each member and ask the group members individually to what extent they felt their ideas were taken into account. Although such traditional methods may be part of an action research project, action researchers generally feel that these methods are insufficient to capture the complexity of human interaction. These researchers are likely to introduce a variety of ways of understanding the system and to encourage the consideration of rich data,

including the feelings and experiences of participants and the meanings they attribute to their interactions.

Interpretation of these rich and diverse data is central to the inquiry process. The group members attach meaning not only to systematically collected data but also to their interactions, including those between the researcher and the practitioners. Academic interpretation is only one perspective in the process of attributing meaning. Given that the group is working to agree on different ways of operating and different outcomes, the academic interpretation may have the least impact because the participants' criteria are usefulness and relevance. Both the process and content knowledge brought to the group's collective sense-making process by the action researcher will be interpreted in conjunction with the full set of knowledge brought by the members of the group.

### Common Elements in Action Research

The broad assortment of approaches that are labeled action research share some defining attributes: a discourse-based learning cycle, an expanded definition of knowledge, and an inherently political nature. Each of these places strong requirements on the action research group's interaction patterns.

#### *A Discourse-Based Learning Process*

Action research is a discourse-based inquiry and reflection process through which stakeholders and participants in the real-life situation come together to make choices, plan, and take action. If the action research group is able to establish itself as an ongoing learning community, the action and its consequences feed back into the learning of that community, establishing a cycle of experiencing, reflecting, planning, and action taking. Common steps include:

- establishing the group to collectively engage in communication designed to raise consciousness and increase mutual understanding and to create a sense of common purpose
- inquiring by gathering relevant data and knowledge from each other and other sources, sometimes including scientific knowledge and a

formal data-gathering process applying formal scientific approaches

- interpreting and reflecting on the meaning of the information and knowledge assembled, and its relationship to purposes
- deciding on and planning action focused on solving the problems being addressed and achieving the purposes that the group has collectively defined
- reflecting on the results of the action that feed back into an ongoing inquiry, reflection, and action-taking cycle

A major role of the action researcher is to facilitate that process while modeling it, thereby increasing the capacity of the group to develop knowledge. When this capacity has been developed, all members will function as action researchers.

### *An Expanded Nature of Knowledge*

Scientific knowledge deals with the theoretical connections between variables—and is aimed at answering questions such as whether carrying out a particular action will lead to a particular outcome. A more diverse set of knowledge is required to define effective practice, and making decisions regarding practice requires the group to interpret patterns of information and pull together diverse knowledge sets. Even with a firm grasp of what is objectively known, and even with deep know-how about how to achieve particular outcomes, the group is still faced with the challenge of how diverse participants who may not start out knowing or trusting each other can find consensus about how to proceed.

Beyond objective knowledge, two other kinds of knowledge are required for effective action research. One is the knowledge participants develop of each other—relational knowledge—that enables them to understand and feel empathy for the others' points of view. This is the knowledge that allows the group members to go beyond their experience of the world and engage in reflection and action planning that incorporates the views and purposes of others. The second kind of knowledge is the reflective knowledge that comes from a truly collaborative interchange, and that equips the group to be critical of the status quo and to reformulate purpose. It enables the group to get beyond a problem-solving

orientation and collectively describe and create their real-life situation as they would like it to be.

Different action research groups and their members may begin the process with different competencies in and orientations to these different kinds of knowledge. In work settings, managers and technical employees may be heavily steeped in technical knowledge, and may see relational and reflective knowledge as unimportant to achieving their purposes. First-line employees, however, may orient themselves to these latter forms of knowledge, which determine their trust in the process and focus them on creating a workplace where they experience meaningful interpersonal relationships and where their purposes are taken seriously. Inherent in effective action research is developing an appreciation for these different forms of knowledge that allow a community of participants to move forward together.

### *Political Processes*

Integral to action research is the capacity of the group to create power dynamics where the members of the action research group are all heard, and their knowledge, preferences, and perspectives are taken into account. Words like *participative*, *equal*, *democratic*, *social justice*, and *emancipation* are used by action researchers in different kinds of settings. All of these terms carry the notion that the formerly disempowered will become empowered to influence the choices made and directions taken. Achieving this requires a process where those with formerly privileged knowledge and power, including the action researchers themselves, do not dominate the process. Ultimately the choice of action is politically determined. The goal of action research is to ensure that the political process is participatory and builds on the knowledge and purposes of the members.

---

## AFFECT CONTROL THEORY

---

*Affect control theory* (ACT) is a mathematical theory of social interaction developed by David Heise in the 1970s. Based on symbolic interactionist ideas, ACT explains how interpersonal interactions are constrained by the symbolic culture contained in language and the meanings it associates with things. The theory describes how actors cognitively and affectively negotiate these cultural meanings to maintain a “working definition” of the situation. It also makes predictions about behaviors, emotions, and identity attributions that occur in culturally situated interactions. Thus affect control theory helps us understand both inter- and intragroup processes.

ACT proposes that interactions confirming cultural meanings require minimal cognitive processing because such situations feel normal and expected. In contrast, when an interaction does not confirm standard cultural meanings, people attempt to cognitively interpret it, while being signaled by their emotions that the situation is unexpected. A core proposition in the theory is the *control principle*, which says that people attempt to restore the meanings in a situation after deviation from the cultural standard, typically by generating new social behaviors.

### Cultural Sentiments

ACT assumes that individuals understand social events by labeling their elements—including

identities, behaviors, settings, and emotions. The labels in turn evoke affective meanings that are shared with a larger culture. These affective meanings are conceptualized and measured using three universal dimensions of meaning that Charles Osgood found to account for a substantial amount of the variation in the lexicons of over 20 language cultures. First, *evaluation* is a measure of a concept’s goodness or badness measured on a continuum from *bad, awful* to *good, nice*. Second, *potency* is a measure of a concept’s power and ranges on a continuum from *powerless, weak, small* to *powerful, strong, big*. Third, *activity* is a measure of a concept’s liveliness or quietness and ranges from *slow, quiet, old* to *fast, loud, young*. ACT refers to the affective meanings measured on these dimensions as sentiments. *Sentiments* are trans-situational, generalized affective responses to specific symbols that are widely shared in a culture (or subculture).

These three fundamental dimensions of meaning serve as cultural abbreviations that describe important affective information about all elements of an interaction—identities, behaviors, emotions, and settings. These dimensions are core to our understanding of intra- and intergroup processes. The evaluation (good–bad) dimension helps characterize processes like status and affiliation at the interpersonal level and solidarity and cohesion at the group level. The potency dimension characterizes power relations between social actors and between social groups. The activity dimension characterizes the expressiveness of identities and interpersonal behaviors as well as feelings of excitement or quiet.

The three dimensions of meaning operate cross-culturally, but the sentiments associated with particular labels are specific to a culture or subculture. ACT researchers have empirically compiled sentiments associated with hundreds of identities, behaviors, setting, emotions, and traits into cultural dictionaries. Cultural dictionaries have been compiled for the United States, Canada, Japan, China, Germany, and Northern Ireland, and in the future this work will be extended to include other cultures. All elements of an interaction (identities, behaviors, settings, emotions, traits) are indexed along the same three dimensions of meaning. This provides a common metric for use in the theory’s equations that describe social interaction. Every

label evokes culturally specific amounts of goodness, powerfulness, and activity. In the U.S. cultural dictionary, for example, the identity of *outlaw* is quite bad, slightly powerful, and somewhat active. The behavior *reward* is extremely good, quite powerful, and slightly active.

### Interaction

Although all social concepts evoke cultural sentiments, the meaning of a particular element of an interaction may change as the interaction develops. ACT proposes that individuals label elements of a social interaction with concepts common to their culture, and those concepts have sentiments associated with them. In addition, these concepts provide a reference point throughout the interaction, allowing any observer of the interaction to determine if the interaction deviates from culturally normal behavior. ACT contains equations that specify how each social element of an interaction will contribute to altering the sentiments of those elements. For example, if an outlaw rewards a sheriff, observers will change their impressions of that particular outlaw, that particular sheriff, and that particular rewarding behavior. On the evaluation dimension the outlaw will no longer be seen as bad, but much closer to neutral, and the rewarding will be seen as only slightly good. The element's altered sentiments in a situation are referred to as *transient impressions*.

Differences between the cultural sentiments and the transient impressions reveal the degree to which a situation is culturally normative. In affect control theory, differences are called *deflection*; higher levels of deflection suggest less culturally normative events. An example of such an event is an outlaw rewarding a sheriff, because according to the affect control equations it is not normal for a bad person to do something good for a good person. The theory suggests that when an interaction is not harmonious with cultural expectations, people experience unusual emotional, behavioral, and cognitive responses.

First, actors will experience this deflection, or incongruence in meaning, emotionally—with larger incongruencies generally producing more intense emotions. An actor's emotion will be positive or negative depending on both how positive the event is and whether the incongruence is more positive than that actor's identity. An outlaw rewarding a

sheriff is engaging in an interaction that suggests that the view of this outlaw should be better than the typical cultural view of an outlaw. This incongruence in the direction of increased goodness means the outlaw will experience positive emotions, such as being thankful or relieved in response to the interaction.

Second, actors experiencing this deflection, which was initially signaled by emotions, will try to restore the normative definition to the situation through additional interaction. The theory predicts that actors will strive to restore the definition of the situation even if the emotion experienced was positive. Thus, in the example of the outlaw who rewarded the sheriff, the outlaw could yell at the sheriff or the sheriff could convict the outlaw to restore cultural sentiments. ACT suggests that behavioral responses are often the easiest method for controlling the inconsistencies created during interaction.

Third, for interactants who cannot restore the definition of the situation behaviorally and for observers who are not participating in the interaction, the situation can be resolved cognitively. For a mild deflection, accepting the transient impression may restore a working definition of the situation (in this case, deciding that this outlaw is not as bad as other outlaws). For more extreme deflections, relabeling elements of the situation is another possibility (e.g., the actor is not an outlaw but merely a rival, or the behavior was not really rewarding but taunting). ACT does not make specific predictions about when a behavioral or cognitive approach to resolving the incongruency will take precedence, but it does suggest that a working definition of the situation must be restored for individuals to make sense of their interactions and the larger social world.

### Mathematical Foundation

ACT is a mathematical model with the theoretical principals encoded in equations. *Impression-formation equations* specify the transient impressions of elements after an interaction occurs. Similarly, *labeling equations* can indicate how elements of interaction could be redefined by an observer. *Behavior-prediction equations* lead to predictions of what actions interactants might take to restore a working definition to the situation. *Emotion equations* predict emotions the

interactants are likely to experience as the result of an interaction.

All of the ACT equations are generated from empirical data for a particular culture. These equations as well as the cultural dictionaries have been implemented in computer programs such as INTERACT (<http://www.indiana.edu/~socpsy/ACT>), which allows simulations and predictions of interactions with all the ACT equations. These predictions can then be used to make specific hypotheses about emotional, behavioral, and cognitive reactions that are then subject to empirical testing.

Researchers have made fruitful use of affect control theory to study stereotyping and intergroup relations, the dynamics of therapeutic support groups, leadership structures within task groups, political identification and action, and responses to injustice. This research relies on a variety of methodological approaches, including laboratory experiments, formal cross-cultural comparisons, ethnographic studies, and survey research.

## AFFIRMATIVE ACTION

---

*Affirmative action* refers to efforts to provide equal opportunities for all in employment and education. This entry focuses on affirmative action in the United States because it has been the primary site for social science research on the issue. Affirmative action policies and programs take measures to increase the representation of women and racial/ethnic minorities in employment and higher education through the use of targeted recruiting and training, formalizing personnel practices, preferential treatment in hiring and educational admissions, and sometimes the use of quotas. The motivation for affirmative action is to redress historical inequalities between social groups by “leveling the playing field” for groups that are disadvantaged by past and current discrimination. Affirmative action has led to important changes in intergroup relations, and its history serves to highlight both the effectiveness and limitations of laws aimed at changing existing relations between social groups that differ in power and status.

### History

Throughout its 45-year history, affirmative action has been met with controversy and debate. While presidential committees since the 1940s had been wrestling with nondiscrimination clauses in federal contracts, the first mention of the term *affirmative action* came in 1961 from Executive Order 10925 issued by President John F. Kennedy. Executive Order 10925 was the first legal mandate requiring organizations that do business with the federal government (federal contractors) to “take affirmative action” to ensure that hiring and promotion practices are free of discrimination. Following the Civil Rights Act of 1964, President Lyndon B. Johnson issued Executive Order 11246 (E011246) in 1965, creating the first affirmative action policy to be enforced enough to provoke controversy and debate. E011246 applies to the federal government

and to federal contractors with a contract of at least \$50,000 and 50 or more employees. Initially, the policy was targeted at eliminating discriminatory barriers for racial/ethnic minorities, but it was modified in 1967 to protect groups based on color, religion, sex, and national origin. While E011246 only requires that the federal government and the businesses that contract with the government have affirmative action plans, many noncontracting organizations have adopted policies that enhance diversity and provide evidence against potential discrimination lawsuits.

Affirmative action can be distinguished from equal opportunity policies that simply prohibit discrimination by its call for actions to eliminate barriers to equal opportunity. The presumption behind affirmative action is that even race- and gender-neutral policies can operate in ways that advantage some groups over others. As Johnson relayed in his speech justifying E011246, "You do not wipe away the scars of centuries by saying: 'now, you are free to go where you want, do as you desire, and choose the leaders you please' . . . and still justly believe you have been completely fair." This inequality in access may be the result of current and past discrimination, institutional forms of racism and sexism that bias measures of merit, and/or the tendency of people to hire those they know or who have similar backgrounds.

To ensure that equal opportunity exists, affirmative action policies require employing organizations and schools to allocate resources toward (1) evaluating workforce and enrollment statistics and (2) taking proactive measures to balance the representation of women and racial/ethnic minorities with respect to their availability for hire or admission. In evaluating statistics, employers and educational institutions evaluate the proportion of qualified women, African Americans, Native Americans, Latinos/as, and Asian Americans and compare this proportion to the number employed or admitted and retained. When any target group is underrepresented relative to their availability, federal contractors are required to develop affirmative action plans that include goals and timetables for making good-faith efforts to remedy the problem. Goals for meeting affirmative action plans include targeted recruitment and

training, formalizing job posting procedures to promote equal access to hiring information, and in certain cases, giving additional weight or assigning extra points to race- and gender-disadvantaged applicants in hiring and admissions decisions.

While much of the controversy surrounding affirmative action has focused on the use of quotas, the law forbids the use of quotas except in circumstances in which courts order it as a remedy for cases of blatant discrimination. In 1978, the Supreme Court ruled against the use of explicit quotas in the case of the *Regents of the University of California v. Bakke*. In this case, Allan Bakke, a White applicant who was not admitted to the medical school at the University of California, Davis, sued when several minority applicants were accepted to the medical school despite having lower grades and test scores than he did. In this case, the university was reserving 16% of admissions spots for minority applicants and evaluating the qualifications of the White students separate from the minority students. The Supreme Court ruled that this was unconstitutional, but in addition wrote that schools could treat the minority status of applicants as one among other characteristics in making admissions decisions. This ruling, then, made explicit quotas illegal but certain forms of preferential treatment permissible.

Since the *Bakke* case, there have been a number of other important legal cases that have limited the methods by which colleges and universities can implement affirmative action plans. Appellate courts ruled that the admissions plans for the University of Texas Law School and the University of Georgia violated the equal protection clause of the 14th Amendment. In a landmark case in 2003, the U.S. Supreme Court ruled that the University of Michigan's point system for undergraduate admissions made race too prominent of a factor, but the law school's practice of considering race, but not assigning a specific weight to it, was permissible. This case was important because the justices affirmed that broad social value can be gained from diversity in the classroom. In addition to the court rulings, California and Washington have passed propositions banning any form of preferential treatment based on race, color, sex, or national origin, and Florida has banned race-based preferential treatment in college admissions.

### Impact of Affirmative Action on Workplace Composition

Has affirmative action been effective at increasing the number of women and people of color in the workplace? To answer this question, many studies have compared the proportion of women and people of color in the federal workforce, where affirmative action is required, to that in the private workforce, where affirmative action is not required. Several studies have consistently shown that the percentage of women, Hispanics, and Blacks in the government workforce is higher than the percentage in the private workforce. In addition, research studies have shown that women and minorities are more likely to advance to management in the public sector, and that occupational advance has led to smaller race- and gender-related earnings gaps in the public sector. While these studies suggest that affirmative action may increase workplace diversity, the broader differences between private and public sector jobs make it difficult to draw conclusions about the independent effect of affirmative action.

There are other studies that more successfully isolate the impact of affirmative action by comparing the growth of women and minority employment among organizations with federal contracts to that among similar organizations with no affirmative action requirements. Studies of changes in the period in which affirmative action was most stringently enforced (1974–1980) showed the employment of Black men and women growing at a faster rate and the employment of White men growing at a slower rate among federal contractors than among similar establishments without federal contracts. Studies also showed that compliance reviews are an important form of enforcement. Federal contractors that had undergone a compliance review had twice as much Black male employment growth as such businesses that had not been the subject of a compliance review. Another important factor in understanding the impact of affirmative action is employment growth more generally. Federal contractors that had many job openings were more likely to increase their representation of Black employees than contractors with less growth in the early years of affirmative action. A number of studies have also shown that affirmative action raised the occupational levels of

people of color, which in turn reduced the earnings gap between Whites and people of color. In addition, federal contractors have granted more promotions to people of color than have noncontractors.

Early studies comparing federal contractors to noncontractors underestimated the effectiveness of affirmative action because many noncontractors implement voluntary affirmative action plans. More recent studies have accounted for this by comparing the workplace composition of firms that report having an affirmative action plan to those that report not having one. The results are consistent with previous research, showing that organizations with an affirmative action plan have more women and minorities, a higher proportion of women and minorities in high prestige jobs, and a smaller earnings gap.

One of the major controversies surrounding the debate about affirmative action involves the claim of reverse discrimination. Opponents of affirmative action argue that in giving advantages to women and people of color, qualified White men are discriminated against. To assess the validity of this argument, some researchers have looked for evidence that when women and minorities are hired through affirmative action plans, their qualifications for the job are less than what is needed to perform well. Economists have approached this question by examining whether the redistribution of workers has come at the expense of quality and productivity. While the difficulties in assessing productivity across organizations limits the available evidence, econometric studies conducted during the late 1970s and late 1980s, when affirmative action was most strictly enforced, showed that the industries under the most pressure to comply with affirmative action plans were no less productive than other industries. In addition, company-level analyses showed that affirmative action obligations and changes in workplace composition had no negative effect on company profits. In fact, more recent research has shown that companies that employ the highest proportion of women and minorities enjoy higher returns on their stocks than the market average, while those that employ the lowest proportion of women and minorities had stocks that underperformed relative to the market average.

One of the most commonly relied upon ways that opponents of affirmative action assess whether

affirmative action results in reverse discrimination is to compare the qualifications of employees who benefit from affirmative action to the qualifications of those who do not. While this approach enjoys the most media attention, it is poor science because measures of merit are often intrinsically tied to institutional forms of sexism and racism. Subjective measures are subject to implicit and explicit race and gender bias, while objective measures like standardized testing have been shown to be culturally biased and poor predictors of performance. Research using data from employers in Atlanta, Los Angeles, Boston, and Detroit has revealed that among employers most committed to affirmative action plans, women and minorities had lower average qualifications than White males, but their performance on the job was no different.

### **Impact of Affirmative Action on Diversity in Higher Education**

Affirmative action in education has been even more controversial than in employment, experiencing more legal challenges on charges of reverse discrimination. The appellate and supreme courts have ruled in favor of plaintiffs charging reverse discrimination, and in so doing have effectively eliminated quotas and severely limited race-based preferences in college admissions.

Research has suggested that prior to the current restrictions, affirmative action led to more diversity in higher education. Recent empirical research analyzing student data from 28 elite colleges and universities in 1951, 1976, and 1989 showed that race-based affirmative action significantly increased the number of Blacks admitted to and attending elite institutions. In addition, findings showed that ethnic minorities graduated at the same rate as Whites. Another recent study of the University of Michigan Law School showed similar findings. As in the employment arena, the evidence—that students admitted as a result of race- and gender-sensitive policies graduate at the same rate as those admitted without affirmative action—seriously hampers claims of reverse discrimination. While most studies have provided this evidence, one study has found that Blacks admitted to elite law schools entered with lower average credentials than White students and were less likely to graduate and pass the bar. This study has sparked a great

deal of controversy and has been criticized in a number of publications for its methods and the author's interpretations. In any case, research has shown that even when students do not finish law school, simply attending increases annual earnings and thus serves to boost the life outcomes of people of color.

One of the factors that the Supreme Court has taken into account in ruling on affirmative action is the social value gained by diversity. A large body of research has shown that diversity leads to positive learning outcomes for both Whites and people of color. Research has shown that interactions in diverse settings improve the ability to take the perspective of others, and that heterogeneous groups outperform homogeneous groups when members perceive their contribution to be important. In addition to the direct benefit of diversity, ethnic minorities are more likely than Whites to use their education to benefit society—professionally and through civic engagement. Thus, increasing the representation of minorities in higher education institutions has been shown to have long-term positive social outcomes.

### **Impact of Affirmative Action on Intergroup Relations**

Because affirmative action is unique in its proactive approach to reducing inequality, there are a number of important ways in which attitudinal responses to the law and its impact expand our understanding of intergroup relations. Attitudes about affirmative action vary significantly according to how it is defined. Research has shown that people tend to be the most supportive of outreach programs and formalized job postings, while there is greater resistance to preferential treatment practices. Attitudes about affirmative action also vary according to the gender, race, political ideologies, and prejudice levels of individuals. Research has shown that women, people of color, political liberals, and those who hold the least prejudiced attitudes tend to be more supportive of affirmative action. The popular press has characterized affirmative action as a racially polarizing policy that divides Whites and Blacks. Research has shown that Whites do tend to be less supportive of affirmative action than are Blacks, but the extent of polarization has been exaggerated. Both Blacks and Whites tend to oppose quota

systems and support outreach programs. Though Whites resist preferential treatment practices more than do minorities, there is a significant proportion of Whites and minorities who support and oppose such forms of affirmative action.

People express opposition to special preferences in hiring and admissions because such preferences are perceived to violate norms of fairness and justice. While attitudinal survey research has shown that people who oppose affirmative action believe it is unjust, it has also shown that such a concern affects opposition differently depending on the race and gender of the group benefiting from the policies, as well as the race and gender of the respondents. For example, concerns about justice drive resistance to race-based affirmative action more than sex-based affirmative action. In other words, people's social locations and attitudes about other groups have greater explanatory power regarding resistance to affirmative action than do people's adherence to fairness and justice norms. One study also found that prejudice levels mediated people's tendency to misconstrue affirmative action programs as justice violating when they were explicitly designed not to advantage certain groups over others.

In moving beyond explanations rooted in principles of fairness, social psychologists have developed a number of different theories for understanding variations in attitudes about affirmative action. Scholars who place primary importance on the role of racial prejudice have theorized that individualist values, which lead to resentment against Blacks for their struggles to succeed economically (symbolic racism), conflicting interests between social groups, and the preference for social dominance, drive resistance to affirmative action. All of these theories differ in important ways, but they share the basic notion that dominant groups oppose affirmative action because it threatens their privileges. These theories provide the most purchase for understanding why Whites and males resist affirmative action, but the theories do not adequately address why groups that stand to benefit from affirmative action policies sometimes also oppose them.

Given the controversy surrounding affirmative action and the widely publicized complaints about reverse discrimination, those who benefit from affirmative action may be concerned about perceptions that their success is not merit based. A number of laboratory studies have provided support for this

concern, showing that when affirmative action is mentioned to people prior to their being asked to evaluate women and men job applicants, women are rated as less competent. In addition, laboratory research has shown that when people believe they have been granted preferential treatment or are led to believe others believe this, their general and task-specific performance is lower. Recent research has linked this disempowering effect to resistance to affirmative action, showing that when political ideology, support for gender-based affirmative action, symbolic racism, and perceived discrimination are accounted for, racial minorities are more likely to oppose special hiring preferences for their own group when they have a close friend who is White. This finding suggests that when the perception of the dominant society is close to home, resistance to affirmative action is greater.

The history and impact of affirmative action serve to highlight the nature of modern race and gender relations. Efforts to eliminate barriers to equal opportunity have improved the educational and labor market outcomes of women and minorities. In spite of these gains, affirmative action faces a formidable battle in winning over the support of those who stand to gain from the current system of inequality. So long as Whites and males oppose equalizing policies like affirmative action, those who benefit from the policies also incur the costs by being perceived as less worthy than others of their successes. This lag in attitudinal change is both a reason for affirmative action and an unfortunate consequence of laws aimed at forcing changes in existing status hierarchies.

## AGEISM

---

When we perceive other people, there are three primary criteria upon which we automatically and initially categorize them: race, gender, and age. This categorization process follows from the natural tendency of the mind to categorize objects in its environment to facilitate everyday cognition and action. The categorization of others on these dimensions becomes so well learned that it is automatic in social perception. Unfortunately, while categorizing people according to these characteristics does indeed facilitate social cognition, it is also the first step in stereotyping of, and prejudice toward, groups. While researchers have long studied racism and sexism, they know comparatively little about prejudice against someone based on their age, referred to as *ageism*. While it is certainly true that people have prejudices and stereotypes about virtually any age group, the vast majority of research on age prejudice has focused on the most common form of ageism: prejudice toward older people, particularly those over 74 years of age.

One reason that ageism has been underinvestigated by researchers is that it is institutionalized within American and many other Western cultures. In other words, negative views of older people are very much a part of our everyday shared experiences and lives, and older adults tend to buy into the truth underlying the stereotypes, that those who experience ageism are not perceived as “victims.” An example of how ageism is institutionalized can be found in greeting card stores. In the birthday card section, the basic message (though

jokingly presented) is “I’m sorry to hear you’re another year older” and that it is bad to get old.

### Forms of Ageism

Ageism takes many forms. It affects how some people speak to older adults. This language style, though grounded in good intentions, is experienced by many older people as patronizing and condescending. On the basis of stereotypes about the loss of cognitive abilities as we age, younger adults will often be overly polite, speak louder and slower, exaggerate their intonation, speak in a higher pitch, and use simple sentences. This “baby talk” has been found to be the same type of speech style that people use to talk to children, pets, and even inanimate objects. Interestingly, some older adults don’t mind being spoken to in this way. Research has shown that older adults who are not functioning at a healthy level (physically, emotionally, or cognitively) actually prefer this speech style because it communicates a feeling that the younger person perceives them as needing to be taken care of, and this dependency relationship is comforting to the older adult. Older adults who are healthy, however, may find such speech styles offensive.

Research has indicated that people have very negative attitudes toward aging and adults over 55, and particularly over 75. However, when asked about their attitudes toward their elderly boss, or grandfather, or neighbor, respondents in research studies have a positive attitude toward the specific older adult. This led to confusion among some early researchers who were not really sure if prejudice against older adults existed. As it turns out, it does, and people have many different and at times contradictory views of the older adult (for example, sometimes as a “sage” or “perfect grandparent,” and sometimes as “impaired” or a “shrew” or “curmudgeon”). One contributing reason for this may be that we tend to think about stereotyped outgroups along two dimensions: warmth and competence. We tend to view older people with whom we are familiar (such as family, friends, coworkers) as warmer but less competent than other older people. Research indicates that we regard other elderly people as cold and either incompetent or competent.

These divergent ways of treating older people according to age stereotypes also can be linked to

two different types of ageism. With *benevolent ageism*, the perceiver believes that older people need help and are dependent, and that younger people have an obligation to care for older people. The motivation and attitude toward older people is kind, helpful, and positive. In contrast, *malignant ageism* rests on the belief that older people are worthless, negative, and a burden on society. The motivation and attitude of these perceivers are quite negative and hostile toward older adults. These very different attitudes toward older people can lead to different perceptions of their warmth and competence, and those perceptions, in turn, can lead to very different beliefs, stereotypes about, and behavior toward elderly people.

### Motivation for Ageism

A fundamental question is, “*Why* are people ageist?” Older people are a unique group for prejudice researchers to study because, just by living long enough, these people move from the ingroup to a stereotyped outgroup. Given this fact, why would a younger person be motivated to insult and denigrate a group to which he or she will eventually belong? Though there are many potential, contributing motivations, one theory has shown substantial and compelling empirical evidence supporting the idea that ageism is motivated by *fear*. Terror management theory suggests that culture and religion are creations that impose meaning and order on our world. This order helps us keep at bay our feelings of fear about our mortality and the random nature of the universe. According to the theory, as we go through childhood, we associate good behavior with being rewarded and protected by our parents. This good feeling about ourselves, our self-esteem, therefore forms a buffer against fears of our eventual death. Research on terror management theory consistently has shown that when people are reminded about their mortality, they feel more anxiety. Because older people remind us of our mortality, we may avoid or even denigrate them to help us deny the possibility that we too will eventually get old (and die). Several studies therefore have shown that older people are stereotyped and discriminated against by younger people so they can cognitively distance themselves from their elders and blame them for their “sorry state” (being old). In so doing, young people deny

that such a fate will befall them, and their anxiety recedes.

Though more research is needed on the motivations behind age stereotypes and prejudice, this theory has the most current empirical support and is highly regarded by many ageism researchers.

### Internalization of Ageism

If a whole society is communicating to you that old age is bad, that it is something to be feared, that your cognitive and physical abilities are declining with every day, and that your worth to society is fairly low (because you are no longer working), you, as an older person, may start to believe it. This can have negative effects on self-concept and self-esteem and may even influence a person’s longevity. One study found that older adults who had more positive self-perceptions of aging lived an average of 7.5 years longer than those with a more negative view of their aging. Interestingly, research has shown that the self-esteem of older people is not affected by ageism in society and age stereotypes and prejudice. In fact, some studies have shown the self-esteem of older adults to be double that of those of high school age. Again, if older adults believe that the ageist behavior of others is not prejudicial, but rather is merely communicating a societal, commonly understood “truth” about older adults, then older adults may not perceive anything negative about their ageist treatment by younger people.

This is an important point to discuss in a bit more detail. Researchers have found utility in distinguishing between the “young-old” (ages 55–74) and the “old-old” (ages 75 and higher). Most of the negative stereotypes about aging and older people are derived from our perceptions of the old-old. These two groups of older adults react to ageist treatment very differently. In a recent survey of over 850 older adults, respondents were asked about their experiences with ageism and how it made them feel. The young-old noted several incidents of ageist behavior directed at them, and it made them very angry (because they do not think of themselves as “old”). The old-old, however, were either unwilling to admit they’d experienced ageism, or they just did not interpret that behavior as ageist (because, as mentioned earlier, they perceived it as reflecting a true state of affairs—they *were* dependent and they

were failing in their cognitive and physical abilities). If they did mention they experienced ageism, they said they were not bothered by it.

### Pervasiveness of Ageism

Research has found that ageism is so pervasive in society that even those who work in helping professions show ageist attitudes. In medical schools, little training has typically been devoted to gerontology or geriatrics, because it is not seen as an exciting field in which to specialize. Older people are viewed by some doctors as rigid, depressed, senile, or untreatable. Some doctors view treating older patients as futile or as a waste of time, because they are going to die soon anyway. Indeed, studies have shown that some doctors are less willing to pursue expensive treatments and aggressive procedures or therapies with older patients, and are more likely to order pain medication to stabilize them until they die. Other studies have shown that doctors regard the same disease (e.g., cancer) as a surprise and a tragedy in a 5-year-old but not in an older adult. Researchers have referred to this as “healthism.” Some mental health professionals may shy away from accepting older clients because they view older people as not really having serious problems, but rather as just feeling lonely and wanting to talk to someone. On a positive note, these biases in the medical and psychological professions are indeed changing as increasing attention is devoted to training doctors and psychologists in gerontology, in response to the growing demand for such training brought about by the retiring baby boomers.

At the extreme, malignant ageism can result in exploitation, neglect, or abuse of older adults, and even in violent behavior toward them that leads to their injury or death. Unfortunately, this type of abuse is on the rise, and it tends to be overlooked because (1) physicians have, until only fairly recently, been less acquainted with this form of abuse and (2) the elderly victim is too embarrassed or afraid to report it. Elder abuse is not restricted to the United States, as researchers have uncovered such abuse in Japan, Puerto Rico, and other cultures.

Though ageism is most prevalent in the United States (with exceptions such as traditional Hawaiians, who revere their elders) and other Western nations, other countries around the world are increasingly

becoming more ageist. Recent research suggests that as Eastern cultures become more industrialized, and more like the West—due to trade, tourism, and increasing global connectedness—they may tend to adopt more Western views of death, aging, and the role of the older person in society.

### Reducing Ageism

How then can ageism be reduced? From an early age, children must learn that getting older does not mean one will eventually be a witch or a bad or grumpy person (as most fairy tales suggest). Society needs to educate children, employers, policymakers, and health care professionals about the pervasiveness of ageism and how it has very real, harmful effects on older adults. Opportunities for older people to contribute to their community should be created, and contact between younger and older people should be encouraged. Older people should be regarded with respect. In so doing, society will enhance the quality of life for older adults and enhance intergenerational interactions.

## ALLPORT, GORDON (1897–1967)

---

Gordon Willard Allport is renowned for his work on the psychology of prejudice and his formulation

of the highly influential *contact hypothesis*. His work pioneered a focus on the cognitive antecedents of prejudice; it demonstrated how social psychological research can address important social issues and have a tangible impact on policy and practice. This entry looks at his life and works.

Allport was born in Montezuma, Indiana, in 1897. His father was a physician, and his mother was a former schoolteacher. When he was 6 years old, his family moved near Cleveland, Ohio, where he spent all his school years. Allport had three older brothers, one of whom, Floyd, was also a social psychologist and contributed to the establishment of modern experimental social psychology. Gordon Allport completed his bachelor's degree at Harvard in 1919, and he then spent a year teaching English and sociology at Robert College, in Istanbul, Turkey. Returning to Harvard, he was awarded a PhD in 1922; his doctoral dissertation was entitled "An Experimental Study of the Traits of Personality: With Special Reference to the Problem of Social Diagnosis."

Following completion of his PhD, Allport was awarded a fellowship to study in Europe. He spent one year in Berlin and Hamburg, Germany, where he was introduced to the Gestalt theory of mind. He then spent a year in England at Cambridge University before returning to United States and eventually becoming a faculty member of Harvard University from 1930 to his death in 1967. Allport also served as president of the American Psychological Association.

### Allport's Work

Opposed to the strictly one-sided psychoanalytic and behaviorist approaches to the study of personality, Allport emphasized the uniqueness of the individual and argued that problems need to be treated in terms of present circumstances instead of childhood experiences. His theoretical views on personality resulted in two books, *Personality: A Psychological Interpretation* (1937) and *Pattern and Growth in Personality* (1961). In *The Individual and His Religion* (1950), Allport discussed the development of religious attitudes and ideologies, as well as the relationship between religion and intergroup attitudes and behavior. This work led to what is perhaps Allport's most important contribution to social psychology.

### *The Nature of Prejudice*

Allport's 1954 book, *The Nature of Prejudice*, contains his most influential theoretical contribution to social psychology. Focusing on intergroup conflict and in particular on interracial relations in the United States, the book provides a broad perspective on defining, explaining, and reducing prejudice.

Allport was one of the first theorists to focus on the cognitive antecedents and processes that contribute to expressions of prejudice. He argued that stereotyping and categorization per se are functional aspects of people's thinking processes, but that when combined with social inequalities they can propagate biased attitudes and evaluations of others. Thus, through social comparison with outgroups, people locate themselves and their group in the world. Allport's analysis suggests that although the cognitive mechanisms involved in social categorization and stereotyping may sometimes lead to negative intergroup attitudes, this is not inevitably the case.

This led to the important observation that if more general psychological processes relating to categorization are involved in the formation of negative intergroup attitudes, then encouraging people to shift their conceptualizations of group membership from strictly defined criteria, such as race, to more inclusive categories, like common humanity, may weaken antagonistic relations and prejudice between ethnic groups.

### *The Contact Hypothesis*

A milestone theoretical contribution of *The Nature of Prejudice* was Allport's formulation of the *contact hypothesis*. Allport considered whether simply bringing together members of groups that differ in terms of race, religion, or national origin could reduce stereotyping and prejudice. He argued that, in many cases, contact on its own might not be sufficient to improve intergroup attitudes. Rather, there are prerequisite situational conditions that enable intergroup contact experiences to result in positive attitude change. The "four necessary conditions" Allport identified were equal status during contact, the existence of common goals, cooperation in achieving such goals, and institutional support (e.g., laws, authorities, customs).

Over the past 50 years, a great deal of research has been devoted to testing and amending the basic principles of the contact hypothesis, and contact is now one of the most widely used psychological interventions for reducing prejudice and improving intergroup relations. Much of this research initially focused on extending Allport's four key conditions for positive contact outcomes, leading some to suggest that the approach had too many such conditions to prove workable.

A recent meta-analysis conducted by Thomas Pettigrew and Linda Tropp directly addressed this criticism. The meta-analysis identified 515 studies conducted between 1949 and 2000 with 713 samples and a total of 38 participating nations. The result of this meta-analysis was a robust and statistically significant negative effect of contact on prejudice, an effect that remained even for contact that did not meet any of Allport's initial four conditions. Contemporary research on contact has, therefore, begun to examine other issues, including which *forms* of contact best reduce prejudice. For instance, researchers have found that a unique form of contact, cross-group friendship, is more effective at improving outgroup attitudes than less intimate forms of contact. They also have discovered that indirect forms of contact, where contact is experienced vicariously through others or through simply imagining a positive outgroup encounter, can have a positive effect on outgroup attitudes.

More than 50 years after the first publication of *The Nature of Prejudice*, its core ideas continue to inspire and guide scholars and policymakers focused on the assessment, explanation, and attenuation of prejudice, and this is Allport's enduring legacy.

## AMBIVALENT SEXISM

---

*Ambivalent sexism*, a subtle but effective method of keeping the gender equality gap from shrinking, contains two complementary belief systems about women that have the contrasting valences of subjective benevolence and hostility. Benevolent sexism masks the more overt hostile sexism by giving seemingly caring reasons for discriminatory behaviors toward women. Thus, ambivalent sexism can be a difficult prejudice to root out.

Historical conceptions of sexism assume the hostile belief that women are inferior to men and unfit for positions of leadership, especially those involving power over men. In this view, women who adhere to traditional roles are undervalued and viewed with contempt, while those who challenge such ascribed codes of behavior are resented as overstepping natural and cultural boundaries. While this notion of sexism has prevailed for a long period of time, a more recent conceptualization reveals that traditional beliefs about women may be more complicated than previously assumed.

Rather than depicting women in only openly hostile ways, more recent depictions show that most people (both men and women alike) tend to hold dual conceptions about women: benevolent and hostile sexism. Acting together, these aspects of ambivalent sexism reward women for avoiding situations that make them seem nonfeminine and for choosing situations that make them seem feminine. Or, as Glick and Fiske have described, the two components act as “carrot and stick” to encourage women to “remain in their place.” Women receive rewards (i.e., the carrot) when they follow the rules, but are punished (i.e., receive the stick) when they do not.

### Components

Hostile sexism is the belief that women are by nature inferior and thus unfit for and incapable of

holding positions of authority, especially over men. Hostile sexists tend to see a power struggle between the sexes and express resentment of women for manipulating men—whether by bludgeoning men with “feminist demands” or controlling men through sexual seduction. Accordingly, hostile sexists (both men and women) may experience anger toward “feminist” women who challenge prescribed gender roles and/or shirk “their moral and biological duty” of acting as a subordinate to a presumably stronger male counterpart. Because laws, organizational policies, and norms of social desirability often serve to protect women, expressions of hostile sexism may have diminished in recent years.

Benevolent sexism also works against the promotion of women as equals, but in a very different way. This construct idealizes women as mothers, wives, and caregivers. In addition, benevolent sexism assumes that women both have a purity that men do not and also need protection, as they are too weak and good to defend themselves against those who might otherwise do them wrong. Rather than lowering the status of women by directly characterizing them as less competent, benevolent sexism subtly reinforces the idea that women are more fragile and should be protected and provided for by men. In return, women are expected to confine themselves to a social sphere in which they can nurture the next generation, serve as counterparts to their adoring husbands, and create comfortable homes.

Hostile and benevolent sexism work to balance each other and together function (more effectively than hostility would alone) to relegate women to a second-class status. Benevolent sexism may be more palatable to most people (especially women) than hostile sexism because it appears to reflect good intentions rather than antagonism. That is, women who allow themselves to be patronized reap some benefits and earn the adoration of their male protectors, while women who do not conform to the model are subjected to the negative consequences provided by hostile sexism, including censure, hate, and resentment.

### Sources

Three structural foundations underlie ambivalent sexist beliefs. The first is acceptance of a patriarchal

system. Benevolent sexism is patronizing care taken of someone assumed to be unable to make decisions or act as an independent adult; it is related to paternalism and the presumed benevolent authority parents exercise over their children. This implicitly treats women as children, advocating that men be guardians of women’s minds and bodies, exerting a protective influence over women because of their alleged vulnerability. In a complementary fashion, hostile sexism reinforces patriarchal assumptions that men should be in charge. However, hostile sexism more directly asserts women’s presumed inferiority (e.g., viewing them as too emotional to lead).

A second component reflects biological and social gender differentiation. Men’s physical power is often equated with social power. Sex is a fundamental biological and social category that tends to foster sharp social distinctions in most societies (e.g., gender stereotypes), forming the basis for a division of labor. Women (due to their greater biological ties to reproduction) are associated with nurturing and domestic life, whereas men are associated with more powerful societal roles and leadership positions. These roles reinforce both benevolent sexism (e.g., viewing women as warm and expressive—traits linked to the nurturing role) and hostile sexism (e.g., viewing women as less competent because they less often occupy leadership roles).

A third component of ambivalent sexism is heterosexuality, the premise that both sexes need a heterosexual romantic relationship to be fulfilled. Sexuality affords women a dual role. On one hand, women may be viewed as good wives and mothers, or agents and targets of intimacy and affection (i.e., benevolence). On the other hand, women may be viewed as seductresses, using their sexual power to take control over men and attempting to emasculate them (i.e., hostile). The presumption that women use sex as a tool by which to control men elicits hostile resentment and attitudes that sexually demean women. However, because sex is rewarding and fosters emotional intimacy, subjectively benevolent views romanticize women (e.g., as fair and pure princesses). Thus, ambivalent sexism encourages polarized categorizations of some women as “sluts” and others as “angels.”

### Measuring Ambivalent Sexism

The most commonly used measure of ambivalent sexism is the Ambivalent Sexism Inventory, which separately assesses each component of sexism. The measure was created by Glick and Fiske in 1996, and since then it has been widely validated in more than 25 countries (e.g., the U.S., Turkey, Brazil, the Netherlands) with samples ranging from 200 to 2,000. The measure goes beyond previous boundaries by examining sexism as more than the traditional, hostility-based view in which sexist behaviors are solely motivated by a dislike of women. Thus, an example of benevolent sexism is: "Many women have a quality of purity that few men possess." And an example of hostile sexism is: "Women seek to gain power by getting control over men." The ambivalent nature of sexism can be seen in the duality of women's roles expressed here. Women are described as both pure beings and power-hungry creatures.

Research using the measure has shown that the constructs of benevolent sexism and hostile sexism are positively correlated with each other (correlations range across samples from .37 to .74), and tend to be more highly correlated in women than in men. Hostile sexism is also correlated with other measures, such as "protestant work ethic" and "social dominance," while benevolent sexism has been correlated with "right wing authoritarianism." When hostile sexism is statistically controlled, benevolent sexism is often no longer a significant predictor for constructs like modern sexism or traditional sexism. Such an effect may be taken as further evidence that benevolent sexism is a unique construct that gives sexist behaviors a protectionist aura. In these studies, men tend to score higher than women on the hostile components of sexism, but there are rarely gender differences on the benevolent sexism component, with both groups at least partially endorsing this behavior.

### Consequences

The consequences of ambivalent sexism can be severe. As with most forms of subtle discrimination, the slow buildup of unfair treatment over time exacerbates the impact of any one sexist interaction. Any belief system that systematically keeps one group from living and working at its full

potential limits everyone in society. When women are forced out of the workforce by prejudice, beaten in their homes for expressing ideas contrary to those of their husbands, and treated as second-class citizens on the basis of gender, an environment is created where neither women nor men can thrive. While the process of change involves a cultural shift in attitudes toward women, recognizing the consequences of sexist behavior is an important first step in achieving equality. Ambivalent sexism complicates the prospects for exposing the negative effects of sexism because of its subjectively positive component, which leads many people to view sexism as not as bad as other forms of prejudice. Specifically, women are more accepting of benevolent sexism (due to its apparent favorability toward women) and, in turn, are more willing to accept hostile sexism because it is "softened" by benevolent sexism.

## ANTICONFORMITY

---

*Anticonformity* refers to behavior that is deliberately designed to go against the position advocated by one or more others. Also known as *counterformity*, anticonformity most typically occurs in group settings when an individual rebels against the dominant or majority opinion. It conjures up the image of the maverick or deviant who purposefully disagrees publicly with the positions of others in the group, even when he or she agrees privately with these same positions.

Anticonformity stands in contrast to two other important types of response to social pressure:

conformity and independence. Conformity and anticonformity are essentially opposites. Whereas with *conformity*, an individual is motivated to cooperate, follow, and fit in with the group, with anticonformity, he or she is motivated to disagree with, disrupt, and oppose the group. In research settings, conformity is usually measured by movement toward the majority opinion, and anticonformity by movement away from it. Independence can look like anticonformity, but its motives are different. With *independence*, the goal is simply to be true to one's self, regardless of how one's views might be received by others. The term *non-conformity* encompasses both anticonformity and independence.

A real-life example of anticonformity was widely reported in the American media during the Christmas season in 1994. A man from Little Rock, Arkansas, was served with a court injunction, raised at the behest of his neighbors, ordering him to remove some of the over 3 million lights from the Christmas display at his home. The display was attracting too many sightseers and too much traffic to his exclusive residential neighborhood for his neighbors' liking. The man could have conformed to his neighbors by removing some of his lights. He could have shown independence by neither adding nor removing any lights. Instead, the man chose to anticonform. Soon after the injunction was served, he defied it by increasing the number of lights in his display. This entry examines the origins of anticonformity, describes some theories, and offers a few examples.

### Background and History

In 1957, British psychologist Michael Argyle published what was probably the first study to demonstrate anticonformity under controlled conditions. Argyle asked male students to evaluate a painting by Marc Chagall, *Poète Allongé*, which was chosen deliberately because of its "unusual and ambiguous character." Participants were told that they were working with a student partner, when in fact their partner was Argyle's confederate. In one condition, each student learned that his opinion of the painting had been rejected by his partner (e.g., "What you say is trivial, for the picture is so meaningful as a whole"). Participants were then given an opportunity to rate the painting a second time,

and social influence was measured by the change in participants' ratings toward or away from the rating given by the "partner." Argyle found that most participants, 58%, were uninfluenced by their partner; they showed independence by sticking with their original opinion. Another 35% showed conformity by moving toward the partner's position. The remaining 8% of participants, however, showed anticonformity; they became even more extreme in their disagreement with their partner.

In the early 1960s, Richard Crutchfield and Richard Willis published the earliest theoretical work on the distinction between anticonformity, conformity, and independence. Working independently, both proposed that although anticonformity and conformity are opposites in terms of underlying motives and measurement, they are, ironically, quite similar conceptually in that both are determined by the group's position. Thus, both are properly regarded as forms of *dependent* behavior. Both stand in contrast to independence, therefore, where the individual is not influenced one way or the other by social forces. Crutchfield and Willis concluded that anticonformity, conformity, and independence should not be conceptualized and measured merely by different degrees of positive or negative movement along a single-dimension line segment, the standard practice of Argyle and other early researchers. Rather, the three responses should be seen as falling at the vertices of a triangle.

### Theories of Anticonformity

Social scientists have proposed a number of motives that attempt to explain why anticonformity may occur in certain situations. One motive, first formally identified by Jack Brehm, is known as *psychological reactance*. It is based on an individual's perceived rights and freedoms. When people are members of a group, they can come to believe that their rights as individuals are being eliminated or threatened with elimination. Under such conditions, Brehm proposed, people may react by taking steps to restore their freedom.

One clear way to reclaim a freedom is to do the *opposite* of what the source of the threat suggests; that is, to anticonform. So if people in a neighborhood group say to one of their members, "Surely,

you must agree with us that we have too much traffic at night in our neighborhood. You need to take down some of your Christmas lights,” the target individual might respond in words or deeds, “Who gave you the right to tell me what to do on my own property? Actually, I think my display would benefit by adding even more lights.” Another example of anticonformity consistent with reactance motivation is known as the *Romeo and Juliet effect*. As in Shakespeare’s tragic drama, attempts by parents in Western cultures to restrict their teenagers’ freedom to date may backfire, leading to increased dating.

Other recognized motives for anticonformity include the desires to (a) promote change and innovation; (b) establish or project one’s individuality or uniqueness; (c) avoid bad group decisions (i.e., *groupthink*); (d) avoid the appearance of sycophancy; (e) disconfirm another’s negative expectations regarding one’s skills, attributes, or abilities; and (f) distance oneself or group from dissimilar, disliked, or unattractive others.

An example of this distancing occurred in the 1930s following the rise of Nazism. Prior to World War II, a type of swastika had been the official insignia of the U.S. Army’s 45th Infantry Division. The swastika of the 45th was chosen initially because it had been an ancient cosmic and religious symbol in many cultures (e.g., Navajo Indian culture). After a mirror-image swastika was adopted by Hitler and the Nazis in 1935, however, ranking officers in the 45th Division felt obliged to change their insignia in order to dissociate the 45th from anything related to Nazism. The division’s swastika was replaced in 1939 by a thunderbird.

### Anticonformity by Overconformity

Another probable example of anticonformity based on disassociation from the Nazis was demonstrated by Freud following the Nazi annexation of Austria in 1938. According to a biographer, the 82-year-old Freud was allowed to emigrate to England, but only after he had signed an affidavit stating that he had been under no pressure from Nazi authorities. After signing, Freud offered to add “I can recommend the Gestapo to anyone,” but his offer was turned down. Given that the intent of Freud’s offer was to register his disagreement with

and opposition to the Nazis, in perhaps the only way available to him under the circumstances, his offer reflects anticonformity.

This example is important because it illustrates that although anticonformity is usually measured by movement away from a group’s position, it can sometimes be indicated, ironically, by movement toward the group, provided that such movement is excessive. This brand of anticonformity was first identified by Willis and dubbed *overconformity*.

### The Anticonformist

Anticonformity refers to a type of behavior. Yet, a person who consistently engages in anticonformity across time and settings can be regarded as a type of person—the anticonformist. Most evidence supporting the existence of anticonformists is anecdotal. Nevertheless, there have been a few systematic attempts to identify the characteristics and etiology of anticonformists. One provocative account was offered by historian of science, Frank Sulloway. Based on archival records, Sulloway found significant evidence that innovators, iconoclasts, and rebels in the history of science, religion, and politics tend to be later-borns.

To explain these findings, Sulloway proposed that because of firstborns’ typical role as surrogate parents, and through the normal process of sibling competition for parental attention, firstborns generally identify with their parents. Firstborns, therefore, are predisposed to conformity and conventionality. Later-born children, in contrast, are outsiders to an established group from birth—their parents and older siblings. Thus, they are primed to rebel against the establishment, particularly against the seemingly arbitrary authority that is typically exerted over them by elder siblings, and hence tend toward anticonformity.

The primary force that drives change in history, therefore, is not located between families divided by social class, as Marx proposed. Rather, Sulloway argued, it is located within families divided by birth order, a function of small-group dynamics.

## ANTI-SEMITISM

---

*Anti-Semitism* is prejudice toward Jews and Jewish culture. From a social psychological perspective, it is a devaluation of the group of Jews and their culture or a devaluation of a Jewish person, because she or he is a member of the social category. A common definition refers to anti-Semitism as hostile beliefs—expressed by attitudes, myths, ideology, folklore and imagery, discrimination, and violence—which destroy the worth of Jews and Jewish culture. In its most comprehensive sense, it is hostility toward Jews as “Jews,” and thus an expression of devaluation and of inequality between groups. Anti-Semitism is expressed by individuals, groups, or institutions against Jewish people, groups, or culture through the categorization of Jews as negatively different or Jewish culture as strange. Jews are seen not as individuals but as a collective that brings problems to a community, often in a secret way.

The group-focused nature of anti-Semitism links it to other expressions of prejudice, such as anti-immigrant prejudice, prejudice against Muslims, and sexism, all within a syndrome of group-focused enmity. The special importance of anti-Semitism is derived from two features. First, anti-Semitism has occurred worldwide for centuries. Second, its most destructive expression has been reflected in persecution: the German Crusade

of 1096, the expulsion of Jews from England in 1290, the Spanish Inquisition, the expulsion from Spain in 1492 and from Portugal in 1497, and the Holocaust of Nazi Germany.

Anti-Semitism seems to be prototypical of a number of prejudices. It encompasses nearly every aspect of prejudice toward an outgroup. Anti-Semitism has many individual-level facets, ranging from subtle anti-Semitic stereotyping and antipathies to blatant expressions of anti-Semitic racism and discrimination. In many societies, the collective memory has retained anti-Semitic racial stereotypes (Jewish character or appearance), religious stereotypes (Anti-Christ), secular stereotypes (profiteer), and political anti-Semitic stereotypes (Jewish conspiracy). Some modern expressions of anti-Semitism, which have been a subject of controversy since the 1990s, are Islamist anti-Semitism and a critique of Israeli policies that is fed by anti-Semitic prejudices.

### Psychological Foundations

Stereotypes and images of the “collective Jew” are very persistent. Cultures transport and transfer anti-Semitic stereotypes and myths through social representations that are part of the collective memory. The social psychology of anti-Semitism focuses on individual causes within social contexts, reaching from prejudices to genocide.

Early psychodynamic approaches attribute its causes to intrapsychic crises and conflicts, resulting, for example, from feelings of guilt or infirm ego strengths. The Frankfurt School’s project on the authoritarian personality by Theodore Adorno and his colleagues had a particularly significant influence on research on anti-Semitism. This personality approach refers to psychodynamic processes and explains anti-Semitism by reference to the individual trait of an authoritarian personality, which is developed through punitive socialization and characterized by obedience. The researchers believed that this personality primes individuals to be persuaded by propaganda and anti-Semitism. Several studies have shown that authoritarianism predicts anti-Semitism. Current studies also demonstrate that dominance-orientated people are prone to be anti-Semitic. Social dominance theory criticizes the psychodynamic approach of the Frankfurt School. Authoritarianism is a pathological condition that

does not explain institutional behavior and ideological processes in society. Prejudices are legitimizing ideologies for social hierarchies between groups within a society, and people who are high in social dominance orientation are motivated to keep groups like Jews in lower status positions.

The social identity approach taken by Henri Tajfel and his colleagues gives a clearer picture of the link between individual and contextual causes of prejudices. From this perspective, anti-Semitism is explained as a group-focused devaluation in the context of intergroup relations. The social-cognitive categorization of Jews and Jewish culture as an outgroup is thought to be responsible for the development of some anti-Semitic sentiments. Primary reference groups (ingroups), which define the social identity of an individual group member, communicate anti-Semitism. Members of an ingroup differentiate themselves from Jews and Jewish culture and demand conformity to the ingroup's norms and ideologies. The ingroup's social-cognitive characterization of Jews as an outgroup is thought to be responsible for the development of anti-Semitic beliefs and attitudes. Anti-Semitic sentiments in extremist groups clearly show this dynamic, but it can also be detected in anti-Semitism of peer groups or familial socialization.

The satisfaction of several overlapping needs and motives by anti-Semitism is linked to its group-focused nature. Five such needs and motives are:

1. Anti-Semitism functions to reinforce self-esteem derived from group membership. Anti-Semitism can strengthen social identities, such as those defined by the ideology of a homogeneous nation. Difference and differentiation can have a detrimental effect on self-esteem through social identity processes, and may trigger prejudices—especially if social identities are felt to be threatened. Anti-Semitic stereotypes of Jewish conspiracies keep such threats alive.
2. Anti-Semitism fulfills the function of legitimizing devaluation of those who compete or are perceived to compete with the ingroup, contributing to the suppression of outgroups and the superiority of the ingroup. Racist images of Jews serve this function.
3. Anti-Semitism can bind individuals to groups and their opinions. Anti-Semitism links people

to a “group of regulars.” People gain recognition by others through expressing the normatively “correct” opinion of the group.

4. Anti-Semitism fulfills a knowledge function. It explains what is going on, and why things happen. For example, a belief in Jewish conspiracy explains why some groups suffer. Myths about the Zionist threat and the conspiracy of Judaism that wants to rule the world are extreme examples. These functions are fed by anti-Semitic stereotypes, which bind these beliefs together and relate them to other prejudices.
5. Anti-Semitism may alleviate feelings of guilt about matters of historical fact. An often-reported expression of anti-Semitic sentiments is blaming the victims.

In addition to such cultural and individual causes, several other contextual factors permit or promote anti-Semitism. Studies show that stereotypical media presentations of Jews and Jewish culture over time, a denial of collective anti-Semitism by political and cultural elites, and lack of contact and experiences with Jews and Jewish culture also are critical causes of anti-Semitism. The power of the old anti-Semitism can be evoked by those who rely on threats to groups and sentiments that can be linked to stereotypes kept in the historical memory. Studies in Europe show that anti-Semitism is a regular part of right wing populism, together with xenophobia and authoritarian orientations. These attitudes are especially exerted by populists who make use of freedom of speech and rely on the assumption that the majority feels and thinks the same way. Right wing populists frequently challenge and break laws against anti-Semitism, and anti-Semitic racism is a core element of right wing extremism. However, groups and individuals who are aware of the norm against anti-Semitism also sometimes fall back on anti-Semitic stereotypes, for example, in the manner in which they criticize Israeli policies.

### New Anti-Semitism

Current research on anti-Semitism is characterized, in particular, by controversies about the difference between the old and new forms of anti-Semitism.

The old or classical anti-Semitism is an overt devaluation of Jews that refers to negative, racist stereotypes (e.g., racist images or stereotypes associated with the Anti-Christ or Devil) and is often tabooed and outlawed. The new anti-Semitism is based on traditional anti-Semitic stereotypes that are expressed in claims about current societal events such as a worldwide Jewish conspiracy or Israeli terror, which is interpreted to be Jewish. For example, the new anti-Semitism is represented by a specific Islamist, anti-Zionist anti-Semitism founded on myths of conspiracy. Several studies show that since 2000 (the Second Intifada), anti-Semitism has been on the increase in Muslim communities. Large parts of this Islamist anti-Semitism are being justified by claims that Muslims are victims of Israeli policies, which are represented and mythologized as Jewish. Another facet of the new anti-Semitism is the “secondary anti-Semitism,” occurring in Germany and other European countries, that involves denying historical anti-Semitic events, such as the genocide at Auschwitz, and demanding a *Schlussstrich* (“final closure”) to the history of the Holocaust. Other facets of the new anti-Semitism are the positions that Jews benefited from exploiting their suffering during the Holocaust and that other communities suffered more from World War II than the Jews did. These arguments entail denying the persecution of the Jews and their status as victims. Polls show that this secondary anti-Semitism is increasingly spreading into the mainstream of many civil societies.

Often anti-Semitism is hidden by a critique of Israel. This new expression of anti-Semitism is found in right wing populism, Islamist propaganda, and sometimes left wing ideologies. Israeli policies against Palestinians are sometimes defined as “Jewish” and are thus attributed to religious rather than nationalistic causes. This anti-Semitic critique is linked to two other themes: first, a comparison of Israeli policies to the crimes of the Nazis in the Third Reich; and second, a separatist ideology categorizing Jews as a strange community that is not part of society. A topic causing serious disputes and ideological debate is the question of which criticisms of Israeli politics represent anti-Semitism. For example, some argue that any criticism of Israel represents anti-Semitism, whereas others claim that virtually no criticism of Israel has anti-Semitic roots.

The German study group on “group-focused enmity” proposes that the presence of one or more of the following four criteria indicates that a criticism of Israel may be considered anti-Semitic:

1. The denial of the right of Israel to exist and the right of its self-defense (i.e., anti-Zionism);
2. a historical comparison between Israeli policy concerning Palestine and the persecution of Jews in Nazi Germany;
3. the evaluation of Israeli policy with double standards (i.e., political measures are criticized in Israel but not in other countries); and
4. the transference of anti-Semitic stereotypes to Israel and, in turn, the transformation of Israel into the myth of “the collective Jew.”

If criticism of Israel does not meet any of these criteria, it is not considered anti-Semitic. Criticism of Israeli policies in Palestine is possible without anti-Semitic sentiment, but analyses show that it seems to be very difficult to criticize Israel without referring to one of these components of anti-Semitism.

### Implications

The group-focused enmity criteria mentioned earlier give a basis for detecting new expressions of anti-Semitism from a nonideological point of view. Unfortunately, the discourse on anti-Semitism has always been charged by ideological positions. This partly explains why current surveys show that it is difficult for people to speak about Jews and Jewish culture without referring to stereotypes. In many societies, such anti-Jewish sentiments are misused for propaganda. In Europe, anti-Semitism has become a critical part of right wing populism.

Additional elements tied to anti-Semitism are anti-immigrant prejudices and authoritarian orientations, which are often precursors of attacks on Jews, synagogues, and Jewish schools. In many European cities, Jewish buildings still have to be protected by police. Also, innumerable efforts are being made to combat traditional and modern anti-Semitism. Above all, programs focus on the education of schoolchildren and young adults, but anti-Semitism is still prevalent among elderly people. However,

although many organizations and countries support campaigns against anti-Semitism, evidence about the effectiveness of these approaches is rare. Social psychological research offers evidence showing that actions that promote positive intergroup contacts and self-esteem, lower intergroup threats, and strengthen empathy and perspective taking can reduce prejudices like anti-Semitism. However, evidence is needed to establish the effectiveness of such interventions specifically with anti-Semitism. In addition to analysis of interventionist approaches, more substantive research on other aspects of anti-Semitism is needed. Although many scientists agree that anti-Semitism still exists and poses a severe threat to democracy, some fundamental questions have to be answered. For example, rising anti-Semitism in Eastern Europe has to be explained more exactly. The rise and dissemination of anti-Semitic stereotypes, anti-Semitism in elderly people, Islamist anti-Semitism, the anti-Semitism of elites, and many more phenomena need to be understood. And over and over again, we have to explain the unexplainable: Auschwitz.

## APARTHEID

---

*Apartheid* is an Afrikaner word that means “separateness” or “apartness.” It represents a cluster of policies that were designed to achieve “total separation” between races in South Africa, the effect of which was to preserve the economic and political privilege of the White minority. The application of apartheid led to a vast program of social engineering that lent constitutional legitimacy to the subjugation of the non-White majority. In this entry, the theory, practice, demise, and legacy of apartheid will be discussed, with a focus on its effects on intergroup thoughts, feelings, and behaviors.

### Historical and Theoretical Context

Apartheid in South Africa cannot be understood without being placed in its historical context. For centuries, descendants of the Dutch settlers (the Afrikaners) coexisted uneasily with native African tribes who were being displaced by Afrikaner territorial expansion. Afrikaners also found themselves increasingly in competition with the British, who began to assume political and economic control of much of southern Africa. The tension between the two imperial forces reached a head during the Boer Wars, which entrenched British influence and extinguished the political independence of the Afrikaner republics. The period after this defeat was marked by the growth of a distinct Afrikaner identity, which gradually reasserted itself culturally, linguistically, and politically under British rule.

As South Africa became increasingly urbanized, Afrikaners began drifting into the cities, where they perceived themselves to be the victims of British racism and cultural imperialism. A new class of urban Afrikaner poor emerged that had to compete with cheap labor from Black migrants. Traditional racial hierarchies were realigning around class, and many poor White Afrikaners found their traditional privileges to be under threat. The fear was that British capitalist imperialism would result in Afrikaners being “lumped together” with other minority ethnic groups and afforded the same kind of

second-class citizenship that Black, Colored, and Indian South Africans had received. Political sympathies began drifting toward segregationists, who worked to revive the fortunes of the Afrikaners relative to the British colonizers and the ethnic minorities.

The policy that became known as apartheid was designed to entrench Afrikaner power relative to these two traditional threats. The model for race relations in South Africa (and many other nations) in the early 20th century was a British imperialist model, in which Blacks and Whites were geographically segregated within a single polity. Whites ruled over Blacks politically, and Blacks were expected to assimilate to White culture in order to become competitive within the socioeconomic system.

Apartheid theorists in the 1940s argued that this horizontal system of White supremacy was unsustainable because it would breed frustration, violence, and rebellion from the ethnic minorities. Under apartheid, Afrikaners, Anglos, Coloreds, and various Black tribes would be given separate homelands, which would coexist within the nation of South Africa. By giving each ethnic group its own political and cultural space, it was argued that racial conflict would be reduced because each ethnic group would be free to develop its own political and cultural identity independent of the others.

As an intellectual abstraction, apartheid is consistent with “dual identity” models of intergroup relations, whereby subcultures are encouraged to foster a distinct identity while at the same time embracing what they share at the superordinate (national) level. Indeed, much of the rhetoric that was used to promote apartheid focused on its potential to liberate Afrikaners from British domination and to reduce interracial conflict.

In reality, though, the implementation of apartheid reinforced the type of horizontal White supremacy it defined itself against. Rather than reducing racial conflict, it dramatically deepened inequities between White and Black South Africans, and intensified the frustration, violence, and rebellion that it was designed to diminish. Rather than allowing for subcultures to flourish, apartheid became an intellectual masquerade that allowed both Afrikaners and British descendents to maintain their traditional racial privilege.

### How It Worked

In practice, the policy of apartheid comprised two separate programs: “grand apartheid” and “petty apartheid.” Grand apartheid involved an ambitious and brutal process of social engineering. Black immigration into White areas was halted, and many Black migrants considered “surplus” to economic requirements were deported to “homelands.” Mass relocations of ethnic minorities in South Africa resulted in hundreds of thousands of people being forcibly removed from their homes. The “homelands” offered Blacks were disproportionately small and arid.

Slums that had grown up after World War II were demolished and replaced with “townships,” where Blacks had no permanent property rights. Many of the townships were placed just inside Black homeland borders, and White-run industrial plants were relocated just outside the borders. This was designed to encourage Blacks to migrate to the homelands, at the same time as offering South African industrialists access to “foreign” labor that was not entitled to the same rights offered to those in Afrikaner areas.

Services for Black people were boosted in the Black homelands but dramatically cut in “White areas,” a strategy designed to coax Blacks to settle in the Black homelands. This epic program of relocation required that Blacks be under close surveillance and that their movements be closely regulated. Black workers needed permits to leave the homelands to seek work and to live in Black townships: Hundreds of thousands of Blacks were imprisoned for not having a pass or for traveling to a place without permission. Institutions were manipulated to prevent the desegregation of the races. For example, school curricula were redesigned to actively discourage economic assimilation of Blacks. Interracial marriage and even sexual relations between races were prohibited by law.

Those Black and Colored South Africans who remained in White areas were segregated from the White population. This policy—known as petty apartheid—involved racial segregation of services and facilities such as parks, public transportation, and restaurants. The policy was essentially a formalized version of the segregation policies that existed in many countries in the early- to mid-20th

century, such as those used in the United States during the Jim Crow era. “Grand apartheid” was the most dramatic and distinctive manifestation of the policy of total separation, but for outsiders, it was “petty apartheid” that came to symbolize the injustices of South African race relations. Although the complexities of grand apartheid were difficult to capture and communicate to international audiences, the “White only” signs associated with petty apartheid provided images that pricked the consciences of liberal Whites around the world.

South Africa’s policy of institutionalized segregation (masquerading as the defense of cultural identity) emerged at about the same time that racist practices were being actively contested and overthrown in many parts of the Western world. As a result, South African apartheid became a high-profile cause among international activists who campaigned for civil liberties and the dismantling of institutionalized racism.

### Opposition and Demise

For Black South Africans, the introduction of apartheid resulted in economic marginalization, disempowerment, humiliation, and organized resistance. Intellectuals such as Steve Biko drew inspiration from the Black Power movement in the United States and worked to develop Black pride and nonviolent opposition to apartheid in Black South Africans. Advocates of Black consciousness reinforced the notion that Blacks must stop their psychological subservience to and economic dependency on Whites, and that Blacks should ultimately rule South Africa. The psychological transformation was buttressed by a military operation, largely coordinated by the African National Congress (ANC). Led by Nelson Mandela, the ANC coordinated underground cells of militia who carried out sabotage attacks and assassinations.

In response, White South Africa was galvanized in their antipathy toward what they perceived to be agents of terrorism and communism. An army of police, intelligence agents, and conscripts was built up to crush resistance. A covert civil war developed between Black militias and the Broederbond, a secretive society of pro-Afrikaner advocates who engaged in their own military resistance with the blessing of the South African government.

From the mid-1970s, a number of insurrections broke out in poor Black townships. These expressions of people power were often poorly organized and easily crushed. But images of Black protest and heavy-handed attempts by police to quell the revolts increased pressure on the international community to coerce South Africa into reform. In the 1970s, economic sanctions and sporting boycotts turned South Africa into a pariah state. A gulf developed between mainstream Whites within and outside South Africa. To outsiders, apartheid was illegitimate, irredeemable, and morally repugnant. In contrast, many Afrikaners perceived themselves to be a misunderstood last line of defense against chaos, communism, terrorism, and godlessness. The apartheid debate became severely polarized within and outside South Africa.

In the 1980s, the energies of the ANC gradually moved from armed resistance to collective protest and mobilization. South Africa experienced an unprecedented wave of marches, riots, and boycotts, this time with significant support from Indian South Africans and international media and activists. In the face of social and economic decline, the National Party diluted some of the more interventionist aspects of apartheid, before formally negotiating ways to resolve the 40-year conflict. In 1994, multiracial elections were held for the first time, and Mandela became the first Black president of South Africa.

Since then, apartheid has been morally and intellectually discredited within South Africa as well as outside it. Morally, it is considered indisputable that governments need to protect the rights of all its citizens, not just those of racial elites. The intellectual case for apartheid has been dismantled by social psychological work on the *contact hypothesis*, which argues that intergroup relations are best managed when members of different cultures are allowed to interact with equal status, and with support from norms and institutional authorities that protect against racism. Today, the term *apartheid* lives on as a metaphor that is occasionally invoked to describe and condemn any policy that is seen to segregate and promote inequities between social groups.

## ASCH, SOLOMON (1907–1996)

---

Solomon Asch was born in 1907 in Warsaw, Poland, and emigrated in 1920 to the United States. He remains one of the most influential social psychologists of the 20th century. His research on *impression formation* and *social influence* constituted innovations that revolutionized the field of social psychology. The questions he sought to answer, namely how people form impressions of others and when they are influenced by others, continue to inspire research to this day.

His ideas about impression formation and social influence, borrowed from the domain of vision, are examined in this entry and illustrated with some of his most famous experiments. The importance of his work for the subfield of group processes and the more general field of social psychology is also discussed.

### Impression Formation

Asch's research was based on German Gestalt theory, which can be translated as the theory of the "whole." According to Gestalt theory, when we see a face, we do not first perceive one eye, then the other eye, then the mouth, and so on. Instead, we immediately see the entire face (a gestalt), and this face is more than the sum of its parts (e.g., if an eye and the mouth changed places, we would perceive a very different face).

Asch was not the first psychologist to be interested in how people perceive others, but his approach was radically different from that of previous researchers. Earlier scholars were interested primarily in perceptual accuracy—whether people could accurately guess the personalities of other individuals, whereas Asch was more interested in process—in learning *how* people form impressions of others. He conducted research designed to answer three questions about impression formation, which were derived from Gestalt theory. First, when people receive items of information about an individual, do they form a coherent and unified impression of that individual? Second, do some items of information organize the overall impression? And third, do early items influence how later items are interpreted?

### Fundamental Questions

To answer his first question, Asch gave participants the following list of traits characterizing a fictitious "person X": *intelligent, a hard-worker, skillful, warm, determined, practical, and cautious*. Participants then wrote a sketch of person X and answered questions about other characteristics (e.g., *generous, friendly*) of that person. Asch found that participants formed a coherent and positive impression of person X based on the traits they were given.

To answer his second question, Asch gave participants another list of traits with a single change: *warm* was replaced by *cold*. This time participants formed a negative impression of person X. When Asch replaced the traits *warm* and *cold* with *blunt* and *polite*, nothing happened. Thus, in regard to his second question, Asch found that certain traits (*warm* and *cold*) were central for organizing participants' impressions of person X, whereas other traits (*blunt* and *polite*) were not.

To answer his third question, Asch gave participants one of two lists in which the order of the traits was reversed (either *intelligent, hard-worker, impulsive, critical, envious* or *envious, critical, impulsive, hard-worker, intelligent*). He found that participants' impressions of person X were more favorable when they received the first list than the second, revealing a primacy effect in which early traits in the list guided participants' interpretation

of later traits (e.g., *impulsive* may be understood to mean spontaneous in the first list and aggressive in the second list).

### *Explaining Attitudes*

The results Asch obtained suggest that people have implicit theories about others. For instance, we may believe that if someone is warm, then he or she is also generous. Such implicit theories may help to explain certain stereotypes. For example, we may believe that if X is a gypsy, then he or she is also a musician. Asch's theory-driven approach to impression formation did not go unchallenged. For example, Norman Anderson argued that when forming an overall impression of an individual, people use a data-driven approach in which they evaluate each trait associated with the individual (*intelligent, hardworking, etc.*) and then combine (e.g., through adding or averaging) these evaluations.

The controversy between theory-driven and data-driven impression formation went on for some years, but was finally resolved by Susan Fiske and Steven Neuberg in 1990. According to these scholars, people's first tendency is to place others into a familiar category (e.g., French). If the categorization does not fit the evidence, and if people are motivated to obtain a better fit and have the cognitive capacity (and time) to do so, they will go through additional steps. First, they will try to confirm their initial categorization. If this fails, they will try to recategorize the person in a way that makes sense of most of his or her characteristics. Finally, if this fails, they will default to "piecemeal integration," which involves simply adding or averaging all of the person's characteristics.

### **Social Influence**

Social influence is another domain in which Asch had an indelible impact. Imagine a sentence asserting that a little rebellion now and then is a good thing and is as necessary in the political world as storms are in the physical world. In addition, imagine that this sentence is attributed either to U.S. President Thomas Jefferson (the real author) or to Vladimir Lenin, one of the leaders of the Communist Revolution in Russia. Not surprisingly, Asch found that participants in the United

States were more likely to agree with the sentence when it was attributed to Jefferson than to Lenin. One could interpret this result as evidence that admiration for Jefferson generalized to the sentence when it was attributed to him, whereas disdain for Lenin generalized to the (same) sentence when it was attributed to him.

This is not the best explanation for what Asch found, however. Rather than terminating his study after participants expressed their level of agreement with the sentence, Asch also asked them the meaning of the sentence. He found that this meaning differed depending on the ostensible author. When Jefferson was the author, rebellion was interpreted to mean peaceful political change. When Lenin was the author, rebellion was interpreted to mean violent revolution. In line with the Gestalt perspective, Asch concluded that changing the ostensible author of the sentence did not change participants' attitude toward the statement, but rather the meaning of the statement.

### *Surprising Results*

In all the experiments summarized so far, the stimuli that participants judged were rather ambiguous (i.e., there were no clear-cut right and wrong answers). In subsequent studies, Asch sought to determine whether he could obtain the same results using unambiguous stimuli. In these studies, he showed two cards to participants. One card contained three lines of different lengths (a, b, and c). The other card contained a single (standard) line that was the same length as one of the lines on the first card. Participants' task was easy: They simply had to say which line on the first card was the same length as the standard line. The stimuli were unambiguous, as indicated by the fact that participants tested alone hardly ever made errors.

Asch was interested, however, in whether participants tested in a group situation where other people made incorrect judgments about the line lengths would still answer correctly. So, he created a situation in which a single naïve participant was confronted by several people (experimental confederates) who gave unanimously incorrect answers on several trials of the line judgment task. Asch expected that the incorrect majority would have little or no influence on participants' judgments, but his prediction turned out to be wrong.

Participants conformed to the erroneous majority answer about one third of the time. This finding surprised Asch, but turned out to be one of the most influential findings in social psychology.

Asch did subsequent experiments to clarify the conditions under which people do and do not conform to group pressure. For instance, he varied the number of confederates and their level of unanimity. He found, for example, that the presence of a single confederate who gives correct answers substantially reduces the group's tendency to yield to the majority. Later research by others demonstrated that conformity can also be affected by such factors as the publicness of participants' responses and their liking for other group members. The impact of these variables has often been explained in terms of two motives: the desire to respond accurately and the desire to be liked. Asch's research on conformity also inspired other important work on social influence. Two examples are Stanley Milgram's studies on obedience to authority and Serge Moscovici's research on minority influence.

### His Legacy

The enduring legacy of Asch's work is due to several factors. His theoretical perspective was elegant, and his results were clear-cut. More important, the two phenomena he studied—impression formation and social influence—are everyday occurrences and play a major role in interpersonal and intergroup relations. Although Asch was not a highly prolific writer during his lifetime, the fact that his 1952 textbook is still widely cited provides strong evidence for his influence in the field.

## ASSIMILATION AND ACCULTURATION

---

During much of the 19th and early 20th centuries, the term *assimilation* was used to describe the process by which immigrants inevitably gave up their culture of origin for the sake of adopting the mainstream language and culture of their adopted country. However, by the late 20th century, the term *acculturation* was adopted by scholars to describe the more fundamental process of bidirectional change that occurs when two ethnocultural groups come into sustained contact with each other. From this latter perspective, assimilation is only one of the many acculturation strategies that immigrant and national minorities may adopt as they strive to adapt to mainstream society.

Such strategies have become more and more necessary as immigration, legal or illegal, has become increasingly common across the globe. Through immigration and the recognition of the rights of indigenous and national minorities, most 19th-century nation-states have been transformed from being more or less unicultural to being multicultural, multi-ethnic, and multilingual states. Following the height of nation building in 19th-century Europe, the term *host majority* was ascribed to the “core founding members” of a nation who constituted the dominant ancestral community in control of the state.

Traditionally, host majorities expected immigrants to assimilate to the culture and values of the receiving society. Host majorities have found it easier to assimilate immigrants when their cultural differences were reduced to exotic manifestations such as ethnic restaurants, music, and dance. However, host societies have found it difficult to share jobs, housing, and welfare with immigrants, whom they often see as unentitled to compete for such limited resources and as contributing to the growing cultural and physical insecurity of the society. At stake is whether or not host communities

wish to accept, nurture, assimilate, or reject the distinctiveness of immigrants as members of cultural communities. Ultimately, will dominant majority members allow immigrant minorities not only to maintain their distinctive culture and language, but also to transform the institutions, culture, and values of the host society?

This entry examines various models of acculturation and how strategies of acculturation may be linked to political views, socioeconomic characteristics, and personality traits.

### Acculturation and Deculturation

From the cross-cultural psychology perspective, acculturation implies that both immigrants and host majority members are influenced and transformed by their intercultural contact and are expected to modify some aspects of their respective cultures. Host majority members enjoy some control over the degree of contact they have with immigrants and may experience acculturation either through direct interpersonal contacts in school and at work or through indirect contacts via mass media portrayals. However, relative to dominant majorities, cultural minorities are more likely to be transformed by such intergroup contacts. Immigrants and national minorities have in common their vulnerability to the tolerance or intolerance of dominant host majorities, whose demographic strength, prestige, and institutional power within the national state can result in much acculturative pressure.

The following types of minorities are likely to experience much acculturation pressure: first- and second-generation immigrants, sojourners, refugees, asylum seekers, and national minorities. An extreme case of acculturation pressure was that of South and North American aboriginals in the 17th through 19th centuries, as they had no control over the unwanted, massive, and sustained immigration of Northern Europeans whose demographic, economic, technological, and military supremacy physically decimated their indigenous communities while causing acculturation pressures that often resulted in outright deculturation. The term *deculturation* is used to describe the cultural, linguistic, religious, psychological, and health breakdown that occurs in minority communities that experience sustained contact with a dominant

majority, which by ignorance, indifference, or design has sought to subjugate immigrant or indigenous communities through forced assimilation, segregation, cultural genocide, ethnic cleansing, or extermination.

### From Uni-Dimensional to Bi-Dimensional Models of Acculturation

In Western societies, much of the early acculturation research focused on the adaptation strategies of immigrant minorities as they interacted with the dominant host majority. This almost exclusive focus on the acculturation process of immigrants imposed a form of “collective dispositional bias,” which often blamed immigrants for not sufficiently or successfully adapting to the culture, habits, and values of the receiving society. Furthermore, traditional models of immigrant acculturation were uni-dimensional, as they proposed that during immigrants’ lifetime, they shifted from exclusive grounding in their culture of origin to a bicultural phase reflecting maintenance of the heritage culture and adoption of the host culture, to complete assimilation to the dominant host majority culture.

Criticisms of the uni-dimensional model led to the development of bi-dimensional models of acculturation. In his bi-dimensional model, John Berry proposed that the maintenance of the immigrant culture and adoption of the host majority culture could be portrayed as independent dimensions instead of contrasting points on a single continuum of cultural change. Thus, whether immigrants achieve competence in the host majority language could have little to do with their maintenance of their heritage language. An adaptation of the Berry model asserts that immigrants and national minorities may endorse five acculturation orientations, including the assimilationist strategy proposed in traditional uni-dimensional models. Immigrants with an *integrationist* orientation want to maintain certain aspects of their culture of origin while also adopting key features of the culture of the host community. Those with a *separatist* perspective seek to maintain their language and culture of origin while rejecting key aspects of the host community culture. Immigrants who adopt the *assimilationist* strategy want to abandon their culture and/or language of origin

for the sake of adopting the culture and/or language of the host community. The *marginalized* feel alienated from their culture of origin and experience sustained rejection by members of the dominant host majority, a double jeopardy often leading to anomie. Immigrants may also endorse an *individualist* acculturation orientation as they define themselves and others on the basis of their personal characteristics and achievements rather than on their group membership. Such individualists are not concerned with maintaining the immigrant culture or adopting the host culture, as they are more involved with achieving their personal goals in their country of adoption.

### The Interactive Acculturation Model

It is only in the last decade that researchers have focused their attention on the acculturation orientations held by host communities, which by virtue of their dominant position and control of immigration and integration policies have a substantial impact on the acculturation orientations adopted by immigrant and national minorities. The interactive acculturation model (IAM) was proposed by Richard Bourhis to better account for the intergroup processes that characterize relations between host majority members and cultural minorities. The IAM framework includes the following elements: (a) immigration and integration policies that can affect the climate of intergroup relations between immigrant and host communities, (b) acculturation orientations adopted by host community members toward specific groups of immigrants, (c) acculturation orientations adopted by immigrants within their country of adoption, and (d) interpersonal and intergroup relational outcomes that are the product of combinations of immigrant and host community acculturation orientations. As a complement to other acculturation frameworks, the IAM focuses on the cultural adoption strategies of immigrant and host majority members rather than on their dual group identities or desires for intergroup contact.

The IAM takes into account how public policies regarding immigration and integration relate to the acculturation orientations endorsed by host majority and immigrant group members. While most democratic states have formulated and applied immigration policies regulating the national

origin, type, and rate of immigration accepted within their boundaries, public policies designed to facilitate the integration of immigrants and national minorities within mainstream society remain the exception rather than the rule. State integration policies consist of the approaches adopted by national, regional, and municipal governments to help immigrants and host communities adapt to the growing ethnic, linguistic, and religious diversity of modern states.

The IAM proposes four clusters of ideologies that can shape the integration policies adopted by democratic governments of multiethnic states. As a heuristic for analyzing integration policies, these four clusters can be placed along a continuum ranging from the pluralism and civic ideologies at one end of the continuum to the assimilationist and ethnist ideologies at the other end. Depending on political, economic, demographic, and military events occurring at the national and international levels, state integration policies can shift from one ideological orientation to the other. The IAM proposes that adoption of state integration policies may reflect and also shape host community acculturation orientations, as well as more general opinions concerning the ideal or preferred ways of integrating minorities within mainstream society. Political tensions may emerge between factions of the host majority holding rival ideological views on immigration and integration issues. The polarization of ideological positions regarding such issues may lead to the formation of political parties whose main platform is to change state policies on immigration and integration issues. While left wing parties may endorse public policies at the pluralist pole of the ideological continuum, right wing nationalist or religious parties may advocate integration policies situated at the assimilationist or ethnist side of the continuum.

The IAM proposes that the acculturation orientations of dominant host majority members can have a major impact on the acculturation orientations of immigrant minorities. Dominant host community members may endorse five acculturation orientations they wish immigrants to adopt: integrationism, assimilationism, segregationism, exclusionism, or individualism. These acculturation orientations are measured using the validated Host Community Acculturation Scale (HCAS).

*Integrationism* is endorsed by host community members who accept that immigrants maintain

some aspects of their heritage culture, and also accept and value that immigrants adopt important features of the host majority culture. Integrationists value a stable biculturalism/bilingualism among immigrant communities, which, in the long term, may contribute to cultural and linguistic pluralism as an enduring feature of the host society. *Assimilationism* corresponds to the traditional concept of absorption, whereby host community members expect immigrants to relinquish their language and cultural identity for the sake of adopting the dominant culture and language of the host majority. *Segregationism* is exemplified by host community members who accept immigrants' maintenance of their heritage culture, as long as the immigrants keep their distance from host members, as they do not wish immigrants to transform, dilute, or "contaminate" the host culture and value system. Host community members who adopt this orientation discourage cross-cultural contacts with immigrants, prefer immigrants to remain together in separate urban or regional enclaves, and are ambivalent regarding the status of immigrants as rightful members of the host society. *Exclusionism* is adopted by members of the host majority who deny immigrants the right to adopt features of the host community culture. Exclusionists also deny immigrants the choice to maintain their heritage language, culture, or religion and believe that some immigrants have customs and values that can never be socially incorporated within the host community mainstream. *Individualism* is an orientation endorsed by host community members who define themselves and others as individuals rather than as members of group categories such as immigrants or host community members. Because it is personal qualities and individual achievements that count most, individualists will tend to interact with immigrants in the same way they would with other individuals who happen to be members of the host community.

The IAM proposes that acculturation orientations endorsed by host community members may be concordant or discordant with those held by members of specific immigrant communities. The degree of concordance between the acculturation orientations of host community members and immigrants may result in harmonious, problematic, or

conflictual relational outcomes. Intergroup relational outcomes include cross-cultural and bilingual communications, interpersonal and intergroup misunderstanding, prejudice and stereotyping, social and institutional discrimination in employment, housing, education and interpersonal relations. Harmonious relational outcomes include optimal intergroup understanding and can be expected when immigrants and host community members both adopt the integrationist and individualist acculturation orientations. Problematic relational outcomes are expected when the acculturation orientations of host majority members and immigrants are partially concordant or discordant. For instance, problematic outcomes, including intergroup misunderstanding and miscommunication, may emerge when immigrants endorse integrationism while host community members endorse assimilationism for immigrants. Problematic outcomes may also emerge when host majorities represent immigrants as endorsing mainly separatism, while immigrants perceive the host majority to be mainly segregationist or exclusionist. Conflictual relational outcomes including discrimination, hate crimes, and intergroup violence can be expected from host majority members who endorse segregationism or exclusionism, especially for immigrants perceived as threatening. Faced with systemic discrimination and hostility from host majority members who are segregationist and exclusionist, immigrants who adopt separatism or marginalization may eventually resort to outright conflict strategies through civil disobedience, rioting, criminal activity, armed struggle, or terrorism.

### Studies of Host Community Acculturation Orientations

Numerous empirical acculturation studies have been conducted with dominant host community undergraduates, thus controlling for the educational and socioeconomic status of respondents in urban centers such as Los Angeles, Montreal, Paris, Brussels, Geneva, and Tel Aviv. These studies have shown that individualism and integrationism are the most strongly endorsed acculturation orientations toward immigrants. Endorsement of welcoming acculturation orientations such as individualism and integrationism may reflect the meritocratic

and individualistic university organizational culture, which favors the equal treatment of individuals, regardless of race, color, or creed. Studies have shown that assimilationism, segregationism, and exclusionism are the least endorsed acculturation orientations among college students, though in recent years endorsement of segregationism by students has increased somewhat in both Québec and France.

Overall, undergraduates endorsed more welcoming acculturation orientations toward “valued” immigrants than toward “devalued” immigrants or national minorities. For instance, undergraduate students in Tel Aviv more strongly endorsed the individualism and integrationism orientations toward Jewish immigrants from Russia and Ethiopia than toward the devalued Israeli Arab national minority in Israel. Conversely, Jewish undergraduates more strongly endorsed the segregationism and exclusionism orientations toward Israeli Arabs than toward Jewish immigrants from Russia and Ethiopia.

Does left wing versus right wing political affiliation influence acculturation orientations toward devalued groups? In Israel, left wing Labour identifiers more strongly endorsed the individualism and integrationism orientations toward Israeli Arabs than did Likud party identifiers. Conversely, Likud Party identifiers more strongly endorsed the segregationism and exclusionism orientations toward Israeli Arabs than did Labour party identifiers. Most important, right wing Likud Party identifiers were unique in more strongly endorsing the segregationism and exclusionism orientations than the individualism and integrationism orientations toward Israeli Arabs. Political parties are created and remain popular to the degree that they offer “solutions” to the fears and aspirations of their electorate. The right wing Likud Party platform nurtures a sense of threat to the vitality and national security of the Jewish majority in Israel. Threats felt from the presence of Israeli Arabs make it particularly difficult for Likud Party sympathizers to accept any type of relationship with Israeli Arabs, and “justifies” keeping Arabs segregated and excluded from the Jewish dominant majority.

Right wing nationalist parties in other settings, such as France and Québec, also nurture feelings

of threat and cultural insecurity toward devalued immigrants as a way of maintaining mobilization in favor of their respective nationalistic causes. Right wing nationalist parties gain much of their support from host majority electorates by nurturing feelings of symbolic and realistic threats especially from the presence of “devalued” immigrants whose demographic presence is often portrayed as overwhelming and out of control.

Even though host majorities may endorse each acculturation orientation to a different degree cross-culturally, the social psychological profile of each acculturation orientation remains similar regardless of the national background of respondents. Study results obtained in Montreal, Los Angeles, Paris, Geneva, Brussels, and Tel Aviv suggest that this is the case. Individualism and integrationism are two “live and let live” acculturation orientations the correlates of which were quite similar cross-culturally. Individualists and integrationists felt comfortable with immigrants, wanted close relations with both valued and devalued immigrants, including as best friends, and felt that immigrants in general wanted good relations with members of the host majority. Individualists and integrationists did not endorse the authoritarian or social dominance orientation and ethnocentric ideologies, and they were more likely to identify with “left of center” political parties in their respective sociopolitical settings.

Assimilationists, segregationists, and exclusionists all rejected immigrants and their culture, endorsed the social dominance orientation and authoritarian and ethnocentric ideologies, and were more likely to identify with right wing political parties. Importantly, they were more likely to feel that their ingroup identity was threatened by the presence of immigrants, especially “devalued” ones. They were also more likely to feel insecure culturally, linguistically, and economically as members of their own group, while wishing to avoid immigrants as colleagues at work, as neighbors, or as best friends. In each cultural setting, specific social psychological variables differentiated the assimilationist, segregationist, and exclusionist acculturation orientations. Taken together, these social psychological correlates of acculturation orientations attest to the construct validity of the HCAS and also support some basic premises of the IAM.

### Studies of Immigrant Acculturation Orientations

Empirical cross-cultural studies have examined acculturation orientations endorsed by immigrants and national minorities using variants of the Immigrant Acculturation Scale (IAS) developed by John Berry and his colleagues. In many cultural settings, immigrants endorse integrationism to a greater degree than assimilationism and separatism, and marginalization is rarely endorsed. Exceptions to these findings are Turks in Germany, lower economic status Turks in Canada, and some indigenous minorities in various parts of the world, who endorse separatism more than integrationism. Overall, feelings of being the victim of prejudice and discrimination are the most important correlates of separatism and marginalization. While newly established immigrants may at first adopt integrationism or assimilationism, sustained experience of discrimination and exclusion in the host society may shift acculturation orientations to separatism or marginalization. Acculturation orientations can also be endorsed differently in the public and private domains. In the public domain, immigrants may endorse linguistic integration through bilingualism and assimilation at work, whereas in the private domain they may practice separatism through religiously and ethnically endogamous marriages.

Acculturative stress may be experienced as a result of intercultural contacts that highlight differences between the heritage culture of immigrants and that of the dominant host majority. This is more likely to occur when the “cultural distance” between the heritage culture of immigrants and that of the receiving society is large. As proposed by Anthony Richmond, immigrants may suffer more acculturative stress when their migration was involuntary (*reactive emigration*) than in cases where individuals voluntarily chose to emigrate to a country to which they were attracted (*proactive emigration*). For most immigrants, acculturative stress is related to the experience of culture loss and anxieties about how to adapt to the country of settlement.

While higher education is associated with less acculturative stress, immigrants who suffer an important drop in occupational status can suffer much acculturative stress, especially when their

foreign diplomas are not recognized in the country of settlement. Immigrant women who seek more egalitarian sex roles in their country of settlement are more likely to experience acculturative stress than men, especially when sex roles in the country of origin were quite traditional. While acculturative stress is more likely to be experienced by immigrants who settle at an older age in their country of adoption, personality factors such as introversion or extraversion, internal or external locus of control, and degree of self-efficacy have also been linked to acculturative stress.

As developed by Colleen Ward, ethnocultural identity conflict (EIC) stems from identity conflict occurring when the multiple social identities developed as a result of emigration become incompatible with each other. EIC can be prevalent for immigrant youth, who experience difficulties in harmonizing the traditional values of their parents with the modern values of their host majority age peers. Infrequent contact with host majority peers, interethnic tensions, threats to cultural continuity, and perceived discrimination are aggravating factors that contribute to EIC. Furthermore, immigrants who endorse the separation, assimilation, and marginalization acculturation orientations are more likely to experience EIC than those who endorse integrationism.

Despite the pressures of acculturative stress and ethnocultural identity conflict, immigrants can be quite resilient in their psychological and sociological adaptation to their country of adoption. While psychological adaptation refers to good mental health and a sense of well-being, sociocultural adaptation involves a set of social competencies that enable minority individuals to live successfully in their intercultural world. Studies with immigrants showed that the relationship between psychological and sociocultural adaptations increased over time and tended to be stronger in cases where the cultural distance between the immigrant culture and that of the host community was small rather than large. The complementary link between psychological and sociocultural adaptation was stronger for immigrants with the integrationism and assimilationism orientations than for those with the separation and marginalization acculturation orientations.

A recent comparative study of immigrant youth from 13 countries showed that better psychological

and sociocultural adaptation was related to endorsement of the integrationism orientation but not very related to endorsement of assimilationism and separatism, and least related to the marginalization acculturation orientation. Results also showed that perceived discrimination against ingroup members was the single strongest predictor of poor psychological and sociocultural adaptation. The 13-country study showed that immigrant youth who endorsed the integration orientation experienced less ethno-cultural identity conflict, less anxiety and depression, and fewer psychosomatic symptoms than their peers who endorsed assimilationism, separatism, and especially the marginalization acculturation orientation. Immigrant endorsement of integrationism was also shown to be positively correlated with the traits of extraversion, emotional stability, sociability, agreeableness, sensation seeking, and open-mindedness. In addition, endorsement of integrationism was found to be related to higher self-esteem, which in turn was a strong predictor of immigrant adaptation. Immigrant youth who endorsed integrationism were those whose social identification was dual, who were more likely to be bilingual, and who had both ingroup and outgroup peer contacts. Conversely, separatism was positively correlated with neuroticism, anxiety, impulsivity, sensation seeking, and aggressiveness, and negatively correlated with extraversion, sociability, self-assurance, and self-esteem.

Studies found that assimilationism is positively related to task-coping and emotion-coping orientations, and thus contributes to the reduction of emotional distress associated with stressful situations. Personality traits that were associated with assimilationism were agreeableness and sociability, as well as neuroticism, anxiety, closed-mindedness, and field dependence. In immigrants' quest to endorse integrationism and assimilationism, they may also adopt the less desirable habits and customs of the host majority. For instance, one study showed that immigrant youth who endorsed integration and assimilation were at higher risk than separatists of adopting health-compromising behavior such as smoking and drinking alcohol. In line with the IAM, immigrants who are confronted by mainly segregationist and exclusionist host majority members may reduce acculturative stress and avoid conflictual

relational outcomes by adopting separatism rather than integrationism or assimilationism.

Finally, marginalization is the acculturation orientation associated with the least desirable psychological and sociocultural correlates. Marginalization is associated with neuroticism, anxiety, closed-mindedness, and unsociability. Similarly, a link has been found between marginality, alienation, anomie, deviance, and psychosomatic stress. Being a victim of discrimination was found to be the single most important predictor of marginalization.

### Conclusion

Much fundamental and applied research remains to be done to do justice to the complexity and subtlety of immigrant–host community relations in multi-ethnic settings. In line with the interactive acculturation model (IAM), more empirical studies are needed to explore how concordant and discordant acculturation orientations between immigrant and host communities can result in harmonious, problematic, or conflictual relational outcomes, not only in regard to intercultural communication and prejudicial attitudes but also in behavioral outcomes such as prosocial behaviors, employment equity, discrimination, intergroup conflicts, and hate crimes.

Emerging research is currently exploring the acculturation orientations of immigrant communities toward coexisting, competing, or rival “other” immigrant communities, either long established following earlier immigration cycles or more recently arrived as a result of current immigration waves. Likewise, in culturally divided societies, acculturation orientations endorsed by national minorities toward the dominant majority are being explored. More acculturation research should be conducted with sojourners, refugees, and asylum seekers as they adapt to increasingly multi-ethnic and multilingual receiving societies. Multiple identity research dealing with the interplay of subnational, national, supranational, and transnational identities across the world also calls for more complex elaborations of current acculturation models. The very premise of considering host societies as being composed of single or dual host communities may already be an oversimplification, both conceptually and empirically. Host societies of the future may well be constituted of multiple host

communities, all of which are ethnic and linguistic minorities sharing two or more official national languages but no obvious core founding majority.

## ATTACHMENT THEORY

---

*Attachment theory* was developed by John Bowlby to explain personality and social development from the cradle to the grave. The theory focuses on the experience, expression, and regulation of emotions at both normative (species-typical) and individual difference (person-specific) levels of analysis. This focus is not surprising given how important emotions and affect regulation are to interpersonal functioning in all types of close relationships.

Bowlby believed that the attachment system serves two primary functions: (1) to protect vulnerable individuals from potential threats or harm and (2) to regulate negative affect following threatening or harmful events. The normative component of attachment theory specifies the stimuli and contexts that normally evoke and terminate different kinds of emotions, as well as the sequence of emotions usually experienced following certain relational events. The individual difference component addresses how an individual's personal history of receiving care and support from attachment figures

shapes the goals, working models (that is the interpersonal attitudes, expectancies, and cognitive schemas), and coping strategies that she or he uses when emotion-eliciting events happen in relationships. This entry examines Bowlby's original ideas and the evolution of his theory among later researchers.

### Normative Features of Attachment Theory

Bowlby's fascination with the emotional ties that bind humans to one another began with an astute observation. In all human cultures and indeed primate species, young and vulnerable infants display a specific sequence of reactions following separation from their stronger, older, and wiser caregivers. Immediately following separation, infants protest vehemently, typically crying, screaming, or throwing temper tantrums as they search for their caregivers. Bowlby believed that vigorous protest during the early phases of caregiver absence is a good initial "strategy" to promote survival, especially in species born in a developmentally immature and very dependent state. Intense protests often draw the attention of caregivers to their infants, who would have been vulnerable to injury or predation during evolutionary history if left unattended.

If loud and persistent protests fail to get the caregiver's attention, infants enter a second stage, known as despair, during which they usually stop moving and become silent. Bowlby believed that from an evolutionary standpoint, despondency is a good second strategy to promote survival. Excessive movement could result in accident or injury, and loud protests combined with movement might draw predators. According to this logic, if protests fail to retrieve the caregiver quickly, the next best survival strategy would be to avoid actions that might increase the risk of self-inflicted harm or predation.

After a period of despair, infants who are not reunited with their caregivers enter a third and final stage—detachment. During this phase, the infant begins to resume normal activity without the caregiver, gradually learning to behave in an independent and self-reliant manner. Bowlby believed that the function of emotional detachment is to allow the formation of new emotional bonds with new caregivers. He reasoned that emotional ties

with previous caregivers must be relinquished before new bonds can fully be formed. In terms of evolution, detachment allows infants to cast off old ties and begin forming new ones with caregivers who might be able to provide the attention and resources needed for survival. Bowlby also conjectured that these normative stages and processes characterize reactions to prolonged or irrevocable separations in adult attachment-based relationships, which might also have evolutionary adaptive value in terms of maintaining, casting aside, or forming new romantic pairs.

In addition to identifying the course and functioning of these three distinct stages, Bowlby also identified several normative behaviors that infants commonly display in attachment relationships. Such hallmark behaviors include sucking, clinging, crying, smiling, and following the caregiver, all of which serve to keep the infant or child in close physical proximity to the caregiver. Bowlby also documented unique features of the caregiver and his or her interaction with the infant that are likely to promote attachment bonds. The features include the competence with which the caregiver alleviates the infant's distress, the speed of responsiveness of the caregiver to the infant, and the familiarity of the caregiver. These behaviors and features are also believed to be critical to the development of adult attachment relationships. Debra Zeifman and Cynthia Hazan, for example, have noted that most romantically attached adults repeatedly engage in hallmark attachment behaviors such as sucking, clinging, prolonged eye contact, and extensive belly-to-belly body contact. Mario Mikulincer and Phillip Shaver have documented the importance of the responsiveness of romantic partners in the formation of attachment security.

### Individual Difference Features of Attachment Theory

Attachment theorists after Bowlby have proposed that different attachment patterns (in children) and attachment styles or orientations (in adults) reflect different ways of regulating affect, particularly controlling or dampening negative affect in stressful, threatening, or overly challenging situations. Individual differences in patterns of attachment in 12- to 18-month-old children were first documented by Mary Ainsworth and her colleagues

using the Strange Situation. The Strange Situation involves a sequence of separations and reunions of caregivers (usually mothers) and their children. It assesses how children regulate negative emotions vis-à-vis their caregivers when the children are upset. Even though most children are distressed when left alone at this age, securely attached children tend to reduce their negative emotions by using their caregivers as a "secure base," and they resume other activities fairly quickly after reuniting with them in the Strange Situation. Anxious-resistant children, by comparison, remain distressed and often exhibit anger or resentment toward their caregivers during reunions episodes. Anxious-avoidant children, who display fewer overt signs of distress but usually have elevated heart rates, remain distant and emotionally detached from their caregivers during reunions, opting to calm themselves in a self-reliant manner.

During later stages of development, one of the key differences between secure and different types of insecure individuals is how their negative emotions are regulated and controlled based on their specific beliefs and expectancies about the availability of comfort and support from their attachment figures. Highly secure individuals have learned from past caregiving experiences to follow "rules" that permit distress to be acknowledged and motivate them to turn toward attachment figures as sources of comfort and support. Highly avoidant adults, in contrast, have learned to follow rules that limit the acknowledgment of distress and encourage the use of self-reliant tactics to control and reduce negative affect when it arises. Highly anxious people have learned to use rules that direct their attention toward the possible source of distress, to ruminate about it, and to worry that their attachment figures will never fully meet their persistent needs for comfort and support.

Mikulincer and Shaver have recently proposed a process model that outlines the sequence of events that underlie the emotional coping and regulation strategies of people who have different attachment histories. For example, when stress or a potential threat is perceived, highly secure individuals remain confident that their attachment figures will be attentive, responsive, and available to meet their needs and help them lower their distress and anxiety. These beliefs, in turn, should increase their

feeling of security, which should deactivate their attachment systems, allowing them to use constructive, problem-focused coping strategies that over time are likely to solve their problems.

Highly insecure individuals follow different pathways. When highly anxious individuals encounter attachment-relevant stress or threats, they are uncertain as to whether their attachment figures will be sufficiently attentive, available, and responsive to their needs. Such worries should sustain their distress and keep their attachment systems activated, resulting in the use of emotion-focused coping strategies such as hypervigilance to signs of possible relationship loss and ruminating over worst-case scenarios. When highly avoidant individuals feel stressed or threatened, they experience—but may not consciously acknowledge—anxiety at a physiological level. To keep their attachment systems deactivated, highly avoidant persons work to inhibit and control their emotional reactions by using avoidant coping strategies.

These three emotion regulation/coping strategies—problem-focused, emotion-focused, and avoidance-focused strategies—are the source of many of the interesting cognitive and behavioral outcomes that have been discovered in people who have different attachment styles or orientations. More securely attached individuals, for instance, typically experience more intense and mild positive emotions in their romantic relationships and fewer intense and mild negative emotions, whereas the reverse is true of more insecurely attached persons. Recent longitudinal research has also documented connections between an individual's early attachment pattern (being classified as secure or insecure in the Strange Situation at age 1) in relation to his or her mother and emotions experienced and expressed with a romantic partner 20 years later. In addition, individuals classified as insecure (either anxious-avoidant or anxious-resistant) in the Strange Situation at age 1 are rated by their teachers as less socially competent during early elementary school. Lower social competence, in turn, predicts greater likelihood of being rated as insecurely attached to same-sex friends at age 16, which in turn predicts both the experience and expression of greater negative affect in relationships with romantic partners when individuals are in their early 20s. Thus, indirect but theoretically meaningful links exist between

early attachment experiences and later attachment-based relationships in early adulthood, just as Bowlby anticipated.

### Conclusion

In conclusion, attachment theory was developed to account for different patterns of personality and social development across the entire life span. According to Bowlby, understanding the experience, expression, and regulation of emotion—particularly negative emotion in response to events that activate the attachment system—is essential to understanding how and why individuals with different attachment histories behave as they do in their close relationships.

## ATTITUDES TOWARD WOMEN SCALE

---

The *Attitudes Toward Women Scale* (AWS), developed by Janet T. Spence and Robert Helmreich in the early 1970s, measures attitudes about the rights and roles of women—relative to men—in occupational, educational, and relational domains. As an *attitude* measure focusing on gender *roles*, the AWS assesses opinions about the behavioral

patterns deemed appropriate for men and women in society. Examples include believing that men should be more responsible for supporting their families, whereas women should be more responsible for nurturing their children.

Spence and Helmreich created versions of the AWS with 55 items, 25 items, and 15 items, which were published in 1972, 1973, and 1978, respectively. Sample items on the AWS are as follows: "There are many jobs in which men should be given preference over women in being hired or promoted" and "Under modern economic conditions with women being active outside the home, men should share in household tasks such as washing dishes and doing the laundry." Respondents indicate their level of agreement with each statement on a four-option scale. A summary score is created across all scale items such that higher numbers indicate more egalitarian gender-role attitudes. More than three decades of research have demonstrated all three versions of the AWS to be reliable, consistently yielding the same results, and valid, accurately measuring what they are intended to measure. These properties have added to the usefulness and importance of the scale.

This entry addresses the background of the AWS, the significance of the scale, changes over time in gender-role attitudes, and new directions in their measurement.

### Background and History

When discussing the history of the AWS, it is interesting to note the relevance of the career history of its primary founder, Janet Spence. Earning her PhD in 1949, Spence was a pioneering figure for women in psychology at a time when the field was largely dominated by men. In 1984, with the American Psychological Association approaching its centennial, she served as its sixth female president, and in 1988, she served as the first member-elected president of the American Psychological Society (now the Association for Psychological Science).

In the 1970s, during the second wave of the feminist movement, Spence's research interests turned to gender. In response to research findings that people liked competent, academically successful males more than incompetent ones, Spence became interested in how people would perceive

competent *women* in stereotypically masculine domains and whether this would relate to their gender-role attitudes. Although there were gender-role attitude measures already in existence, such as Clifford Kirkpatrick's Belief-Pattern Scale for Measuring Attitudes Toward Feminism published in 1936, the items were relatively outdated. In need of a more contemporary means of measuring gender-role attitudes, Spence, along with her colleague Robert Helmreich, developed the original 55-item version of the AWS. They then discovered, to their surprise, that male and female college students, even those with more traditional gender-role attitudes, formed positive impressions of competent women with masculine interests.

### Significance of the AWS

Though neither the first, nor the most recent, measure of gender-role attitudes, the AWS is the most widely cited and used, serving as a reference point for more recently developed measures. Spence has attributed the popularity of the AWS to its emergence as one of the first gender-role attitude measures in the early 1970s, when interest in gender research was growing exponentially in psychology.

Because the AWS has been used so widely to measure gender-role attitudes, comparisons of these attitudes can be made across time (as discussed in the next section) and across cultures. Investigators have used the AWS in at least 15 different countries (including Brazil, Canada, Croatia, Czech Republic, India, Philippines, South Korea, and Spain) on five different continents (Asia, Australia, Europe, North America, and South America). In addition, the AWS used on college students has also been adapted for use with adolescents and with the general population in the United States. Although findings from these studies are diverse, consistent patterns emerge. For example, women and female adolescents typically report more egalitarian gender-role attitudes than their male counterparts. Though the gender-role attitudes of parents and their children show a moderate degree of association, students consistently report more egalitarian attitudes than their parents or grandparents. In addition, more traditional gender-role attitudes are reported by those lower in socioeconomic status and those stronger in religious affiliation.

### Change Over Time

The consistent use of the AWS over a period of more than three decades has allowed gender researchers to track changes in gender-role attitudes over time. It is interesting—and no accident—that the AWS appeared at a time when women in the United States were more forcefully asserting their rights to attain the same educational and employment status as men. Given that the actual behaviors and roles of U.S. women were changing as they increasingly entered traditionally male-dominated domains, it became important to examine whether there were corresponding changes in societal attitudes about male and female gender roles. Research does, indeed, indicate that gender-role attitudes are becoming less traditional over time, especially among college students in the United States. For example, Janet Spence and Eugene Hahn compared gender-role attitudes (using the AWS) in four different student cohorts assessed at the same university in 1972, 1976, 1980, and 1992, finding the most egalitarian attitudes in 1992 and the least egalitarian attitudes in 1972. In a more comprehensive examination of changes in gender-role attitudes that included 71 different samples of U.S. college students, Jean Twenge found that gender-role attitudes became steadily more egalitarian in both male and female students over a 25-year period from 1970 to 1995. In addition, although males had more traditional attitudes than females at every point in time, these gender differences decreased in size from 1986 to 1995.

### Limitations and New Directions

Despite its usefulness, the AWS has limitations. Certain items on the scale appear outdated (e.g., “It is ridiculous for a woman to run a locomotive and for a man to darn socks”). Another criticism levied against the scale, which applies particularly to more recent samples of female college students, is that it shows *ceiling effects*. Ceiling effects occur when most or all responses on a measurement scale cluster around the high (or, in the case of the AWS, the more egalitarian) end. This lack of variability in scale responses can lead to difficulty in determining what relationships the scale shows with other variables (e.g., educational level or religiosity), an important goal of research. Despite

this problem, these ceiling effects are, in and of themselves, a phenomenon of interest. That is, because these ceiling effects are a more *recent* phenomenon occurring mostly on certain AWS items in *female* college students, researchers can gain a better understanding of change over time in gender-role attitudes and can also make interesting comparisons between male and female students.

Over time, it has become less socially acceptable in the United States to express negative attitudes toward women openly. Because the AWS is an overt measure of attitudes, it could be argued that some of the egalitarian responses on the AWS might not accurately reflect the respondents’ true beliefs. This has led to the construction of more subtle measures of gender-role attitudes, such as the Modern Sexism Scale developed by Janet Swim and her colleagues. This scale assesses the extent to which respondents deny that discrimination against women still exists, and it has been shown to be a different kind of gender-role attitude measure than more overt measures. It might seem sensible, therefore, to discontinue the use of overt measures of gender-role attitudes in favor of more subtle measures; however, this action would be short-sighted in the end. Both overt and subtle gender-role attitude measures are vital because they serve distinct research purposes. Most importantly, because the AWS has been used consistently in research since the early 1970s, its continued use will allow gender researchers to examine how gender-role attitudes change over time well into the future.

---

## ATTRIBUTION BIASES

---

*Attribution* refers to the way in which people explain their own behavior and that of others. An *attribution bias* occurs when someone systematically over- or underuses the available information when explaining behavior. There is evidence that when we are making judgments about the behavior of our own group (the ingroup) and that of other groups (outgroups), we show attributional biases that favor the ingroup. Specifically, where ingroup members are concerned, we explain positive behaviors in terms of internal characteristics (e.g., personality) and negative behaviors in terms of external factors (e.g., illness). Conversely, where outgroup members are concerned, we explain positive behaviors in terms of external characteristics and negative behaviors in terms of internal characteristics. The study of attribution biases is an essential aspect of group processes and intergroup relations because these biases can fuel negative relations between opposing groups. Understanding how and why attribution biases arise, however, facilitates the development of interventions to reduce them.

This entry outlines the basic theory, discusses how it applies in individual and group contexts, and describes research showing how attribution bias may be mitigated.

### Attribution Theory

Following the pioneering work of Fritz Heider, Harold Kelley developed a theory of causal attribution based

on a scientific analysis of how people should explain, or attribute, their own or others' behavior by using the available information in a systematic manner. Heider and Kelley investigated the *locus of causality*, whether behavior is caused by something internal or external to the actor (the person performing the behavior). Later work, by Bernard Weiner, identified three further causal dimensions in terms of which attributions can be classified: *stability*, the extent to which causes are stable and permanent versus temporary and fluctuating; *controllability*, the extent to which causes can be influenced by the actor; and *globality*, whether a cause is global in nature or specific to a given situation.

Of most relevance to the issue of intergroup attribution biases is locus of causality. An *internal* attribution is any explanation that locates the cause as being internal to the person, such as personality, mood, abilities, attitudes, and effort. An *external* attribution is any explanation that locates the cause as being external to the person, such as the actions of others, the nature of the situation, social pressures, or luck. Thus, if people see a mother shouting at her child and decides that she is doing this because she is an aggressive person, they are making an internal attribution. In contrast, if they decide that she was reprimanding the child for behaving badly, they are making an external attribution.

### Individual Attribution Biases

Kelley's model is a rather idealized account of how people make causality judgments. Given that we normally have limited time and resources, we have a tendency to use heuristics, or shortcuts, when making social judgments, rather than taking into account all of the available information. As a result, researchers have observed a number of systematic biases that are made when people are assessing the causes of behavior.

There are three well-documented attribution biases. The *correspondence bias* refers to the fact that behavior is often viewed as a reflection of an actor's corresponding internal disposition even when it was actually caused by situational factors. The *actor-observer bias* arises when we attribute other people's behavior to internal causes and our own behavior to external causes. Both of these effects can be explained by perceptual salience.

The people being observed are the most salient aspect of the situation, as they are actually performing the action—they and their behavior appear to go together, so an internal attribution is made. In contrast, when making self-attributions, we are focused outward and the situation is salient, and thus we attribute causality for our behavior to external factors.

The *self-serving attribution bias* refers to our tendency to make internal attributions for our successes and external attributions for our failures. If students excel in an exam, for example, they are likely to think this is because they are very intelligent, but if they fail, they may attribute this to the poor quality of their teacher. In contrast to the *perceptual* processes underlying correspondence and actor–observer biases, the self-serving attribution bias has a *motivational* basis. We are motivated to view ourselves in a positive light, to have high self-esteem. Attributing success to internal causes boosts our feelings of self-worth, whereas attributing our failures to external causes protects us from feeling bad when we do not do well. Together, these processes enable us to maintain and enhance our self-esteem. Extending these findings, research has shown that as well as making attributions that favor the self, we are also motivated to make attributions that favor *groups* to which we belong over groups to which we do not.

### Intergroup Attribution Biases

*Intergroup* attribution refers to the ways in which members of different social groups explain the behavior of members of their own and other social groups. A person attributes the behavior of another person not simply to individual characteristics, but also to characteristics associated with the group to which the other person belongs. Moreover, the group membership of the perceiver, or attributor, can also affect the intergroup attribution process.

Social psychologists have investigated how we make attributions in an intergroup context. Hindus (a minority group) and Muslims (a majority group) in Bangladesh read scenarios about an individual from either their ethnoreligious group or the other group, and they were instructed to imagine that this person had behaved in either a positive or a negative way toward them (e.g., a passerby either

helped or failed to help the participant when he or she had fallen off a bike). Among Muslim participants, positive behavior of a Muslim (an ingroup member) and negative behavior of a Hindu (an outgroup member) tended to be attributed to causes rated as internal, stable, uncontrollable by others, and global. In contrast, positive behavior of a Hindu and negative behavior of a Muslim were typically attributed to causes rated as external, unstable, controllable by others, and specific. Notably, Hindu participants showed considerably less intergroup bias in attributions, suggesting that these biases are stronger among majority groups than minority groups.

Research has also considered whether there are biases in attributions made for the historical actions of entire outgroups. (Non-German) Jewish and (non-Jewish) German participants were asked why they thought Germans mistreated Jewish people during the Second World War. Jewish participants were more likely to attribute the behavior of the Germans to internal characteristics such as German aggression than were German participants. In a further study, Dutch participants were asked to make internal or external attributions for behavior in two historical contexts: Dutch behavior toward Indonesians during the colonization period (negative ingroup behavior) and German behavior toward the Dutch during the Second World War (negative outgroup behavior). Participants were more likely to make internal attributions about negative outgroup behavior than negative ingroup behavior, and more likely to make external attributions about negative ingroup behavior than negative outgroup behavior.

Finally, there is evidence for *linguistic* intergroup attribution biases. People tend to use relatively abstract terms to describe the negative behavior of an outgroup member and the positive behavior of an ingroup member, because this implies that the behavior is generalized to the personality of the actor. In contrast, people use relatively concrete terms to describe the negative behavior of an ingroup member and the positive behavior of an outgroup member because this implies that the behavior is specific to a particular context.

To summarize, in an intergroup context, we tend to make attributions regarding locus of causality that favor the ingroup over the outgroup.

This is a form of self-serving attribution bias, but instead of enabling us to view ourselves in a positive light compared to other individuals, it enables us to view the groups to which we belong positively compared to other groups. Specifically, we tend to explain the positive behavior of ingroup members in terms of internal characteristics but the positive behavior of outgroup members in terms of external characteristics. In contrast, we tend to explain the negative behavior of ingroup members in terms of external characteristics, but the negative behavior of outgroup members in terms of internal characteristics. We also have also a tendency to make biased intergroup attributions based on linguistics, globality, stability, and controllability.

So why do we make these intergroup attribution biases? According to social identity theory, we tend to favor our own group over other groups to maintain a positive perception of the ingroup and therefore maintain a high level of self-esteem. We make intergroup attribution biases to ensure that our group is perceived in a positive light compared to other groups. Three findings support this social identity explanation. First, making group membership salient prior to completing an intergroup attribution task increases the extent to which participants show intergroup attribution biases. Second, intergroup attribution biases are stronger among participants who highly identify with their ingroup. Third, it has been demonstrated that making internal attributions about ingroup members and making global attributions about the negative behavior of outgroup members predicts higher self-esteem.

### Reducing Intergroup Attribution Biases

According to social identity theory, making our group membership salient increases intergroup bias, as we are motivated to maintain a positive perception of our own group relative to other groups. To reduce attributional bias, it is therefore necessary to change the nature of categorization. One way of doing this is *cross-categorization*, which involves crossing a dichotomous categorization with a second categorization. In the case of Hindus and Muslims in Bangladesh, for example, it is possible to introduce a second categorization, the distinction between Bangladeshi and Indian

nationality. This cross-categorization creates four groups. For a Bangladeshi Muslim, the double ingroup refers to those who share both group memberships (other Bangladeshi Muslims), the partial ingroups are those who share one group membership (Bangladeshi Hindus and Indian Muslims), and the double outgroup refers to those who share neither group membership (Indian Hindus). People tend to favor double ingroup members and show the greatest discrimination against the double outgroup. Intergroup bias against partial ingroup members, however, is reduced compared to the double outgroup. Thus, seeing an outgroup member as being an ingroup member on a second dimension has benefits for intergroup relations. Research on intergroup attribution biases mirrors these findings. Bangladeshi Muslim study participants made the most positive attributions about a Bangladeshi Muslim protagonist and the most negative attributions about an Indian Hindu protagonist. Attributions made about Bangladeshi Hindus and Indian Muslims were, however, significantly more positive than those made about Indian Hindus.

In sum, intergroup attributional biases arise because of our motivation to maintain a positive social identity, and these biases contribute to the maintenance and exacerbation of conflict between groups. Research has shown, however, that changing our perceptions of intergroup categories through cross-categorization can lead to reductions in intergroup attribution biases. This research therefore makes an important contribution to our understanding of how intergroup relations can be improved.

## AUTHORITARIAN PERSONALITY

---

Why would a progressive society line up behind a ruler who invades other nations unprovoked? What would lead ordinary people to carry out orders that risked their nation's future in order to commit genocide? Nazi Germany posed such questions to many social scientists. *Authoritarian personality theory* (APT), based in psychodynamic theory, was developed to explain these behaviors and their psychological underpinnings. Studies based on APT have shown that prejudice is related to the outlook of the people who hold such views rather than to characteristics of the groups they disdain. Thus the social significance, testable hypotheses, and intellectual ambition of APT has drawn much attention and criticism and inspired a wide variety of new research. In addition, the cross-culturally robust association of authoritarianism with prejudice, stereotyping, political attitudes and behavior, and social and political values continues to inspire research in personality and social psychology, political science, sociology, and political psychology. This entry examines the concept, supporting evidence, criticisms, and responses to these critiques.

### Historical and Theoretical Context

During World War II, scholars Theodor Adorno and Elsa Frenkel-Brunswik, who were German refugees, joined American psychologists Daniel J. Levinson and R. Nevitt Sanford at the University of California, Berkeley. The group was given funding from the American Jewish Committee to research the psychological roots of anti-Semitism. However, their study became substantially broader, representing the intellectual ambition to solve major societal problems by understanding the interplay of human development, psychology, and societies. Their theorizing incorporated two predominant schools of thought: psychodynamics, and culture and personality, and it addressed relations within families, between groups, and between leaders and their societies. Participants in this research included professional men and women,

homemakers, longshoremen, civic volunteers, veterans, psychiatric patients, and prisoners, among others, from the West Coast of the United States. For this reason, the research taught Americans much about their own authoritarianism and prejudice.

The Frankfurt/Berkeley school, as the group was called, viewed following hateful authorities as being at least as problematic as hateful leadership itself, for without assent and cooperation, what power does a leader have? Their approach was thus one of the first to prioritize understanding mass political psychology. According to the authoritarian personality theory (APT) that Adorno, Frenkel-Brunswik, Levinson, and Sanford published in *The Authoritarian Personality* in 1950, three elements are necessary to produce an authoritarian personality: (1) being raised in a culture that vilifies certain groups (e.g., European anti-Semitism and U.S. racism), (2) needing to be loved by one's parents, and (3) having parents who are punitive and unaffectionate.

The psychodynamic process states that when parents scorn their children, children adopt the prejudices of their parents and society in an attempt to become pleasing to their parents. As children try to gain moral acceptability by obeying authorities who are prejudiced, they adopt the predilections for conformity, blind submissiveness to authority, and intolerance of difference. This makes them especially vulnerable to messages from authorities that denigrate the weak and the deviant. In expressing such prejudices, children can view themselves as acceptable. Hence, the combination of psychological motivations, the cultural context of prejudicial ideologies, and particular family practices account for how cultures transmit prejudice across generations.

### Evidence of the Authoritarian Personality

Interview studies of adults by Elsa Frenkel-Brunswik attempted to explicate these psychodynamic processes. Such evidence is now met with skepticism because of concerns about retrospective memory and interviewer biases. However, the existence of an authoritarian "personality," or syndrome of traits, including conformity, submission, and intolerance, was demonstrated with standard personality techniques, including interviews, projective tests, and extensive scale development.

Adorno and his colleagues' research, especially that of Daniel Levinson, showed that people differ reliably from one another in the general tendency to be prejudiced. That is, those scoring high on the F-scale (fascism scale) also tended to score high on anti-Semitism scales; on generalized ethnocentrism scales that tap prejudice against "Negroes," Mexicans, Japanese, "Okies," immigrants, and foreigners; and on scales measuring patriotism and political-economic conservatism. In fact, prejudiced individuals are likely to endorse logically contradictory statements, so long as the statements indicate culturally normed disdain for members of excluded groups. For example, Adorno and his colleagues found that authoritarians are likely to endorse both of these anti-Semitism scale statements: "Districts containing many Jews always seem to be smelly, dirty, shabby, and unattractive" and "Jews seem to prefer the most luxurious, extravagant, and sensual way of living." Such findings suggest that authoritarianism does not stem from rational beliefs, but rather from motivation or cognitive style.

Prejudiced people often feel that their perceptions and feelings about denigrated groups stem from qualities of denigrated groups themselves. But research on authoritarianism has documented that people prejudiced against one group tend to be prejudiced against other groups who are disrespected in their societies. This finding provides a completely different interpretation of the cause of prejudice than that of naïve psychology. Rather than prejudice being due to properties of the vilified group, such as their immorality or crudeness, it means that prejudice stems from the psychological outlook of the perceiver. This finding therefore provides psychology with an agenda to research what, exactly, that outlook is and how it works.

### Criticisms of Authoritarian Personality Theory

In fact, the finding that certain individuals are more robustly prejudiced, conservative, insecure, and punitive than others had been empirically documented early in the 20th century by pro-Nazi researchers (e.g., Jaensch) and anti-Nazi (e.g., Lenski) researchers in Europe and the United States. APT attracted both more attention and more criticism than that research. This may be because both world wars showed the costs of intergroup hate,

but also because of APT's moral and political implications and of developments in psychological theorizing and research methods.

One major criticism of APT concerns the validity of its personality measures. Richard Christie and Marie Jahoda, among others, have noted that the scales developed by Adorno and his colleagues are not balanced with equal numbers of protrait and contrait items. That is, the scales contain only items with which someone highly authoritarian would agree. For this reason, it is unclear whether the scales simply measure authoritarianism as *response acquiescence* (the tendency to simply agree with statements), or whether the contents of the scales matter. Further, this measurement problem can inflate correlations among different scales because if some participants are "yay-sayers" and others are "nay-sayers," that would produce positive correlations among different scales regardless of item content.

Another kind of criticism is both political and theoretical. People who view patriotism and conservatism as prosocial and moral may be discomfited by the finding that patriotism and conservatism correlate strongly with forms of prejudice the West came to disapprove of following the Nazi genocide, such as anti-Semitism and anti-Black racism. Scholars including Edward Shils and Milton Rokeach think that extreme intolerance could be exhibited on both ends of the political spectrum, and they believe that communists, for example, should score high on intolerance. In fact, Adorno and his colleagues had postulated the same idea, but they found no empirical evidence for left wing authoritarianism. In 1960, Milton Rokeach proposed the D-scale (dogmatism scale) as an alternative to the F-scale in an attempt to capture intolerance among both right and left wingers, but found comparable empirical results for the F-scale and the D-scale.

Another criticism of APT is that there is very little evidence for the psychodynamic processes it posits. In fact, there is evidence against the hypothesis that punitive parents produce authoritarian children. From the 1950s on, as psychology came to insist on empirical evidence and experimentation and reject the unobservable unconscious processes associated with Freudianism, more psychologists were ready to disregard Elsa Frenkel-Brunswick's psychodynamic research and Theodor Adorno's rejection of positivism.

Finally, the research focus of APT on individual differences produces a logical contradiction: How can normative prejudice in a society be explained by features that only some people in that society have? Tom Pettigrew's 1958 dissertation examined racism among South African and American Whites and showed that authoritarianism does little to explain racist behavior when racism is normalized in a culture. This criticism led many social psychologists to reject consideration of individual differences in prejudice. It can also be said that APT does not answer important questions about the culture of prejudice, such as why particular groups get vilified in the first place, why prejudice against the same group rises and falls, nor how prejudicial ideologies may change or spread outside of socialization, although answers to such questions are still being generated. Despite including some progressive theorizing about gender, *The Authoritarian Personality* shares a cultural shortcoming with its contemporaries: It did not develop a sexism scale as an aspect of group prejudice.

### Responses to Criticisms

After decades of neglect, the major questions raised by authoritarian research concerning the normativity of prejudice, how psychological motives lead to prejudice, how prejudice is socialized, and the relation of culture to intergroup relations have been reconsidered by a wide variety of scholars.

#### *Scale Redevelopment*

Canadian psychologist Bob Altemeyer reviewed research on authoritarianism and determined that the most central elements of the authoritarian syndrome were authoritarian submission, conventionalism, and authoritarian aggression. He developed balanced scales called Right Wing Authoritarianism (RWA) that include all three concepts and are reliable, valid, and widely used around the world. RWA corresponds to the public's political behavior, including voting in many societies. The scales have distinguished among the voting records of North American legislators, evidence that connects authoritarianism with national leadership.

#### *Scale Balance and Left Wing Authoritarianism*

Altemeyer also tried to develop a left wing authoritarian measure, but in convenience samples

it does not show parallel patterns with RWA. Reviews by William Stone corroborate the fact that authoritarianism and the tendency to be prejudiced against groups characterizes conservatives more than liberals. In the Soviet Union and satellite nations, Walter Stephan and his colleagues have shown that those higher on RWA were more likely to endorse communism and the Communist Party, consistent with the idea that authoritarians conform to the norms promoted by authorities in their societies. Recently, Alain van Hiel and his colleagues found that extreme left wing activists in Western Europe have very high scores on a new left wing authoritarianism scale, and this correlates with liberal economic views.

#### *Psychodynamics and Personality Development*

Consistent with the psychodynamic view, but also with other socialization and genetic development theories, Altemeyer showed that people within families have similar levels of authoritarianism. More recently, Christopher Weber and Christopher Federico have shown that RWA corresponds with anxious attachment. In terms of general personality, studies in several countries show that RWA correlates with being less open to experience and more conscientious. Thus, although APT appears wrong in the particulars concerning socialization, authoritarianism does correspond with people's orientations toward close relationships and their temperament.

#### *Other Conceptualizations*

Rather than accept the description of authoritarianism as a prejudice *syndrome* or as essentially *political*, theorists have sought to identify its core psychology by emphasizing either a socioemotional or cognitive orientation. Those with a socioemotional orientation have conceived of authoritarianism as whether an individual is tough-minded or tender-minded (Ted Goertzel, Hans Eysenck), is easily threatened (David Winter, Bill Petersen), is uncomfortable and unsuccessful with personal autonomy (Detlef Oesterreich), sees conformity as the means to social order (Stanley Feldman), or perceives the world to be a dangerous place (John Duckitt). The psychological habits that may underlie generalized conservatism and prejudice may include fear of uncertainty (Michael

Hogg), intolerance of ambiguity (Glenn Wilson), cognitive rigidity (Richard Christie), need for cognitive closure (Arie Kruglanski), and closed-mindedness (Milton Rokeach). John Duckitt's conception of authoritarianism also addresses how different elements of cultural context may be important in the development of authoritarianism. Duckitt argues that in more collectivist societies, conformity is emphasized, and along with the presumption that the world is threatening, this context should especially lead to the development of authoritarianism. Correlational models in several countries are consistent with this theory. Finally, Phil Tetlock and Jim Sidanius have each developed approaches to political cognition to account for extremes on both the right and the left.

### Authoritarianism and Culture

Authoritarianism in individuals correlates robustly across nations with their right wing political affiliation and voting, prejudice against women, gays, immigrants, foreigners, and subordinated ethnic and religious groups. Cultures can also be considered more or less authoritarian, and can become more or less authoritarian depending on how insecure they are. For example, cultures that privilege conformity and hierarchicality are considered by some to be more authoritarian, and periods of war may produce more authoritarian behavior, as seen in content analyses of popular culture, endorsement of leaders, and voting patterns. Authoritarianism may be conducive to certain aspects of group living, such as cooperation and ingroup identification.

## AVERSIVE RACISM

---

*Aversive racism* is a form of bias that is not overtly expressed but may reflect the attitudes of a substantial portion of people in societies that have strong egalitarian traditions and norms. Much of the research on aversive racism has focused on the orientation of Whites toward Blacks in the United States, but similar attitudes have been found among members of dominant groups in other countries with strong contemporary egalitarian values but discriminatory histories or policies. In contrast to the traditional form of racism, which is expressed openly and directly, aversive racism operates in subtle and indirect ways. For example, the negative feelings that aversive racists have toward Blacks do not manifest themselves in open hostility or hatred. Instead, aversive racists' reactions may involve discomfort, anxiety, and/or fear. That is, they find Blacks "aversive," while at the same time rejecting any suggestion that they might be prejudiced. Despite its subtle expression, aversive racism has consequences that are as significant and pernicious (e.g., the restriction of minorities' economic opportunities) as those of the traditional, overt form. This entry provides a fuller description of aversive racism and its expressions, then looks at strategies for combating it.

### Nature of the Attitudes

A critical aspect of the aversive racism framework is the conflict between aversive racists' denial of personal prejudice and underlying unconscious negative feelings toward and beliefs about particular minority groups. For example, because of current cultural values in the United States, most Whites have strong convictions concerning fairness,

justice, and racial equality; however, because of a range of normal cognitive, motivational, and sociocultural processes that promote intergroup biases, most Whites also have some negative feelings toward or beliefs about Blacks. They may be unaware of these feelings or try to deny them to retain a self-image as unprejudiced, but when engaged in social categorization, for example, they will find that their cultural stereotypes are spontaneously activated.

### *Identifying Aversive Attitudes*

Generally, aversive racists may be identified by a constellation of characteristic responses to racial issues and interracial situations. First, aversive racists, in contrast to old-fashioned racists, endorse fair and just treatment of all groups. Second, despite their conscious good intentions, aversive racists unconsciously harbor feelings of uneasiness toward those of other races (e.g., Blacks) and thus try to avoid interracial interaction. Third, when interracial interaction is unavoidable, aversive racists experience anxiety and discomfort, and consequently they try to disengage from the interaction as quickly as possible. Fourth, because part of the discomfort that aversive racists experience is due to a concern about acting inappropriately and appearing prejudiced to themselves and others, aversive racists strictly adhere to established rules and codes of behavior in interracial situations that they cannot avoid. Finally, their feelings will get expressed, but in subtle, unintentional, rationalizable ways that disadvantage minorities or unfairly benefit the majority group. Nevertheless, in terms of conscious intent, aversive racists intend not to discriminate against people of color—and they behave accordingly when it is possible for them to monitor the appropriateness of their behavior.

Recent research in social cognition has yielded new techniques—such as the Implicit Association Test, which uses response times to pairs of stimuli—for tapping the “implicit” stereotypic or evaluative (e.g., good–bad) associations that people have toward other groups, but possibly without full awareness. These techniques are very useful for distinguishing between aversive racists, who endorse egalitarian views and unprejudiced ideologies but harbor implicit racial biases, and unprejudiced people, who also endorse egalitarian values

but do not have significant implicit prejudice or stereotypes. Consistent with the aversive racism framework, whereas the majority of Whites in the United States appear “nonprejudiced” on self-report (explicit) measures of prejudice, a very large proportion of Whites also demonstrate implicit racial biases. Overall, studies have found that Whites’ generally negative implicit attitudes and stereotypes are largely dissociated from their typically more positive overt expressions of their attitudes and beliefs about Blacks.

The aversive racism framework also helps to identify when discrimination against Blacks and other minority groups will or will not occur. Whereas old-fashioned racists exhibit a direct and overt pattern of discrimination, aversive racists’ actions may appear more variable and inconsistent. Sometimes they discriminate (manifesting their negative feelings), and sometimes they do not (reflecting their egalitarian beliefs). Nevertheless, their discriminatory behavior is predictable.

### *Predicting Aversive Behavior*

Because aversive racists consciously recognize and endorse egalitarian values and because they truly aspire to be unprejudiced, they will *not* act inappropriately in situations with strong social norms when discrimination would be obvious to others and to themselves. Specifically, studies have shown that when they are presented with a situation in which the normatively appropriate response is clear, in which right and wrong are clearly defined, aversive racists will not discriminate against Blacks. In these contexts, aversive racists will be especially motivated to avoid feelings, beliefs, and behaviors that could be associated with racist intent. Wrongdoing of this type would directly threaten their image of themselves as nonprejudiced.

Aversive racists still possess unconscious negative feelings and beliefs, however, which will eventually be expressed in subtle, indirect, and rationalizable ways. For instance, discrimination will occur in situations in which the normative structure is weak, the guidelines for appropriate behavior are vague, or the basis for social judgment is ambiguous. In addition, discrimination will occur when an aversive racist can justify or rationalize a negative response on the basis of some factor other

than race. Studies show that under these circumstances, White aversive racists may engage in behaviors that ultimately harm Blacks, but in ways that allow the racists to maintain their self-image as unprejudiced and that insulate them from recognizing that their behavior is not color-blind.

Evidence in support of the aversive racism framework comes from a range of paradigms. For instance, White bystanders who are the only witnesses to an emergency (and thus are fully responsible for helping) are just as likely to help a Black victim as a White victim. However, when White bystanders believe that others also witness the emergency (distributing the responsibility for helping), they are less likely to help a Black victim than a White victim. In personnel or college admission selection decisions, Whites do not discriminate on the basis of race when candidates have very strong or weak qualifications. Nevertheless, they do discriminate against Blacks when the candidates have mixed qualifications. In these circumstances, aversive racists weigh the positive qualities of White applicants and the negative qualities of Black applicants more heavily in their evaluations, which provide justification for their decisions.

Analogously, aversive racists have more difficulty discounting incriminating evidence that is declared inadmissible when evaluating the guilt or innocence of Black relative to White defendants in studies of court decisions. In interracial interactions, Whites' overt behaviors (e.g., verbal behavior) primarily reflect their expressed, explicit racial attitudes, whereas their more spontaneous and less controllable behaviors (e.g., their nonverbal behaviors) are related to their implicit, generally unconscious attitudes.

### Combating Aversive Racism

Traditional prejudice-reduction techniques have been concerned with changing conscious attitudes—old-fashioned racism—and obvious expressions of bias. Attempts to reduce this direct, traditional form of racial prejudice have typically involved educational strategies to enhance knowledge and appreciation of other groups (e.g., multicultural education programs), emphasize norms that prejudice is wrong, and involve direct (e.g., mass media appeals) or indirect (dissonance reduction) attitude change techniques. However, because aversive racism is pervasive, subtle, and complex, the traditional techniques for eliminating

bias that focus on the immorality of prejudice and illegality of discrimination are not effective for combating it. Aversive racists recognize that prejudice is bad, but they may not recognize that *they* are prejudiced.

Nevertheless, aversive racism can be addressed with techniques aimed at its roots at both the individual and collective levels. At the individual level, strategies to combat aversive racism can be directed at unconscious attitudes. For example, extensive training to create new, counterstereotypical associations with social categories (e.g., Blacks) can inhibit the unconscious activation of stereotypes, an element of aversive racists' negative attitudes. In addition, aversive racists' conscious attitudes, which are already favorable, can be instrumental in motivating change. Allowing aversive racists to become aware, in a non-threatening way, of their unconscious negative attitudes, feelings, and beliefs can stimulate self-regulatory processes. Such processes not only elicit immediate deliberative responses reaffirming conscious unprejudiced orientations (such as increased support for policies that benefit minority groups), but also produce, with sufficient time and experience, reductions in implicit negative beliefs and attitudes.

At the intergroup level, interventions may be targeted at processes that support aversive racism, such as ingroup favoritism. One approach, represented by the *common ingroup identity model*, generally proposes that if members of different groups are induced to conceive of themselves more as an alternative single, superordinate group rather than as two separate groups, attitudes toward former outgroup members will become more positive through processes involving pro-ingroup bias. Thus, changing the basis of categorization from race to an alternative dimension can alter who is grouped as "us" and who is grouped as "them," undermining a contributing force for contemporary forms of racism, such as aversive racism.

For instance, Black interviewers are more likely to obtain the cooperation of White respondents when they emphasize their common group membership (such as shared university identity, as indicated by insignia on their clothes) than when they do not. Intergroup interaction within the guidelines of the contact hypothesis (i.e., the idea that contact between groups improves intergroup relations) and antibias interventions with elementary schoolchildren that emphasize increasing their circles

of inclusion can also reduce bias through the processes outlined in the common ingroup identity model.

The manifestations of aversive racism are more subtle than are those of old-fashioned racism, but aversive racism has consequences as significant as blatant bias. Even though it is expressed in indirect and rationalizable ways, it operates to systematically restrict opportunities for Black members of other traditionally underrepresented groups. In addition, because aversive racists may not be aware of their implicit negative attitudes and only discriminate against Blacks when they can justify their behavior on the basis of some factor other than race, they will commonly deny any intentional wrongdoing when confronted with evidence of their bias. To the extent that minority group members detect expressions of aversive racists' negative attitudes in subtle interaction behaviors (e.g., non-verbal behavior) and attribute the consequences of aversive racism to blatant racism, aversive racism also contributes substantially to interracial distrust, miscommunication, and conflict.

Nevertheless, aversive racism can be addressed by encouraging increased awareness of unconscious negative feelings and beliefs, emphasizing alternative forms of social categorization around common group membership, and providing appropriate intergroup experiences to support the development of alternative implicit attitudes and stereotypes and reinforce common identities.

## BANALITY OF EVIL

---

A recent morning's newspaper had a charming snapshot of a laughing soldier playing an accordion, surrounded by equally cheerful, laughing women, all clearly having a carefree time of it. But the reader soon discovers a shocking fact. It is a photo of a playful off-duty moment for the staff of the Auschwitz death camp, which came from a photo album documenting many such ordinary moments. The article's author, Neil Genzlinger, comments that "yes, the genocide was conducted by real human beings who kicked back after a day's work, flirted with the ladies, shared a joke, played with the dog" (2008, B14).

The reader's shock is much like the reaction that Hannah Arendt had observing the war crimes trial of the Nazi Adolph Eichmann. Arendt was surprised, disconcerted, deeply unsettled. She expected the man, who had sent countless Jews to their deaths, to look and act evil, to embody "evilness." But instead she was struck by his *ordinariness*, his *depthless normality*. Her book *Eichmann in Jerusalem* characterized this as the "banality of evil."

The book initially generated a storm of controversy from those who thought Arendt was trivializing the evils that the Third Reich committed. Now it is read as calling attention to the fact that when acts of evil are committed by an organization, the various actors in the organization will not show all, or even many, of the personal characteristics that a single individual perpetrating similar

evil actions would manifest. They seem like rather ordinary people.

Assume that this realization is true. The disturbing consequence of this realization is that large-scale actions of evil, such as genocide, do not require large armies of evil individuals to carry them out. Instead, ordinary people can become entrained in the processes that produce the evil outcomes and thereby make those terrible outcomes possible. Two questions need to be asked here: How is it that these ordinary people become enlisted in the process, and what are the consequences for them of their enlistment? Psychological theory and research provide at least partial answers to both of these questions.

In psychology, the "banality of evil" notion has become linked to the famous experiments by Stanley Milgram, which are described in the entry "Obedience to Authority." Coincidentally, both *Eichmann in Jerusalem* and the first reports of the Milgram research appeared in 1963, so the world faced the ordinariness of the Nazi functionary Eichmann at about the time it faced the fact that, if ordered to do so, many ordinary citizens of New Haven, Connecticut, were willing to administer presumably dangerous, perhaps life-threatening, shocks to another person in a learning experiment. (The use of *presumably* here is important. Many descriptions of the Milgram experiment ignored various cues that it was, in fact, acceptable for the respondent to continue giving the shocks because the experimenter had asserted that the shocks would be painful "but cause no permanent damage.") Later, Philip Zimbardo's well-known

Stanford prison experiment (described in the entry of that name) was read as showing that undergraduate students, role-playing prison guards in a realistic simulation of a prison environment, were also willing to engage in quite cruel actions toward other students who were in the prisoner role. This added a distressing new element to the findings of the Milgram studies. In the Milgram studies, the respondents' actions were those that they were directed to take by the experimenter, who was present to see that they obeyed his orders. In contrast, the students in Zimbardo's experiment themselves designed and then independently enacted many of the cruel actions that were taken. That evil actions were within the repertoire of at least many people seemed well established.

Certainly Milgram thought so. In a letter to the sponsor of his research, Milgram wrote:

In a naïve moment some time ago, I once wondered whether in all of the United States a vicious government could find enough moral imbeciles to meet the personnel requirements of a national system of death camps, of the sort that were maintained in Germany. I am now beginning to think that the full complement could be recruited in New Haven. A substantial proportion of people do what they are told to do, irrespective of the content of the act, and without pangs of conscience, so long as they perceive that the command comes from a legitimate authority. (quoted in Blass, p. 100)

For Americans, this unpleasant conclusion has received intermittent confirmation: My Lai and Abu Ghraib are familiar names. However, many social psychologists would contest a generalization about the ease with which people could be brought to harm others. They would point to some more particular aspects of the Milgram experiments that perhaps allowed the respondent to continue to administer the shocks because those shocks were not going to do permanent harm to the person receiving them. One key to understanding the Milgram situation is this: When the learner protested and asked that the experiment be stopped, the experimenter heard this as well as the respondent, and the experimenter instructed that the experiment continue. Respondents would probably read this as telling them that the learner wasn't

really being hurt, and this sort of reassurance from a person who was assumed to have expertise about this enabled some respondents to continue. The importance of this expert reassurance was demonstrated by Milgram himself. In one condition, Milgram arranged to have the regular experimenter called out of the room while the earlier shocks in the series were given. The experimenter asked another respondent, who had been doing a record-keeping job, to take his place and continue the experiment. That person, who was actually a confederate of Milgram's, told the teacher to continue administering the shocks. At some point in the learner's protests, the typical respondent refused to continue; this experimenter did not have the expertise to provide valid assurances that continuation was safe. A further interesting response was shown by several of these respondents. The replacement experimenter stepped to the shock generator, announcing that if the respondent would not continue the process, then he would. These respondents moved to restrain the experimenter from doing so, thereby protecting the learner from harm! Suddenly a very different image of the respondents emerges. In a similar fashion, one could point to several elements of Zimbardo's study that were critical to producing the disturbing behavior of his student guards.

So it is possible to contend that the Milgram and Zimbardo studies' subjects were not displaying the sort of full-blown evil behavior that Eichmann displayed. This said, a disturbing possibility remains. Had those individuals remained in the experimental contexts over longer time periods, they might have become habituated to what they were doing, and their ethical concerns might have faded away as they adapted to their tasks. Or they might have dehumanized the victims by attaching labels such as "rodents" to them. Or they might have cast them as members of outgroups who threatened the existence of the ingroup. By means of these mechanisms, they would eventually do voluntarily and independently what they were coerced to do by the situations in which they found themselves. They might, in other words, have moved toward becoming evil-doers.

An insight can be drawn from this. The hierarchical social components of organizations can be structured in ways that bring about tremendously destructive harm to individuals. Of course, we

know that this is possible when the organization's leaders seek to bring about this harm. That is what the Nazi regime of Adolph Hitler and his collaborators has shown us. What we must now realize is that organizations can drift into harm-doing practices even without most individuals in the organizations desiring that this come about.

How this occurs is a topic that social psychologists are now studying, both experimentally and in observational studies. They begin with the understanding that people seek to discover how to conduct themselves in organizations by observing the actions of the people around them. This is a version of what social psychologists call the *situational perspective*. In the organizational instance of this perspective, people look to other, more experienced people to "see how we do things here." When they do this, how others behave may lead them ethically astray, and they may not become aware of it. Organizations can fragment tasks and parcel them out among different individuals so that no one individual is aware that the sum of the fragments produces harmful outcomes. Also, contagion phenomena can exist. Suppose others are "making their numbers" by committing actions that the new person thinks are ethically bad. But suppose that the new person also sees that these rule-bending individuals are getting bonuses and promotions from their superiors. It will be very hard for the new person to resist the temptation to bend the rules. This in turn may lead to escalating pressures in which rule bending turns to rule breaking.

## BLACK SHEEP EFFECT

---

In everyday language, a "black sheep" is a group member who is undesirable and stands out from the group in such a way as to attract disapproval from the rest of the group. In social psychology, the term *black sheep effect*, coined by José Marques, refers to a more specific phenomenon in which someone who is socially undesirable (unlikable) is liked less if he or she is a member of your group (an ingroup member) than if he or she is a member of a group to which you do not belong (an outgroup member). Conversely, someone who is socially desirable (likable) is liked more if he or she is a member of your ingroup rather than a member of an outgroup. Put another way, socially desirable ingroup targets are judged more favorably than socially desirable outgroup targets, while socially undesirable ingroup targets are judged less favorably than socially undesirable outgroup targets. Likable and unlikable ingroup members are judged more extremely than likable and unlikable outgroup members.

The black sheep effect usually emerges in association with a more favorable evaluation of the ingroup than the outgroup as a whole (*ingroup bias*). The black sheep effect is also more pronounced (a) if the person doing the judging identifies strongly with his or her ingroup, (b) if the dimension on which the target is evaluated is highly relevant to establishing an overall favorable evaluation of the ingroup in comparison to a relevant outgroup, and (c) if the situation is one in which intergroup differentiation in favor of the person's ingroup is important.

### Social Identity and Ingroup Favoritism

Explanation of the black sheep effect draws on social identity theory and self-categorization theory. One basic assumption of these theories is that, with few exceptions, when group membership is salient (when it is the psychological basis of information processing, self-conception, and behavior), people engage in ingroup-serving perceptual and judgmental biases and hold partisan intergroup attitudes. This ingroup favoritism generates ethnocentrism and leads people to prefer ingroup members and features to outgroup members and features. It is not surprising, then, that people evaluate ingroup members in general, and socially desirable ingroup members in particular, more favorably than similar outgroup members.

From this, one might suppose that overall one would favor a socially desirable or undesirable ingroup member over a socially desirable or undesirable outgroup member; after all, ingroup members should be favored over outgroup members. This is where the black sheep effect is counterintuitive and in conflict with social identity theory—as indicated above, socially undesirable ingroup members are disliked more than socially undesirable outgroup members.

Proponents of the black sheep effect believe that this conflict is only apparent. They argue that socially desirable ingroup members support the ingroup's overall positive image and thus attract positive reactions from other members of the group, whereas socially undesirable ingroup members undermine such an image and thus attract negative reactions. Rather than being in contradiction to the social identity framework, the black sheep effect corresponds to a more sophisticated form of ingroup favoritism. By derogating unlikable ingroup members, people are protecting, and thus promoting, the positive image of the ingroup as a whole.

### Subjective Group Dynamics

José Marques, Dario Paez, and Dominic Abrams have recently developed the subjective group dynamics model to explain the cognitive and motivational antecedents of the black sheep effect. This model proposes that people's reactions toward socially undesirable (or deviant) ingroup members involve two interrelated processes.

First, and as proposed by social identity theory, people attempt to establish a clear-cut difference

between ingroup and outgroup categories. In pursuit of positive differentiation of the ingroup as a whole from the outgroup, people adopt a *descriptive focus*, in which they focus on and emphasize intergroup differences and pay little attention to intragroup differences. A descriptive focus directs attention to those characteristics of a person (e.g., born in Lisbon, Portugal) that allow category assignment (e.g., this person is more likely to be Portuguese than British) rather than to characteristics that allow one to determine whether the person is likable or unlikable.

However, in some situations, there may be salient ingroup members who display behaviors that conflict with the expectations associated with a positive ingroup image—for example, dishonest members of a political party, traitors, or otherwise socially undesirable ingroup members. In this context, people adopt a *prescriptive focus*. This focus directs attention to characteristics that are imbued with value but are not associated with a particular social category (e.g., being dishonest). Thus, a prescriptive focus allows one to determine whether a person is socially desirable or undesirable but does not allow one to determine the social category to which he or she belongs (e.g., whether the person is British or Portuguese).

While adopting a prescriptive focus, people react favorably toward ingroup members whose behavior supports their conviction that the ingroup is “right” or is “better than” the outgroup. Concomitantly, people react negatively toward “deviant” ingroup members because their behavior departs from standards that sustain the perceived relative superiority of the ingroup (i.e., the ingroup's subjective validity). Outgroup members, whether socially desirable or socially undesirable, are much less relevant to the definition of the ingroup's identity, and thus they invite less extreme reactions. The black sheep effect, therefore, ensues from an internalized social influence process in which people subjectively reinforce their confidence in the ingroup by upgrading normative members and derogating deviant members in an attempt to reestablish the group's positive social identity.

### Empirical Evidence

Research has supported the above analysis. For instance, in one study it was found that Belgian

students, presented with likable or unlikable Belgian or North African target students, judged the likable Belgian targets more positively than the likable North African targets and the unlikable Belgian targets more negatively than the unlikable North African targets. Also, law students evaluated a good performance by another law student more positively than a similar performance by a philosophy student and evaluated a poor performance by a law student more negatively than a similar performance by a philosophy student.

In a similar vein, high school students evaluated likable students from their own school more positively than similar students from a rival school and evaluated unlikable students from their own school more negatively than similar students from a rival school. In addition, the black sheep effect generally co-occurred with more favorable evaluations of the ingroup than the outgroup as a whole.

Research has also shown that the black sheep effect occurs only when what defines group members' social desirability is deemed relevant for generating positive differentiation between the ingroup and outgroup. For example, if the ingroup is a soccer team, being a good athlete will matter more to its members than being a good musician. Other research has shown that participants who identify strongly with their group are more favorable toward likable and less favorable toward dislikable ingroup members than toward similar kinds of outgroup members. This is not the case with participants who either identify weakly with their group or are allowed to subjectively leave that group by disidentifying with it.

Other research directly supports tenets of the subjective group dynamics model. For example, there is evidence that people upgrade likable others and derogate unlikable others when these others are perceived as ingroup members. The effect does not occur when the targets are described as simply interpersonally similar to, or different from, the participants or are described as outgroup members. This supports the idea that the black sheep effect indeed emerges as a consequence of the perceived interdependence of self and ingroup members for the maintenance of a positive social identity.

In a similar vein, there is evidence that evaluations are particularly extreme in the case of norms that are central to and legitimize the group's existence—in comparison to outgroup members,

ingroup members who uphold such norms are particularly favorably evaluated, while those who deviate from the norms are particularly unfavorably evaluated.

## BOUNDARY SPANNING

---

Every group or social system has a boundary that separates it from other groups or systems and defines who is in the group and who is outside of it. *Boundary spanning* represents the actions that are taken by members of a group to manage those

boundaries, particularly interactions with outsiders. Boundary-spanning activities may be a formal part of some individuals' jobs or informally carried out by members of the group. How a group manages its boundaries has implications for other group processes and the performance of the group.

Early research on groups within organizations identified two broad functions of boundary spanning—information processing and external representation. *Information processing* involves gathering and assessing data from outside the group and providing summaries and conclusions to members of the group. *External representation* has to do with providing information to outsiders and trying to shape their perceptions of the group. More recent research has divided these broad categories into specific functions, such as *mapping* (building a model of the external environment), *filtering* (keeping troubling information from the group), and *negotiating* (developing goals and schedules). Scholars have argued that the optimal amount of boundary spanning is related to the uncertainty of environment in which the group operates and the nature of the technology it uses.

One of the important effects of boundary spanning concerns the permeability of the boundary of the group. *Permeability* refers to the ease with which information and resources can pass into and out of the group. The permeability of the group's boundary can affect the group's processes and potentially its performance. On the one hand, if a group has too few or overly restrictive interactions with outside groups, the group can become "overbounded." If this is the case, the group may become isolated and detached from the environment. This can lead to isolation, inaccurate perceptions of other groups, and ineffective internal group processes, such as "groupthink." On the other hand, if a group becomes "underbounded" by having such a porous boundary that interactions with outsiders become predominant, the group may have difficulty developing cohesiveness, establishing shared commitments, and agreeing on a common course of action.

Not surprisingly, much of the research on boundary spanning has been conducted with groups in organizations. For many such groups, such as engineering groups or product development teams, interactions with other groups are critical for successfully performing their tasks;

thus, some of the most fine-grained analyses of boundary-spanning activities have been conducted with these groups.

One comprehensive study of boundary-spanning activities in product development teams identified four categories of activities. One set of activities, termed *ambassador activities*, was directed primarily toward upper levels of the organization and focused on protecting the team from outside pressure, persuading others to support the team, and lobbying for resources. The second set of activities, labeled *task coordinator activities*, included such things as resolving product specifications, obtaining feedback on the new design, and negotiating solutions for coordination problems. The third set, described as *scout activities*, related to general scanning of the external environment as opposed to interactions aimed at addressing a particular issue. In product development groups, examples of scout activities included collecting general technical information and investigating broad market trends inside and outside the organization. The final set of activities, termed *guard activities*, represented internal activities designed to prevent information from leaving the group.

Product development teams that concentrated on ambassador and task coordinator activities and displayed relatively low levels of scout activities were most successful in completing their tasks. Groups with other profiles of activities were less successful. These results illustrate two important points about boundary spanning. First, it is not simply the amount of external interaction that contributes to successfully managing interdependencies. Second, some types of external interactions may contribute to success, while others may not. In particular, very general and unfocused interactions that continue throughout the group's life may make it difficult for the group to concentrate on the specific external interactions necessary to complete work that is highly interdependent.

Some jobs within organizations have formal boundary-spanning responsibilities. The boundaries may be between different groups within an organization or between the organization and outside entities. These types of jobs frequently involve simultaneous negotiations with both entities. A number of factors can influence the approaches boundary spanners take in dealing with their responsibilities, including the boundary spanner's

relations with his or her own group or organization (for example, how much latitude the boundary spanner is given), the relationship between the boundary spanner and the outsider (for example, the history of the interactions between the entities), and the personal characteristics of the boundary spanner (for example, his or her sensitivity to social cues and ability to adapt to different situations).

Research has shown that individuals who hold boundary-spanning positions often experience stress and dissatisfaction because of the conflicting and ambiguous demands they face. However, such positions offer benefits to individuals in terms of career advancement and the opportunity to build relationships within the organization.

## BRAINSTORMING

---

*Brainstorming* is a technique for idea generation in which the focus is on generating as many ideas as possible on a topic in a noncritical fashion. The term is often used for any interaction that involves sharing of ideas, but formal brainstorming typically

follows a set of guidelines or procedures. Research on brainstorming has focused on comparing the effectiveness of group brainstorming and individual brainstorming. This has led to the development of theoretical models of the social and cognitive processes involved in group idea generation. These models have relevance for an understanding of creative processes in a wide range of groups and teams. Research has also provided much useful information for improving the practice of brainstorming in organizations.

Brainstorming provides an interesting example of the various factors that may influence group task performance. One of the major issues in studying groups has been comparing the functioning of groups to appropriate individual performance baselines to determine whether groups are beneficial or harmful for performance. This has been one of the focal issues in group brainstorming research. The research has also provided important insights for optimizing work team performance that involves the sharing of information or ideas.

Brainstorming research has three major goals. One is to discover the causes of production losses in groups. Another is to develop theoretical models of the group creative process. The third is to generate ways to enhance brainstorming in groups and overcome productivity losses. After discussing the foundations of brainstorming, this entry describes all three areas of research.

### History and Background

Brainstorming was initially popularized by Alex Osborn, an advertising executive who published several books in the 1940s and '50s on the creative process. In these books, Osborn highlighted the use of brainstorming in coming up with novel ideas. He argued that it is important for creativity that one refrain from being critical during the idea generation process. To be creative, one has to let one's ideas flow in an unrestrained manner without concern for quality. Expressing a lot of ideas no matter how wild they are increases the likelihood that good ideas will be generated. Any type of negative or evaluative feedback might kill the motivation for unbridled creativity.

Osborn also assumed that group brainstorming is effective because it allows individuals to build on the ideas of others. Osborn's various books helped

popularize brainstorming, and it is still the foundation for much of what passes as group creativity exercises or procedures. For example, IDEO corporation, a top product development company, bases its product development sessions on the principles outlined by Osborn.

Osborn's ideas were based on his own intuitions and experiences of working with groups and individuals in the advertising field. He was also well versed in the general literature on the group creative process, and many of his ideas still have merit. However, controlled studies have challenged one of his claims. He suggested that group brainstorming would be twice as effective as individual brainstorming. At first glance, this prediction seems sensible, because several individuals are likely to be able to generate more ideas than a single individual can. However, a fairer comparison involves a group of people who generate ideas together versus the same number of people who generate ideas by themselves (what is known as a *nominal group*). Research has consistently revealed that interacting groups generate fewer ideas than do nominal groups. For example, a group of four brainstormers might only generate half as many unique ideas as the total number of unique ideas generated by four individual brainstormers. The poorer performance of interacting groups in comparison to nominal groups is termed a *production loss*, because interaction is associated with a loss of productivity relative to the potential of the group members working alone.

### *Explanations for Production Losses*

A variety of factors have been implicated as responsible for productivity losses in brainstorming groups. Research by Michael Diehl, Wolfgang Stroebe, and Bernard Nijstad has supported the role of *production blocking*. These researchers propose that the major problem in group brainstorming is that only one person can speak at a time, blocking the others from sharing their ideas. While one group member is speaking, the other group members may forget their ideas, or they may become less motivated to share these ideas because of the blocking experience. Studies have examined different aspects of this blocking effect and have concluded that not being able to present ideas as they occur is a critical factor to the relatively poor performance of interacting groups.

Another factor that may be important in inhibiting performance in groups is concern about others' reactions to one's ideas, or *evaluation apprehension*. Although brainstorming rules specify that group members should not criticize each other's ideas and should withhold judgment about their quality, individuals in groups may still be concerned about the impression they make on others. People generally have a desire to make a positive impression and hence often censor what they say to maintain such an impression. This kind of behavior is another reason why group brainstorming may be less effective than individual brainstorming.

### *Social Comparison and Brainstorming*

One inevitable feature of group brainstorming is that it allows individuals to compare their rate of performance and overall quality of ideas with those of others. Several studies have highlighted some interesting consequences of this social comparison process. One result of such a process is that the performance of group members may converge in both rate and quality. That is, group members may become more similar over time in their pace of idea generation and the types of ideas they generate. Such convergence is, of course, contrary to the goal of encouraging a wide range of ideas and divergent thinking. The social comparison process can also be involved in production losses. In laboratory groups there appears to be a tendency for social comparison to lead individuals to reduce their efforts and thus lower the overall performance of the group. Another interesting result of social comparison is that group members may perceive their performance as more positive than it really is. Whereas people working alone do not have a reference point for evaluating their performance and thus may feel uncertain about the quality of their performance, people working in groups may discover that they are doing at least as well as others. This in turn may cause them to have an inflated view of their performance.

Research by Bernard Nijstad has suggested that another reason for this inflated perception of performance is the general flow of ideas in groups. In individual brainstorming there is likely to be periodic difficulty in coming up with ideas. In contrast, in groups there are fewer times when no ideas are

being generated since there are multiple potential contributors to the process. Several researchers have sought to demonstrate that group idea exchange can stimulate a higher level of creativity than just individual brainstorming. These researchers generally assume either that social-motivation factors or cognitive stimulation can overcome the inhibiting effects of group interaction.

## Models of Brainstorming

### *Social-Motivational Strategies*

Whenever group members collaborate on generating ideas, various social pressures may motivate them in their search for more creative ideas. Although, as noted above, social comparison can reduce performance, the tendency of individuals to compare their performance with that of others can also motivate them to work harder. Several studies have found that when individuals feel individually accountable or are aware of how well they are doing in comparison to other group members, there is increased motivation and increased generation of ideas. Group members can also be motivated by intergroup competition when they find out that the performance of their group is lower than that of some referent group.

An important factor in the success of groups is the extent to which they set high goals. When someone in authority sets high goals, these goals significantly increase the brainstorming performance of both groups and individuals. One practice that may also be helpful to groups is the use of trained facilitators or explicit rules that can serve as a substitute for facilitators (such as encouraging full participation and discouraging talking about non-task-relevant issues). Although it has been found that group creativity can be enhanced by various motivational factors, similar benefits accrue for individual brainstormers. No studies have found that the level of motivation in groups allows them to exceed the performance of nominal groups.

### *Cognitive Models*

The prediction that group brainstorming should be more effective than individual brainstorming derives from the notion that ideas shared in the group should stimulate group members to think of

additional ideas. This assumption underlies several cognitive models of group brainstorming. Paul Paulus and Vincent Brown have proposed a semantic network model to explain the potential benefits of brainstorming. This model assumes that concepts are stored in long-term memory and are related in a network so that some concepts are more strongly related to one another than to other concepts. Ideas that are shared and have some degree of relatedness to a concept can stimulate that concept and thus make it available for additional ideas.

Some concepts may be more accessible than others and may thus be more easily retrieved during the idea generation process. As a result, it is likely that the initial phases of idea generation will focus on these. However, once these concepts have been tapped to some extent, individuals may increase efforts to search their knowledge base, leading to exploration of somewhat less accessible concepts or categories of ideas. This cognitive model assumes that both attention to shared ideas and memory of these ideas are critical for continued generation of creative ideas in groups.

Several studies have demonstrated the importance of both of these factors in enhancing the stimulating potential of shared ideas. For example, when ideas are presented that are relatively common or typical for a topic, they are remembered better and stimulate the generation of additional ideas more than do relatively unique or atypical ideas. This model also suggests that some of the real benefits of group brainstorming may only be evident after individuals leave the group and have some time to reflect on the shared ideas. The memory of these ideas may stimulate additional ideas during such a time of solitary reflection. This type of effect is sometimes called *incubation*, since it is presumed that ideas stimulated in group interaction may not be fully realized until the individual has had time to let this stimulating effect continue throughout his or her semantic network.

Bernard Nijstad and Wolfgang Stroebe have also developed a cognitive model of brainstorming that focuses on search for ideas in associative memory (SIAM). These researchers emphasize the important role of both long-term memory and working memory—a temporary storage system where one deals with the stored material. This involves a central executive system that actively searches for cues

(the idea retrieval phase) that can then be the basis for a flow of ideas (the idea production loop). When blocking occurs in groups, this may interfere with both stages of this cognitive process.

Although it has some conceptual overlap with the Paulus and Brown model, the SIAM model makes some unique predictions. The SIAM model assumes that transitions from one idea to another within a category will be quicker than transitions from one category to another. Therefore, external stimulation should be helpful for facilitating the change to a new category but not for within-category ideation. This has been found. Also, when individuals experience failures in the search process (by having difficulty coming up with new ideas), they may become dissatisfied with the process and stop. This is less likely in groups in which individuals have fewer failures in coming up with new ideas and therefore enjoy the process and stay with it.

### Ways to Enhance Brainstorming

Based on the two cognitive models, it is not surprising that approaches to brainstorming that limit cognitive interference and maximize attention to ideas from others are most beneficial. That would explain the positive results obtained with brainwriting, which involves the exchange of ideas on pieces of paper. For example, in one study participants in groups of four sitting around a table wrote ideas on pieces of paper. Participants passed each piece of paper to the person on their right for reading and the addition of another idea. When each piece of paper contained four ideas, it was placed in the center of the table. Paul Paulus and Huei-Chuan Yang found that this procedure increased the number of ideas generated by groups by 40% compared to nominal groups of participants who wrote ideas alone. Even more striking, when group participants continued writing ideas in a subsequent solitary session, the group brainstorming experience led to 89% more ideas than the nominal experience. So instead of showing a production loss due to group brainstorming, this study demonstrated a significant production gain.

A more popular approach to overcoming the production loss of group brainstorming has been *electronic brainstorming*, which involves generating ideas by exchanging them on a computer network. The advantage of this system is that it can be

programmed to function in a variety of ways and can include voting and decision-making features. This is sometimes labeled a *group decision support system*. For example, one system provides participants with a window at the bottom of the computer screen in which to generate an idea and then send it to the pool of ideas. Another window at the top displays ideas generated by the group. These ideas are arbitrarily divided into folders, and participants are exposed to the ideas in one of these folders each time they generate an idea. Several studies have found that this kind of exchange of ideas in groups avoids the productivity loss problem. This is not difficult to explain, since there is little production blocking using this procedure—participants can type ideas as they occur. In fact, as groups increase in size, there tends to be an enhanced productivity compared to similar-size nominal groups. Most studies indicate that this enhancement occurs when group size reaches eight or more.

Although the reduction of production blocking appears to be a straightforward explanation for part of the benefit of brainwriting and electronic brainstorming, it cannot explain the production gains. However, these gains can be explained by social motivational and cognitive mechanisms. The brainwriting procedure enhances the degree of accountability and may produce a sense of competition in groups, which in turn may motivate group members to work harder and persist longer than solitary brainwriters. Electronic brainstormers are typically anonymous, so the accountability factor cannot explain their productivity. There may, however, be an increased sense of competition as group size increases with the larger number of ideas being shared in the folders.

In most of these studies, the participants were in the same room, so social facilitation may have increased the motivation level in the larger groups. It is also possible that the shared ideas in brainwriting and electronic brainstorming provide cognitive stimulation. With increased group size, there is increased exposure to novel ideas. A factor that may be important is the extent to which the procedure insures attention to the shared ideas. The brainwriting procedure encourages attention because it requires participants to monitor the ideas. In electronic brainstorming this is not necessary. Participants can ignore the shared ideas and focus only on generating their own.

When participants are encouraged to attend to others' ideas because they expect to be tested on their memory of these ideas, electronic brainstorming with only four participants leads to the generation of more ideas than nominal groups generated. This benefit is maintained in a subsequent solitary ideation session, just as in the case of brainwriting. Thus far, research has not clearly determined the relative importance of the motivational and cognitive factors in brainwriting and electronic brainstorming. It seems likely that both factors contribute to their benefits.

## BYSTANDER EFFECT

The *bystander effect* refers to the inhibiting influence of the presence of others on a person's willingness to help someone in need. Researchers have found that, even in an emergency, a bystander is less likely to extend help when he or she is in the real or imagined presence of others than when he or she is alone. Moreover, the number of others is important, such that more bystanders lead to less assistance, although the impact of each additional bystander has a diminishing impact on helping. The bystander effect is well illustrated by the events surrounding the brutal murder of Kitty Genovese in 1964, which had a major impact on bystander intervention research in particular and helping research in general. After summarizing the Kitty Genovese story, this entry reviews the sequence of decisions a bystander may engage in when encountering a person in need of help, as well as the processes of social influence and diffusion of responsibility that may affect these decisions.

### Kitty Genovese and Bystander Intervention

In the early morning on March 13, 1964, a woman named Kitty Genovese was returning home late from work when a man with a knife viciously attacked and sexually assaulted her in the parking lot of her apartment complex. As reported in the *New York Times*, for over half an hour 38 respectable, law-abiding people heard or saw this man attack her three separate times. The voices and lights from the bystanders in nearby apartments interrupted the killer and frightened him off twice, but each time he returned and stabbed her again. None of the 38 witnesses called the police during the attack, and only one bystander contacted authorities after Kitty Genovese died.

While some details of this story as initially reported have since been contradicted by evidence, the story has become a modern parable for the powerful psychological effects of the presence of others. The story serves as an extreme example of how people sometimes fail to react to the needs of others and, more broadly, how behavioral tendencies to act prosocially are greatly influenced by the situation. Moreover, this tragic event sparked a good deal of research on prosocial behavior,

which examined when people do and do not extend help (referred to as *bystander intervention*). The seminal research on bystander intervention was conducted by two social psychologists, Bibb Latané and John Darley. These researchers, and subsequently others, found that bystanders do care about those in need of assistance, but nevertheless often do not help them. Whether they extend help depends on how they make a series of decisions.

### Bystander Decision Making

The circumstances surrounding an emergency in which an individual needs help tend to be unique, unusual, and multifaceted. Most people have never encountered such a situation and have little experience to guide them during the pressure-filled moments when they must decide whether or not to help. Latané and Darley's decision model of bystander intervention elaborates the sequence of decisions leading to a bystander's response.

According to Latane and Darley, before helping another, a bystander progresses through a five-step decision-making process. A bystander must notice that something is amiss, define the situation as an emergency or a circumstance requiring assistance, decide whether he or she is personally responsible to act, choose how to help, and finally, implement the chosen helping behavior. Failing to notice, define, decide, choose, and implement leads a bystander not to engage in helping behavior. Examinations of the bystander effect have focused mainly on the role social influence plays in individuals noticing something is wrong and defining the situation as an emergency and on how the presence of others can cause diffusion of the responsibility to help. Research indicates that social influence and diffusion of responsibility are the fundamental processes underlying the bystander effect during the early steps of the decision-making process.

### Informational Social Influence

If a bystander is physically in a position to notice a victim, factors such as the bystander's emotional state, the nature of the emergency, and the presence of others can influence his or her ability to realize something is wrong and that assistance is required. In general, positive moods, such as happiness and contentment, encourage bystanders to notice

emergencies and provide assistance, whereas negative moods, such as depression, inhibit helping. However, some negative moods, such as sadness and guilt, have been found to promote helping. In addition, some events, such as someone falling down a flight of stairs, are very visible and hence attract bystanders' attention. For example, studies have demonstrated that victims who yell or scream receive help almost without fail. In contrast, other events, such as a person suffering a heart attack, often are not highly visible and so attract little attention from bystanders. In these latter situations, the presence of others can have a substantial impact on bystanders' tendency to notice the situation and define it as one that requires assistance.

In situations where the need for help is unclear, bystanders often look to others for clues as to how they should behave. Consistent with social comparison theory, the effect of others is more pronounced when the situation is more ambiguous. For example, when other people act calmly in the presence of a potential emergency because they are unsure of what the event means, bystanders may not interpret the situation as an emergency and thus act as if nothing is wrong. Their behavior can cause yet other bystanders to conclude that no action is needed, a phenomenon known as *pluralistic ignorance*. But when others seem shocked or distressed, bystanders are more likely to realize an emergency has occurred and conclude that assistance is needed. Other social comparison variables, such as the similarity of other bystanders (e.g., whether they are members of a common ingroup), can moderate the extent to which bystanders look to others as guides in helping situations. In sum, when the need for help is unclear, bystanders look to others for guidance. This is not the case when the need for assistance is obvious.

### Diffusion of Responsibility

If a person does notice a situation and defines it as requiring assistance, he or she must then decide if the responsibility to help falls on his or her shoulders. Thus, in the third step of the bystander decision-making process, diffusion of responsibility rather than social influence is the process underlying the bystander effect. *Diffusion of responsibility* refers to the fact that as the number of bystanders increases, the personal responsibility

that an individual bystander feels decreases—and as a consequence so does his or her tendency to help. Thus a bystander who is the only witness to an emergency will tend to conclude that he or she must bear the responsibility to help, and in such cases people typically do help. But bystanders diffuse responsibility to help when others are present. In the case of Kitty Genovese, it seems that all the bystanders made the assumption that others were present and would intervene, and so they felt little or no personal responsibility to help. Diffusion of the responsibility to help is reduced, however, when a bystander believes that others are not in a position to help. For example, in one study, participants who believed that the only other witness to an emergency was in another building and could not intervene were much more likely to help a victim than were participants who believed that another witness was equally close to the victim.

Diffusion of the responsibility to help is increased when others who are viewed as more capable of helping (e.g., a doctor or police officer) are present. Research suggests that in emergency situations where a victim will suffer greatly if help is not forthcoming, bystanders relieve themselves of responsibility by asking “experts,” such as firefighter or paramedics, for assistance, thus indirectly helping. But when the costs of helping and not helping are both high, bystanders feel a strong conflict between the desire to act and the fear of helping. For example, in the case of Kitty Genovese, bystanders may have felt the need to help because the cost of not helping would be her death, but the possibility of being hurt or killed themselves deterred them from acting. Bystanders often resolve this conflict by concluding that someone else will help (i.e., diffusing responsibility), thereby psychologically reducing the perceived cost of not helping the victim.

### Normative Social Influence

A bystander’s decision regarding his or her personal responsibility to help may be affected by situational norms and expectations for behavior. For example, in a library patrons are expected to be quiet and in a classroom students may speak up in a respectful and orderly way, but at a party people may be much less inhibited. When bystanders in an emergency situation assess their personal responsibility to act, social expectations for behavior may

influence their decision. Researchers have demonstrated the effect of situational expectations on helping behavior by presenting people with an emergency in an area they have been told not to enter. Bystanders previously warned not to enter an area where an emergency was occurring were far less likely to help than were those told they could enter the area. Thus, when an emergency occurs, the social context can be a powerful determinant of bystanders’ decision to intervene.

### Conclusion

The bystander effect refers to the socially inhibiting presence of others on helping. When it is unclear whether there is a need for help, the presence of others tends to influence the first two steps of the bystander decision-making process (i.e., noticing something is wrong and defining the circumstance as requiring assistance). Whether or not a bystander will feel personally responsible to help is influenced by the number of others actually present (or assumed to be present) and their ability to help. Latané and Darley’s initial investigations of the bystander effect sparked a wealth of research on helping behavior, which has expanded beyond emergency situations to include everyday forms of helping. By illuminating the power of situations to affect individuals’ perceptions, decisions, and behavior, study of the bystander effect continues to influence the course of social psychological theory and research.

## CATEGORIZATION

---

*Categorization* is the process of understanding things by knowing what other things they are equivalent to and different from. It is a process that is widely studied in cognitive and social psychology and in philosophy and linguistics. This entry offers an overview of categorization and outlines its functions, then describes the major views on category structure and representation and on category learning, formation, and use (drawn mainly from cognitive psychology). It also examines social psychological perspectives on biased stimulus processing and sense making, and concludes by considering a range of ongoing debates and controversies in the field.

### Describing the Process

The categorization process could also be called classification or grouping, but it is helpful to preserve the term *classification* for the formal, behavioral process of separating things and *categorization* for the psychological process and experience. Thus a biologist who separates life forms into different species is engaged in a formal scientific process of classification (taxonomy), but the psychological process that the biologist uses to perform this task is categorization. Importantly, it is also the same process people use to decide that the person doing the classification is a biologist and not a psychologist, physicist, or astrologer.

As the previous example illustrates, categorization is widely regarded as the cognitive process

that is central to the way people understand things in the world. Indeed, some writers use the term *category* in almost the same way they use *concept*. Categorization takes on an added importance in social psychology, since people categorize themselves and other people. In fact, discussions of categorization are central to discussions of group processes and intergroup relations because groups are based on categories of people.

The major contemporary theories of group processes and intergroup relations—social identity and self-categorization theories, along with more specific models such as the common ingroup identity model, optimal distinctiveness theory, and the ingroup projection model—therefore all address the process of categorization quite directly.

Fundamentally, categorization is about attaining knowledge or understanding. The central concerns of social psychology relating to social norms, influence, attitude change, and socially shared cognition suggest that knowledge and understanding develop consensually. That is, different people tend to develop related understanding of the same things. In large part, this rests on their developing compatible ways of categorizing the self and other people and things.

People can also categorize the same things in radically different ways. Other people could see your furniture as their firewood or your pet dog as their lunch. This potential for disagreement, however, actually points to the success of members of human societies in coordinating their categorizations in harmonious ways. The triumphs and achievements of human civilization (and not just

social ills and conflict) rest upon the widespread consensus that emerges in categorization, despite the infinitely variable number of ways that any object (let alone sets of objects) can be categorized.

Categorization can be understood as a blend of three elements, including *background knowledge* (i.e., expectancies and explicit or implicit beliefs), *perceived equivalence* (i.e., how objects are seen to be the same as some other objects but different from others), and *category use* (i.e., explicit labeling). These three things can be understood as elements that constrain each other. Thus it is possible that explicitly using a category label like “Black” or “men” may affect the degree to which we see people as equivalent to each other. This can in turn affect our store of knowledge about relations, so that after using or developing an explicit category label, we may not only come to see those people as equivalent but also come to know that Blacks or men are similar to each other in certain ways. This knowledge may constrain our future perceptions of equivalence and use of labels.

### The Functions of Categorization

There are two major views on the functions of categorization. The first is the view of categorization as a sense-making process that involves overlaying meaning on elements. This approach is most famously associated with Jerome Bruner, who developed seven principles of veridical perception.

#### *Bruner’s View*

Bruner argued that perception is a decision process and that decisions involve discriminating between stimuli and between categories of stimuli. This decision process follows a chain of inference from detecting cues to determining the categorical identity of the stimulus (which could lead to the search for further cues). These categories comprise sets of specifications about which stimuli can be grouped as equivalent. A category is most likely to be used when it is accessible to perception (because it matches the perceiver’s past experience or current goals) and where there is high degree of fit between the category and the stimuli viewed. Veridical perception involves the perceiver’s taking stimulus input and forming categories, and then using those categories to form

new inferences and predictions about events and objects that he or she is likely to encounter. In this way, categorization allows perceivers to go beyond the information given in order to develop an understanding, rather than an exact reproduction, of the world.

More than 50 years after their publication, these principles remain fresh and vitally applicable, even though categorization is intensely researched and the research undergoes rapid change. In the field of intergroup relations, part of this vitality stems from the incorporation of the ideas of veridical perception into self-categorization theory and into social cognitive work on construct accessibility.

#### *Allport’s Analysis*

The other key contribution that has remained fresh and vital for a similar period of time has been Gordon Allport’s analysis of categorization as a simplification process involving the reduction of information. Allport argued that categorization is a response to the overwhelming burden of information that confronts perceivers (especially when they perceive other people). Following his thinking, we have so many daily encounters that we are forced to group or type others in order to cope. We therefore tend to group stimuli into the largest categories that we can get away with. That is, according to Allport, we tolerate abstract, imprecise categories as a response to a complex world.

In the process of simplification, many of these abstract, imprecise categories, such as group memberships, can end up being highly irrational and distorted. They may contain a “kernel of truth,” but they have a high probability of being wrong—and such irrational, errant categories can form just as easily as more rational, truthful categories. According to this view, and later adaptations of it, categorization can be seen as an errorful process that is used in preference to more accurate individuated or piecemeal perception only due to the limitations of our processing capacity.

Allport’s view was subsequently championed in the social cognitive approach to intergroup relations that was dominant in the latter part of the 20th century. It starkly contrasts with Bruner’s view, which has been championed by self-categorization theorists and others. One way of highlighting the contrast between these views is to consider an

everyday interaction such as waiting for and then getting on a bus.

In the Brunerian view, when we are confronted with stimulus cues such as people sitting on a bench and someone in a uniform driving a bus, we are likely to search for cues that suggest the existence of known categories, or to form new categories to make inferences and predictions. One such categorization might involve distinguishing between bus passengers and the bus driver to make accurate inferences about the roles and actions of members of each group. The Allportian view would suggest that it is the presence of a large number of people that leads us to form categories that allowed us to treat the members of those categories in identical ways, but at the cost of inevitable error.

### The Structure of Categories

Cognitive psychologists have identified three major long-standing approaches to category structure and representation: the classical view of categories, the prototype approach, and the exemplar view. There are also more recent mixed and variable structure approaches, and all of these views can also be observed in social psychology, including in analyses of phenomena such as outgroup homogeneity and stereotype change.

#### *Classical View*

The classical view of categories is that they have all-or-none defining features. The philosopher Ludwig Wittgenstein illustrated the implausibility of this view through the example of the category “game.” He demonstrated that despite the fact that people have no trouble using this type of category in everyday life, it is actually very difficult to come up with a set of all-or-none defining rules for the category “game” that includes things as diverse as children’s amusements and the Olympic games.

In the 1970s, the classical view was also demonstrated to be inconsistent with evidence that many categories are fuzzy and share relatively vague family resemblances with others. Furthermore, category members vary in the degree to which they are typical of a category. Thus, a hijacker is an atypical example of the category “criminal,” and a bank robber is a typical (good) example, yet they are both criminals in an absolute sense.

#### *Prototype View*

The prototype view of the nature of categories was popularized in the work of Eleanor Rosch, who argued that categories are based on an abstract summary or prototype. Thus, less typical examples of a category are more different from the prototype than are more typical examples. Rosch also argued that categorical systems are hierarchically organized into a system of levels, where more abstract or general categories include more specific categories. That is, there is a basic level of categorization for a category system.

The basic level for a category system is the level at which the instance is spontaneously named and recognized most rapidly (e.g., when we are shown a picture of a dining chair and then asked to identify what it is, we say “chair” rather than “piece of furniture” or “dining chair” because “chair” is the basic level for this system). The idea of category abstraction is central to self-categorization theory and the common ingroup identity model, but the idea of a fixed basic level that can be applied to social categories is more controversial.

#### *Exemplar View*

The exemplar view of category structure is that categories are stored as a collection of instances of the larger category. According to this view, there is no abstract summary, but merely a set of stored representations or exemplars of the category. Thus, a social category such as men or Blacks would be stored in the memory of the perceiver as a set of traces about the members of that category who had been encountered.

There has been a great deal of debate in cognitive psychology about the merits of the exemplar and prototype views, but there are more recent attempts to show that categories can have both exemplars and prototypes (in particular for dealing with exceptions). There is also research that suggests that categories can vary from having a form that is closer to an exemplar to one that is closer to a prototype representation.

### Category Learning, Formation, and Use

The major approaches to category learning, formation, and use have been based on the ideas of similarity-based formation and theory-based

formation. The purely similarity-based approaches will not be discussed in this entry, as they seem inadequate as accounts of the ways that categorization takes account of meaning and experience. Category formation appears to be based on internally coherent theories about the function and nature of things rather than just on the basis of surface appearances or gross similarities.

Indeed, cognitive researchers have shown that objects could be seen as similar or different depending on the order in which they are presented. Thus Mexico might be seen as like the United States, but the United States might be seen as different from Mexico. Evidence such as this can lead us to ask, as Douglas Medin did, if something is said to be similar to something else in certain respects, then where do those respects come from?

The answer that has had the most extensive implications for the study of social groups is contained in psychological essentialism, the idea that categories may have a coherent core or essence that binds category members together. This idea has been applied to social categories in research over the last two decades. Psychological essentialism for social categories is often equated with the notion that some categories are natural and have a biological (e.g., genetic) core, while other categories lack this core. The belief in the psychological essence of a group or category has therefore been linked to analyses of race and racial prejudice.

Psychological essentialism complements and is sometimes confused with Donald Campbell's concept of entitativity. This is the idea that social groups may be perceived to a greater or lesser degree as entities or things (a point rejected by individualist stances that claim only individual things are real). Entitativity was developed from the gestalt principles of perception to argue that a group is perceived to be more real and coherent to the extent that its members are perceptually alike, are close together, share a common fate, and form a coherent figure or form. Much of the research effort in this area has focused on seeking to demonstrate that certain types of groups (e.g., families or sporting teams) are more entitative than others (e.g., people waiting at a bus stop and sports crowds).

Social psychologists have been more interested than cognitive psychologists in categorization effects on judgment (e.g., in research on multiple categorization). These effects, first studied by

Henri Tajfel and his colleagues, include the intraclass (assimilation) effect (i.e., increased perceptions of similarity within categories) and the interclass (contrast) effect (i.e., increased perceptions of difference between categories). In social psychological terms, categorization effects are applied by group members through the development of standards and norms that are different from the ones developed by other relevant groups. Within the group, members converge on those standards and norms (usually through the processes of social influence). The nature of these effects remains debatable. In particular, the question is whether categorization effects are distortions and/or biases or accurate but contextually variable reflections of reality.

The dominant social cognitive approach has argued that categorization is used because limited capacity leads to biased processing, which in turn creates distortions. Categorization is seen as an application of selective attention to both stimuli that occur spontaneously and constructs that are already stored in our cognitive systems. In other words, it is believed that categorization takes place because of the need to be selective when detecting stimuli, and categorization is in fact designed to make stimulus information that is overwhelming for the system (or too diffuse) manageable.

However, self-categorization and other sense-making approaches argue that categorization is a veridical, context-dependent, sense-making process that produces accurate perceptions from a current perspective (which follows from the process of salience). Henri Tajfel argued that categorization allows perceivers to derive meaning by making different classes of stimuli (social and non-social stimuli) coherent. In self-categorization theory, perceptions about the self are organized in hierarchical categories that are contextually activated through the process of salience (the extent to which a particular self-categorization becomes psychologically prominent).

It is important to note that self-categorization theorists believe that variations in self-perceptions reflect real changes, as experienced from the point of view of the perceiver. The sense-making approaches share the idea that categorization is a process that helps perceivers understand their surroundings, but in each of these treatments, there is a particular key construct that plays the major role: coherence (in optimal distinctiveness theory),

explanation (in the social judgment approach), and assimilation and contrast (in approaches based on categorization effects and construct activation).

### Ongoing Debates

The contrast of these perspectives sets the scene for some debates and unresolved issues. The first debate revolves around how information-processing capacity affects categorization processes. The idea of capacity limitations is of central importance to social cognitive approaches to categorization. Here, categorization and stereotyping are viewed as necessary but imprecise shortcuts for people overloaded with information from their environments. Accurate judgments are only considered possible when people have time and are willing to put in the effort to attend to the unique features of the individuals they encounter.

This understanding of categorization has been challenged by the alternative meaning-seeking view espoused by self-categorization theorists. From this perspective, instead of leading to errors, the process of categorization is seen to provide a meaningful framework for understanding and predicting the behavior of people in different social contexts.

The second major debate regarding these two approaches revolves around the issue of whether categorizations produce distortions or accurate reflections of reality from a perspective. The selective attention model suggests that categorization and stereotyping produce distortions of reality because these processes are seen to lead people to exaggerate equivalences of members of particular groups. In this view, the accuracy of group judgments can only be determined with reference to the characteristics of the unique individuals who make up the group.

Alternatively, several accuracy-oriented approaches propose that stereotypes are based on real characteristics of social groups. The reflection-construction model argues that beliefs about categories reflect, modify, and influence the construction of reality. According to this model, the accuracy of particular stereotypes will determine whether categorization enhances, or reduces, the accuracy of perception. An alternative accuracy-oriented approach to stereotyping has been derived from self-categorization theory, in which it is proposed that appropriate categorizations always serve to

increase the match between perception and reality. According to this model, all perception is categorical, and categorization allows people to represent reality from their particular point of view. Thus self-categorization theorists argue that apart from the perceiver's belief in the accuracy of his or her perception, accuracy of perception can only be established with respect to the degree to which some relevant ingroup member agrees with the judgment.

The third debate revolves around whether categories are stored and retrieved from memory (when they are accessible) or spontaneously created anew for each situation. The self-categorization theory version of the sense-making account tends to assume that categories are constructed on the spot for each new social encounter. What is assumed to be relatively stable is long-term background knowledge about the world that is used to help construct an infinite number of possible categorizations to suit each new social context. It is less clear from this perspective what form this long-term background knowledge takes if it is not categorical. The alternative view put forward by the selective attention perspective argues that categories are stored and retrieved from memory. This approach can more easily explain why categories that have recently been activated, or are chronically accessible, are more likely to be used than older, less chronically accessible categories. To resolve this debate, it will be necessary to determine whether remembering a category is the same as reusing it.

The fourth debate relates to whether some categories are pervasive and constantly applicable or whether all categories are utterly context dependent. Many social cognitive researchers argue that there are a small number of basic and primary categories, such as gender, ethnicity, and age that are automatically and unconsciously activated in interaction. Alternatively, self-categorization theorists argue that there is no basic level or set of categories that is primary. Indeed, self-categorization theory emphasizes that categorization is highly variable and context dependent and that it would be a mistake to suggest that gender, ethnicity, or any other category will always be used to categorize others in interactions. A possible resolution of this issue is to view basic and primary categories as operating at a background level of perception and intruding into judgments about members of those

categories even when those categories are not explicitly salient.

One final issue that social models of categorization will need to resolve is whether categories are based on hierarchical structures much like those shown in tree diagrams. The assumption of hierarchical structures is adapted from cognitive research and appears in self-categorization theory, the common ingroup identity model, and the ingroup projection model. Some recent evidence from cognitive psychology suggests that the idea of hierarchical structures does not seem to capture the way people make inferences about natural object categories. This raises similar questions about social categories that often do not have clear tree-like structures. For example, Texas is part of America, but we know that not all Texans are Americans.

social and historical context, has received an enormous amount of attention over the past several decades. In this entry, charismatic leadership is defined, along with the conditions conducive to its appearance and typical features of its communication. An illustrative example is then presented, followed by some of the limitations of this form of leadership.

### Defining the Concept

First introduced by German sociologist Max Weber, the word *charisma* comes from the Greek word *χάρισμα* (*kharisma*), meaning “gift” or “divine favor.” Following this original definition, charisma refers to an extraordinary quality of a person that allows him or her to charm and influence others. In the common vernacular, charisma is often treated as a powerful personal appeal or magnetism that captivates others. The charismatic leadership approach emphasizes heroic leaders with forceful, dramatic personalities and widespread appeal; recent examples include leaders such as Jack Welch, Bill Clinton, and Arnold Schwarzenegger.

However, charisma is very much in the eye of the beholder, suggesting that charismatic leadership is more accurately understood as a *relationship* between leaders and followers. Charismatic leadership emphasizes the importance of symbolic behaviors, emotional appeals, and the role of the leader in making events meaningful for followers. It focuses on understanding how a leader can influence followers to make sacrifices, commit to difficult or seemingly impossible objectives, and achieve much more than was initially expected. Charismatic leadership is, therefore, not solely a property of the leader’s charisma, and focusing on the leader alone ignores the unique circumstances that are crucial in each instance of charismatic leadership. While a leader with extraordinary gifts and qualities is a critical element in this relationship, aspects of the followers and the situation are also important in understanding why some leaders are viewed as charismatic and others are not.

A significant element is that followers who are frightened, threatened, or uncertain are more likely to view a leader as a charismatic savior. Followers are more susceptible to a charismatic leader and his or her vision if they are insecure, alienated, and fearful about their physical safety or economic

---

## CHARISMATIC LEADERSHIP

---

*Charismatic leadership*, combining a leader with powerful personal magnetism and a particular

security, or if they have low self-esteem or a weak self or social identity. Therefore, charismatic leadership is more likely to emerge during a crisis or during a situation of desperation or uncertainty. The leader presents a vision or set of ideas promising a solution to the crisis and a better future (whether achievable or not), and followers are attracted to this gifted person and come to believe in his or her exceptional powers and vision for a better future.

To retain his or her followers, however, the leader must also demonstrate or convince others of his or her ability to deal with the crisis or threat and move followers in the direction of a better future. Accordingly, charismatic leadership is a process that resonates in the exceptional personal attributes of the leader, as well as the fit between those attributes and the needs of followers, against the backdrop of a crisis or undesirable state of affairs.

Research has emphasized the critical importance of the charismatic leader's vision, including aspects of both the content and delivery style of the leader's message. Charismatic leaders are able to distill complex future ideals into simple messages with widespread and emotional appeal, such as Martin Luther King, Jr.'s "I Have a Dream" speech. They also use a variety of communication techniques to appeal to their followers, such as using colorful, vivid language and imagery rooted in shared values.

Charismatic leaders also frequently employ symbols to their advantage, including the site of their speech, visual symbols, props, music, and lighting to enhance the appeal of their message and increase the level of excitement and emotion in followers. Similarly, they use tone of voice, inflection, pauses, and gestures to increase the intensity and emotional meaning of their message. Charismatic speeches frequently incorporate analogies, repetition, metaphors, and stories to bring the vision "alive" for followers, and communicate optimism that, together, group members can achieve the promise of a better future if they are willing to support the leader and are prepared to make sacrifices for his or her cause.

### A Historical Illustration

A familiar example of an admired leader, Mohandas Gandhi, illustrates the ingredients of the charismatic leadership relationship. First, Gandhi's followers often credited him with possessing extraordinary

gifts, and his flare for dramatic gestures such as fasting, simple dress, and spiritual rituals produced a heroic persona that challenged current norms and conventional behavior of the time. Second, Gandhi came to power in response to a desperate situation: the crisis in India in the wake of British colonization and oppression. Third, Gandhi offered a powerful vision of a better future, including a self-governing India where its citizens would live under their own laws free from outside interference. Fourth, Gandhi's vision, rooted in the basic values of Indian culture, attracted a tremendous following. His dynamic vision created a contagious atmosphere that inspired his followers to seek independence. Gandhi's followers were also motivated by his repeated smaller successes along the way to independence, including tax reforms and the recognition of non-Christian marriages. Finally, Gandhi led the country to independence from the British, although his ultimate vision of Hindus and Muslims living in peaceful cohabitation was never achieved. His principles of nonviolence transformed his own country and inspired future leaders all over the world.

Overall, Gandhi's followers realized many of the beneficial outcomes of charismatic leadership, as Gandhi is credited with broadening and elevating the interests of his followers, generating awareness and commitment to the mission of the group, and motivating followers to go beyond their own interests and sacrifice for the good of the Indian people as a whole. This example illustrates that charismatic leadership involves the actual characteristics of the leader as well as characteristics that are attributed to leaders by followers within a given situation. If the leader's extraordinary qualities do not clearly resonate with the values and needs of followers, he or she is likely to be rejected as a radical or mocked as delusional. However, if the leader's extraordinary qualities provide a good fit for, or proposed solution to, followers' needs and anxieties, followers may even exaggerate how exceptional their leader is and idolize him or her. In this way, a charismatic leader may attain a seemingly magical or superhuman persona in the eyes of his or her followers.

### Limitations and the Darker Side

Charismatic leadership has been defined as a rare form of leadership in which the leader is often

irreplaceable because of followers' dependence on the leader's skills. Therefore, social movements and change processes are often difficult to maintain once the charismatic leader is gone, and followers struggle to carry on the momentum of change. In addition, because charismatic leadership often results in unquestioning obedience to the leader's directives, followers themselves may be less likely to develop leadership skills and experience that will sustain the change process after the leader is gone.

In addition, charismatic leadership also has a darker side. None of the ingredients of the charismatic leadership relationship guarantee that the leader's vision will be morally defensible or ethical, nor do they prohibit followers from carrying out unethical or violent behaviors in pursuit of the leader's vision. Charismatic leaders of the past such as Adolf Hitler and Jim Jones were able to create widespread appeal for their visions of racial superiority and revolutionary suicide, respectively. Due to the extraordinary, even heroic qualities that followers may attribute to such charismatic leaders, these leaders may begin to believe that they really are exceptionally qualified to determine the fate of their followers, resulting in increasingly autocratic, manipulative, dictatorial leadership that is intolerant of dissent or alternate points of view.

In addition, due to their often powerful appeal and nonconventional or radical visions for the future, charismatic leaders are often extremely divisive figures that create bitter enemies as well as devoted followers. In some situations, the charismatic leader may prove so divisive that he or she paralyzes the change process. In other situations, charismatic leaders become public targets for the opposition, and consequently leaders such as Gandhi, King, and John F. Kennedy were ultimately assassinated for their beliefs.

Finally, it is important to note that charismatic leadership is often a fleeting phenomenon that can be gained or lost as circumstances change. Charismatic leadership can be lost if the crisis ends, or if followers become more confident and feel that they are capable of solving problems on their own. Also, charismatic leaders may make decisions that result in failure, seem to betray their core vision or followers' needs, or focus more on obtaining power and influence for themselves than on supporting the greater cause for followers'

benefit. Other more attractive and credible leaders may challenge the vision or the effectiveness of the current leader.

In addition, charismatic leaders may become victims of their own success. As the change movement grows larger and more powerful, or as their organizations expand in scope and influence, charismatic founders may become increasingly irrelevant or lack the expertise to deal with new challenges. There is also the possibility that their unconventional behaviors may become distracting or counterproductive as the focus shifts from creating change to implementation and performance.

## CHILDREN: STEREOTYPES AND PREJUDICE

---

*Prejudice*, the holding of negative attitudes toward others based on the groups to which they belong and the stereotypes attached to these groups, continues to be a major source of strife and conflict throughout the world. Do children show prejudice and have stereotypes? If so, how do stereotypes and prejudice arise in early life? What are the different ways that prejudice and stereotypes emerge in childhood, and what forms can they take? These are the questions that are addressed in this entry.

People commonly think that young children are innocent and devoid of stereotypes and prejudice. However, research in developmental and social psychology has shown that children exhibit many types of biases at an early age. These can be based, for example, on someone's gender, race, ethnicity, nationality, or body type. The findings suggest that understanding the origins and nature of prejudice in children should be a high priority if we are to establish effective policy for combating its negative consequences. Given that stereotypes and prejudice are hard to change in adulthood, most psychologists agree that interventions must be implemented early in life to be successful.

### Origins of Prejudice

Developmental and social psychologists have suspected that prejudice in children may originate from the child's early ability to categorize the social world. Children develop the ability to recognize characteristic features of people from their own group and other groups, and then use this information to cluster individuals together in social categories. Adults are known to be more accurate at recognizing a face from their own racial group than from an unfamiliar racial group. That this type of face processing is not present in infants at 3 months of age suggests that it is not innate. In fact, it emerges by 6 months in infants living in an environment with little racial diversity (i.e., a racially homogeneous environment). This indicates that facial input from the infant's visual environment is a key contributing factor. Therefore, at an early age children show categorization ability based on race.

Evidence suggests that such social categorization can result in preference for one's own group. Psychologists have investigated this in studies using a visual preference task. In this task, infants are presented with examples from two racial categories simultaneously, and how long they look at each example is used to indicate preference. Studies using this task show that by the time they are 3 months old, infants prefer to look at faces of their own racial group rather than those of other racial groups. This preference is not typically shown by newborns and is only present in 3-month-old infants living in a predominantly racially homogeneous environment. These findings suggest that the early development of own-race preference in infancy is linked to living in an environment that exposes the children only to own-race individuals.

Developmentally, infants have social categorization ability and, depending on their environment, this may result in certain group preferences. However, at this stage they do not have the ability to express prejudice or stereotypes due to their limited cognitive and linguistic abilities. As infants become young children, they often express biases directly or explicitly in the words they use to describe different social groups, or more indirectly or implicitly by forming mental associations linking their own group (rather than other groups) with positive experiences, emotions, or attributes (i.e., showing implicit biases).

### Implicit Biases in Children

Recent studies have provided evidence for when implicit biases emerge in childhood. Using the Implicit Associations Test (IAT), researchers have shown that adults have biases toward others, which they are not aware of, based solely on race. This is evidenced by the fact that White adults more quickly associate negative words with out-group (Black) faces than with ingroup (White) faces. These findings have spawned an industry of IAT studies, with much debate about the extent to which such associations reflect prejudice or bear on behavior, such as discrimination toward others.

Some developmental studies have examined implicit bias in childhood using IAT-type methodologies. One study of White British children, using a child-friendly pictorial IAT, found that implicit racial and national biases were present from 6 to

16 years of age. This children's version of the IAT measured the relative strength of association between a concept (e.g., "White British" or "Black British") and an attribute (e.g., "good" or "bad"). Implicit bias was judged to be present if the children showed faster reaction times for stereotypical (e.g., "White British" and "good") than counter-stereotypical (e.g., "Black British" and "good") associations. Studies have also found that these implicit biases remain in older children who typically show reduced *explicit* bias. This research suggests that implicit biases based on associations made between different categories and their attributes (either positive or negative) are established early in life and remain stable, relatively hard to change, and less open to conscious control.

Other studies have looked at how children evaluate the intentions of an individual from a different racial group, in an ambiguous but familiar everyday peer encounter, to determine whether children have implicit biases. The studies found that 6- to 9-year-old European American children attributed more positive intentions to a White child than to a Black child in potential "pushing" and "stealing" peer encounters on the playground.

Does this suggest that implicit biases are automatic in children? The answer would appear to be "no"—since these biases were found only among European American children in racially homogeneous schools; European American children of the same age, in the same school district, but enrolled in heterogeneous schools did not attribute more positive intentions to their ingroup than the outgroup; in fact, race was not used to attribute negative intentions.

### Explicit Prejudice in Children

Prejudice takes many forms in childhood. This is not surprising, given that what counts as prejudice changes as children develop both cognitively and socially. The nature and complexity of a 5-year-old child's group-related attitude will be manifestly different from a 14-year-old adolescent's attitude. So implicit biases are only one form of childhood prejudice, and there is an extensive history of research in developmental psychology revealing other forms of prejudice in childhood that provides a broader picture.

Developmental research has examined prejudice in the form of explicit preference for one social group over another. Early work on this form of explicit bias included the doll test, which showed that Black American children in segregated schools preferred White dolls to Black dolls. This research was influential in *Brown v. Board of Education*, the 1954 Supreme Court case that outlawed school segregation in the United States. Other measures have examined explicit forms of prejudice by asking children to attribute positive (e.g., "clean," "smart") and negative (e.g., "mean," "dirty") traits to a White child or a Black child or to both children. Explicit forms of ethnic prejudice based on the above measures are known to develop from 4 to 5 years of age among ethnic majority children. Unlike implicit prejudice, which remains relatively stable once it appears in childhood, explicit ethnic bias typically declines in ethnic majority children from approximately 7 years of age.

Some psychologists explain this developmental trend in ethnic majority children's prejudice by attributing it to young children's poor cognitive ability to judge people from different groups using individual characteristics (e.g., friendly, hard-working). Instead, these researchers argue that cognitively immature children judge an individual based on the group to which he or she belongs (e.g., boys or girls). Thus, according to this analysis, children show prejudice because they cannot see the similarities between individuals in different groups and the differences between individuals in the same group. However, recent studies have found a weak relationship between this cognitive ability and children's prejudice, and there is an extensive literature showing that cognitively mature adults can still show prejudice. So a cognitive explanation does not seem adequate for explaining why explicit prejudice declines during middle childhood.

### Self-Presentation and Explicit Prejudice

Some researchers have argued that the developmental decline in explicit ethnic prejudice reflects children's concern about social desirability, in particular their increasing awareness of how others might perceive them and how they can promote a positive impression of themselves to significant others. This self-presentation account contends that children develop the ability to strategically

control their expression of prejudiced attitudes and behavior. Developmental research certainly indicates that by middle childhood, children have the social-cognitive capacity to understand self-presentational motives and engage in self-presentational behavior.

Importantly, children's self-presentation of prejudice requires attention to prevalent social norms about the explicit expression of prejudice. Social norms prescribe cultural expectations regarding attitudes, values, and behavior. These expectations may be specific to social groups or more widespread within society. Once children understand these social norms, they may strategically present themselves as acting in accordance with them, thereby giving a positive impression of themselves to relevant and significant others.

In support of this argument, developmental psychologists have recently shown that group norms affect the self-presentation of young children's explicit ethnic prejudice and the development of children's prejudiced exclusion of peers. This research has found that increasing children's *accountability* to their peer group, in that their actions are visible and may have to be defended, causes children to increase or decrease their prejudiced judgments in line with the dominant norm in their group.

For example, one study found that 5- to 16-year-old White British children who were highly aware of the social norm against expressing explicit racism spontaneously showed little explicit racial prejudice. In contrast, children with little awareness of this norm inhibited their racial prejudice *only* when their group's antiprejudice norm was made salient by increasing their accountability to the group. Still other studies have shown that children can increase rather than inhibit their prejudice based on national group membership when they are made accountable to their national ingroup. This finding fits with studies showing that national prejudice is often seen as more legitimate or acceptable than racial prejudice. These studies show that the self-presentation process operates to encourage prejudice in the domain of nationality, whereas with race, children typically self-present by inhibiting their prejudice.

The next section describes another facet of prejudice recently studied by developmental scientists, namely explicit judgments about social exclusion,

which often show a different developmental pattern from the explicit forms of prejudice described earlier.

### Explicit Judgments About Social Exclusion

Researchers have recently begun to assess children's evaluations and reasoning about the exclusion of ingroup and outgroup peers within everyday group settings. This research provides a broader insight into the development of prejudice and use of stereotypes in childhood. Developmental research has demonstrated that from a young age, children emphasize moral reasoning (e.g., fairness) when judging social exclusion based on group membership, such as gender or race, in straightforward or unambiguous situations (e.g., "Is it all right or not all right to exclude a boy from a ballet club?"). However, children often resort to stereotypes to justify exclusion when complexity or ambiguity is added. For example, who should a ballet group pick when only one space is available and two children want to join—one who matches the stereotype or one who does not? Moreover, this research has found that with age, children also begin to use more socially conventional reasoning (e.g., the need to adhere to social norms or stereotypes, concerns about effective group functioning) to justify exclusion of their peers based on either race or gender. Such referencing of social norms and group functioning may serve as a proxy for prejudice and stereotypes.

For example, one recent study found that, when asked to make decisions about exclusion in complex situations, the majority of children between 6 and 12 years of age increasingly justified racial or gender exclusion using socially conventional reasons, such as mentioning how an individual challenges the gender stereotype ("It will be weird to have a boy wearing leotards, so they should choose the girl."). Moreover, a range of studies have shown that children's identification with the person who is the excluder is related to their justifying racial or gender exclusion based on socially conventional reasons. These findings indicate that older children, who are less likely to show the explicit biases described in the previous section, are nonetheless willing to condone prejudice and social exclusion using stereotypical reasoning. Together, these studies suggest that with age, children in

everyday situations find less direct and more subtle ways of showing bias and stereotyping.

Other recent developmental research has documented age-related increases in social exclusion judgments, with older children excluding peers who challenge both moral principles and their own group norms about loyalty to the group. This increased social exclusion of deviant (i.e., “black sheep”) peers by older children reflects the growing importance of group identity as children age and advance their understanding of how groups operate. Specifically, this research has found that younger children evaluate the actions of their peers only in terms of morality, that is, adherence to moral norms such as fairness or equality, or as selfish, that is, acting out of self-interest. Older children, however, judge peer group members in terms of both their morality and their adherence to group norms about what a genuine group member should do in different settings.

### Conclusion

Research indicates that children develop prejudice and stereotypes from an early age. The foundation of this prejudice and stereotyping is the development of social categorization during infancy. Infants begin to show categorization ability in the domain of race and also show a visual preference for faces from their own group. Implicit biases are known to appear around 6 years of age and remain relatively stable through childhood into adolescence, though some evidence suggests implicit racial attitudes are more negative in ethnically homogenous environments. Explicit racial prejudice measured through preference or trait attribution tasks appears around 4 to 5 years of age in racial majority group children, but generally decreases from middle childhood. In contrast, children’s reasoning and judgments about social exclusion can become more biased with age, as children begin to use stereotypes and conventional reasons to justify social exclusion in everyday complex situations. Psychologists have typically explained developmental trends in children’s prejudice using either a cognitive development or self-presentational account.

Prejudice and stereotyping begin in early childhood, often making it difficult to change these attitudes in adulthood. For this reason, we need to take

seriously attempts to reduce these problematical phenomena in childhood. Indeed, research suggests that reducing prejudice in children can be accomplished through a variety of methods, including the promotion of intergroup contact, social–cognitive skills, empathy, moral reasoning, and tolerance.

## CHILDREN'S GROUPS

---

Peer groups constitute the primary source of children's socialization outside of the family. Competence in the peer group is critical for many aspects of children's development, including cognitive development and school achievement as well as social, emotional, and personality development. Within their groups, children are more or less accepted by their peers, more or less visible, more or less dominant, and more or less connected to other group members. These individual differences in peer group experiences are associated with different socioemotional outcomes later in development. As a result, much of the scholarship concerning children's peer groups has been devoted to measuring and explaining the sources of individual differences in children's integration into the peer group and the developmental consequences of these differences. More recent and less extensive research literature addresses questions about children's attitudes toward their own group and groups of other children.

### History

Contemporary research interest in children's peer relationships is usually traced to the discovery by Harry Harlow in the 1950s that infant rhesus monkeys reared with their mothers but without exposure to other young monkeys failed to acquire the social skills necessary for successful adaptation to group living. Harlow and his students also discovered that the profound social and emotional deficits resulting from early maternal deprivation could be largely overcome by "peer therapy" provided by extended play with younger monkeys.

Later, psychologists studying the origins of adult psychopathology began to find that difficulties in childhood peer relations were a regular antecedent of serious problems later in life. Thus, children's functioning in the peer group appeared to be formative in the development of competence and to have long-lasting consequences. Since the 1970s, scholars have worked to measure and characterize development and individual differences in children's peer group experiences; to identify the correlates and causes of differential success in the peer group; to determine the origins in family

experiences and in the peer group itself of children's behavior, skills, and social understanding that contribute to such individual differences; and to explain peer group processes that contribute to development and adjustment.

### The Peer Group in Development

Observations of children in family, child care, and laboratory settings, as well as cross-culturally in small villages of hunter-gatherer societies, show that peer relationships emerge late in the second year of life and become increasingly complex and a more regular part of children's social experiences over the course of childhood. By middle childhood, children spend a third or more of their time in the company of their peers and begin to express a preference for spending time with peers. Peer relationships are more egalitarian than those with adults, feature more play and more conflict, and tend to be less stable and enduring than relationships in the family. Hence, children's peers provide unique experiences not available in the family and unique opportunities for acquiring a wide range of social and emotional competencies.

Perhaps one of the most interesting characteristics of children's peer groups is that even with children as young as 3 or 4 years of age, whenever children assort themselves voluntarily, these groups are composed almost exclusively of same-sex children. The amount of time children spend with opposite-sex peers declines over childhood and remains short until adolescence. Sex segregation begins early and trumps any other characteristic on which children self-segregate, including race. Girls precede boys in preferring to play with their own sex during the toddler and early preschool years, but by childhood boys are more exclusionary. Children of both sexes establish and police the boundaries of their sex-segregated groups, teasing or rejecting peers who play with children of the opposite sex. Perhaps as a result, children who spend larger amounts of time in opposite-sex peer groups than is typical for their age tend to be less popular and well adjusted than children who prefer same-sex group play.

Because sex segregation appears early, is robust, and appears to be universal, scholars have endeavored to explain why it occurs, how experiences

differ in boys' and girls' groups, and the functions of sex-segregated play for development. Eleanor Maccoby's work has been influential in promoting and studying such questions. Maccoby has proposed that sex segregation occurs because of incompatibilities in boys' and girls' play and interaction styles. Boys' play is predominantly active, physical, rough, and competitive and occurs in large groups, whereas girls' play is characteristically quiet, social, verbal, and cooperative, occurring in dyads or small groups. Therefore, to understand sex segregation, researchers must explain how sex differences in play style develop as a function of biology and socialization. This is currently an active area of inquiry in developmental psychology.

Researchers have also documented that boys' and girls' groups differ in the structure and thematic content of their interactions, the density of their social networks, their relationship goals and concerns, the types and amount of peer stress encountered in the group, and group members' interpersonal qualities (such as trust, validation, and closeness). There is much less research on how these different experiences relate to development. Some research suggests that the amount of time children spend in same-sex peer groups influences how sex-typed their behavior is, and substantial research points to sex differences in adjustment, especially in adolescence. For example, boys are more likely to exhibit behavior problems, whereas girls are more likely to exhibit anxiety and depression. One reasonable hypothesis is that different experiences in boys' and girls' peer groups contribute to sex differences in developmental outcomes. Research is currently addressing this hypothesis.

### Individual Differences in Peer-Group Acceptance

Jacob Moreno's work in the 1930s on the interpersonal forces of attraction, repulsion, and indifference set the stage for much of the research in the latter part of the 20th century on children's acceptance by their peer group. This work has emphasized that different children are perceived differently by their peers, with some children being well liked and widely accepted, while others are rejected, and still others are ignored.

### Measurement

Children's peer group acceptance is most commonly described using sociometric classifications. A frequently used method for indexing sociometric status was developed by John Coie in the 1980s. In this procedure, children are asked to select among their peers those they like most and those they like least from a roster of children in their group (e.g., in a class or camp cabin). Children are then classified into categories based on how preferred they are by their peers. *Popular* children are liked by many peers and disliked by few. *Rejected* children are disliked by many peers and liked by few. *Controversial* children are liked by many peers but disliked by many others. *Neglected* children are seldom singled out as being either liked or disliked. *Average* children are those who are liked by some and disliked or ignored by others, and generally do not fit any of the other categories.

There is some debate about whether such selections should be limited to same-sex peers or should include both sexes, how large the reference group should be (e.g., classroom vs. school), and the type of cut-off score that should be used for creating the categories. Different methods yield more or less extreme groups, which are, in turn, more or less stable over time and may be more or less predictive of optimal or problematic outcomes.

Another frequently used procedure is to ask children to rate each of their peers on a single scale that varies from "like very much" to "dislike very much." The average rating a child receives from his or her peers reflects how accepted the child is in the peer group. This method does not yield different sociometric categories, but because it permits children to evaluate all of their peers, and not only those liked most and least, some investigators argue that it provides a more valid measure of peer group acceptance.

### Causes and Correlates

Regardless of the method used, children who differ in peer group acceptance have been found to have different behavioral profiles, self-perceptions, socioemotional adjustment, patterns of school achievement, and attitudes and cognitions about their peers. Initially, research identified broad dimensions of social behavior such as aggression, withdrawal, and prosocial behavior as correlates

of various sociometric status groups. For example, rejected children tend to be more hostile and aggressive toward their peers, whereas popular children tend to be more friendly and cooperative. Experimental studies of playgroups formed by combining previously unacquainted children have shown that such behavioral differences shape children's sociometric status.

In more recent years, researchers have uncovered substantial complexity both in the sociometric categories themselves and in the kinds of behavior, cognitions, and attitudes associated with children's sociometric status. There are thus subtypes of rejected children, such as withdrawn children and especially aggressive children. Interestingly, not all types of aggression are associated with rejection. Indeed, only about half of aggressive children are rejected by their peers. Experimentally constructed groups of rejected and "unrejected" children have shown that in early childhood, peer rejection is associated with higher rates of instrumental aggression to obtain desired objects or positions. Among older children, angry, impulsive aggression in response to provocation, as well as unprovoked, person-centered aggression, is also associated with rejection.

Furthermore, different types of aggression are associated with rejection in girls' groups and in boys' groups. Whereas physical aggression is often characteristic of rejected boys, relational aggression in which children use nonphysical means such as gossip to exclude, harass, or threaten others is more characteristic of rejected girls. In addition, the extent to which aggression causes peer rejection depends on how normative it is in the peer group; in peer groups where aggression is more frequent, it is less likely to result in rejection. Likewise, shyness and withdrawal are associated with rejection only in later childhood when they become nonnormative, although the picture is more complicated for children from non-Western cultures (e.g., China).

Similar distinctions have been made among popular children. For example, some children perceived as popular by their peers are more domineering, assertive, and manipulative than they are prosocial and cooperative. Prosocial behavior tends to be associated with peer acceptance in groups where positive peer-directed behavior is relatively common.

In addition to differing in social behavior, children from different sociometric groups also exhibit distinct patterns of social information processing. In the 1980s, Kenneth Dodge formulated an influential model of individual differences in how children encode, interpret, and act on social information during interactions with peers. Empirical research has largely confirmed the basic tenets of this model. For example, rejected children tend to perceive and interpret ambiguous social behavior by their peers as hostile, a characteristic termed the *hostile attribution bias*. They also endorse hostile goals and coercive solutions to social problems, evaluate aggressive solutions positively, and overestimate how well liked they are by peers.

Popular children, in contrast, more accurately encode social cues, attribute benign intentions to ambiguous behavior by peers, and generate prosocial solutions to social problems. Research has shown that such differences in social information processing originate in representations or schemas that are automatically activated during encounters with peers. Attempts to alter children's social perceptions and cognitions and/or their social problem-solving strategies have produced some limited changes in peer acceptance. This suggests that how children encode and interpret others' behavior, and their goals and solutions when they encounter conflict or difficulty with peers, may be causally related to their peer group status.

### Outcomes

A lack of acceptance by peers has been regularly shown to predict a host of negative developmental outcomes for children, including poor school attitudes and achievement, psychological maladjustment, and delinquency. Longitudinal studies have shown that such associations are especially robust for children who are stably rejected by their peers over time, particularly for those who are aggressive and disruptive. It is as yet unknown to what extent these associations are driven by the negative peer experiences these children encounter, by their failure to acquire important skills from peer group socialization because of their lack of integration in the group, by exposure to the socializing influences of other deviant peers, or by some underlying quality of the children themselves or experiences outside the peer group that feed both peer rejection

and other social and emotional problems. There is empirical evidence for each of these potential mechanisms, as well as evidence for more complex theoretical models that posit multiple, interacting influences.

For example, existing vulnerabilities in the child that might predispose him or her to poor outcomes (such as aggression or hyperactive, impulsive behavior) appear to be exacerbated by negative experiences with peers, such as rejection or victimization. Some research has found that children's reputation in their peer group is self-perpetuating and that peers are likely to discount information about a child when it runs counter to the peer group's prevailing perceptions of the child. This contributes to the stability of children's sociometric status as well as their social and emotional experiences in their peer group, and makes it difficult for children with low social status to improve their standing.

### Children's Social Networks

Children's immediate peer groups are embedded in larger social networks of peer relationships that provide unique experiences as well. Social network analysis identifies and examines patterns in children's specific peer affiliations. This contrasts with the sociometric approach, which focuses on children's acceptance by their larger peer group. Research on children's social networks is comparatively recent and has been influenced by conceptual frameworks from sociology.

To identify their social networks, children are asked questions such as who "hangs around with" whom, who belongs to which groups, and which children do not belong to any group. Rosters are not used so that children are limited to reporting on peers about whom they are knowledgeable. Because of the verbal and cognitive demands of this procedure, it is typically used only with children past third grade. By combining children's responses statistically, researchers can create a map of children's affiliations with one another based on shared perceptions across respondents. A child is typically considered to belong to a particular group or network if so identified by 50% or more of his or her peers. On average, network size tends to increase between elementary school and middle school, then decrease over high school.

Additional measures are often derived to index how central, visible, or influential such affiliative networks or cliques are. Some are considered *nuclear*, others *secondary*, and others *peripheral*. Higher centrality groups tend to be larger than groups on the periphery. Children themselves can also be identified as more or less central within their own affiliative networks. The correlates of centrality are different for boys and girls. For boys, athletic ability, leadership, dominance, and perceived popularity tend to be important for high network centrality. For girls, academic skills and achievement, leadership, and perceived popularity tend to be correlated with network centrality. There is little research as yet concerning how group processes such as norm establishment and maintenance, leadership, and cohesion might vary as a function of group size or centrality.

In addition to declining in size with age, peer networks become less exclusive and more permeable so that children increasingly belong to more than one clique and the interconnections increase among different groups. Boys' groups generally tend to be more interconnected and less exclusive than girls' groups, possibly because they are larger overall. Across short periods of time, up to 6 weeks, affiliative networks remain stable with relatively little change in members. Instability increases over periods of a year or more, and younger children's groups are generally less stable than high school groups.

Theory and empirical research have focused on the factors and processes that underlie children's affiliative group formation and influence. Factors important to group formation include propinquity, familiarity, and similarity. Children are most likely to affiliate with classmates and other close associates than with children in their school or neighborhood with whom they have less systematic contact. This appears to be especially true for younger children, whose classrooms are more likely to be self-contained. Familiarity is also an important determinant of group affiliation, often more important than dissimilarities in academic performance or socioeconomic status.

Nevertheless, a key force in peer group affiliation is similarity based on features such as age, race, physical characteristics, academic achievement, parents' income, and qualities such as aggressiveness or popularity. Some scholars have

suggested that these shared attributes may provide grounds for mutual validation and approval during a period when social identities are developing. Similarity within children's peer groups may also reduce intragroup conflict and other threats to the group's cohesiveness and integrity.

Thus children choose to affiliate with peers who are like them, and within-group socialization processes can consolidate, amplify, or alter children's behavior and attitudes over time. Research on the socialization of children's attitudes and behavior within their peer group is relatively recent and largely limited to adolescents. The bulk of this research has been devoted to peer group affiliations among aggressive or delinquent adolescents. One of the strongest predictors of continuing aggression and problem behavior in adolescence is affiliation with peers who also use illegal substances or engage in other risk-taking, violent, or delinquent behaviors.

Thomas Dishion has coined the term "deviancy training" to describe the processes of reinforcement and approval within adolescent boys' affiliative networks that serve to maintain or increase such behavior and associated normative beliefs. Although less researched, similar processes have been shown to operate within affiliative networks formed on more positive attributes (such as academic achievement, in which members maintain or increase their similarity with respect to academically relevant behaviors). Some research has also shown that peer group affiliations can reduce a child's negative attitudes, such as racism, when the peer group's attitudes are more positive. Because of the heightened importance of peer group acceptance for adolescents, coupled with the salience of identity formation and general impressionability during this period, it is possible that peer group socialization effects are stronger or qualitatively different during adolescence than in adulthood. This issue has yet to be addressed, however.

An independent research literature on children's attitudes toward their own groups versus other groups has shown that, like adults, children have more positive attitudes toward their own group (ingroup favoritism) and more negative attitudes toward other groups (outgroup prejudice). The developmental picture is not yet clear, in part because of measurement limitations, but it appears that ingroup favoritism develops by age 5, whereas

outgroup prejudice may be weaker until middle childhood. Also like adults, children's ingroup favoritism depends on factors such as the status of the child's group; children in low-status and/or minority groups are less positive about their own group and sometimes even favor the outgroup. This research area has been concerned primarily with explaining the childhood roots of social stereotyping and racial prejudice. It would be interesting and productive to integrate research and theory on children's peer group affiliation, acceptance, and socialization with work on the formation and maintenance of their intergroup attitudes.

## CIVIL RIGHTS LEGISLATION

---

*Civil rights legislation* is a broad term that may be applied to any laws or legal rulings designed to protect the basic human rights of individuals anywhere in the world. These rights include any of a

range of principles that ensure freedoms, liberties, and general happiness to which all humans are considered entitled from birth, such as free speech, religious freedom, participation in electoral processes, due legal processes in the court system, and so forth. The term *civil rights legislation* is most commonly used to refer to laws passed during the civil rights movement of the 1960s in the United States, but the term could be applied more broadly to describe legal action to protect human rights further back in history as well as across the globe. For example, civil rights legislation in the United States arguably began with the Constitution of 1787, and civil rights are a concern for all nations interested in ensuring rights and freedoms for its citizens. Thus, for example, the United Kingdom instituted affirmative action policies to ensure equal opportunities for Catholics and the poor, and South Africa established anti-apartheid measures to end to segregation.

In the United States, civil rights legislation is accomplished through bills passed into law, court rulings, and executive orders. The most salient examples of U.S. civil rights legislation have concerned Blacks and women, but civil rights legislation has been extended to a wide range of groups and people in society. Which groups deserve legal protection against civil rights violations and what constitutes a “civil right” remain points of controversy. Nevertheless, the ultimate goal of civil rights legislation is to provide equal freedoms and liberties for those who are most threatened and who may not have the political voice for social change without such legislation. This entry presents a historical overview of civil rights legislation and related controversies, considers the impact of such laws, and describes monitoring and enforcement efforts.

### Historical Background

Civil rights in the United States are enacted both by the passing of laws that promote civil rights and by the overturning of laws that threaten civil rights. These legal actions can take place in the legislative, judicial, and executive branches of government at both the federal and local level. Legislative bodies can pass laws that enact greater civil rights protection or remove laws that threaten civil rights.

For example, the United States Congress passed a series of civil rights acts in 1957, 1960, and 1964 that provided further protection against discrimination for a wide range of groups, establishing protected classes such as race, sex, and nation of origin. The Voting Rights Act of 1965 outlawed literacy tests and other barriers to voting, and the Fair Housing Act of 1968 outlawed discrimination in the housing market. In 1990 the Americans with Disabilities Act added the physically disabled to the list of protected classes.

Laws that threaten civil rights also can be deemed unconstitutional through judiciary decisions such as those handed down by the United States Supreme Court. For example, many schools in the early 20th century were racially segregated under the notion that the education system was “separate but equal”; however, the Supreme Court ruled this system unequal and unconstitutional in the 1954 *Brown v. Board of Education* case, setting the stage for the mandatory desegregation of American schools.

The president of the United States may encourage civil rights through executive orders. For example, President Lincoln’s executive order of 1862—the Emancipation Proclamation—set the stage for the abolition of slavery, and President Truman’s executive order in 1948 formally desegregated the military, allowing Black and White soldiers to serve in the same units, equally.

The goal of American civil rights legislation is to ensure civil rights for all citizens and guarantee that those civil rights are applied equally across different groups of people. Much of the civil rights legislation in the United States is designed to protect classes of individuals who may be at greater risk of discrimination or harm. Currently protected groups at the federal level include those based on race, color, ethnicity, national origin, religion, sex, age (that is, those 40 and over), disability, and veteran status. This protection is meant to prevent discriminatory treatment in such areas as employment, the housing market, voting access, and education.

### Related Controversies

Controversies have emerged concerning the methods for ensuring civil rights protection, who should be protected, and what constitutes “civil rights.”

One important controversy surrounds the issue of whether civil rights legislation should be approached in a “color-blind” or a “color-conscious” way. A color-blind approach puts the focus on protection of minorities through ensuring equal treatment regardless of minority or majority status, while a color-conscious approach puts the focus on preferential treatment of minorities as a means of overcoming more subtle or institutional discriminatory barriers.

Martin Luther King, Jr. famously endorsed a color-blind society where people would “not be judged by the color of their skin,” but he did so in an era when blatant prejudice was far more common than it is now. Color-blind approaches today may be problematic, especially because they often involve the denial of real barriers that minorities continue to face. Striking a balance between ensuring equal treatment while helping to surmount existing barriers remains a challenge in the establishment of civil rights legislation.

Other controversies have emerged concerning which minority groups should be protected by civil rights legislation. Some groups are explicitly denied civil rights without much social outcry, such as convicted felons who are denied the right to vote in some states. However, the issue of protection can become quite controversial with respect to many groups, and civil rights legislation is often passed in the face of considerable public resistance. For example, the Civil Rights Act and Voting Rights Acts of the 1960s were signed into law despite considerable outspoken opposition. More recent times have seen resistance to the legal protection of certain immigrant populations or minorities based on sexual orientation. What makes a group deserving of civil rights protection is a point of ongoing, often heated, debate. For example, the passing of Proposition 8, an initiative on the November 8, 2008, California State ballot that denied same-sex couples the right to marry, continues to fuel heated conflict between liberals who opposed the proposition and many churches that supported it.

What is a “civil right” in the first place is also a point of controversy and is reflected in the language used to discuss civil rights. For example, distinctions have been made between “civil rights” and “special rights,” with the term *civil rights* describing proposed legislation to protect groups

that are generally seen as deserving protection, and the term *special rights* used disparagingly to refer to proposed legislation to protect groups that some people believe do not to deserve such protection. It could be argued that hate-crimes legislation, such as parts of the Violent Crime Control and Law Enforcement Act of 1994 that impose harsher sentencing for crimes against individuals based on their race, religion, and so on, is a kind of civil rights legislation designed to protect minorities from crimes directed against them because of their minority status. However, such laws have been criticized as unfairly endowing minorities with special rights or protections that should not differ from one group to another. Similar arguments against special rights have been made concerning various instantiations of affirmative action, as well as gay rights propositions.

Another point of controversy concerns legislation that restricts civil rights during times of particular danger or threat. For example, shortly after September 11, 2001, the Patriot Act was signed into law, lifting restrictions on electronic surveillance and monitoring on the grounds of increasing national security. While these laws are intended for the protection of the country, they are criticized for compromising the civil rights of those who do not pose a threat.

### Effects of Civil Rights Legislation

Sociologists in the early 20th century doubted that civil rights legislation would affect public opinion, as exemplified by William Graham Sumner’s observation that “stateways do not make folkways.” This statement suggests that laws do not determine public opinion or cultural views, but that instead public opinion and cultural views determine laws.

Some would even argue that civil rights laws do not change people’s attitudes toward the group being protected and may even have a negative effect for those groups. For example, such legislation may not remove prejudice, but instead may change the form of its expression from blatant forms to more subtle forms, as has been suggested by modern racism and sexism theorists. Political scientists have argued that civil rights legislation from the 1960s led to various backlashes, including the Southern shift from predominantly majority Democratic to majority Republican support. Similarly, social

dominance theorists have argued that advances in civil rights legislation for an oppressed group are often balanced through countermeasures that ensure the continuing balance of social power in favor of majority groups. Other research on “shifting standards” warns that the protection of various minorities may lead to the application of lower standards for evaluating their performance, which can also have harmful consequences.

Nevertheless, positive shifts in American attitudes toward Blacks since the passage of civil rights laws in 1960s have been documented, moving from majority endorsement of segregation and beliefs in the inferior ability of Blacks to a majority electing its first Black president in Barack Obama. Attitudes toward women also shifted toward greater equality following civil rights legislation protecting women.

Further questions remain concerning the impact of civil rights legislation on the attitudes and behaviors of the protected groups themselves. Does such legislation offer psychological relief to those it protects? Or does it introduce new psychological challenges, such as the reinforcement of the stereotype that minority groups inherently need protection? These questions are being increasingly researched and debated in the social sciences.

### Monitoring Activities

Once civil rights legislation is enacted, it needs to be monitored and enforced to be effective. The passage of legislative acts, judicial rulings, and executive orders does not guarantee that civil rights will be established and upheld. Consequently, various public and private organizations have emerged in the United States to help monitor and enforce civil rights legislation. At the federal level, the 1957 Civil Rights Act established the United States Commission on Civil Rights to investigate civil rights violations, and the Equal Employment Opportunity Commission was created in 1961 to monitor employment discrimination in the private sector.

Private organizations, too, have emerged to monitor enforcement of civil rights laws, such as the American Civil Liberties Union and the Southern Poverty Law Center, legal associations committed to monitoring and prosecuting civil rights abuses within the purview of the law. At the

international level, organizations like Amnesty International monitor civil rights activities throughout the globe, including the United States, where policies such as prisoner detainment without due process and capital punishment practices have been criticized.

## CIVIL RIGHTS MOVEMENT

---

The term *civil rights movement* refers to the activist efforts of Black Americans and their allies during a particular historical period (1955–1968) to claim certain basic civil rights previously withheld from Blacks and to end legalized segregation. These efforts were designed to overturn laws and customs of racial segregation, racialized disenfranchisement, and violence against Blacks. Thus the civil rights movement represents one of the most comprehensive and concerted efforts by U.S. citizens to bring about social changes that would both directly improve the lives of Blacks and

expand intergroup contact and facilitate the development of improved intergroup relations.

From a broader perspective, the struggle for civil rights in the United States did not begin or end with the events of this period. A more thorough examination of the civil rights movement among Blacks would take into account a history of Blacks' efforts to secure civil rights from the moment of their arrival in this country as slaves. It would also include modern-day efforts to secure equity in education, housing, health care, and all areas of economic life. Moreover, civil rights efforts by other groups include the women's movement, the Chicano movement, the Native American movement, and the gay liberation movement, and civil rights efforts continue to this day and throughout the world. This entry focuses first on the narrower meaning of the term *civil rights*, looking at the history and impact of the efforts to claim Black Americans' civil rights, and then touches briefly on related efforts.

### Background and Context

After the Civil War, many states passed a number of racially discriminatory laws, and racial violence against Blacks was both brutal and widespread. In 1896, the Supreme Court held in *Plessy v. Ferguson* that legalized segregation was constitutional as long as separate but equal public facilities (e.g., schools) were provided to Blacks. Organizations such as the Ku Klux Klan, which engaged in concerted and organized acts of violence against Blacks that included murder, flourished in the early part of the 20th century. In this context, civil rights efforts on the part of Blacks and other groups were focused primarily on legal efforts to overturn racially discriminatory laws and congressional lobbying to secure legislative assistance at the federal level. These efforts made some progress, culminating in the 1954 *Brown v. Board of Education* decision in which the U.S. Supreme Court overturned *Plessy v. Ferguson* and held that separate schools for White and Black Americans could never be equal and thus were not constitutionally permissible.

Although the Court ordered the desegregation of all public schools "with all deliberate speed," school desegregation efforts at the elementary, secondary, and college levels were difficult to enforce. Federal military personnel were required to enforce

desegregation orders in places such as Little Rock, Arkansas, as well as at the University of Alabama and the University of Mississippi, and many cities in the South chose to shut down their public school system for a year or longer rather than integrate the schools. Years later, Thurgood Marshall, the lead attorney who brought *Brown v. Board of Education* to the Supreme Court, quipped: "Now I know what 'deliberate speed' means—it means 'very slowly.'" Impatience with the slow progress of the use of legislation and the courts to effect change led directly to the civil rights movement.

### Historical Highlights

The civil rights movement was distinguished by a shift away from the use of litigation as the prime strategy for winning new rights toward a focus on the use of direct action—civil disobedience, non-violent resistance, and mass mobilization—to effect social change. Rather than seeking support primarily from legislators and judges, civil rights activists sought broader support for the cause and demanded the enforcement of laws that already existed.

#### *The Montgomery Bus Boycott*

Trained in nonviolent civil disobedience, Rosa Parks was arrested on December 1, 1955, for refusing to give up her seat on the bus in Montgomery, Alabama, to a White male passenger. In response, the Women's Political Council and the NAACP organized a bus boycott in Montgomery to protest both Rosa Parks's arrest and segregation and discrimination in the bus system. The boycott was tremendously successful, and the Montgomery Improvement Association was formed to continue the boycott. Dr. Martin Luther King, Jr. was elected to lead the Montgomery Improvement Association, which sought broad change in Montgomery, including but not limited to its bus system. The bus boycott lasted for a year, culminating in 1956 in a Supreme Court ruling in *Browder v. Gayle* that outlawed segregation in public buses.

King and other leaders of the Montgomery Improvement Association joined the group to other civil rights organizations in other areas of the South, leading to similar boycotts and eventually to

the formation of the Southern Christian Leadership Conference in January 1957. King's leadership of the Southern Christian Leadership Conference and the Montgomery Improvement Association, the success of the efforts in Montgomery, and the expansion of those efforts across the U.S. South made King a national figure.

During the early 1960s, organizations such as the Southern Christian Leadership Conference, the Congress of Racial Equality, and the Student Nonviolent Coordinating Committee engaged in broad efforts to end desegregation laws. Sit-ins were used effectively in many areas to protest and challenge laws enforcing racial segregation in public facilities. In 1964, four organizations together (the NAACP, Congress of Racial Equality, Southern Christian Leadership Conference, and Student Nonviolent Coordinating Committee) engaged in a broad voting rights campaign by bringing college students from around the country to Mississippi to register voters.

This activism was met with strong resistance. Civil rights activists were subjected to beatings and brutal treatment and arrest by police, headquarters and meeting sites were bombed, and individual activists were murdered. The strength of this resistance played a role in the success of the civil rights movement. Television images of police attacking nonviolent demonstrators with weapons, fire hoses, and attack dogs, as well as images of government officials attempting to bar Black students from schools and colleges, played an important role in changing broader public opinion.

### *The 1963 March on Washington*

In August 1963, a number of civil rights groups and leaders collaborated on the March on Washington that took place at the National Mall in Washington, D.C. The march was organized to push for greater civil rights protections, including greater legal protections in the South, fair housing and employment, a federal employment program, and voting rights. With more than 200,000 demonstrators participating, it was a tremendous success and widely televised. King delivered his most famous speech, "I Have a Dream," at the Lincoln Memorial during this demonstration.

After the march, King and other leaders met with President John F. Kennedy in the White

House to push for passage of civil rights legislation. Kennedy agreed to support the legislation, but it was not clear he had the votes to pass it. The bills that comprised this legislation—the Civil Rights Act (1964), Voting Rights Act (1965), and Fair Housing Act (1968)—were passed not during the Kennedy Administration, however, but during the succeeding Johnson Administration. The Civil Rights Act of 1964 prohibited discrimination on the basis of race or sex in schools, public facilities, government, and employment, effectively ending Jim Crow segregation in the South. Initially fairly weak in enforcement capabilities, the law was strengthened in subsequent Civil Rights Acts (e.g., Civil Rights Acts of 1968 and 1991).

The Voting Rights Act prohibited literacy tests to register to vote and provided federal oversight of voting registration in areas where there had been evidence of discrimination in voter registration. The Civil Rights Act of 1968 is commonly referred to as the Fair Housing Act, in that it provided clearer enforcement provisions against discrimination in the sale, rental, and financing of housing.

### **Aftermath and Ongoing Struggles**

The Civil Rights Act of 1964, the Voting Rights Act of 1965, the Fair Housing Act of 1968, and Executive Order 11246 of 1965, which ordered the use of affirmative action to ensure the lack of discrimination in employment and federal contracting, gave many the sense that the issues for which the movement had fought most strongly—voting rights, antidiscrimination laws in employment, housing, and education, and increased attention to and therefore consequences for violent acts against Blacks—had been largely resolved. Optimism was high that the changed legal and social climate would lead to effective changes in the lives of Blacks. However, 1968 was also significant because it was the year in which both Martin Luther King, Jr. and Robert F. Kennedy were assassinated, thereby depriving the movement of its most visible leader and of an important political ally.

The optimism of the 1960s civil rights movement victories gave way to the slow erosion of the hard-won gains over the coming decades. School desegregation efforts slowly dissolved beginning in the 1980s, as federal courts released pressure on

districts to continue those efforts. Schools have slowly resegregated in many places, and today schools in many areas are as segregated as they were before *Brown v. Board of Education*. In 2007, a more conservative Supreme Court overturned school desegregation efforts in Seattle and Louisville in *Parents Involved in Community Schools v. Seattle School District No. 1*. In their decision, the justices effectively turned *Brown v. Board* on its head and argued that taking race into account in assigning students to schools was unconstitutional.

Affirmative action policies designed to improve the access of underrepresented groups to colleges, employment, and federal contracting have also lost favor among many people, and recent legislative efforts and court rulings have resulted in many affirmative action policies becoming illegal in several states.

The civil rights movement, as a formal, national struggle, may have ended in the late 1960s, but many groups have continued and expanded civil rights efforts to the present day, both in the United States and throughout the world. In the United States, efforts continue to create racial equity in health care, employment, primary and secondary education, and access to higher education.

### Related Efforts

Moreover, other movements have persisted in pursuing civil rights for other groups. Examples include efforts to pursue employment rights by the United Farm Workers of America, and recent demonstrations of support for undocumented workers in the United States.

The gay rights movement has been one of the longest standing civil rights movements in the United States. The movement began in New York with the Stonewall Rebellion, a series of rebellions that emerged from frustration over police raids on gay bars to arrest gay men for illegal sexual activity. Over a period of decades, these efforts have succeeded in decriminalizing homosexual sexual activity across the United States. Efforts to secure the right to same-sex marriage have been stronger in recent years, and recent court cases have been examining antigay marriage statutes across the country. One of these cases will likely go to the Supreme Court in the coming years.

Transnationally, social change efforts, and particularly the use of nonviolent protest and direct action to secure civil rights, have been modeled on the civil rights movement. Examples of such movements include the successful efforts to end apartheid in South Africa, the efforts of students and other activists to secure human rights in China and Myanmar, and movements to secure human rights and create economic change in the Soviet Union and the eastern European nations in the late 20th century.

## CLIQUES

---

A *clique* is a small, exclusive, tightly knit group of people. Membership in such groups usually depends on social status and can have negative connotations (e.g., “Goths,” “geeks,” or “nerds”). However, the term need not be negative; for instance, *clique* is used to refer to close groups of friends like those commonly seen in high schools, organizations, and neighborhoods. This entry looks at some of the research related to this phenomenon.

### Cliques as Social Hierarchies

In early research, Warner argued that cliques are intimate informal groups of friends that represent a triumph of class over democratic values in the American school system. According to this perspective, cliques are part of the social structure that prevent people of lower social status from socializing with those of higher social status. At the same time, the clique functions to include members of the higher class with others of their kind. In other words, the clique system ordinarily helps reward those who are higher in class and punish those of a lower class.

Subsequent research has focused on the formation of cliques among children and in organizations, and on the impact of cliques within larger social structures on individuals' satisfaction with those structures. In development, adolescents from all social classes form cliques. However, students from middle-class backgrounds tend to switch friendship groups with shifting interests, whereas students from working-class backgrounds place more emphasis on loyalty and stability.

Furthermore, perhaps surprisingly, while positive perceptions of self and other are important determinants of interaction, personality characteristics are unrelated to clique formation. In contrast, IQ, social class, and how favorably children are perceived by their teachers predict clique formation in classroom settings.

### Gender Differences

Cliques may have different meanings and functions for adolescent boys and girls. In adolescence, girls appear more interpersonally competent and are more concerned with intimacy and exclusivity in their friendships than are boys. These differences are reflected in friendship patterns, with preadolescent girls tending to form exclusive dyads or triads, and boys forming larger, more loosely knit groups. Being in a clique can have negative effects on girls' self-esteem, with the clique encouraging expressions of jealousy and competition. In contrast, there can also sometimes be positive effects of clique membership for girls, with recent research by Henrich and his colleagues reporting its helpful effects on peer relationships and school adjustment.

### Related Constructs

Among adults and adolescents, cliques are characterized by high levels of conformity. Research suggests that cliques exemplify homogeneity in academic performance, showing remarkable consistency in academic achievement, substance use, and aggression. These findings seem to reaffirm the popular conception that cliques are breeding grounds of peer pressure and conformity. However, research suggests that conformity can also result from selection processes, with similar individuals choosing to associate with one another.

High levels of conformity go hand in hand with the tendency for cliques to be highly cohesive groups. Cohesive groups tend to exert more social influence, and their members are typically more committed to the group. There is an inverse correlation between group size and cohesiveness. As more and more members join a group, it becomes more difficult to maintain cohesion. This is consistent with the characterization of cliques as typically small groups.

## COALITIONS

---

A *coalition* is defined as two or more individuals or groups who act jointly to affect their own and others' outcomes. Coalitions, which can be found at every level of human organization, arise in situations where people are in conflict over the allocation of scarce outcomes but need each other to reach an agreement. This entry begins by describing the game approaches used to study coalition formation, and then examines some of the predominant theories used to explain coalition-building behavior.

### Coalition Games

To understand coalition formation as a group process, social psychologists have adopted an approach that has its roots in game theory. In this approach, parties (individuals or groups) are called players, and the format in which these players negotiate about forming a coalition is called a coalition game. Moreover, the outcome that is obtained when forming a coalition is usually a quantitative measure such as money or points. The two main questions that are addressed in this research are "Which players will be included in the coalition?" and "How will they distribute the outcomes of the coalition?"

Coalition games have been categorized in a number of ways. One distinction between coalition games is whether all coalitions that are allowed to form also yield the same reward or whether each possible coalition yields a different reward. The first type of game is called a *simple game*. The second type of game is called a *multi-valued game*. Another distinction between coalition games is whether the individual parties are assigned resources or not. These resources are comparable to votes in a political convention. Resources are assigned in most simple games but are not assigned in most multivalued games.

The coalition games most often investigated by social psychologists are simple games in which three or more people are each assigned a number of resources (e.g., votes), and learn that they need a certain total number of resources to obtain a positive outcome. Because this number exceeds the number of resources of any individual, they can

only obtain the positive outcome if they join forces. For example, in a three-person group, the members A, B, and C can be assigned two, three, and four votes, respectively. They may then learn that \$100 will go to the members of any coalition that controls at least five votes.

### Static Theories of Coalition Formation

The resources that people control are important in two distinct ways. First of all, the resources have a *strategic function* in that they determine people's power position or bargaining strength. For example, people's resources may determine how many alternatives they have to form a coalition. In general, people or parties with many resources will have more opportunities to form a winning coalition. Second, the distribution of resources also has a *normative function* in that they determine how parties prefer the outcomes of the coalition to be distributed. For example, the *minimum resource theory* assumes that the coalition members will want to distribute the coalition outcomes in proportion to their initial resources, such that members with twice as many resources should obtain twice as much from the coalition outcomes.

The essence of most theories of coalition formation is that the selection of coalition partners and the distribution of the coalition outcomes across its members are strongly related. The preferred distribution of coalition outcomes thus determines who people prefer as their coalition partner. Combined with the assumption that people want to maximize their own outcomes, minimum resource theory for example predicts that people want to be part of a coalition that contains as few resources as possible. In the example above, with five votes needed for a winning coalition, this means that the members with two and three votes will team up because this would yield each of them a higher share of the coalition reward than would teaming up with the member controlling five votes. The members of the coalition with two and three votes would obtain 40% and 60%, respectively. When teaming up with the member controlling four votes, their shares would be lower—33% (2/6) and 43% (3/7), respectively. Controlling many resources may thus not always be an advantage, a finding that is also referred to as the *strength-is-weakness effect*.

Whereas minimum resource theory assumes that people take the distribution of resources as a basis for the distribution, other theories stress the importance of alternative dimensions. *Minimum power theory* assumes that people primarily focus on the power dimension (i.e., on whether members are really needed to form a winning coalition). A person's pivotal power is defined by determining how many winning coalitions would turn into losing coalitions if the member withdrew. This theory assumes that members want to distribute coalition outcomes in proportion to the power of their positions. Based on reasoning similar to minimum resource theory, this leads to the prediction that people want to be part of a coalition that is minimal in terms of total pivotal power.

### Dynamic Theories of Coalition Formation

Static theories assume that members agree on the basis for distribution. This gives the impression that coalition formation is a process where members take the dimension for distribution as a given and simply calculate which coalition will then yield them the highest outcomes. Dynamic theories of coalition formation are more process oriented and acknowledge that members may disagree about the dimension that should be used to distribute coalition outcomes. By assuming that people are mainly self-interested and that their primary aim is to maximize own outcomes, dynamic theories of coalition formation resemble static theories. The main difference between these theories is that dynamic theories also assume that self-interest colors the selection of dimensions for distribution.

*Bargaining theory* assumes two possible distribution rules; the proportionality rule (that also forms the basis of minimum resource theory) and equal distribution. According to this latter rule, the outcomes of the coalition should be distributed equally to all members of the coalition. Self-interest may shape the preference for distribution rules. Group members with many resources will prefer to distribute outcomes in proportion to the resources each member possesses. Such a rule would be to the disadvantage of members with few resources; they would obtain higher outcomes if the coalition outcomes were distributed equally.

Bargaining theory states that self-interested members may initially disagree on which rule to

follow. To solve the disagreement, members are expected to subsequently meet each other half-way. Bargaining theory thus sees coalition formation as a dynamic bargaining process that starts off with disagreement, and after bargaining, results in settling and agreement. When members outside a coalition make a competing offer to tempt the coalition members to leave it and form a new coalition, the situation becomes even more dynamic, and new distributions will emerge during the process.

A final theory to consider here is *equal excess theory*, which places greater emphasis on bargaining strength. This theory assumes that the distribution that members of a coalition initially demand is determined by what they can reasonably expect to receive in their best alternative coalition. The excess that the current coalition can offer over this best alternative will then be divided equally. Suppose, for example, that two members, A and B, bargain over how to distribute the coalition outcomes of \$100, while knowing that the best alternative for A pays \$50, and for B pays only \$30. Because the best alternatives of A and B add up to \$80, the total excess in this case would be \$20 (\$100 - \$80). The expected distribution after an equal split of the excess would then be \$60 for A (\$50 + \$10) and \$40 for B (\$30 + \$10). Similar to the process of counteroffers that underlies bargaining theory, other members may subsequently tempt the coalition members into forming a new coalition, which implies that standards for distribution will change during the bargaining process.

### Empirical Support and Theoretical Limitations

The emphasis of coalition research has traditionally been to determine which of the proposed theories most accurately provides the answers to the questions of who will be the members of the winning coalition and how the coalition outcomes will be distributed over the members. In general, the dynamic theories have obtained more empirical support than the static theories. Situational characteristics and personal characteristics may, however, strongly affect how people bargain. Such factors may therefore affect the predictive accuracy of the theories. For example, experienced bargainers seem less likely than inexperienced

bargainers to distribute the coalition outcomes equally, and women appear to show a greater preference for equality than do men.

A related and more general issue concerns the primary motivation of bargainers. The theories cited above—whether static or dynamic—all agree on one thing: The primary motivation is self-interest. Parties are first and foremost assumed to strive to maximize their own outcomes, and this in the end determines which coalitions will be formed and how the coalition outcomes will be distributed to the coalition members. This focus on self-interest fits with the game-theoretic foundations of these theories and research on coalition formation. However, social psychology also acknowledges motives other than self-interest.

As social beings, we also care for the other people's outcomes. The *social utility model* of coalition formation has formalized this broader perspective on human motivation by distinguishing fairness as a separate motivator. The basic tenet of the model is that people assign a positive value to both self-interest and fairness, but that situational and personal characteristics may affect the weights of each of these motives. With this model, it is now also possible to explain why sometimes people want to include others in a coalition even if the coalition would be winning only if these others were left out. Self-interest alone could not explain such behavior, because coalition members obtain higher outcomes if they share the coalition payoff among few members rather than among many members. People may, however, consider it to be unfair if others are left out. This view accords with the notion that people are reluctant to exclude and ostracize others. People with a more prosocial motivation appear especially sensitive to what happens to those who are excluded.

In a similar vein, research has shown that it matters whether outcomes are positive or negative. Whereas most research on coalition formation has focused on positive outcomes, some research has studied how coalitions form when the winning coalition can allocate a negative outcome and so determine which parties have to pay. Because people assign a greater weight to fairness when outcomes are negative, people are more likely to include all parties in the coalition agreement.

## COGNITIVE CONSISTENCY

---

*Cognitive consistency theory* encompasses a broad group of theoretical statements whose central core is that people prefer consonance among their cognitions, thoughts, feelings, and behaviors. These theories seek to explain individuals' discomfort with inconsistency in their social lives. Although theories of cognitive consistency initially focused on individuals as the unit of analysis, research has recently shown that cognitive consistency is a central component of intergroup and intragroup relationships as well. This entry looks at a precursor theory and then examines the development of cognitive consistency theory and its application to both groups and intergroup processes.

### Balance Theory

Most influential of the early cognitive consistency models was Fritz Heider's balance theory. The

principle of psychological balance can be applied to any set of cognitions, but it is described most easily as a set of relations between a reference person (P), another person, perhaps a friend (O), and an attitude object (X). These relations were said to be balanced when they were consistent. For example, if P likes O and both P and O like the object X, the cognitions are said to be consistent or balanced.

However, if person P likes O but they differ in their evaluation of X, then the relationships are imbalanced or inconsistent. The perception of cognitive inconsistency produces a strain toward balance in which P attempts to restore consistency by changing his or her attitude toward the object X or toward the friend O. The steak lover who is friends with the vegetarian experiences tension whenever their food preferences are discussed; as much as these two people like each other, there is tension over their food preferences and a drive to establish balance.

Much foundational research was conducted under the rubric of balance theory. Balanced relationships are viewed more positively than imbalanced ones, imbalanced relationships cause more tension than balanced ones, and there is a desire to bring imbalanced relations into balance. But balance theory had very little to say about the characteristics of P, O, and X that would make imbalance most troubling or about the methods people would use to attempt to restore balance to dissonant relationships. It was in part to address this void that, in the late 1950s, there arose a new theory: cognitive dissonance.

### Cognitive Dissonance

In 1957, Leon Festinger published *A Theory of Cognitive Dissonance*. In some ways, dissonance theory is similar to balance theory. The state of cognitive dissonance occurs when people believe that two of their psychological representations are inconsistent with each other. Put another way, a pair of cognitions is inconsistent if one cognition follows from the obverse of the other. For example, some people believe that they should give money to the poor but refuse to give change to someone who asks for it. These two cognitions are dissonant because not giving alms follows from the obverse of these people's belief. Had they believed that giving money to the poor was either wasteful

or counterproductive (the opposite of their actual beliefs), the action of passing by without giving would have logically followed. As things are, the action is dissonant.

Holding two or more inconsistent cognitions arouses the state of cognitive dissonance, which is experienced as uncomfortable tension. This tension has drive-like properties and must be reduced. One of the major innovations of dissonance theory compared to prior models of consistency such as balance theory, however, is that it speaks in terms of magnitude. Most dissonance research does not compare how people respond to consonant and dissonant relationships among cognitions, but rather how they respond to cognitions that are dissonant to varying degrees.

Perhaps the most famous study in dissonance research makes this point very well. Festinger and his colleague, J. Merrill Carlsmith, asked research participants to perform a series of boring tasks: turning pegs clockwise, then turning them counterclockwise, taking the pegs out of the peg board, putting the pegs back into the board. After an extended period, the experimenter thanked the participants, telling them that the task was completed.

The study was about expectations and performance, he said, and some participants had been told that the task was interesting and exciting, while others had been given no expectation. This explanation of the study's purpose was false, but it was a necessary component of the real experiment. The experimenter then said that the research assistant who was supposed to tell the next participant that this dull, boring task was actually interesting and exciting had failed to arrive. Would the participant be willing to help out and take the assistant's place?

The participant knew that the task was actually boring and dull and that it was generally wrong to lie to people to raise their hopes. However, the experimenter was doing important work and was even offering to pay the participant for this relatively trivial task. Almost all participants agreed to lie to the waiting stranger (actually a research assistant), and they then rated the pleasantness of the peg-turning task. The researchers were interested in how participants who were highly paid to lie rated the study compared to those who were poorly paid. They found that those paid \$20 to tell the lie rated the study as having been more boring

than those only paid \$1. This counterintuitive finding was well explained by dissonance theory: Those paid \$1 had less justification for lying to the waiting stranger and thus more need to distort their impressions of the task to match their attitude-inconsistent statement.

This experimental paradigm was later refined and simplified into an “induced compliance” method. In this method, participants are persuaded to make a counterattitudinal statement under conditions in which (1) they believe they are free to refuse (i.e., there are no prohibitively large inducements or punishments for refusal) and (2) the statement, if made, will have some aversive consequences. A classic example is advocating a noxious political position in an essay that will be shown to impressionable high school students. Compared to those who either are not free to refuse or believe their actions will have no consequences or lesser consequences, those who act under these conditions come to agree more with their counterattitudinal position.

### Application to Groups

Shortly after the pioneering study described above, Elliot Aronson and Judson Mills applied dissonance theory to aspects of a social group. They tested whether an unlikable group would become better liked if it had been difficult to join. They recruited female participants for a “sexual discussion group.” After an initial screening, participants were supposedly connected via speakers and microphones to a discussion of sexual behavior. In reality, participants were made to listen to a tape of people having a boring conversation about the secondary sexual characteristics of various insects. Participants then rated how enjoyable the conversation had been.

As in the peg-turning study, the key variable of interest was something unexpected. Before allowing participants to listen to the discussion, the experimenters explained that many people found discussions of sexual topics disturbing, and to show that they were comfortable discussing such topics, participants would have to read a list of words. For some participants, the list was fairly mundane, for others, lurid and obscene. Those participants given the more extreme screening task were more likely than the others to report that the subsequent

discussion group (which was intentionally made as boring as possible) was in fact interesting.

After having been made to suffer so intensely, participants who had read lurid words to this stranger needed to justify their effort by claiming that the experience had been worth it. Their dislike of the discussion group was in conflict with the effort they had expended to enter it, and they resolved this dissonance by changing their impression of the group to be more consistent with their effort. They came to like the discussion better and to like the group members better than those who had not suffered to join the group. This work is relevant to hazing and initiation rituals, as making a group difficult to join apparently increases that group’s attraction.

Other studies have shown that groups can alter the magnitude of cognitive dissonance and the direction that its resolution takes. One study showed that people in groups can diffuse responsibility for their inconsistent actions and experience less dissonance. Individuals who were engaged in a group project to write an essay inconsistent with their attitude apparently convinced themselves that their own portion of the inconsistency was less than that of the group, and therefore, they experienced less discomfort as a result of the group project. Another study in a group context showed that people who act in a manner inconsistent with a fundamental attitude of their group respond to inconsistency not in the usual manner of changing their attitudes toward the issues, but rather by derogating the outgroup. For example, members of the Republican Party in the United States who wrote an attitude-inconsistent essay advocating the Democratic candidate for president resolved their inconsistency by derogating the outgroup—that is, Democrats.

### Intergroup Processes

A more recent expansion of cognitive inconsistency research has taken it in a direction relevant to intergroup processes. Working from both cognitive dissonance theory and social identity theory—which describes when and why individuals identify with, and act as members of, social groups—researchers have begun to investigate what is termed *vicarious dissonance*. They have found that, in addition to experiencing personal cognitive dissonance when

we make our own choices or act in ways that are counterattitudinal, we may also experience dissonance vicariously whenever members of our social groups make choices or act in ways that are inconsistent with their attitudes. Because we are in many social groups, the opportunities to experience dissonance on behalf of fellow group members are numerous. The conceptual proposition that is at the core of vicarious cognitive dissonance is that dissonance brought about by the actions of a prototypical member of a social group will lead us, as fellow group members, to change our attitudes, even though we have no direct responsibility for the dissonance-inducing behavior.

In a typical vicarious dissonance study, a person is induced to evaluate speeches made by other group members, typically members of the same group or school as the participant. The participant overhears the group member agree to make an attitude-inconsistent statement under conditions that classically evoke dissonance. If the speechwriter and the actual participant share a common group identity, then the participant too experiences attitude change, despite having done nothing that should provoke dissonance. Moreover, the magnitude of the dissonance is a function of the strength of the social identification that participants feel with their social group.

This finding has broad implications for intergroup processes. For example, in cultures that emphasize group harmony and cohesiveness, the experience of vicarious dissonance should be quite high. One recent study in that area found that East Asians, who often do not show personal dissonance effects, strongly experienced vicarious dissonance when a fellow group member acted in an inconsistent manner. This finding was the latest in a series that has shown that, while personal inconsistency is dissonance provoking primarily in Western cultures, interpersonal dissonance also occurs in collectivist cultures such as those of Japan and Korea.

A representative study conducted with Japanese and Canadians of European descent showed that European participants experience dissonance when making difficult choices for themselves as individuals but that Japanese experienced dissonance only when making choices for fellow group members. These results suggest that group-based dissonance processes may be universally pervasive and therefore relevant to a wide range of people and situations.

Cognitive consistency research began in an individual context, with occasional research studies examining people as members of social groups. This research on individuals focused on their suffering from imbalanced relationships or dissonant cognitions as a function of mental representations inside their heads. The current interest in social identity and cultural psychology, however, has led to an explosion of research examining consistency from the perspective of the embeddedness of people in their cultures and within the social groups that comprise those cultures.

## COLLABORATION TECHNOLOGY

---

The emergence of the Internet over the past 40 years has created a rich new arena for group activity. Specifically, where physical collocation was once a requirement for both group membership and communication, computer networks now create the opportunity to form and maintain groups independent of time and space. These are often called *distributed groups*. Tools for supporting distributed group work and play are collectively referred to as *collaboration technology*.

Early forms of collaboration technology emerged in the 1960s and 1970s as by-products of the first computer networks, such as the ARPAnet. Over time, many applications (e.g., electronic mail, or e-mail) designed to support remote computer operations came to be valuable on their own and

have become nearly ubiquitous as communication tools. The emergence of the Internet in the 1980s, and the explosion of network use associated with the rise of the Web in the 1990s, have accelerated the development of collaboration technology. Today, this technology spans a wide array of applications and services. Some of these would be recognizable to the builders of the ARPAnet (e.g., e-mail and instant messaging), but others probably could not have been imagined by them (e.g., virtual worlds, such as Second Life, and social networking sites, such as Facebook).

The development, adoption, and use of collaboration technology raise key questions about group processes and intergroup relations. Specifically, in traditional groups, physical proximity plays a central role in group formation, maintenance, and communication. In contrast, distributed groups mediate their activity through collaboration technology. Therefore, the success of distributed groups depends, to a large extent, on the ability of collaboration technology to allow distributed groups to perform as well, or maybe even better than, collocated groups. Much of the history of collaboration technology can be understood as attempts either to mimic the benefits of collocation (“being there” technology) or to exploit certain features of collaboration technology to create new benefits (“beyond being there” technology).

### “Being There” Technology

An important thrust in collaboration technology is an emphasis on real-time interaction that allows distributed participants to engage in activity at a distance as if they were collocated. Landmark instances of “being there” technology include (a) applications to share common views and control of documents and drawings, now common in the form of data conferencing tools such as WebEx; (b) applications that provide greater awareness of distant group members (e.g., “busy” or “away from desk”), now popular in the form of instant messaging tools such as MSN Messenger; and (c) applications to see and hear distant group members, such as videoconferencing. More recent instances of “being there” technology include virtual worlds such as Second Life, which provide simulated geographies and built environments in which individuals interact via computer-generated avatars.

Some “being there” technologies have achieved tremendous success and have come to define entirely new genres of interaction and affiliation. Consider, for example, adolescents’ use of text messaging and the proliferation of “textese.” Other forms of “being there” technology, such as data conferencing, have received broad adoption in certain contexts, such as within corporations to support distributed work teams. And even more novel “being there” technologies, such as virtual worlds, in some cases have attracted large numbers of users (e.g., the hundreds of thousands using Second Life) who have created vibrant “inworld” economies. Despite this growth, virtual worlds remain outside the mainstream of collaboration technology use.

### “Beyond Being There” Technology

An equally important thrust in collaboration technology is an emphasis on asynchronous interaction. This allows people who are not in the same place at the same time to engage in a collaborative or collective activity. Landmark instances of “beyond being there” technology include (a) applications to collect, process, and distribute user-contributed content—Wikipedia is the best known example; (b) applications to exploit, analyze, and visualize links and ties among individuals, such as the social-networking site Facebook; and (c) applications to process and distill patterns from collective behavior, such as the pagerank algorithm used by Google to sort the results of searches in terms of the frequency of pointers to a site. More recent instances of “beyond being there” technology include applications to aggregate small increments of human attention and labor into large-scale efforts, such as von Ahn’s “games with a purpose” (e.g., tagging all extant images on the Web), Amazon’s Mechanical Turk, NASA’s “clickworkers” (e.g., classifying craters from photographs of the Martian surface), and “crowdsourcing” (e.g., attempting to harness expertise that is dispersed and difficult to locate, such as use of the Innocentive Web site).

Some “beyond being there” technologies have achieved tremendous success and have come to define entirely new modes of production and work organization, such as Wikipedia or open source software projects. Similarly, pagerank and Google have redefined how people seek information—“to

google” is now a recognized verb form. Other forms of “beyond being there” technology, such as crowdsourcing, have also produced notable successes. For example, Mechanical Turk was used to accelerate the search for Jim Grey, a famous computer scientist who was lost at sea. Grey’s colleagues used Mechanical Turk to get thousands of volunteers to prescreen tens of thousands of satellite images of open ocean searching for evidence of Grey’s boat. Figuring out how to use crowdsourcing to integrate closely coupled, cognitively complex work has proved more elusive.

### New Directions in Collaboration Technology

Current research suggests important directions for the development of the next generation of collaboration technologies. In terms of “being there” technology, for example, continuing increases in network bandwidth, combined with advances in video resolution, have resulted in videoconferencing systems that show life-sized views of distant group members with sufficient clarity to reveal subtle nuances of communication, such as gaze direction and body language. Researchers have known for some time that users dislike videoconferencing due to the fuzziness of remote images, poor audio quality, and “choppiness” in video and audio transmissions. Modern systems, such as Cisco’s Telepresence, address these concerns by combining high definition video, spatially located audio (i.e., voices come from the direction of the speaker’s image on screen), and uniform room furnishings to create the illusion that distant group members are all together in the same space. The success of these systems may depend as much on their technical performance as it does on successful elaboration of group procedures and practices to accommodate the systems. Specifically, scheduled use of videoconferencing (e.g., formal meetings) does not create opportunities for spontaneous encounters. By contrast, continuous video links between remote public spaces do allow for chance meetings, which are an important way of coordinating work.

In terms of “beyond being there” technology, advances in productivity and performance will require a better understanding of what motivates individual contributions to contribution-based production systems. For instance, the success of recommender

systems, such as those used by Netflix and Amazon, depends on users rating or evaluating a sufficient number of movies or books. Motivating these contributions involves system designs that reduce free riding. In particular, people are more likely to make contributions when they feel that others, especially similar others, are also making contributions. In the future, the design of these “choice architectures” will be as significant to the success of “beyond being there” technologies as the design of the underlying technologies and interfaces.

## COLLECTIVE GUILT

---

Guilt is an unpleasant emotional reaction that occurs with the perception of having committed

some type of moral violation. Historically, psychological research on guilt has focused on the feelings of guilt that arise when people feel personally responsible for causing illegitimate harm to others. Recent research has revealed that people can have similar feelings of guilt when their *group* is perceived to be responsible for illegitimately harming members of another group. This *collective guilt* results from sharing a social identity with others whose actions represent a threat to the positivity of that identity. Thus even though others were responsible for the harm or moral violation, and the individual is not directly implicated in the harm-doing, the individual can still have feelings of collective guilt.

A wide range of intergroup inequalities can elicit these feelings, from the receipt of unearned benefits or privileges that members of other groups do not receive to more extreme forms of harm-doing, including genocide. Given the aversive nature of collective guilt, people are motivated to avoid or decrease its intensity. There are several methods for doing so; these generally involve distorting perceptions of the ingroup's behavior (e.g., minimizing the extent of harm done, denying the harmful actions entirely) or justifying its actions (e.g., because the victims deserved their outcomes or the ingroup had legitimate reasons for causing the harm it inflicted). Use of all of these options can help to maintain a positive social identity when even the gravest of ingroup harm-doing is confronted.

Despite its aversive nature, feeling collective guilt can lead to positive social outcomes, such as reducing negative attitudes toward the harmed outgroup and promoting intergroup reconciliation through apologies or reparations. These benefits are particularly likely when repairing the harm done is perceived to be not too difficult or costly, so that correcting the wrongs committed by the ingroup seems both feasible and worthwhile.

### What Causes Collective Guilt?

Several factors influence whether, and how much, collective guilt is experienced in response to reminders of ingroup harm-doing. First, one's social identity must be salient. For one to experience collective guilt, one must perceive oneself as a member of a social group that has committed illegitimate harm

against an outgroup. This produces a perceptual shift from thinking of oneself in terms of "I" or "me" toward thinking of oneself in terms of "we" or "us." In this way, the self can be linked with past or present ingroup harm-doing. For instance, contemporary Americans can certainly claim that they personally did not participate in slavery or the colonization of indigenous peoples. Nonetheless, when contemporary Americans think about themselves as part of the historical legacy, from which they may even benefit in the present, they can experience collective guilt based on the past actions of the larger "we."

The second factor that influences the extent to which collective guilt is experienced is collective responsibility. In order to feel collective guilt, it is important for people to perceive their group as responsible for the harm done to the outgroup. One basis for attributing responsibility to a group is perceiving that group as having benefited from the harm done to the outgroup. For instance, existing racial inequality can be framed in terms of the consequences that it has for outgroup members, or in terms of the consequences that it has for ingroup members. Thus researchers framed racial inequality in the United States in terms of Black disadvantage or White privilege. The framing of racial inequality as "Black disadvantage" allowed White participants to feel less collectively responsible for the harm done to the outgroup, which lessened collective guilt. Framing racial inequality as "White privilege" increased White participants' feelings of collective responsibility for the harm done to the outgroup, leading to greater collective guilt.

The third factor that influences the experience of collective guilt is the perception that the ingroup's actions toward the outgroup were illegitimate. Collective guilt requires that people see their ingroup's actions as unjustified, immoral, or wrong based on existing ingroup norms. Because it is threatening to conclude that one's group has acted unjustly, people will employ a number of strategies that are aimed at justifying the ingroup's actions. To the extent that the ingroup's harmful actions can be interpreted as legitimate and reflecting noble intentions—especially those that can be construed as protecting the ingroup from harm—collective guilt for even the most severe harm will be lessened.

The experience of collective guilt is not simply a function of empathy for those harmed. Rather, the

experience of collective guilt reflects the distress that is aroused when the ingroup's morality is questioned. Two studies have directly tested whether empathy for the victims or distress about one's own social identity determines the extent to which collective guilt is experienced. In these studies, perceiving the ingroup (i.e., men) as responsible for the inequality that harms the outgroup (i.e., women) was found to increase collective guilt via self-focused distress and not by empathy for the outgroup. This not only discounts the view of guilt as stemming from empathy, but it also supports the notion that guilt is a self-conscious emotion.

### What Reduces Collective Guilt?

There are numerous means by which collective guilt can be undermined. For this reason, collective guilt has been described as a fragile emotion. Collective guilt can be lessened in at least four ways.

First, people can deny the ingroup's harmful actions, or downplay the severity of the harm done to an outgroup. Perceiving fewer victims or even fewer ingroup members as involved in the harm-doing can lessen collective guilt.

Second, people can deny the ingroup's responsibility for harm done to an outgroup. For example, men could blame women who are raped by suggesting that women somehow encourage the perpetrators, whether through their appearance or behavior. By blaming female victims for the harm done to them, men can escape feeling any collective guilt for their group's harmful treatment of women. Moreover, people can deny the existence of collective responsibility, choosing instead to claim that only individuals are responsible for their behavior. For instance, American soldiers who served in Vietnam could deny collective responsibility for the harm done to Vietnamese civilians by suggesting that such harm was committed by a few bad ingroup members and those alone should be held responsible. When individual members of the ingroup are singled out for blame, then people can escape feeling collective guilt for the group's harmful actions.

Third, people can claim that their group's behavior was legitimate. For instance, Jewish research participants have reported that Israel's harm to Palestinians is justified because it is in response to Palestinian terrorist attacks against

Israel; such claims undermine feelings of collective guilt. The same is true of Americans. When Americans are reminded of the 9/11 terrorist attacks on the United States, they are less likely to feel collective guilt for subsequent harm done to Iraqis—U.S. actions in Iraq are seen as a legitimate response to al Qaeda-sponsored terrorism. Another way to legitimize the ingroup's harmful treatment of outgroups is to dehumanize the victims. By portraying members of outgroups whom we harm as either animals or machines, we can make our ingroup's behavior appear natural and even necessary. Such perceptions allow people to escape feeling collective guilt for harm-doing that is intentionally inflicted.

Fourth, people can focus on the benefits of the harm done to outgroup members, rather than the costs. For instance, Dutch research participants who read a benevolent description of their ingroup's historical colonization of Indonesia (e.g., "they built roads and schools") experienced less collective guilt than those who read a less benevolent description of their ingroup's colonization (e.g., "they annexed land and killed natives"). When the harmful treatment of the outgroup is portrayed as turning out positively, then people can escape collective guilt for their group's harmful actions.

People's feeling collective guilt may not be sufficient to translate into their reconciliation with the outgroup and future positive behavior toward outgroup members. In order to initiate action, people must also feel some amount of efficacy to bring about desired changes and believe that it is possible to make up for the harm done. For instance, when men were led to believe that the difficulty of making reparations to women for the harm done to them (e.g., the economic disadvantages women have suffered due to institutionalized sexism) would be very costly, collective guilt was lower than when the cost was deemed to be more moderate and therefore potentially manageable. Thus, when people believe they can bring about change that will result in more positive relations between groups, feelings of collective guilt are most likely to encourage reparations for past harm.

Although collective guilt is an aversive emotion, it is predictive of a number of positive social consequences. A variety of studies have shown that the more White Americans feel collective guilt for

racial inequality, the more they support affirmative action programs for the harmed group. Feelings of collective guilt also predict support for apologies to the harmed group, as well as financial reparations. Perhaps most important, feeling collective guilt for racial inequality can decrease racism.

## COLLECTIVE INDUCTION

---

*Collective induction* is the cooperative search for rules and principles. For example, members of a scientific research team observe patterns and regularities in some domain (e.g., biology), propose a theory to explain them, derive hypotheses from the theory, and use experiments or controlled observations to test the hypotheses. If the results of their research support the hypotheses, team members become more confident in their theory. If the results fail to support the hypotheses, team members revise or reject their theory. This entry discusses research on collective induction that models the behavior of scientific research teams and similar cooperative groups, such as auditing teams, air crash investigators, and art experts.

### An Experimental Procedure for Research

In studies of collective induction, group members are gathered around a table and informed that their objective is to induce a rule based on standard playing cards with four suits (clubs, diamonds, hearts, and spades) of 13 cards each. Aces are given the numerical value 1, deuces 2, and so on up to kings, which are given the value of 13. The rule may be based on any of the characteristics of the cards, such as suit (e.g., “diamonds”) or number (e.g., “eights”), or any combination of numerical and logical operations on suit and number (e.g., “red queens,” “even diamonds alternate with odd spades,” “red queens or black jacks”). The experimenter then places a card that is an example of the rule (e.g., the eight of diamonds for the rule “diamonds”) on the table.

Each trial consists of three stages: (1) each group member records his or her hypothesis about the rule, (2) the group proposes a hypothesis, and (3) the group plays any one of the 52 cards. As cards are played, the experimenter arranges them on the table in a way that provides information about what the correct rule might be (with cards that are examples of the rule placed beside one another, and cards that are not examples placed below the last card played). This procedure continues for 10 trials, at which point the group makes a final hypothesis and is informed whether it is correct or incorrect.

### Collective Versus Individual Induction

Groups solve these rule-learning problems better than the average individual (e.g., 20 four-person groups versus 20 individuals). Beyond this, groups have been compared to the best of an equivalent number of individuals (e.g., 20 four-person groups versus the best 20 of 80 individuals). In this research, the group or individual solves the problem from one array of hypotheses and card plays (as described above), or from two, three, four, or five arrays of hypotheses and card plays. In all cases, card plays can be viewed as “evidence” regarding the correct rule. Including two or more arrays is useful, because this group models the procedure of a team of scientists conducting two or more simultaneous experiments in a particular domain (e.g., synthesizing a compound).

With one, two, three, or four arrays of hypotheses and card plays, groups perform at the level of the second-best individuals. With five arrays, however, groups perform at the level of the best individuals. This is interesting, because it is relatively uncommon for groups to perform at this level. Studies varying both the number of hypotheses and the number of card plays (or evidence) demonstrate that card plays are relatively more important than hypotheses in helping groups determine the correct rule. Although group members are generally able to generate and propose an adequate number of hypotheses, they need sufficient evidence to test and evaluate them.

### Simultaneous Collective and Individual Induction

Many scientific research teams conduct experiments and also exchange hypotheses and/or evidence with independent individual scientists who are working on the same problem. For example, a team of virologists at the Centers for Disease Control may exchange hypotheses and experimental results with independent researchers in other laboratories. In research on such simultaneous collective and individual induction, a group and one or more individuals solved the same problem at the same pace in separate rooms.

In four conditions, the group and individual(s) (1) exchanged hypotheses and card plays on each trial, (2) exchanged hypotheses only, (3) exchanged card plays only, or (4) solved the problem independently without exchange. Groups performed better than the individuals, and both exchange of hypotheses and exchange of card plays improved group and individual performance. Moreover, group performance was improved relatively more by exchange of card plays, whereas individual performance was improved relatively more by exchange of hypotheses. This again shows that groups are able to generate sufficient numbers of hypotheses but need evidence to test and evaluate them. Additional analyses indicated that, across successive pairs of trials, groups influenced individuals more than individuals influenced groups.

### The Processes of Collective Induction

After the correct rule is chosen by the experimenter and an initial example is designated, all proposed

hypotheses are either plausible (consistent with the evidence to that point) or “nonplausible” (inconsistent with the evidence to that point). Research indicates that groups use an interesting and orderly process of choosing group hypotheses from members’ individual hypotheses. If at least two group members propose correct and/or plausible hypotheses, the group selects one of them. However, if only one member or no member proposes a correct or plausible hypothesis, the group selects among all the proposed hypotheses (correct, plausible, or nonplausible). If a majority of members proposes the same hypothesis, the group chooses this hypothesis, but if there is no majority, the group takes turns in choosing each member’s hypothesis over successive trials. On approximately 20% of the trials, the group proposes an emergent hypothesis that no member has proposed, but these emergent hypotheses are rarely correct.

If one group member proposes the correct hypothesis on a trial, the final group hypothesis will be correct with a very high probability (.99), but if no group member proposes the correct hypothesis, the final group hypothesis will be correct with a very low probability (.01). Thus, groups are remarkably good at recognizing and adopting a correct hypothesis if it is proposed by a member, but they are remarkably poor at forming correct emergent hypotheses that no group member has proposed.

### Conclusion

Research on collective induction yields several general conclusions. Collective induction is superior to the induction of the average individual and equal to the induction of the best individual when the group is given a large amount of information from many arrays of hypotheses and card plays. Group induction benefits more from increasing evidence than from increasing hypotheses. Groups influence individuals more than individuals influence groups in simultaneous collective and individual induction. Groups follow an orderly process in forming hypotheses from the hypotheses of their members. And finally, groups rarely form correct emergent hypotheses that no member has proposed, but groups can eventually recognize and adopt correct hypotheses if they are proposed by a member. These results increase our understanding of how

cooperative groups, such as scientific research teams, auditing teams, air crash investigators, and art experts, engage in collective induction.

## COLLECTIVE MOVEMENTS AND PROTEST

---

The study of *collective movements and protest* has roots in the 19th century and has long been part of the social sciences curriculum. In the 1970s, new theoretical approaches and new empirical methodologies revitalized the field. The next several decades witnessed an efflorescence of research by practitioners of various social science disciplines—especially sociology, but also political science, history, and anthropology. Some researchers focused on the internal dynamics of collective mobilizations, including interpersonal processes; others addressed the ways broad social and political contexts shaped movements and were shaped by them. Building on the scholarly advances of the previous 30 years, researchers in the early 21st century have been raising new questions.

### Historical Background

Social and political transformation in the recent past and anticipated future led Americans and Europeans in the 19th century to reflect on collective movements and social protest. The social sciences emerged at this time, in the wake of the American and French Revolutions. Industrialization

and urbanization had brought increasing numbers of people together in new ways and added new tactics and modes of organization to long familiar forms of popular protest. The emergence of democratic politics impelled the educated and well-off to try to understand the thinking of the large numbers of their fellow citizens who were acquiring the right to vote, and to understand popular participation in transgressive as well as routinized forms of political action.

One very influential interpretation of popular collective action came to be known as the “collective behavior school” by virtue of its emphasis on the ways in which the actions of people in collectives seemed to defy what one would expect of a rational individual. This approach was developed by several important writers in late-19th-century France and continued by U.S. writers well into the 20th century. Writers in this tradition saw unusual fads, senseless panics, riotous crowds, and even social revolutions not merely as separate curiosities but as phenomena with common properties subject to common explanation. Some writers in this tradition stressed the ways in which the interactions of people could lead to a surrender of the capacity for realistic assessment of the consequences of action. In this line of thought, group members would uncritically imitate each other, buoyed up by group approval, with collectively irrational results. This variant made social psychological processes central to their explanations. The French writer Gabriel Tarde was one of the foundational figures with his stress on the sources and consequence of “contagion” as otherwise puzzling actions spread from one person to another. In the United States, a major figure was Herbert Blumer, who classified crowds into distinctive varieties and for whom crowd behavior went through a succession of lawlike stages.

A second approach was to stress the significance of social context. A very common argument in this tradition was that social transformations in the modern world, especially rural to urban migration, industrialization, and access to mass communications, broke down the traditions that had held people in their conservative grip. Consequently, they disrupted the networks of family and village that had socialized the young and monitored the actions of adults, and exposed people to an unfamiliar social world in the growing towns and the new

routines of an industrializing order. As people moved from village to town, such processes both removed the inhibitions that had been built into rural life and exposed the urban newcomers to messages from manipulative elites that they were unable to evaluate. The combined result of such processes was dangerously irrational behavior. This argument about modernizing contexts as a source of collective irrationalism could be combined with the social psychological properties of collectives by contending that those shorn from the familiar and customary order were prone to seek companionship in mass organization and to listen to leaders promising simple solutions to the ills of modern life. Pioneering French sociologist Émile Durkheim influentially described modernizing change in Europe as a breakdown of customary norms and practices. The notion of breakdown seemed to several generations of social scientists to explain why contemporary Europe and North America fostered apparently irrational movements despite the advances of science and technology. In the 1960s, American sociologist Neil Smelser synthesized this line of thinking in his book *Theory of Collective Behavior*.

Other approaches were also being developed, both in theory and in empirical observation. Students of European labor movements, including Marxists as well as others, thought at least some kinds of protest derived from accurate understandings of material conditions on the part of workers in the modern industrial sectors. Investigations into labor movements sometimes drew upon considerable empirical research both on the contexts of work and on such collective actions as strikes. Labor movements acquired a rather special position for some observers. This was especially so in Europe, where it became common to distinguish two classes of collective phenomena, the “social” movement and the “national” movement, the former stressing actors whose common class interests infused their self-representation, identity, and action and the latter acting on the basis of real or imagined commonalities of history, language, culture, and geography. This mode of classification suggested on the one hand that labor movements were the core of social movement studies, and on the other that nationalism was the proper subject matter of other scholars with other tools.

Nonetheless, the general sense that there was a range of phenomena that suggested collective

irrationality was intuitively appealing to those afraid of riotous crowds, bemused by odd fashions and fads, saddened by the erosion of valued traditions, and/or appalled by revolutions. The rise of fascist movements after World War I seemed to lend additional credence to this picture, since these movements were seen as both irrational and popularly supported, and since they were commonly understood as originating in modern, mass societies battered by the shock of war followed by economic crises. The general notion that collective behavior was a type of temporary psychopathology remained strong.

### New Evidence and New Ideas

During the 1960s, the accumulation of a wide variety of new evidence called into question some of the prevailing theories, and new theoretical approaches were soon developed. Over the next several decades, there was an explosive growth in research in the field. Good research into the participants in the so-called ghetto disturbances in many U.S. cities strongly indicated that the events tended to involve long-time residents of those cities, not newcomers torn loose from some other way of life. New research by social historians of France and England revealed that participants in many urban disturbances in the 18th and 19th centuries were people without criminal records, with stable occupations, and with families. Research by social historians and anthropologists on migrants from countryside to town in the past and present showed strong propensities to maintain ties to village life rather than to experience complete ruptures. Protest began to seem a form of political action rather than a collectively induced bout of irrationality, more to be thought of among other political phenomena than in the company of fads and crazes, and deserving of more scrutiny by political scientists and less scrutiny by students of mental aberration.

At about the same time, social scientists were suggesting four new models for the explanation of protest, drawing on extensive empirical investigation for support and building conceptual bridges to other fields of social research.

### *Resource Mobilization*

To the pioneers of this approach, John McCarthy and Meyer Zald, the core actors in protest and

other forms of collective action were organizations engaged in the strategic deployment of available resources, rather than individuals committed to irrational actions. Such organizations had actual and potential access to such resources as the time of supporters of organizational goals or the funds supplied by sympathizers. They might be constrained in various ways by resource deficits; an organization that could rely on the time of passionate enthusiasts might well make different strategic decisions from one that relied on donations from cooler sympathizers. One organization might launch street protests and another hire lobbyists. One might develop mechanisms to arouse and sustain commitment to highly risky personal actions, while another recruited professional specialists in making fundraising appeals. McCarthy and Zald paid a good deal of attention to the ways in which movement organizations might permit a professionalized stratum to make a career in the movement. The ways in which movements might “frame” issues and actions could be seen by adherents of this model as rational strategies for inducing commitments of resources from actual or potential contributors of time or money or as devices to achieve various goals in dealing with opponents, other movement organizations, or the public. Through the resource mobilization model, social movement theory was able to appropriate ideas drawn from the sociology of organizations.

### *Political Process*

Emerging at about the same time, the political process model looked at movement organizations as engaged in strategic interactions with their environment, including potential allies and opponents, governments, and the public. Movement organizations were seen as modifying their strategies and tactics in light of the responses of their environments and of their successes and failures in attaining goals. For organizations that were engaged in extremely contentious causes or that embraced forbidden tactics, simply surviving in the face of opponents’ counteraction was likely to be among the key goals. As researchers came to chart the ways in which organizations altered their actions in response to success and failure and to other actions by allies and opponents, phenomena that had to earlier generations seemed instances of irrational belief and

action seemed explicable as evolving organizational strategy. When Suzanne Staggenborg and David Meyer analyzed social conflicts through the lens of movement–countermovement interaction, they were drawing on this young, lively theoretical tradition. Social movement organizations could be seen as one kind of contender for influence, along with the interest groups that had long been noted by students of democracy. The concept of “opportunity” became central to such interpretations, since movements were seen as adapting to available possibilities. Through the political process model, social movement theory was able to draw on ideas developed by political scientists.

### *New Social Movement (NSM) Theory*

Scholars, at first particularly in Europe, were paying attention to what protesters were demanding and noted a reduced emphasis on the class-based themes with which certain branches of social movement scholarship had been preoccupied. A variety of new concerns seemed to dominate recent protest politics—feminism, human rights, critiques of consumer culture, concerns over alternate lifestyles—and these concerns were often carried by less hierarchically structured and less centrally controlled organizations than the long-familiar unions and socialist parties, and with significant middle-class participation. The new movements seemed as much about expressing identities as about satisfying interests, and as much aimed at altering cultures as at altering the distribution of material well-being, often describing themselves as something new. Scholars like Alain Touraine and Alberto Melucci saw the explanation in broad changes in European social context after World War II. The achievement of working-class prosperity in postfascist Europe not only reduced the intensity of the class-based conflicts of the past, but also incorporated working-class politics within the framework of securely democratic political processes and extensive social welfare institutions. But new issues emerged and energized a different kind of social movement activism on behalf of other goals.

Critics who took a broader historical or geographical view were quick to point out that the sorts of identity issues that postwar new social movement (NSM) theorists held to be new could be

found in the working-class mobilizations of the industrializing era or that environmental issues had emerged not only among the well-off citizens of prosperous democracies but in the slums of places like Rio de Janeiro. While some social movement scholars tended to be simply dismissive of NSM theorists, however, their attention to identity, culture, the diversity of participants, and the ways goals and organizational forms shift in response to long-term broad changes in economy and polity were drawn on by many others, even if specific claims about novelty and geography proved empirically untenable. In addition, through new social movement theory, the study of movements was able to draw on ideas from the sociology of culture.

### *Collective Action*

This fourth innovation took the rational individual actor as central. The “collective action problem,” as understood by economists like Mancur Olson, was explaining how individual human beings could manage to come together for collective goals. This was initially only incidentally a question of how they could come together in social movement activism in particular.

This could be thought of as several separable problems.

- *The free rider problem.* Why should a rational individual participate in collective action for a collective objective (even if that individual were to benefit from success), rather than sit back and let others take the risks and pay the costs?
- *The problem of trust.* In circumstances under which the participation of many would be essential to achievement of the goal, why should a rational individual trust those essential others to participate, especially if the risks of failure would be to leave one significantly less well off than before (for example, dead, imprisoned, fired, or poorer)? This can be formulated in terms of the well-known game prisoner’s dilemma.
- *The problem of personal efficacy.* To the extent that one could trust that many others would participate, why would one pay the costs and run the risks of participation unless one thought that one’s own addition to the collective action would be the crucial difference between success and failure?

Since it is evident that there is a great deal of social movement activism, either these dilemmas are in practice solved in some way or the issues are poorly posed. Some social movement scholars essentially accept the agenda of trying to explain how rational individuals come to participate in social movement activism. Some argue that there are many ways of resolving these dilemmas and that participants do not invariably experience them as a problem to be overcome. (If, for example, people experience the solidarity of shared danger as a reward, then the apparent cost of risky collective action is simply an observer’s error.) Through collective action theory, whether embraced, modified, or rejected, social movement scholars came to refine their sense of the rewards and costs of action.

### **The Standard Agenda**

Since the 1960s, these four approaches, separately or in combination, have informed the interpretation of data gathered by an increasingly numerous body of researchers using a wide array of empirical materials. Archival research, statistical analyses, sample surveys, ethnographies, and other techniques have been used in the study of social movements. Even more than by the embrace of new theories, social movement scholarship for the past several decades has been distinguished from that of the 19th century and earlier 20th century by drawing on superior research.

Together these approaches constituted an agenda for the study of protest movements that became the main line of approach for the next several decades. The standard agenda saw movements as episodes in which actors of various sorts developed strategies and tactics that made the best of available resources, reacted to threats or seized opportunities they for the most part did not themselves create, and struggled to frame issues in ways that would energize supporters, attract allies, neutralize opponents, appeal to powerholders, or justify their actions to themselves. Different elements of this agenda appealed variously to scholars committed to “structuralist,” “culturalist,” or “rationalist” modes of explanation, who invested much energy debating whose mode of explanation was more fundamental. For those of a more structuralist bent, a good explanation

would be one that would delineate the institutions that endowed various actors with differing interests and resources; culturalists tried to grasp prevailing values within which movement activists maneuvered to demonstrate the worthiness of their purposes and methods; and rationalists tried to show how actors endowed with particular interests would hit on particular strategies to defend and advance them.

Other researchers, however, found the standard agenda too constraining and in increasing numbers were urging the field to move into new directions.

### Recent Directions

#### *Expanded History*

Increased attention to the interactions of movements with their contexts, including other organizations and especially governments, moved beyond short-term studies of particular episodes or campaigns to long-term historical change. Movement scholars explored the ways patterns of mobilization, expression of demands, targets, tactics, and modes of movement organization changed in response to large social, economic, and political changes like urbanization, the growth of effective states, democratization, or, in the late 20th century, globalization. Charles Tilly argued that there are “repertoires of contention” that are available to participants in conflict and that these repertoires are formed at particular historical junctures. The “demonstration,” for example, entered the repertoire of contention in Europe in the early 19th century and then spread far and wide. So the ways in which people engage in conflict tends to be situated within a limited array of culturally available forms, although at important moments new forms are invented or old forms stop being used. Historians have made enormous contributions to the study of particular forms, such as the “food riot” that was of great importance in English and French history from the 17th century into the 19th century. By extending the terrain of research back before the era of democracy, it became possible to conduct empirical research into how subsequent democratization reshaped social conflict. These forays into the past by social movement scholars dovetailed with the movement among historians to write “history from below.”

#### *Expanded Geography*

In addition to shining the light of scholarship into the past of the countries that became wealthy democracies, scholars took note of the great geographic concentration of high-quality empirical research within the wealthier parts of the world. These were places where data collection was easier, and they were the places social movement scholars lived and worked. But this meant a restriction on the range of social contexts within which protest and collective action more generally were being studied. Beginning in the 1970s in Mediterranean Europe, the greatest wave of democratization in history opened up new opportunities to conduct research and posed an array of interesting comparative questions for students of protest and collective action. Spanish and Portuguese scholars explored the role of protest mobilizations in those countries. The role of social movements in the termination of military regimes in the 1980s was one important focus of new study in Latin America. With the development of the ensuing democratizing regimes, students of that region’s protest patterns were examining which sorts of movements, grievances, and actions were continuing those of the military period and which were new. They were addressing as well which aspects of mobilizations grew weaker in the democratic period. With the fall of European Communist regimes in 1989 and beyond, the democratic transition in South Africa of the 1990s, and democratic movements and transitions in Asia, similar sorts of questions were framing research in those places as well. Those aiming at large theoretical statements were coming to have a much greater range of well-researched cases on which to draw, and this was as much a challenge to generalization as it was a spur to new theory. Some scholars were arguing for a broader geographical extension still, bringing together into a comparative framework the forms of social movement activism of wealthy democracies and the forms of protest characteristic of non-democratic regimes.

#### *Transnational Processes*

One rather special aspect of the geographic expansion of protest studies was attention to movements that themselves moved on a large geographic stage. Students of protest and collective

action were paying a lot of attention to movements that in some sense crossed borders, which could come in many guises:

- participants traveling to distant sites for concerted action
- organizational ties that crossed national frontiers
- protesters targeting institutions of transnational governance like the International Monetary Fund or the World Bank
- immigrants becoming involved as participants or as objects of protest
- transnational institutions having an impact on national politics (which became increasingly common within the European Union)
- transnational identities playing a conspicuous role in social conflict (for example, in Islamicist movements)
- protesters in one part of the world learning from protesters far off through vivid television footage and exchanging ideas through e-mail and the Internet

### *Bringing Back Emotion*

In rejecting the older collective behavior model of irrational action induced by collective processes, some scholars were suggesting that the field had gone too far in the direction of seeing movement organizations and individual participants engaged in consciously calculated behavior toward specified ends. Some scholars were now arguing that protest and activism were as much matters of the heart as of the head. In considering the claims of injustice that so often were a part of movement life, could one do without taking into account situations that elicit anger, disgust, and humiliation? Could one explain why one appeal succeeds in mobilizing participation and another does not without taking into account the ways in which shame can become pride? Could one understand how social activism was sustained over time without considering the pleasure social activists sometimes take in the fellowship formed in working together for a common purpose?

### *Microprocesses in Context*

Researchers were using varied methodologies to address the interpersonal mechanisms that brought

people into protest, studying recruitment into a very wide variety of organizations and causes, from peaceful protest carried out in public view to violent acts prepared by clandestine organizations. Participants were interviewed while demonstrations were taking place, in prison after arrest, or years after various events took place. Researchers collected participants' accounts of the processes that led them to activism and of their lives while they were activists. This research suggested that recruitment was frequently a network phenomenon. People often went to their first meeting or first demonstration because a friend was going. Although people sometimes chose movements out of deep affinity for a cause, it also often happened that deep ideological affinity only developed as a consequence, not a cause, of participation. Particularly in the subset of causes known as "high risk activism," participation itself led to increased trust in fellow activists and increased distance from previous acquaintances outside the movement. Activist groups could thus develop distinctive subcultures.

### *Beyond Organizations and Beyond the State*

Following the standard agenda, a great deal of research had accumulated on the ways in which organizations recruited members, crafted strategies and tactics, and dealt with each other in forming alliances, competing for resources, and opposing one another as they struggled to shape state policies. Thus the *movement organization* and the *state* became central concepts for the analysis of protest. Some researchers aimed at reconceptualizing the study of protest in ways that made one or both of these concepts less central.

#### **Movement Subcultures and Milieu**

Some scholars, like David Meyer, suggested that there were movement subcultures formed around adherents of change, who took their propensity to protest from cause to cause, and from organization to organization, and whose careers as protesters and activists were an important object of study. The formation and sustenance of such subcultures seemed a new subject matter not exhausted by the study of the strategies of movement organization. Others suggested that one could identify venues where activists, potential activists, and nonactivists

met and created protest-oriented places that functioned as sources of protest identity and recruitment, yet were distinguishable from the organizations into which they fed. Particular bars, cafes, concerts, parks, or neighborhoods could be places strongly flavored by certain social and political attitudes and outlooks, shaping and nurturing protest but readily overlooked by an exclusive focus on organizations that acted.

### Reconsidering the State

Some held that the same sorts of processes that protesters deployed in relation to states occurred in relation to other defined sites of hierarchical power. Others went further, suggesting that if the structures that sustain social hierarchies are located inside each of us through beliefs taken in as children or fostered by social interactions as adults, then one could think of action directed at changing such attitudes, socialization processes, and interactions as crucial sites of change. In this perspective, a group of people meeting in each others' homes for the purpose of mutual support in inner change could be thought of as participating in social activism even if no publicly visible protest against public policies ensued. The field of protest studies, in fact, has significant disagreement over how to define a social movement. For some, the existence of publicly visible actions in interaction with a state is critical, but for others any concerted action, whether publicly visible or hidden away somewhere, and whether directed at a state or not, constitutes a sign of social movement activism.

### Consequences

While much of protest and movement activism involves claims of acting on behalf of change, the study of the effectiveness of collective action in bringing about change has emerged as a relatively neglected area of research. The difficulties are of several sorts:

- *Conceptual.* What sorts of change should be looked for? And on what time scale?
- *Analytic.* Since movements are generally happening at the same time as many other things, demonstrating the precise impact that movements have had on policy changes can be a difficult task.

- *Relevant data.* Since data on policy change are generally going to be quite different from data on movement actions, the incorporation of appropriate data will often mean a very much larger research endeavor.

Despite these difficulties, scholars were recognizing the study of movement impact as a necessary addition to the research agenda.

### Conclusion

Four decades after new theory and superior empirical research challenged the kinds of analysis that had developed in the 19th and early 20th centuries, the study of protest, collective action, and social movements is livelier than ever, moving in new directions, and with the kinds of disagreements among practitioners that, in raising basic questions, inspires new research.

## COLLECTIVE SELF

---

*Collective self* is a term used in social psychology to refer to those aspects of self that derive from the groups a person identifies with or belongs to as a member. When the collective self is active, a person construes the self as “we” based on attributes that are shared with other group members, rather than simply as “I” based on attributes that are uniquely personal. Viewed historically, this psychological focus on a social self rather than an individual self has been slow in coming, though the concept has long been recognized in sociology. The collective self taps into group membership and is activated when a particular group becomes salient at a moment in time. When this happens, the person draws on a relevant group membership to make inferences of self-worth and sometimes to take action in concert with others. Research and theory in this field is at the intersection point of social psychology and sociology, though there have been some recent contributions within political psychology.

### Two Kinds of Self

The idea that the self-concept develops exclusively from individual experience held sway in social psychology for many years, ignoring much of what early sociologists such as G. H. Mead and Charles Cooley had to say about the interplay between individuals and their society, and about how the self is socially constructed. More recently, social psychologists have come to accept that in characterizing the self as a purely individual entity a great deal of psychological meaning is lost. Many contemporary

scholars have argued that there are two kinds of self, the individual self and the collective self. Each has its peculiar body of self-knowledge and both provide a means of self-definition.

The individual self is organized around a set of personal attributes that, like a fingerprint, are unique and differentiate a person (“I”) from all others (“you”). So, for example, if I am kind but fastidious, hardworking but temperamental, shy but reliable, then such attributes are what make me a different person from you. In contrast, the collective self is constructed from attributes that are shared with other members of the ingroup. Its function is to differentiate the person from others who are not group members, thus distinguishing “we” from “they.”

People belong to a variety of groups, some of which are important in defining a number of collective selves, such as ethnicity, race, gender, and nationality. One’s membership in groups can vary in salience at different times. If someone is Swiss and crosses into Italy, it is highly likely that nationality, in this case based on attributes shared with others who are Swiss, will be highly accessible (i.e., easily brought to mind).

By learning to identify with a particular group, a person acquires a specific collective self and a set of group norms that can guide how to think and act appropriately.

### Collective Action

Because the individual self and the collective self are aspects of the self-concept, both are located within the person and function at that level. Unlike the individual self, the collective self provides the person with a mechanism for responding to a social situation in unison with others. It can both motivate and guide behavior in one-on-one encounters with members of outgroups, or when a person is acting as part of a larger group (e.g., as in a political demonstration). The collective self can therefore serve as a platform for *collective action*, which social identity theory (SIT) equates with *social change*.

As conceived by Henri Tajfel, social change is predicated on a belief system in which intergroup boundaries are thought to be impermeable to “passing,” for example, the Hindu caste system in India. As a result, a lower status individual can

improve his or her self-esteem defined by caste only by challenging the legitimacy of the higher status group's position. Whether or not some form of group action is possible depends on how the status quo (the existing status and power hierarchy) is perceived. Is it secure or insecure? If lower status individuals think it is stable, legitimate, and therefore secure, it may be impossible to imagine a different world—an alternative social structure.

In such circumstances there is no path for collective action. However, there are socially creative strategies that groups can use to foster a positive self-image for the collective self:

- Subordinate groups can make intergroup comparisons on novel or unorthodox dimensions that favor their group. For example, in a French study by Gerard Lemaire, children took part in an intergroup competition to build the best hut. Lemaire found that when groups were provided with poor building materials, and therefore could not win, they became creative by emphasizing how good a garden they had made.
- Groups can try to change the consensual value attached to ingroup characteristics (e.g., scientists with insufficient funds to purchase sophisticated equipment can highlight the conceptual advances of their work).
- They can compare themselves favorably with other groups also of lower status (e.g., working-class Hispanics pinpointing ways in which they are superior to working-class Whites).

The contexts in which collective action occurs require a belief system with distinctive features. First, lower status people need to believe that the status quo is illegitimate, unstable, and thus insecure. Second, they need to have cognitive alternatives (i.e., conceive of a different and more promising social order). If both of these conditions are met, direct *social competition* is likely. This manifests itself in actual intergroup conflict. Such conflict could take several forms, including civil rights action, political lobbying, public demonstrations, and even terrorism, revolution, or war. As Stephen Reicher has observed, social movements typically emerge under these circumstances.

SIT incorporates both social psychological concepts and social structural (macro) concepts, as does *system justification theory*. John Jost and his

associates developed this theory to bring ideology to center stage—an ideology that favors the status quo, even when this conflicts with the interests of the individual or of the group. Ironically, lower status group members sometimes subscribe to this ideology even when it legitimizes their current status and maintains their position of disadvantage. Members of a subordinate group may do this to reduce uncertainty by assuming that it is better to live in disadvantage and be certain of one's place than to challenge the status quo and enter unknown territory.

### Collective Self-Esteem and Ethnicity

A group-based definition of the self can lead to depressed self-esteem, for example, among members of disadvantaged minorities. Studies of young children's ethnic identity in the United States and elsewhere have provided supporting evidence. A series of American studies of ethnic choices made by children from the late 1930s to the early 1960s showed that

- White children identified with and preferred to be with White children;
- Black children identified with and preferred to be with White children;
- Black children had lower self-esteem.

In 1954, the eminent Black American researcher Kenneth Clark appeared as a witness in the landmark United States Supreme Court case *Brown v. Board of Education*. He testified that generations of Black children's self-esteem had been extensively damaged over time. Flowing from this case, the legal decision to outlaw school segregation was instrumental in legitimizing the civil rights movement in the United States.

Clark's research was criticized for its assumption that doll preferences reflected children's self-esteem levels. However, Graham Vaughan found two stable trends in international ethnic identity studies that are consistent with Clark's conclusions: (1) ethnic minorities that are disadvantaged (educationally, economically, politically) are typified by lowered self-esteem when intergroup comparisons are made and (2) social change in the status relationship between ethnic groups leads to a significant improvement in minority pride and

individuals' feelings of self-worth. By 1970, the ethnic choices made by Black children in the United States reflected the phenomenon of "Black Is Beautiful" that followed the success of the American Black Power movement in the late 1960s. There was a similar trend in a series of New Zealand studies of cohorts tested in different time periods. Young Maori children switched from pro-White choices to pro-Maori choices against the backdrop of a Brown Power movement.

Findings from ethnic identity research testify to the power of the collective self as a focal point in the processes of social movements and social change. Collective self-esteem can be linked to psychological health. A heightened sense of pride in one's ethnicity or gender, or any other valued social category, can contribute significantly to a positive view of oneself defined in group terms.

## COLLECTIVISM/INDIVIDUALISM

---

*Collectivism* is a societal orientation toward promoting the well-being of the collective, whereas *individualism* is a societal orientation toward the well-being of individuals. Collectivism and individualism are important concepts in group processes and intergroup relations because these concepts capture two fundamental motivations of homo sapiens: "getting along" and "getting ahead." Because humans are social animals living in a group that often has complicated internal structures (e.g., an organization), we must get along with other group members while simultaneously trying to get ahead of them.

Collectivism and individualism can be understood as two significant ways to deal with these two fundamental human needs at the level of society. Society consists of multiple groups that compete with one another for resources for survival. Thus, in addition to an individual's need for survival, the group has its own need for survival. Collectivism can then be considered a solution that attempts to maximize harmony and solidarity among group members (i.e., "getting along"), while minimizing the potentially destructive effect on the group as a whole of egotistic behaviors on the part of individual group members. In contrast, individualism can be considered as a solution that attempts to maximize the pursuit of self-interest (i.e., "getting ahead"), while minimizing the oppressive effect of the group on individuals.

When faced with competition from other groups, a group is likely to adopt a collectivistic approach because intergroup competition requires a degree of solidarity among members within the group. When a group does not face significant competition from other groups and has sufficient resources to share, it should be more receptive to an individualistic approach. Ultimately, collectivism and individualism are two adaptive approaches to the prevailing intra- and intergroup conditions. This entry looks at the history of these two social orientations and describes different ways that each may be expressed in society.

### Historical Background

The Confucian system, which developed in China around the 5th century BCE, represents a collectivistic solution to the potential tension between

“getting along” and “getting ahead.” Under this system, harmony within five cardinal relationships is emphasized: father–son, husband–wife, elder–younger, emperor–subject, and friend–friend. The emphasis is placed on understanding one’s roles, fulfilling one’s duties, and showing deference to authority. These, in turn, strategically reduce within-group competition, smooth interpersonal relationships within a group, and maintain group solidarity.

The Greek philosophers of the 5th century BCE were some of the earliest individualist philosophers. Aristotle’s *Nichomachean Ethics* is mainly concerned with how an individual can live a virtuous life and attain the highest possible human goal of *eudaimonia*, or personal well-being. This is in stark contrast with the Confucian emphasis on societal well-being and how to create a nation characterized by cohesion and interpersonal harmony. Although some Western philosophers have endorsed a form of collectivism (e.g., Jean-Jacques Rousseau, Karl Marx, Émile Durkheim), many other Western philosophers explicitly endorse various forms of individualism (e.g., Adam Smith, John Locke, Thomas Hobbes).

Geert Hofstede’s 1980 book, *Culture’s Consequences*, ignited an interest in collectivism and individualism in psychology. In this book, Hofstede examined work-related values of IBM workers from 40 nations and identified four important cultural dimensions: “masculinity,” “power distance,” “uncertainty avoidance,” and “individualism.” In this survey, the United States ranked ahead of all other nations on individualism. In the 1980s, Harry Triandis and his colleagues conducted numerous cross-cultural studies comparing the United States with so-called collectivist nations such as Japan, China, and Korea, and legitimized the study of collectivism and individualism in academic psychology.

In 1991, two prominent social psychologists, Hazel Markus and Shinobu Kitayama, published an influential paper that specified systematic psychological differences between collectivist and individualist nations in terms of people’s self-concept, motivation, cognition, and emotion. This work rendered collectivism and individualism one of the most popular research topics in social psychology in the 1990s.

Two related constructs, individualism–collectivism and independent and interdependent self have

provided, over the past two decades, powerful frameworks for understanding cross-national variations in the self-concept, interpersonal relationships, and various other social behaviors. However, these constructs have also been subject to some criticism, including the charge of conceptual ambiguity and problems over the existence of various subtypes. Most notably, Daphna Oyserman and her colleagues published a meta-analysis (i.e., quantitative analysis of all the published studies on self-reported individualism–collectivism) in 2002, which concluded that the difference in individualism–collectivism of North Americans and East Asians is negligible. Since the publication of the meta-analysis by Oyserman and her colleagues, many prominent researchers in the field have called for alternative conceptual frameworks and methodologies to be adopted in cultural and cross-cultural psychology. However, it should be also noted that when response sets are statistically controlled, self-reported individualism scores were highly correlated with Hofstede’s original results.

An additional critique of individualism–collectivism research revolves around its relatively static view of culture. With globalization and increasing international immigration, there is substantial cultural fusion. Ronald Inglehart and his colleagues collected survey data on values and attitudes from around the world for the last 20 years, concluding that, in many parts of the world, people’s values have shifted from traditional attitudes (akin to collectivism) to self-expression (a feature of individualism) as a reflection of modernization. However, some of the cross-national differences have remained relatively unchanged over the last two decades. For instance, although Japanese have become more individualistic during that time, so have Americans. Thus, the magnitude of cultural difference between Japan and America has not decreased.

### Varieties of Collectivism

The Confucian style of collectivism is primarily concerned with how to maintain harmonious relationships at various dyadic levels. Because of its emphasis on dyadic relationships, the idea is that group members tend to have strong ties with other members, and their interpersonal relationships are as important as each member’s relationship with

the group as a whole. Whereas the Confucian style of collectivism emphasizes hierarchy and dyadic relationships (i.e., hierarchical and relational collectivism), other forms of collectivism emphasize collective actions and cooperation in general (i.e., horizontal and group collectivism).

For instance, in an agricultural society that requires an irrigation system, a large number of members have to work together to accomplish one common goal. In this context, one's identification with the entire group becomes more important than dyadic relationships between group members. In addition, in a situation in which collective action and cooperation are required, a large proportion of group members share the same status, and therefore, relationships are not as hierarchical as a Confucian-style collective organization. Sports teams (e.g., football, soccer) represent this type of collectivism. The distinction between relational and group collectivism is similar to Ferdinand Tönnies's distinction between a small village-like community (*gemeinschaft*) and an association-based society (*gesellschaft*).

In relational collectivism, relationships are the self's defining features, and either personal goals are deemphasized in favor of interdependent goals or no distinction between personal goals and significant others' goals is made. Similarly, in group collectivism, the fluidity of the self in its relationship to the group as a whole is expressed as a sense of sharing a common fate with other group members and in the belief that the experience of one ingroup member affects all other members of the group. The fulfillment of one's collective responsibility by promoting the interest of one's group or significant others is of primary concern in both forms of collectivism. The emphasis on group goals and interdependence is associated with greater exertion of effort and higher levels of cooperation among group members, who not only identify closely with their groups but also regard their individual contributions as vital to their groups' accomplishments and overall well-being.

Instead of striving explicitly to actualize a "true" self, collectivist individuals strive to cultivate and maintain deep bonds with significant others and/or important ingroup members. This involves maintaining harmony and adjusting to others' (or the group's) needs, which in turn affects the type of emotions (e.g., calm, contentment) that are idealized

and experienced. Because harmony is emphasized, similarity rather than uniqueness is valued. The private self—its desires, opinions, inclinations, and so on—may be kept cleanly separate from and seen as irrelevant to public interactions (e.g., in Japan, this is expressed by two terms: *honme*, the private self, and *tatema*, the public self).

The context-dependent nature of the self is apparent here. While an individualist might make a context-independent claim such as "I am hard-working," a collectivist might say "As a teacher, I am outgoing, but as a husband, I am quiet." The self in collectivist societies is experienced as part of a network of social roles and obligations, and friendship is no exception. Opportunities to create friendships tend to be fewer in collectivist societies, as they are created based on preexisting networks. In fact, friendships are not "created" so much as "given" in collectivist societies such as Ghana. In contrast to individualist cultures, where it is more common and desirable to have many friendships, with various levels of personal intimacy, friendships in collectivist cultures tend to be more binding, with a variety of obligations. The depth and obligation of collectivist friendship also limits the sheer number of friends one can maintain. In Ghana, most people view having many friends as "foolish" or naïve, given the impossible level of commitment and strain that they place on one's resources.

As indicated above, collectivist groups tend to be less permeable: They are difficult to freely enter and exit. As people's social ties are relatively set, social goals focus on maintaining the relationships one already has instead of forming new relationships. Consequently, people in a collectivist society tend to draw a sharper distinction between members of one's ingroup and strangers than people in an individualist society, where strangers are regarded as potential future friends. Indeed, in collectivist cultures, the emphasis on harmony, cooperation, and cohesion tends to be limited to ingroup relationships. Interactions with strangers and outgroup members may be characterized by a lack of concern or even hostility and discrimination during intergroup conflicts. Furthermore, differences between ingroup and outgroup communication have been noted in collectivist societies, where generally speaking communication with ingroup members is more effective than communication with outgroup members.

Another area where collectivists pay greater attention to distinctions between an ingroup and outgroup than do individualists is in the allocation of available resources. Given that relationships with ingroup members are of great importance, material resources tend to be shared equally within collectivist groups: A tribe's catch can be distributed and shared among its members; a dish bought at a restaurant can be distributed among those at the table. However, when the task involves distributing material resources to strangers, decisions are based on the recipient's level of contribution, which is more typical of exchanges among individualists. Collectivists also behave more like individualists in favoring contribution over membership when goals of productivity and competition take precedence over goals of interdependence and solidarity.

In terms of work-related behaviors within collectivist contexts, working with ingroup members tends to result in better performance than working alone. Individual performance of collectivists is also enhanced when respected ingroup members are involved in assigning specific goals and tasks. Compared to their individualist counterparts, leaders and superiors in collectivist cultures are more likely to provide nurturance and guidance to subordinates, who are expected to show loyalty and devotion in return.

Collectivism also has important implications for group decision making and conflict resolution. For example, the focus on maintaining ingroup cohesion and harmony means that relationships among ingroup members may be valued more than the tasks themselves during the decision-making process. Also, greater attention is paid to the goals and concerns of the collective than to the needs of individual members. Conflicts within the ingroup tend to be avoided whenever possible. When such conflicts do arise, attempts are made to reach agreement or consensus within the group. This often requires willingness on the part of group members to modify their own preferences in order to conform to the group's position.

### Varieties of Individualism

The defining characteristic of individualism is the priority it accords to individual goals over group goals. This worldview features the individual as a self-contained entity with a well-defined self–other

boundary. Personal goals are defining characteristics of this autonomous entity and may be in opposition to the social world. In such cultures, importance is placed on self-reliance, personal cultivation, personal choice, uniqueness, and self-expression.

Like collectivism, individualism manifests in different forms. One common typology that has been used to describe different types of individualism is horizontal versus vertical individualism. Both types of individualism are characterized by the emphasis on the autonomy and uniqueness of individuals. However, horizontal individualism tends to stress equality between individuals, whereas vertical individualism emphasizes competition and being the best in comparison to others.

Although some forms of individualism are considered antagonistic toward society (e.g., rugged individualism), the pursuit of self-interest can be beneficial both to individuals and society. For instance, in the 19th century Alexis de Tocqueville observed that Americans, despite their individualism, help strangers much more willingly than do the French, precisely because Americans understand that many others do not have anyone else to rely on; he called this “the doctrine of self-interest properly understood.” In other words, when self-interest is pursued with moderation, individualism does not necessarily interfere with the well-being of society.

The emphasis on the development and expression of one's unique, “true” self constitutes a cornerstone of the formation and experience of friendship in individualistic societies. According to most forms of individualism described above, friendship involves the meeting of two distinct and fundamentally separate beings, whose connection must be created via a mutual sharing of unique and authentic selves and/or common interests. Romantic companionship should also be a celebration and exploration of exciting and unique traits in this context. With different friends reserved for the sharing of specific interests, friendships in such societies also become more compartmentalized.

True individualist friendship, like the true self, should be genuine and spontaneous. Friendships should feature spontaneous acts of affection, should not arise out of obligation, and may involve but should not be predicated on practical or material support. Friendships have varying degrees of intimacy, and those that require self-censorship or

too much obligation can easily be deemphasized or even left. This ideal is reflected in the high American divorce rate. Indeed, many Americans show a permissive, noncommittal view of love.

Relationships with groups and associations also reflect the above model of low-cost, low-commitment, personally expressive relationships. Groups in individualist cultures are more permeable. That is, they are easy to join and leave, requiring little obligation (e.g., a book discussion group). With high intergroup mobility, there are many potential ingroups, and it is relatively easy to stay with those that meet one's personal needs and leave those that do not. Intergroup mobility is supported by Americans' high level of general trust in others, and this facilitates social exploration and making friends.

With the primary focus of attention on the pursuit of personal goals, needs, and desires, the distinction between ingroup and outgroup does not take on the same degree of importance in individualist cultures as it does in collectivist cultures. In other words, people who are individualist oriented tend to treat friends and strangers more equally. Their communication with ingroups and outgroups tends to be similar, not varying much in overall effectiveness. Also, because individualists experience greater opportunities and need to interact with outgroup others, they tend to be more skilled than collectivists are at communicating with strangers.

Research also indicates that an individualist orientation is associated with a phenomenon known as social loafing, which refers to the tendency of individuals to exert less effort when working as part of a group than when working alone. The higher occurrence of social loafing among individualists may partly be due to the greater value being placed on personal outcomes as opposed to collective welfare. It is also known that individualists perform better when they are given a choice in the type of tasks that they will undertake.

Individualism also affects how important group decisions, such as the allocation of material resources, are made. In most situations, people in individualist cultures are inclined to allocate rewards based on group members' individual contributions rather than their membership because, in their view, group achievement reflects the sum of individual inputs. In individualist cultures, where

connections between people are loose, task concerns prevail over relationship concerns when making group decisions. Without having to worry as much about harmony and cohesion within the group, members tend to be more outspoken about their feelings, attitudes, and opinions. It is considered acceptable for individuals to place personal goals ahead of group goals. When disagreements arise within the group, maintaining one's own views and problem solving via open and direct communication is seen as helpful, whereas conforming to group pressure is considered a personal weakness.

In addition to particular views toward friendships and groups, individualism has been associated with specific emotional experiences. For example, pride, a socially disengaging emotion, clearly sets the self apart from surrounding others. Among individualists, positive emotions are desired, regardless of whether they are socially engaging or disengaging. This is not the case among collectivists, because pride signals a disruption in harmony with others.

The ethos of individualism is liberating to the individual, but it is also associated with anxiety and identity crises. In the United States, for instance, increased personal freedom to choose one's occupation, spouse, and system of values over the last 50 years has been accompanied by an increased anxiety; this has been referred to as the age of the "me" generation and as an "age of anxiety." Young Americans report experiencing significant pressures to actualize their potential and define their identity, and they are plagued by the impending fears and guilt of failing to choose the best opportunities available to them. In this sense, the personal autonomy and independence that is central to American individualism has its downside.

## COMMON-IDENTITY/ COMMON-BOND GROUPS

---

Some group memberships are based on sharing a category membership (e.g., women), while others are based on attraction to fellow group members (e.g., groups based on friendships). Based on this distinction, in 1994 Deborah Prentice, Dale Miller, and Jenifer Lightdale identified two primary types of groups to which people may belong. This typology allows researchers to make predictions of how behaviors differ between the two types of groups. *Common-identity groups* comprise members who share a social category and are attracted to the group as a whole as well as its overarching identity. More specifically, members of common-identity groups are attracted to the group's norms, goals, activities, and other defining features. In contrast, *common-bond groups* comprise members who are attracted to one another as individuals.

## Background

The distinction between common-identity and common-bond groups is reflected in the two primary and competing approaches to the study of groups within social psychology. Twentieth-century social psychology heavily emphasized the study of the individual. The focus of much of this research was how the person impacted his or her group. Kurt Lewin defined a group as the sum of its interpersonal bonds, implying that attraction to group members forms the basis for groups. The social identity perspective challenged this definition, arguing that groups can be formed under minimal circumstances and members can identify with groups based on shared attributes. Thus, the social identity perspective asserts that attraction to a group can involve attraction to its identity rather than to its individual members.

The distinction between common-identity and common-bond groups is relevant to the distinction between the individualistic and social identity perspectives. Research on common-identity and common-bond groups focuses on the different functions that each kind of group provides for its members as well as the different processes that occur within each kind of group.

## Differences Between the Two Kinds of Groups

The distinction between common-identity and common-bond groups has been applied to a variety of real-world groups (e.g., college eating clubs, online communities). In their original study of attachment to different types of groups, Prentice and her colleagues speculated that common-identity and common-bond groups differ in terms of fairness, longevity, and conflict. Recent research has demonstrated that these groups may also differ in members' responses to group norms and the factors they use in forming impressions of themselves, other group members, and their social identity.

### *Fairness*

Prentice and her colleagues predicted that members of common-identity and common-bond groups would differ in their preferences for how rewards should be distributed among members. They argued that, from a social identity perspective, group

members who are made aware of their social identity should perceive members as interchangeable and homogeneous. Hence, within common-identity groups, members should demonstrate a preference for resources to be distributed equally among all members. In contrast, people in common-bond groups, who are attached to individuals within the group, should prefer equity relationships in which members receive rewards in proportion to their contributions (i.e., each individual gets what he or she deserves on the basis of his or her inputs).

In a later study, Sonja Utz and Kai Sassenberg found that members of common-bond groups operate according to an egocentric principle of maximizing their rewards and minimizing their costs with respect to their own contributions. This suggests that in common-bond groups, personal goals are more salient than group goals. In contrast, Utz and Sassenberg found that members of common-identity groups operate according to an altruistic principle of maximizing the group's rewards and minimizing its costs through their own contributions. Thus, consistent with a social identity perspective, these results suggest that in common-identity groups, group goals are more salient than personal goals because the group provides an important source of identity.

### *Longevity*

Another difference between common-identity and common-bond groups is related to the longevity of the group. Common-identity groups should last longer than common-bond groups because members' commitment to the former is determined by their attraction to the group's identity and norms rather than to their interpersonal relationships with other members. Commitment to common-identity groups should be stronger than commitment to common-bond groups because identity and norms tend to fluctuate very little, whereas interpersonal relationships frequently change and even dissolve, and members may leave the group. Using observations of real-world groups, researchers have found that lasting communities have strong group identities and discourage members from having strong interpersonal relationships that could negatively affect allegiance to their group. For example, Elizabeth Seeley and her colleagues found sex differences in preferences for

group type that may have consequences for the longevity of the group. These researchers found that women were attached to groups in which they felt close to the other members, while men rated groups as important when they were attached to individual members and the group as a whole. If the common bonds in a group disappear, the group may no longer be valuable for women, whereas the common identity of the group would allow men to remain attracted to it. Thus some men's groups may last longer than women's groups because of the greater importance of group identity.

### *Conflict*

Prentice and her colleagues also suggested that members of common-identity and common-bond groups may differ in how they react to conflict. They reasoned that if there is internal conflict within the group, common-identity groups might be less affected by it than common-bond groups because the former are not dependent on harmony among members. Conflict within common-bond groups, however, can have serious implications for the group's existence. But common-bond groups are not always damaged by internal conflict. Prentice and her colleagues suggested that external threat to a common-bond group may encourage members to come together for a common cause and thereby transform the group into a common-identity group. Indeed, in field studies, Simon Bernd and his colleagues found that people with a common identity are more likely to participate in group activities, such as collective action, and less likely to leave the group than are members of groups that are based on mutual attraction among members.

### *Group Norms*

Research on chat rooms by Sassenberg and his colleagues elucidated some differences in the precursors of norm adherence within common-identity and common-bond groups. This work demonstrated that individuals in common-identity groups exhibit higher levels of identification with their chat rooms than do individuals in common-bond groups. Moreover, identification predicted individuals' adoption and expression of group norms, implying that differences in common-identity and

common-bond group members' adherence to group norms are explainable by identification with the group. This research demonstrates the importance of identification processes in adopting and expressing group norms. Identification with the group appears to be a key component in understanding when and why members of these two types of groups adopt group norms. Further, identification processes may differ due to the reasons people join groups, affecting a variety of group behaviors and group norms.

### *Impression Formation*

How group members form impressions of themselves and others is another distinguishing feature of common-bond and common-identity groups. Related to social identity theory, self-categorization theory posits that people's tendency to categorize themselves as group members is influenced by the social context (e.g., the extent to which their group identity is made salient through comparison with a relevant outgroup). According to self-categorization theory, when categorized as members of a group, people see themselves in terms of their group's shared attributes. Accordingly, members of common-identity groups should describe themselves in terms of their similarity to other group members and to shared group attributes. This should not be true for members of common-bond groups, which emphasize members' personal identities rather than their shared identity. Russell Spears and his colleagues developed the social identity model of deindividuation effects, or SIDE model, which predicts that because common-bond groups are based on mutual attraction of members, people in these groups should be concerned with distinguishing themselves from other members. These differing motivations, in turn, should produce differences in how members of common-identity and common-bond groups form impressions of other members. More specifically, while members of common-identity groups use group attributes and the group identity to form impressions of one another, members of common-bond groups use information about individual members to form impressions.

Studies of common-identity and common-bond groups clarify two differing perspectives on the sources of people's attachment to groups (i.e., attachment to individual members versus attachment to

the group identity) and demonstrate important differences in processes that occur within these two types of groups.

## COMMON INGROUP IDENTITY MODEL

---

The *common ingroup identity model* represents a strategy for reducing prejudice that assumes that intergroup biases are rooted in fundamental, normal psychological processes, particularly in the universal tendency to simplify a complex environment by classifying objects and people into groups or categories. This process of categorization often occurs spontaneously on the basis of physical similarity, proximity, or shared fate. When people or objects are categorized into groups, actual differences between members of the same category tend to be perceptually minimized, and differences between members of different groups become exaggerated and overgeneralized.

### Social Categorization and Bias

Social categorization, the categorization of people into different groups, has another unique feature. When a person categorizes others into groups, these categories are fundamentally differentiated between groups to which the perceiver belongs (ingroups) and groups to which the perceiver does not belong (outgroups). Because people derive their self-esteem in part from the prestige of groups to which they belong, members are motivated to regard their ingroup in a positive light compared to other groups. Upon social categorization, people typically express more positive beliefs, feelings, and behaviors toward ingroup members than toward outgroup members. Hence, social categorization can enable ingroup favoritism to service ego-enhancing motivations as long as the situational context reinforces the importance of the categorical distinction between the groups.

Although a preferential ingroup orientation can evolve into a more destructive, anti-outgroup attitude (i.e., prejudice), the mechanisms of ingroup favoritism can also provide a means to reduce prejudice and discrimination. This latter assertion is the essence of the common ingroup identity model.

### Social Categorization and Recategorization

The common ingroup identity model recognizes the fluidity of social categorization processes and the reality that people belong to a variety of groups that are hierarchically organized in terms of inclusiveness. For example, people are members of families, neighborhoods, cities, regions, and nations. Modifying goals, motives, expectations, or factors within the immediate situation provides the opportunity to shift the level of category inclusiveness that will be dominant. This fluidity of social categorization, and consequently, the salience of a particular social identity, are important because of the implications for altering the way people think about others in terms of their ingroup or outgroup membership, and therefore, how positively they feel about them. Specifically, the common ingroup identity model proposes that inducing people to recategorize ingroup and outgroup members within a common boundary inclusive of both groups (e.g., a school, a city, a nation, humanity) redirects the cognitive and motivational

forces that drive ingroup favoritism to increase positive attitudes toward others who were previously seen primarily in terms of their outgroup membership.

The development of a common ingroup identity does not necessarily always require each group to forsake its less inclusive group identity completely. It is possible for members to conceive of two groups (for example, parents and children) as distinct units within the context of a superordinate (i.e., family) identity (as “subgroups within one group” or a “dual identity” representation). When group identities and the associated cultural values are central to members’ self-identification or when they are associated with high status or highly visible cues to group membership, it may be very threatening for people to be asked to relinquish these group identities or, as perceivers, to be “color-blind.” Indeed, demands to forsake ethnic or racial group identities to adopt a color-blind ideology would likely arouse strong reactance and result in especially poor intergroup relations. There is support, however, for the idea that if people continued to regard themselves as members of different groups—*but all playing on the same team* (i.e., part of the same inclusive entity), intergroup relations between the “subgroups” would be more positive than if members only considered themselves “separate groups.”

The common ingroup identity model acknowledges that other approaches to addressing social categorization can also affect intergroup relations. For instance, *deategorizing* people—seeing them in an individuated or personalized way instead of as members of a group—can also reduce intergroup bias. However, whereas recategorization of people within a common ingroup identity reduces intergroup bias by enhancing evaluations of original outgroup members, deategorization reduces intergroup bias by reducing positive regard to original ingroup members through eliminating the forces of social categorization that promote ingroup favoritism in this circumstance.

### Functional Relations, Categorization, and Bias

The common ingroup identity model recognizes that although social categorization can be sufficient to produce intergroup bias, intergroup threat,

competition, and conflict can further contribute to negative relations between groups. In particular, realistic group conflict theory argues that the major cause of intergroup bias and prejudice involves zero-sum competition between the groups over valuable resources. More broadly, whether relations between groups are conflictual or harmonious is determined by the functional relations between the groups. When the relationship is primarily competitive, intergroup relations would be expected to be prejudice-ridden and conflictual, whereas when the relations between groups are primarily cooperative, relations between the groups would be harmonious.

In the classic Robbers Cave study, for example, Sherif and his colleagues studied 12-year-old, middle-class boys at a 3-week summer camp in an experiment about the creation and reduction of intergroup bias and conflict. These boys were initially assigned to two groups. To permit time for group formation within each group (e.g., norms and a leadership structure), these groups were kept completely apart for the first week. During the second week, the investigators introduced intense competitive relations between the groups in the form of repeated competitive athletic activities—centering on tug-of-war, baseball, and touch football—in which only members of the winning group received rewards. As expected by the functional relations account, the introduction of competitive activities generated derogatory stereotypes and very physical, hostile conflict between these groups. In the third week, only after the functional relations between the groups were altered by introducing a series of goals (e.g., finding leaks to the camp's water supply, collecting money to watch a popular movie, and moving a stalled truck carrying lunch up a hill to the dining area)—goals that could not be achieved without cooperating with each other—did the relations between the groups become more harmonious.

Although there was no formal assessment of the psychological processes involved in just *how* cooperation between these groups reduced intergroup animosity, from the perspective of the common ingroup identity model, intergroup cooperation likely reduced intergroup conflict because working together toward their common goal changed the boys' perceptions of their intergroup boundaries from an "us" and "them" orientation to a more inclusive "we" (i.e., common ingroup) orientation.

This process was particularly exemplified when one of the boys exclaimed after the achievement of moving the truck, "We won the tug-of-war against the truck." Subsequent laboratory studies offer support for this interpretation of how cooperation reduces intergroup biases by producing recategorization within a common ingroup. In addition, other bias-reducing interventions that rely on related principles of the functional approach (e.g., techniques such as the jigsaw classroom and some forms of cooperative learning) may operate psychologically through common identity as well as through functional relations directly.

### Empirical Support for the Common Ingroup Identity Model

Formally, the common ingroup identity model identifies potential antecedents and outcomes of recategorization, as well as mediating processes. The general framework specifies the causes and consequences of a common ingroup identity. Specifically, different types of intergroup interdependence (e.g., cooperative or competitive relations) and cognitive, perceptual, linguistic, affective, and environmental factors can alter individuals' perceptions of the different groups. These resulting cognitive representations (i.e., one group, two-subgroups within one group—a dual identity, two separate groups, or separate individuals) are then proposed to result in specific cognitive, affective, and overt behavioral consequences involving intergroup attitudes. Thus, the causal factors that include features specified by contact theory (i.e., cooperation, equal status, opportunity for self-revealing interaction, and egalitarian norms supported by local authorities) are proposed to influence members' cognitive collective representations of the memberships that then, at least in part, mediate the relationship between the causal factors and intergroup attitudes (i.e., feelings, beliefs, and behaviors). In addition, a common ingroup identity may be achieved by increasing the salience of existing common superordinate memberships or by introducing factors (e.g., common goals or fate) that are perceived to be shared by the memberships.

The common ingroup identity model has received considerable empirical support. In an early exploration of the causal role of common ingroup identity in reducing bias, members of two

separate laboratory-formed groups of American college students who were homogeneous with respect to sex and racial composition were induced through various structural interventions (e.g., seating arrangement, dress) to maintain their original group identities (i.e., conceive of themselves as different groups), recategorize themselves as one group, or decategorize themselves (i.e., to conceive of themselves as separate individuals). The manipulations to encourage recategorization and decategorization each reduced bias, and as predicted, did so in different ways. Specifically, recategorizing the memberships into one group reduced bias by increasing the attractiveness of former outgroup members, whereas decategorizing members of these groups reduced bias by decreasing the attractiveness of former ingroup members. Identical findings were obtained when the recategorization and decategorization manipulations were implemented with Black and White Portuguese children, who have different social status and a shared history of intergroup conflict.

Also, manipulations that have been demonstrated to reduce prejudice, by inducing cooperative interaction or structuring positive intergroup contact in ways specified by contact theory, have been shown in laboratory research to reduce bias by changing intergroup cognitive representations from two separate groups to one group. Specifically, intergroup cooperation leads to stronger inclusive, one-group representations, which in turn predicts more favorable outgroup member evaluations. In addition, investigations across a variety of intergroup settings offer converging support for the idea that the features specified by contact theory (i.e., cooperation, equal status, opportunity for self-revealing interaction, and egalitarian norms supported by local authorities), reduce intergroup bias because they transform members' representations of the memberships from separate groups to a single, more inclusive group. Participants in these studies included students attending a multi-ethnic high school, banking executives who had experienced a corporate merger involving a wide variety of banks across the United States, and college students from blended families with households composed of two formerly separate families trying to unite into one.

Common ingroup identity not only increases positive evaluations of others, but also increases cross-group friendship selection, helpfulness, trust,

confidence in suggestions for innovation, and even forgiveness. In addition, creating a common ingroup identity has been found to increase positive forms of behavior, such as self-disclosure and helping, across original group lines and to be effective for improving relations between groups, such as ethnic and racial groups, that have extended histories of intergroup bias. In a particularly dramatic example, emphasizing common humanity increased Jewish students' willingness to forgive Germans for the Holocaust.

### Conclusion

Overall, the research evidence reveals consistent support for the key principle of the common ingroup identity model: Successfully inducing ingroup and outgroup members to adopt a more inclusive, one-group representation inclusive of both groups reduces the groups' bias toward one another. Furthermore, this fundamental principle has been supported across studies that used a variety of methodological approaches, involving participants of different ages, races, and nationalities. Consequently, this model can inform the development of powerful prejudice-reducing interventions.

## COMMON KNOWLEDGE EFFECT

---

The *common knowledge effect* describes the impact on group decision making of whether knowledge relevant to a decision is shared by all group members prior to discussion. Specifically, laboratory studies have shown that information known by everyone prior to discussion has a more powerful influence on decisions than information not shared by everyone. The common knowledge effect demonstrates that an irrelevant factor—the number of members who know a particular piece of information—can affect group decisions. If a piece of unshared information is crucial to making a correct decision, the result may be an incorrect decision. This entry looks at the common knowledge effect and some possible explanations for such outcomes, then discusses what research has shown about promoting better decisions.

### The Decision-Making Process

When a group comes together to make a decision, the members must combine and process the information that is relevant to the decision. Typically, the group has a discussion during which members mention information that they believe is relevant to the decision. The information that the members bring to the discussion may initially be known by all of the members (shared) or known by only one or a few members (unshared). A primary goal of group discussion is to inform members of information that they did not know prior to the discussion, that is, to discuss the information that was initially unshared.

Ideally, in the end, the group's decision should reflect all of the relevant information, whether that information was initially shared or unshared. However, research shows that information that was shared prior to the discussion tends to influence group decisions more than information that was unshared prior to the discussion. Thus, the same fact will likely have more influence on the group's final decision if it is initially known by all of the group's members than if it is initially known by only one group member, regardless of how pertinent the fact is to the decision at hand. This is known as the *common knowledge effect*.

The common knowledge effect can negatively affect the quality of group decisions. A group may

reach a different decision depending on whether important information is initially shared or unshared. This difference is especially problematic when the shared information favors an incorrect decision alternative and the unshared information favors a different, correct decision alternative. In such a case, known as a *hidden profile*, groups are unlikely to discover and decide on the correct alternative. Instead, even after discussion, groups are likely to decide on the incorrect alternative that was favored by the information shared by all of the members prior to discussion.

### Theoretical Explanation

Why does information have more influence on the group decision when all members know it prior to the group discussion than when only some members know it? One explanation focuses on the content of group discussion, that is, which information group members actually tend to discuss. Arguably, discussion of unshared information is more important than discussion of shared information because unshared information may alter the opinions of members who lacked the information prior to the discussion. Discussion of initially shared information is less important because all of the group's members have had the opportunity to consider that information prior to the group discussion.

In decisions involving both shared and unshared information, however, group discussion tends to focus on the shared, rather than the unshared, information. A particular piece of information is more likely to be mentioned if all group members know about it prior to the discussion than if only one or a few group members know about it prior to the discussion. Initially unshared information is often not mentioned at all. In hidden profile tasks, for example, groups tend to discuss the shared information, which favors the incorrect alternative, whereas they often fail to mention the unshared information, which would allow the group to discover the correct alternative. Consequently, if the group bases its decision on the information that is actually discussed, that decision will be affected more by the initially shared information because the group discusses more shared than unshared information.

But the tendency of groups to discuss more shared than unshared information does not fully

explain the relatively strong influence of shared information on group decisions. Even when the group discusses unshared information, that information does not necessarily affect the group's decision. For example, in hidden profile tasks, groups that discuss more unshared information are not always more likely to discover the correct alternative. Although the tendency of groups to discuss more shared than unshared information is an important factor in the common knowledge effect, it is not the only factor.

The group members' prediscussion opinions are another factor in the common knowledge effect. In addition to affecting a group's decision directly, through group discussion, information also affects a group's decision indirectly, by affecting the initial opinions of the group's members. When members first consider decision-relevant information, prior to any discussion, they tend to form opinions about the correct decision. During group discussion, a member learns the opinions of the other members. In fact, the members' opinions are often the first thing the group discusses, prior to the discussion of any specific information. Those initial opinions, in turn, often have a strong influence on the group's final decision.

Groups often appear to use relatively simple methods of combining their members' initial opinions into a group decision, such as averaging those opinions or choosing the alternative that is initially favored by a majority of the members. Initially shared information can affect all of the members' prediscussion opinions. Initially unshared information, however, can only affect one member's opinion prior to the group discussion. When the group combines all of its members' opinions into a group decision, the shared information will tend to have more influence on the group decision because it has influenced the opinions of more group members.

Why do groups base their decisions primarily on their members' initial opinions, even when unshared information is revealed during the group discussion? After all, when several members learn new facts, they should realize that their initial opinions were based on an incomplete subset of the relevant information and change their opinions. However, when unshared information is discussed, it tends to come up late in the discussion, after the group has already discussed some amount of shared information. That early discussion of

shared information may bolster members' confidence in their initial opinions. Members may also interpret new information to be consistent with their opinions.

In addition, unshared information cannot be confirmed by other members, so members who hear the new information may doubt its validity. Individuals who discuss shared information are evaluated more positively by other group members, and members who know a large amount of shared information tend to have more influence on the group decision. Moreover, full consideration of new information requires time and cognitive effort. Groups may be motivated to process unshared information superficially to reach consensus more quickly, particularly if they do not believe that more effortful processing of that information will lead to a significantly improved group decision.

Thus, the common knowledge effect seems to be explained primarily by two phenomena: the tendency to discuss more shared than unshared information and the tendency to base the ultimate decision heavily on the group members' initial opinions, which are based on the information members have prior to discussion. Groups do, however, sometimes overcome the common knowledge effect. To do so, they must both discuss and carefully consider their unshared information.

### Fostering Better Decisions

Research has identified a number of conditions that increase the likelihood that groups will discuss and be influenced by information that is unshared prior to the discussion. For example, groups are more likely to decide on the correct alternative in a hidden profile task if they rank order all of the alternatives, rather than simply choosing the single alternative that they think is best. Rank ordering forces the group to consider all of the alternatives, which may lead to the discussion of unshared positive information about an initially rejected alternative.

Groups that believe they are making a decision that has an objective correct answer tend to discuss more unshared information and make better decisions than groups that believe they are making a decision that does not have a single correct answer. Groups whose members initially disagree about the correct decision are also more likely to discuss and use unshared information. All of these factors

encourage a group to discuss more information, including information that was unshared prior to discussion, and to base its final decision on all of the relevant information, rather than settling too quickly on a decision that was favored by the group members' initial opinions.

But laboratory research may overestimate the severity of the problem posed by the common knowledge effect. In everyday decisions, shared and unshared information may generally favor the same alternative, or the most relevant information might typically be shared. In such cases, the additional time and effort that would be required to discuss and consider unshared information might not result in a better decision. Moreover, real groups may be more motivated and have more time than experimental groups to discuss and consider more of the available information before committing to a decision. Further research is needed to understand the impact of the common knowledge effect on important real-world decisions.

## COMMONS DILEMMA

---

The *commons dilemma* is a specific class of social dilemma in which people's short-term selfish interests are at odds with long-term group interests. The commons dilemma, also known as the *common pool resource* (CPR), the *resource dilemma*, or the *take-some dilemma*, was inspired by the metaphor of the Tragedy of the Commons that Garrett Hardin discussed in his seminal 1968 *Science* article. This story describes a group of herders with open access to a common parcel of land on which to let their cows graze. It is in each herder's interest to put as many cows as possible onto the land, even if the commons is damaged as a result. The herder receives all the benefits from the additional cows, but the damage to the commons is shared by the entire group. Yet if all herders make this individually rational decision, the commons is destroyed and all will suffer.

The commons dilemma stands as a model for a great variety of resource problems in society today, such as water, land, fish, and nonrenewable energy sources like oil and coal. When water is used at a higher rate than the reservoirs are replenished, fish consumption exceeds its reproductive capacity, or oil supplies are exhausted, we face a tragedy of the commons.

In the 1980s, researchers created an experimental game version of the commons dilemma involving a common resource pool (filled with money or points that could be converted into money or lottery tickets) from which a group of individuals could harvest. If the sum of their harvests per round of the game is lower than the replenishment rate, the pool is maintained. The individuals are each tempted to harvest as much as possible, but if they do, all suffer and the resource is depleted, upon which the game ends.

#### Factors Promoting Conservation in Commons Dilemmas

Commons dilemma researchers have studied conditions under which groups and communities are likely to under- or overharvest the common resource in both the laboratory and field. Research programs have concentrated on a number of

motivational, strategic, and structural factors that might be conducive to commons management.

### *Motivational Solutions*

The research shows that some people are more motivated than others to manage the common resource responsibly. Using the commons dilemma game, researchers found that people with prosocial value orientations harvest less from a resource during a period of scarcity. Prosocial individuals are also more inclined to engage in sustainable environmental behaviors such as taking public transportation (instead of the car) and conserving energy and water, as well as to explain their decisions in terms of environmental impact.

Motivation to conserve a common resource is also promoted by people's group ties. When people identify with their group, they are more likely to exercise personal restraint, as well as to compensate for greedy harvest decisions of ingroup members more than for those of outgroup members. Similarly, in the field strongly knit communities are usually better at managing resource shortages than communities with weak social ties. It might be that group identity promotes a long-term perspective on resource management that makes it easier for people to sacrifice their immediate interest on behalf of their local community. It could also be that group identification increases the social interdependencies between community members so that they care more for the social rewards and punishments of their community. This needs further investigation.

The state of the common resource can also shape motivations. One motivational factor is people's attributions of the state of the commons. Research has manipulated the reasons people were given for resource overuse. When greedy people were seen as causing the depletion, participants were greedier than when there was deemed to be a natural cause (like a sudden drought). Resource uncertainty further contributes to overharvesting. In commons dilemmas, uncertainty about the pool size tends to increase individual harvesting and expectations about how much other people harvest. When there is uncertainty, people overestimate the size of the resource and perceive greater variability in how much other people take. Similarly, uncertainty about the replenishment rate of the

pool also increases harvesting. The most likely explanation is that people have an optimistic bias.

### *Strategic Solutions*

Strategic factors also matter in commons dilemmas. One often-studied strategic factor is the order in which people take harvests from the resource. In simultaneous play, all people harvest at the same time, whereas in sequential play people harvest from the pool according to a predetermined sequence—first, second, third, and so on. There is a clear order effect in the latter games: The harvests of those who come first—the leaders—are higher than the harvest of those coming later—the followers. The interpretation of this effect is that the first players feel entitled to take more. Whereas with simultaneous play, people may adopt an equality rule, with sequential play, individuals adopt a “first come, first served” rule. Another strategic factor is the ability to build up reputations. Research found that people take less from the common pool in public situations than in anonymous private situations. Moreover, those who harvest less gain greater prestige and influence within their group.

### *Structural Solutions*

Much research has focused on when and why people would like to structurally rearrange the commons to prevent a tragedy. Hardin stated in his analysis of the Tragedy of the Commons that “freedom in a commons brings ruin to all.” One of the proposed solutions is to appoint a leader to regulate access to the commons. Not surprisingly, groups are more likely to endorse a leader when a common resource is being depleted and when managing a common resource is perceived as a difficult task. Interestingly, groups prefer leaders who are elected, democratic, and prototypical of the group, and these leader types are more successful in enforcing cooperation. There is a general aversion against autocratic leadership—although it is quite an effective solution—possibly because of the fear of power abuse and corruption.

Another structural solution is the privatization of the commons, and this has been shown in experimental and field research to be very effective. However, it is difficult to imagine how common movable resources such as fish, water, and

clean air can be privatized. Privatization also raises concerns about social justice, as not everyone may be able to get an equal share. Finally, privatization might erode people's personal and social motivations to cooperate in preserving a resource.

The provision of rewards and punishments might also be effective in preserving common resources. Selective punishments for overuse can be effective in promoting domestic water and energy conservation, for instance, through installing water and electricity meters in houses. Selective rewards also work, provided that they are open to everyone. An experimental carpool lane in the Netherlands failed because car commuters did not feel they were able to organize a carpool. Hence, they showed a reaction against this pro-environment intervention.

There has been much field research on commons dilemmas that has combined solutions obtained in experimental research. The seminal work of Elinor Ostrom and her colleagues is worth mentioning. They looked at how real-world communities manage communal resources such as fisheries, land irrigation systems, and farmlands and came up with a number of factors conducive to successful resource management. One factor is the resource itself. Resources with definable boundaries (e.g., land) can be preserved much more easily than can resources without such boundaries. A second factor is resource dependence. There must be a perceptible threat of resource depletion, and it must be difficult to find substitutes. The third is the presence of a community. Small and stable populations with a thick social network and social norms promoting conservation do best. A final condition is that there are appropriate community-based rules and procedures in place with built-in incentives for responsible use and punishments for overuse.

### Conclusion

As populations grow and resources become scarcer, there is a need for policies to avoid commons tragedies. It is encouraging that commons dilemma research is increasingly applied to local and global environmental problems. The emphasis is shifting from pure laboratory research toward research testing combinations of motivational, strategic, and structural solutions.

## COMMUNICATION NETWORKS

---

The term *communication networks* describes the structure and flow of communication and information between individuals within a group. Within many groups (e.g., a typical office), formal and informal communication patterns are often determined in a top-down, hierarchical fashion, where members direct communication to others at the same level or below but not above. Much of the research on the effects of communication networks was conducted in the 1950s; after a long hiatus, researchers are again exploring the effects of communication networks. The primary foci of classic research on communication networks had been to measure how network structure affects information flow, and how position within the networks may affect an individual's status within the group. More recent work has focused on how communication networks affect group-level properties. This

entry discusses both classic and more recent approaches to the study of communication networks within groups.

### Why Study Communication Networks?

The overwhelming majority of research on group dynamics has studied interacting groups in which communications from each member are sent to the entire group, with no constraints on communication (a prototypical example would be a jury sitting around a table). This type of communication network is common in many small real-world groups, such as juries; however, it is not common in larger groups and institutions. In larger groups communication is likely asymmetrical, where different individuals receive and transmit information heterogeneously across the entire group. First, many groups do not necessarily meet in a specific location at the same time, but rather consist of a number of asynchronous communications within subsets of group members. Second, as group size increases, there may be evolutionary constraints on the optimal number of group members performing any given task. Robin Dunbar has speculated that as groups increase in size, the brain's processing capacity may constrain the number of individuals with whom one can optimally communicate. This evolved constraint likely leads to recurrent and structural patterns across all groups in terms of communication networks. Therefore, it is important to study the development and effects of communication networks within groups, especially among larger groups (for example, within organizations).

### Classic Research

The first systematic research on communication networks was conducted by Harold J. Leavitt of MIT and Alex Bavelas of Bell Laboratories in the 1950s. This work was stimulated by formal mathematical models derived from graph theory. By placing partitions between participants seated at a table, Leavitt and Bavelas manipulated communication structures within groups of varying sizes. For example, in a five-person group, members could communicate within a *circle* structure, in which each person can only share messages with those on either side of him or her. Alternatively,

communication could take place within the structure of a *wheel*, with one central member (the hub) through which all communications must pass. One consistent result in such early research was that the centralization of a communication network (i.e., the degree to which some members of the group had more communication partners than others; e.g., the wheel is more centralized than the circle network) was a strong predictor of the efficiency of problem solving; that is, the more centralized a network, the more efficient the group was at solving problems. Later research by Marvin E. Shaw qualified this finding to show that centralized groups solve relatively simple problems better than decentralized groups, but when problems become more complex, centralization can hamper problem solving. Another consistent finding of this research was that more centralized group members are more satisfied with the group process than are more peripheral members.

### Recent Advances

Most of the research on small group decision making in the 1950s through the 1980s was conducted in groups with symmetrical communication networks, in which each member's communication was received by the entire group. Therefore, there were few advances within the field of communication networks during this time period. Bibb Latané and his colleagues revived interest in communication networks in the late 1980s, pointing out that in large groups, individual group members cannot necessarily communicate with the entire group at the same time. Latané's dynamic social impact theory includes a principle of immediacy, which assumes that influence between any two members in a group is predicted by the likelihood that they can easily share communications.

Latané and his colleagues tested the implications of his dynamic social impact theory by conducting computer simulations, in which agents were situated in a two-dimensional space, where the strongest influence between agents occurred with immediate neighbors. Each agent was randomly assigned a binary opinion on an issue (e.g., Republican vs. Democrat). Following from other assumptions of dynamic social impact theory, individual agents in the simulations also varied in strength (i.e., some were more influential than others), and agents were

influenced by the number of other agents sharing or opposing their preferences.

After simulating a number of rounds of communication, in which each agent's opinion was compared to the opinions of fellow agents, the researchers found that opinions either were maintained or changed as a function of the strength, immediacy, and number of other agents, and several group-level phenomena emerged. Opinions in the group typically consolidated (or polarized); that is, whichever opinion was most commonly held within the group became even more common after simulated communication. Because communication networks constrained communication, opinions also became regionally clustered, such that agents shared opinions with other agents who were physically close to them in the two-dimensional space, and who were thus able to exert greater influence over them. Latané and his colleagues then tested whether these phenomena that emerged in simulations also occurred within actual groups discussing issues in communication networks configured via e-mail exchanges. Both group-level phenomena observed in the computer simulations—consolidation and clustering—also emerged within groups of people discussing issues. Subsequently, Latané and his colleagues have shown that the “geometry” of communication networks—how they are organized—can determine the extent to which groups' opinions will consolidate and cluster as a function of communication. For example, as communication networks become more “clumpy” or hierarchical, consolidation and clustering of opinions tend to increase.

Mathematicians and physicists have also recently shown interest in using computer simulation to test some of the implications of constrained communication networks within large groups. One recent line of evidence was provided by Duncan Watts and his colleagues. Watts used computer simulation to solve the “small-world problem” posited by Stanley Milgram: If most people communicate with others within local networks (as social impact theory assumes), how can any two randomly chosen people within the larger group be connected by a surprisingly small number of links (“six degrees of separation”)? Watts showed that simply adding a small number of random communication links between people can create such small world networks even within extremely large

groups. Recent empirical research has provided further support for the “six degrees of separation” idea popularized by Milgram.

Another solution to the small-world problem involving computer simulation with communication networks has been provided by Albert-Laszlo Barabasi and his colleagues. Barabasi has shown that communication networks within large groups share properties with what are known as “scale-free” networks. In a scale-free network, some individuals within the larger group have many more communication partners than others; in the terms of earlier work on communication networks, such members can be said to be more centralized. Scale-free networks are another way to solve the small-world problem; when a small number of members within a large group have a large number of communication partners, it takes a relatively small number of links to join any two randomly chosen group members.

### Conclusion

The field of communication networks, a classic area of research within group dynamics, recently has been reactivated, partly as a function of advances in computer science. The fact that many group decisions are made by subsets of members, without all group members present at any given time, creates a need for more research in this area.

## COMPLIANCE

---

*Compliance* is one of a variety of ways in which people can be influenced by others. Two meanings have been attached to the term. Investigators such as Leon Festinger, Herbert Kelman, and Paul Nail define compliance as a change in public behavior without private acceptance. (As discussed below, when others influence both public behavior and private acceptance, the form of social influence is called *conversion* or *internalization*.) More recently, Robert Cialdini has offered a second definition of compliance that ignores the distinction between public and private. He defines compliance as *acquiescence* to a request. Each definition has generated a different set of questions and research findings. This entry examines both definitions.

### Compliance as a Change in Public Behavior

Research on compliance as a change in public behavior has addressed such questions as (a) What causes people to comply? (b) Why is it important to distinguish between compliance and private acceptance? and (c) Can compliance lead to private acceptance?

#### *What Causes People to Comply?*

Research shows that for people to comply, two conditions must be present. First, people must believe that the influencing agent has the ability to reward them for compliance or punish them for noncompliance. And, second, they must believe that the influencing agent has the ability to monitor their compliance or failure to comply. As an example, consider a worker's decision to comply with her supervisor's request to work faster. While

she may not agree with her supervisor, she is likely to comply because the supervisor controls important rewards (e.g., salary) and punishments (e.g., the power to have her fired) and is able to monitor her response.

Groups may represent another source of compliance, such as when a holdout juror yields to group pressure despite privately disagreeing with the verdict. In this instance, "going along to get along" reflects *normative influence*. In contrast, if the individual believes that the verdict is correct, the influence would reflect *conversion* because his private beliefs would be consistent with his public behavior. The influence in this case would reflect *informational influence*.

#### *Why Is It Important to Distinguish Between Compliance and Private Acceptance?*

By knowing the basis for someone's acceptance of influence—compliance versus conversion—one can better predict when the response is likely to be performed. In the case of compliance, the influencing agent (e.g., a group) must retain control of resources valued by the target person and be able to monitor whether or not the person complies. However, if the person privately accepts the influencing agent's position, the agent's ability to reward or punish the person and to maintain surveillance are unnecessary for the response to be performed. The person will perform the behavior because it is internalized, that is, it is consistent with her private beliefs.

#### *Can Compliance Lead to Private Acceptance?*

Numerous studies have shown that compliance can lead to private acceptance via a variety of mechanisms. Perhaps the best documented mechanism is the one proposed by Leon Festinger in his theory of cognitive dissonance. According to this theory, inconsistency between public behavior and private beliefs produces a tension known as cognitive dissonance. This tension motivates people to reduce their discomfort by changing their private beliefs to be more consistent with their public behavior. Studies show that belief change is most likely to occur when there is minimal pressure to comply and the compliance is public. When too much force is used to gain compliance, there will

be less cognitive dissonance and therefore less pressure to change private beliefs to be consistent with public behavior.

Another theory that can account for the impact of compliance on private beliefs is Daryl Bem's self-perception theory. According to this theory, people use their behavior to infer their private beliefs, particularly when they are uncertain about these beliefs. For example, when a group subtly induces a member to contribute to a charitable cause and the individual is later questioned about his feelings about the charity, he might reason that, because he made the donation, he must have positive beliefs about the charity.

A third explanation for how compliance produces private acceptance relates to the finding that compliance can provide people with the opportunity to gain new information that could change their private beliefs. Evidence for this mechanism can be found in studies of role playing where individuals were induced to write an essay favoring a position counter to their beliefs. Results show that this experience modifies individuals' private beliefs in the direction of the position taken in the essay, because writing the essay forces them to acquire new information that can potentially change their beliefs. In sum, then, there are multiple ways in which compliance to pressure can ultimately lead to private acceptance.

### Compliance in Response to a Request

Research on compliance with a request has focused on the strategies often used by professionals to gain compliance from potential clients. These professionals include fund-raisers, salespeople, advertisers, political lobbyists, and recruiters, to name a few. Their requests may be explicit, such as an invitation to donate to a charitable cause, or implicit, such as an advertisement touting the advantages of owning a brand of clothing without directly asking for a purchase.

Relevant research has addressed two questions: (1) What underlying motives of people do compliance professionals attempt to capitalize on? (2) Based on these underlying motives, what specific compliance strategies do professionals employ? According to Robert Cialdini, those who employ compliance-gaining strategies capitalize on three basic motivations of the target audience: (1) to

form accurate perceptions of reality, (2) to develop and preserve meaningful social relationships, and (3) to preserve a positive self-concept.

#### *Motivation to Form Accurate Perceptions of Reality*

People want to be effective decision makers. To meet this goal, they need to have accurate perceptions of reality because inaccurate perceptions are likely to produce poor decisions. Capitalizing on this motivation, compliance professionals have developed several effective strategies for gaining compliance. One such strategy involves presenting oneself as an authority or expert on the subject matter under consideration. The strategy relies on targets' tendency to rely on *heuristics*, or simple rules of thumb, to make decisions. In this particular case, target persons would be relying on the heuristic "experts know what's best." Examples of this strategy include an advertisement showing a NASCAR driver recommending a brand of motor oil and a waiter informing dinner guests that *coq au vin* is his favorite item on the menu.

To increase the perceived value of their product, compliance professionals also make use of the notion of scarcity. They attempt to capitalize on the belief in many people's minds that the quality of a product is a function of its scarcity—the less available the product, the better its quality. Examples of this strategy include stating that there is a "limited supply" of the product, or it is available only to the first 50 callers, or "it's a limited time offer."

Another tactic used by professionals to increase the perception that a product is a "good deal" involves the "that's-not-all" technique. The compliance agent first makes an offer and then immediately sweetens the deal by lowering the price or increasing the benefits. Sometimes this tactic is used in combination with the scarcity tactic, as when the target is informed that the special carving knife can be purchased for \$30, but if "you respond in the next hour you will also receive a free set of paring knives and cutting board."

#### *Motivation to Develop and Preserve Meaningful Social Relationships*

People often want to form new relationships and maintain existing relationships. It is therefore

not surprising that people are more likely to comply with a request from someone they like than from someone they dislike. The positive feelings underlying compliance may be based on the similarity or attractiveness of the person making the request. A compliance tactic based on the motivation to preserve meaningful social relationships is used by the American Cancer Society. This tactic involves enlisting group members, such as neighbors, to solicit donations from fellow neighbors. Evidence for the effectiveness of such tactics was obtained in a study showing that attractive solicitors for the American Heart Association produced almost twice the amount of compliance as unattractive solicitors.

Norms, or agreed upon rules of conduct, are an important part of maintaining social relationships. Compliance professionals frequently make use of one such norm, the norm of reciprocity, to elicit compliance. The strategy involves providing the target person with a gift, such as address labels, greeting cards, or a calendar, accompanied by a request for a donation. The recipient, feeling indebted to the donor, feels obligated to reciprocate by making a donation.

Another compliance tactic that capitalizes on the norm of reciprocity is the “door-in-the-face” strategy. A requester makes an extreme request (e.g., a \$200 donation), which is certain to be rejected. This is followed by a more moderate request (e.g., a \$25 donation). Target persons, feeling obligated to make a reciprocal concession, tend to comply by agreeing to the more moderate request. A substantial amount of research documents the efficacy of this strategy. While the prevailing view is that reciprocal concessions are the mechanism that makes this work, some researchers contend that the key mechanism is “perceptual contrast.” That is, the more moderate request is accepted because, in comparison to the extreme request, it appears to be a very minimal request.

#### *Motivation to Preserve a Positive Self-Concept*

Finally, people desire to maintain a positive view of themselves, and compliance professionals often attempt to capitalize on this motivation. Viewing oneself as a person who is consistent and who adheres to commitments contributes to one’s positive self-perception. One well-documented

compliance strategy, “the foot-in-the-door” strategy, capitalizes on the need for consistency. People are first asked to comply with a small request, which is usually granted. This is followed by a larger request.

Research shows that complying with the smaller request makes people more likely to comply with the larger request. For example, one study showed that people who first agreed to put a small sign in their window were more likely to agree to a subsequent request by a different solicitor to place a large sign on their lawn than were people who were not first given the small request. Presumably, people complied with the larger request because they wanted to be consistent with their image of themselves as helpful. Groups often employ this tactic when socializing new members. For example, the group may initially request that the new member make only a minimal contribution to group effort, which is followed by escalating demands.

A second compliance strategy, known as “lowballing,” capitalizes on targets’ desire to view themselves positively by adhering to commitments. Take the case in which a customer in an auto showroom makes an initial commitment to purchase a car. Lowballing occurs when the salesperson initially agrees to sell the car at a lower price than she intends to get. Subsequently, after “consulting” with her manager, she ups the price by informing the customer that features that were supposedly included in the original offer, such as undercoating and power steering, will cost extra. Customers often comply with the additional request, presumably because they want to view themselves as the type of person who adheres to commitments.

### **Conclusion**

Groups commonly pressure members to comply with their wishes. This entry examined two meanings attached to the term *compliance*. Early researchers defined compliance as public behavior without private acceptance. Research in this tradition has produced important insights about the conditions under which compliance leads to private acceptance. More recently, researchers have employed a definition of compliance that ignores the distinction between public behavior and private acceptance. Instead, compliance is defined simply as acquiescence to a request. This definition has

stimulated a great deal of research on the motivational underpinnings of compliance and the tactics that groups and individuals use to induce people to comply. Research resulting from these two lines of inquiry has enriched our understanding of social influence in both dyadic and group contexts.

## COMPUTER-MEDIATED COMMUNICATION

---

*Computer-mediated communication* (CMC) refers to the exchange of messages via computer technologies, as opposed to face-to-face communication. It includes familiar technologies, such as e-mail or telephony; less common, but also popular technologies, such as video conferencing, instant messaging (IM; exchanging short text messages), and blogging (writing in an online diary);

and a wide variety of less familiar tools. CMC allows people to communicate at a distance, across both space and time. These technologies can alter the ways that people converse with one another in both positive and negative ways. It is important to group processes and intergroup relations in two ways: First, the use of CMC instead of face-to-face conversation can alter the ways that people interact with each other, affecting such things as group performance and people's liking for one another. Second, CMC itself makes it possible for people to interact with a more diverse set of individuals, spanning many time zones and countries. Thus, CMC technologies can broaden social networks, helping people to know individuals from around the world.

The appropriateness of any particular CMC tool for group communication will depend on what the group is trying to accomplish. Researchers are continuously working to create newer and better CMC technologies that will better support group processes and intergroup relations. This entry examines the various types of CMC technologies, their effects on the conversational process, and their impact on social networks.

### CMC Technologies

There are many types of CMC technologies, each of which can have different effects on group processes. These technologies can be differentiated along several dimensions. First, CMC technologies vary according to the *mode of communication* supported, such as typing, voice communication, facial expressions, or gestures. A common way of talking about this is in terms of richness—the more aspects of face-to-face communication (words, intonation, facial expressions, etc.) available in a CMC technology, the richer that technology is said to be. Thus, video is richer than telephony, which in turn is richer than instant messaging. Second, CMC technologies vary according to the *type of social group* they are intended to support. Some, such as IM, are used predominantly by pairs of colleagues, friends, and family members. Others, such as teleconferencing and online chatrooms, can support small groups. Yet others, such as blogs and e-mail distribution lists, can support communication among hundreds, thousands, or even millions of people. Third, CMC technologies vary according

to whether they are intended to support real-time (*synchronous*) communication, in which speakers and listeners are both present at the same time and can respond immediately to each other's messages, or whether they are intended to support different-time (*asynchronous*) communication, such as when someone reads and responds to an e-mail that was sent the day before.

The characteristics of a given type of CMC (mode of communication, type of social group, synchronous vs. asynchronous) have implications for the types of group processes that can be supported. For example, e-mail can be a good method for exchanging documents or notifying others of an upcoming event such as a party or presentation, but it is not as effective as the telephone for making rapid decisions. Instant messaging can be slower than a telephone call, because people typically type more slowly than they speak, but it provides a written record of the discussion that can be referenced in the future.

### Effects of CMC on Conversational Processes

Face-to-face conversation is an essential part of most all group processes; it is the basic mechanism by which people exchange ideas, come to agreement, negotiate outcomes, and perform other group tasks. Three key aspects of conversational processes are often altered when people communicate via CMC: the types of communicative behaviors people perform, the role of conversational context, and turn taking.

### Words, Intonation, and Nonverbal Behavior

In conversations, listeners attend to the words being spoken, but they also listen to *how* these words are spoken, and they watch facial expressions, hand gestures, and other nonverbal behaviors for insight into what the speaker means. Imagine, for example, hearing someone say, "I'm so happy!" versus "I'm so happy." With the rising intonation suggested by an exclamation mark, the speaker sounds much happier. Similarly, listeners' nonverbal behaviors are important sources of information for speakers. Speakers monitor listeners' gaze and facial expressions to assess whether or not they are listening and understand the message.

How well CMC supports group activities depends in large part on the type of task people are doing. When the goal is informal chitchat, most any kind of synchronous communication will suffice, including the telephone and IM. The reasoning here is that nonverbal and vocal cues are less important for such conversations than they are for tasks requiring more social delicacy, such as negotiations. For these more delicate tasks, richer media like video conferencing are more appropriate (in some cases people may actually travel long distances to conduct these conversations face-to-face). Tasks that involve talking about physical objects, such as maps, architectural diagrams, or pieces of technology, also benefit from CMC tools that include video. Here, however, the kind of video that is most useful does not show a partner's face, but rather a view of the work space, so that people can share a view of the objects they are talking about.

At the level of conversational processes, researchers have found that specific attributes of media influence how people communicate with one another. For example, when people can't see their partners, they are more likely to say things that are impolite, a phenomenon known as *flaming*. A common explanation for this is that when people can't see a partner they feel less constrained by social norms that prohibit rude behavior. They don't have to look at a partner's upset facial expression or listen to him or her yell in response. Flaming is particularly likely when people are anonymous—for example, when they use fictitious screen names in chat rooms—and thus cannot be held personally accountable for what they say.

Communication via CMC has also been studied with respect to interpersonal deception. In text-based media like e-mail or IM, not only are visual cues missing (e.g., "shifty eyes") but also the person who is lying has more time to carefully compose falsehoods. In fact, police agencies can create entirely false personas in text chat rooms, as is the case when agents pretend to be young girls in order to catch sexual predators. The lack of visual cues to the typist's identity and the additional time available to carefully craft typed messages create opportunities to deceive on a much larger scale than that commonly available in face-to-face groups.

Perhaps because lying is easier when text-based media are used, members of groups that interact

virtually often show less trust in each other than do members of collocated groups. Trust among members of virtual groups can be increased if people interact informally with one another first, either face-to-face or via CMC. Once people get to know one another, trust levels in virtual and collocated groups are similar.

### Context

Conversations take place within a larger setting, such as a workplace, school, or home, and this setting helps shape what kinds of messages are appropriate and how they should be understood. In CMC, the sender of a message may not know the context of the recipient, and thus accidentally violates social norms. One example of this is sending jokes or other personal IM messages to recipients who are projecting their computer screen to an audience. In such circumstances, the entire audience will see the possibly inappropriate message.

The absence of context also affects people's interpretations of events. It becomes easy for people to misinterpret others' responses or failures to respond. If someone fails to respond to an e-mail message, it could be because he or she is intentionally ignoring it, or it could be because the person is very busy. When cell phones become disconnected in the heat of an argument, it could be because the signal was dropped or it could be because the other party hung up in anger. Several studies have found that when context is lacking, people tend to make what social psychologists call the *fundamental attribution error*: They overattribute the causes of events to their partner's dispositional characteristics (e.g., laziness, lack of interest) when those causes actually involve situational constraints, such as the quality of the technology (e.g., bad connection).

A flip side of the ambiguity of CMC is a phenomenon known as *plausible deniability*. People are aware that their communication partners can't see what they are doing, and they can thus pretend to miss messages when they really just don't want to respond. Plausible deniability is risky, however, for the reasons stated above: The sender of the message is most likely to assume that a nonresponse is due to partner characteristics, not the situation. The ambiguity of context in CMC also enables

people to multitask, switching between multiple conversations or between a conversation and some other activity. Because of the invisibility of the context, conversational partners can't see that they do not have a person's undivided attention.

When context is lacking, the careful negotiation of engagement in an interaction is disrupted. When people are face to face, they use a series of nonverbal cues (looking at the other person from a distance to see if he or she is busy, establishing eye contact, moving into speech range, etc.) to initiate a conversation. In virtually all types of CMC, the information needed for this engagement process to go smoothly is missing. As a result, it is easy to interrupt people when they are busy. For example, when making a telephone call there is no way to determine if the called person is sleeping, cooking, painting, or otherwise engaged—the person is simply interrupted in the middle of whatever he or she was doing. The same holds true for senders of IM messages, although some IM clients allow people to indicate their availability for communication (e.g., setting their status as "away"). E-mail spammers take advantage of this lack of context by sending hundreds or even thousands of unwanted messages each day.

### Turn Taking and Conversational Participation

In a typical conversation, people take turns speaking and listening in an orderly fashion, using turn-taking signals such as tone of voice; questions like, "What do you think, John?"; and eye gaze. In CMC, many if not most of these cues are missing. This has both negative and positive effects on group interaction. On the negative side, it can be more awkward to change speakers in CMC, especially in large groups such as multiparty audio conferences. On the positive side, however, shier people find it easier to speak up when they do not have to attend to these turn-taking cues. In fact, one of the earliest goals of text-based CMC tools was to increase the evenness of participation among members of group by making everyone anonymous. That way, it was reasoned, people of lower status or with greater fears of speaking would contribute more. These systems were fairly successful, but as one might imagine, people did not like having anonymous partners and the tools were never used to any great degree.

### Using CMC to Broaden Social Networks

In addition to its effects on individual conversational processes, CMC can help grow people's *social networks*—the set of people they know and who those people know. But CMC can also introduce problems into these new social relationships.

#### *Meeting New People*

When people are all collocated in the same physical area, they tend to bump into one another in common areas such as cafeterias, hallways, or coffee shops. Social norms dictate greeting acquaintances in such settings, so unplanned conversations often arise. These conversations strengthen interpersonal bonds. The majority of CMC technologies do not support this kind of informal communication, though there are some exceptions. For example, there are thousands of online chat rooms where one can go to discuss topics of common interest with people one has never met in real life. In some cases, longer term friendships and even marriages have developed from chat room interactions. Another place that people encounter new potential friends is in virtual social environments such as Second Life, which even includes large (virtual) public events like concerts or presentations to bring people together. Social networking sites like Facebook and MySpace also allow people to extend their networks by facilitating connections between friends of friends. At the same time, these sites allow people to maintain existing close relationships after life changes, such as moving away for college.

One of the values of meeting new people online is that these people tend to be more diverse than those one would meet in one's neighborhood. In one chat room, for example, a typical discussion included people from the United States, Canada, Mexico, Germany, and Australia. Over time, many of these people became close friends and some even traveled to other countries to meet face-to-face. Interaction across cultures brings interesting new challenges for many people, because cultures differ in communication styles, politeness norms, opinions about what topics are appropriate versus inappropriate, and norms for who should take the lead in discussions. Most of what we know about CMC is the result of studies conducted in Western

cultures, particularly the United States, Canada, and Europe. An important area for future work is to understand how CMC changes group process among different cultural groups and in intercultural communication.

#### *Longer Term Relationships*

An intriguing aspect of virtual relationships is that people are more likely to disclose personal information about themselves to those they meet online than they are to disclose such information to face-to-face acquaintances. This can have both benefits and costs. On the positive side, disclosure of personal information, especially when reciprocated, can speed up the development of deep and long-lasting relationships. On the negative side, however, disclosure of personal information to unfamiliar others can be risky and in some cases has led to serious consequences such as identity theft or predatory behavior.

Although CMC can broaden social networks and lead to deep friendships, it can also introduce problems into social relationships. Earlier, this entry discussed phenomena that surround a single interaction, either face-to-face or via CMC. These phenomena have a way of adding up over time, shaping the quality of the interactions among a group of people and influencing the outcomes of their activities. The erroneous overattribution of problems to others' personal characteristics rather than technological limitations is one example. When failures to respond are attributed to ill will or laziness on the part of one's partners, this can't help but negatively impact future interactions. Similarly, confusions that arise because visual or auditory cues are missing in CMC may not be noticed until much further down the line, when they have already had significant consequences. Perhaps for these reasons alone, social interactions via CMC are often less successful than those among collocated individuals, at least in the short run. With more time and experience with CMC, groups are often able to overcome these problems.

## COMPUTER SIMULATION

---

*Computer simulation* uses the computational and storage capacity of computers to model complex and dynamic systems of behaviors. In a typical application, a model of group process includes:

- *agents* (group members) who act and interact;
- *attributes* that describe these agents;
- behaviors that the agents can display (*behavioral repertoire*); and
- *functional rules* that specify how agents' attributes affect their behaviors and how other agents' behaviors affect these attributes.

Through a series of computational steps, the model generates the interaction of agents as it unfolds over time. At any point, the state of the interaction is described by the current values of agents' attributes. Such a computational model is a theory. It symbolically represents a real-world process, and its

validity can be evaluated by comparing its output to empirical observations. Structurally, the theory is embodied in the choices of attributes and behaviors that are included in the model. Dynamically, the theory is captured by the functional rules. These rules describe how agents' attributes (knowledge, mood, etc.) affect their behaviors and how the behavior of each agent changes the attributes of others, and thus their subsequent behaviors. Using the capacity and flexibility of computational modeling, one can combine many theoretical ideas across different levels of analysis (individual, small group, organizational, and community) into a unified and coherent working model.

### An Example: Mate Selection

Consider modeling how potential mates choose partners. Suppose the domain of interest is mate selection in a heterosexual, monogamous community of unattached agents. Characterizing the domain in this way implies that mating occurs when a female and a male agree to form a union and leave the pool of unattached agents. Hence, each agent's gender is a necessary attribute and a necessary functional rule is that same-sex agents will not mate. These structural components of the model are necessary but often are not of primary theoretical interest. For example, one might develop the model based on the following propositions:

*Attractiveness proposition:* Each agent has a level of attractiveness that summarizes her or his value as a mate.

*Process assumptions:* (1) a meeting is a temporary pairing of two agents, (2) a proposal to a mate may occur if the two parties in a meeting are of the opposite gender, (3) either party may initiate a proposal, and (4) for a proposal to result in mating, the recipient of a proposal must accept.

*Proposal proposition:* The probability that a person initiates a proposal is positively related to the level of attractiveness of her or his partner in a meeting.

*Acceptance proposition:* The level of attractiveness of the proposer is positively related to the probability that a proposal will be accepted.

*Rejection proposition:* The more often a person's proposals are rejected, the more likely the person will be to initiate and accept a proposal.

These propositions and assumptions comprise a simple model of mate selection. The simplicity is imposed for exposition purposes. For example, the model as outlined assumes that unions once formed remain intact. More realistically, some attached partners may reenter the pool, but the process that determines this reentry would have to be specified. Moreover, representing attractiveness as one-dimensional is simplistic. In practice, attractiveness is determined by many attributes, which are weighted differently by different agents. Also, the domain of interest could be expanded to include homosexual and bisexual agents. This expansion would require adding additional attributes and functional rules to the process. Adding such complexity is limited primarily by the creativity and ingenuity of the modeler. The medium of computer simulation easily accommodates complexity.

Even within this simple model of mate selection, translating the theoretical propositions into computational steps adds complexity. Consider the proposal proposition. Two agents, M and F, meet. Each has a specified level of attractiveness and these are stored in the variables  $M_{attr}$  and  $F_{attr}$ . Does F propose a union? There are two general approaches to translating attributes into behavior. One might define a *deterministic* functional rule: If  $M_{attr}$  exceeds a critical threshold of attractiveness, then F will propose. This approach requires an additional attribute, namely an attractiveness threshold for each agent. Alternatively, one might define a *stochastic* rule that adjusts the probability of F proposing as a positively increasing function of  $M_{attr}$ . This stochastic approach requires that the program complete three steps: (1) compute the probability of the event as a function of relevant attributes, (2) sample a value from a probability distribution, and (3) compare the sampled number to the computed probability of the event. If the sampled random number is greater or equal to the probability of the event (in this case, F proposing), then the event occurs; otherwise, it does not. A stochastic approach implicitly recognizes that variables other than those represented in the computational steps may determine whether the event of interest occurs, and these extraneous contributions are modeled as

random processes superimposed on the processes that are explicitly incorporated in the model.

### Computational Models in Social Psychology

In the 1968 *Handbook of Social Psychology*, Robert Abelson reviewed the early history of computational modeling in social psychology. His and subsequent works include many examples of computer simulations of group behavior. In 1988, Thomas Ostrom edited a special edition of the *Journal of Experimental Social Psychology* that featured computational models of social behavior. Ostrom characterized computational models as the "third symbol system" for theorizing—verbal language and mathematical systems being the other two. He argued that computational models combine the precision and deductive power of mathematical systems with the flexibility and complexity of verbal expression. In the 2000 *Handbook of Research Methods in Social and Personality Psychology*, Reid Hastie and Garold Stasser presented two examples that illustrate the process (and possible pitfalls) of computational modeling: the IMP (impression and memory processor) model of impression formation and the DISCUSS model of small group discussion and decision making. Each model is presented in sufficient detail to illustrate how one constructs and evaluates models and how computational models interact with verbal and mathematical theories and empirical observations. In 2000, Daniel Ilgen and Charles Hulin compiled a set of papers that describe applications of computational models and commentary on these applications. Their book documents the richness and variety of models in organizational and group behavior.

### Computational Modeling of Group Process

An attractive feature for the study of group process is that a model can represent multiple levels of analysis: the individual, the small group, the organization, the community, and society. Bridging levels of analysis permits scholars to explore the implications of what happens at one level for what is observed at another level. For example, S. M. Kalick and T. E. Hamilton used a model similar to the foregoing example, in which individuals prefer attractive mates, and showed that such a process resulted in mates that were similar in attractiveness.

They concluded that similar levels of attractiveness within couples does not imply that people seek mates who are similar to themselves in attractiveness. It is possible that an apparent preference for matching attractiveness is an emergent feature of the process, not a preference of the individual agents. Bibb Latané and his colleagues provided another example of bridging levels. A major tenet of social impact theory is that the influence exerted on a person increases as the number of sources of influence increases. One implication is that majority positions are more likely to gain than lose adherents. As a result, it seems that minority dissent would disappear over time, causing opinions in a group or community to converge on a shared position. However, Latané and his colleagues demonstrated that another major tenet of social impact theory modulates the process of majority influence: The impact of a source depends on its psychological immediacy. One component of immediacy is proximity in a communication network. They modeled communities of agents that were connected by various configurations of communication channels. Over the course of several rounds of “talking,” agents learned their neighbors’ opinions and adjusted their individual opinions toward the opinions expressed by their neighbors. Latané and his colleagues noted three emergent features at the level of the community. First, the number of agents holding minority opinions decreased (*consolidation*). Second, neighborhoods of agents who agreed emerged (*clustering*) and disparity of opinions survived across neighborhoods (*continuing diversity*). That is, neighborhoods of minority opinion survived within an overall pattern of majority influence. Third, when multiple issues were tracked simultaneously, opinions across issues became increasingly correlated over time (*correlation*), an unintuitive by-product of consolidation and clustering. Thus, the dynamics of social impact, modeled as communication and influence between individuals, generated neighborhoods of like-minded people, pockets of minority dissent, and characteristic belief profiles across multiple issues.

## CONFORMITY

---

*Social influence*, defined as changing one’s perceptions, opinions, or behaviors in response to real or imagined pressure from others, is a fundamental aspect of group life. Various forms of social influence have been identified, including *compliance* (going along with a direct request from others), *obedience* (following the orders of a legitimate authority figure), and *conformity* (changing one’s perceptions, beliefs, or actions in the direction of a perceived group norm). This entry focuses on conformity, examining some of the definitional and measurement issues that researchers face, the motivations that lead people to conform, the impact of having a partner (social supporter) on resisting group pressure, and the role of individual differences in determining conformity.

### Classic Studies

Two lines of classic research had a great impact on how social psychologists think about conformity. In one set of studies published in 1935, Muzafer Sherif demonstrated the power of social influence to change people’s perceptions of highly ambiguous stimuli. Sherif made use of a perceptual illusion called the *autokinetic effect*, which occurs when people are asked to concentrate on a stationary

point of light in a dark room. Under these circumstances, people (who are not informed the light is actually stationary) perceive movement in the light. Some think it moves only a little; others think it moves a lot. Sherif found that, when groups of three people were brought together and asked to say out loud how far the light moved, their judgments gradually converged over trials. In other words, they developed a group norm about the distance the light moved. Moreover, this norm had a lasting impact on participants' perceptions. When later asked to make estimates alone, their responses continued to be influenced by the group estimate. Subsequent research demonstrated that conformity to the norm group was still evident a year later. It is important to note that, in these studies, there was initially no norm to which participants could conform. Instead, they created this norm through mutual social influence, and it then influenced their private responses.

A second set of studies, published by Solomon Asch in 1951, demonstrated the power of social influence to change people's perceptions of highly unambiguous stimuli. Thus, in contrast to Sherif, Asch was interested in the conditions under which people would yield to group pressure even though the group was obviously incorrect. To answer this question, Asch assembled groups of seven to nine people for a study on visual perception. The experimental task, which involved matching the length of a standard line against three comparison lines, was quite easy. Each group contained one naïve participant who answered next-to-last. The remaining "members" were confederates of the experimenter and gave unanimously incorrect answers on 12 of 18 trials. Asch found, to his surprise, that conformity occurred even in a situation where the majority gave clearly erroneous answers. Participants' responses agreed with the erroneous majority approximately one third of the time, and 27% of participants conformed on at least 8 trials. In contrast, control participants (who made judgments privately) gave incorrect answers less than 1% of the time. Although the level of conformity that Asch obtained may seem surprising, it is worth noting that participants' responses were correct approximately two thirds of the time and 24% of participants never conformed.

Together, Sherif's and Asch's studies stimulated a tremendous amount of interest in when and why

groups elicit conformity from their members. Scores of studies have been conducted on this topic in the years since their groundbreaking research was published, and much has been learned.

### Definitional and Measurement Issues

As noted above, we define conformity as change in a person's perceptions, beliefs, or actions in the direction of a perceived group norm. Although seemingly straightforward, this definition masks several complexities regarding how conformity is conceptualized and measured.

#### *Movement Versus Agreement Conformity*

Defining conformity in terms of change is useful, because it allows us to differentiate conformity from *behavioral uniformity*, which involves independent agreement in the absence of perceived group pressure. Simply knowing that a person agrees with a group norm at one point in time does not allow us to make a confident judgment about the source of that agreement. Perhaps the person independently arrived at the group's position without any knowledge of the group norm or any desire to adhere to it—an instance of behavioral uniformity. In contrast, knowing that the person disagreed with the group at Time 1 and then shifted toward it at Time 2 would increase our confidence that the group exerted influence on the person—an instance of conformity. This is especially true if others who shared the person's initial position, but were not exposed to group pressure, failed to change their position.

Although the criterion of movement is useful in defining conformity, it has potential pitfalls. For example, in some cases a person who independently agrees with a group norm but is tempted to abandon it may fail to take this action because of group pressure. Here, conformity is revealed by *refusal to change*. Response inhibition as a reaction to group pressure has also been discussed under the rubric of "conformity by omission," which is contrasted with the more commonly studied "conformity by commission." In the commission case, conformity involves performing a behavior because of group pressure that one would not otherwise perform (e.g., saying a prayer one does not believe in because classmates are saying

it). In the omission case, conformity involves failing to perform a behavior because of group pressure that one would otherwise perform (e.g., not saying a prayer one does believe in because classmates are not saying it).

Another potential problem with the movement criterion involves the temporal relationship between exposure to group pressure and response to this pressure. We have implicitly assumed that conformity occurs immediately after pressure is exerted, but this is not always the case. One counter example is *anticipatory conformity*, in which a person expects future group pressure and responds to it by moving toward the group norm before the pressure is applied. Another counter example is *delayed conformity*, in which a person experiences group pressure, is unable or unwilling to conform immediately, but moves to the group norm at some later time. In both cases, there is a causal link between pressure and conformity, but this link is hard to detect.

### *Public Versus Private Conformity*

Our discussion so far has emphasized overt (behavioral) responses to group pressure. However, conformity can involve covert (attitudinal or perceptual) responses as well. Two general categories of conformity have therefore been distinguished—*public agreement (compliance)* and *private agreement (acceptance)*. If conformity is defined as movement toward a group norm, then compliance refers to overt behavioral change in the direction of that norm, whereas acceptance refers to covert attitudinal or perceptual change. For example, if an individual initially refused to sign a petition advocating abortion rights, learned that a group advocated these rights, and then signed a petition favoring these rights, the person would be showing compliance. In contrast, if an individual privately believed that abortion should be outlawed, learned that a group advocated abortion rights, and then changed his or her private opinion about these rights, the person would be showing acceptance.

The relationship between compliance and acceptance is potentially complex. An individual could exhibit compliance but not acceptance (e.g., because he or she fears group reprisal for deviance but does not privately accept the group's position), acceptance but not compliance (e.g., because he or she privately accepts the group's position but fears

sanctions from outgroup members for taking a public stand agreeing with the group), or both compliance and acceptance (e.g., because he or she accepts the group's position and wants to encourage others to adopt this position). Whether conformity reflects compliance and/or acceptance has implications for how a person will behave when the group is absent. For example, a person who conforms at the public but not at the private level is unlikely to endorse the group's position when responding privately. In contrast, a person who conforms at both levels is likely to endorse the group's position even when the group is absent.

The distinction between compliance and acceptance is applicable to *nonconformity* as well as conformity. Several forms of nonconformity can be distinguished, but two of the most important are independence and anticonformity. *Independence* occurs when a person initially disagrees with a group and exhibits neither compliance nor acceptance after being exposed to group pressure. In other words, the person stands fast when faced with disagreement. In contrast, *anticonformity* occurs when a person initially disagrees with a group and moves even further away from its position (at the public and/or private level) after being exposed to pressure. In other words, the person becomes more extreme in his or her initial position when faced with disagreement. Ironically, then, anticonformers are just as responsive to group pressure as are conformers, but they manifest their susceptibility in a very different way (by moving away from, rather than toward, the group).

### **Motivational Bases of Conformity**

People conform to group pressure because they are dependent on the group for satisfying two important goals. One is the desire to have an accurate perception of reality, and the other is the desire to be accepted by other members.

### *Informational Influence*

There is a great deal of evidence that people want to hold correct beliefs about the world, because such beliefs lead to actions that maximize the probability of rewarding outcomes. Some of our beliefs about the world (e.g., oatmeal cooks better in hot water than cold water) can be verified

by using objective tests (e.g., leaving oatmeal in hot vs. cold water for 5 minutes and then tasting it). In contrast, other beliefs (e.g., the U.S. should maintain its nuclear arms capability; the federal government should institute stronger environmental regulations) cannot be verified using objective standards and hence must be verified using social tests, namely comparing our beliefs to those of other people whose judgment we respect. If these others agree with us, we gain confidence in our beliefs. If they disagree with us, we lose confidence. Because disagreement is disturbing, we are motivated to eliminate it, and one way to do so is to conform to group norms.

According to this analysis, people sometimes conform to groups because they are uncertain about the correctness of their beliefs and believe the group is more likely to be correct than they are. This kind of conformity reflects what Morton Deutsch and Harold Gerard labeled *informational influence*. In general, informational influence produces private acceptance as well as public compliance. This is illustrated in the work of Muzafer Sherif, discussed earlier. His research indicated that people judging an ambiguous stimulus exhibited both compliance (when they made judgments in others' presence) and acceptance (when they later responded privately).

Because informational influence is based on insecurity about one's beliefs, we would expect it to be more common when an individual feels dependent on others for information. Consistent with this assumption, people conform more when they are working on ambiguous tasks than on unambiguous tasks. In addition, they conform more when they have doubts about their own task competence and when they think other group members are highly competent on the task.

### *Normative Influence*

In addition to wanting to hold correct beliefs about the world, people are motivated to be accepted by other group members. The desire for social acceptance is very powerful in a wide range of situations and explains why people are typically quite uncomfortable if they think others currently reject them or are likely to do so in the future. For example, the results of one study indicated that, of 25 people who conformed very little or not at all,

19 expected negative group evaluation. In contrast, of 24 people who conformed a great deal, 17 expected positive evaluation from other group members. Additional evidence demonstrates a factual basis for nonconformers' fear of punishment. Many studies of reaction to deviance show that group members do indeed reject people who deviate from group consensus, depending on such factors as the extremity and content of the deviate's position, the presumed reason for the deviate's behavior, and the deviate's status in the group. Because actual or anticipated rejection is so disturbing, people try to minimize it by conforming to group norms.

According to this analysis, people sometimes conform to groups because they are motivated to be liked (or at least not disliked) and believe that other members will feel more kindly toward them if they conform to rather than deviate from group norms. This kind of conformity reflects what Deutsch and Gerard labeled *normative influence*. In general, normative influence produces public compliance but not private acceptance. This is illustrated in the work of Solomon Asch, discussed earlier. Few of Asch's participants reported changing their perceptions of the experimental stimuli during the group pressure situation, and subsequent studies indicated that participants' private responses after leaving the situation often differed from their public responses in that situation.

Because normative influence is based on insecurity about one's acceptance, we would expect it to be more common when an individual feels threatened for deviating from group norms. Consistent with this assumption, group members conform more when working for a common goal rather than individual goals, presumably because they believe that deviance on their part will be punished more severely in the former case. As might be expected, however, conformity in common goal groups is substantially reduced if members believe that this behavior will lower the group's probability of attaining a positive outcome. Another factor that increases normative influence is surveillance by other group members. People who are concerned about others' evaluations ought to conform more when their behavior is public rather than private, and conformity is in fact higher in the former condition.

### Mixed Cases

Although informational and normative influence have been discussed here as though they are mutually exclusive, they occur simultaneously in at least some group situations. This is a major premise of *social identity theory*, which seeks to explain a range of social influence phenomena, including conformity. This theory assumes that disagreement with others produces uncertainty only when one expects to agree with these people. For this reason, disagreement with ingroup members produces more uncertainty than disagreement with outgroup members. In addition, the theory assumes that some ingroup members are more influential than others. More specifically, a member's influence depends on how much his or her position embodies what is unique about the group—the norm that differentiates the ingroup from outgroups. Members who are closer to this norm are more influential than those who are further from it. Finally, the theory assumes that conformity involves private acceptance as well as public compliance, because people believe that ingroup norms provide valid evidence about reality. A substantial amount of research is consistent with the social identity explanation of conformity.

### Social Support and Conformity Reduction

Asch investigated the impact of group unanimity on conformity by having a single confederate dissent from the erroneous majority by giving correct answers on the line-judging task. The presence of this *social supporter* reduced conformity dramatically, from 33% to 6%. In later research, Asch found that participants who were opposed by an eight-person majority and had a supporter conformed far less than participants who were opposed by a three-person majority and did not have a supporter. Subsequent work by other researchers demonstrated the generalizability of the social support effect by showing that it reduces conformity on a wide range of stimuli (e.g., visual perception items, attitudes) and for a wide range of people (e.g., male and female adults, normal and mentally retarded children). In addition, social support remains effective even after the supporter leaves the situation, as long as participants continue to judge the same type of stimulus and the supporter does not repudiate his or her dissenting position.

The effectiveness of social support can be explained in terms of the supporter's ability to reduce informational and/or normative influence. In the case of informational influence, social supporters can lower participants' dependence on the majority for information about reality. For example, in one study, participants received support from a partner who either had normal vision (and hence could see the stimuli clearly) or wore extremely thick glasses and failed a "vision test" in the participant's presence. Consistent with an informational influence explanation, the competent supporter was more effective in reducing conformity. In the case of normative influence, social supporters can lower participants' fear of punishment for deviation from the group norm. Research indicates that people who dissent from majority consensus with a supporter are much less apprehensive about being rejected than are those who dissent alone. The presence of a supporter may reduce participants' fear of retaliation because they believe the supporter will absorb some of the majority's anger toward deviates. This should not be the case, however, if majority members are assumed to dislike the supporter, for example because they are prejudiced against his or her racial group. In such cases, participants may expect that a perceived alliance with the supporter will increase, rather than decrease, the majority's hostility toward them and hence may continue to conform.

### The Role of Individual Differences

Does everyone who enters a group pressure situation respond in exactly the same way to it? Of course not. Every conformity experiment that has been conducted has found that some people conform more than others. This universal finding challenges conformity researchers to discover characteristics of participants that reliably affect how they respond to group pressure. A variety of such characteristics, including age, race, sex, cultural background, and personality, have been studied in an effort to meet this challenge. To illustrate the impact of individual differences on conformity, participants' sex and cultural backgrounds are discussed next. In both cases, the behavioral predispositions that people acquire prior to entering a group pressure situation can affect how they respond to that situation.

For many years, the conventional wisdom was that females are more susceptible to group pressure than are males. Today, we know that the relationship between sex and conformity is more complicated. Using meta-analytic techniques that combine the results of many studies, Alice Eagly and Linda Carli found that women were indeed more influenceable than men. However, the overall size of this effect was small, and it depended on the setting in which the research was conducted. Sex differences in influenceability were strongest in group-pressure situations where participants were under surveillance by other group members. In contrast, women were only slightly more influenceable than men in conformity experiments that did not involve surveillance and in attitude change studies where participants listened to persuasive communications. Several explanations for sex differences in conformity have been offered. The most plausible is based on the different social roles that men and women are taught to play in our society. According to this explanation, men are taught to be more dominant and assertive than women, and people of both sexes are more likely to exhibit gender-consistent behavior in public (group-pressure) settings than in private settings.

Just as men and women who grow up in the same culture have different socialization experiences that can affect their responses to group pressure, so people who grow up in different cultures may learn different ways of responding to group pressure. To investigate this possibility, Michael Bond and Peter Smith examined cultural differences in conformity using a large meta-analysis involving participants from 17 countries (Belgium, Brazil, Canada, Fiji, France, Germany, Ghana, Great Britain, Holland, Hong Kong, Japan, Kuwait, Lebanon, Portugal, the United States, Zaire, and Zimbabwe). These researchers measured the relationship between the individualism–collectivism of the countries and the amount of conformity that residents displayed on Asch's line judgment task. Individualism is a cultural orientation that emphasizes independence, autonomy, and self-reliance. Collectivism is a cultural orientation that emphasizes interdependence, cooperation, and social harmony. Bond and Smith found that cultural values were indeed related to conformity—people in collectivist cultures displayed more conformity than did people in individualist cultures. Although

the interpretation of these results is not completely clear, it is plausible that collectivists conform more than individualists because they give greater weight to collective goals and are more concerned about how other people view their behavior and are affected by it.

So far, this entry has focused on how cultural differences *between* societies affect conformity, but cultural shifts *within* societies may also be important. To examine this possibility, Bond and Smith examined the impact of intracultural change on conformity in the Asch paradigm, using data from the United States. They found that conformity levels generally declined from the early 1950s to the mid-1990s. These findings are intriguing, but hard to interpret. Were cultural changes the only (or even the primary) cause of the reduced conformity, and, if so, which of the many cultural changes that occurred in the U.S. were responsible?

### Conclusion

Some 75 years after Sherif's classic work using the autokinetic effect, social psychologists continue to be intrigued by the causes and consequences of conformity. Since the 1980s, much of the work on conformity has shifted from an exclusive interest in majority influence to a focus on similarities and differences between majority influence and its mirror opposite, minority influence (or innovation). The lively debate that has ensued has greatly extended our understanding of the nature of social influence in groups.

## CONSERVATISM

---

As used in popular discourse, the term *conservatism* typically refers to a political ideology. Political conservatism is often contrasted with liberalism, and the two are often conceptualized as occupying opposite ends of a single ideological continuum. Conservatism comprises two primary dimensions: (1) a preference for tradition over change and (2) promotion (or tolerance) of inequality. These two dimensions often (though not always) are correlated with one another. This is partly attributable to the fact that, throughout history, nontraditional social systems have tended more toward egalitarianism than traditional ones. Interestingly, in cognitive psychology, the term *conservatism* is used in reference to the insufficient updating of judgments and estimates in the light of new information.

Such cognitive conservatism is conceptually related to the resistance to change and traditionalism characteristic of conservative political ideologies. However, this entry is concerned with political rather than cognitive conservatism.

Among the first to present a psychological theory of political conservatism, Wilson proposed that conservatism constitutes a general psychological dimension that can be useful in explaining people's attitudes across a broad spectrum of social issues. Building on this notion, an accumulation of research over the past few decades has uncovered a number of psychological variables associated with conservatism. This entry will discuss these variables, as well as the three motivational categories into which they can be grouped, to present a comprehensive overview of the psychological mechanisms and correlates of political conservatism.

In addition to the two core aspects of conservatism (resistance to change and tolerance of inequality), conservatism has a number of peripheral aspects, including the desire for order and stability, idealization of authority figures, preference for gradual versus revolutionary change, and conformance to traditional social norms. Some of these factors are directly associated with the core dimensions of the conservative ideological belief system; some are not.

Because conservatism (like liberalism) encompasses numerous goals and pervades multiple facets of life, people adhering to conservative ideologies can endorse different views and beliefs that may occasionally conflict with one another. For example, it is not uncommon for conservatives to support *both* increased military spending and the push for smaller government. The matter is further complicated by the fact that manifestations of conservatism are in constant flux depending on the social issues that present themselves to individuals and societies at different points in time; for example, today's neoconservative (or neocon) movement bears limited resemblance to mainstream American conservatism of just a few decades ago. Accordingly, the specific meaning of what constitutes conservative attitudes and beliefs inevitably changes and evolves over time. Nonetheless, even with this unavoidable fluctuation, identifying major social and psychological factors related to the core values of conservative ideology is feasible and valuable.

### Motives Associated With Political Conservatism

Numerous theories of conservatism have stressed the role of motivation in explaining individuals' adherence to conservative ideology. Nonetheless, to date, no single theory of conservatism has been able to fully explain all of conservatism's many manifestations. A recent review of research on conservatism suggests that the key to developing a comprehensive understanding of the psychology of conservatism lies at the intersection of several psychological theories that highlight the cognitive and motivational factors involved in conservatism. This comprehensive review identifies a specific set of social-cognitive motives significantly associated with political conservatism and classifiable into one of three categories: epistemic concerns, relating to knowledge and belief structures and their acquisition; existential concerns, relating to the meaning and transience of a person's existence; and ideological concerns, relating to the collection of social and political ideas (i.e., ideology) that shapes a person's worldview.

#### *Epistemic Motives*

An epistemic motive is a motive relating to cognition, or thought, and the acquisition of knowledge and beliefs. The accumulation of research evidence strongly suggests that political conservatives tend to be more closed-minded and rigid in their thinking than people on the opposite end of the ideological spectrum. In other words, individuals who subscribe to conservative ideologies are more likely than those who do not to have a high degree of need for cognitive closure. This does not mean that no liberals possess that need, or that the thinking of political liberals is never rigid or dogmatic in nature. Nonetheless, an extensive review of the available evidence indicates that conservatives are significantly more likely than their liberal counterparts to have this need for closure.

Individuals who have a high need for closure tend to be intolerant of ambiguity. Indeed, conservatives are more likely to be more intolerant of ambiguity than liberals and, as compared to their liberal counterparts to prefer "black and white" delineations of reality to "shades of gray." Related to the intolerance of ambiguity is the absence of integrative complexity. Integrative complexity

refers to the differentiation and synthesis of multiple perspectives, or dimensions. Generally speaking, conservative ideologues have been found to be less cognitively complex than their liberal ideologies. Authoritarianism, political-economic conservatism, and possession of right wing opinions have all been found to correlate positively and consistently with psychological dogmatism (the steadfast adherence to a belief or attitude with limited willingness to entertain evidence that conflicts with that view).

One assumption of Wilson's theory of conservatism is that people who hold politically conservative attitudes are less predisposed to seek out stimulating experiences than are liberals. This theoretical assertion is substantiated by correlational evidence that conservatives are, in fact, generally less open and receptive to novel and exciting experiences of various kinds and in a variety of domains. For example, compared to liberals, conservatives are less likely to volunteer for psychology experiments that require openness to experience, they place less value on having an exciting life, are less imaginative, and score lower on openness to experience and sensation-seeking scales.

#### *Existential Motives*

Existential motives are motives related to the person's very existence, its meaning, and the threat of its termination. In this category belong needs of self-esteem and self-actualization, but also fear, the perception of threat, and consequent anger directed at the threatening parties. Because the concepts of conservatism and authoritarianism are closely linked (with the latter considered a specific manifestation of the former), research on authoritarianism has provided a number of insights into the psychology of conservatism, with specific reference to existential motives.

Contemporary as well as classic theories of authoritarianism have suggested that factors such as low self-esteem, fear, and aggression may contribute to a person's willingness to adhere to a politically conservative ideology. Although there is relatively scarce evidence suggesting that political conservatism and lowered self-esteem are, in fact, related, there is considerable research evidence supporting the notion that fearfulness is related to conservatism, as is the perception of threat.

Theories of authoritarianism have also suggested that conservatives are particularly aversive to potential losses, which might help explain their general preference for maintenance of the status quo over change. Findings suggesting that this is the case include data showing that negatively framed persuasive messages (which emphasize potential losses) motivate changes in the behavior and behavioral intentions of authoritarians more effectively than positively framed persuasive messages (which highlight potential gains). Fear of death is also correlated with conservatism, along with increased tendency to hold views of women and minority-group members that are congruent with traditional stereotypes.

### *Ideological Motives*

In addition to individual differences in social and political attitudes associated with authoritarianism and conservatism, early theorizing also postulated that threats levied at the level of the political system are more menacing to individuals who are highly authoritarian. This hypothesis is also set forth by Jost's recent theory of system of justification, which suggests that there is an ideological motivation to defend the existing social system against instability and threat and this motivation is strongest among those on the right wing of the ideological spectrum. Considerable experimental and archival research supports the idea that in times of societal turmoil, people are more prone to make more politically conservative decisions and judgments, and to defer to authoritarian leaders in order to regain social stability and security. Such findings highlight the fact that conservatism is not solely an individual-difference variable; situational factors can also play an important role in inducing the tendency to embrace conservative ideologies.

### **Conclusion**

As discussed in this entry, political conservatism is related to a number of different epistemic, existential, and ideological motives. It has been suggested that virtually all of these can be thought of as originating in attempts to manage feelings of uncertainty and fear, which, in turn, are closely linked to (1) resistance to change and

(2) endorsement of inequality—the two core dimensions of conservatism.

Resistance to change is beneficial to the management of uncertainty in that it prevents the introduction of the unknown and disruption of one's present reality. Fear, however, is inextricably intertwined with the promotion of inequality, since it can both precipitate the endorsement of inequality (as a means of keeping less powerful, revolutionary segments of society at bay) and arise from it (by breeding discontent, turmoil, and even violent struggles).

Epistemic motives facilitate the acquisition of stable and firm beliefs, which in turn provide guidance and help people navigate their often complicated and ambiguous realities. Existential motives also encourage achieving and maintaining stability and certainty, and opposing change and avoiding entry into the novel and insecure terrain that inevitably accompanies it. Both epistemic and existential motives, thus, are inherently served, to a certain extent, by resistance to change. Finally, ideological beliefs (as to the inevitability and justice of the status quo) can help reduce uncertainty and feelings of threat and worthlessness by providing those who embrace them with a sense of conviction and purpose.

Because ideology is instrumental in shaping people's worldviews, and worldviews have important consequences for interpersonal interaction at the individual, group, and societal levels, understanding the forces that attract individuals to particular ideologies is of great value to society. This entry traced the accumulation of more than half a century of psychological research on conservative ideology. The results of this labor provide illuminating insights into the specific cognitive motivational factors that underlie political conservatism.

## CONSPIRACY THEORIES

---

*Conspiracy theories* are sets of often erroneous beliefs that people use to explain malevolent and/or unlawful acts that are perceived to be directed by and in favor of a small and powerful group that works in secret against a larger group of unwitting victims. This entry describes research on conspiracy theories as well as closely related phenomena. It starts by considering the association between conspiracy theories and rumors and the social functions of stereotypes. Next, it describes the research findings on conspiracy theories—when they are most likely to be conceived, the nature of the people who subscribe to conspiracy theories, and the theories' effects. The entry concludes by describing explanations for the existence of conspiracy theories and conspiratorial thinking.

### Conspiracy Theories and Related Phenomena

Given that there is little research on conspiracy theories, it is worthwhile to consider the properties that most conspiracy theories share: Conspiracy theories are usually conceived as explanations for events that provoke widespread social anxiety and

uncertainty, conditions under which people are eager for explanations; the content of conspiracies is emotionally laden and their discovery can be gratifying; the evidentiary standards for corroborating conspiracy theories is typically weak, but conspiracies that survive in the public consciousness are resistant to falsification; the survivability of conspiracy theories is aided by psychological biases and distrust of official sources; and conspiracy theories of one form or another are held by most people.

Conspiracy theories and rumors are examples of informal social communications. As such, they share several properties. First, rumors are particularly likely to flourish during periods of social uncertainty and anxiety. Indeed, rumor research began in the 1940s as rumors came to the attention of government officials who were concerned that they would undermine the war effort. Second, the definition of rumor, proposed by Robert Knapp as "a proposition for belief of topical reference disseminated without official verification," is similar to but more general than the definition of conspiracy theories. Third, Knapp noted that the content of rumors expresses and gratifies collective emotional needs. This emotional dimension differentiates rumor from news. So, for example, the news that *Churchill is now in Washington* is likely to elicit little emotion compared with the rumor that *the Jews are avoiding the draft*. It is, of course, a small step to conclude that the latter rumor could blossom into a conspiracy.

Knapp showed that rumor content can be coded with respect to its emotional content. A sample of 1,089 rumors collected in 1942 showed that 2% were wish based (e.g., *the Japanese do not have enough oil to last 6 months*), 25% were fear based (e.g., *the entire Pacific Fleet was lost at Pearl Harbor*), 66% were hostile (e.g., *that Churchill blackmailed Roosevelt into provoking war with Japan*), and 7% escaped categorization. It is noteworthy that of all the rumors, 50% concerned intergroup tensions, and they were mostly anti-administration (i.e., government, army, and navy), anti-British, or anti-Semitic. The emotional content of rumor is suspiciously similar to that in conspiracy theories, and is predominantly focused on intergroup relations. Rumors are often slanderous, express intergroup hostilities, and scapegoat minority groups.

In 1981, Henri Tajfel proposed a functional account of stereotyping: Stereotypes provide positive images for ingroups, justify actions committed or planned, and provide explanations for widespread social uncertainties. In fact, many of the stereotypes identified by Tajfel fulfill all of these functions simultaneously. For example, Nazi propaganda depicted Jews as child molesters, explained German hyperinflation in the 1920s as the result of Jews controlling the banking system, and explained that Jews were plotting world domination. In this case, the accusations were depictions of Jews that were intentionally diffused by Nazi propagandists in an attempt to forge a common outgroup to promote German unity and serve Nazi aspirations for further power.

Conspiracy theories, rumors, and stereotypes have existed for centuries. Historical accounts demonstrate that tens of thousands of women accused of being witches were tortured and killed in Europe from the 15th through 17th centuries. The identification of women as witches was largely driven by rumor and religious superstition, and appears to have been more likely to occur during crop failures. In the modern world, rumors and conspiracies are now easier to diffuse than at any time in the past. While this is true, there is reason for optimism. On a historical time line, superstition is in decline; skepticism, rationality, and the scientific method are on the increase; and perhaps most importantly, it is possible to combat false rumors using the same technology that aids their spread.

## Research on Conspiracy Theories

### *When Do Conspiracy Theories Arise?*

Conspiracies often originate in government propaganda that is designed to manufacture support for war. Enemies are said to be conspiring to launch an attack, are developing weapons, or are implicated in an attack on the homeland. For example, in the lead up to the Iraq war in 2003, polls showed that 22% of the American population believed that Iraq was directly involved in the attacks on September 11, 2001, while a further 35% believed that Iraq was not directly involved, but had given substantial support to Al Qaeda. Further, 32% claimed that it was very likely, and 37% believed it somewhat likely that Saddam Hussein was personally involved in the September

11th attacks. Over time, 21% to 24% of Americans believed that weapons of mass destruction had been found in Iraq. These false beliefs developed independently of political affiliation, and were more far more prevalent for viewers of some news sources (e.g., Fox News) than others (e.g., PBS). The more of these false conspiracy beliefs that people possessed, the more they were in favor of war with Iraq. Like stereotypes, conspiracies can be used to justify planned actions.

Conspiratorial thinking increases in prevalence when there are widespread social uncertainties, as found during war or in the aftermath of terrorist attacks, and when there are natural disasters like tsunamis or earthquakes or outbreaks of lethal disease. This fact is evidenced by the profusion of documentaries, books, movies, and magazine articles dedicated to explaining events like the September 11th terrorist attacks, and the more than 2,000 volumes on John F. Kennedy's assassination. This suggests that conspiratorial thinking is driven by a strong human desire to make sense of social forces that are self-relevant, important, and threatening.

### *Who Subscribes to Conspiracy Theories?*

While there is some evidence for individual differences that lead people to be more or less susceptible to belief in conspiracy theories, it is also true that some conspiracy theories are believed by large majorities of the population. For example, there is evidence that approximately 90% of the American population believe that President Kennedy was assassinated by a conspiracy of one or more of the following: Cuban exiles, the Central Intelligence Agency, the Mafia, the Dallas police, pentagon officials, and/or Lyndon Johnson, as opposed to the official lone suspect, Lee Harvey Oswald. In fact, polling data suggest that most people believe in at least some conspiracies.

Research suggests that in general people tend to either believe in conspiracies or not. It shows that general belief in conspiracies has several correlates. First, while there is no evidence for associations with gender, education level, or occupation, there is evidence that Blacks and Hispanics are more likely to believe conspiracies than are Whites. The association between ethnicity and belief in conspiracies appears to be mediated by anomie (a sense of social dislocation) and lack of trust in

other people, the police, and government. Further, people are also particularly likely to believe in conspiracies that they feel are directed at their group. Blacks, for example, are particularly likely to believe that the federal government plants drugs in their communities.

### *Outcomes of Belief in Conspiracy Theories*

Exposure to media that endorse conspiracies increases belief. There is evidence that viewing the Oliver Stone movie *JFK* increased belief in the conspiracy to assassinate President Kennedy and decreased belief in the official account that Lee Harvey Oswald acted alone. A further outcome was that compared with people who were about to view the movie, those who had seen it expressed less interest in political participation. It may be that distrust of those in power predicts and is caused by belief in government conspiracies.

Given relatively high rates of incidence of AIDS and sexual transmitted infections among Blacks, researchers have investigated belief in AIDS conspiracies—that AIDS was created by the federal government to kill Blacks—and attitudes toward condom use. This research has shown that the more male Blacks believe in this conspiracy, the less favorable their attitudes toward condom use are, and in turn the less likely they are to use condoms. There is also evidence that these beliefs lead to distrust of research institutions and are a significant barrier to getting Blacks to participate in AIDS clinical trials.

An alternative possibility is that Blacks have developed these beliefs because of real discrimination. For example, starting in 1932 and continuing for 40 years, the Public Health Service working with the Tuskegee Institute studied the effect of syphilis on the bodies of 399 Black men by withholding treatment and allowing them to die, despite the discovery of penicillin as a standard cure in 1947. It is clearly worth noting that governments do at least occasionally conspire against their own citizens.

## Explanations for Conspiracy Theories

### *Hofstadter and the Paranoid Style*

Richard Hofstadter's work in history explored the emergence of conspiracy theorizing within

American democracy. Hofstadter's vision was a consensus view of democracy; competing groups would represent the interests of individuals, but would do so within a political system that everyone agreed would frame the bounds of conflict. For Hofstadter, people who felt unable to channel their political interests into representative groups would become alienated from this system, which would make them vulnerable to charismatic rather than practical and rational leadership, and would eventually undermine democracy and lead to totalitarian rule. Those so alienated from the system would not trust the statements of opposition parties as being a fair disagreement, rather, differences in views would be regarded with deep suspicion. Such people alienated from the system would develop a paranoid fear of conspiracy.

According to Hofstadter, the paranoid style is not individual pathology, rather, it originates in social conflict that raises fears and anxieties, leading to status struggles between opposed groups. The paranoid style and resulting conspiracy theorizing derives from a collective sense of threat to one's group, culture, way of life, and so on. Extremists on either side of the political spectrum could be expected to develop a paranoid style. On the right, McCarthyism represented the paranoid style—paranoid notions of rife communist infiltration of American institutions; on the left are examples such as the conspiracy of slaveholders against abolitionists or fears of international bankers.

Hofstadter's approach is notable because it places the root of conspiracies in intergroup processes, which means that his theory can account for the ebb and flow of conspiracy theories over time. Since Hofstadter's theory was conceived, however, there have been a number of advances in social psychology that can account for the role of biases in information processing.

### *Psychological Biases*

*Biased Assimilation and Attitude Polarization.* John McHoskey provided an explanation for the difficulty of falsifying conspiracy theories. McHoskey gave advocates and opponents of the JFK conspiracy a balanced description of arguments for and against the conspiracy to assassinate President Kennedy. His proposal was that people

who favored or opposed the conspiracy theory would regard the statement as evidence in favor of their position. This would occur because proponents on both sides engaged in biased assimilation. According to this phenomenon, information that supports one's position is uncritically accepted, whereas contrary information is scrutinized and discredited. Further, because of attitude polarization, when people encounter ambiguous information, they tend to endorse their original position even more strongly than they did prior to encountering the information. This proved to be the case for both advocates and opponents of the JFK conspiracy.

*The Fundamental Attribution Error.* Philosopher Steve Clarke proposed that conspiratorial thinking is maintained by the fundamental attribution error. According to the fundamental attribution error, people overestimate the importance of dispositions (e.g., individual motivations or personality traits) and underestimate the importance of situational factors (e.g., random chance, social norms, and so on) in explaining the behavior of other people. Clarke pointed out that conspiratorial thinking typically makes this error, asserting that devious, self-interested, or malevolent people conspire to make some event come to fruition, such as an assassination, terrorist attack, or elaborate cover up. People maintain adherence to their conspiratorial thinking because to dispense with the conspiracy would be to discount human motives in events. Research provides much evidence that people commit the fundamental attribution error.

Further, Clarke suggests that the ultimate reason that people make the fundamental attribution error is because we are evolved to do so. His reasoning is that we evolved in tightly knit groups where understanding the motives of others was critical for the detection of malevolent intentions. Clearly, the cost of making an error in identifying others' insidious motives is small relative to the cost of not identifying such motives, and so we are psychologically attuned to discount situational factors over dispositional factors in explaining others' behavior.

## CONTINGENCY THEORIES OF LEADERSHIP

---

What makes leadership effective in a group or organization? Scholars have been preoccupied with addressing this key question perhaps since the inception of leadership as a formal field of scientific inquiry. One classic approach that gained prominence during the 1970s and 1980s is contingency theories of leadership. *Contingency theories* hold that leadership effectiveness is related to the interplay of a leader's traits or behaviors and situational factors.

### History and Background

The contingency approach to leadership was influenced by two earlier research programs endeavoring to pinpoint effective leadership behavior. During the 1950s, researchers at Ohio State University administered extensive questionnaires measuring a range of possible leader behaviors in various organizational contexts. Although multiple sets of leadership behaviors were originally

identified based on these questionnaires, two types of behaviors proved to be especially typical of effective leaders: (1) *consideration*, leader behaviors that include building good rapport and interpersonal relationships and showing support and concern for subordinates and (2) *initiating structure*, leader behaviors that provided structure (e.g., role assignment, planning, scheduling) to ensure task completion and goal attainment.

About the same time, investigators from the University of Michigan's Survey Research Center conducted interviews and distributed questionnaires in organizations and collected measures of group productivity to assess effective leadership behaviors. The leadership behavior categories that emerged from the University of Michigan were similar to the consideration and initiating structure behaviors identified by the Ohio State studies. The University of Michigan investigators, however, termed these leadership behaviors *relation-oriented behavior* and *task-oriented behavior*. This line of research was later extended by Robert Blake and Jane Mouton in 1964 to suggest that effective leaders score high on both of these behaviors (high-high leaders).

Although research consistently supported the dichotomy between task and relations leadership behavior, little evidence suggested that these leadership behaviors were related to increased leadership effectiveness in group performance. Inconsistent findings characterized the bulk of research in this area, and soon the focus of attention on leadership behaviors as direct predictors of leadership effectiveness shifted. However, researchers did not abandon the task versus relations dichotomy altogether. Instead, an alternative approach was developed that emphasized the potentially critical role of the situational context in linking leadership behaviors or traits to effective outcomes. This alternate approach became known as the *contingency theories of leadership*.

## The Contingency Approach

### *The Contingency Theory of Leadership Effectiveness*

In the 1960s, Fred Fielder advanced the first theory using the contingency approach, the *contingency theory of effectiveness*. The main idea of this

early theory is that leadership effectiveness (in terms of group performance) depends on the interaction of two factors: the leader's task or relations motivations and aspects of the situation. The leader's task or relations motivation is measured through the Least Preferred Coworker scale (LPC). This scale asks leaders to recall a coworker (previously or currently) they work with least well and to characterize this individual with ratings on a series of 8-point bipolar adjectives (e.g., distant-cold). High LPC scores reflect more positive descriptions of the least preferred coworker, whereas low LPC scores evidence more negative perceptions. Fielder argued that an individual with a high LPC score is motivated to maintain harmonious interpersonal relationships, whereas an individual with a low LPC score is motivated to focus on task accomplishment.

The interpretation of exactly what high and low LPC scores mean has been the subject of much controversy and debate. For example, Robert Rice suggested that scores on the LPC represent values and attitudes, whereas other scholars have drawn linkages between high and low LPCs and task versus relations leadership behaviors. Fielder contended that task and relations motivations are stable traits that are not easily amenable to change. Therefore, attempts to encourage a high or low LPC leader to adapt to changing situations would be difficult, if not altogether futile. To optimize the possibility of an effective group outcome, this model advocates matching a high or low LPC leader to the right type of situation.

The model purports that task or relations motivations are contingent on whether the leader can control and predict the group's outcome (i.e., situational favorability). Situational favorability depends on three assessments: (1) whether the leader perceives cooperative relations with subordinates (leader-member relations), (2) whether the task is highly structured with standardized procedures and measures of adequate performance (task structure), and (3) whether the leader's level of authority is punishing or rewarding group members (position power). The combination of leader-member relations, task structure, and position power creates eight different situational types, known as octants 1–8, that have been more broadly categorized as favorable situations, intermediate situations, and unfavorable situations. Each different situational type is most

effectively handled by either a high or low LPC leader. Specifically, high LPC leaders are most effective in influencing group performance in intermediate situations, and low LPC leaders are most effective in favorable or unfavorable situations.

Fielder's contingency model has been used in training programs and has received a lion's share of research attention. A large number of studies and three meta-analyses more or less support the model's postulations. However, almost half a century after its introduction, further clarifications and future studies may be warranted to iron out both theoretical and methodological issues associated with the model. Nevertheless, many scholars consider the work by Fielder and his colleagues a classic contribution that inspired consideration of person and situational aspects in leadership.

### *Path-Goal Theory*

*Path-goal theory* was originally developed by Martin Evans in 1970 and expanded by Robert House in 1971 into a more complex contingency theory. Drawing on expectancy theory and the Ohio and Michigan leader behavior studies, House suggested that a leader should help elucidate the path for followers to achieve group goals. This involves the leader employing particular behaviors in specific situations to increase follower satisfaction and motivate efforts toward task accomplishment. The theory identifies four types of leader behavior that include supportive (relations oriented), directive (task oriented), achievement oriented, participative leader behavior, as well as two aspects of the situation, namely, follower characteristics and task characteristics.

In situations where the task is dull or taxing, the theory predicts that supportive leadership behaviors may increase followers' interest in task accomplishment and encourage followers' expectations of a successful outcome. In turn, this may motivate followers' efforts to achieve the task. In situations where the task is ambiguous or complicated, directive behaviors such as clarifying the task at hand and stressing rewards contingent on good performance could increase followers' positive expectancies. This may consequently motivate followers' efforts to achieve designated goals.

A large number of studies have examined postulates derived from path-goal theory. Overall,

these studies provide mixed support for the theory. Various scholars have argued that it may be premature to draw any firm conclusions regarding the validity of the theory because of methodological limitations associated with past research and sparse empirical attention to various variables outlined in the model. For example, little empirical research has investigated participative and achievement-oriented leadership styles. However, path-goal theory has made an important contribution in highlighting the potential influence of leaders on followers' motivation and performance. Moreover, it has informed the development of subsequent leadership theories, such as the *substitutes for leadership theory* by Steve Kerr and John Jermier and the *self-concept-based theory of charismatic leadership* by Boas Shamir, Robert House, and Michael Arthur.

### *Normative Decision Model*

Many contingency theories define leadership effectiveness in terms of group performance or team satisfaction. However, the normative decision model is a unique contingency theory in its exclusive focus on providing prescriptions to optimize the leader's decision-making process. The normative decision model, originally developed by Victor Vroom and Phillip Yetton in 1973 and later revised by Victor Vroom and Arthur Jago, emphasizes situational factors more than leadership behaviors. It outlines a set of five different decision-making strategies that range on a continuum from directive to participative decision making. These strategies include two types of autocratic styles (the leader decides alone), two types of consultative styles (the leader consults followers but decides alone), and a group decision-making option (group consensus).

The optimal strategy for decision-making situations may be reached by answering "yes" or "no" to seven questions on a decision tree that may or may not characterize the decision-making situation. Some examples of these situational considerations include the importance of decision quality, the likelihood that followers' would accept and implement the decision, and the amount of available information needed for the decision. The decision tree takes into account seven decision rules or heuristics that eliminate decision options that

would jeopardize decision quality or hinder decision acceptance. In this way, decision-strategy options are realized from a feasible set that purports to optimize effective decision making.

A number of field studies and experiments conducted in various countries provide support for the model. For instance, in 1988, Vroom and Jago reported accumulated evidence that decisions following the decision tree were almost twice as likely to be successful than decisions that did not use the prescriptions advocated by the model. Furthermore, leaders who make decisions following the decision tree tend to receive favorable ratings from subordinates. Despite solid empirical evidence validating the model, scholars have noted various limitations. For example, while acknowledging the utility of the model, Sternberg questioned whether leaders are able to accurately answer the questions posed by the decision tree (e.g., forecasting follower acceptance). Overall, the normative decision model contributes an understanding of decision-making processes that underscores the significance of the situation.

### *Situational Leadership Theory*

The situational leadership theory put forth by Paul Hersey and Ken Blanchard in 1969 proposes that leadership effectiveness depends on the leader's ability to tailor his or her behavior to the demands of the situation, namely, the subordinate's level of maturity. This theory builds on the earlier Ohio and Michigan studies and extends Blake and Mouton's work in emphasizing a combination of task and relation behaviors (but here task and relation behaviors are called directing and supporting). Hersey and Blanchard highlight four different types of leadership behavior based on combining directive and supportive behavior: telling (high directive, low support), selling (high directive, high supporting), participating (low directive, high supportive), and delegating (low directive, low supportive).

The leader's function is to continually evaluate and adapt his or her behavior to each follower's task maturity (i.e., ability) and psychological maturity (i.e., willingness) to complete the task at hand. For instance, when a follower has lower maturity, it prescribes that a leader should tell the follower how to get the job done. When a follower is more mature, he or she does not need as much

direction or significant support in accomplishing the task. In this case, it would be best to delegate the task to the follower.

Although intuitively appealing, the situational leadership theory has not received extensive research attention. Studies support the theory's postulate that low maturity followers benefit from directive behavior, but more empirical verification of the remaining postulates is warranted. The theory has been criticized for its narrow focus on only one situational variable, but it has contributed to the understanding of leadership effectiveness by underlining the need for leaders to adapt their behavior to different situations.

### Conclusion

Fred Fielder's seminal work helped to springboard the development of a series of notable contingency theories that account for both leader and situational variables. The complexity of contingency theories, however, has drawn criticism for a lack of parsimony. Furthermore, contingency theories have been viewed as a more mechanical approach that neglects considerations of instances of extraordinary leadership and group processes. Nevertheless, contingency theories of leadership remain an important contribution to the understanding of leadership effectiveness.

## COOPERATION AND COMPETITION

---

Group members are generally expected to cooperate with one another. In fact, groups exist precisely because their members cooperate to achieve shared goals. If this cooperation mutates into competition, groups often fall apart or suffer a schism. In contrast, groups as a whole are often expected to compete with one another. This competition can take the form of friendly rivalry (e.g., two baseball teams trying to win a game), but all too often it is hostile and destructive (e.g., two nations trying to obtain scarce resources). Clearly, then, *cooperation* and *competition* are fundamental aspects of the social psychology of groups.

### Defining Cooperation and Competition

Based on early research by the social psychologists Morton Deutsch and Muzafer Sherif, *cooperation* can be characterized as overt or verbal behavior that is intended to help another person achieve his or her goals at the same time as one achieves one's own goals. It is behavior aimed at “doing well together”—at maximizing outcomes for oneself and others. Cooperation is usually associated with a perception of “non-zero-sum” goal relations (achieving one's own goals helps others achieve their goals, and vice versa) and promotive interdependence (one's own behavior is affected by the behavior of others, and vice versa, in ways that advance both parties' goals).

*Competition* is overt or verbal behavior that is intended to hinder another person from achieving his or her goals at the same time as one achieves one's own goals. It is behavior aimed at “doing better than others”—at maximizing outcomes for oneself relative to others, that is, securing an advantage for oneself. Competition is usually associated with a perception of “zero-sum” goal relations (achieving one's own goals hinders others from achieving their goals, and vice versa) and competitive interdependence (one's own behavior is affected by the behavior of others, and vice versa, in ways that impede each other's goals).

Individualism is a third class of behaviors in which people act as though, in effect, others did not exist. It is behavior aimed at “doing well for oneself”—at maximizing one's own outcomes with no regard for others' outcomes. It is associated with a lack of perception of any goal relations and any interdependence. Individualism can sometimes look like cooperation and sometimes look like competition, but psychologically it is neither.

### Evolution and Genetics

The theme of cooperation and competition is prominent across a wide variety of disciplines, probably because it speaks to fundamental assumptions about human nature and the kinds of human society that are possible. The British political philosopher Thomas Hobbes in his classic 1651 book *Leviathan* promulgated a very pessimistic view of human nature in which competition ruled supreme. He proclaimed that the natural state of humankind is a “war of all against all” in which lives are “solitary, poor, nasty, brutish, and short.”

More recently, Darwin's theory of evolution, first published in 1859, set the stage for a scientific explanation for the primacy of human competitiveness. According to Darwin, life is all about gaining competitive advantage in promoting one's own genetic makeup. Indeed, in 1976, Richard Dawkins famously coined the term *selfish gene* to convey the biogenetic imperative responsible for the essential competitiveness and dog-eat-dog nature of human life.

Others, however, have argued that competition is not always adaptive. For example, it has been suggested that natural selection may operate at the group level, whereby individuals sacrifice their

own genetic makeup for the inclusive fitness of the group or the species to which they belong. According to this position, cooperation can be beneficial in promoting genetic fitness.

### Game Theory and Rational Choice

Biogenetic and evolutionary debates aside, social and behavioral scientists have generally assumed that humankind is rationally self-interested. This rational self-interest, in turn, is assumed to cause people to behave uncooperatively. However, accumulating evidence shows that people can be extraordinarily irrational and impetuous in the decisions they make about whether to compete or cooperate with others.

The classic research paradigm for studying cooperation and competition is the prisoner's dilemma and a variety of related "experimental games." The prisoner's dilemma is a "two-person, mixed-motive, non-zero-sum game." This means that two people are involved, they each experience a conflict between being motivated to cooperate and motivated to compete, and the outcome of their interaction can be that both parties gain or that both parties lose. In contrast, a zero-sum game is one in which one party's gain is always the other's loss.

The general set up is that you play a game with another participant in which you are confronted with a payoff matrix, usually representing monetary outcomes. One of four things can happen. If both you and your opponent are cooperative, then you both get a good payoff, but if you are cooperative and your opponent is competitive, then you do very badly and your opponent does very well. If you are competitive and your opponent is cooperative, then you do very well and your opponent does very badly, but if you are both competitive, then you both do disastrously. Literally thousands of studies have shown that players in this game tend to make competitive choices that lead to mutually disastrous outcomes, over and over again.

However, choices become more cooperative if the players are allowed to speak to one another—this opportunity is typically not available, as most experimental games are noninteractive. Players are also more cooperative when rules of fairness are made explicit or the game is construed as an investigation of human interaction or conflict resolution; otherwise players' default assumption is that

it is a competitive context in which one should be selfish and competitive.

There are also individual differences in the propensity to be cooperative or competitive. Some people (*prosocials*) are more inclined to make cooperative choices than are others (*individualists* and *competitors*), who are more likely to make generally more selfish choices. This variable of *social value orientation* is relevant to understanding cooperation in everyday life. Prosocials are more likely to be self-sacrificing in their close relationships, are more likely to help others, and are more likely to make donations to noble causes. Prosocials also tend to be older and have more siblings, especially sisters, than people who are more self-oriented. Some people also are simply more trusting of others—not surprisingly, because they believe that others are honest and cooperative, they themselves are more likely to be cooperative.

### Social Dilemmas

Of more direct relevance to the study of groups is research on group-level social dilemmas—such as the *commons dilemma* and *public goods dilemmas*. These dilemmas involve crises of trust in which individuals fail to behave cooperatively to benefit the collective because they do not trust other members of the collective to behave cooperatively. The commons dilemma describes a situation in which a resource can be sustained only if people who use the resource show restraint in using it. An example is fisheries—if people fished responsibly, the fishery would be sustained indefinitely and everyone would benefit, but if people selfishly overfish, the fish would disappear forever and everyone would suffer. A public goods dilemma describes a situation in which a resource can be sustained only if people who use the resource make a sufficient contribution to it. An example is public radio—if people who listen to public radio make a contribution, it thrives and benefits all users, but if people free ride by listening to public radio without contributing, it goes off the air and everyone suffers.

Research on social dilemmas finds that when self-interest is pitted against the collective good, the usual outcome is competition and resource destruction. The problem is exacerbated when different groups access a limited resource. International competition over limited resources such as rain

forests, whales, and wetlands tragically accelerates their disappearance.

Dilemmas are very difficult to resolve. Often, *structural solutions* are required to force people to cooperate, conserve, and behave unselfishly. Structural solutions include measures such as limiting the number of people accessing the resource, limiting the amount of the resource that people can take, facilitating free communication among those accessing the resource, and shifting the payoff to favor cooperation over competition. Structural solutions ultimately rest on being able to hand over management of the resource to a powerful authority to implement measures, manage the bureaucracy, and police violations. This can be difficult to achieve.

Two factors that have been shown to engender cooperation and resource preservation in social dilemmas are communication between group members and feelings of group identification. Communication can be effective for several reasons. For example, it can involve explicit promises of cooperation, allow group members to coordinate their actions, or promote feelings of group identification. Group identification, which can also be based on factors other than communication, has been shown to build mutual trust among group members—people tend to trust ingroup members and therefore are more likely to sacrifice self-interest for the greater good of their group. Leadership plays a critical role in this process because a leader can transform selfish individual goals into shared group goals by building a sense of common identity, shared fate, interindividual trust, and joint custodianship of the collective good.

### Interdependence and Realistic Conflict

In the early 1950s, Muzafer Sherif conducted a classic series of studies of cooperation and competition among individuals and groups—the boys' camp studies. These were naturalistic studies conducted at boys' summer camps, in which Sherif and his associates were able to set the boys' goals that required individuals to cooperate and goals that required groups to cooperate or to compete—the goals generally involved tangible resources, for example being able to show a movie at camp. His main findings from these studies were that the boys' perceptions of their goal relations to one

another determined whether they would compete or cooperate, and that the competitive/cooperative nature of the behavior determined the way in which individuals and groups more widely perceived and treated each other.

Sherif promoted an influential theory, *realistic conflict theory*, to explain the relationship between goals and individual and group behavior. It is called *realistic* conflict theory because Sherif focused on real tangible goals (e.g., money, land) rather than symbolic goals (e.g., status, prestige). He argued that individuals who share goals that require interdependence for their achievement cooperate and form a group, whereas individuals who have mutually exclusive goals (i.e., if one person achieves the goal the other does not) compete. Interindividual competition prevents group formation or contributes to the collapse of an existing group. At the intergroup level, mutually exclusive goals produce intergroup conflict and ethnocentrism, while shared goals requiring intergroup interdependence for their achievement (what Sherif termed *superordinate* goals) reduce conflict and encourage intergroup cooperation.

Other researchers have emphasized different aspects of realistic conflict theory. For example, Morton Deutsch focused in great technical detail on the nature of the goal relations rather than on cooperative/competitive behavior; Chester Insko, John Scholpler, and Jaap Rabbie and their colleagues focused on the role played by interdependence in producing cooperative group behavior and competitive intergroup behavior; and others focused on negotiation and bargaining and on the role of shared superordinate goals in resolving conflict and building social harmony.

### Minimal Groups and Social Identity

The role of shared goals, interdependence, and cooperative behavior in group formation and intergroup behavior was challenged by a famous series of laboratory experiments published in 1971 by Henri Tajfel and Mick Billig and their associates. Participants were placed in ad hoc groups ostensibly on the basis of a trivial criterion—there was no group interaction, membership was anonymous so no one knew who was in the group, and the group had no past and no future. All that the participants had to do was allocate points between an anonymous

ingroup member (not the self) and an anonymous outgroup member. The remarkable finding was that even such minimal groups produced competitive intergroup behavior in which participants favored their ingroup over the outgroup. Since this original study, thousands of minimal group studies have replicated the basic finding that social categorization alone can produce competitive behavior toward outgroup members and cooperative behavior toward ingroup members.

The results of the minimal group studies contributed to the development of *social identity theory*, which argues that people define and evaluate who they are in terms of the groups they belong to—in other words, they derive a social identity from the groups with which they are affiliated. Because the self and the group are psychologically “fused,” group evaluations (i.e., the group’s status and prestige in society) become self-evaluations. According to this analysis, then, intergroup relations are a competition over the scarce zero-sum resource of status. Hence, intergroup relations are marked by distrust and are intrinsically competitive. In contrast, intragroup relations are generally cooperative—members pull together in an atmosphere of mutual trust to cooperate to achieve group goals that secure a relative advantage for their group over other groups. Cooperation and competition are thus consequences of group membership; though they can act as cues to whether someone is a member of one’s own group or a member of a rival outgroup.

Subsequent work has suggested several complexities in intergroup and intragroup relations. Although intergroup relations are intrinsically competitive, the way that competition is expressed can vary as a function of people’s perceptions of the nature of the relations. For example, members of low-status groups who see little realistic possibility of social change tend to pursue creative and indirect forms of competition, such as choosing different dimensions of comparison with the dominant group or simply comparing themselves with other low-status groups, whereas those who sense the real possibility of social change are more likely to directly compete with the dominant group. Relatedly, members of dominant groups who feel secure in their high status often behave generously to lower status groups, whereas those who feel insecure often use their power in a harsh manner.

Although intragroup relations are generally cooperative, this is not always the case. Within groups, particularly those that are central to members’ identity, people are highly vigilant about what the group stands for and what its prototypical norms and practices are. In these cases, people continually assess how prototypical they and others are of the group, which leads to competition over actual and perceived prototypicality. This competition can be extremely fierce, leading to marginalization of competitors and suppression of dissent. It is not unusual for subgroups to form to promote their own image of the group that casts them as more prototypical than others—this can lead to schisms that destroy the group.

### Superordinate Goals and Social Harmony

As discussed above, Sherif believed that superordinate goals can reduce competition between groups and thus improve intergroup relations. Not surprisingly, substantial research has been conducted to explore this idea. Sherif’s argument was that if two groups recognize a shared and valued goal that cannot be achieved by unilateral action, then the goal structure is transformed from zero-sum to non-zero-sum. This transformation encourages cooperative interdependence and interaction between the groups, which in turn generates mutual goal satisfaction and hence favorable intergroup attitudes.

There are a number of potential limitations to this analysis, stemming from the social identity idea that groups define who members are and that members therefore have a vested interest in protecting and promoting the distinctiveness of their group and social identity. One problem with superordinate goals is that they may abolish competition only as long as the goal is in place—once the goal is satisfied, the groups fall back into their old ways. An example of this is the World War II strategic alliance between Britain, the United States, and the Soviet Union to defeat Germany and Japan. As soon as the common enemy was defeated, the superordinate goal was satisfied and mutually exclusive goals of global dominance generated 45 years of a highly competitive cold war between the Soviet Union and the West.

It is plausible that superordinate goals involving superordinate identities should produce a more

enduring transformation of competition into cooperation—after all, such goals should create a common ingroup and shared identity within which trust and cooperation should prevail. This is a nice idea, but it can backfire. One problem is that groups may disagree about the extent to which the superordinate identity reflects their attributes. For example, numerical minorities often feel that superordinate identities are being “imposed” on them and their own attributes are underrepresented in the identity. They therefore feel they do not really fit the superordinate identity—they are not prototypical of it and therefore do not belong. Another problem is that, because groups cherish the distinctiveness of their own identity, a superordinate identity can represent a profound identity threat. An example is the view held by some British people that membership in the European Union (EU) will destroy what is unique about British identity.

However, many researchers believe that a superordinate identity can transform intergroup competition into cooperation under certain conditions. They argue that, in order to be effective, a superordinate identity must have a balanced representation of each subgroup’s attributes, explicitly recognize and maintain the distinctiveness and integrity of each subgroup, and place value on each subgroup’s contribution to the superordinate identity. Overall, this set of conditions allows subgroups to see themselves as distinct and valued groups, with complementary roles, all working together toward shared goals.

### Negotiation

Cooperation is very important when two individuals or representatives of two groups are negotiating to reach an agreement. If both sides adopt a staunchly competitive orientation (according to Chester Insko and John Schopler’s discontinuity effect, this is more likely to be the case in intergroup than interpersonal encounters), the process of reaching an agreement can be very time consuming at best or a total failure at worst.

Intergroup negotiations are particularly difficult when the negotiators feel they are being observed by their groups. In such cases, they often feel that they need to be highly competitive to protect and promote their group and to signal their loyalty to it. One way to combat this competitive mind-set is

to conduct the negotiations in a setting away from public scrutiny and to have a mutually trusted third party act as mediator. A trusted mediator can encourage cooperation by reducing emotional heat, rectifying misperceptions, proposing novel non-zero-sum compromises, facilitating graceful retreats, and inhibiting unreasonable claims. For example, in the late 1970s, U.S. president Jimmy Carter sequestered Egypt’s president Anwar Sadat and Israel’s prime-minister Menachem Begin at Camp David near Washington, D.C., and acted as a mediator between the two men. After 13 days, an agreement was reached that ended a state of war that had existed between Israel and Egypt since 1948.

In the absence of mediation, groups that genuinely want to reach a solution have to take the initiative themselves. One effective strategy, first suggested in 1962 by Charles Osgood, is called *graduated and reciprocated initiatives in tension reduction* (GRIT). This strategy capitalizes on the universal human norm of reciprocity and is designed to build trust. One party announces its cooperative and conciliatory intent (allowing clear attribution of a nondevious motive), clearly specifies a small concession it is about to make (activates reciprocity norm), and invites its opponent to do likewise. The initiator then makes the concession exactly as announced and in a publicly verifiable manner. There is now strong pressure on the other party to reciprocate. In this way, the two parties slowly resolve their differences through reciprocal concessions.

### Conclusion

Cooperation and competition play critical roles in how people behave within and between groups. Within groups, people generally have a shared sense of self and a shared interest in promoting group welfare. Members trust each other and work cooperatively to achieve objectives that cannot be achieved alone. In contrast, relations between groups are often competitive. This competition can involve tangible resources, as emphasized by realistic conflict theory, or status and prestige, as emphasized by social identity theory.

One of the great challenges for society is to transform competitive intergroup relations into harmless rivalry or respectful and trust-based

cooperation in pursuit of shared goals and a shared sense of self. This is not easy to achieve, but can be accomplished under certain conditions. For example, respected authorities can help to resolve social dilemmas and facilitate intergroup negotiations. Superordinate goals can temporarily transform intergroup competition into cooperation and, under certain conditions, lay the groundwork for a more enduring change in intergroup perceptions and self-conceptions.

## COOPERATIVE LEARNING

---

*Cooperative learning* refers to instructional methods in which students work in small groups to help one another learn. There are many quite different approaches to cooperative learning, but in general, groups are composed of high, average, and low achievers and contain from two to four children.

Cooperative activities have been common for as long as education has existed, and research on cooperative learning goes back to the early days of the 20th century. However, development, research, and use of more formalized cooperative learning methods began in the 1970s, when various groups in the United States and Israel, in particular, initiated ambitious programs of research and development intended to create cooperative learning models that could be used in a broad range of elementary and secondary schools. In one form or another, cooperative learning has been used and studied in every major subject, with students from preschool to college, and in all types of schools. It is used at some level by hundreds of thousands of teachers. One national survey in the 1990s found that 79% of elementary teachers and 62% of middle school teachers reported regular use of cooperative learning.

There have been hundreds of studies of cooperative learning focusing on a wide variety of outcomes, including academic achievement in many subjects, second-language learning, attendance, behavior, intergroup relations, social cohesion, acceptance of classmates with handicaps, attitudes toward subjects, and more. This entry focuses primarily on research on achievement outcomes of cooperative learning in elementary

and secondary schools and on interpersonal and affective outcomes.

### Theoretical Perspectives on Cooperative Learning and Achievement

Although there is a general consensus among researchers about the positive effects of cooperative learning on student achievement, there remains a controversy about why and how cooperative learning methods affect achievement and, most importantly, under what conditions cooperative learning has these effects. Different groups of researchers investigating cooperative learning effects on achievement begin with different assumptions and explain the achievement effects of cooperative learning quite differently. The following sections review research on cooperative learning methods derived from the three most widely known of these perspectives.

#### *Motivational Perspectives*

Motivational perspectives on cooperative learning presume that task motivation is the most important part of the process. Other processes are believed to be driven by motivation. Therefore, these scholars focus primarily on the reward or goal structures under which students operate. From a motivationalist perspective, cooperative incentive structures create a situation in which the only way group members can attain their own personal goals is if the group is successful. Therefore, to meet their personal goals, group members must both help their groupmates to do whatever enables the group to succeed and encourage their groupmates to exert maximum efforts.

Not surprisingly, motivational theorists build group rewards into their cooperative learning methods. In methods developed at Johns Hopkins University, students can earn certificates or other recognition if their average team scores on quizzes or other individual assignments exceed a pre-established criterion. Methods developed at the University of Minnesota often give students grades based on group performance, which is defined in several different ways. The theoretical rationale for these group rewards is that if students value the success of the group, then they will encourage and help one another to achieve.

#### **Empirical Support for the Motivational Perspective**

Considerable evidence from practical applications of cooperative learning in elementary and secondary schools supports the motivational position that group rewards are essential to the effectiveness of cooperative learning, with one critical qualification. Use of group goals or group rewards enhances the achievement outcomes of cooperative learning if, and only if, the group rewards are based on the individual learning of all group members. Most often, this means that team scores are computed based on average scores on quizzes that all teammates take individually, without teammate help.

For example, in Student Teams-Achievement Divisions, or STAD, students work in mixed-ability teams to master material initially presented by the teacher. Following this, students take individual quizzes on the material, and the teams may earn certificates based on the degree to which team members have improved over their own past records. The only way the team can succeed is to ensure that all team members have learned, so the team members' activities focus on explaining concepts to one another, helping one another practice, and encouraging one another to achieve. In contrast, if group rewards are given based on a single group product (for example, the team completes one worksheet or solves one problem), there is little incentive for group members to explain concepts to one another, and one or two group members may do all the work.

A review of 99 studies of cooperative learning in elementary and secondary schools involved durations of at least 4 weeks and compared achievement gains in cooperative learning and control groups. Among the 64 studies of cooperative learning methods that provided group rewards based on the sum of group members' individual learning, 50 (78%) found significantly positive effects on achievement, and none found negative effects. The median effect size (a way of measuring the strength of an effect) among the studies for which effect sizes could be computed was +.32 (32% of a standard deviation separated cooperative learning and control treatments). In contrast, among the studies of methods that used group goals based on a single group product or provided no group rewards, the median effect size

was only +.07. Comparisons of alternative treatments within the same studies found similar patterns; group goals based on the sum of individual learning performances were necessary to the instructional effectiveness of cooperative learning models.

### *Social Cohesion Perspective*

A theoretical perspective somewhat related to the motivational viewpoint holds that the effects of cooperative learning on achievement are mediated by the cohesiveness of the group. The quality of the group's interactions is thought to be largely determined by group cohesion. In essence, students will engage in the task and help one another learn because they identify with the group and want one another to succeed. A hallmark of the social cohesion perspective is an emphasis on team-building activities in preparation for cooperative learning and self-evaluation during and after group activities. Social cohesion theorists have historically tended to downplay or reject the group incentives and individual accountability that motivational researchers believe are essential.

In social cohesion methods, students generally take on individual roles within the group. In the *jigsaw puzzle* technique, students study material on one of four to six topics distributed to the group members. They meet in "expert groups" to share information on their topics with members of other teams who have the same topic, and then each student presents the topic to his or her own team (in which the members each hold a piece of the puzzle). In *group investigation*, groups take on topics within a unit studied by the class as a whole, and then further subdivide the topic into tasks within the group. The students investigate the topic together and ultimately present their findings to the class as a whole.

#### **Empirical Support for the Social Cohesion Perspective**

The achievement outcomes of cooperative learning methods that emphasize task specialization are mixed. Research on the original form of the jigsaw puzzle method has not generally found positive effects of this method on student achievement. In contrast, there is evidence that when it is well implemented, group investigation can significantly increase student achievement.

### *Cognitive Elaboration Perspective*

Research in cognitive psychology has long held that if information is to be retained in memory and related to information already in memory, the learner must engage in some sort of cognitive restructuring, or elaboration, of the material. One of the most effective means of elaboration is explaining the material to someone else. Cognitive elaboration theorists explain the effectiveness of cooperative learning in terms of the effects of explanation itself, rather than motivation or social cohesion.

#### **Empirical Evidence for the Cognitive Elaboration Perspective**

Numerous studies have found that students working on structured "cooperative scripts" can learn technical material or procedures far better than can students working alone. Although both the "recaller" or explainer and the listener learned more than did students working alone, the recaller learned more. Thus the students who gained the most from cooperative activities were those who provided elaborated explanations to others. Students who received elaborated explanations learned more than those who worked alone, but not as much as those who served as explainers.

### *Reconciling the Three Perspectives*

Although the three perspectives on cooperative learning seem quite diverse, there are both theoretical and empirical reasons to expect that methods incorporating multiple perspectives have particular promise. For example, provision of group goals based on the individual learning of all group members might affect cognitive processes directly by motivating students to engage in peer modeling, cognitive elaboration, and/or practice with one another. Group goals may also lead to group cohesiveness, increasing caring and concern among group members and making them feel responsible for one another's achievement, thereby motivating students to engage in cognitive processes which enhance learning.

### **Outcomes**

Numerous outcomes of cooperative learning beyond achievement have been studied in elementary and

secondary schools. One of the most widely studied is intergroup relations. Studies of cooperative learning methods of many types find that students who have worked in groups with peers of different ethnicities are more likely to make friends who are different from themselves, and to have positive attitudes toward students of other ethnicities.

Beyond intergroup relations, studies have found positive effects of cooperative learning on such outcomes as self-esteem, acceptance of mainstreamed students, attitudes toward school, and attitudes toward the subject being studied in groups.

### The Future of Cooperative Learning

More than 35 years after cooperative learning research began in earnest, cooperative learning remains strong in both research and practice. Cooperative learning is a component of comprehensive school reforms, curriculum and instructional reforms, and programs to improve intergroup relations. More research and further development is still likely to be fruitful, but cooperative learning has as good a record of research and research-informed practice as any approach in the history of education.

## CROSS-CATEGORIZATION

---

Categorization of people into “us” and “them” is a fundamental characteristic of how we perceive social groups. Sometimes, however, this simple dichotomization is not enough to fully capture the complexity of intergroup relations. Cross-categorization takes account of this complexity. *Cross-categorization* (or *crossed categorization*) describes intergroup contexts defined by not one but two dimensions of social categorization. Take, for example, age and race. Instead of comparing oneself with others just according to age (“I’m young, and they are old”) or just in terms of race (“I am White, and they are Black”), in cross-categorization contexts, both of these dimensions are salient and meaningful. In these situations, four possible social category combinations are each defined by two constituents: young and White, young and Black, old and White, old and Black.

This introduces greater complexity into the perceived intergroup relations. Social comparison can no longer simply refer to “us” (the *ingroup*) versus “them” (the *outgroup*), but others are defined in terms of two shared memberships (a *double ingroup*), two nonshared memberships (a *double outgroup*), or a mixture of shared and nonshared memberships (a *mixed membership group*). Cross-categorization is important for the study of group processes and intergroup relations in two key ways. First, it has given researchers greater power in describing, explaining, and improving intergroup relations in more complex categorization contexts. Second, it has proved effective as a way of encouraging less reliance on negative stereotypes

when forming impressions of others. Both of these approaches are described in this entry.

### Modeling Complex Intergroup Relations

With respect to its provision of a richer model for describing intergroup relations, cross-categorization has enabled a greater understanding of the dynamics of prejudice and discrimination for people socially excluded on multiple criteria. Perceiving multiple identities can create convergent bases for discrimination: multiple differences that reinforce existing boundaries. For instance, a White man may feel not quite so different from a White woman but may feel considerably more different from a Black woman, when gender is salient alongside race (creating a double outgroup). Here the salience of an additional categorization has reinforced the differences described by the initial dichotomy. Converging category differences are a problem because they reinforce discrimination experienced by individuals who are already excluded on one criterion. They also characterize many instances of ethnopolitical conflict. For example, in Belfast, Northern Ireland, Catholics and Protestants tend to live in different places (e.g., Ardoyne vs. Shankhill Road), espouse different politics (Nationalist-Republican vs. Unionist-Loyalist), and even support different football teams (e.g., Cliftonville vs. Linfield); part of the problem is precisely that there are few social categories cross-cutting the religion dimension.

To capture the sort of complex intergroup relations outlined above, research has identified different patterns of evaluation across the four combined groups formed from crossing categorizations. The patterns can be represented by notation referring to the relative composition of ingroup and outgroup identities (labeled “i” and “o,” respectively). For instance, the *additive pattern* specifies that double ingroups (ii) are evaluated more positively than double outgroups (oo), with mixed membership groups (io and oi) evaluated in between these two extremes ( $ii > io = oi > oo$ ).

The patterns are important because they specify the impact of shifting attention away from converging categorizations that reinforce social divides (e.g., Republican/Catholic vs. Loyalist/Protestant) to dual-identity categorizations that emphasize a common ingroup (e.g., Young-Catholic and

Young-Protestant). Put another way, in contexts defined by converging categorizations (such as religion and politics in Northern Ireland), encouraging perceivers to focus on shared ingroup identities (mixed membership groups), instead of converging differences (double outgroups) can improve intergroup relations. This is because typically, evaluations of mixed membership groups (io or oi) are more positive than evaluations of double outgroups (oo).

There are also certain conditions that can orient perceivers to focus on these mixed membership groups, further increasing their value for improving intergroup relations. A positive mood or encouraging a focus on ingroup identities leads to a *social inclusion pattern* ( $ii = io = oi > oo$ ). This pattern is beneficial because evaluations of mixed membership groups (io or oi) become as positive as they are for total ingroup members (ii). In contrast, negative affect or encouraging a focus on outgroup identities leads to a *social exclusion pattern* ( $ii > io = oi = oo$ ). The social exclusion pattern is to be discouraged because evaluations of mixed membership groups (io or oi) become as negative as evaluations of people defined as double outgroupers (oo).

This research shows us that if we want to tackle bias along converging divisions by emphasizing shared identities (mixed membership groups), then this will be most effective under conditions that orient the perceiver to shared identities (such as a positive mood). It will be less effective when outgroup memberships are emphasized (such as when perceivers are in a negative mood). Where converging identities define conflict, building cross-cutting ties that create mixed membership groups may be an important way to foster more harmonious intergroup relations. Furthermore, mixed membership groups have the additional advantage of emphasizing both shared and nonshared identities simultaneously. This is important because placing too much emphasis only on what conflicting groups have in common (and not what makes them unique) can backfire, eliciting even greater bias. Mixed membership groups strike the important balance between inclusion and distinctiveness.

### Countering Negative Stereotypes

As well as describing complex intergroup relations, and outlining the optimal conditions needed to

promote tolerance and inclusion within these contexts (i.e., focusing on mixed membership groups), cross-categorization also provides a means for more personalized interventions designed to encourage less bias in impression formation. This second line of research examines the impact of exposure to multiple identities on the cognitive style adopted by individuals when forming impressions of others. The idea here is that considering cross-cutting ties can reduce prejudice because rather than applying a negative stereotype to someone just because he or she is a member of a stigmatized group, people come to appreciate that social categories are fluid, flexible, and dynamic and that there are many different (and positive) ways in which any one person can be described. As such, the impact of any one negatively valued identity is reduced.

For cross-categorization to promote a cognitive style less reliant on stereotypic expectations, the perceived categories must form combinations that tend *not to go together* (that is, are surprising or nonoverlapping). Research has shown that encouraging people to form impressions of crossed category groups that tend to go against expectations (e.g., “woman mechanic,” “gay soldier”) leads to a lesser reliance on stereotypes. To achieve this outcome, however, the category dimensions involved must be related (e.g., gender and occupation: most mechanics are men, most soldiers are heterosexual) because it is only under these conditions that perceivers will be surprised by counterstereotypical combinations (and prompted to engage in more systematic thought to resolve the inconsistency with expectations). These processes are not elicited when categories are uncorrelated (e.g., race and gender). One is not, for instance, surprised to meet a Black man or Black woman.

Research has found that participants asked to form an impression of surprising combinations, such as “woman mechanic” and “male nurse,” used stereotypes of the constituent categories less to describe the target than to describe new or emergent (nonstereotypic) attributes. Emergent attributes are typical of neither constituent category and are produced following a mental resolution of the incongruent information. They indicate a cognitive redefinition of the target person that no longer relies on stereotypic expectations.

The less stereotypic approach to impression formation evoked by thinking about crossed

categorizations offers a potentially useful tool for encouraging more flexible approaches to impression formation. Developmental research offers some support for the idea that the model could be usefully applied to education. For instance, primary school children can be taught to classify along multiple dimensions using pictures of men and women engaging in stereotypically feminine occupations (e.g., hair stylist, secretary) and stereotypically masculine occupations (e.g., construction worker, truck driver). Exposure to these correlated categorizations (and the counterstereotypic combinations the children can be encouraged to generate) can lead to significant reductions in gender stereotyping.

In sum, cross-categorization research has been valuable in two important ways. First, it has offered an experimental paradigm that is attuned to the complexity of contemporary intergroup relations. It has helped us understand the dynamics of prejudice and exclusion when people are members of two stigmatized groups, and the conditions that encourage a focus on what people have in common, as well as what makes them different. Second, it has offered a means of encouraging more flexible approaches to impression formation. When perceivers are exposed to crossed categorizations that challenge stereotypic expectations, this can elicit changes in the way people form impressions, reducing reliance on single, divisive categories and encouraging a more complex, differentiated and tolerant view of others.

## CROWDING

---

*Crowding* can be characterized as the experience of stress due to exposure to too many people in too little space. One constant since the great plagues has been a continual increase in population. The urbanization of civilization has exacerbated dense population growth, and the population of our planet is now close to 7 billion, increasing at a rate of 1% a year. These trends have contributed to conditions of crowding in some countries and cities. Researchers have explored the many factors that influence crowding and how the harmful effects of this experience can be reduced.

Studies have examined the various spatial and social factors that influence the experience of crowding. Any time groups come together, they vary in size and spatial arrangement. These two factors can influence a wide range of social and task behaviors in groups. The literature on crowding involves extensive studies with both humans and nonhuman animals in laboratory settings and real-world contexts. This research has led to the development of a variety of models for understanding the effects of crowding.

Crowding is generally defined as a negative experience related to high levels of physical density (a large number of people per unit of space). Density can be increased by adding people, decreasing space, or both. The type of density most closely related to popular understanding of crowding is *social density*, the number of people in a given space or area. Pure social density variations involve increases in the size of the group while the space is constant. In contrast, *spatial density* involves variation in the area allotted

to a specific group. Density can vary for spaces within a particular building or home (inside density) and for spaces outside (outside density, such as a city's population). Effects of density depend on the type of density involved and the type of measures obtained.

### Research Approaches

There have been many approaches to studying the effects of crowding. Some studies with humans and animals have explored the effects of natural variations in density. Animal studies have examined the effects of group or herd size on social behavior and mortality. Studies with humans have examined how the degree of crowding in different areas of cities relates to these same types of measures. These naturalistic studies are essentially correlational, which means that they examine the relationship between variables without any certainty as to what causes what. A crowded neighborhood could have a higher mortality rate because of crowding, but this also could be because it also has more pollution, noise, and a lower economic status or because it draws people in need of close access to medical services. Experimental studies can provide more conclusive data on the extent to which a crowding variable causes certain effects. Investigators can manipulate different types of density in both laboratory and field settings and determine the extent to which these variations of density affect various measures of performance, behavior, or well-being.

### Density and Animals

Research with animals has been able to investigate links between density and negative outcomes in naturalistic settings. Early study of the growth of a herd of deer marooned on an island in Chesapeake Bay found evidence of stress, social deterioration, and death as density in the herd grew. Studies of mice and rats allowed to reproduce and "overpopulate" their environments found severe negative effects of density in these animal colonies. Several studies housed animals in environments where they were forced to share needed resources with large numbers of other animals. In most of these studies, colonies continued to grow over time until they peaked and the population

declined. Along the way, various types of social pathology emerged and characterized the colony's decline.

These studies found effects of increasing density that may well be more severe than those found in humans. This may be because humans possess more sophisticated ways to deal with the demands posed by crowding. Thus studies of animal density are best used as a platform for the development and evaluation of hypotheses that should be studied in humans.

### *Density and Humans*

Since humans experience density both in short-term situations (as in a subway car) and in long-term situations (e.g., crowded college dormitories), studies have examined density in both. For example, several laboratory studies have evaluated the effects of short-term variations in density on task performance. Increasing either social or spatial density has detrimental effects on task performance, especially if the task is relatively complex.

Density and crowding also seem to have emotional and physiological consequences. High levels are often associated with negative feelings, especially for males with insufficient space. Density has been associated with elevated blood pressure, skin conductance, and levels of stress hormones such as cortisol or epinephrine. These measures suggest that crowding may induce responses related to stress. Thus, extended exposure to the stressful conditions of crowding may affect health. Crowding in prisons has been associated with elevated illness rates and mortality. Illness-related effects have also been observed for those living in other crowded environments, such as college dormitories and naval vessels.

Since crowding is often experienced as unpleasant, it is not surprising that it may lead individuals to become less sociable. Crowded individuals may avoid eye contact, sit farther apart in public spaces, and reduce the frequency of interacting with others. Unfortunately, this tendency to avoid social contact interferes with the ability to seek out social support from others in times of need or, in turn, to provide such social support. This type of support is a critical factor in our ability to cope with stress. The lack of such support systems make us more vulnerable to the negative effects of stress. Another

negative effect of crowding on social behavior is increased aggressiveness.

### **Models of Crowding**

The effects of crowding can most simply be understood from the perspective of environmental stress. Environmental events that threaten harm or challenge one's resources are considered stressors. Lazarus and Folkman and others have proposed that how one perceives or appraises stressful events and how one deals or copes with them are critical determinants of the effects of stressors. Many negative effects of crowding follow from having to deal with unwanted interactions or spatial intrusions. When there are too many people or too little space, these problems increase. The arousal produced by such stress can be related to poorer performance on complex tasks and changes in physiological functions. Long-term exposure to such stress may lead to illness or even death.

The psychological model of stress suggests that effective coping responses may reduce the impact of stressors. The reduction in sociability or social withdrawal observed under crowded conditions can be seen as a means of coping with crowding. However, there is little systematic research on different coping strategies and crowding. For example, men have been found to cope with dormitory crowding by avoiding spending time in their rooms, whereas females may do the opposite, spending more time in crowded dorm rooms and getting more involved with roommates. However, the avoidance strategy used by males could backfire if it undermines the social support system that they need to confront a variety of life stressors other than crowding.

Research on crowding and other environmental stressors has found that perceived control is an important factor in understanding the causes and consequences of stress. Most crowding phenomena can be understood from this perspective. When environmental conditions produce a sense of loss of control, negative effects on health and behavior are likely to result. This loss of control can be caused by feelings of too much stimulation or overload, the experience of more interaction than desired, or feelings of constraint or interference if one is unable to attain one's goals (e.g., privacy, getting to work on time).

Repeated experiences of such loss of control can produce a degree of passivity or learned helplessness in which individuals do not actively assert their options or freedoms (e.g., social withdrawal). Even when people do not become passive or helpless, they may withdraw from other people as a way of regaining control over social interactions. In crowded dormitories where residents reported many unwanted and/or uncontrollable social contacts, coping behavior included reduced sociability and withdrawal and persisted outside the dormitory. The control perspective suggests that if individuals can attain some sense of control in a crowded environment, the negative impact of the crowding experience can be reduced. Studies have shown that if individuals are given some degree of control over their exposure to crowding (e.g., they are allowed to leave the situation any time they wish), the effects of crowding are reduced.

Other research on dormitories and prison housing also supports a control perspective. Paulus and his colleagues found that the number of individuals in a housing unit (social density) rather than the amount of space per person (spatial density) was the most important factor in the effects of crowded housing. Large open dorms with many inmates but considerable space were related to more illness than double rooms with less space per person. Some of this effect may have been due to enhanced contagion, but stress hormones have also been linked to crowding-related health problems. Similarly, architectural designs that varied in the number of people sharing resources in college dormitories (e.g., lounges, bathrooms, hallways) also varied in perceived crowding and social behavior. Hence, high social density seems more likely than high spatial density to lead to social interference and negative interactions.

### Practical Implications

If we assume that the population on the planet will continue to grow, what can we do to reduce the detrimental effects of crowding? The importance of appraisal and coping suggests several strategies. One possibility is to modify people's perception of crowding. If individuals are forewarned about the effects of crowding, they might be able to develop better psychological and behavioral coping strategies to deal with crowding. People can alter their

commuting time, reduce time spent in a crowded room, or develop ways to navigate a crowded store. One interesting issue is whether we eventually habituate and adapt to the experience of crowding, thus reducing its negative effects.

There is some evidence for this type of adaptation effect, but other evidence that exposure to crowding can actually increase one's sensitivity to crowding. Which effect occurs may depend on personal characteristics such as ability to screen out external stimulation, coping style, and the nature of the experiences encountered in crowded conditions (e.g., supportive versus antagonistic). Of course, one way of adapting is to avoid crowding by using the behavioral strategy of social withdrawal. The lack of friendliness and social isolation evident in many crowded cities may reflect this. Although such withdrawal may help an individual to cope, it may ultimately not be beneficial to have many people socially uninvolved or distant in their relationship with one another.

A number of studies have also provided evidence that certain architectural modifications can reduce the impact of crowding. For example, in prison dormitories with open sleeping areas, partitions between beds reduce negative effects. Similar positive effects of partitions can also be observed in office environments. Other architectural features, such as elevated ceilings, more windows, and access to doors, have reduced feelings of crowding. The beneficial effects of such architectural interventions may derive their effects on feelings of control. Adding partitions in a dorm can allow residents to limit and control interactions more effectively. In one study, dividing a long corridor dormitory in half reduced the effects of crowding; a suite design in dormitories that allowed for more effective control of interactions (compared to corridor-style dorms with double rooms) was also associated with less crowding.

## CROWDS

---

Crowd events exemplify the complex two-sided relationship between the individual and social reality. On the one hand, crowd action reflects the structure and culture of the society within which it occurs. On the other hand, crowd action reflects back on society, serving to shape and reshape the world in which we live. In sum, the crowd encapsulates the core paradox of human action: the fact that we both determine and are determined by the social world. It follows that an adequate understanding of crowd psychology will provide general insights into the nature of human sociality.

Yet, both within the academic discipline of psychology and beyond, crowds are seen as asocial and irrational, an aberration from the normal workings of society rather than a reflection of them. This desocialized view did not arise despite the social nature of crowd action, but precisely because of it. Modern crowd psychology arose as part of the response to European industrialization and the rise of a society in which the laboring masses were separated both physically and socially from the ruling elites. In this context, the dominant classes harbored acute fears that the masses would rise up to challenge the social order. These fears coalesced around the figure of the crowd, seen as the masses in action.

Both mass society theories in general, and crowd psychology theories in particular, reflected the ideological perspective of elite progenitors. This perspective, rather than acknowledging that the various forms of mass movement—syndicalism, socialism, anarchism—reflected alternative visions of the social order, held that mass movement was a threat to the very possibility of social order. Mass movements were not based on radical

ideas but on a lack of ideas, in this view; masses and crowds were quite simply mindless. This perspective was exemplified in the work of the most influential of all crowd psychologists, Gustave Le Bon. This entry begins with a look at his classic crowd theory, then turns to more recent theories of crowds, crowd dynamics, and social change.

### Classic Crowd Theory

According to Le Bon, when people become anonymous within a crowd—a process he called “submergence”—they lose their sense of individual self but, in being part of the mass, gain a sense of invincible power. Having lost their selfhood, and hence their ability to think and judge, people become subject to “contagion.” This refers to the notion that ideas, and more particularly emotions, spread automatically and rapidly among crowd members. Sometimes these emotions arise haphazardly, Le Bon said, but more generally they are generated through “suggestion.” That is, Le Bon argued that the loss of selfhood among crowd members is accompanied by reversion to a collective (or “racial”) unconscious—hence, the tag *group mind theory*, which is often given to this approach. The racial unconscious generates the impulses that govern action. Because the racial unconscious is held to be atavistic, the defining characteristics of crowd action are considered to be equally primitive.

Crowds, according to Le Bon, are powerful only for destruction. People, he claimed, descend several rungs on the ladder of civilization by virtue of joining crowds. Or, to cite a passage that reveals as much about Le Bon’s politics as his science: “Many special characteristics of crowds, such as their impulsivity, irritability, incapacity to reason, the absence of judgement and of the critical faculty, the exaggeration of emotions, and others besides, can equally be seen amongst inferior forms of evolution such as savages and children” (1895/1947, pp. 35–36).

Le Bon’s ideas have been translated into modern social psychology through the notion of deindividuation. While there are a variety of deindividuation approaches, they share in common the notion that immersion in a group leads to a loss of normal judgment and control over behavior. They can be seen as retaining the negative half

of the concept of submergence—the notion of loss of selfhood, while discarding the positive half—the notion that people gain a sense of power.

Despite its longevity, the group mind tradition was challenged virtually from its inception. Floyd Allport dismissed the notion of a consciousness separate from the minds of individuals as a meaningless abstraction, and he insisted that the individual in the crowd behaves just as he or she would behave alone, only more so. Allport initiated an individualist tradition that sought to explain social behavior in general, and crowd behavior in particular, in terms of the characteristics of the actors. If crowds were violent, it reflected the violent nature of their members. Ironically, this is at odds with Allport's own account of crowd conflict. He argued that the distinctive response profiles that normally govern our individual behavior break down under the arousal of crowd conditions. Instead, a shared instinctual substrate dominates behavior—particularly the urge to destroy whatever stands in the way of satisfying our basic needs.

Behind the apparent opposition between Le Bon and Allport (or, more accurately, the individualist tradition), they share certain key assumptions. First, both assume that the individual self is the sole basis of reasoned judgment and behavioral control. The difference is that group mind approaches see this self as obliterated in the crowd, while individualist approaches see it as accentuated. Second, both traditions see crowd conduct, and specifically, crowd violence, as pathological. However, while group mind theories locate pathology in generic crowd processes, individualist theories characterize individual crowd members as generically pathological. Third, the two approaches explain conduct by processes internal to the crowd and hence ignore the role of social context.

These commonalities are interlinked. That is, if the psychic structure that ensures control over action (i.e., the individual self) is conceptualized in asocial terms, it becomes impossible to understand the social basis of behavioral control. Consequently, both classic traditions of crowd psychology are unable to explain the socially meaningful pattern of crowd action. As many studies have shown, far from being randomly destructive, the nature of collective action and the

targets of crowd violence faithfully reflect the social belief systems of participants.

### Normative Theories of the Crowd

In the 1960s and 1970s, a new wave of collective unrest struck the Western world. This time, however, the demographics of academia were far different from those at the start of the century, and many theorists related to crowd as participants rather than the targets of action. As a result, they were far more attuned to the perspectives of crowd members and the meanings of their action. This gave rise to a variety of models that stressed the normative processes governing crowd behavior.

Ralph Turner and Lewis Killian's emergent norm theory (ENT) examined how crowd norms emerge out of the intense interactions that occur during events. ENT suggests that the homogeneity of crowds is largely an illusion. Rather, as people mill around, prominent individuals (or "keynoters") will seek to define the reality of the situation and propose specific forms of action. Over a period, certain voices will become predominant and hence norms will emerge that may temporarily shape coordinated crowd action. The strength of this approach lies in its close analysis of the microsocial interactions through which shared understandings are formed during events. Its weakness lies in its inability to specify which voices get heard or how the local norms developed within the crowds relate to broader belief systems. ENT may explain the patterning of crowd action, but it does not explain how this patterning comes to be socially meaningful.

Stephen Reicher's social identity model of crowd behavior addresses precisely this point. As the name suggests, this model is based on the social identity tradition in social psychology and, more particularly, on self-categorization theory (SCT). The core ideas here are (a) that the shift from interpersonal to intergroup behavior is underpinned by a psychological shift from personal identity to social identity, and (b) that when any given social identity is salient, we act in terms of the beliefs, values, and norms associated with the relevant category (what it means to be British, a Catholic, a feminist, or whatever). To put it slightly differently, social identifications are both irreducibly social, in the sense that they are historical and cultural products, and

profoundly personal, in the sense that they define who we are and what we count as significant. They therefore provide a psychological process that links the individual to society and explains how the behavior of individual group members is governed by social meanings.

Whereas these processes apply to groups in general, there are two distinctive features of crowds as a particular type of group, both of which have implications for the normative process. First, crowds are face-to-face groups that typically confront ambiguous or novel social situations. Consequently, crowd members are not able to rely on predefined norms that prescribe exactly how they should act. Rather, as ENT suggests, they have to elaborate situationally appropriate norms. However, unlike ENT, SIM proposes that they do so within limits set by their social identity. Thus, situational norms are more likely to be accepted to the extent that they are seen as consonant with the broad category definition. Pacifists confronted by the police may choose from a number of actions: a sit-down protest, a silent vigil, singing songs of protest. However, they are unlikely to throw stones or initiate physical conflict.

How, then, do crowd members translate the general parameters of social identity into specific local norms? It can be done through discussion, although the fast-moving pace of crowd events frequently makes this impossible. Often, then, norms will be inferred from the actions of typical group members, but only as long as those actions are seen as broadly consistent with category norms. This is the so-called inductive aspect of categorization.

The second distinctive aspect of the crowd has to do with the issue of power—which, as discussed, was stressed by Le Bon but then forgotten by his successors. In everyday life, people are often unable to act on those aspects of their social identity that would be repressed by powerful outgroups such as the police. However, when gathered together in the crowd, members have sufficient support to overcome such repression. The important thing is that people will not do just anything with their power. They will do only those things deemed proper in terms of their category beliefs. By the same token, people can fully express only their social identities in crowds. Far from crowd power being associated with inchoate action, as

Le Bon proposed, it allows a uniquely privileged insight into the collective beliefs of social groups. As the French historian Henri Lefebvre has argued, it is only in crowds that people escape their everyday concerns and become the subjects of history.

### Crowd Dynamics and Social Change

The social identity model may be able to explain how crowd action reflects existing social belief systems. However, there is the danger that such a one-sided emphasis on how society shapes crowds leads to a neglect of how crowds shape society. The elaborated social identity model of crowd behavior (ESIM) aims to provide a more two-sided perspective.

ESIM starts by noting that the original social identity model only partially recontextualizes crowd action. Thus it might relate crowds to broader social categories, however, in common with other crowd models, it largely ignores the immediate interactional context of crowd action. That is, crowd events typically involve interchanges between crowd members and another group, typically the police or other authorities. Yet the spotlight tends to rest on the crowd alone, and the explanatory focus tends to be on factors internal to the crowd, such as the group's mind, personality, or social identity. A more dynamic approach begins by examining crowd processes—and, more specifically, social identity processes—within the unfolding interplay between the parties to an event. That is, it must be both historical and interactive.

In order to understand when change will (or will not) occur, ESIM involves another step. That step involves re-envisioning the concept of social identity as people's model of where they stand in a system of social relations and the actions that are proper or possible within that position. It follows that, when people enter into a crowd event on the basis of one social position but are repositioned through crowd interactions, their identities will be changed through the experience. This will happen when two conditions are fulfilled: (1) an asymmetry between the way in which the (police) outgroup construes the social position of crowd members and the way crowd members construe their own position and (2) the (police) outgroup has sufficient power to impose their version of reality upon the situation.

Characteristically, in these events, a majority of crowd members see themselves as liberal subjects who are claiming the right to protest, but who consider their relationship to the police and the state as positive. However, the police see them as oppositional and dangerous. Moreover, the police translate this perception into the concrete reality of cordons, lines of police horses, and even charges to disperse the crowd. The experience of being positioned as the opposition and of being deprived of what they believe to be their rights leads these crowd members to reconceptualize themselves as oppositional, and hence to pay more heed to oppositional forces within the crowd. Such a change of identity alters their sense of what forms of action are appropriate in this newly understood world. Notably, this change legitimates the conflict against police and thereby leads to an escalation of violence among crowd members.

However, this is not the only transformation that occurs. Crowd members also change their sense of how they relate to other groups in society—notably, other oppositional groups that previously were seen as outgroups come to be seen as part of a broader ingroup. They change their feelings of efficacy and their expectations of support from others, their commitment to future action, even their sense of what their action is about and of what counts as success. Often, the act of protest and of revealing the partial nature of the state and its authorities becomes an end in itself. In short, crowd processes can serve to reconfigure the balance of forces in society.

Note that ESIM does not suggest that crowd action always leads to radicalization. It is equally possible that where people consider themselves oppositional but are treated positively by the police and authorities (i.e., perceive that their rights are being protected and facilitated rather than denied), this asymmetry will lead to a process of deradicalization and de-escalation of conflict. More generally, however, the conditions for any sort of change (asymmetries of representation and power) are relatively rare. More often, outsiders share the self-understandings of participants and act in ways that consolidate rather than destabilize identities. In this way, ritualized crowd events such as official ceremonies mourning the deaths of monarch and political leaders may serve a critical role in preserving existing social relations. Overall,

ESIM is not a narrow model of those few crowd events that transform society. Rather, it is a more general model of how identity can simultaneously shape and be shaped by collective action.

### Broadening the Relevance of Crowd Psychology

Thus far, crowd research has concentrated on the way in which participants' experience of events affects them. However, there are two senses in which the relevance of crowds for society is considerably wider: (1) crowd members identify themselves as members of larger social categories and (2) members of the wider community may perceive the crowd as representing them. Especially with categories so large it is inconceivable that everybody could ever get together (nation, religion, "race," etc.), crowds are the "imagined community" made manifest. The fate of the crowd therefore affects category members in general. This is particularly true where events reflect on the relationship between the ingroup and a relevant outgroup. Thus, for instance, the American civil rights demonstrations and urban riots of the 1960s and 1970s were critical for redefining Black identity and reframing overall race relations—and the same could be said for the British urban riots of the 1980s.

Second, although ESIM has been developed to analyze the immediate interactions between parties in crowd events, the logic of ESIM, notably its insistence on a historical and interactive analysis of group processes, can equally be applied to more mundane group phenomena. Thus, instead of treating identity as a contextual given that determines group behavior, it becomes necessary to examine how ingroup identity—or, more precisely, the balance of influence between more or less radical voices in the group in terms of defining the collective position—is framed by the nature of intergroup relations.

In sum, crowds play a critical role in forming the social identities through which people relate to each other in society. The crowd provides a privileged site to investigate the processes of human sociality. Crowd psychology needs to be brought back from the margins of the discipline—an exotic, spectacular, but ultimately peripheral concern—to its core.

## CULTS

---

Organized around a charismatic leader who demands unquestioning obedience, *cults* are strongly cohesive groups of people who are committed to a transcendent worldview that they believe is morally superior. They are rigidly authoritarian, and they are very effective in using common methods of social influence to achieve their goals. Because many people argue that cult influence is coercive and destructive to the psychological well-being and individuality of members, it is important for group researchers to examine the ways in which cults are typical and atypical of other groups.

Cults are not a new phenomenon, but the attention they have received has increased dramatically in the past several decades. Many scholars attribute the presence of cults in the United States, for example, to the culture of change that typified America in the 1960s. Social and political turmoil surrounded America's involvement in the Vietnam War; civil unrest characterized Blacks' and women's struggle for equality; religious influence began to decline as people searched for different ways of understanding. This culture was fertile for groups whose beliefs conflicted with mainstream dogma, giving rise to the number and popularity of cults.

The numbers of cults and their members are difficult to estimate. At the low end, researchers have estimated several hundred cults; at the high end, researchers have estimated as many as 3,000 such groups across the world. One reason that estimating the number of cults is challenging is because most cults do not survive to become mainstream groups and thus may be overlooked. Also challenging is estimating the number of cult members. Data suggest that relatively few people report having personal, direct contact with cult groups; however, such data often conflict with those reported by cults. The members of cults may be motivated to misreport their size, either to appear larger and stronger than they truly are or to avoid scrutiny from skeptical outsiders and law enforcement agents. Estimation is also made difficult by the challenges involved in precisely defining cults. This entry begins with a look at this issue, then discusses cult leadership and structure, concluding with a description of socialization processes cults use.

### Defining Cults

There is no standard, consensual definition of cults among social scientists, but most definitions focus on the importance of a charismatic, living person who leads an essentially elitist group that believes in their own moral and social superiority. Their commitment to the leader and his or her message is so strong that members may become overly dependent on the group to meet basic psychological needs. The strong bonds among members heighten their conformity to behavioral norms and their willingness to be influenced by the leader and each other.

A primary challenge for social scientists is distinguishing cults from other groups with similar dynamics. Some scholars have noted that cultic structure, thought control, and socialization practices are not that different from those in groups like the military and fraternities and sororities. In addition, the term *cult* can be applied so generally that it includes most religious and political groups. Outside the scientific realm, the term is used even more loosely, referring to groups of people who are devoted to a fashion trend, the latest gadget, a popular celebrity, a lifestyle, and so on.

Moreover, the term conjures stereotypes of brainwashed zombies who surrender their possessions to the group, who sexually abuse women and children, and who aggress against mainstream culture. Although such stereotypes are valid for some cultic groups and/or their members, they are not applicable to them all. Indeed, these stereotypes may be largely based on extreme cults whose sensationalized media representation comes readily to mind (e.g., the People's Temple, Branch Davidians, Heaven's Gate, Aum Shinrikyo).

Consequently, some scholars—often labeled cult apologists—have begun to call cults *new religious movements* (NRMs). The term is less affectively charged, but not without problems. For example, not all cultic groups are temporally or even ideologically new; and even established, mainstream religions like Christianity would have been considered cultic at their inception. Further, what is considered to be cultic is sometimes a subjective judgment to describe any ideological or social outgroup.

### Cult Leadership and Structure

Central to most definitions of cults is a self-appointed leader, one who views himself or (less commonly) herself as having a divine calling. Some cult leaders claim to be messianic or prophetic; however, such claims tend to be unverifiable, fueled by members who want to believe in the leader and his or her message. The claims are also fueled by the leader's enigmatic past. Members may know very little about the leader's life, other than what the leader wants them to know. Research suggests that cult leaders tend to have a tumultuous background characterized by crisis, emotional instability, and poor social relationships. Such a

history could influence individuals to crave the power and influence that is associated with leading groups.

These generalizations should be regarded cautiously, however, because the data are usually based on hindsight and cannot be used to confirm causal paths. Regardless, at some point leaders become quite effective in persuading others that they have a special, exclusive hold on Truth. The leader's influence cannot be understated. He or she rules with an authoritarian style, regulating every experience in the members' day, including work, diet, social activities, sex, and marriage. The leader is so important in the lives of cult members that cults often do not survive when he or she dies or moves on.

Like most groups, cults quickly form a structure and goals, which vary considerably across cults. Some groups are organized around the theme of humankind's demise, and their goal is to recruit members to a path of salvation. Others are organized around political and social themes, and their goals may include aggressing against institutions that counter those themes. The degree to which cults are tightly structured around these beliefs and their leader varies, as does the degree to which cults operate in isolation from mainstream society. Some groups allow members to continue living and working in mainstream society, whereas others require members to break away completely from their past life and individuality to embrace a new identity in the cult ("social implosion"). In addition, many cults structure themselves as a family, with the leader occupying the most central position as a loving parent. Those structurally closest to the leader are trusted, loyal, full members who have access to the leader's private teachings. They are the closest to reaching the cult's vision of enlightenment, and they may have special signifiers of their elevated status.

### Socialization in Cults

Once relegated to city streets and airports, recruitment now occurs in more familiar, personal settings. For example, prospective members may be recruited in their homes (e.g., face-to-face, electronically over the Internet) or through their social networks (e.g., family, friends, coworkers). Researchers have found that these personal strategies are very effective in

forming and maintaining cults because they decrease the likelihood that prospective members will respond defensively to cult messages, or that they will process those messages at a deep level.

### *Member Traits*

A common question that arises in the context of cults is, “Who becomes a cult member?” As social psychological studies remind us, we could all be ideal recruits under the proper circumstances. It should not be surprising, then, that researchers have had little success in finding personality traits that reliably predict vulnerability to cult influence. Most prospective members show no signs of substantial psychopathology or intellectual deficits. (Generally, people with severe mental illness are poor members because they do not remain in the group for a long time.)

Recruits tend to be educated young adults from the middle or upper socioeconomic classes—characteristics that enable their curiosity and the search for meaning and identity. Their families are typically intact, but researchers disagree over whether or not these families promote healthy autonomy. Any lack of autonomy may help to explain the appeal of cults that organize themselves like a family.

### *Cultural Context*

Looking at factors outside the individual, sociologists have focused on large-scale cultural patterns that foster cult influence. Cults tend to emerge and flourish during times of societal chaos, disorganization, and change, like when shifts in collective values and worldviews occur. Further, individuals are most likely to join cults when they are experiencing temporary disorganization in their personal lives. Such disorganization may occur when young adults leave the familiarity of home and family for a job or school in an unfamiliar city.

The group’s central message, total love and acceptance, is easy to understand and does not require cognitive elaboration. In fact, deep processing among members is discouraged. Socially disconnected prospective members are showered with love (“love bombing”), given hope that the group can answer all their questions and provide the stability that seems to be missing in larger society.

Once they become new members, individuals find that information is controlled inside the group. Outside information—especially information that is damaging to the group and its message—is blocked from reaching members (similar to the mindguards of groupthink). Information about the group that is communicated externally is also strictly monitored and controlled.

New and full members participate in a variety of activities that raise their commitment to the cult. They are partnered with old timers who serve as benevolent mentors, and they spend much of their day with other members. The relative uniformity in members’ characteristics and worldviews validates the group and its beliefs, and it increases the group’s cohesion. Ritualistic confession is a common activity that exposes the members’ shortcomings to each other, a vulnerability that can enhance trust and solidarity. These activities enable the group to monitor the thoughts and actions of its members, ensuring that members comply with group norms. Long days of working, recruiting, exercising, chanting, and praying exhaust members to the point where they are unable to elaborate on the group’s message.

Eventually, members may be expected to recruit new members, give their assets to support the group’s mission, and renounce outgroups. These physical and socioemotional sacrifices enhance commitment by producing cognitive dissonance that is resolved by forming more positive attitudes toward the cult. In most cases, these sacrifices unfold gradually, operating according to the foot-in-the-door phenomenon. New members are asked a small request (e.g., attend meetings), and their compliance increases the likelihood that they later will comply with larger requests (e.g., sever all ties with family). Intragroup cohesion and commitment to the leader are important in cults, sustaining members’ participation and belief, even when the leader’s vision of truth is invalidated by reality.

### *Exit Strategies*

Not all people who join cults remain in them. There are a variety of reasons for why members leave a cult. They may voluntarily leave because the group no longer satisfies important needs or interests, or because they have external roles that draw them away from the cult. Members may also

leave involuntarily, such as when the group asks marginal members to leave, or when family members forcibly remove members. The reasons members leave a cult and the presence of a supportive postcult support network likely affect cult members' reintegration into mainstream society.

Research generally suggests that former cult members experience an initial period of adjustment difficulties. These difficulties often involve disorientation and discomfort in having to make their own decisions, a sense of shame over being influenced by the cult, problems in relationships that were severed during membership, and the loss of personal property that now belongs to the cult. With the passage of time, former members begin to integrate into society and to overcome these challenges, such that their psychological well-being is comparable to those in the general population.

In today's milieu of political and social unrest, it would not be surprising to see more and newer cults emerge. Group researchers are ideally suited to study cults, focusing particularly on such intragroup processes as information management, the construction of members' shared mental models, and how cults use social influence to achieve their goals. Such intergroup processes as outgroup derogation, impression management, and minority influence would also be viable foci of study. Whether social scientists regard cults as evil, destructive groups who prey on hapless individuals or as ideological minorities whose right to exist and express a different worldview should be protected, these researchers have much to contribute to society's understanding of cults.

---

## CULTURE

---

To give a single, uncontroversial definition of culture is a difficult task. Any definition of culture is itself an expression of a theoretical stance. With this caveat, this entry offers a definition that conveys a conception of culture widely used in contemporary psychology. Broadly, *culture* is a collection of information (or meanings) that is (a) nongenetically transmitted between individuals, (b) more or less shared within a population of individuals, and (c) maintained across some generations over a period of time.

This definition of culture excludes behavior or artifacts. Artifacts may take a material form, such as tools, machines, and objects, or a more symbolic form, such as stories, poems, and pictures. Social institutions such as rituals, laws, and the like are special kinds of artifacts that combine both material and symbolic forms. Information or meaning may be inferred from overt behavior or artifacts, because it causes the behavior or behavior that produces the artifacts. Behavior and artifacts may act as markers of culture, but they are not part of culture themselves.

### Groups and Cultures

Although a culture is often associated with a large-scale group, such as a nation state, smaller groups (e.g., Little League baseball teams, work groups)

and organizations can have cultures as well. More generally, cultures and groups are conceptually interdependent. The second component of the culture definition offered earlier stated that cultural information is more or less shared among individuals in a population. A population is often, though not always, defined by a group. Here, a group is understood as a collection of individuals who *self-consciously regard themselves as members of the group*, and as an entity with an existence independent from specific members. Therefore, it is possible to speak of the culture of a group as the totality of nongenetic information more or less shared among members of that group. The culture of a group is thus a property of that group.

However, the culture of a group includes what the group means and what it means to be a member of that group. These meanings include information (a) that the group exists (usually in contrast to other groups); (b) that it has a unique past, some current state, and potential continuity into the future; (c) that some individuals (but not others) are group members; (d) that there is a way to determine group membership (and the rules by which membership is determined); and (e) that to be a member of the group means to have certain psychological and behavioral characteristics. In this sense, culture and group are coconstitutive: The constitution of a self-reflective group presupposes the existence of its culture (a definition of the group, at the very least), and the culture of a group presupposes the existence of the group.

The set of meanings (a) through (e) above, about a group and group membership, may be called a *group identity*. Group identity in this sense differs from *social identity*, which was defined by the founder of social identity theory, Henri Tajfel, as “the individual’s knowledge that he belongs to certain social groups together with some emotional and value significance to him of his group membership” (1972, p. 292). In Tajfel’s sense, social identity is an individual’s representation of his or her own group membership, and it presupposes a group identity. That is, given the existence of a group and its meanings, an individual may define himself or herself as a member of the group. This self-definition as a group member, with its attendant emotional and value significance, contributes to the individual’s social identity.

Nonetheless, a population of individuals who share some cultural information does not have to be

a self-reflectively defined group. For instance, social scientists could define a set of individuals as a population purely on the basis of some arbitrary criterion (e.g., geographical location, historical period, age, gender, sexual orientation), regardless of whether those individuals have a self-reflective definition of themselves as a group. Even then, it is possible to speak about their culture, given the definition offered earlier. Culture can thus be described for a set of people who lack a group identity.

### Cultural Transmission and Small Group Processes

Cultural transmission, the process by which cultural information is transmitted from one person to another, is central to the sharing of cultural information in a group and the maintenance of culture over generations. Recent theorizing suggests that cultural transmission often occurs within the context of face-to-face social interactions among people in their joint activities. For instance, children acquire much of their culture through interaction with their parents and teachers in concrete social contexts, such as family activities and classrooms. Workers acquire organizational cultures through everyday interactions with colleagues and supervisors in small work groups. In other words, the locus of much cultural transmission is small face-to-face groups, including dyads.

Some cultural transmission is carried out purposefully, whereas other cultural transmission occurs as an incidental side-effect of other activities. At least one participant in a joint activity should possess some cultural information, and present it to other participants in a form that is understandable to them. In turn, those other participants should provide some (perhaps tacit) feedback regarding their acquisition and appreciation of the cultural information. As a result, the information becomes shared among participants. However, not all those who are present end up with the same information—the cultural information learned by a particular participant depends on that person’s perspective, prior knowledge, and the like. Consequently, no cultural information is uniformly distributed within a group. “Shared” culture in a group is thus often shared only to the extent that is necessary for its use in members’ joint activities.

Cultural transmission can occur among group members, as illustrated by Muzafer Sherif's classic investigation of emergent norms in 1936. In a laboratory setting, he projected a small speck of light onto the wall of a darkened room and asked participants to make judgments about its apparent movement. In this situation, people tend to experience a perceptual illusion called the *autokinetic effect*, in which there is some apparent movement of the light, although it is in fact stationary. In one condition, Sherif had two or three naïve participants report their perceptions of movements individually and privately at first, and then publicly, in a group setting. Although there were individual differences in initial perceptions, the participants' perceptions of the perceived autokinetic movements converged when the participants were in a group. Here, cultural information about a frame of reference—a "usual" or normative range of perceived movements in the light—was transmitted among group members incidentally as a side effect of their joint activity of participating in an experiment.

For information shared within a group to become part of the group's culture, it must be transmitted vertically across generations. In 1961 Robert Jacobs and Donald Campbell showed that a group norm induced by having confederates report arbitrarily large autokinetic movements in Sherif's experimental situation could persist over generations. For instance, in one condition, a naïve participant began the experiment with two confederates, who were instructed secretly by the experimenter to report very large movements in the light. Once everyone had reported their views about the light's movement, one of the confederates was removed from the group and replaced by a second naïve participant. Everyone again reported their views about the lights' movement, and then the last confederate was removed, to be replaced by yet another naïve participant. This pattern of activities was repeated 10 more times. No further confederates were added to the group; after each trial, the "oldest" group member was simply replaced by someone who was totally new to the experiment. This procedure was meant to represent generational changes in society at large. Despite the fact that the two confederates that instituted the original norm were gone by the third trial, that norm persisted in groups until the fifth generation. This suggests that in small groups, as

well as in society, culture can be transmitted from one generation to the next.

When a group continues to exist, despite changes in membership, and information is shared and transmitted across generations, the group develops a culture. In 1982, Richard Moreland and John Levine called *group socialization* the process by which new members acquire a group's culture and go through resulting temporal changes in status and commitment to the group. Newcomers enter a group almost like apprentices; as they acquire the group's culture, they become full members, engage in the group's activities as main participants, and impart their cultural knowledge to "younger" generations. At this point, they are fully committed to the group. Nonetheless, as they approach the time for their departure to other groups, they begin to extricate themselves from group activities, reduce their commitment to the group, and eventually retire from it. An important aspect of group socialization is cultural transmission, and the process by which cultural information is gained and lost by group members over time.

Enduring groups are typically *institutionalized* groups. That is, they are often legally sanctioned organizations within a broader society, or are parts of such organizations. Institutionalized groups are psychologically treated as part of the social reality that transcends particular individuals' perceptions and agreements; this appears to facilitate cultural transmission, and strengthens the tendency for new group members to internalize a group culture. Using Jacobs and Campbell's experimental paradigm, Lynne Zucker examined cross-generational cultural transmission in different settings in 1977. In one setting, the confederates were described as other participants of a psychological experiment. In the other settings, the experiment and the other participants were described as part of an institution, namely a company or a work group within a company. Naïve participants introduced into institutionalized groups internalized their groups' norms about autokinetic movements more strongly, and passed them on to newcomers more fully, than did participants who construed their groups as part of a mere psychological experiment. An institutionalized group and its culture go hand in hand.

### Culture in Large Populations and Groups

Much of the discourse about culture in psychology focuses on large geopolitical regions (e.g., Europe,

Asia), nation states, and ethnic groups. Geert Hofstede's 1980 book, *Culture's Consequences*, provided a broad framework for such research, highlighting individualism and collectivism as the new foci for research in psychology. Hofstede described individualism as a cultural pattern that emphasizes the individual's goal pursuit and well-being, whereas collectivism emphasizes the sustenance of collectives, such as extended families and kinship groups. Individualist and collectivist cultures echo such well-known concepts as Ferdinand Tönnies's *gemeinschaft* and *gesellschaft* and Émile Durkheim's mechanical and organic solidarity, which the founders of social science developed to describe social and cultural changes in the transition from the traditional lifestyle to the modern society in western Europe in the late 19th and early 20th centuries. Hofstede showed that more individualistic countries tend to be richer, whereas more collectivistic countries tend to be poorer. North America, western Europe (the United Kingdom, the Netherlands, Italy, Denmark), and Oceania (e.g., Australia, New Zealand) are more individualistic, whereas Asia (e.g., Pakistan, Taiwan, Thailand) and Latin America (e.g., Venezuela, Colombia, Chile) are more collectivistic.

Related cultural differences have been found in small group processes, suggesting that small groups may be more real social agents, or more entitative in Campbell's sense, in collectivist than in individualist regions of the world. First, in collectivist Hong Kong, people spend more time in small groups than they do in the individualist United States. People with collectivist Chinese cultural backgrounds also tend to work harder in small groups than alone, whereas people with individualist American cultural backgrounds are more likely to loaf in groups. Small groups also exert stronger social influence in collectivist regions than in individualist regions of the world, at least as measured by responses to conformity pressure. And collectivists tend to hold small groups more responsible for wrongdoing than do individualists, attributing equal or greater agency to groups than to individuals for misbehavior.

Linking cultural difference in individualism and collectivism to the self and social behavior, Harry Triandis in 1989 argued that different types of self-concepts are prevalent in different parts of the world, and that culture influences social behavior through the activation of self-concepts. Hazel

Markus and Shinobu Kitayama in 1991 postulated two types of culturally shaped self-concepts. People with an independent self, found mostly in individualistic cultures, regard the self as bounded and separate from others. The independent self is a unitary and stable entity, characterized by private and inner attributes (e.g., honesty, kindness), that motivates people to express their unique selves, promote their personal goals, and assert what is on their minds. In contrast, people with an interdependent self, found mostly in collectivist cultures, regard the self as inherently connected to significant others (e.g., daughter, husband) and to ingroups (e.g., a citizen of a country, a member of a political party). This motivates them to belong and fit in, occupy their proper places, engage in appropriate actions, promote the goals of others, and "read other people's minds." More recently, Richard Nisbett and others in 2001 argued that culture can influence general cognitive styles. An analytical style, associated with individualistic cultures, focuses a person's attention sharply on an object, while largely ignoring its background. In contrast, a holistic style, associated with collectivistic cultures, has a broader focus of attention that includes both the object and its context. Thus, combining the ideas of culture, self, and cognition, the "standard theory" of East-West differences emerged. It suggests that Western individualism promotes independent self and analytic cognition, whereas Eastern collectivism promotes interdependent self and holistic cognition.

Consistent with the standard theory, there is empirical evidence for the prevalence of independent self-concepts in North America and interdependent self-concepts in East Asia. In comparing self-concepts in America, Australia, Hawai'i, Japan, and Korea, it was found that Americans and Australians had more individualist and less collectivist self-concepts than Japanese and Koreans, with Hawaiians in between these two groups. When European Americans, Asian Americans, and Koreans described themselves in their own words, it was found that European Americans' self-descriptions contained the highest proportion of personality trait terms, Koreans the lowest, and Asian Americans in the middle, again suggesting the American tendency to characterize the self using individual-centered descriptors.

One of the cultural differences in cognition involves the fundamental attribution error. Social

psychological research in the 1960s and 1970s, mainly conducted in North America, showed that people have a strong tendency to explain someone's behavior in terms of the person's dispositions, while underestimating the importance of the context in which the behavior occurred. This tendency was said to reflect a basic limitation of the human cognitive system, but it later turned out to be an error observed more often in North America than elsewhere. Cross-cultural comparisons between the United States and India, as well as between the United States and Hong Kong, showed that the "fundamental" attribution error was not so fundamental after all. Indians and Chinese do not exhibit the error as often as their American counterparts.

A cultural difference between North America and East Asia has been found in emotions as well. A large scale, cross-cultural project comparing people's happiness (often called subjective well-being) showed a substantial difference between North America and East Asia—North Americans tended to be much happier than East Asians. Paralleling these findings, cross-cultural comparisons in self-esteem have shown a strong tendency for North Americans to have higher self-esteem than Japanese. A related finding involves the optimism bias—a belief that in the future, one is more likely to experience positive events, but less likely to experience negative events, than the average person. Although this bias is strong in North America and western Europe, it is much weaker in East Asia, especially in Japan, although a recent study suggests that there is a universal tendency toward unconscious positive self-regard. Taken all together, these findings reveal cultural differences in how people think and express their feelings about life and themselves. These differences are typically interpreted as arising from differences in self-concepts—individualists optimistically pursue their happiness, whereas the pursuit of happiness by collectivists is tempered by a sense of obligation to others.

Overall, there is evidence for broad cultural differences postulated by the standard theory of East–West differences.

### Recent Trends in Culture and Psychology

The standard theory of East–West cultural differences has been refined in recent years. First, individualism and collectivism have been found to be

two separable cultural orientations, and independent and interdependent selves are now regarded as distinct self-concepts that can coexist in the same person. This means that some cultures can be both individualistic and collectivistic, whereas others can be neither. Similarly, some people can show both independent and interdependent self-concepts, and others can show neither.

Second, although the culture of individualism and its link to the independent self appears to be strong, empirical support for the link of collectivism to the interdependent self is modest. In a further refinement, the interdependent self has been differentiated into a self connected to significant individuals (relational self) and a self that is socially connected to groups (collective self). In particular, there is some evidence that East Asian collectivism is characterized by a strong interpersonal bond between close people who are connected by reciprocal exchanges of resources, whereas North American individualism often involves large social groups in which people engage in generalized resource exchanges.

Third, although Triandis's original theorizing emphasized the importance of situational variability in the accessibility of different types of selves, situational variability in cultural differences has been generally overlooked in cross-cultural research. Nonetheless, research has shown that cultural information can be "primed" to increase its cognitive accessibility temporarily, and thereby affect psychological processes. Flexible and situated theorizing about cultural differences is especially important in today's globalizing world, where many people are bicultural or multicultural. These individuals can often switch their cultural mind-sets easily and seamlessly, depending on whatever cultural information is salient in a given situation.

### Conclusion

Globalization has increased the exchange of people, resources, and information across human populations in different regions of the world. When people are exposed to information from other regions, they have greater opportunities to compare themselves to those from those regions. With increasing opportunities to compare themselves to others, people have become more aware of their own cultural uniqueness and have self-reflectively differentiated

themselves further from others. In other words, they have become more articulate about their culturally based group identities and attendant social identities. When identity differentiations were based on cultural differences, cultural identities emerged and became more prominent; as a result, identity politics became part of the popular discourse. The 2001 atrocity of the September 11th attacks on the World Trade Center, arguably a symbol of globalization, highlighted the ideas of cultures and cultural identities because many believed cultural differences were fundamentally involved in this terrorist act. Thus, the concept of culture has now been moved to the center stage of the contemporary academic and popular discourse, with an accompanying sense of urgency.

## CULTURE OF HONOR

---

In cultural anthropology and social psychology traditions, a *culture of honor* is one in which values and behavioral norms place a strong emphasis on status and reputation. Having honor implies being respected by others. For males, this means demonstrating toughness and the willingness to use aggression if one’s reputation is challenged or to avenge a perceived insult. For females, codes of honor often focus on avoiding behaviors that could bring shame or dishonor to oneself or one’s family. This usually means placing a strong emphasis on female modesty and moral (particularly sexual) purity. This entry begins with an overview, then looks more closely at the internal workings of honor cultures, and concludes with a brief summary of related concepts.

### Overview

Cultures of honor often have elaborate informal conventions about politeness, codes of conduct, and proper rules for redressing grievances. Honor cultures also tend to be characterized by extreme sensitivity to insult that must often be met with a violent response. Values associated with honor cultures include social interdependence, collectivism, emphasis on family, modesty (for females), and relatively traditional views about gender roles. Emotions tend to be centered around shame, pride, humiliation, and anger, but also politeness and respect. Thus, honor encompasses many things: It is a set of prescriptive norms outlining acceptable and unacceptable behavior between individuals, families, and social groups; it is a measure of an individual’s social worth and self-esteem; and it is associated with the experience of several moral emotions.

The study of honor has a relatively long history in cultural anthropology, with detailed ethnographies focusing on Mediterranean and Middle Eastern honor cultures. More recently, social psychological research on honor, beginning with work by Richard Nisbett and Dov Cohen in the 1990s,

has had as its main focus the study of aggression in the defense of male honor in the southern United States. Many other cultures around the world have strong honor traditions, including parts of Central and South America and many Islamic cultures.

In addition, certain subcultures such as the military, the Mafia and the world of organized crime, and subcultures within inner cities emphasize honor or related constructs. Thus, honor cultures can exist at the national or regional level (e.g., Spain, the southern United States), or they can exist in smaller units (e.g., military forces, inner-city street gangs). In short, a “culture” arises wherever interdependent groups of individuals share a common frame of reference. As individuals acquire knowledge of the attitudes, values, norms, and behavioral customs of the group, they become socialized members of the culture.

### Development of Cultures of Honor

Cultures of honor tend to develop in places that have little or no formal law enforcement to redress grievances and thus requiring individuals to protect themselves. For example, much of the U.S. South and Southwest remained a largely lawless frontier relatively late in the settlement of the United States. Honor cultures also tend to develop in places where the economy is dependent upon a portable commodity for wealth. For instance, herding-based cultures often place strong emphasis on personal honor, because livestock (and thus, its owner’s wealth) is susceptible to theft. In frontiers and herding-based cultures (as well as subcultures such as criminal gangs that operate beyond the reach of law enforcement), those men who can best cultivate a reputation for toughness and the quick use of aggression in response to challenges are often the most respected and enjoy the greatest social status.

### Honor and Violence

Cultures of honor tend to be characterized by high rates of violence, both among males and by males against females. Ethnographic work, analyses of homicides, laboratory experiments, and field studies have all demonstrated relatively high rates of violence, and endorsement of honor-related violence in cultures of honor.

Analyses of homicides in the United States, beginning in the latter part of the 19th century, have noted that the South has long been a much more violent region than the rest of the country, a trend that continues today. These regional differences tend to be magnified when looking at rural versus urban populations, Whites versus minorities, and violence specifically related to honor concerns (e.g., argument-related homicides, lovers’ quarrels) compared to felony-related violence. Though some of this regional difference may be due to factors such as poverty and higher temperatures in the South, a number of studies have implicated cultural values of honor directly.

In survey research, Dov Cohen and Richard Nisbett found that individuals from the southern United States endorsed violence more than individuals from the northern United States when it was used to protect personal reputation, family, or property, though Southerners did not endorse violence more in the abstract. In laboratory experiments by Cohen, Nisbett, and their colleagues, southern U.S. males were more likely than northern U.S. males to respond to insults with anger, elevated physiological responses suggesting a readiness to aggress, dominant physical behaviors, and actual aggression.

A number of studies have also noted a connection between honor norms and the relative acceptance of male violence against female intimate partners. For example, students from Brazil (a culture of honor) were more likely than northern U.S. students to believe a man loses honor if his wife is unfaithful, and they were in turn more likely to see a husband’s violence in response to suspected infidelity as justified. Similarly, Chilean students (compared to a non-honor-culture sample of Anglo-Canadians) believed a husband to be justified in hitting his wife, but only if the violence was related to a potentially honor-threatening event.

### Mechanisms of Persistence and Change

Despite changes in the initial conditions that give rise to honor cultures, norms about honor may be stubbornly persistent. For example, despite the transition in the U.S. South from a frontier region with a herding-based economy to a region that increasingly resembles the rest of the nation demographically and economically, elements of the culture of

honor remain. Several macro- and microlevel forces can work together to perpetuate cultural norms of honor.

At the macrolevel, norms about honor are sometimes formalized symbolically into the laws or legal traditions of societies. For instance, “honor killings” are still frequently legitimized or excused in parts of the Arab and Muslim world. Similarly, laws about gun control, foreign policy, and national and self-defense often reflect (and reinforce) greater acceptance of violence in cultures of honor.

Place names can also serve as macrolevel symbols that reflect and reinforce cultural norms about violence. For example, southern U.S. towns (e.g., Guntown, Mississippi; War, West Virginia) and businesses (*Shotguns Bar BQ*, *Warrior Electronics*) more frequently contain violent words than northern U.S. towns and businesses.

At the microlevel, psychological processes such as pluralistic ignorance may reinforce cultures of honor by leading men to misperceive the attitudes of their peers. Southern men, for example, are especially likely to overestimate the extent to which their peers would behave aggressively in various hypothetical conflict scenarios.

However, cultural views about honor can change with demographic and economic shifts. Honor norms appear to hold less sway when there are other routes to honor and status besides family name, or where there are other avenues for mobility and advancement. For instance, recent survey data from Saudi Arabia (a culture with strong honor-based traditions) suggests that individuals who self-identify as middle class endorse honor less strongly than those from the upper or lower classes.

### Related Cultural Concepts

Cultures around the world differ in the emphasis they place on individuals’ social standing. For example, the concept of “face” in some East Asian cultures and “machismo” in many Latin American cultures have in common with cultures of honor

a concern with public reputation as a central organizing principle of social life. However, there are also important distinctions between these constructs and cultures of honor.

For instance, in most cultures that emphasize saving face, public image threats usually lead to inwardly directed emotions such as shame and embarrassment, rather than outwardly directed anger and aggression, which are more common in honor cultures. Likewise, while the macho Latin American male is often caricatured as quick-tempered and violent, overly aggressive masculinity in honor cultures is often frowned upon as immature or dishonorable. Thus, honor codes entail specific rules for when anger and aggression may be expressed.

## DECATEGORIZATION

---

*Decategorization* refers to a process of reducing the salience of ingroup–outgroup distinctions. An important consequence is that negative behaviors associated with ingroup–outgroup distinctions, such as prejudice, stereotyping, and intergroup discrimination, are also diminished. When a category distinction is particularly salient, people act and think in terms of ingroup–outgroup memberships rather than in terms of personal identities. This type of social categorization has two consequences. First, outgroup members are depersonalized, treated as relatively interchangeable and undifferentiated elements of a social category; their individual characteristics are ignored, and group-based appraisals, such as stereotypes, are used to judge them. Second, intergroup distinctiveness is enhanced, thus facilitating competition and discrimination. Given this situation, decategorization should have beneficial consequences for social interactions.

### Three Aspects of Decategorization: Individuation, Differentiation, and Personalization

Individuation reduces intergroup biases and conflicts because the more that group members are considered as discrete individuals, the less their group membership is likely to be relevant. Deindividuation of group members has several negative consequences, such as disregard, dehumanization, and aggressive

responses. Thus, individuation should promote positive emotions and evaluations. In particular, individuation is likely to (a) dispel the perception of outgroups as homogeneous, (b) facilitate the perception of self–other similarities, and (c) encourage perspective taking and empathy.

Marilynn Brewer and Norman Miller emphasized two other processes fundamentally related to decategorization: *differentiation* and *personalization*. In their model, categorized, differentiated, and personalized interactions are part of a continuum: Categorization represents the extreme in which only groups are salient, personalization the pole in which only individual features are relevant, and differentiation stands in between, characterized by an intermediate level of salience of both categorical and personalized aspects. Thus, according to Brewer and Miller, differentiation does not refer to an elimination of category boundaries, but to their blurring. With differentiation, within-category differences are perceived as relevant, unique, and distinctive information and, as a consequence, can promote the perception of different subgroups within the broader category. The groups remain the basis of social interactions, but perceived internal homogeneity within the categories is reduced.

From a practical point of view, differentiation can be produced in different ways. First, people can be instructed to pay more attention to intra-group differences, partially reducing the salience of group membership. Second, different categorizations can be applied to the same individuals. Crossed categorization, in fact, diminishes the

salience of the original ingroup–outgroup distinction, although alternative categorizations are likely to gain importance. Third, the ingroup and outgroup can be joined in a single category that includes both, as proposed by the *common ingroup identity model*. In this case, the type of judgments generally reserved for ingroups, in which both group membership and individual differences are taken into account, are applied to the individuals previously categorized as outgroup members who are now members of the new broader category.

Personalization, which represents one pole of the continuum described by Brewer and Miller, is related to the comparison between the self and other *individuals*. Group memberships are irrelevant: These interpersonal comparisons cross group boundaries. However, whereas individuation involves primarily perceiving group members as distinct individuals, personalization involves recognizing personal, idiosyncratic information that is relevant for the self and facilitates the recognition of similarities between the self and individuals previously categorized as outgroup members. Information processing is based on individual information collected during the interpersonal interaction, not on category-based preconceptions such as stereotypes and prejudice. As a result, categories become less useful tools because they are not very informative for the perception of self and others.

Miller subsequently proposed an alternative definition of personalization, considering it as a feature generally related to a focus on personal information, involving phenomena such as self-disclosure, mutual trust, and empathy. In this conceptualization, both personal and category-based features can be highly salient at the same time, for instance when individuals who are well aware of their memberships in different groups reciprocally self-disclose or adopt the other's perspective. In general, greater personalization, viewed in this way, creates more positive attitudes toward others.

### The Generalization Process in Decategorized Contact

According to Brewer and Miller, whether an interaction, in which people are in contact with one another, is characterized by categorization,

differentiation, or personalization has important consequences for the generalization process, in which the outcomes of a specific interaction between people are extended to other social contexts.

Category-based contact is likely to lead to a change in attitude toward the entire outgroup: When ingroup members interacting with outgroup members consider all the people involved in that contact situation, including themselves, as interchangeable representatives of their respective groups, the judgments formulated during contact are easily extended to the entire categories. However, according to Brewer and Miller, when contact is characterized by categorization, it is unlikely that interactions will be experienced or perceived as positive; it is more likely that they will be imbued with the negative cognitions, evaluations, and affect generally related to ingroup–outgroup distinctions. Thus, a generalization process will readily occur, but it will most likely focus on negative rather than positive outcomes of contact.

Differentiation, in contrast, creates an enhanced perception of group variability and increases complexity of group judgments. Increased variability and complexity undermine views of the outgroup as monolithic, reducing category-based judgments of its members. Because outgroup members are no longer perceived as interchangeable elements of a category, it is difficult to treat them as identically characterized by stereotypical traits. The risk involved in differentiation is that the perceived distinctions among outgroup members may lead to subtyping of outgroup members. These subtypes can be treated as being inconsistent with the general image of the group, and then treated as exceptions, leaving global perceptions of the category fundamentally unchanged. If subtyping occurs, generalization would be limited.

The generalization process involved in personalization is conceptually different. It is based on the fact that repeated interpersonal interactions are able to disconfirm negative stereotypes of the outgroup because others are seen as unique individuals who are more similar to the self than to the prototype of a category. As a result, individuals eventually become aware that category-based judgments are inaccurate or inefficient for understanding members of the other group. Thus, in future interactions, with the same person or other

members of the group, people will be less likely to base their perceptions on category membership, progressively undermining a cognitive habit that is now seen as misguided, uninformative, and effectively useless. From a practical standpoint, this process should be active in contexts characterized by desegregation, in which people have a range of personalized experiences with individual outgroup members.

### Empirical Evidence

David Wilder examined various experimental conditions in which outgroup members can be individuated and the salience of group boundaries degraded. This happens, for instance, when participants interact with group members who display a variety of different behaviors or who disclose personal, idiosyncratic information. Alternatively, perceivers may be encouraged to adopt a careful, deliberative examination of group members. The effects of these manipulations are clear: When individuation occurs, group-level phenomena, such as perceived outgroup homogeneity and ingroup favoritism, are less prominent. However, in further work, Wilder showed that full generalization from positive contact to favorable attitudes toward the outgroup is possible only when the known individuals are presented as typical members of their category.

Several studies have also been conducted to directly test the decategorization model proposed by Brewer and Miller. The results are generally consistent with the model. Judgments of previously unknown outgroup members are more positive when interactions between ingroup and outgroup members are focused on individual characteristics (a social focus), rather than on the task they are working on (a task focus). This result is amplified when individuals cooperate, rather than compete. However, as Hewstone has noted, group membership was still salient in this research, and thus, interactions were not fully decategorized or individuated. Miles Hewstone, Rupert Brown, and their collaborators have further found, across various settings and adopting different methodologies, that positive effects of contact are generalized to the whole outgroup mainly when interactions involve individuals who are considered typical exemplars of the outgroup or when group memberships are

highly salient during contact. Thus, as Miller noted in his revision of the Brewer and Miller personalization model, some degree of attention to group membership is required for generalization of the benefits of personalization to occur.

### Critiques and Limitations

The decategorization process is generally considered an effective way to create positive interactions in which interactants like one another, but there is the risk that its scope is limited to the specific situation of contact. As acknowledged by Brewer and Miller, positive personalized contact does not automatically generalize to attitudes toward the person's group as a whole. Generalization is more likely to occur if, after personalized contact, people come to believe that the relevant social categories are uninformative and of little use. Under these conditions, people are more likely to renounce the use of these social categories in future interactions.

But there is a problem: Is it really possible for human beings not to use categories? Categorization is a basic process in human perception, which simplifies an otherwise overwhelmingly complex environment. Thus, using categories may not be a question of will, but rather a necessity of human cognition. Moreover, people tend to be socially motivated to use categories in their perceptions and judgments. Group memberships are part of self-definition and thus involve self-esteem appraisals and sentiments such as pride and loyalty. From this perspective, it is unlikely that individuals could sustain complete decategorization. Nevertheless, it is possible to recognize and appreciate the individuated characteristics of people who are members of another group. Furthermore, not only can the development of positive connections through personalization produce more favorable attitudes toward those individuals, but to the extent that social categories are seen as salient, these attitudes can generalize to other members of the group as well.

---

## DEHUMANIZATION/ INFRAHUMANIZATION

---

*Dehumanization* occurs when a person or group is perceived as less than human, is likened to a nonhuman, or is treated in a way that disregards the person's or group's humanity. Social psychologists have generally studied dehumanization in contexts of intergroup conflict and violence, such as war and genocide, because the phenomenon appears to be intimately involved in them. In these contexts, dehumanizing perceptions are frequently expressed, and they play a central role in enabling aggressive behavior and freeing aggressors from normal moral restraints.

This entry discusses the concept of dehumanization and presents the different approaches that social psychologists have taken to understand it. After laying out these theoretical perspectives, the entry discusses recent work on more subtle forms of dehumanization, focusing on the phenomenon of *infrahumanization*, in which members of outgroups are denied attributes that distinguish humans from other animals. This phenomenon is intriguing because it can occur in the absence of any intergroup antagonism, it is separate from processes of outgroup derogation, and it takes place unconsciously. Last, other recent perspectives

on subtle forms of dehumanization, in which people are automatically associated with different kinds of nonhumans, such as animals and robots, are presented.

### What Is Dehumanization?

How dehumanization should be defined is rarely made explicit in the social psychology literature, but the term tends to be used in a few distinct but related ways. First, people can be dehumanized by being seen as lacking important human attributes, such as when they are perceived as deficient in intelligence, rationality, or refinement. Patronizing views of “primitive” people or ethnic groups as coarse, stupid, and simple exemplify this sense of dehumanization. Second, people can be dehumanized by being explicitly denied their full humanity, such as when they are openly described as subhuman or as barbarians. A historical example is the way in which Blacks in the United States were once officially declared to be worth three fifths of a human being.

These first two senses of dehumanization focus on what certain people are perceived to lack relative to others: how they are less than human. A third sense involves seeing others as being more like nonhumans. This can take the form of perceiving a group as having more of some nonhuman attribute than other people, or overtly likening the group to nonhumans. For example, certain groups have been attributed bestial qualities or likened to animals. Jews were described by Nazis as vermin, Tutsis were described as cockroaches by Hutus during the Rwandan genocide, and immigrant groups are sometimes likened to germs.

A fourth sense of dehumanization refers to ways in which people are treated. Some kinds of interpersonal behavior can be described as dehumanizing if they harshly violate moral principles about how human beings should be treated. Dehumanization in this sense can be said to occur even if the maltreated person is not explicitly perceived as lacking humanity or as being nonhuman by the perpetrator. Examples of this sense of dehumanizing treatment might include torture, degradation, exploitation, and treating people as instrumental means to ends. A common thread in these examples is that dehumanizing treatment denies human dignity to people.

### Theories of Dehumanization

Psychologists have proposed a variety of ways of accounting for dehumanization. One account, proposed by Daniel Bar-Tal, argues that dehumanization is a form of *delegitimizing belief*. These beliefs are elaborated in culturally accepted ideologies that represent hated outgroups in extremely negative ways, often portraying their members as demons or monsters. In this view, dehumanization is an outgrowth of *demonization*. By removing the legitimacy of the outgroup, beliefs such as these reinforce the superiority of the ingroup and justify its aggressions.

Another theoretical account, associated with the work of Susan Opatow and Albert Bandura, views dehumanization as a form of *moral exclusion* or *moral disengagement*. When people dehumanize others, they place the others outside of the boundary within which normal rules of morality and fairness apply. As a result, moral restraints on inhumane behavior are weakened. For example, nonhuman animals fall outside the boundary of moral concern for many people, and moral rules governing how we should treat our fellow human beings do not apply to them. If members of a group are seen as animallike, we are therefore less likely to apply these moral rules in our dealings with them. Moral exclusion allows perpetrators of aggressive behavior to feel disengaged from the suffering that they inflict and therefore less prone to experience moral emotions such as guilt and shame that inhibit aggression.

A third account of dehumanization, proposed by Shalom Schwartz and colleagues, argues that it hinges on human values. A group is likely to be dehumanized when its members are seen as lacking *prosocial* values that express concern for others and when their values are seen to be dissimilar from those of the ingroup. Values express fundamental cultural goals and ideals, so when others are seen as having discrepant values, their shared humanity is called into question. If *they* do not share in *our* humanity, then they are less than human.

A recent theory of dehumanization, propounded by Lasana Harris and Susan Fiske, links the phenomenon to stereotyping. The content of group stereotypes varies along dimensions of warmth and competence, and researchers have proposed that dehumanization can occur when groups are

stereotyped as both cold and incompetent. Drug addicts and homeless people are often perceived in this way: neither interpersonally agreeable nor personally capable. Research has shown that groups such as these evoke disgust and fail to activate parts of the brain that are involved in social cognition processes, such as the attribution of mental states to other people. By implication, members of groups that are denied competence and warmth are seen as inanimate (and contaminating) objects rather than as human beings with thoughts and feelings.

These alternative accounts of dehumanization share several similarities. They present dehumanization as a phenomenon that mainly applies to extreme outgroups, accompanies very negative perceptions of these groups, and is closely tied to the maltreatment of outgroup members. They tend to see dehumanization as a process that serves psychological or social functions. These may include affirmation of a group's superiority, enablement of violent behavior, justification of past aggression, or blocking of unpleasant feelings such as guilt and vicarious distress at other people's suffering. These theories therefore contribute to our understanding of dehumanization as a factor in human evil.

### Infrahumanization

The theories of dehumanization reviewed here all share the view that it is an intense phenomenon that is closely linked to violence, aggression, and intergroup conflict. Some recent work argues that subtler forms of dehumanization also exist and that these occur in everyday social perception. Members of different groups may unconsciously perceive one another as less than fully human, even when their groups are not in conflict.

This new approach to the study of dehumanization was pioneered by Jacques-Philippe Leyens and his colleagues, who first investigated which characteristics are seen as distinctively human. They focused their attention on emotions, distinguishing between *secondary emotions*, which are unique to humans (e.g., nostalgia, envy, delight), and *primary emotions*, which we share with other animals (e.g., sadness, anger, happiness). Leyens and colleagues found that people often consider secondary emotions to be essential components of humanness and inferred that if outgroups are

subtly dehumanized, they should be seen as having these emotions to a lesser extent than ingroup members. No such ingroup–outgroup difference would be expected for primary emotions, which are not distinctively human.

In many studies, using questionnaires as well as implicit social cognition methods, Leyens and colleagues have confirmed these predictions: Uniquely human emotions are reserved for the ingroup, but other emotions are attributed equally to ingroup and outgroup. By implication, outgroup members are implicitly perceived as closer to animals than ingroup members, and for this reason the effect is dubbed *infracumanization*. People do not merely fail to ascribe uniquely human emotions to outgroup members but actively resist doing so and respond negatively to outgroup members who display them. The *infracumanization* effect is found even between groups that are not in conflict, and it is not simply a product of derogatory views of the outgroup, as both positive *and* negative secondary emotions are attributed to the ingroup.

Recent research and theory have proposed additional subtle forms of dehumanization. Nick Haslam and colleagues have argued that just as people are often denied uniquely human attributes such as secondary emotions (i.e., *infracumanization*), they can also be denied attributes that compose “human nature.” Whereas uniquely human attributes involve refinement, sophistication, and rationality and are seen as products of socialization, human nature attributes involve warmth, imagination, vivacity, and emotion and are often seen as innate. Haslam argues that when groups are denied uniquely human attributes, they are implicitly likened to animals, and when they are denied human nature attributes, they are likened to robots or machines.

Several studies support these claims: Groups perceived as lacking uniquely human attributes were associated with animals, and groups perceived as lacking human nature attributes were associated with robots. Additional studies suggest that similar processes can occur outside the domain of group perception. There is evidence that people tend to see others as having fewer human nature traits than they themselves have, implying that individuals see themselves as more human than others.

Dehumanization is a crucial concept for understanding intergroup conflict and especially for

understanding how conflicts can move from passive hatred and suspicion to active violence and hostility. It can disable people’s usual moral restraints by portraying others as nonhuman or less than human and therefore undeserving of respect, dignity, and protection. However, recent research and theory suggest that milder forms of dehumanization also exist, suggesting that people habitually attribute lesser humanness to other people and implicitly liken them to nonhumans. The implications of these subtle forms of dehumanization for intergroup relations remain to be seen.

## DEINDIVIDUATION

---

*Deindividuation* refers to the process whereby people engage in seemingly impulsive, deviant, and sometimes violent acts when they cannot be personally identified (e.g., in groups, in crowds,

when communicating on the Internet). Deindividuated behavior can occur for two reasons. Some deindividuated situations can reduce accountability, meaning that when people are hidden within a group, for example, they cannot be easily traced or blamed for their actions. As such, the effects of deindividuation can sometimes be viewed as socially undesirable (e.g., rioting). However, research has shown that deindividuation also strengthens adherence to group norms. Sometimes these norms conflict with the norms of society at large, but they are not always negative. As such, the effects of deindividuation can be rather inconsequential (e.g., “letting loose” on the dance floor) or even positive (e.g., helping people).

This entry provides an historical view of crowd behavior, examines the issues of accountability and group norms, and discusses the particular instance of computer-mediated communication.

### History and Background: Analyses of Crowd Behavior

Theories of *crowd behavior* provided the origins of modern deindividuation theory. In particular, the work of Gustave Le Bon in 19th-century France promulgated a politically motivated criticism of crowd behavior. At the time, French society was volatile, and protests and riots were commonplace (e.g., the revolutionary crowds of 1848 and the Paris Commune of 1871—see Émile Zola’s *Germinal* and Victor Hugo’s *Les Misérables* for literary accounts of the time). Le Bon’s work, which described group behavior in general as irrational and fickle, therefore found much support at the time.

Le Bon believed that being in a crowd allows individuals to act differently than they would act when alone. Being submerged in a large group of people allows an individual to react on impulses that would normally be controlled and perform behaviors that would normally be self-censored. Some of these behaviors, in the words of Le Bon himself, can be “primitive, base and ghastly.”

Le Bon argued that such undesirable behaviors can arise through three mechanisms. First, anonymity prevents people from being isolated or identified from others in a crowd. Being unable to be differentiated from others leads to a loss of personal responsibility, a sense of being untouchable,

and a loss of self-control. Le Bon further argued that this loss of control leads to contagion, in which a lack of responsibility spreads throughout the crowd and everyone begins to think and act in the same manner. Finally, people in the crowd become more suggestible. In other words, being in a crowd leads to blind acceptance of the demands of being in a crowd, and people unquestioningly follow the impulses that emanate from a common unconscious. Le Bon’s analysis suggests that crowds are messy, incoherent, and often dangerous rabbles in which people are not capable of self-control and are the victims of a common and inferior mind.

Le Bon’s work was very influential. For example, in the 1920s, Sigmund Freud argued along similar lines that crowds unlock people’s unconscious impulses. Individuals’ basic impulses (derived from the *id*) are controlled by crowd leaders, who, via a process similar to hypnosis, bring out the animalistic tendencies within all people involved. Similarly, in the 1920s, William McDougall argued that crowds bring out people’s instinctive primary emotions, such as anger and fear. Because everyone experiences these basic emotions and because people are less likely to have more complex emotions in common, the basic emotions will spread rapidly within a crowd as people express them. It was argued that this process, similar to Le Bon’s idea of contagion, leads to deregulated and impulsive behavior.

### Deindividuation and Accountability

Modern theories have applied and extended early principles to understand people’s behavior in smaller groups and in other contexts, such as when people have the opportunity to interact with others while concealing their identity and remaining anonymous. The term *deindividuation* was coined by Leon Festinger and colleagues in the 1950s to describe situations in which people cannot be individuated or isolated from others. According to Festinger and colleagues, being deindividuated brings about a loss of individuality in its members.

Similar to Le Bon, Festinger and colleagues proposed that being deindividuated (in particular within a group) reduces normal constraints on behavior, and people can do things they normally would not do because they are not directly accountable for their actions. They are in a sense liberated

to do what they like. Festinger and colleagues found support for this idea by demonstrating that participants who were engaged in a group discussion about their parents while being dressed alike in a dimly lit room were more likely to make negative comments about their parents than were participants in a control condition. In other words, the deindividuated situation allowed participants to express views that they would normally keep to themselves.

Philip Zimbardo is responsible for the development of the deindividuation theory most commonly known today. Zimbardo was more specific about what variables would lead to a state of deindividuation, as well as the behaviors that should result from deindividuation. Specifically, Zimbardo said that factors leading to a state of deindividuation were anonymity, responsibility (shared, diffused, or given up), group size and activity, altered temporal perspective (so that focus is more on the here and now than on the past or present), arousal, sensory input overload, physical involvement in the act, reliance on noncognitive interactions and feedback, a novel or unstructured situation, and altered states of consciousness (such as those brought about by the use of alcohol and drugs). Zimbardo claimed that all these factors act to minimize self-observation and evaluation, reduce concern for social evaluation, and lead to a weakening of controls based on feelings of guilt, shame, fear, and commitment. Thus, thresholds for expressing inhibited behaviors are lowered, and these behaviors are typically impulsive and often negative and antisocial.

In the 1970s, Zimbardo conducted a series of experiments in which participants were deindividuated by being dressed in Ku Klux Klan-style clothing. In one experiment, female participants were asked to deliver shocks to another female participant (who was in fact a confederate) as a response to incorrect answers in a learning task. Results revealed that the deindividuated participants gave shocks that were twice as long in duration as those given by participants who were not dressed in the deindividuating clothing. Zimbardo and his colleagues also carried out the famous Stanford prison experiment, in which student participants were deindividuated as prisoners or prison guards in a simulated prison setting at Stanford University. The students in the position

of guards were physically brutal to the students who were deindividuated as prisoners, so much so that the experiment had to be terminated early.

Ed Diener provided a theoretical clarification of Zimbardo's theory by introducing the concept of *objective self-awareness*. Objective self-awareness is high when people's attention is drawn inward toward the self and people actively monitor their own behavior. On the other hand, objective self-awareness is low when their focus is directed outward and people monitor their own behavior less or not at all. According to Diener, deindividuation is caused by a reduction in objective self-awareness, and factors that can reduce this self-awareness (e.g., anonymity or being in a group) can bring about deindividuation. Under conditions of deindividuation, attention is therefore drawn away from the self, and people are less capable of monitoring their behavior in relation to internal norms and standards.

To support this idea, Diener and colleagues observed the behavior of more than 1,300 children one Halloween in the 1970s, focusing on 27 homes where, on their visit, the trick-or-treating children were invited to take one candy from a table. Half of the children were asked where they lived and were asked for their names; half were not asked for this individuating information. Results revealed that deindividuated children and children in groups were more than twice as likely to take more than one candy. Diener and colleagues argued that the groups and anonymous children transgressed because the deindividuating conditions reduced their objective self-awareness and freed them from the normal constraints on their impulse to take more candies.

Steven Prentice-Dunn and Ronald Rogers reformulated Diener's theory in the 1980s by introducing the distinction between public and private self-awareness in deindividuated contexts. *Public self-awareness* is said to decrease due to anonymity such that people become less aware of how they appear publicly to others. Anonymous individuals, for example, are less aware about how they present themselves, and as a result, their behavior will tend to be antinormative, or against accepted norms and standards. Also, *private self-awareness*, or awareness of internal norms and standards, was argued to decrease due to the physiological arousal of being in a group and the high levels of group

cohesiveness. People therefore become less aware of their internal standards of behavior, and this will also lead them to behave more impulsively. The unique contribution here is that deindividuation is said to influence behavior by reducing the level of explicit control that people have over their thoughts and actions.

Some archival observations support this view. For example, Brian Mullen conducted a content analysis of the newspaper accounts of 60 lynchings committed in the United States between 1899 and 1946. He found that the larger the lynch mob, the more savagely they murdered their victims. In this case, the arousal of being within a large group with a common purpose increased the extent to which the group performed atrocities. The same principle can apply to anonymity. It has been found that cultures whose members conceal their identities before battle (e.g., by use of face paint) have historically been more likely to commit gruesome acts toward their prisoners than those who do not hide their identities.

### Deindividuation and Group Norms

Much of the theorizing about deindividuation up to this point has focused on how deindividuated states cause antinormative behavior. Although, in general, factors such as anonymity tend to increase antisocial behavior and increase aggression, not all research findings support this view. For example, Zimbardo found that soldiers paradoxically gave electric shocks of shorter duration when they were deindividuated in the Ku Klux Klan-style clothing he used in his earlier study. Furthermore, Robert Johnson and Leslie Downing adopted a similar paradigm but dressed female participants in either the Ku Klux Klan-style clothing or in nurses' uniforms. The participants dressed in the nurses' outfits were significantly less aggressive.

These results suggest that aggression and antisocial behavior are not inevitable by-products of deindividuated situations. In some cases in which norms and standards promote aggressive behavior (e.g., soldiers dressed in uniform may trigger norms associated with fighting and aggression), this may be the case. However, when norms and standards instead promote positive, nonaggressive behavior (e.g., nurses dressed in uniform may trigger norms associated with caring and helping),

behavior may be far from negative. In other words, deindividuated behavior increases adherence to the salient norms of the situation. Gustave Jahoda pointed out a real-life example of this effect of deindividuation. In some Islamic countries, women wear the full-length, dark-colored chador, which, instead of allowing women to engage in antinormative behavior, implies a strong system of norms of behavior to which women adhere.

Following this line of reasoning, some critics of traditional deindividuation theories argue that while group membership can have prosocial and antisocial consequences, these consequences should not necessarily be attributed to a loss of individual selfhood. Steve Reicher, Russell Spears, and Tom Postmes have argued that the notion of a *loss of selfhood* relies, inaccurately, on an individualistic conception of the self. Rational action is equated with the individual self, and group membership is equated with the loss of identity and of rationality. According to Reicher and colleagues, this position limits our understanding of deindividuation phenomena.

Drawing on *social identity theory* and *self-categorization theory*, Reicher and colleagues proposed that group membership does not automatically entail a loss of self. In each individual, there are many levels of the self. The self is not only the individual's personal identity or what separates that individual from other individuals. It also encompasses a range of possible social identities related to group memberships. That is, the self is also determined by properties that are shared with others, such as race, gender, and age. When at any given time a person feels part of a group, he or she will be attuned to the norms of that group. For this to occur, people do not need to be physically present with the group or be physically marked as a group member in any way. In turn, knowledge of the group's norms will guide people's behavior. In their *social identity model of deindividuation effects*, Reicher and colleagues argued that these social identity principles determine how people will behave in deindividuated situations.

Revisiting Zimbardo's paradigm in which participants were asked to wear Ku Klux Klan-style hoods and cloaks, Reicher and colleagues argued that asking people to wear such garments should have different effects on behavior depending on the salient social identity and what is happening in

the deindividuated context. Reicher and colleagues argued that manipulating deindividuation by immersion in a group should reinforce the salience of a prominent social identity (should one be prominent) at the expense of personal identity. So if personal identity is salient, wearing Ku Klux Klan outfits may increase personal focus, and people will rely on their own individual norms to guide their behavior. But if a group identity is salient, the deindividuation manipulation is more likely to have the effect of promoting behavior consistent with the norms of the group that people feel part of at the time, whether they are prosocial or antisocial.

Support for these ideas comes from a range of work on crowd behavior and group behavior in the laboratory. In one study, Reicher asked science and social science students to watch either a provivisection (science norm) or antivivisection (social science norm) video. Half of the participants took part as individuals, and half participated in groups. Further, half of the participants were anonymous via the use of masks. In the group condition, the masks were different colors to mark the different groups. Results revealed that people conformed more to their group norm when they were tested within a group. That is, scientists in groups were more provivisection than scientists tested as individuals, and social scientists were more antivivisection under these same conditions. Further, science students were more provivisection when they were deindividuated and when group membership was salient (the group-anonymous condition) than in the individual-anonymous condition. So when group membership is salient, anonymity can serve to increase adherence to the norms of that group.

### Computer-Mediated Communication

A modern example of deindividuation phenomena in action can be seen in *computer-mediated communication* (CMC; e.g., e-mail, blogs, social networking sites, chat rooms). CMC has provided people with new ways of communicating with each other, and the unique feature of CMC is that unlike many other media, people can communicate anonymously if they so wish. Just as traditional research on deindividuation predicts, CMC is therefore characterized by increased hostile, negative

interactions known as *flaming* and increased levels of personal disclosure.

Theorists typically attribute this type of behavior to the physical anonymity afforded by the medium. It is argued that the anonymity of CMC frees people from normal constraints on behavior, allowing people to behave impulsively and often antisocially. However, some research shows that although the deindividuated context of CMC blurs people's individual characteristics, an important consequence of this is that it also enhances the salience of groups and their associated norms.

As such, some research shows that people who are deindividuated by being anonymous on the Internet often adhere *more* to the norms of their groups than when they and others are identifiable. For example, research by Russell Spears and colleagues shows that group polarization, or the heightened expression of attitudes consonant with ingroup prototypical norms, occurs under anonymous CMC conditions. People's views, expressed anonymously, become more group-like and therefore more normative than antinormative. This is increased further if group identity is made salient.

Investigating the effects of anonymity on behavior in CMC is currently an active area of research in psychology. Therefore, a long tradition of research dating back to the 19th century continues today as individuals and groups find new ways to interact with each other.

## DELPHI TECHNIQUE

---

The *Delphi technique* is a structured forecasting and decision-making method that assesses and summarizes the individually held opinions and judgments of group members with little or no discussion or deliberation among the members. Named for the legendary Delphic oracle, this method involves surveying members repeatedly, with the results of each round of surveys informing the framing of the questions for subsequent rounds. The Delphi technique avoids some of the limitations of traditional group decision-making procedures and is particularly useful when the group members are so widely divided on issues that a face-to-face discussion will not be productive.

### Origin of Delphi

The Delphi method was developed by decision makers at the RAND Corporation, which is a non-profit institute that conducts problem-focused research in public policy, science and technology, international issues, energy, and the environment. Recognizing the inherent difficulty of reaching consensus among experts about future trends and events, the developers named their method after the famed Delphic oracle of Greek mythology. History claims that those who wondered about their future could consult the oracle for guidance and, in some instances, receive accurate if somewhat ambiguous prophecies of what lay in store for them. One king of legend, for example, asked the oracle if he should settle a dispute with a neighboring territory

through warfare. The oracle assured him that such an attack would bring about the fall of a great empire. Only when his army was soundly defeated and his kingdom lost did he realize that the prophecy referred to his own empire.

The modern developers of the Delphi technique turned to groups to reduce the ambiguity of the oracle's prediction about the future and also increase its accuracy. They recognized the value of basing decisions on the collective wisdom of a group. When many individuals examine an issue, the group's decision is informed by more ideas, and novel solutions and insights may emerge from the discussion. A group's scrutiny may also find and correct errors that may go unnoticed by a lone individual. Biases, however, can introduce inaccuracy into the decisions made by groups during face-to-face deliberations. The more rhetorically forceful members of the group may convince others to adopt their position, more through force of argument than through rational persuasion. Members may feel uncomfortable expressing their position in the group context, particularly when they are relatively new to the group and find that they disagree with what seems to be the group's emerging consensus. Members may also be so deferent to those with more authority in the group that they do not air dissenting views. To counter these negative group processes, the originators of Delphi recommended surveying members of the group individually, before any deliberations occurred, to capture their views before they were influenced by others in the group.

### Using the Delphi Method

The Delphi method was initially used for forecasting trends—particularly technological developments—and assessing the relative importance of alternatives. The Delphi method is particularly well suited to handling ill-formed problems, ones that cannot be solved by a systematic review of the available data or the application of a rational decision-making method that will identify the best or most satisfying solution. A group may wish, for example, to identify the economic changes that may result from global environmental and political events; set national priorities for the next decade; explore ways to improve health care; find and rank the causes of employee dissatisfaction; and set

budgetary initiatives. Given the enormity of these issues, the group may begin the process by using a Delphi method to narrow the issues and identify tentative solutions.

The Delphi coordinator would begin the process by developing a short list of questions on the topic and then gathering the answers of a carefully selected group of respondents. Responses are then pooled and communicated back to the respondents, who are asked to restate their responses to the original items, comment on others' responses, or respond to new questions that emerged as important in the first round of surveying. This process is repeated until a solution is reached.

Delphi procedures vary considerably from this basic formula, but most include these basic elements. The method is a highly structured one, for it requires a coordinator who selects the respondents, designs the survey questions, collects the data from respondents, and develops each interim summary and report. By design, respondents usually do not know who else is in the Delphi group. Delphi is a group procedure, but it avoids face-to-face group discussion and deliberation to encourage openness and a free-wheeling flow of ideas. Delphi is also an asynchronous and geographically dispersed decision method, for the respondents respond when they can, at different times, rather than at the same time and in the same place (such as a conference room table).

Delphi is also an iterative procedure in that the question-answer process is repeated several times. On the first assessment, participants list their own solutions to the questions posed, but their responses are summarized by the coordinator, who then feeds the information back to the group. The group members cannot directly discuss any issues or ideas raised in the first round, but they can at this point amend their original answers or offer new points and insights. As this process is repeated, a consensus emerges, and in some cases, participants may be asked to vote on the validity of the conclusions that emerge. The coordinator may stop the process after only one iteration if a solution emerges quickly, but complex, unclear problems usually require many more iterations.

Group composition is a critical determinant of the success of Delphi. In most cases, a Delphi group includes between 5 and 20 respondents because the responses of too many respondents

can be difficult to summarize for subsequent iterations. Originally, the process called for surveying experts who had different opinions on the issue but had neither the time nor the inclination to meet in a traditional face-to-face meeting. If, however, generalizability is desired, then the coordinator should use proper sampling procedures so that the results are representative of the views of those beyond the Delphi group itself. Moreover, and as with most group methods, the quality of the results will be determined by the involvement and motivation of the members. If respondents do not take the time to respond diligently and thoughtfully, then the Delphi will yield little useful information.

### Advantages and Limitations

As a performance technique, Delphi can be very usefully applied when issues need clarification, when the opinions of a wide range of people are important, and when face-to-face meetings are impossible for the people whose input is required. The method also encourages a deep, reflective analysis of an issue because participants can take the time they need to consider the issue. Unlike a face-to-face deliberation, in which the discussion moves at a pace set by the collective, participants in a Delphi can respond after they have considered the issue fully.

The method is not without certain limitations. First, the project planners must clearly conceptualize the question they wish to answer; since the group members will be responding individually, they will not have the opportunity to clarify the question via discussion. The coordinators must therefore make certain that the questions posed are unambiguous so that each individual is responding to the same set of assumptions. Coordinators must also avoid phrasing their questions in a way that might bias the responses of the group members. Second, because it involves repeated assessment of members' opinions via surveys, a Delphi is, as originally conceived, a relatively slow procedure. Time and effort were needed for the organizer to write and send out the surveys, collect responses, and generate the next round of questions. Furthermore, if respondents were not motivated to complete and return the questionnaire, then the process broke down completely.

Despite these drawbacks, the limited evidence pertaining to the effectiveness of Delphi suggests that the technique is more effective than an unstructured problem-solving session. The method is particularly effective when the group has the opportunity to meet in later rounds of the process to deliberate in a face-to-face situation. Also, technology offers some solutions to these drawbacks. The Delphi method was developed as a paper-and-pencil technique; the coordinator developed the questions, mailed them to respondents, respondents mailed back their responses, and the coordinator developed the summative report before starting the next iteration. Modern Delphi methods use computer-based group support systems to coordinate the process.

## DEPERSONALIZATION

---

*Depersonalization* is a concept developed by self-categorization theorist John Turner and his colleagues in the 1980s to refer to the process of thinking of the self at a particular time as a group member rather than as a unique individual. Depersonalization can be seen as a process of stereotyping, but unlike other forms of stereotyping related to perceiving other people as group members, it involves self-stereotyping. To put it another way, depersonalization is the transformation from thinking of oneself as “I” or “me” to “we” or “us.”

*Self-categorization* theorists believe that depersonalization underlies all group behavior, ranging from helping behavior to violent and brutal conduct such as genocide. It is argued that none of these phenomena is possible without people coming to see themselves as members of groups.

Depersonalization is a vitally important concept with an unfortunate name. Depersonalization does not refer to a loss of self but to a change in the self at a particular time, that is, from seeing oneself as an individual with individual attributes, opinions, and so on to seeing oneself as a group member who shares attributes, opinions, and indeed a social identity and is therefore in these ways identical to or interchangeable with fellow group members. Depersonalization is thus very different from the concept of *deindividuation* developed by Philip Zimbardo and colleagues, which involves a loss of individuality, or to the concept of *dehumanization*, which relates to perceptions of other people as nonpeople. This entry describes the process and provides some examples.

### How It Works

Depersonalization is a consequence of the salience of a social category or group identity, in the sense that depersonalization takes place as a consequence of a particular group or social category membership becoming salient (psychologically switched on or activated). For example, when the social category of parent is salient (as in a meeting of parents at a school in order to seek government funding), it is likely that people will have a depersonalized self-perception; that is, they will perceive themselves as more similar to, and to a certain extent interchangeable with, other parents.

In such situations there is likely to be a shared perception of common goals (e.g., improving learning conditions, organizing sporting or social events for children) and normatively valued ways to achieve these goals. Alternatively, in situations in which the social category of parent is not salient, the same people will tend to think of themselves as individuals. The term *depersonalization* has been used in a related but different sense by Michael Hogg and colleagues (e.g., in *uncertainty-identity theory*) to reflect the way in which the perception of self and others is captured in terms of the relevant context-specific category prototype.

Self-categorization theory argues that the depersonalization of self-perception is the basic process underlying group phenomena such as social stereotyping, group cohesiveness, ethnocentrism, cooperation and altruism, emotional contagion and empathy, collective action, shared norms, and social influence processes. Therefore, in all situations in which people come to think and act together as a group, the process of depersonalization is believed to take place.

### Some Examples

To understand what depersonalization is and is not, it is useful to consider a range of examples. Let us take a chilling but familiar example of extreme forms of collective action. The atrocities committed on September 11, 2001, by Islamic militants who were prepared to commit suicide to maximize the death and destruction they wrought on America (and many visitors from other countries) is an example of depersonalization. The self-categorization analysis of this situation is that the people flying planes into buildings were not acting as individuals but as members of a group in conflict with Americans (and others), and the extent of this depersonalization was so great that these people were prepared to die for their cause while killing others.

Lest it be assumed that this process is wholly destructive and negative, bear in mind that hundreds of emergency service workers also willingly placed themselves in the utmost danger to rescue trapped victims (broadly speaking, members of their American ingroup) from the burning towers. The deaths of these emergency workers can also be explained in terms of depersonalization.

To take a less violent but equally pressing issue, the success of the campaign to halt global warming also depends (according to self-categorization theory) on depersonalization. To the extent that people come to see themselves not as individuals, and not even as citizens of nations or residents of towns, but as human beings who together share a planet (i.e., they “think global”), they are more likely to act (locally) to reduce carbon emissions. A similar idea can be seen in the work on *recategorization* or *common ingroup identity* by John Dovidio, Samuel Gaertner, and colleagues in relation to prejudice reduction.

In the work of Stephen Reicher and colleagues, depersonalization is held to explain instances of collective action such as crowd behavior at a political rally. Mass behavior (many people doing the same thing at the same time, perhaps even in different situations) is difficult to explain in terms of the individual needs, values, or motivations of the many different people involved. Depersonalization is offered as an explanation of the way people not only come to see a cause as their cause (and as an expression of their values and beliefs) but also as an explanation of the way in which appropriate conduct or forms of action are rapidly agreed on (e.g., that a protest should be peaceful).

There are instances in which depersonalization can be confused with individual self-perceptions and processes. The actions of people trapped in a burning building who trample others to death are sometimes interpreted as collective or mob action when they are more properly understood as efforts for self-preservation. If the people trapped in the burning building were genuinely acting in a depersonalized manner, they would be more likely to seek to rescue the other people than to harm them.

The salience of a categorization does not inevitably lead to depersonalization and interchangeability with other group members. In a nightclub, for example, where heterosexual men and women scan the room for attractive potential partners, gender is a highly salient category, and men and women perceive clear differences between those categories. It would be wrong to suggest, though, that men in those circumstances typically see themselves as interchangeable with other men or that women see themselves as interchangeable with other women, but both these things can become possible (perhaps following a conflict between men and women).

Depersonalization is also important for understanding the phenomena of stereotyping and racism, in which people subject members of particular ethnic, cultural, or religious groups to unfavorable treatment on the basis of negative beliefs about those groups. To take an example, attacks on highly identifiable Muslim women increased significantly after September 11, 2001, as non-Muslim Americans began to see all Muslims as responsible for the atrocities that had occurred. As these examples demonstrate, the concept of depersonalization can help explain extreme forms of racism without

resorting to the pathology of certain individuals as an explanation. Depersonalization seems to present in collective behavior that is regarded as both socially desirable and undesirable.

## DESEGREGATION

---

*Desegregation* is a political and social process designed to end and reverse the undesirable effects of racial segregation by creating a more balanced representation of members of different groups. Racial segregation, prevalent throughout the world, occurs in many areas of social life, such as schools, workplaces, the military, and housing. In the United States, attempts to combat it centered on school desegregation, which in turn generated considerable social and political upheaval. Because most research on desegregation focuses on school desegregation of Blacks in the United States, that is the main focus in this entry. Specifically, the entry first reviews recent U.S. policy changes that deal with de facto segregation and patterns of resegregation in schools. It then examines school desegregation effects on academic achievement and intergroup relations.

The fight for desegregation of American schools began after realization that segregated Black and White schools created unequal opportunities for Black students. As a result of segregation, Black achievement suffered and relations between the two groups worsened. In infancy, we learn to simplify and categorize people into those belonging to our group (i.e., ingroup) and those belonging to some other group (i.e., outgroup). Simultaneously, we come to prefer our ingroup, while attributing negative stereotypes to outgroups. Furthermore, we treat ingroup members as individuals, whereas we tend to see outgroup members as a homogeneous social category. Desegregation is based on the belief and scientific finding that segregation perpetuates our tendency to ethnically categorize people and discriminate against outgroup members.

### Historical Overview and Policy Changes

Multiethnic societies face many challenges. Although their subgroups often depend on one another for survival, these societies are plagued by intergroup rivalries, and their histories are marked by struggles for equality. Simultaneously, each group needs to preserve its own identity and even independence. As group members gravitate toward their ingroup, while distancing themselves from outgroups, de facto segregation emerges. Occasionally, segregation becomes the law (i.e., de jure segregation), as when Blacks were excluded from White schools in the United States. Although met with harsh criticism and opposition, the landmark 1954 U.S. Supreme Court decision, *Brown v. Board of Education*, sought to end and even reverse harmful effects attributed to de jure segregation.

*Brown v. Board of Education* initiated both voluntary and court-ordered attempts to end de jure segregation. The 1980s and 1990s were marked by attempts to end de facto segregation. Specifically, districts voluntarily initiated desegregation, explicitly adopting race-conscious student assignment policies and using either a weighted lottery or a system of tiebreakers to increase enrollments of either Whites or non-Whites. In Seattle, priority was given to students with a sibling in their school of choice. Racial tiebreakers were applied when a school's composition differed more than 15% from that of the district. Thus, in

oversubscribed schools wherein the percentage of Whites exceeded their percentage in the district, Black students received priority, whereas a White student was assigned to a second-choice or lower-choice school. Closeness to school was considered next; the final tiebreaker was a lottery. Other districts, such as Jefferson County, Kentucky, adopted similar systems.

Adoption of race-conscious student assignment policies soon led school districts to face legal hurdles, typically because race was used to determine admissions. Higher education settings made race one among many individualized factors that determined admissions—considerations often not possible in K–12 schools, where admissions cannot be based on prior achievement to the same extent as in higher education settings. Opponents of race-conscious assignment policies noted that these policies counter a color-blind ideal, perpetuating instead the idea that race matters most.

The courts shifted between favoring and opposing race-conscious student assignment policies. Challenges to race-conscious assignment policies succeeded initially. Over time, however, courts began favoring them. Thus, in two influential cases combined in *Parents Involved in Community Schools* (Seattle and Jefferson County), wherein mothers of two White boys challenged their district's rejection of their son's choice of school, both the district courts and circuit courts of appeals ruled that voluntary race-conscious assignment policies not only serve, but are also narrowly tailored to meet, governmental interests. This change in view followed the influential 2003 *Grutter* case, wherein the Supreme Court rejected a challenge to the University of Michigan Law School's affirmative action policy and affirmed *Regents of the University of California v. Bakke*, 1978. The Court ruled that race can serve as one of many criteria that determine K–12 and college admission decisions. Subsequently, however, the plaintiffs in *Parents Involved in Community Schools*—arguing that higher education contexts differ from K–12 schools—appealed to the Supreme Court, which reversed the application of *Grutter* to lower-level K–12 schools and ruled instead that the Seattle and Jefferson County race-conscious student assignment policies violated the Fourteenth Amendment's equal protection clause. This decision ended struggles against de facto

segregation and limited the domain of *Grutter* to higher education contexts.

At the same time, over the past 16 years, courts lifted more than 35 court-imposed desegregation orders by granting school districts *unitary status*, which usually meant a return to neighborhood schools. The landmark 1991 *Board of Education of Oklahoma City Public Schools v. Dowell* and 1992 *Freeman v. Pitts* cases clarified qualifications for unitary status as being (a) compliance with the desegregation order for a limited time, (b) elimination of segregation to the extent practicable, and (c) displayed commitment to the district's constitutional obligations. The principle of *schooling closer to home*, which guided this process of a return to neighborhood schools, leads, unfortunately, to resegregation. In Oklahoma City, the percentage of Whites in Black schools decreased from 34% in 1988 to 21% in 2000—a pattern typical of other unitary districts.

Although some think a return to neighborhood schools will improve their quality by strengthening community attachment and increasing parental involvement and social capital, examination of Nashville public schools showed that racially isolated Black schools were located in zones with few assets and numerous liabilities: impoverishment, with 43% of the residents lacking a high school diploma (compared with 15% in neighborhoods of integrated schools); high crime rates; and a lack of libraries, hospitals, and higher education institutions. Predominately White and racially integrated schools, on the other hand, boasted more affluent neighborhoods.

### Consequences for Achievement

The adequacy of these policies is best evaluated after their effects are considered. Recent shifts from desegregated schooling to growing resegregation would not be important had desegregation failed to improve academic achievement. Indeed, according to a National Academy of Education report, earlier studies and both narrative accounts and a summary of six meta-analytic reviews showed little evidence of benefit. More recent evidence, however, seems more positive. Those who attend integrated schools are more likely to graduate from high school; attend and graduate from college; have higher and more realistic occupational

aspirations and obtain better paying jobs; and exhibit a smaller educational achievement gap. A National Academy of Education committee resolved this discrepancy in outcomes by suggesting that the larger, state-level databases of these later studies increased their sensitivity to beneficial effects.

The magnitude and persistence of desegregation benefits have been debated. Narrative reviews and meta-analyses suggest that voluntary plans benefit Black achievement more than mandatory plans and that younger attendance at desegregated schools yields more benefit. Furthermore, according to the National Academy of Education report, desegregation does not affect achievement of Whites.

Experts argue that achievement differences between minority students attending segregated and desegregated schools reflect differential funding. Until recently, local property taxes funded public schools, enabling districts in wealthier communities to receive more funding and spend more money per student. These disparities also occur within districts. Schools with higher proportions of poor students receive less funding from local sources. Race is marginally related to local funding, which on a local level means that minority schools receive less funding than White schools. Making all this particularly problematic, higher spending promotes achievement. Desegregated schools are presumably wealthier than segregated inner city public schools because districts typically achieve desegregation by busing minority students into existing predominantly White schools. Thus, patterns of local funding perpetuate disparities in wealth and contribute to the achievement gap between inner city and desegregated schools.

Nonetheless, achievement levels of White students in integrated, affluent suburban schools exceed those of their minority counterparts. Contributing to this gap is that these so-called integrated schools, even when balanced in percentages of White and Black students, remain segregated on a more fundamental level—with both outside and inside forces operating to create within-school segregation. First, Blacks, and perhaps other minority students, start at a disadvantage. More White than Black children were enrolled in preschools by 1991. Their home environments likely differed. In integrated affluent suburban schools, although median family income is \$80,000, that of White

students exceeds that of Blacks. Minority students often live in neighborhoods with fewer material advantages, lower family property values, and fewer books and computers in homes.

These differential starting achievement levels promote within-school segregation. To students' misfortune, instead of offering remedial instruction, schools overwhelmingly place minorities in lower tracks, taught by less qualified teachers who, like the rest of the society, have lower expectations for minority students. Moreover, Black students continue their struggle for equal education even after high school. For example, their ability to understand racism and deal with it predicts their achievement in colleges and universities.

Given these considerations, the persisting achievement gap is not surprising. In 2001 the National Center for Educational Statistics found only 1 in 100 Black 17-year-olds able to read and interpret technical data, compared with 1 in 12 Whites. After high school, Black students' reading and math skills match those of White eighth graders. In the 2000 U.S. census, 72.3% of Blacks older than age 24 had completed high school (compared with 83.6% of Whites), and Blacks were only half as likely as Whites to have completed a 4-year college—a difference that holds when controlling for prior test scores and socioeconomic factors. Moreover, standardized test scores and high school graduation rates are even lower in predominately minority schools.

Economic disadvantages among minorities in general and academic tracking in particular have undermined effective desegregation policy. Though it is tempting to blame school boards, schools, and historical and economic patterns for the policy failure, blame also rests on prejudicial attitudes. Burdens of desegregation have often fallen on Black and Latino students. White students frequently have not enrolled when reassigned to Black schools—a resistance that has continued even in high-performing schools with affluent students. Private schools further contribute to segregation. Consistent with *symbolic racism theory*, wherein the negative White racial attitudes that are formed in early childhood are later covertly expressed by opposing busing or affirmative action programs, parents exhibit exaggerated negative reactions to the system-produced negative characteristics of public schools—such as discipline

problems, insufficiently challenging academics, and too few extracurricular opportunities—to justify enrollment of their children in White private schools.

### Consequences for Intergroup Relations

Although initiated primarily to offer equal educational opportunities, school desegregation also impacts intergroup relations. In particular, school racial composition affects intergroup friendships, conflicts, and comfort. *Contact theory* posits that in addition to quantity of racial contact, equal status, authorities supportive of intergroup contact, and cooperative endeavors to achieve common goals augment development of intergroup friendship and reduce conflict. Meta-analytic evidence clearly shows that contact reduces prejudice. Furthermore, this benefit generalizes beyond those in the immediate situation, meaning that integrated schools improve attitudes not only toward outgroup students attending them but also toward other members of those outgroups. This contact effect is particularly strong for children and college students, further emphasizing integrated schooling's importance. Although equal intergroup status, support for intergroup contact by authorities in the situation, and intergroup cooperation toward common goals further augment contact's benefits, contact also reduces prejudice between groups lacking these conditions, perhaps because it induces liking, reduces threat and anxiety, or a combination.

Critics sometimes attribute prejudice-reducing contact effects to selection bias, arguing that unprejudiced people are drawn to contact, whereas prejudiced persons avoid it. Yet experiments and studies that allowed no choice of avoiding contact show particularly beneficial effects. Emphasizing the importance of more personalized contact, White students randomly assigned to roommates of different ethnicities were both more comfortable when interacting with minorities and more likely to develop interracial friendships than were Whites assigned to same-race roommates. Furthermore, programs that encourage cross-racial understanding without providing opportunity for intergroup contact are less effective than those programs providing contact.

Beneficial contact effects are evident by age 3. Whereas Anglo-British children attending majority

White schools favored their ingroup over the outgroup and judged cross-race dyads as less likely to be friends than same-race dyads, those in more diverse schools did not similarly differentiate same-race and cross-race dyads. Childhood contact is particularly important in that prejudice develops early and often becomes resistant to change.

In addition to contact theory, two other theories bear on the development of both friendships and conflicts in multiracial settings. *Macrostructural theory* argues that racially heterogeneous settings are conducive to the development of both many interracial conflicts and many interracial friendships. *Group threat theory* argues that interracial conflict is determined by the relative size of the groups, with equal-sized groups having more overt interracial conflict than numerically disproportionate groups.

Supporting macrostructural theory, a study that measured students' and teachers' perceptions of both interracial friendliness and interracial conflict showed greater schoolwide racial heterogeneity to be linked to both increased interracial friendliness and conflict. Yet tracking, which necessarily reduces within-classroom heterogeneity, was associated with decreased friendliness but increased conflict. Though consistent with contact theory, this conflict effect counters macrostructural theory. Support from authorities in the setting, as measured by schools' proportion of minority teachers, was associated with reduced conflict but was unrelated to friendliness. Consistent with much research, cooperative interracial contact while working on interdependent goals increased friendliness and reduced conflict. When schools required more group work, students perceived more interracial friendliness, and teachers reported less conflict. However, the association between integrated extracurricular activities and reduced conflict did not extend to friendliness. Consistent with group threat theory, lessened friendliness characterized biracial schools with equal-sized groups of students, but contrariwise, their teachers did not perceive more conflict. Students in small racial minorities were more likely to select friends from their own group.

Besides influencing friendships and conflicts, contact influences one's feelings of comfort when one is interacting with outgroup students. Furthermore, racial composition further moderates

comfort. For Blacks, a higher percentage of White students was associated with increased comfort when interacting with other-race students. All other racial or ethnic subgroups displayed a curvilinear relationship, with higher percentages of Whites associated with greater comfort only to a point. The points beyond which subgroups associated higher White percentages with decreased comfort in their intergroup interactions are as follows: Asians, 39%; Latinos, 33%; and Whites, 44%. Thus, when students attend diverse schools wherein Whites are a numerical minority, they are more comfortable in their interactions with outgroup students. Together, these findings indicate that the relationship between heterogeneity and friendliness is curvilinear.

In sum, desegregated schooling benefits intergroup relations. Greater opportunity for interracial school contact increases interracial friendships. These benefits have been shown to be long-lived in that desegregation becomes perpetuated later in life via the increased interracial interaction among adults who attended desegregated schools and their more effective subsequent functioning in desegregated settings. Desegregated schooling augments the development and stability of interracial friendships for both minority and majority groups, leads to more positive intergroup attitudes both in the workplace and in general, contributes to greater civic engagement, and enables students to acquire racial acceptance. White students who attend integrated schools are more tolerant and less fearful of Black peers than are White students attending segregated schools. Likewise, White students assigned Black roommates express more positive attitudes to affirmative action policies. Even though these effects apply to students of all racial groups, recent research shows that contact is less effective at reducing intergroup bias among minority than among majority group members. The prejudiced attitudes expressed by majorities during the contact likely lead minorities to experience intergroup contact more negatively. Researchers need to further investigate this finding and seek ways to improve contact experiences of minorities.

### Conclusion

School desegregation faced enormous challenges from the start and was never fully implemented.

Perceptions that it had failed encouraged courts and policy makers to abandon voluntary race-conscious student assignment policies, creating a return to neighborhood schooling. The racial achievement gap persists and temporally varies, having narrowed between 1970 and 1980 but widened by 1988. Desegregated schools, though deficient, are better than inner-city public schools or neighborhood schools. Integrated schooling better minority achievement and intergroup relations, making the return to segregated or neighborhood schools problematic. Research on implementation of desegregation in other countries, and in other domains, such as the workplace and housing, is needed.

## DEUTSCH, MORTON (1920– )

---

Morton Deutsch is a *conflict theorist*. He has made sizable contributions to the body of knowledge on interpersonal and intergroup conflict, social injustice and oppression, and trust and threat.

Deutsch was born in 1920. He completed his undergraduate training at City College of New York, took a master's degree at the University of Pennsylvania, and earned his PhD from the

Massachusetts Institute of Technology in 1948, where he was one of the last students of Kurt Lewin. From 1948 to 1956, he was on the faculty of New York University. He left there to spend 8 years as a researcher at Bell Labs. In 1958, he became a licensed therapist. In 1963, he joined the faculty of Teachers College at Columbia. He retired from Columbia in 1990, but as of this writing remains active in the International Center for Cooperation and Conflict Resolution (ICCCR) at Columbia, which he founded. This entry provides an overview of his research.

### Cooperation and Competition

Deutsch's impact was immediate. His doctoral dissertation contrasted the performance of cooperative groups (in which all members received the same reward for an output) and competitive groups (in which magnitude of reward was determined by each individual's contribution to the effort). He found the cooperative group members to be communicative, helpful, friendly, and supportive; oriented toward achievement; able to reach consensus; capable of coordinating efforts; and highly productive. By contrast, competitive group members were obstructionist, disrespectful of others' opinions, and inattentive; had little sense of "we-ness" and little interest in supporting others; were unconfident; frequently lacked consensus; and were uncoordinated and unproductive.

This result led Deutsch to ask how to instigate cooperation within a group. He concluded that *trust* is a key prerequisite. He defined trust informally as "confidence that [one] will find what is desired rather than what is feared" (*Resolution of Conflict*, 1973, p. 148) and formally as the subjective probability of a positive outcome occurring exceeding the subjective probability of a negative event occurring. Immediacy of the outcome also impacts trust—a positive outcome that is very likely to occur, but not for a long time, is unlikely to induce much trust, for example.

If the target of trust is another person, one must try to determine the person's intentions, and the reliability of those intentions, before assigning probabilities to the positive and negative outcomes. Perceived reliability is a function of the person's motivation to perform the intention; the person's commitment to the behavior; the extent to which

the behavior is clearly focused on a target; and the extent to which the desired outcome can be produced only by that one specific behavior.

Under this framework, a person who states an intention to donate money for a good cause can be trusted to follow through on the intention if the money is needed immediately (motivation) and if the cause is important to the person (commitment); is directed toward one specific goal (focus); and needs only monetary support, with no other resources being relevant (specificity). Failure to meet any of these conditions (e.g., the money will be applied to a diffuse set of endeavors) will decrease trust that the person will act.

After developing this model, Deutsch executed some studies examining the conditions under which interpersonal trust is more and less likely to develop. His primary focus was on individual differences and the extent to which they can predict differences in trusting. He found, for example, that highly authoritarian people are less trusting than low-authoritarian people. His notion of *motivational orientation* had even more impact. Deutsch argued that people enter into an interaction with an overarching goal for the outcomes. While many such goals can be stated, three dominate: cooperation, or maximization of outcomes for all individuals; competition, or maximization of the difference between own and others' outcomes; and individualism, or maximization of own outcomes with no concern for others.

Deutsch found cooperators to always be quite trusting; individualists to be trusting when the intended behavior had to be publicly announced or when participants could interact with each other; and competitors to never really be trusting, even if there was public commitment to an intended behavior (although this intervention was most likely to produce some cooperation in competitors) or opportunities for communication (especially harmful; competitors either declined the chance to interact or used the experience to send misleading messages). Motivational orientation has since become a standard variable in the study of *cooperative interaction*.

### The Trucking Game

Deutsch, in collaboration with Robert Krauss, also developed a new paradigm for studying negotiation

behavior. The Trucking Game pits two individuals against each other as owners of rival shipping companies. The opponents are located on opposite sides of a space, and they must move a loaded truck from a warehouse to a delivery site on the other side of the space. The trucks thus travel in opposite directions. Individual profit from the business is a function of how quickly the load gets delivered.

Each person has the option of using either a private, winding road that takes a while to navigate (and hence returns a small profit) or a short, public single-lane road that returns a large profit. The conflict is that if both drivers decide to use the single-lane road at the same time, they will meet in the middle, causing a delay in delivery, and hence a decline in profits, while the conflict is resolved. The optimal strategy is to alternate use of the public and private roads, and an interesting question is how frequently individuals discover that solution.

Deutsch, however, added another component that became the defining feature of this paradigm: At each end of the public road are gates, and each driver controls the gate nearest his or her warehouse. Each person thus has the ability to make the public road nonfunctional for the other. One could, for example, close one's gate after the other person has already started down the public road, forcing him or her to return to his or her warehouse and use the private road, which would produce a loss of money on that round. The gate thus constitutes a threat, and Deutsch was especially interested in how threat impacts cooperation.

In his original studies, neither, one, or both of the truckers had the ability to close a gate. These conditions constitute no, unilateral, and bilateral threat, respectively. The results were striking: In the no-threat condition, both parties ended with net gains; in the bilateral-threat condition, both ended with net losses; and in the unilateral-threat condition, both also ended with net losses, although the losses were not as severe as in the bilateral-threat condition, and the threatener incurred less of a loss than the threatened. The key point, though, is that an individual who could harm with no fear of retaliation nonetheless lost money. Deutsch's conclusion was that it is better to have a weapon than not (and if your opponent has one, it is better for you not to have one), but it is best of all for neither party to be armed.

### Insights

Deutsch's further research into cooperation and competition led him to two important insights. The first he termed his *crude law* of interpersonal relations: The phenomena that result from cooperation or competition themselves produce cooperation or competition. For example, cooperation produces trust, and cooperation results from trust. The law is important because it explains how to produce cooperation or competition rather than what happens when cooperative or competitive behavior occurs. In this way, it complements his original work. Deutsch labeled it a *crude law* because it deals with cause-effect relationships only in passing; its purpose is instead to describe underlying influences (Deutsch himself described it as *genotypical*).

Deutsch's second insight dealt with the nature of *justice*. He came to believe that the negative effects of competition were endemic of a larger societal problem of unjust resource distribution. In his view, cooperation produces people who are good group members, and the hallmark of cooperation is a just system of reward. From the crude law, it follows that rewarding people justly will lead to enhanced cooperation, which in turn makes people more group regarding. Deutsch thus argued that equality or need-based reward schemes will be associated with harmonious relations, and equity-based rewarding will be associated with impersonal relations. Implementing fairer reward schemes would, then, minimize societal conflict. He believed, however, that there are strong social pressures against acknowledging the existence of injustice, and without such acknowledgment, attempts to bring forth new schemes are unlikely to succeed. Deutsch thus called for research into techniques for counteracting these pressures.

The remainder of his career was dedicated to this goal, with a particular emphasis on the efficacy of education. Indeed, the ICCCR was created not only as a place for cross-disciplinary collaboration on issues of conflict and justice but also as an outreach organ for training others in conflict resolution and enhancement of social justice.

## DEVIANCE

---

The term *deviance* describes situations in which people violate social rules and conventions. However, there may be many motives and causes for engaging in deviant behavior, and there may also be causes for defining other people's behavior as deviant. This entry reviews sociological and psychological perspectives on deviance.

### Sociological Perspectives

Sociologists have analyzed how social order is sustained both in society as a whole through laws, institutions, and distribution of wealth, and through microsociological mechanisms of personal relationships, roles, and influence. Most everyday actions, such as buying and selling items, arriving for work in the morning, driving a car, and greeting people, are governed by clear social rules. People's understanding and following of these rules are essential for the smooth running of society.

### Anomie

Émile Durkheim viewed deviance as a *social fact*, an inevitable part of how society functions. He argued that deviance is a basis for change and innovation, and it is also a way of defining or clarifying important social norms. One reason that people engage in deviant behavior may be a state of *anomie*, which is the absence of clear social norms. For people to understand what these norms are, the rules need to be tested occasionally. As an example, among stock market speculators, the boundary between clever dealing and improper dealing is defined by laws. Most of the time, however, inappropriate behavior is likely to be regulated by informal social processes. The groups surrounding these individuals are likely to put pressure on them to behave in line with relevant norms.

Robert Merton's theory of anomie proposed that deviance is often a response to situations in which goals cannot be achieved through conventional behavior. In democratic societies, people from wealthier, better connected, and more privileged circumstances have easier routes to personal success and prosperity. When others realize that routes to achievement are blocked, they experience *strain* and are likely to turn to tactics that will help them get past the blockages. Merton regarded deviance as only one of several possible reactions to frustration, and his ideas have much in common with other theories (see *relative deprivation*, *social identity theory*, and *system justification theory*). Merton proposed five types of reaction: conformity, innovation, ritualism, retreatism, and rebellion. Both innovation and rebellion are forms of deviance. Whereas innovation is likely to involve breaking rules to achieve normative objectives (e.g., stealing to become rich), rebellion involves challenging the rules or objectives themselves (e.g., campaigns to legalize abortion or criminalize certain types of drug use or protests such as the march in which more than a million people gathered in London to oppose Britain's involvement in the Iraq war).

Various types of social control inhibit deviance. Primary groups such as families, work groups, or teams and close social groups may control deviance through direct or immediate sanctions over their members. If a child is disobedient, a parent can respond immediately, just as a sports referee can immediately exclude a cheating player. In close-knit communities, there is a high level of primary control, so if a member breaks an important rule, that member is in significant danger of exclusion from the group. In some cultures, the family reputations of people may be put at risk if a member engages in a criminal or shaming activity. Extreme reactions such as so-called honor killing of women for committing adultery, or even for having been raped, highlight the fact that deviance is not easily defined in terms of a specific behavior. Instead, deviance is defined by the formal or informal rules imposed by other people in the social context in which the behavior occurs. Social control is also exerted through secondary groups that are more abstract, such as organizations that use formal power and regulations, as well as through membership in larger

social categories such as gender, which are associated with wider social norms. Travis Hirschi, analyzing the causes of delinquency, proposed that social control is based on bonds of attachment, commitment, involvement, and belief.

### *Labeling*

Edwin Lemert distinguished between primary and secondary deviance. *Primary deviance* involves relatively trivial, but generally tolerated, departures from rules. For example, people occasionally take items of office stationery (pens, sticky tape, etc.) for personal use. When committing such acts, most people feel able to sustain the idea that they are still honest and law abiding, acting within the bounds of their roles, and that these acts are minor exceptions. Linked to these forms of primary deviance, sociologists also observe that societies allow certain *norms of evasion*. For example, drivers on freeways often travel a little faster than the official speed limit. It is widely accepted that breaking the limit will be tolerated, but only up to a point. These norms provide fuzzy boundaries. People who show that they conform to most rules are usually given a little freedom to bend some rules, but if authorities so choose, they can impose the rules strictly.

*Secondary deviance* describes a situation in which a person has been publicly identified as deviant, such as by being classified as mentally unstable or criminal. Howard Becker argued, on the basis of his research on marijuana smokers, that deviant behavior is simply behavior that people label as deviant. *Labeling theory* emphasizes that being labeled can generate a self-fulfilling prophecy whereby others behave toward the labeled person in ways that confirm or reinforce the label. A person who is labeled finds himself or herself unable to escape. To understand deviance, we have to also understand why behavior gets labeled as deviant. Critics of labeling theory have argued that it underplays the responsibility of the deviant for his or her own behavior. It is clear that some behavior is so reprehensible or so unusual that intervention is required, such as to protect potential victims (e.g., of school massacres, pedophilia, lynchings).

The gradation from deviance that is merely labeled and deviance that may objectively be a risk

to the group is illustrated by situations of ideological opposition. For example, during the Cold War, different sides applied completely different views of what behavior and indeed which opinions and values were acceptable. During the McCarthy era of the 1950s, the Soviet Union regarded capitalism as despicable, and the United States regarded Communism to be criminal. On both sides, some individuals who sympathized with the opposite side shared information or secrets that posed real threats to the security of each. These individuals were tried and sometimes executed as spies. Regardless of a person's beliefs, merely being labeled as a Communist in the United States meant being at great risk. Similar divergences between Islamic fundamentalism and Western democracy pervaded the period of the U.S. presidency of George W. Bush.

The focus of social control over deviance shifts to different individuals and groups depending on the broader social and historical context. For example, in the 1960s, surveys showed that people in the United States felt greater distance from homosexual and lesbian people than they did from alcoholics, prostitutes, former convicts, and former mental patients. Since then, homosexuality has generally shifted from being viewed as being highly criminal to being viewed as noncriminal.

Sociologists distinguish between deviance at different levels of analysis. Some deviance departs from cultural norms and values, such as women in Catholic countries who decide to use birth control. Other deviance is defined in terms of individual pathology (e.g., psychosis, extreme neurosis). Some deviance is expressed by individuals within a group (for example, a student who wears unusual clothes), and other deviance can be expressed by a group within society (for example a gang or a cult). The idea of *deviant subcultures* is important because it highlights that groups can generate their own sets of norms, and people within those groups feel they are not deviant even though the group as a whole may be viewed as deviant by others.

### Psychological Perspectives

#### *Individual Propensity to Deviate*

Early psychological approaches to deviance emphasized the biological and psychodynamic roots of deviance. For example, theorists such as

William Sheldon argued that criminals had a particular (muscular) type of body shape. Although it is plausible that certain types of crime might require particular body shapes (e.g., a cat burglar may need to be athletic), it is not plausible that there is a generally criminal body type (stock market fraudsters come in all shapes and sizes). A great deal of research tried to predict criminality on the basis of personality traits (e.g., research by Hans Eysenck, who proposed that criminality resulted from high levels of psychoticism, extroversion, and neuroticism).

*Psychoanalytic theory* (e.g., the work of Sigmund Freud and Erich Fromm) emphasizes the role of *socialization*. This perspective argues that parents instill in their children a respect for rules and authority, represented by the superego. This superego is an internalized control system that motivates people to follow social rules, to respect law and order, and so on. That is, conformity is thought to be important for people's self-concepts. However, criminality can be viewed as a product of many forces aside from either biological factors or parental socialization practices. The absence of a stable home and the presence of negative socializing agents may play a role, but all these aspects of socialization may in turn be affected by other factors, such as poverty within the home and in the wider community. Approaches that focus on differences between individuals are useful when explaining why some people break rules more often than others do, but those approaches do not help explain why people are deviant in some situations rather than others, why people label others as deviant, or how they react toward deviant individuals.

Other perspectives on deviance include *evolutionary theory*, which argues that physically stigmatized (deviant) group members may receive hostile and exclusionary reactions from others because they pose a threat to survival of the group. Norbert Kerr has suggested that people may be sensitized to the possibility of being rejected because it has so many consequences for their physical and psychological well-being.

#### *Norms and Conformity Pressure*

The main thrust of social-psychological research into deviance has been on the way that (a) individual

deviants respond to group pressure and (b) groups respond to individual members who deviate from the group norms. Muzafer Sherif's experiments on norm formation in the 1930s illustrated that in ambiguous situations, people quickly form norms. In his *autokinetic effect* experiments, participants viewed an illusion in which an objectively stationary point of light in a dark room appears to move (possibly a consequence of eye movements). The light was shown on a series of trials, and participants were asked to estimate the distance moved on each trial. When people listened to judgments made by others, they quickly converged to make estimates within the same range. Dependency on others was also illustrated by Solomon Asch's conformity experiments. Participants were asked to say which one of a series of lines was the same length as a comparison line. When three confederates gave a unanimous incorrect answer, many of the genuine participants ignored what they could see and agreed with the confederates. These experiments illustrate the pressure to uniformity in groups. People feel that they should be in agreement, especially about the physical world.

Leon Festinger proposed that group uniformity pressure is based on the group's ambition to move toward particular goals (*group locomotion*) and the desire among group members to validate their opinions about the nonphysical world (*social reality*). The social reality function involves the process of both evaluating the accuracy of opinions and validating (confirming) the accuracy of those opinions. A group usually comprises people who are similar in important respects (e.g., sharing a religion, culture, leisure interest, or objective). When a member of the group differs from the modal opinions of others, the group's locomotion is impeded, and its sense of social reality is undermined. The group will therefore engage in communication to deal with the problem. Possible solutions are to evict the deviant from the group, to pressure the deviant to conform, or to change the group's opinion to agree with the deviant. Dorwin Cartwright and Alvin Zander added two further reasons why groups desire uniformity: Uniformity helps define the group's boundaries and distinctiveness from other groups, and uniformity strengthens the cohesiveness of the group.

### *Minorities as Deviants*

An important criticism of Festinger's model is the assumption that people want to compare themselves with others who are similar. Contrary to that assumption, sometimes people prefer to compare with others who are dissimilar (worse) because doing so allows people to enhance their self-concept. People might also find dissimilarity useful because it allows them to contrast their own position with that of a rival or enemy. Equally fundamental is the assumption in Festinger's model that influence is likely to be unidirectional, namely, from the majority to the minority. Serge Moscovici proposed a theory of minority influence that explains why a deviant group member can change the majority opinion under some circumstances. Moscovici's *genetic* model proposes that any member of a group can potentially exert influence on others. Echoing Durkheim's theorizing, Moscovici has held that deviants play a key role in bringing about social change. To illustrate this, Moscovici and colleagues showed how judgments of whether physical stimuli (a blue slide) were blue or green could be influenced by a minority if the minority showed an incorrect (green) but consistent response. Moscovici identified that in these situations, even though the majority opinion is known (we generally agree what blue looks like), a consistent message from a minority can make us reconsider our judgments. Further research suggested that a minority group member's opinion has greater influence when the person combines his or her consistency on that particular opinion with flexibility (e.g., agreeing with the majority in opinions on other topics). Thus, in strong contrast to Festinger's ideas, Moscovici holds that groups progress and develop as a result of conflict. Whereas people succumb to normative influence from majorities (i.e., people simply conform without changing their private opinions), conflict from minorities makes groups reevaluate their ideas and perspectives and allows them to innovate.

### *Reactions to Deviant Group Members*

Given the potentially disruptive impact of a dissenting minority, it is not surprising that research also examines how people react toward deviant group members. One of the most widely reported studies was published in 1951 by Stanley Schachter.

He composed groups of 8 to 10 people, who had to reach agreement on the appropriate treatment or punishment for a delinquent. The groups included three confederates, one of whom conformed to the group's modal opinion, one of whom disagreed (the *deviate*), and one who gradually changed from the deviate to the modal opinion (the *slider*). Results showed that communication was directed more frequently toward the deviant than toward the other confederates and that the deviant was less likely than other confederates to be treated favorably. Subsequent evidence suggests that there may be a threshold effect with deviants. A deviant who exhibits the potential to change (to conform) is worthy of investment of time and effort because this change will reinforce the group. A deviant who is very extreme or whose opinion seems rooted in a more pervasive difference with the group is more likely to be ignored or rejected from the group altogether. This fits with research on minority influence showing that extreme minorities are less influential on the rest of the group than moderate minorities are.

An important question is how people make sense of deviant behavior within their group. John Levine and colleagues have shown that deviant members who shifted toward the majority opinion were viewed as seeking greater approval from the group whereas deviants who shifted away were viewed as being independent and assertive. The interpretation of behavior may also depend on other things in the context. For example, dissent in a group may be acceptable if it does not threaten the group's outcomes, but if it involves harm to the group (e.g., by reducing its rewards or by revealing important information to a rival group), it is likely to invite much harsher reactions. On the other hand, Edwin Hollander's research on idiosyncrasy credit shows that people who have shown loyalty to a group in the past may be permitted to dissent from the majority and to influence the majority. More recently, research has argued that some deviance might actually be normative, in the sense that group members will accept deviant views if those views are believed to be espoused in the interests or defense of the group.

### *Deviance in Intergroup Situations*

Deviant group members are also judged differently depending on the intergroup context. That is,

people may consider how differences between their own and other groups are affected by the presence of deviant individuals. José Marques and colleagues demonstrated a *black sheep effect* (see the entry titled Subjective Group Dynamics), whereby people derogate deviants in their own groups relatively more than deviants in other groups. This is thought to be motivated by people's desire to sustain a positive social identity. A deviant in the ingroup threatens the validity of social identity (based on the idea that *we* are right and we agree with one another). Dominic Abrams and colleagues also distinguished between two types of deviance in intergroup situations. *Antinorm deviance* describes a situation in which, when compared to the majority in a group, a group member expresses views that are relatively opposed to the member's own group and agrees with or supports an outgroup. *Pronorm deviance* is the situation in which a person shows more extreme endorsement of his or her own group and rejection of the outgroup (e.g., a fanatic). People tend to be more sensitive, and react more strongly, to antinorm deviants. An interesting consequence is that people are often positive toward outgroup members who are antinorm deviants. This is because such deviants lend credibility and support to the ingroup's social reality. The importance of social interaction in groups as a mechanism of social control is demonstrated by developmental psychology research. As young as 8 years of age, children seem to learn that groups expect their members to be loyal and conform, and these young children also recognize that ingroup deviants will be criticized. This understanding appears to be based on children's ability to take different social perspectives and also on actual experiences of belonging to a range of social groups.

### *Deviant Groups*

As noted earlier, whereas early research emphasized how groups expect and enforce loyalty and conformity, sometimes resulting in phenomena such as *groupthink*, they do not always derogate deviants. Some groups have norms that encourage originality and innovation, and others are themselves involved in challenging the status quo. These include deviant subcultures such as gangs, as well as groups that are in conflict over their rights or

resources. Early theories of crowd behavior (e.g., that of Gustave Le Bon) argued that people become more primitive when they are in a crowd, an idea echoed by Edward Diener's research on deindividuation in groups, showing that feeling anonymous and unidentifiable in a group can reduce self-regulation and constraint among the group members.

Although there is evidence that people may become more violent and extreme when they are in groups, it does not seem that this is always because they have lost self-control. Social identity theorists such as Stephen Reicher argue that groups may establish or develop a norm to confront authority or behave in extreme ways, and when people's group identity is salient, they follow these norms more closely (see the entries titled Referent Informational Influence Theory and Social Identity Theory). This position raises the question of who defines an act as deviant and highlights that deviance is frequently defined in relative (norm-violating) rather than absolute (lawbreaking) terms.

## DISCRIMINATION

---

*Discrimination* refers to the differential treatment of people because of the social groups to which they belong. In this definition, *differential treatment* refers to any observable differences in behavior toward people who belong to different groups. Discrimination may emerge in verbal or nonverbal behavior, involve positive or negative acts, and stem from an actor's benevolent or malevolent intent of which he or she is or is not aware. People can be discriminated against on the basis of gender, ethnicity, religion, age, nationality, immigrant and socioeconomic status, and many other bases. Discrimination, therefore, is said to occur when similarly qualified and/or behaving people are treated differently (e.g., receive different salaries, mentoring, eye contact), such that social group membership rather than individual attributes better explain differential treatment. Because social psychologists have studied discrimination against, as well as stereotypes about and prejudice toward, a variety of groups, we know that discrimination, representing differential treatment, is sometimes related to but is conceptually distinct from prejudice (one's feelings about a group) and stereotypes (one's beliefs about a group).

There is an important irony about discrimination, namely, that most of us value fairness but have the potential to discriminate (either individually or collectively). In fact, most of us would be

upset by the suggestion that we had discriminated against another person. To discriminate implies that we have judged a person unfairly on the basis of the groups to which he or she belongs rather than on the basis of his or her ability, skills, and/or character. Because, across cultures, people endorse egalitarian ideals, most people feel guilty and self-critical when confronted with evidence that their thoughts or behaviors violate ideals of fairness. As a result, images of the kind of person who discriminates against others are at odds with images of self as fair and principled. Discrimination is, however, a persistent social reality, being neither a thing of the past nor a problem exhibited by the rare few among us who reject egalitarian ideals.

The goal of this entry is to facilitate an understanding of the irony of discrimination. Toward that end it begins by distinguishing between blatant and subtle acts of discrimination. Then, before presenting examples of discrimination toward various groups, it also considers what most people think discrimination looks like versus what contemporary forms of discrimination typically look like.

### **Blatant Discrimination: What We Think Discrimination Looks Like**

When asked to imagine an instance of discrimination, most people call to mind images of blatant discrimination, or overt and unmistakable acts of discrimination such as the actions of hateful people who behave in negative ways that exclude others because of the groups to which those others belong. Discrimination is perceived to be a set of negative actions that follow from malevolent intent and effectively undermine or exclude others. These sorts of blatant acts of discrimination parallel acts of old-fashioned racism. Black citizens of the United States were not, for instance, allowed to commingle with Whites, being banned from entry into locations available to Whites or, when allowed to enter, required to stay in separate spaces (e.g., back of the bus, different schools).

Although social psychologists long have acknowledged that discrimination may be manifest in positive or negative acts, primary attention has been focused on negative acts of discrimination that have been assumed to be relatively more typical instances of discrimination and of greater consequence. In his seminal work, for instance,

Gordon Allport defined ethnic discrimination as the denial of equal treatment of ethnic outgroups via verbal rejection, exclusion, or physical attack. Likewise, in their recent social psychology textbook, Elliot Aronson, Timothy Wilson, and Robin Akert defined discrimination as unjustified negative or harmful actions that are expressed toward people simply because they belong to a particular group. The unjustified negative and harmful actions specified by such definitions refer to blatant acts of discrimination, such as open acts of hostility, verbal and physical aggression toward, and/or social and economic exclusion of members of particular groups.

Classic conceptualizations of discrimination such as those noted above, however, have overlooked several pervasive and problematic forms of discrimination. Not all acts of discrimination can be clearly classified as positive or negative. Some forms of discrimination are inherently neither positive nor negative. Other forms of discrimination may be positive in one context and negative in others (e.g., repeating comments to ensure understanding). What constitutes a positive or negative act may also vary from the perspective of an actor versus the perspective of the targets of discriminatory actions. A young man may sincerely seek to be helpful when opening a door for an aging person, whereas the aging person may perceive the same act an insulting instance of discrimination that follows from stereotypes of one's frailty. It is important to note that the classic conceptualization of discrimination cannot address the important question alluded to in the introductory paragraphs, namely, if most people fancy themselves to be fair and principled people who define discrimination as unfair, then how might those same people sometimes behave in discriminatory ways (as individuals or groups)?

### **Subtle Discrimination: What Contemporary Discrimination Typically Looks Like**

What people think discrimination looks like and what discrimination actually looks like are different things. As noted, acts thought of as discrimination tend to be blatant in that they are (1) negative, (2) linked to malevolence toward a group, and (3) harmful. In the absence of any of these three pieces, acts become more subtle forms of discrimination

from the perspective of the actor. As a result, one may treat people differently solely on the basis of the groups to which they belong (e.g., opening doors for aging people but not young people, and for women but not men) but have trouble seeing such acts as instances of discrimination. After all, how could my behavior be discriminatory if I did not treat someone negatively (e.g., I kindly opened the door), I feel benevolence toward the group to which someone belongs (e.g., I adore women), and/or I behaved in a way that does not harm and may even help another?

### *Discrimination Without Malevolence*

Discrimination often occurs because of the operation of basic cognitive and (via ingroup) self-enhancing processes, with no malevolent intent toward other groups. For instance, when people are classified as ingroup and outgroup members, there is an accentuation of similarities within groups (we are similar to one another, they are all similar) and differences between groups (they are very different from us). These processes of *categorization* motivate various forms of discrimination (e.g., allocating more rewards to ingroup than to outgroup members). It is interesting to note, however, that differences in how ingroup and outgroup members are treated often stem from ingroup-favoring biases rather than outgroup-rejecting tendencies. This is because, as long ago noted by Allport, we value that with which we are familiar and protect that which we value, such that the love of one's ingroup often leads to discrimination without feelings of malevolence toward outgroups.

### *Controlling and Explaining Away Acts That Could Result From Malevolence*

Even when actors with malevolent intent behave in negative and harmful ways (and commit acts typically seen as discriminatory), these realities coexist with the fact that people value fairness, see themselves as fair, and reject discrimination as unfair. There are several things people attempt to do to negotiate the ambivalent thoughts aroused in such situations. One may try to control behavior to avoid discrimination, but some behaviors are more subject to conscious control than others are. We may readily be able to control what we say,

but discrimination may still emerge in the behaviors over which we have less control, such as speech errors and eye contact. In addition, when malevolence exists outside of awareness and/or coexists with benevolent intent, acts of discrimination may be justified, perpetuated, and explained away in group-irrelevant terms (e.g., Christopher was better qualified than Jamal; race had nothing to do with it).

### *The Most Subtle Form of Discrimination: Institutional Discrimination*

Discrimination can occur individually or institutionally. Institutional discrimination exists when systematic policies and practices of an institution disadvantage or exclude certain social groups. In many situations, institutional discrimination results from judgments made on secondary rather than primary characteristics. Ethnicity and gender, for instance, may be consciously eliminated as criteria for hiring, but other criteria that are less directly related to performance may disadvantage participation of members of some groups. For example, racial profiling and the use of height and weight requirements to select firefighters (disadvantaging women) enforce discriminatory behaviors across actors, regardless of their personal beliefs about ethnicity or gender. Social institutions such as the criminal justice system, the labor market, the housing and retail markets, the education system, and the health care system use policies and procedures that systematically disadvantage or exclude members of certain groups. In such instances, all individuals within an institution are required to uphold and enforce discriminatory practices, such that acts of discrimination cannot be attributed to any individual or set of individuals. Instead, discrimination results as a mere function of doing "business as usual."

Considering the foregoing points, a full and complete answer can be provided to the question that motivated this entry; namely, if most people fancy themselves to be fair and principled people who define discrimination as unfair, then how might those same people sometimes behave in discriminatory ways (as individuals or groups)? What people think discrimination looks like and how discrimination is actually manifested are different things. We reject the unfair and negative treatment

of people because of the groups to which they belong, but because discrimination often takes more subtle forms that are hard to see, discrimination can still occur when it slips by undetected by those who discriminate.

Subtle acts of discrimination are, however, keenly felt by the targets of discrimination. Subtle acts of discrimination tend to have a contradictory duality whereby niceties of one sort (e.g., opening doors) are misaligned with other behaviors of import (e.g., who gets a raise). As a result, subtle discrimination is insulting and marginalizing, causing people to question their abilities, exhibit poor cognitive performance, and report lower self-esteem. To illustrate the range of adverse effects that acts of subtle discrimination have on the targets of discrimination, this entry turns to concrete examples of discrimination toward groups that have been the target of a great deal of social-psychological theory and research.

### Examples of the Content and Consequences of Contemporary Discrimination

As noted, many groups are discriminated against. To illustrate the content and consequences of discrimination, this section describes research examining discrimination against Blacks, women, aging people, and gay men because these groups have been most thoroughly studied by social psychologists.

#### *Discrimination Against Ethnic Minorities*

Contemporary theories of racism note that Whites' attitudes toward racial and ethnic minorities are often ambivalent (i.e., positive and negative) and that contemporary forms of racial discrimination are often subtle. Each theory suggests that Whites who score low on prejudice (also called modern, aversive, symbolic, or ambivalent racists) can be distinguished from those who score high on prejudice (old-fashioned, dominative, or redneck racists), given the presence or absence of positive feelings toward racial and ethnic minorities. Presumably Whites typically harbor negative feelings about other racial or ethnic minorities that result from shared socialization experiences and an internalization of the negative cultural images of those groups (e.g., Blacks are lazy, aggressive). Whites who score high on prejudice endorse and

accept negative cultural images of racial and ethnic minorities. Although Whites who score low on prejudice also harbor negative feelings about other racial and ethnic minority groups (e.g., as the result of shared socialization experiences), they also endorse egalitarian ideals and hold additional sincere positive feelings about minorities and have sympathy for racial and ethnic minorities as victims of past injustices.

The racial attitudes of White people influence their behavior, determining whether and in what form one discriminates. Whites who score high on prejudice are open about their antipathy and behave in consistently negative, rejecting, and blatantly discriminatory ways. By contrast, the ambivalent attitudes of Whites who score low on prejudice inspire more complex and subtle acts of discrimination, such that Whites who score low on prejudice discriminate when discrimination slips by undetected. This occurs when the negative treatment of another person can be justified in terms of race-irrelevant factors; for instance, refusing to hire someone, not because he is Black, but because there were just others who were exceptionally qualified. Subtle (vs. blatant) discrimination is also manifest in body language that may be difficult to detect by the actor (e.g., speech errors, less eye contact), but that may be keenly felt and distressing to the target.

The subtle and harmful nature of more subtle forms of racial discrimination was convincingly documented in a classic set of studies conducted by Carl Word, Mark Zanna, and Joel Cooper. The researchers asked White men to interview either a White or a Black job applicant with similar qualifications, who were trained to behave in similar ways. Findings revealed that the similarly behaving and qualified job applicants were treated differently based on their race. When interviewing a Black (vs. White) applicant, White men made less eye contact, sat less attentively (e.g., at an angle facing away), made more speech errors, and terminated the interviews sooner. Thus, racial discrimination emerged on behaviors that are harder to control and are outside the awareness of White actors.

To examine whether subtle acts of racial discrimination have meaningful consequences for those who are the targets of discrimination, Word and his colleagues asked White men to interview

for a position in a second study. Unbeknown to them, the White men were interviewed by men trained to behave similarly to the participants in the first study. Findings indicated that the men performed differently depending on whether they had been treated like the White interviewee or the Black interviewee in Study 1. When treated like the Black (vs. White) interviewees, the men performed more poorly (as evaluated by themselves and independent observers). The important and adverse consequences of subtle acts of racial discrimination are clear given that jobs are often awarded on the basis of interview performance.

### *Discrimination Against Women*

Stereotypically, women and men are perceived to be complementary opposites who come together to make a whole, given interdependencies in normative heterosexual relations (e.g., child rearing). Women are communal (e.g., nurturing, warm, caring) but not agentic. Men are agentic (e.g., influential, strong, independent) but not communal. Given heterosexual interdependencies, men come to feel a sense of responsibility for the welfare of traditional women that motivates positive sentiment (e.g., stereotypically warm and communal women are evaluated positively). Positive sentiment, however, reflects liking (but not respect) and may mask gender biases that emerge in behaviors that clearly reveal perceptions of women as being less competent than men. For example, feelings that women are warm and caring lead to genuine liking and interpersonal kindnesses (e.g., praise) that can make it difficult for a given man to see gender biases that emerge in his behaviors (e.g., denial of salary raises). These dynamics overlie interactions between men and women in particular contexts (e.g., bosses and employees) and motivate seemingly positive but actually condescending acts of discrimination.

Ambivalent attitudes toward traditional women lead to subtle but harmful acts of paternalistic discrimination in traditional achievement domains (e.g., science, technology), where perceptions of women's lesser competence imply their inability to succeed. In these contexts, women receive few valued resources (e.g., promotions, raises) as a result of their perceived incompetence, but many acts of interpersonal kindness (e.g., praise, flattery).

Although the subtle nature of such behaviors may make it difficult for men to see that such acts are a form of gender discrimination, women can keenly experience acts of paternalistic discrimination as insulting and unfair. When treated paternalistically rather than equitably, women feel angry and perform less well on cognitive tasks. In fact, the paternalistic discrimination of men in traditional achievement domains can actually cause women to perform more poorly than men (e.g., on standardized math tests), where such differences do not otherwise exist.

Nontraditional women (e.g., businesswomen, feminists) are also perceived ambivalently, but in opposite terms from traditional women—as competent but cold. In these situations, feelings of respect based on perceptions of competence may mask the degree to which nontraditional women are disliked. Respect, for instance, may lead one to assign many valued tasks to nontraditional woman, while one's dislike may make it difficult to attribute the successful completion of those tasks to the inherent skills of a nontraditional woman (e.g., attributing it instead to others' help). To the degree that nontraditional women succeed, however, they may present a threat (e.g., to men's position of power or cherished notions of masculinity) that exacerbates dislike. When feelings of dislike dominate, discrimination turns blatant. In such situations, nontraditional women and/or women who are successful in masculine domains are targeted with backlash (or social and economic punishments), sabotage, sexual and/or gender harassment, and other forms of aggression (e.g., ethnic harassment).

### *Discrimination Against Aging People*

Aging men and women are stereotypically perceived as warm but incompetent people who need to be cared for and paternalistically protected. Like traditional women, paternalistic discrimination against aging people is motivated by benevolence but represents a form of sugarcoated discrimination. Such acts of discrimination are contradictory in that they at once convey both liking and disrespect. Younger people adopt a "protector" status and heap trivial niceties (e.g., excessive offers of help, praise for displays of ordinary adult competence) on pitied older men and

women, which functionally masks stereotypic perceptions of incompetence that convey a lack of respect. From the perspective of the paternalistic protectors, it is difficult to detect one's disrespect for and infantilizing behavior toward older people given the fondness one feels as a result of one's cooperative interdependence with aging relatives. However, this behavior has adverse consequences for those who are the targets of discrimination.

Subtle discrimination against older people is often manifested in speech patterns. *Elderspeak* is a pattern of speech accommodations that are used in attempts to communicate more effectively to an older listener given stereotypic perceptions of impaired cognitive functioning and memory. Elderspeak is characterized by loud, slowed speech, limited vocabulary, simplified grammar, shorter sentences, exaggerated intonation, higher pitch, and repetition. It is important to note that elderspeak resembles the way adults talk to children (or baby talk) and when heard out of context is often mistaken for speech directed toward children. Although presumed to follow from a sincere positive regard and desire to accommodate the needs of another, the use of elderspeak typically does not vary with or depend on the comprehension or cognitive abilities of older listeners.

Although presumed to derive from sincere and benevolent attitudes, elderspeak has many adverse consequences. When addressed using elderspeak, older people feel angry, disrespected, and marginalized. Elderspeak also causes aging listeners to exhibit more dependence, question their cognitive abilities, and report lower self-esteem. Thus, subtle discrimination against aging populations has adverse consequences that parallel the effects of subtle discrimination against racial outgroups and women.

### *Discrimination Against Gay Men and Lesbians*

Unlike women, ethnic minorities, or aging people, gay men, lesbians, bisexuals, and transgender people are not protected from discrimination by national laws banning discrimination in the workplace or in housing or education. In fact, campaigns advocating efforts to bar gay men and lesbians from equal rights are openly broadcast and sometimes publicly sanctioned by authority

figures. Because discrimination toward gay men and lesbians is not only tolerated but often sanctioned, it is perhaps not surprising that open acts of hostility and blatant discrimination against gay men and lesbians are relatively common. In fact, as Gregory Herek and his colleagues have noted, as many as 20% of adult lesbians and 25% of adult gay men have reported experiences of victimization related to their sexual orientation. Furthermore, Anthony D'Augelli and his colleagues have shown that more than half of gay, lesbian, and bisexual youth have experienced verbal abuse and 11% have experienced physical abuse because of their sexual orientation. In fact, 2002 Federal Bureau of Investigation statistics indicate that 16% of reported hate crimes are based on sexual orientation, which is likely an underestimate given that gay men and lesbians express reservations about reporting crimes, given concerns about police bias and needs to disclose their sexual orientation.

As noted at the outset, however, most people view themselves as fair and principled people who make decisions on the basis of other people's skills, talents, and qualifications rather than on the basis of the social groups to which people belong. In work situations, discriminatory behavior toward gay men and lesbians is often relatively subtle and more similar to the kinds of discrimination experienced by racial minorities and women. This point was demonstrated in a field experiment conducted by Michelle Hebl and her colleagues. In this experiment, men and women, who were trained to behave similarly, were sent into stores to apply for jobs. In some of the interviews, the men and women presented themselves as gay or lesbian, and in other interviews they presented themselves as straight/heterosexual.

The investigators found no evidence of formal discrimination (e.g., refusing to provide an application) against those who portrayed themselves as gay or lesbian, but there was clear evidence of discrimination in interpersonal behaviors. Compared with the way employers interacted with straight (or heterosexual) men and women, employers were less verbally positive, spent less time interviewing, used fewer words while chatting, and made less eye contact. In other words, although the employers could not be accused of treating gay men and lesbian women applicants unjustly in a formal sense (e.g., refusing to hire), employers

exhibited uncomfortable or more distant behaviors toward people they believed to be gay or lesbian. In addition, it is reasonable to assume that these subtle acts of discrimination (like subtle racism and sexism) could have harmful consequences for gay men and lesbian women.

### Conclusion

The considerations and examples in this entry illuminate several important points. First, discrimination refers to observable differences in behavior because of the social groups to which people belong. Acts of discrimination are likely to occur in two situations. People who endorse negative stereotypes and possess unbridled negative feelings toward other groups behave in consistently negative and blatantly discriminatory ways toward disliked groups. This type of discrimination parallels the blatantly negative and harmful acts of open hostility and exclusion associated with bigots, racists, xenophobes, and White supremacists. By contrast, people who reject discrimination, value the principle of fairness, and feel guilt when their thoughts and behaviors violate ideals of fairness, discriminate when acts of discrimination slip by undetected. These people, like many well-intentioned people among us, display subtle acts of discrimination that are either positively valenced, co-occur with benevolent intent, and/or are perceived as lacking harmful consequences. Regardless of the form of discrimination (subtle or blatant from the perspective of the actor), targets of discrimination often experience insult, feel marginalized, or exhibit a host of adverse behaviors. This entry has focused on the content and consequences of discrimination with an eye toward social justice and recognition that an initial step in attempts to create equal playing fields for all requires an ability to detect, understand, and reject subtle and blatant forms of discrimination.

## DISTRIBUTIVE JUSTICE

---

*Distributive justice*, or *distributive fairness*, refers to the extent to which an outcome or a distribution of outcomes conforms to norms of propriety or fairness. The recognition that people might want not simply to maximize their own payoffs and rewards but also to see goods distributed in a fair fashion has a long history. As a concept in philosophy, notions of fair distribution go back at least to Aristotle's *Ethics*, in which distributive justice is said to exist when each person's outcomes are proportional to his or her merits (or, as we now more often phrase it, outcomes are proportional to each person's contributions to the production of the outcomes). That is, for a favorable outcome from a joint project, the rewards should be divided among those who contributed to the project in proportion to their contributions, their skill, and their effort. When a joint undertaking has a negative outcome, the costs should similarly be borne in

proportion to each person's contribution to the failure of the enterprise. In either case, distributive justice exists when proportionality exists. However, when outcomes are not proportional to contributions, when one party to a distribution receives or gives either too much or too little, then *distributive injustice* exists.

In social psychology, one of the earliest explorations of distributive justice as a topic in its own right is seen in J. Stacey Adams's *equity theory* and in research associated with that theory. Adams suggested that people experience *inequity distress* when they receive or are associated with distributions of outcomes that violate norms of fairness, and in particular, outcomes that violate the Aristotelian rule that outcomes should be proportional to contributions. According to the theory, inequity distress motivates the individual in question either to change the reality of the situation or to alter his or her perception of the situation in such a way as to restore equity.

Consider, for example, a worker who is being paid more than others who are working equally hard and who bring similar skills to the job at hand. According to Adams, the worker in question, if he or she knows about the mismatch of skills and payment, should experience inequity distress and should be motivated to restore equity. The worker might, for example, increase his or her effort so that the now-higher contributions will be proportional to the relatively higher payment he or she is receiving. This is an action that changes the objective ratio of contributions and outcome, but there are also psychological solutions to the underpayment inequity. The worker in question can come to perceive the discrepancy in payment as fair, and thereby reduce equity distress, by altering his or her perceptions of the contributions and outcomes of those involved. Thus, the worker might decide that he or she in fact has special skills that justify the higher payment. Alternatively, the worker might decide that there are other positive outcomes that the other workers are experiencing as a result of being in this job (e.g., the worker might think, "This job is an especially good match for them because the working hours fit their lifestyles, so they have benefits that I do not.").

Equity theory is psychological, not philosophical, because it moves from normative views of what is fair in some objective sense to descriptions

of how people will react to unfair distributions. Because the equity theory describes changes in behaviors and beliefs that are used to restore a feeling of distributive fairness, it serves to relate feelings of unfairness to a variety of possible responses. This multiplicity of possible ways of restoring a sense of equity is both a strength and a weakness for the theory. It is a strength because it allows the theory to explain both cognitive and behavioral reactions to outcome distributions and a weakness because it is often difficult to predict which particular equity-restoring actions a given person might take.

Research on how people award outcomes to others has shown that there are other rules of distributive justice. In many situations, especially those that emphasize performance, outcomes are allocated in proportion to contributions, as Adams suggested. However, sometimes outcomes are divided according to the need of those receiving the outcomes, especially in situations that emphasize supportiveness and caretaking. And in situations where solidarity and a sense of community are a major consideration, or where it is difficult to calibrate contributions or need, outcomes are awarded equally. Indeed, psychologist Morton Deutsch has suggested that the association of each of these rules with the social situations just noted runs both ways, so, for example, not only are need-based distributions chosen most often in situations that emphasize caretaking, but using need-based distributions produces greater emphasis on caretaking and support.

As psychologists have continued to examine distributive justice-related phenomena, it has become clear that justice judgments and related attitudes and behaviors play an important role in how people interact with other individuals and with organizations and social institutions. Theory and research on distributive justice have helped explain situations as different as how people behave in experimental games to increases in employee theft that are observed when wages or other benefits are decreased. Work by Melvin Lerner and others showed that people hold deep-seated ideas about fairness—a "belief in a just world"—that can lead them sometimes to see innocent victims, those experiencing negative outcomes through no fault of their own, as somehow deserving their fate. Such *victim derogation* effects

are in line with the basic psychological processes outlined in equity theory because the impression of the deservingness of the victim is altered to make the situation equitable given the negative outcomes the victim has received.

As the study of the psychology of fairness has progressed, it has become evident that there are not only multiple distributive justice rules but there are also forms of justice that involve, not the outcomes being distributed, but rather the procedures used to decide the distributions in question. In the early 1970s, several studies showed that judgments of *procedural justice*, the belief that social processes and procedures are fair, can affect a variety of attitudes and behaviors in everyday social interactions, in organizational behavior, and in reactions to legal and societal institutions. We now know that procedural justice effects are often as strong as or stronger than distributive justice effects. Indeed, there is evidence that under conditions in which procedural justice is seen as high, differences in distributive justice have little effect.

Studies of the comparative impact of procedural versus distributive fairness have decreased, however, as new theories have emphasized similarities, rather than differences, in the way people react to fairness or unfairness in outcomes and in process. Testing predictions from *fairness heuristic theory*, an account of fairness effects that sees all fairness-relevant experiences—distributive or procedural—as information used to assess the likelihood of exploitation or exclusion, Kees van den Bos and his colleagues have shown what is termed the *substitutability effect*. The substitutability effect arises when whatever type of fairness is encountered first is generalized in the interpretation of subsequent fairness information. Thus, if procedural justice information is encountered first, subsequent distributive fairness information is interpreted to be in line with that early process information. On the other hand, if distributive fairness information is encountered first, then subsequent process information is colored by the positive or negative outcome of fairness impressions.

But why does fairness, distributive or procedural, matter so much to people? The answer seems to lie in the capacity of justice judgments to help people deal with the various personal uncertainties that life brings their way. Van den Bos and his colleagues have shown that the effects of both

distributive and procedural unfairness are stronger when people are uncertain and that fairness effects are strengthened by even peripheral or subtle alarm-producing stimuli (such as flashing warning lights). There is even evidence that the same areas of the brain are activated by fairness judgment processing as are activated by personal uncertainty or alarm processing. The reason that people show inequity distress and related justice phenomena appears to be that a sense of fairness helps them manage uncertainty in their lives, while feelings of unfairness may exacerbate personal uncertainty.

## DIVERSITY

---

Diversity may be conceptualized as variance in human characteristics that leads people to perceive differences relative to the self. *Cultural diversity* refers to variation in social groups within human societies in a given context at a given time. For example, variation in the number of different nationalities, racial and ethnic groups, or religious affiliations that are reflected in a specific population (e.g., residents of the southern United States)

may wax or wane over time as a result of migration patterns. Changes in cultural diversity over time influence the frequency and nature of intergroup contact, with important implications for psychological phenomena. Hence, the study of diversity—particularly social group diversity—has emerged across a number of research traditions within psychology, including cultural psychology, social psychology, industrial/organizational psychology, educational psychology, and clinical/counseling psychology. With regard to groups and group relations, theories and research traditions examining a range of different types of diversity (e.g., social identities, attitudes, values, and experience) have focused primarily on the role diversity plays in shaping group performance and group dynamics. In addition, group researchers have examined policies (e.g., affirmative action) and procedures (e.g., diversity training) that impact organizational goals of maintaining and promoting diversity.

### Diversities Within Diversity

Because the concept of diversity refers to a broad array of human attributes, theorists have found it useful to distinguish different types of diversity. For example, one common practice is to differentiate *social category diversity* from *informational/functional diversity*. Social category diversity is defined by differences in easily identifiable social group attributes such as age, gender, race, and ethnicity. In contrast, informational/functional diversity is defined by variance in less-visible attributes such as attitudes, knowledge, education, and functional background or role within a group. In a similar vein, Douglas Harrison distinguished *surface-level diversity*, which again refers to variance in attributes that can be easily detected, from *deep-level diversity*, which refers to variance in less-visible attributes. In contrast to these approaches, Joseph McGrath proposed a more complex classification scheme comprising five different types of diversity: demographic attributes; task-related knowledge and skills; values, beliefs, and attitudes; personality, cognitive, and behavioral styles; and status within the group. McGrath proposed measuring these types of diversity as multiple dimensions and creating profiles to reflect the complexity of diversity within groups.

The operationalization of diversity (i.e., implementing manipulations and measures of diversity in research studies) has primarily followed two different approaches. In one approach, researchers have examined how diversity is dispersed across groups (e.g., the presence or absence of different racial or ethnic group members within the larger group, the degree of difference in educational background between group members). In the other approach, researchers, particularly those working from a relational demography perspective, have operationalized diversity in terms of numerical proportions of different groups (e.g., numerical minority/majority status). Proportional approaches are more appropriate for capturing some psychological effects. For example, measuring the proportion of individuals who belong to a minority group within a larger group is more sensitive to the relative differences between being a lone individual in a group (e.g., the only Black woman in a group of White women) and being a member of a small minority (e.g., one of three Black women in a group that also includes six White women). Being the “only one” is psychologically different from being a member of a small minority; operationalizing diversity in terms of the mere presence or absence of racial group variance could lead researchers to miss important psychological phenomena.

More recently, Dora Lau and J. Keith Murnighan have used the term *faultlines* to describe a situation within a group where subgroups differ on many correlated dimensions that maximize perceptions of differences between those subgroups. These ideas are drawn, in part, from research on *self-categorization* that has demonstrated that people are more likely to subcategorize others when dimensions of difference appear to covary. For example, if a group is composed of White men and Hispanic women, perceptions of difference between these two subgroups would be stronger than if gender and race or ethnicity were unassociated (e.g., if some of the men were Hispanic and some of the women were White). As faultlines become more salient, people attend more closely to subgroups, with the consequence that subgroup diversity can impact group processes quite profoundly. These theorists would argue, therefore, that we need to measure diversity in ways that capture the strength of faultlines by considering the degree of correlation between group memberships.

### Diversity Theories: Group Performance Versus Dynamics

The overarching question for much research on diversity in groups is whether diversity is beneficial or harmful. Recent reviews of relevant literature highlight two theoretical traditions that conflict when it comes to evaluating diversity's consequences for groups. On one hand, research on diversity and group performance (e.g., task performance, problem solving, creativity) suggests that diversity is beneficial to groups. On the other hand, research on diversity and group dynamics (e.g., group cohesion, satisfaction, commitment) points to potentially harmful consequences associated with increased diversity.

#### *Group Performance*

Early theorists such as L. Richard Hoffman and Harry Triandis argued that increased diversity was beneficial to group performance because diversity improves decision making. Individuals who come from different cultural, educational, and functional backgrounds are likely to also differ in the knowledge and skills they bring to decision-making tasks. As the variability of knowledge and skills increases within a group, so should the performance of the group, particularly when tasks are complex or demand multiple perspectives. These value-in-diversity theories further argue that interacting with diverse peers creates opportunities for people to expand not just *what* they know but also *how* they think. Hence, diversity is hypothesized to promote greater creativity in problem solving because people are forced to break out of mental ruts that undermine creative problem solving.

Hypotheses regarding the value of diversity for group performance have been tested and supported empirically for several types of diversity, including both surface-level (e.g., racial) and deep-level (e.g., knowledge) diversity, although less visible attributes related to knowledge distribution within task groups have received the primary emphasis. With regard to the effects of racial and ethnic diversity, for example, Poppy McLeod and colleagues asked participants in racially and ethnically homogeneous versus diverse groups to spend 15 minutes generating as many ideas as possible to increase tourism to the United States. Results pointed to the benefits of diversity. Ideas generated

by the racially and ethnically diverse groups were more effective and practical than those produced by homogeneous groups.

With regard to deep-level diversity, a large literature has examined whether diversity of knowledge benefits group performance. This research has compared, for example, whether distributed knowledge (i.e., different members of the group have different pieces of knowledge) is better than shared knowledge (i.e., all members of the group have the same knowledge) for task performance. Research by Verlin Hinz and Scott Tindale, for example, has demonstrated that low levels of knowledge diversity (shared information) are associated with less elaboration of information during group discussion. In contrast, when knowledge diversity is high (unshared information—members of the group each have unique information to contribute) elaboration of task-related information increases, leading to improved performance. Research further suggests that these effects are qualified by whether the task requires more complex thinking, by whether the group members are motivated to elaborate on information, and by members' task-relevant abilities.

#### *Group Dynamics*

Researchers who focus on group dynamics have drawn significantly from *social identity theory* and argued instead that diversity is detrimental for groups because it promotes conflict among subgroups within the larger group. This conflict weakens overall group bonding and cohesion.

More specifically, the mere presence of social category diversity (e.g. diverse ethnic groups) within a group prompts categorization and differentiation, in turn fostering ingroup favoritism and ethnocentrism—the tendency to have more positive attitudes and responses toward people who belong to one's own social groups. Thus, greater diversity can promote greater conflict within groups, resulting in less satisfaction, less cohesion (i.e., liking for members of the group), and lower commitment to the group. Researchers further suggest that these effects could be accentuated by intergroup anxiety and mistrust; dissimilar members may be less likely to trust one another and less willing to communicate and cooperate with one another.

Empirical tests of hypotheses about diversity and group dynamics have again examined a range of forms of diversity, but the primary emphasis has been on surface-level diversities related to race, gender, and tenure within an organization or group. Results of these studies are mixed. Research on tenure diversity, for example, shows a negative impact of diversity on turnover within organizations: The more diverse the group is with regard to tenure, the less socially integrated the group is likely to be and the more likely it is that group members will leave the group or organization. Research findings on racial and ethnic diversity largely parallel these effects. The more racially or ethnically diverse a group becomes, the less likely it is that members will communicate with one another informally, the more likely it is that conflict will arise, and the more likely it is that members will leave the group. However, gender diversity appears to have a positive, rather than a negative, impact on group dynamics.

### *Integrating Approaches*

In response to the apparent contradictions in research findings—that diversity benefits performance but undermines group dynamics—several theorists have argued that it is time to reexamine how scientists think about and study diversity. Across reviews, common themes emerge. First, a lack of consistency in how scientists define and operationalize diversity is problematic for interpreting results across studies. Second, scientists have been focusing primarily on testing the main effects of a given form of diversity on a single type of outcome. As a result, there is a lack of appreciation of the complexity of diversity's effects. There are few examinations of possible moderating and mediating factors. Thus, many of the assumptions about the mechanisms underlying diversity's effects remain untested. These reviews call on theorists and researchers to move beyond main-effects approaches, to propose more complex models and to directly assess mediating mechanisms.

In response to these concerns, Daan van Knippenberg and colleagues have recently proposed the *categorization elaboration model*, an integrative model of diversity and group phenomena. According to this theory, diversity can have both positive and negative effects for groups.

Understanding whether and when diversity will be beneficial requires an understanding of how group categorization processes qualify information sharing and elaboration within groups. These researchers have argued that the positive effects of diversity on group performance result from increased elaboration of task-relevant information. However, when social categorization processes threaten valued social identities, favoritism and bias are likely to occur and potentially disrupt elaboration. Hanneke Grotenberg and colleagues recently tested such an argument by manipulating levels of ethnic diversity and knowledge diversity within task groups. When knowledge diversity was high, instructions that emphasized taking advantage of multiple viewpoints improved the performance of ethnically diverse groups. These effects were mediated by information elaboration; the more that group members elaborated on information, the better the group performed.

In summary, research on group diversity points to both benefits and costs of increasing diversity. Recent theories argue that a more complex and nuanced understanding of diversity is required to reconcile these apparently contradictory results. Future research is likely to focus more carefully on moderating and mediating factors that qualify when diversity is beneficial versus harmful, as well as why these effects occur.

### **Diversity Policies**

Organizational policies on diversity are designed to promote equal opportunity and representation of diverse groups within institutions and to create climates that support the inclusion and acceptance of individuals from diverse backgrounds. The need for these policies becomes clear on examination of data that demonstrate the continuing problems of racism and sexism within the United States. Despite decades of improvement since the civil rights era of the 1970s (and the 2008 election of a Black president), members of racial and ethnic minorities continue to face economic, political, and interpersonal prejudice and discrimination in their daily lives, in both educational and employment settings.

For women, discrimination in education has diminished significantly, but women remain underrepresented in core areas of the sciences, including some of the most profitable careers in engineering

and computer sciences. In the workplace, women can still face hiring and salary discrimination and sometimes hostile climates that promote harassment or devalue their contributions. These effects can especially impact working mothers, who face a maternal wall when it comes to promotion and career advancement.

Advocates of affirmative action policies also point out that affirmative action is unique in that it addresses discrimination without requiring discrimination victims to voice their complaints. That is, unlike policies and laws that require individual victims to take personal responsibility for challenging discrimination (e.g., filing a complaint with a human resource office, filing a lawsuit), affirmative action policies require institutions to police themselves. A strong research tradition suggests that people who claim they have been the victims of discrimination may face (often extreme) backlash, which inhibits their willingness to voice concerns even in severe circumstances (e.g., sexual harassment). Hence, policies that do not require individual victims of discrimination to assume responsibility for challenging discrimination play an important role in reducing discrimination in organizational settings.

### *Defining Policies*

Affirmative action policies are the most recognized and perhaps the most misunderstood policies aimed at promoting educational and employment opportunities for members of minority groups. Affirmative action involves practices that protect individuals from discrimination based on status in legally protected social groups, including gender, race or ethnicity, age, and disability. In contrast to equal opportunity policies, which passively support diversity and punish violations of equal treatment, affirmative action policies are proactive in implementing practices that redress inequality. Examples of affirmative action include practices to promote diverse applicant pools (e.g., advertising employment opportunities in a diverse range of newspapers) and federal procurements for minority-owned and woman-owned businesses.

With regard to employment settings, Executive Order 11246, issued by president Dwight Eisenhower in 1965, mandates affirmative action policies for federal organizations and employers

who do business with the federal government. Agencies must evaluate whether they are guilty of discrimination by assessing their employment practices (e.g., representation of diverse groups as a function of the availability of qualified applicants) and must remedy such discrimination when it occurs. For example, an engineering firm that does business with the federal government may have too few female employees relative to the proportion of qualified women with degrees in engineering. In this situation, EO 11264 would require the organization to make an effort to increase the number of women hired in engineering positions.

In educational settings, race-sensitive admission practices are a common form of affirmative action, and these policies have been upheld in recent court rulings. For example, universities may take race into account when evaluating applicants if doing so fits with the university's mission to promote a diverse student body and if the implementation of these policies is sufficiently individualized. Federal court rulings argue that these policies are justified by a state's compelling interest in ensuring diversity within state-sponsored schools.

### *Effectiveness*

Scientists have examined a number of outcomes when assessing whether affirmative action policies achieve their intended effects. With regard to increasing the representation of minority groups in education and employment, the research largely indicates that such policies increase the representation of women and racially/ethnically marginalized groups in both academic and employment settings. In addition such policies appear to promote intergroup contact that results in more positive attitudes toward these groups, although the benefits of contact are qualified by many other factors. In educational settings, further evidence suggests there are indirect benefits for members of nonstigmatized groups (e.g., Whites, men). Students in more racially/ethnically diverse contexts engage in more complex critical thinking than their peers in more homogeneous settings. Critics of the policies point out, however, that the beneficiaries of these policies may experience self-doubt and lowered esteem. Such effects have been demonstrated empirically, but appear to be limited to laboratory settings; these negative effects do not appear to

generalize to real-world educational and employment settings.

### *Attitudes Toward Affirmative Action*

Attitudes toward affirmative action vary tremendously and depend largely on the nature of the policies and perceiver characteristics. People generally favor policies and practices that appear to be “soft” (e.g., outreach programs) over those that are portrayed as “hard” (e.g., choosing ethnic minorities in the case of equally strong candidates). When affirmative action programs are described as valuing merit, they are perceived to be more fair and therefore are received more positively. In addition, people feel most negatively toward affirmative action in educational settings rather than employment settings, although more people benefit from the latter.

When it comes to perceiver characteristics, attitudes toward affirmative action appear to be influenced, not surprisingly, by demographic attributes (e.g., gender, race), individual levels of prejudice, and political ideologies. Women and Blacks, for example, tend to support affirmative action policies more than do men and Whites. Both overt and subtle forms of prejudice are associated with less support for affirmative action policies. In addition, political conservatism reliably predicts support for these programs; people who are most conservative report the least support.

### **Diversity Education and Training**

Diversity education and training programs are designed to foster educational and employment settings that positively support diversity while discouraging intolerance and discrimination. Such programs vary tremendously. Some programs focus almost exclusively on providing employees with an understanding of antidiscrimination laws whereas others seek to foster positive intergroup attitudes through experiential exercises designed to promote empathy with targets of discrimination.

### *Academic Settings*

In academic settings, two perspectives have emerged: antibias education and cooperative learning. Antibias education explicitly focuses on teaching students about the existence of prejudice and

discrimination in society. The goal of these types of programs is to raise awareness about the different types of bias and to help students develop skills that will allow them to understand and counteract their own biases. Although only a limited number of studies have tested these issues empirically, initial evidence points to the efficacy of such approaches. For example, students' attitudes toward stigmatized groups are more positive following participation in psychology courses that focus on issues related to stereotyping and prejudice, particularly when such courses foster introspective awareness.

Cooperative learning programs focus on indirect attitude change through intergroup contact and collaboration rather than explicitly teaching students about cultural diversity, prejudice, and discrimination. Elliot Aronson and colleagues' *jigsaw classroom technique* is a now-classic and widely used approach to fostering cooperative learning. In a jigsaw classroom, teachers divide students into small ethnically and academically diverse groups, distributing materials to be learned across students. Students are then responsible for teaching one another the materials. This method of teaching has produced inspiring results. Students in jigsaw classrooms grow to like and respect each other more, are less prejudiced, and have higher self-esteem compared to students in traditional classrooms.

### *Employment Settings*

In employment settings, employers typically adopt educational strategies that parallel the goals of educational approaches in academic settings. Empirical examinations of the efficacy of such programs in employment settings are limited. However, research points indirectly to the efficacy of diversity training programs. For example, members of racial/ethnic minority groups report perceiving their work settings to be more positive and tolerant in institutions where such programs are implemented. Moreover, programs to promote a positive work climate appear to ameliorate some of the negative effects of racial diversity on group dynamics described above. Not surprisingly, if employees feel coerced or otherwise threatened by the information presented in these programs, it is unlikely such programs will

be successful at reducing intergroup bias and promoting tolerance in the workplace.

### Conclusion

Around the world, demographers agree that cultural diversity within groups and societies is likely to continue to increase over time as technological advances make it easier for people to travel and migrate between regions, and as virtual technologies (e.g., Internet telecommunication) increase contact among people of different nations and ethnic groups. Researchers studying diversity in group settings have been challenged by the difficulty of defining diversity. Although research to date suggesting there are both costs and benefits of diversity within groups may seem contradictory and confusing, one thing is clear: diversity in groups matters. Hence, future increases in cultural diversity and intergroup contact will necessitate a continued effort to understand the role diversity plays in group phenomena, including the factors that moderate and mediate its effects on human cognition, affect, and behavior.

## DOGMATISM

---

*Dogmatism* is a personality characteristic that describes an intolerant and inflexible conviction in one's own beliefs. People who are high in dogmatism will have a narrow political orientation and conform easily to authority. They will tend to be intolerant toward those who are different from themselves and reject points of view that challenge their own beliefs. Dogmatism is associated with a closed-minded way of thinking, and it is related to general extremist tendencies rather than any one specific belief system. This entry describes at the background of the concept, as well as related constructs and their implications.

### History and Background

The psychological concept of dogmatism was introduced by Milton Rokeach in 1960 as a critique of Theodor Adorno and colleagues' *authoritarian personality theory*. According to Rokeach, authoritarianism, which is measured by the *F-scale inventory*, reflects a right wing orientation and so

cannot account for ideological closed-mindedness on the left of the political spectrum. Rokeach believed that a general tendency toward closed-mindedness was unrelated to specific political attitudes; rather it was better conceived as a content-free tendency to rigidly follow the beliefs one holds.

Rokeach consequently developed a scale in an attempt to distinguish content-oriented from content-free *closed-mindedness*. The scale contained two subscales. The first subscale, *dogmatism*, assessed those aspects of closed-mindedness that are content-neutral. The second subscale, *opinionation*, focused on more content-specific tendencies, encompassing the earlier concept of authoritarianism. With this scale, Rokeach wanted to show that the underlying style of thinking was the same for those on both the right (e.g., fascists) and the left (e.g., communists) of the political spectrum.

Rokeach compared extreme right wing groups with left wing groups. The results were partially supportive of his argument that dogmatism was a more general construct than authoritarianism. In one of his studies that compared Adorno and colleagues' authoritarianism scale with his own dogmatism scale, communists had lower F-scale scores than all other groups, including conservatives, liberals, and Labor Party members. This, he argued, showed that the F-scale was actually measuring the authoritarianism of the right. On the other hand, for the dogmatism scale, communists scored the same as conservatives and in fact had the highest score of all the groups tested. Rokeach interpreted these results as evidence that dogmatism is a more general measure of (the content-specific) tendencies tapped by the F-scale.

### Origins of Dogmatism

Rokeach proposed that dogmatic thought arises out of a particular set of early childhood experiences, similar to Adorno and colleagues' explanation for authoritarian tendencies. Specifically, he suggested that repressed anxiety associated with an exaggerated glorification of one's parents would be linked to the development of dogmatic tendencies. By rejecting, out of hand, beliefs that contradict their own, individuals high in dogmatism could achieve the security and certainty they were unable to attain in childhood.

### Related Constructs

It is important to note that there has been dispute over the purported independence of authoritarianism and dogmatism and whether Rokeach's scale could appropriately distinguish the two constructs. In response to this, Bob Altemeyer introduced a new measure of dogmatism that focused, not on the way in which dogmatic individuals think, but on the *definiteness* of the beliefs they hold. He argued that dogmatism is the unjustified conviction in the value of one's beliefs, which is unassailable by evidence to the contrary. He devised a new, 20-item scale to measure dogmatism with the use of items such as "The things I believe in are so completely true, I could never doubt them." This new scale proved more reliable and valid than earlier attempts. For example, it correlated with the *right wing authoritarianism scale*, also developed by Altemeyer, which distinguishes between different kinds of authoritarian personalities, namely, those who are followers and leaders. Moreover, in a follow-up study, Republicans scored higher than Democrats. These results were taken as evidence that even though it is defined as a content-free construct, dogmatism is more useful in explaining the mind-set of right wing than left wing ideology.

Many psychological tendencies have been linked to dogmatism during the past 20 years. Some of these include need for cognitive closure, need for cognition, intolerance of ambiguity, integrative complexity, openness to experience, and uncertainty tolerance. Although these variables clearly have close links with the central tenet of dogmatism, the precise nature of these relationships has yet to be fully explored. Further research is needed to answer the question as to whether left wing and right wing ideologies are distinctive in their content while sharing a common set of characteristics that can be called dogmatism.

### Conclusion

Recent work has extended our understanding of the cognitive processes involved in dogmatic thinking. We know that dogmatic individuals adopt and hold more extreme attitudes and find it difficult to revise their existing beliefs. We know that they react to inconsistent information by ignoring or selectively forgetting it. We also know that they are more likely to show an inability to

ignore previously expressed beliefs when asked to adopt a contrary position. Finally, dogmatic individuals have a tendency to compartmentalize information in memory, which likely contributes to their tendency to persist in their beliefs in spite of information to the contrary.

## DOMINANCE HIERARCHIES

---

*Dominance hierarchies* reliably form in face-to-face groupings of all primate species, including humans. Their defining feature is that higher ranked individuals have more influence, power, and valued prerogatives than those of lower rank.

To avoid an overly simple picture, several qualifications are needed: Rank may be persistently relevant among primates in permanent groups or only occasionally relevant for animals that forage alone; rankings are usually but not necessarily transitive; the relative status of two individuals may depend, in part, on the proximity of allies; sometimes, the highest ranking position is shared by a coalition of two or three individuals; and it is often easier to identify a male ranking than a female ranking.

Often social psychologists speak about small-group status hierarchies in specifically human terms, ignoring their essential similarity to the

status hierarchies of apes and monkeys. Human hierarchies do have unique characteristics, most obviously their dependence on language and complex cultural knowledge, but these are evolved variations on a basic primate theme.

Some social scientists make the dubious claim that *all* human status structures reflect an evolved (primitive) tendency toward hierarchy. To avoid this fallacy, one can distinguish three kinds of hierarchies: (1) face-to-face hierarchies; (2) formal organization hierarchies, such as those drawn on corporate organization charts; and (3) macrolevel socioeconomic systems (or social classes) of large societies. The last two kinds did not exist prior to the development of agrarian societies 10,000 years ago, and they do not occur among nonhuman primates. While such “modern” structures are permeated by face-to-face hierarchies, they are not themselves face-to-face hierarchies, and they are not based on the same biosocial mechanisms that affect status ranking within primary groups. This encyclopedia entry is concerned solely with face-to-face status hierarchies.

Among higher primates, dominance hierarchies have emergent features beyond simple rank ordering. Members of the group prefer to interact with near peers. The highest ranked members (the leaders) perform service and control functions for other members and for the group as a whole, directing relations with other groups and defense against threats to the membership. Social control within the group, including the allocation of status, is achieved partly by high-ranked members’ manipulating the stress of low-ranked members.

### Allocating Ranks

A common misunderstanding is that dominance rank is attained solely by force or aggression, the imposition of the strong on the weak. To the contrary, especially among apes and humans, status interactions are typically nonviolent, often subtle, and, in human terms, “polite” and conforming to accepted norms. High rank may be a prize for which to compete, but it can also result from unforced deference by other group members. Only rarely does competition for rank escalate beyond normal limits, more often among young adult males. Most of us live our adult lives in continual status interaction without overt threat or violence.

Dominance hierarchies, once set, are fairly stable. But when a group newly forms, there must be an initial allocation of ranks, and in established groups, some individuals occasionally alter their positions. How are these initial rankings, and later changes in rank, determined? The short answer is that ranks are allocated either cooperatively, by consensus of those involved, or competitively, when there is disagreement over who should be superior.

Every individual has certain observable signs (or signals) that suggest his or her social status is (or ought to be) high or low. Some status signs are limited to a particular species, such as the silver hair on the back of a dominant male gorilla. Others are similar across primate species. For example, large size, physical strength, vigor, good health, being adult (vs. being juvenile), being male, and (among the higher primate species) having a high-ranked mother are all signs associated with high status, while their opposites suggest low status. For humans, wearing expensive and fashionable clothing is a signal of high status. A beautiful wife, desirable to other men or having a rich dowry, gives prestige to her husband; a rich or powerful husband or protector elevates a woman's perceived rank. Status signs precipitate *expectation states* in the theoretical work of Joseph Berger and his colleagues.

Visualize two females, Ego and Alter, meeting for the first time. If their interaction is very brief or casual, the notion of ranking may never arise. In more extended or serious meetings, each will appraise the status signs of the other, forming some idea of their relative standings. If Ego perceives that Alter's status signs exceed her own, she may immediately defer to Alter. Ego, in explaining such concessions, may offer that Alter belongs in the higher rank, that Alter deserves it, that Alter could easily take it if Ego resisted, or that Alter will be more *competent* in the duties of high rank.

If Ego and Alter do not agree on their relative ranks, the outcome may be decided by one or more short dominance contests between them. A mechanism postulated to operate across primate species is that each individual attempts to "out-stress" or intimidate his or her opponent. The one that succeeds becomes dominant, the other subordinate. As an example, the eyes of two male strangers, Ego and Alter, meet by chance across a room. Ego decides to hold the glance. The chance eye contact

now becomes a dominance contest. Ego's stare makes Alter uncomfortable. Alter may avert his eyes, thus relieving his discomfort while in effect surrendering, or he may stare back, making Ego uncomfortable in return. In the latter case, the "stare-down" continues, with each individual trying to out-stress the other until finally one of the two succumbs to the discomfort (and to the challenger) by averting his eyes. The matter thus settled, the yielder usually avoids further eye contact although the winner may occasionally look at the loser as if to verify his victory. In this context, staring is an assertive sign of high status. Eye aversion is a deferent sign associated with low status.

### Conversation

Speech is the major and unique means of human face-to-face communication, and it provides a large number of status signs. These may be conveyed by specific words ("I came, I saw, I conquered" vs. "I am the dust beneath your feet"), by accompanying gestures (a pointed finger vs. averted eyes), or by intonations (loud and commanding vs. soft and hesitant).

Conversation between Ego and Alter is, by definition, a series of turns in which each person talks while the other listens. Two rules normally regulate turn taking:

1. If one individual is speaking, the other should remain quiet.
2. A listener who is offered the floor should speak.

Violating either of these rules is a dominant action. If both people violate them, there is a dominance contest, with each trying to speak over the other or interrupting the other. An alternative means of acting dominantly is to remain silent while the other person offers you the floor. Such violations are stressful. The contest is resolved, and the situation becomes more comfortable, when one person acquiesces and follows the appropriate rules.

There are other conversational rules of which most of us are consciously unaware but which we nearly all follow. For example, do not look into another person's eyes when no one is speaking (unless in a romantic context or at a distance well beyond normal conversational range), and look at

the speaker's face, particularly if the speaker is looking at you. Violating such rules sends a dominant signal, while following them strictly is a deferential signal. A conversational dominance contest may be so subtle that it is barely perceptible, even to the contenders.

### Testosterone

Testosterone is produced by both sexes but to a greater extent in males than in females. Testosterone is the hormone that is essential for the development of male characteristics in the fetus and the adolescent; however, this entry focuses on circulating testosterone in men. Testosterone is not the most important determinant of dominance, but it promotes dominant behavior. The relationship is reciprocal; that is, changes in dominance behavior or social status also cause changes in testosterone level. Among men athletes, for example, testosterone rises shortly before their matches, as if in anticipation of the competition. After matches, testosterone is higher in winners than in losers. Hypothetically, this provides a feedback loop in which success in competition heightens testosterone, which in turn facilitates future competitive success, and so on. On the other hand, a defeat depresses testosterone, which inhibits future competition. This produces a hormone-reinforced momentum, differentiating winners from losers.

Testosterone may be implicated in the aggressive street behavior of U.S. inner cities, where sociologist Elijah Anderson vividly portrayed the importance of dominance contests. He described how facial expressions, gait, and verbal expressions are used by young Black men to make or deter challenges. This environment of continual vigilance and challenge would be expected to elevate testosterone. Indeed, mean testosterone among young, poorly educated Black men is especially high. (High testosterone is not a general characteristic of Black men but is confined to those who are young and poorly educated.) Elevated hormone levels encourage further dominance competition, which occasionally turns violent. Homicides may occur when a dominance contest between friends or acquaintances, begun over a trivial disagreement, explodes in rage. This tragic outcome is facilitated by the presence of alcohol and a weapon.

## DYADS

---

Strictly speaking, a dyad is any pair of individuals. However, among psychologists, the term *dyad* is usually restricted to pairs of individuals who are expected to exhibit interdependence or relatedness in their thoughts, feelings, and behaviors. When social psychologists study dyads, they typically are studying interactions between two people who have or might anticipate having an ongoing relationship. That is, their research designs typically involve pairs of individuals who influence one another in some manner and often in many ways.

Technically, dyads are one type of group. At times, the study of dyads deals with the same issues as the study of groups of other sizes might deal with. For instance, an organizational psychologist interested in sharing of information between work colleagues might examine the same issue when studying collaboration in groups of two, three, or four individuals. However, much work on dyads involves the study of intimate relationships (e.g., romantic partners or spouses) that likely include phenomena that simply do not exist at all or in the same form in groups larger than two.

### Ways of Categorizing Dyads

Sometimes dyads are categorized by terms used in common language. For instance, dyads might be referred to as strangers, business partners, enemies, friends, romantic partners, or spouses.

Large bodies of psychological, sociological, and anthropological research are organized around these categories. Sometimes, however, psychologists identify dyads by the nature of the interaction the members of the dyad have with one another. For instance, a dyad might be described as an *exchange relationship* in which each person offers something to the other with the expectation of receiving something in return, or as an *authority-ranking relationship* in which one person follows another's directions by virtue of the status the first one possesses. Dyads also are identified sometimes by the functions that individuals serve for one another. For instance, an *attachment relationship* is one in which one individual (the *attachment figure*) serves as a consistent provider of support, encouragement, and sense of security in times of stress through his or her actions or mere presence, while the other person (an attached child, for instance) is the beneficiary of these provisions.

Large bodies of research are organized around the norms that govern dyadic interaction, the functions that dyads serve for their members, or a combination. Sometimes the distinctions between dyads are qualitative, referring to differences in the form, function, or nature of dyads, and creating categories that are truly nominal in nature. For example, mixed-sex dyads may be distinguished from same-sex dyads, or boss–employee or leader–follower dyads might be distinguished from dyads of coworkers. Often, however, there are substantial quantitative variations among dyads, and even within individual members of a given dyad, in terms of some construct relevant to the dyads' form or function. For instance, dyads can vary in terms of the ongoing degree of responsibility members assume for being noncontingently responsive to one another, how secure or trusting or warm the members feel, how similar they are to each other, or how often their interactions are conflictual. Individuals within a single dyad can vary in many of these ways as well. Researchers may use distinct nominal terms to differentiate dyads that vary along a quantitative dimension, referring (for instance) to secure versus insecure pairs of romantic partners. Yet it is wise for researchers to keep the underlying quantitative dimensions in mind while both theorizing and interpreting findings.

### Dyadic-Level and Individual-Level Variables

Whereas some variables may vary within and across dyads (e.g., whether people care for or trust others may be a result of both individual-difference and relationship-specific factors), other variables are strictly of a dyadic nature and cannot be assessed or conceptualized without thinking in dyadic terms because they describe features of dyads rather than individuals. Examples include the amount of self–partner agreement, similarity, or reciprocity, the length of the relationship, or the relationship type. In addition, some constructs vary only within dyads because they involve a comparison between one person and the other. Power and division of labor are examples.

### Ways in Which Interdependence Between Individuals May Arise

Dyadic *interdependence*—relatedness in thoughts, feelings, and behavior—may arise through a variety of processes, including (a) members of the dyad forming the dyad on the basis of similarity or differences, (b) members of the dyad influencing each other, and (c) members of the dyad experiencing the same events across time.

### Special Considerations When Studying Dyads

Precisely because of the interdependence of thoughts, emotion, and behavior found in dyads, special considerations must be made when analyzing data arising from dyadic studies. Interdependence is empirically indicated when the responses of people within the same dyad are more similar to (or different from) each other than the responses of people who are not in the same dyad. Data analysis techniques such as *intraclass correlation* can be used to assess the degree of interdependence. This interdependence often presents data analysis challenges, depending in part on whether members of the dyad are viewed as *distinguishable*. In distinguishable dyads, a meaningful factor can be used to separate the two members of every dyad. This is often decided theoretically (e.g., *should* gender matter in this analysis?) or empirically (e.g., *does* gender matter in this analysis?). In the distinguishable case, researchers sometimes use the individual as the unit of analysis and employ traditional

analytic techniques such as *analysis of variance*, *Pearson correlation*, and *ordinary least squares regression analysis*, but they do so separately for each level of the member-distinguishing variable (e.g., separate analyses for men and women in a sample of heterosexual couples). Special analytic techniques that use the *dyad* as the unit of analysis, such as *multilevel modeling* and *structural equation modeling*, are often used when dyad members are considered to be indistinguishable (i.e., when no variable meaningfully separates the two members of every dyad). Without conducting separate analyses for each level of a member-distinguishing variable, the interdependent nature of the data violates the independence of observations that more traditional analytic techniques assume and require. Often these special techniques also are employed in the distinguishable case. By modeling outcome variables as correlated across the members of each dyad, these techniques usually provide more accurate parameter estimates than do traditional analytic techniques. More complex designs involve individuals simultaneously belonging to multiple dyads, such as a woman who is both a wife and a mother. Several useful guides for analyzing dyadic data, as well as more in-depth treatments of dyadic analysis, have been published.

### The Importance of Considering Dyadic Context for Understanding Social Phenomena

Social psychology has a tendency to focus on individuals and their reactions to standardized social stimuli. The very nature of social phenomena, however, can vary dramatically by dyadic context. For example, people working on joint tasks for which there will be a reward keep track of individual inputs when working with strangers but actually bend over backwards not to do that when working with friends. Offering repayment for a favor can increase liking within a business dyad yet decrease liking within a friendship. Some researchers have even suggested that we are fundamentally different people when interacting with distinct relationship partners such as a parents, romantic partners, and friends. It behooves researchers studying social processes to routinely ask themselves whether their findings might change if the dyadic context were altered.

## DYNAMICAL SYSTEMS APPROACH

---

The *dynamical systems approach* views groups as systems in which collective behavior arises from the flow of information and mutual influence among members. This approach to studying groups uses concepts and methods from systems, chaos, catastrophe, and complexity theories. A *dynamic system* (a general term) is any system that changes over time. A *dynamical system* (a more technical term) is any system whose current state provides a basis for predicting its state in the immediate future. The dynamical systems approach is particularly useful for understanding how groups change over time, whether that means short time spans of minutes and hours or longer

periods of weeks, months, and years. Change includes small fluctuations, rhythmic cycles, and both abrupt and gradual departures from prior patterns.

Scholars who take a dynamical systems approach share an interest in the interplay between stability and instability that underlies continuity and change in groups. This approach has been most commonly applied to collective behavior, from dyads to small groups to crowds and organizations. However, it has also generated theory and research on the patterning of attitudes in groups, on therapeutic outcomes in group members, and on the emotional dynamics of group members. Studies using this approach have demonstrated how the emergence of stable dissenting subgroups is consistent with conformity theories, shown that greater complexity heightens the effectiveness of group therapy, and explained why a modest intervention can have either a small or a dramatically large effect on the accident rates among workers in groups.

### History of Dynamical Systems Approaches to Groups

Most contemporary dynamical systems approaches to modeling groups were developed in the 1980s and 1990s, but precursors were evident decades earlier. Kurt Lewin, one of the founders of group dynamics, proposed an explicitly dynamic approach to studying groups in the 1940s. Application of his field theory approach, however, was hampered by the lack of appropriate methods. In the same era, Robert F. Bales (who was influenced by Lewin) developed one of the earliest methods to measure group interaction, using a fine-grained scale that classified every statement in a group discussion. A statement might be a request for information, for example, or an expression of approval or support. The resulting time series of codes can be examined to detect recurring patterns over time.

A new wave of dynamical systems approaches to groups emerged in the 1980s. A few years earlier, in 1976, mathematician E. C. Zeeman published a *catastrophe model* designed to predict the sudden outbreak of prison riots based on a combination of tension and alienation. Catastrophe models are a set of mathematical models of discontinuous change such as explosions or the sudden collapse of a bridge. However, the adoption of

such analytical techniques by psychologists was not evident until a decade later, after further groundwork adapting catastrophe models to data in the biological and social sciences occurred. The repertoire of dynamical systems applications to psychology was further developed during the rest of the 20th century by applying and adapting methods and concepts from chaos theory and complexity theory. *Chaos theory* revealed that seemingly small events can have a profound impact on how a dynamic system such as a group changes over time. The *complexity theory concept of self-organization*—the spontaneous emergence of new structure and order—provided insight into group formation and the emergence of roles, norms, and routines in member behavior.

### Dynamical Systems Methods for Studying Groups

To study dynamics, groups must be observed at multiple time points. Dynamical systems methods vary widely in the number of time points needed, from a minimum of two for each group to high-quality data streams that provide hundreds or thousands of observations. Data are collected and theory developed and tested via behavioral experiments, coding of group interaction, computer simulation, and mathematical modeling. The results are typically analyzed using graphical plotting techniques, nonlinear regression, and other statistical and mathematical techniques for identifying patterns in time series data. The data may be quantitative or, like Bales's coding of statements, categorical. The best way to illustrate the methods is to describe selected studies that used particular techniques.

### Continuous and Discontinuous Change in Accident Rates

Over several decades of research, evidence accumulated that accident rates in the workplace depend in part on how many people are working together in a subunit. How exactly group size and accidents were related, however, was unclear. Some studies found that accident rates were higher in larger groups, whereas others found that accident rates were highest in smaller or in medium-sized groups. No explanation accounted for these

mixed results until Stephen Guastello applied a *cusp catastrophe model* to the data. Cusp models are a good fit for data in which shifts between two equilibrium states (in this case lower or higher accident rates) are governed by two *control parameters* (features of the operating situation for the group).

The data consisted of accident rates measured at two to four points in time for each subunit. A nonlinear regression analysis of the difference scores (changes in accident rates across time) showed that accidents increased steadily in proportion to environmental hazards (the first control parameter) when units were large. When units were small, however, accident rates could shift abruptly from near zero to much higher rates, and vice versa. Group size was thus the second, *bifurcation* control parameter. The bifurcation is a shift from continuous (smooth, gradual) change to discontinuous (large and abrupt) change with smaller group size. When outcomes fit a nonlinear pattern, as in a catastrophe model, the results from any particular study will depend on what range of hazard conditions and group size was sampled. A catastrophe model made sense of what were apparently contradictory results.

### Chaos and Complexity in Therapeutic Groups

Chaos theory emerged after the unexpected discovery that apparently random dynamic behavior may actually have a complex order. Chaotic patterns were first documented in such phenomena as weather patterns, water turbulence, and dripping faucets. Chaotic dynamics generate behavior that is predictable for a short time but then quickly diverges. This is because very small fluctuations (the proverbial flap of a butterfly's wing) can send a system in a new direction. The empirical study of chaotic dynamics relied on the development of measures of chaos that were eventually applied to other phenomena, including group behavior.

Unlike catastrophe models, which can handle data measured at just a few time points, reliable detection of chaotic patterns requires much longer time series consisting of hundreds and preferably thousands of time points. Analysis of the time series assesses the degree of chaos or complexity that is present. In group research, studies typically investigate

whether the degree of chaos or complexity is associated with some outcome such as creativity, cooperation, or therapeutic effectiveness.

If time series lack adequate length and measurement precision, then reliable detection of chaotic patterning is difficult. Fortunately, less demanding methods are available to measure the complexity of group dynamics. In the past decade, group research has shifted away from attempts to identify chaotic patterns and toward measuring complexity as something that varies both across groups and within groups across time.

In the 1990s, Addie Fuhriman and Gary Burlingame and colleagues analyzed data from four therapy groups that each met for 15 sessions lasting 2 hours each. Every verbal utterance of every participant was coded for therapeutic quality on a 16-point scale, generating around 14,000 codes per group. After calculating the *fractal dimension* (a measure of complexity) for the time series of codes from each of the 15 group sessions, their analysis showed that the average level of therapeutic quality in a session was higher when group members' interaction was more complex—in other words, showed a greater variety of patterning. Other researchers have used fractal dimensions and related measures to study the process of self-organization in groups.

### Self-Organization in Group Formation

Self-organization is the process by which mutual influence among interacting components generates pattern and structure at a collective level. For small groups, David Pincus has characterized these emergent structures as the rules, roles, relationships, and realities (systems of shared beliefs) that develop through social interaction and shape the responses of group members to each other. As patterns emerge, behavior becomes more predictable. Pincus and colleagues have studied self-organization in groups by recording and analyzing the sequencing of contributions from different group members to measure the number and length of conversational patterns. Both conflict between and closeness among group members are positively associated with the emergence of orderly patterns of interaction.

Using a different methodology, Bibb Latané and colleagues studied the impact of interpersonal

influence on a large set of people with previously uncoordinated opinions. They used a simple computer model called a *cellular automata*, which is like a large checkerboard on which every chip (every *node*) can be one of two colors (red or blue, for example). The colors might represent a preference among two political candidates, a judgment of guilty or not guilty, or any set of two contrasting attitudes. At the starting point of the simulation, the “attitudes” of the nodes are set at random. However, at each subsequent time step, the color (the preference) is determined by the influence exerted by a node’s neighbors, who are also either red or blue. Closer neighbors exert stronger influence than more distant neighbors do. In the simulation that Latané and colleagues used, the “nodes” also varied randomly in how persuasive they were and how “supportive” they were of like-minded neighbors. The result of repeated interactions among nodes is that the initially random distribution quickly reorganizes into coherent areas of like-minded nodes. Even if the checkerboard as a whole turns mostly one color, however, pockets of the other color also form and persist because of the mutual support of close neighbors. These computer models provided an elegant illustration of how stable dissenting subgroups can quickly develop and stabilize even in the face of a much larger majority with a different view. The simulation results were later replicated with laboratory studies in which real people interacted on computers and shared their views with those who were closest to them in a social network.

All these studies fit within the dynamical systems framework, based on their use of methods and measures especially suited both to studying changes in group outcomes and to illuminating the dynamic processes that generate these changes.

## EMERGENT NORM THEORY

---

An old joke runs along the following lines. Herald: “The peasants are revolting, My Lord!” Lord: “I know, quite disgusting.” Representations of crowds since at least the Middle Ages have been characterized by this kind of “fear of the masses.” Crowds were seen as dangerous, unpredictable, chaotic, threatening, and inhuman, in that they lacked the capacity for reason and restraint. Familiar phrases such as “the baying crowd” and “the herd instinct” illustrate this infrahumanization. In the 19th century, industrialization and urbanization gave the masses more chances to congregate, and scholars such as Gustave Le Bon continued to emphasize the irrational and chaotic aspects of crowd behavior. In the 20th century, influenced by the prevailing intellectual climate of humanism and the writings of Karl Marx, scholars realized that there was a method to crowds’ apparent madness and that the behavior of violent and terrifying crowds is seldom entirely random. *Emergent norm theory*, the brainchild of the sociologists Ralph H. Turner and Lewis Killian, was one of the most important contributions in this vein.

Like many other sociologists and social psychologists—most notably their contemporary, Muzafer Sherif—Turner and Killian assumed that social behavior is driven by norms. Specifically, they suggested that in extraordinary circumstances, such as civic emergencies and certain types of crowd situations, the mundane norms that govern the course of our everyday lives no longer apply. New norms are required and are created by the crowd.

The type of crowd of most interest to Turner and Killian is the crowd that is not governed by established rules, has no predetermined leaders or leadership structure, and has no formal, prearranged mechanisms for making decisions or selecting leaders. The crowd ought to have been drawn together by a precipitating event that is the focus of the crowd members’ attention, such as a flood, an earthquake, a war, a protest, a strike, or even a power cut that disables the normal mechanisms of authority.

According to Turner and Killian, a key characteristic of such a crowd is that its members share a sense of both uncertainty and urgency. The precise nature of the event that has brought the group together may not always be clear. Crucially, the ultimate outcome of the event and the crowd situation is difficult to determine. There is no agreement in advance on what the crowd is trying to achieve and how. In addition, the crowd can exist only for a limited time and has only a limited time to act. Thus when the crowd first forms, people ask each other questions like, “What’s happened—was it an accident or a terrorist attack?”; “What’s going to happen next?”; “What should we do?”; “What should I do?”; and “Who will act?” Turner and Killian labeled this process of investigations, questions, and rumors *milling*. Through the process of milling, the initial uncertainty experienced by the crowd is reduced, and a shared understanding of the situation begins to emerge.

In the next stage of the formation of emergent norms, called *keynoting*, individuals make positive suggestions for action. A *keynote* can consist of a

verbal suggestion made to the crowd or some part of it (e.g., “Let’s storm the ramparts”), or it can simply consist of a distinctive action (e.g., an individual spontaneously mounting the ramparts, setting an example for others). Keynotes are more likely to be accepted if they converge with the predispositions of a large part of the crowd. For example, if many people in the crowd are angry, aggressive keynotes are likely to be influential. Eventually, through keynoting, a dominant understanding of what is right and wrong in the situation is determined, and the urgency of the crowd is focused on a specific course of action.

At this point, an emergent norm has formed, including a shared definition of the situation and a shared understanding of which behaviors are right or wrong in the circumstances. Initially rather formless and unsure, the crowd appears now to behave with some logic and purpose, and to be capable of enforcing its new norm. Thus, via processes of normative influence that are familiar to social psychologists, crowd members begin to experience pressure to conform to the implicit norm that they perceive to be taking shape. By conforming to this new norm, crowd members influence those around them, who infer from these members’ conformity that the norm is widely accepted.

Turner and Killian point out that the emergent norm does not produce unanimity in the crowd. There is no “group mind” in emergent norm theory. If unanimity appears to exist, it is an illusion reinforced by pluralistic ignorance, a process in which the silence of dissenters is taken for assent. The active and apparently enthusiastic participation of crowd members may be attributable to any number of motives apart from the desire to further the interests of the collective or to validate its norms. This point—that as the situation unfolds, individuals feel and act differently and participate for different reasons—is crucial to emergent norm theory and distinguishes it from other theoretical accounts of crowd behavior.

Turner and Killian flesh out this point by describing different types of participants that one might expect to find in a crowd situation and outlining their motives and how they might behave. The *committed* feel little uncertainty about the appropriate cause of action; they are highly identified with the collective and have a sense of common fate with it. These

crowd members act with little hesitation or vociferously suggest courses of action, and they are very likely to be prominent keynoters. In contrast, the *concerned*, while sharing the sense of common fate possessed by the committed, are sure that something should be done, but are uncertain about what. Although they are unlikely to keynote, they are likely to attend closely to, and eventually accept and act on, suggestions from others. Some participants are not highly invested in the crowd but merely want to see what happens; these people are termed *curious spectators* by Turner and Killian. Still other members of the crowd are *exploiters*, who have shown up merely to capitalize on all the fuss, perhaps for the sheer thrill of violence and destruction, perhaps for loot, to pick pockets, or even to sell souvenirs. Like curious spectators, the failure of exploiters to resist the emergent norm is liable to be taken as support for it. Even though curious spectators are passive and disengaged, and mercenary crowd members are exploiters, the active participants in the crowd are likely to see these individuals’ presence and failure to intervene as tacit signs of approval. In this way, they contribute to the growing illusion of unanimity among crowd members.

### Critiques of Emergent Norm Theory

The descriptive terminology of emergent norm theory is impressive in its intuitive appeal, its vividness, and its detail. Ironically, however, its descriptive felicity has attracted some of its most telling critiques. A problem that many critics have had with the theory is that it tends too often to describe rather than genuinely to explain crowd behavior. If we understand much of emergent norm theory as a causal analysis, it turns out to be circular. Thus Clark McPhail, the sociologist who has published perhaps the most sustained critique of emergent norm theory, notes that exploiters are so designated because they show up and try to capitalize on the situation, curious spectators earn their label by turning up to watch, and the committed are so called because they care about the issue that has brought the crowd together and have strong views on what to do about it. The theory does not specify what causes different people to adopt these roles. Neither does it lay out the conditions that determine

whether a crowd will organize itself along individualistic lines or more collectivistic lines based on solidarity. Further, it is not altogether clear why some keynotes achieve influence and others do not. Turner and Killian argue that “distinctive” individuals and behaviors are likely to shape the emergent norm, but they do not spell out what they mean, exactly, by distinctiveness. Steven Reicher points out that if emergent norm theory ultimately attributes the behavior of crowds to the lead of a handful of distinctive individuals, it weakens its own claim to be a theory of collective behavior proper.

More generally, critics have pointed out that it is not clear in what sense the “collective behavior” of crowds is different from the aggregated behavior of the individuals who comprise the crowd. For example, McPhail argues that while psychological states such as “uncertainty” and “urgency” can be ascribed to individual crowd members, it is not clear they can be ascribed to the collective, at least without resurrecting the group mind hypothesis.

Critics have also alleged that the theory is not specific about how crowds form and are organized. Where emergent norm theory does make clear predictions, empirical support is mixed. For example, according to the theory, rumor is central to the formation of crowds and occurs throughout the milling process. However, field studies of events involving crowds, such as the Detroit riots of 1967, showed that more participants heard about the riots through the mass media than by rumor.

Empirical studies of crowds have produced other problems for emergent norm theory. For example, the theory predicts that conformity to crowd behavior should be strongest when crowd members are identifiable, as participants perceive that the crowd will reward compliance and punish deviance. In contrast to this prediction, most relevant research findings suggest that people are more susceptible to crowd influence when they are anonymous rather than identifiable, and when they are low rather than high in self-awareness. These findings are consistent with deindividuation accounts of crowd behavior.

Other critiques have focused on the extent to which the long-standing norms of the group and the societies in which they are embedded are left behind when crowds form, requiring entirely new

norms to emerge. Critics from various perspectives have asked whether there is really a radical discontinuity between the norms that govern our everyday lives and those that govern crowd situations. One reason to reject the notion of such a discontinuity is that few, if any, crowds are composed of individuals who spontaneously gather with little or no prior history of association. Field studies show that there is some kind of prior organization in most events involving crowds. Also, people tend not to show up alone, but in family, friendship, or peer groups. Once there, people tend to influence and look out for each other, according to their shared and ongoing norms.

Research by Reicher and his colleagues shows that the ongoing social identities and associated normative codes of crowd members, whether as environmental protestors, anarchists, or police, have a profound effect on their behavior in crowd situations. According to their social identity model of deindividuation effects, the creative potential of crowds lies in the ability of their participants to discover group norms that may not have been apparent to them before, and to transform and adapt group norms in light of the new situation.

Despite the many criticisms that have been leveled at emergent norm theory, even its critics have acknowledged the many valuable insights that it contributed to the study of crowds. In particular, its point that crowds have an energizing and creative potential, but nonetheless behave in rational, systematic, and normative ways, has been highly influential. We still have cause to fear some crowds, but it is clear that we should no longer regard them as lacking in all human reason or constraint.

## ENTITATIVITY

---

Research on the perception of *entitativity* addresses the question, “How do we come to see a collection of people as a group?” Entitativity is the degree to which groups are perceived as having the nature of an entity. Thus the perception of entitativity lies at the core of a wide variety of processes that involve groups. It is connected to numerous important processes in intergroup perception and in intergroup relations. This entry distinguishes entitativity from another important group feature, similarity, and discusses the consequences of entitativity for information processing, stereotype formation, collective responsibility, and social identity.

### Perceived Entitativity and Its Antecedents

#### *Perceived Entitativity*

What is entitativity? Entitativity can refer either to the actual *properties* of the group (in which case it is comparable to group cohesion) or to the *perception* of the group as a viable entity rather than a mere collection of people. The research on entitativity in the last decade has mainly focused on how we perceive aggregates of people to be meaningful and unified groups. It answers questions such as these: How and when do we perceive that a given collectivity has the properties that constitute a group? What does it mean for an observer to see an aggregate of individuals as “a group”? Entitativity can be seen as the glue that holds (or is perceived as holding) a group together, the “groupness” or unity of a group. We can observe that

some aggregates of people qualify as groups more than do others. Thus groups vary along a continuum of entitativity on which groups are ordered according to the extent that they are perceived as being “real entities.”

#### *Cues for Perceived Entitativity*

What features influence the degree of entitativity that is perceived in a given group? The perception of entitativity can be based on several different cues. A comparison can be drawn between the perception of objects and the perception of groups. Physical stimuli that are *similar* to each other are more likely to be perceived as part of the same object. In the same vein, perceived similarity among persons enhances the likelihood that those persons will be perceived as a group. Also, physical elements that are seen as moving together in the same direction are perceived as members of the same physical entity. Similarly, persons whose activities are coordinated because they share a *common goal*, and who therefore share a *common fate*, will be more likely to be perceived as a group. Furthermore, the amount of *interaction* among group members, the *importance* of the group to its members, and the *group’s organization and efficiency* facilitate the perception of entitativity.

#### *Types of Groups*

As already noted, groups differ in the level of entitativity they possess. In addition, empirical research has shown that people spontaneously recognize systematic differences among certain types of groups in daily life interactions. The three main types of groups that have been distinguished are intimacy groups, task groups, and social categories. *Intimacy groups* (e.g., family, close friends, support groups) are small groups with high levels of interaction; membership is important to their members, the groups have long histories, and membership in the group tends to be longlasting. *Task groups* (e.g., a committee, a jury, a unit of engineers, members of a professional sports team) are also relatively small and highly interactive, and their members have shared goals and common outcomes. However, task groups are less important to their members than are intimacy groups,

and they are of shorter duration and easier to join and leave. *Social categories* (e.g., women, Blacks, Democrats, Europeans) are very large groups with long histories, relatively impermeable group boundaries, and lower levels of interactions among their members.

These three major types of groups seem to correspond to three important social needs that characterize human beings: belongingness, goal achievement, and a secure sense of self and social identity. Intimacy groups provide the means for members to satisfy the need for belongingness through emotional attachment, love, acceptance, and social support. Participation in task groups helps an individual in achieving goals through mastery, cohesion, success, and efficacy. People also have a strong need to establish and maintain a stable and secure sense of self and social identity. They frequently derive this social identity from the broad range of social categories to which they belong, and this identity can aid in creating positive self-esteem. Often people take pride in their group memberships in large social categories, such as religious, ethnic, or national groups. Thus, perceivers' recognition of these different group types and functions can help them in meeting and fulfilling important social needs.

In addition, these three group types differ in their perceived level of entitativity. People see intimacy groups as very tight-knit groups. Task groups are also seen as meaningful and unified entities, but to a lesser extent than intimacy groups. Finally, social categories are perceived as only moderately entitative groups.

### Consequences of Perceived Entitativity

#### *Information Processing*

The degree of perceived entitativity of a group has important consequences for how individuals process information about groups. Group information is processed differently for groups that are perceived as high in entitativity than for groups that are perceived as low in entitativity. When processing information about a highly entitative group, people spontaneously form an organized impression from the entire group, and this mental image remains consistent across time and situations. The perceivers' assumption is that highly entitative

groups have unified, organized "personalities," and so they try to fit the available information into a coherent impression. Thus, information inconsistent with the existent impression about a highly entitative group needs to be further processed and explained. An important consequence of this more extended, integrative processing of information about unified, meaningful groups is that people remember information better about these groups than about groups that are low in entitativity.

Furthermore, when people receive behavioral information about an *individual group member* of a highly entitative group, they abstract a group characteristic or trait from this behavior and generalize this trait to other group members. For example, if John is a member of a highly entitative group, and he acts in a very intelligent manner, perceivers will infer that other members of the group are also likely to be intelligent. They therefore will label their group as a whole as "an intelligent group." In this way, people treat highly entitative groups as categories, and they develop prototypic representations of these categories. Thus, a certain group becomes associated with a specific configuration of characteristics and traits (e.g., members of Group A are then seen as intelligent, organized, diplomatic but vain). All of these effects are more likely to occur when the group is perceived to be high, rather than low, in entitativity.

#### *Stereotyping*

People's perception of highly entitative groups as meaningful units and generalization of group traits and features across all members comes very close to the act of stereotyping. Stereotyping consists of assigning psychological attributes to group members on the basis of their membership alone. It is an overgeneralization of attributes across all group members. A stereotype itself is a mental representation of a group and its properties, an abstract conception expressed in very general terms. Perceiving a group as being highly entitative leads people to form an abstract representation of the group based on information about individual group members. In this way, members of highly entitative groups come to be perceived as sharing the qualities inferred about other group members, even if the observers don't possess any actual

information about the behavior of the other group members. The consequence of this process is that, in the mind of the perceiver, members of highly entitative groups become psychologically interchangeable with each other.

This perceived interchangeability constitutes an important aspect of stereotyping. If all group members are seen as sharing the same attributes, then generalizing about the group as a whole becomes easier and seems more reasonable. For example, because John acted in a very intelligent way, perceivers abstract the trait “the group is intelligent” and consequently assign this psychological attribute to all members of the group. Hence all group members come to be seen as intelligent.

### *Collective Responsibility*

Another consequence of perceiving a group as high in entitativity is known as *collective responsibility*. Members of highly entitative groups are seen as sharing responsibility for other members’ behavior. If one member of a highly entitative group commits a wrongdoing (criminal or not), then other group members are perceived as being partially responsible for the act, even if they were not directly involved in the misdeed. Other members of the group are seen as collectively responsible for the act simply because they are all part of a tight-knit group. Members of a highly entitative group may be assumed to share responsibility because they share the same views, the same ideology, and the same overall goals as the wrongdoer. The group members of a highly entitative group also might be seen as collectively responsible because they should have been able to prevent the wrongdoer from performing the inappropriate act. Judgments of collective responsibility rest on and are derived from the perception of a group’s entitativity, and do not occur in groups perceived to be low in entitativity.

### **Perceived Entitativity and Perceived Similarity**

One difficulty with the concept of entitativity is that it is sometimes difficult to disentangle its content from that of a number of other group features. Entitativity is often confused with similarity, one

of its important cues. *Similarity* is defined as the extent to which group members are alike on a number of dimensions, for example, goals, personality traits, lifestyle, behavior, and physical appearance. Although similarity is an important predictor of the perception of entitativity, similarity by itself does not provide a complete understanding of perceived entitativity. In fact, entitativity and similarity clearly dissociate under certain circumstances. Similarity is especially an important cue for the perception of entitativity in social categories. All members of a social category share some feature (gender, race, religion, nationality)—that is exactly what binds those groups together. In this way it can be an important cue to the entitativity of some groups. However, similarity is considered a less important indication for entitativity for some other types of groups, such as task and intimacy groups. Of all groups, the family is among the highest in entitativity. Yet a husband, a wife, and a baby are less similar to each other, in spite of their being a strong entity, than the baby is to other babies, or the husband to other men, or the wife to other women. For task and intimacy groups, perceptions of entitativity draw more on common goals, the close interaction among members, and the importance of the group to its members than on the extent of similarities among members.

Furthermore, people tend to see the groups they belong to as more unified and meaningful than other groups. Group members value their membership in their own groups, and generally perceive them as being higher in entitativity than groups to which they do not belong. Conversely, they perceive more variation among members of their own groups than among members of groups to which they do not belong. These differences in perceptions of entitativity and similarity in groups to which one does and does not belong illustrate that similarity and entitativity are perceived differently depending on membership status.

### **Conclusion**

In summary, the perception of entitativity as reflecting the “groupness” of a group occupies a place at the very heart of social group processing. Perceptions of entitativity influence how people process group information in several ways. The concept of entitativity predicts stereotype formation

and provides insight into why people generate stereotypes. Individuals form a coherent, consistent mental representation of the highly entitative groups they encounter in daily life, and they generalize this representation across all its members. Entitativity also is highly functional and helps people to organize and structure their environment. People spontaneously categorize themselves and others into groups. Subsequently, they generalize typical group features across all the members, which is known as stereotyping. Because of the promising value of entitativity in fulfilling characteristic human needs, individuals feel more committed to highly entitative groups.

resources. Faced with this dilemma, individuals often invest further in the failing course of action. *Escalation of commitment* is considered a decision-making bias and is often seen as an economically irrational act. This is because the initial invested resources are sunk costs (costs that have been incurred and cannot be recovered), which should be ignored in subsequent resource allocation decisions. Escalation of commitment has also been termed the sunk cost effect, entrapment behavior, and the “too much invested to quit” problem. This entry examines various expressions of this behavior and possible explanations.

#### Importance

Escalation of commitment has been implicated in many arenas, ranging from individual decisions to organizational investments to governmental policies. Individuals have been shown to escalate their commitments in financial investments, auction bidding, and romantic relationships, as well as in decisions about hiring, firing, and promoting employees. At the organizational level, escalation of commitment has resulted in many multimillion-dollar decision errors. For instance, innovations, construction of plants, acquisitions, and loan decisions have all been shown to involve escalation of commitment.

Escalation effects have even been found to influence professional basketball players' playing time: Players who were higher draft choices gained more subsequent playing time than was merited by their productivity on the court. There have also been demonstrations of escalation at the governmental level. The province of British Columbia's decision to host the world's fair (Expo 86) involved escalation of commitment, resulting in millions of dollars of losses. And, at the national and international level, wars and extended conflict (e.g., the Vietnam War and the war in Iraq) are perhaps the most costly examples of escalation.

---

## ESCALATION OF COMMITMENT

---

Escalation situations are contexts where individuals have invested resources (usually money, but also time or energy) in pursuit of a particular goal, but after making scant progress toward the goal, they must decide to withdraw or commit additional

#### Background and Causes

One of the primary causes of escalation of commitment is the individual's need to justify or rationalize his or her initial choice. By investing additional resources in a losing course of action, decision makers have the opportunity to demonstrate to themselves

and others that their initial decisions were, in fact, worthwhile and “rational” investments.

To illustrate the importance of justification, Barry Staw conducted one of the earliest and most well-known studies on escalation. In this study, business students were asked to play the role of a corporate financial officer in charge of making an important investment decision. Their task was to allocate research and development (R&D) funds to one of two operating divisions of a company that had recently experienced a decline in earnings. Half of the participants allocated the R&D funds to a particular division, were given feedback on their decision, and were then asked to make a second allocation of R&D funds. The other half of the participants did not make the initial investment decision themselves but were told that it was made by another of the company’s financial officers. Feedback was manipulated so that half of the participants received positive results on the initial decisions and half received negative feedback.

The results showed that participants allocated significantly more money to failing divisions than to successful divisions, and the effects were most pronounced when *they*, rather than another individual, were responsible for the initial investment decision. These findings have been replicated by other laboratory studies as well as field research on issues such as the write-off of nonperforming bank loans. Such findings suggest that decision makers often seek to justify an ineffective course of action by increasing their commitment to it. Thus, although economic actors should be prospectively rational and ignore sunk costs, individuals who escalate their commitment appear to be “retrospectively rational,” honoring sunk costs in their subsequent investment decisions.

Although justification is a key psychological cause of escalation of commitment, researchers have systematically tried to examine other factors that can contribute to and exacerbate escalation. These escalation causes can be psychological, project related, social, or organizational. In addition to justification processes, there are numerous psychological causes of escalation. For example, people are most likely to escalate their commitment if their initial decisions are unambiguous, freely chosen, and open declarations. The way people search for and process information can also affect their escalation tendencies, because individuals tend to

search for confirming evidence that helps them to justify past outcomes rather than predict future outcomes.

Similarly, because escalation decisions generally involve losses, people may have a tendency to be more risk seeking in allocating additional resources. This is because losses are generally more painful than objectively equivalent gains are pleasurable. Therefore, although people may be more risk averse in gain situations (to retain the gains), they tend to take more risks in loss situations (to prevent or recoup losses), resulting in escalation of commitment. Finally, long-term personality differences can also increase escalation, with individuals focused on striving for personal achievement more likely to be subject to escalation tendencies.

Project-related causes pertain to objective features of a project or decision. For instance, escalation of commitment is more likely to occur when decision makers believe that there is hope of turning around a losing course of action, which in turn may be more likely to occur when the negative feedback is ambiguous or temporary. Similarly, if the investment payoff is very large or if the costs associated with escalating are deemed to be small, individuals may be more willing to keep escalating.

Social causes often become involved when escalation decisions occur in interpersonal contexts. For instance, when individuals make their investment decisions in public, they can feel a greater need to persist in a losing course of action so that they can save face in front of others. The need for face saving may be particularly strong if individuals’ personal identities are tied to an investment decision. For example, leaders who are strongly identified with a losing course of action may persist simply because consistency and persistence (rather than inconsistency and withdrawal) are patterns of leadership behavior valued by the general public.

Thus, although much initial research on escalation involved simple situations where only one person made an investment decision, subsequent research has identified escalation as a broader social phenomenon. One example of this is auction bidding, where escalation of commitment can occur when multiple parties try to outbid each other. In these and other social settings, factors such as competitiveness and rivalry can further fuel escalation of commitment.

Finally, when we consider the wider context in which escalation decisions often occur, it becomes apparent that organizational factors can also contribute to escalation of commitment. Projects may gain political support over time and become increasingly central to an organization's mission and culture. Projects can also gather supporters as resources and careers become increasingly staked to a course of action. Therefore, decisions that start with the actions of a single manager (or small group of managers) can subsequently grow into major commitments by an entire organization. Once decisions have become embedded within the organizational context, they may also be especially difficult to undo, even when withdrawal is in the organization's best interests.

As outlined above, individual needs to justify decisions are often a starting point for escalation. However, numerous other factors can contribute to the decision-making bias, especially when escalation decisions are viewed as occurring in social and organizational contexts. Because so many factors may contribute to escalation of commitment, escalation can be very difficult to prevent.

Some research has considered how to reverse the causes of escalation to help individuals and organizations de-escalate. For instance, escalation of commitment can be minimized by having a neutral party (someone not involved in the initial investment and the need to justify it) determine the wisdom of allocating further resources to the initial course of action. Nonetheless, there is often a natural momentum toward escalation that can compound early losses into larger and potentially dire consequences for individuals and organizations alike.

## ESSENTIALISM

---

*Essentialism* is a philosophical position on the nature of categories. An essentialist view holds that members of a category all share an inner essence that makes them what they are. Whether or not philosophers agree, people often *believe* that categories have essences, a belief known as psychological essentialism. Some of the categories that may be seen to have essences are social categories or groups. Social psychologists have recently taken an interest in essentialist thinking about groups because it seems to play an important role in stereotyping and prejudice. There is growing evidence that people who perceive groups in essentialist ways are more likely than others to hold negative attitudes toward group members and are more likely to make rapid stereotypical judgments about people on the basis of their group membership.

This entry will discuss the concept of essentialism and review evidence for the role that essentialist beliefs play in group processes and intergroup relations. It first discusses the meaning of essentialism and what it means to have an essentialist perception of a social group. It then reviews research on essentialist thinking in relation to race and ethnicity, gender, and sexual orientation, emphasizing how essentialism is implicated in perceptions, attitudes, and social behavior. It concludes with some remarks about why it is important to study people's beliefs about the fundamental nature of social divisions.

### What Is Essentialist Thinking?

Among philosophers, a category that is believed to have an essence is known as a natural kind. A *natural kind* is a naturally existing class of objects that share deep-seated similarities, with biological species and chemical elements usually offered as examples. All tigers share underlying similarities, as

do all things made of silver—genetic material in one case, and an atomic structure in the other—and these essential similarities make them what they are. Silver is essentially different from a superficially similar metal such as platinum, and a tiger remains a tiger even if it is dressed up to look like a lion.

Philosophers tend to deny that most categories do, in fact, have identity-defining essences, but laypeople often hold essentialist intuitions all the same. People tend to believe that all tigers are fundamentally alike and that what makes them so is some unchanging and unobservable quality of tigerness. They may not know precisely what that essence is, but they generally believe what someone with suitable expertise could tell them. Social psychologists and anthropologists have shown that these intuitions extend beyond the domain of folk biology into folk sociology: People often think that some social groups are like natural kinds.

Essentialist beliefs about social groups appear to have several distinct components. Essentialist thinking involves a belief that a social group is natural and that it has a biological basis. It involves a belief that membership in the group is all-or-nothing: Someone either is in the group or is not. It involves a belief that the group is unchanged through history and that a group member cannot easily cease to be a group member: Membership is immutable. Finally, essentialist thinking implies a belief that similarities between group members are deep-seated rather than merely superficial. To see a group in a nonessentialist fashion—as based on social conventions rather than biology, as fuzzy, as culturally shaped and changeable—is to view it as a social construct.

Social groups are not all equally essentialized. Research suggests that groups based on race, ethnicity, and gender are most essentialized, with people commonly inferring that their distinctive physical features spring from underlying biological differences. In some cases, people may even see differences between races or genders as akin to the differences between biological species. Thus groups differ in the degree to which they are essentialized, and people differ in the degree to which they essentialize groups. The implications of these differences between groups and between people are explored as follows.

### Implications of Essentialist Beliefs

There is ample evidence from several countries that racial and ethnic groups are often highly essentialized—even by young children. It has been argued that essentialist beliefs are inaccurate in this domain because racial and ethnic groups are products of history, have no essential commonalities, and do not represent discrete types. Nevertheless, the visible, embodied nature of ethnic differences seems to promote essentialist thinking, as does people's tendency to selectively reproduce within such groups so that ethnicity appears to be transmitted genetically. The attitudes of people who believe that differences between people, and especially racial differences, are genetically determined have been shown to be more negative toward ethnic outgroups (e.g., Germans' attitudes toward Turks, and White Americans' attitudes toward Black Americans).

Holding essentialist beliefs about race also has interesting behavioral implications. In a study of Asian Americans, those who essentialized race had more difficulty negotiating their bicultural identities and switching between their cultural frames than those who did not. Thus in addition to fostering negative views of ethnic outgroups, essentialist beliefs appear to lead people to see ethnic differences as deep and difficult to bridge.

Gender categories are also commonly essentialized, even by young children. For this reason, people tend to infer that the genders differ in fundamental, unchanging, and nonobvious ways and to exaggerate differences between them. People who endorse higher levels of essentialist thinking—belief in genetic determinism, in this case—tend to show more sexist attitudes toward women. These implications extend to people's relationship to their own gender, as women who believe that gender differences are biologically based tend to see themselves in stereotypically feminine ways.

Essentialist thinking about gender also influences behavior. One study showed that fathers who held more essentialist beliefs about gender differences provided less direct care for their young children and were less involved with them. There is some evidence that men are more likely to essentialize gender than women, and it has been argued that this is consistent with the view that essentialist beliefs make existing status

imbalances between men and women seem natural and inevitable.

Essentialist beliefs about sexual orientation are intriguingly different in their implications from beliefs about race, ethnicity, and gender. Homosexuality usually is not seen as essentialized to the same degree as race and gender. In addition, whereas essentialist beliefs about race and gender tend to be associated with negative attitudes, similar beliefs about homosexuality are often linked to positive attitudes. People with more favorable attitudes toward gay people tend to believe that homosexuality has a biological basis that is unchangeable and inborn, whereas more prejudiced people tend to believe that it represents an immoral or perverse choice. Even if people with antigay attitudes have anti-essentialist beliefs in this way, however, they also have essentialist beliefs that sexual orientations are deep-seated, discrete (i.e., either-or), and linked to many differences between people.

### Why Essentialist Beliefs Matter

The research sketched in this entry demonstrates that people's beliefs about the nature of social groups are important for their group perceptions, attitudes, and social behavior. Other research shows that it is not just beliefs about particular social groups that matter: People who believe that human attributes in general are fixed, biologically based, and deep-seated tend to endorse stereotypes of a wide variety of social groups. Essentialist thinking promotes stereotyping, antipathy to many social groups, acceptance of existing social inequalities, and a tendency to see group differences as chasms that are difficult to bridge. Social psychologists have made great progress in explaining general processes of ingroup–outgroup dynamics. Research on essentialism shows that it is also important to understand people's beliefs about the underlying nature of groups and group differences.

## ETHNICITY

---

*Ethnicity* is a multidimensional concept that involves both objective and subjective dimensions of people's sense of belonging to a community. At its most basic level, an *ethnic group* can be defined as a community of people who identify with each other and who are recognized by others on the basis of a presumed common genealogy, ancestry, or heritage. Ethnic groups are typically characterized by cultural, linguistic, and religious practices and behaviors that are shared among their members and that distinguish their members from those of other groups. Thus ethnic group membership often serves as a meaningful basis of self-definition, as well as an influence on one's experiences and relationships with members of other ethnic groups. This entry defines the term *ethnicity* and discusses how it relates to terms such as *race* and *culture*, then describes the significance of ethnicity for one's self-concept and social relationships.

### Definition and Comparison

In common language, the term *ethnicity* is often used interchangeably with related terms such as *race* and *culture*. Although there is a certain degree of overlap in the definitions of these terms, some important distinctions also remain. Both *race* and *ethnicity* involve a sense of shared genealogy, yet

*race* focuses more on inherited genetic and physical characteristics, whereas *ethnicity* encompasses both a shared genealogy and the cultural, linguistic, and religious practices that may be transmitted across generations within a community. Similarly, both *culture* and *ethnicity* can involve shared cultural, linguistic, and religious practices and behaviors. Typically, however, *culture* refers to a broad range of practices and behaviors that can be shared among all people who live within a particular context, whereas *ethnicity* refers more specifically to those that are shared among people who have a common ancestry or heritage.

Due to this shared ancestry or heritage, people often perceive ethnic groups as consisting of members who share underlying, immutable qualities that define the essence of the group; this is known as *essentialism*. Thus, members of different ethnic groups are sometimes believed to possess characteristics that are deeply rooted in nature and that clearly distinguish them from members of other groups. However, clear boundaries between ethnic groups can often be difficult to determine and may be decided due to a range of social and historical factors, some of which may be relatively arbitrary.

For example, Jewish tradition would describe one as being Jewish depending upon the ancestry of one's mother, whereas in the context of Nazi Germany, being Jewish was defined in terms of whether any Jews could be identified in one's family ancestry. Ethnic group boundaries may also become blurred through histories of cross-ethnic contact and intermarriage, which could result either from voluntary contact experiences (as in the case of immigration) or involuntary contact experiences (as in the case of conquest and/or slavery).

Moreover, what we define as an "ethnic group" is somewhat malleable, in that ethnic categories may be construed more narrowly or broadly depending on the social context in question. For example, in the national context of the United States, the term *Latinos* is often used to refer to a single ethnic group, even though this broad category includes people from a range of ethnic communities throughout North, Central, and South America. Similarly, after many waves of immigration and the passing of multiple generations, ethnic groups that were once considered to be quite distinct (Irish Americans,

Italian Americans, Polish Americans) are now more commonly referred to under the broad label of *European Americans*. Thus, the definitions of ethnic categories, and the meaning and significance associated with those categories, can vary greatly over time and across contexts.

### Significance for Identity

In addition, individual members of ethnic groups may also vary in the extent to which they regard the ethnic group as a meaningful basis of identity. One's subjective identification with an ethnic group, that is, *ethnic identity*, can play an important role in many domains of one's everyday life. Ethnic identities continually develop and grow through participation in cultural activities with other group members, such as ethnic celebrations and holidays, religious practices, and family gatherings. Having a strong identification with one's ethnic group can also contribute to a positive sense of self-esteem, to the extent that one has a positive evaluation of the ethnic group.

As a multidimensional concept, ethnic identity also includes many different components that can influence one's thoughts, feelings, and behaviors. For example, one's ethnic identity may involve feelings of belonging or emotional attachment to the group, knowledge about and engagement in the group's customs and practices, a sense of common fate and shared history among group members, and an internalization of the group's norms and values. People may also adopt different approaches in identifying with their ethnic group, and in cultivating a sense of belonging within the larger society (a process known as *acculturation*).

People may seek *integration*—identification with both the ethnic group and the broader society; *separation*—identification primarily with their ethnic group; *assimilation*—identification with the society at large; or *marginalization*—identification with neither of these communities.

There are also many social and contextual factors that can enhance or decrease identification with one's ethnic group in multi-ethnic societies. For example, if one's ethnic group represents a numerical minority in a given context, that experience can produce an enhanced awareness of ethnic group membership and, often, a stronger sense of identification with the ethnic group. Similarly,

when resources are not equally distributed across ethnic groups in the larger society, recognition of the group's disadvantaged position can lead people to identify more strongly with their ethnic group. Changes in the nature and strength of one's ethnic identification can also emerge from ideologies and social conditions that exist in the social context, such as pressures to reject one's ethnic group and conform to norms of the larger society (e.g., assimilation and color-blind ideologies), or alternatively, acceptance of ethnic group differences and open support for their expression (e.g., integration and multicultural ideologies).

Furthermore, some ideologies based on ethnicity can provoke ethnic conflict and violence, ranging from segregation and exclusion to mass killings and genocide. Although it is natural for people to feel a certain degree of positive bias toward members of their own group, or *ingroup favoritism*, some may view their own ethnic group as far superior to others, thereby using their group's norms, practices, and values as the standard against which all other ethnic groups are evaluated. This *ethnocentrism*, or view of one's ethnic group as superior, can then be used to rationalize and justify the domination and exploitation of other ethnic groups. Strategies are therefore needed to resolve and prevent ethnic conflicts, and to encourage more positive relations between ethnic groups. In large part, strategies to reduce ethnic conflict must focus on transforming institutional structures in order to dismantle ethnic hierarchies and establish social and economic equality among members of distinct ethnic groups. Corresponding to these changes, efforts should also be taken to diminish group members' support for ethnocentric beliefs and ideologies, and to instead promote norms of acceptance and appreciation of ethnic differences.

In sum, ethnic groups are communities of people who are presumed to share a common genealogy, ancestry, or heritage, and whose members participate in shared cultural, linguistic, and religious practices and behaviors. Although members of any given ethnic group are typically perceived as having many characteristics in common, there is often great variability in how strongly group members identify with their ethnic group, and how their group membership affects their life experiences and their relations with members of other ethnic groups. Further

research could usefully examine processes of identification and social relations when people belong to multiple ethnic groups, and how multiple group memberships might shift our perceptions of group boundaries and the strategies we use to improve interethnic relations.

## ETHNOCENTRISM

---

Membership in social groups is more than mere classification; it carries emotional significance as well. Attachment to the groups to which one belongs, or *ingroups*, and preference for these ingroups over outgroups may be a universal characteristic of human social life. *Ethnocentrism* refers to this strong predilection for loyalty and preferential treatment of one's ingroups over other groups, and the tendency to judge and evaluate others from the perspective of ingroup norms and practices.

The study of ethnocentrism has a long history in social science research on intergroup relations. Theories of ethnocentrism incorporate evolutionary perspectives, psychodynamic theory, and social psychological theories of group identity. Research on ethnocentrism documents the powerful effects

of ingroup attachment on both intragroup and intergroup behavior. This entry briefly reviews ethnocentrism, discussing its origins and the role played in it by ingroup bias and examining several theoretical perspectives on the concept.

### History

The concept of ethnocentrism was introduced to social science in a book entitled *Folkways* published by William Graham Sumner in 1906. The apparently universal tendency for human beings to differentiate themselves according to group membership was documented in the rich anthropological observations compiled by Sumner. Sumner adopted the terms “ingroup” and “outgroup” to refer to social groupings to which a particular individual belongs or does not belong. He then went on to speculate that ethnocentrism is a universal consequence of this distinction between ingroups and outgroups. Ethnocentrism was defined as a kind of group self-centeredness characterized by a sense of ingroup moral superiority and contempt for outsiders.

According to Sumner’s analysis, the essential characteristics of an individual’s relationship to ingroups are loyalty and preference. *Loyalty* is represented in adherence to ingroup norms and trustworthiness in dealings with fellow ingroup members. *Preference* is represented in ingroup pride and differential acceptance of ingroup members over outgroup members. Sumner contended further that all groups view outgroups with contempt and hostility and that ingroup peace and cohesion is maintained by intergroup competition and conflict. As a consequence, the term *ethnocentrism* has come to mean both ingroup favoritism and general negativity toward outgroups. The present review will focus exclusively on the ingroup preference aspect of ethnocentrism (also known as *ingroup bias*) in order to distinguish ethnocentrism from outgroup prejudice as a separate topic.

### Ingroup Bias

The fact that individuals value, favor, and conform to their own membership groups (ingroups) over groups to which they do not belong (outgroups) is among the most well-established phenomena in social psychology. Since Sumner’s 1906 book,

hundreds of studies in the laboratory and the field have documented ingroup favoritism in myriad forms. Preferential treatment and evaluation of ingroups relative to outgroups appears in evaluations of group products, application of rules of fairness in the allocation of resources to ingroup and outgroup members, attributions for positive and negative behavior, and willingness to trust and cooperate. Further, the tendency toward preferential treatment appears to arise automatically when any us–them distinction is made salient. Experimental social psychologists have demonstrated that even classifying individuals into arbitrary categories in the laboratory can elicit ingroup–outgroup feelings.

### Mere Categorization

Although the term *ethnocentrism* was originally coined to refer to allegiance to ethnic group identities, people’s tendency to favor members of their ingroups over those in outgroups has been found to extend across all forms of group membership. Groundbreaking experiments conducted by Henri Tajfel and his colleagues in Bristol, England, in the early 1970s demonstrated that merely categorizing individuals into two arbitrary but distinct social groupings was sufficient to elicit ingroup favoritism. When given an opportunity to allocate money to other individuals known only by their category membership, participants chose to allocate higher rewards to members of their own category than to members of the outgroup category, even in the absence of any personal identification of group members, any past history, or any direct benefit to themselves.

### Rules of Fairness

The thing that is most surprising about the results of the Tajfel experiments is that participants were willing to allocate rewards in a way that favored one individual (an ingroup member) over another (an outgroup member) without any apparent justification for the inequality. The fact that allocations deviated from equal distribution suggests that ingroup versus outgroup distinctions alter concepts of what is “fair” or “just.” Equality as a rule of fairness assumes that individuals are the same in all relevant respects and hence deserve

the same outcomes. Other rules of fairness take individual differences into account in determining outcome distributions. The rule of equity, for instance, holds that individuals should receive outcomes proportional to their inputs; thus, those who contribute more in terms of abilities or efforts should also receive more.

One explanation for the presence of ingroup favoritism in the minimal intergroup situation is that participants assume that members of their own group have greater ability or aptitude than members of the outgroup. Such biased evaluation of ingroup members is a basic element of ingroup positivity. Ethnocentrism also influences perceptions of social justice and justice motives in general. Research provides evidence that group identification bounds the scope of people's concerns for social justice, so that motives for justice and fairness are more likely to be applied in dealings with fellow ingroup members than with outgroup members.

#### *Ethnocentric Attributions*

One psychological mechanism that sustains different perspectives on fairness is the attributions that are made about the causes of others' good or bad fortune. If an individual performs well or succeeds because of personal effort, ability, and integrity, then he or she is perceived to deserve positive outcomes. Conversely, if an individual's failure is attributed to personal dispositions such as laziness, incompetence, or dishonesty, then poor outcomes are seen as deserved. However, the relationship between behavior and outcomes is altered if the behavior is attributed to external factors, that is, it is caused by circumstances outside the individual's control. When good performance is attributed to luck or external aid, positive outcomes are not deserved. And poor performance that was caused by bad luck or handicapping circumstances does not deserve bad outcomes.

The attributions that are made for another person's behavior can be influenced by knowledge of the social group to which that individual belongs. In general, failure and negative behaviors exhibited by an outgroup member are more likely to be attributed to internal, dispositional causes than the same negative behavior by an ingroup member (whose behavior is more likely to be attributed to

external or situational causes). Conversely, positive acts and success are more likely to be attributed to internal causes for ingroup members than for outgroup members.

This ethnocentric pattern of attributions was labeled the "ultimate attribution error" by Thomas Pettigrew, and it has been demonstrated in studies of attributions made by members of different ethnic groups, sports teams, schools, religions, and with arbitrary social categories in the laboratory. Because of ethnocentric attributions, ingroup members are given the benefit of the doubt in ways that outgroup members are not. In effect, ingroups are credited more for successes and positive actions than are outgroups, and are less likely to be held accountable for failures or negative actions. This can explain why ingroup members are rewarded more when they outperform an outgroup member, but the same performance is not rewarded as highly when produced by an outgroup member.

#### *Cooperation and Trust*

Group membership also plays an important role in how individuals respond to others when they are in a situation of interdependence where each person's own outcomes are affected by how the others behave. There are different social orientations and motives that individuals might bring to such situations. Most important is whether the individual has a cooperative orientation (where the goal is to satisfy the needs and motives of everyone in the group) or a competitive orientation (where the individual is attempting to maximize his or her own outcomes relative to the others).

One factor that seems to influence choices in interdependent situations is the category membership of the participants. Even when participants are strangers to each other, if they know that they share a common ingroup membership, they are more likely to enter into cooperative responding than if they do not have a shared category membership. Apparently, just knowing that another individual is a member of the same ingroup is sufficient to increase the level of trust and cooperation. Within the ingroup category, individuals develop trust and cooperate in solving shared problems. In situations of interdependence with outgroup members, however, individuals behave less cooperatively.

Ethnocentrism leads individuals to adopt a cooperative orientation toward fellow ingroup members and to behave in ways that promote group welfare rather than individual self-interest. However, they are also more likely to adopt a competitive orientation toward individuals who are members of outgroups, even when facing a common problem. This difference in orientation toward interactions with ingroup and outgroup members gives rise to a pervasive ethnocentric stereotype, namely, that “we” (the ingroup) are honest, trustworthy, and moral, and “they” (outgroups) are treacherous and not to be trusted.

### Summary

The evidence from a number of different domains of social behavior demonstrates the importance of ethnocentric biases. When a particular group identification is engaged, individuals act in ways that favor ingroup members and promote ingroup welfare, even when that behavior is not consistent with individual egocentric motives. However, ethnocentrism also engages preferential biases, extreme attitudes, and competitive orientation toward members of outgroups. Thus, attachment and loyalty to one’s own group benefits the ingroup, but often at the expense of outgroups.

### Theories of Ethnocentrism

Given the pervasiveness of ethnocentric biases in social judgments and social behavior, understanding why people display ethnocentric attachment to their ingroups has been addressed from many theoretical perspectives. A few of the more prominent theories will be reviewed here.

#### Human Sociobiology

Theories of human evolution take into account the overwhelming evidence that the human species evolved in the context of group living. Evolutionary accounts of human psychology are based on analysis of the survival requirements associated with living in hunter–gatherer societies. Sociobiological models of the evolution of human social behavior rest heavily on the notion of inclusive fitness. These models assume that the gene is the basic unit

of selection and that selection favors genes that produce behavior benefiting anyone who carries those genes, including other individuals who possess the same genes by common descent or kin relationships.

One implication of this model of evolution is that there is a genetic disposition for people to behave differentially toward “insiders” (kin and extended family likely to share common genes, ingroups) and “outsiders” (nonkin, outgroups). This idea is the basis for a *sociobiology of ethnocentrism*, which holds that ethnocentric behavior derives from pursuit of inclusive genetic fitness. Cooperation between individuals will occur only to the extent that they have a high proportion of shared genes, since helping close relatives perpetuates an individual’s own genes. Conversely, the likelihood of conflict between individuals or groups of individuals increases as the proportion of shared genes decreases. According to the sociobiological view, the primal ethnic group is the small band of 100 to 200 related individuals, within which the human propensity for cooperative social arrangements is presumed to have evolved. Ethnocentric preference is extended to larger social groups through the development of *markers* (skin pigmentation, hair and facial features, mannerisms, etc.), which signal genetic relatedness among unfamiliar individuals.

#### Psychodynamic Theories

Freudian theory departs somewhat from evolution-based biological models in assigning a greater role to experience and development in the origin of ethnocentric identification. Freud’s own theory of group identification centered on the role of the group leader as the object of identification. Neo-Freudian theory extended this idea to incorporate all symbolic representations of the group as objects of identification. According to this view, group identification and ethnocentrism are the product of projection of the self onto external objects and introjection/incorporation of objects into the sense of self.

A recent extension of psychoanalytic approaches to understanding group identity is *terror management theory*, which is based on the idea that when human beings evolved the capacity for self-awareness, this included awareness of mortality

and the inevitability of their own death. Given the universal instinct for self-preservation, this awareness creates a high level of anxiety, which could lead to paralyzing fear if not sufficiently suppressed. According to the theory, human societies have evolved shared worldviews and cultural values as an adaptation to cope with this anxiety over death. By subscribing to this worldview and living up to cultural values, individuals achieve a sense of validation, self-worth, and a type of psychological immortality that serves to suppress mortality terror.

One implication of terror management theory is that if thoughts of mortality are made salient, an individual will respond by reaffirming his or her own cultural worldview, with intolerance toward different values or cultural views. A number of experiments have demonstrated just such a relationship between mortality salience and ingroup bias. When participants in these studies are induced to think about the prospect of their own death (as compared to other possible negative experiences, such as a painful dental procedure), ingroup preference, intolerance of others, and intergroup bias are significantly increased.

#### *Social Comparison and Uncertainty Reduction Theory*

A classic theory of group formation is provided by Leon Festinger's *social comparison theory of affiliation*, which was developed to explain why members of groups tend to be so similar in attitudes, values, and behavior. A basic premise of Festinger's explanation is the idea that people need a sense of subjective validity for their beliefs about themselves and the world around them. Much of our knowledge or understanding about the world we live in does not come from direct personal experience. We may come to learn that ice is cold and walls are solid by direct contact with these objects, but much of our knowledge about what is right or true—especially our knowledge about social groups and social behaviors—has no such objective referent. To achieve a sense of validation of such beliefs, people engage in *social reality testing*. Beliefs are seen as valid or appropriate when they are shared by similar others. The more uncertain an individual is about the correctness of a belief or attitude, the more important it becomes to find consensual support for that belief.

Agreeing with members of one's ingroup apparently increases certainty and the subjective validity of beliefs and attitudes. Finding out that others disagree reduces certainty—but only if those others are ingroup members. On many issues of values and preferences, we expect to agree with ingroup members but not necessarily with everyone, so learning that outgroup members do not share our opinions or values does not shake our confidence in the correctness of those beliefs. Thus, only ingroup members count as sources of validation, at least for subjective judgments. As a consequence of this relationship between ingroup membership and feelings of certainty, ingroup attachment and bias increases under conditions of uncertainty and doubt.

#### *Social Identity and Positive Distinctiveness*

Ethnocentric loyalty and preference are analogous to self-integrity and self-esteem. Ethnocentrism at the group level parallels egocentrism at the individual level. The comparison between egocentrism and ethnocentrism was reformulated by social psychologists Henri Tajfel and John Turner in terms of a distinction between personal identity and social identity. *Personal identity* refers to self-conceptualizations that define the individual in relation to (or in comparison to) other individuals. *Social identity* refers to conceptualizations of the self that derive from membership in emotionally significant social categories or groups. Just as personal identity derives from social comparison to other individuals, social identity is defined by intergroup comparison. Accentuation of intergroup differences, combined with a need for positive distinctiveness in comparisons between ingroup and outgroup, results in ingroup favoritism.

The shift between personal identity and social identity entails a transformation of the definition of self from the individual to the group level. When group identification is engaged, motivations for self-integrity, preservation, and self-esteem are transferred to the ingroup as a whole. Consequently, ingroup status and collective welfare become important to the individual's sense of well-being. Consistent with this social identification perspective, there is considerable experimental evidence that once the self has become attached to a social group or category, positive affect and evaluations

associated with the self-concept are automatically transferred to the group as a whole. And, conversely, status and achievements of the group are internalized by individual group members regardless of whether or not they have directly contributed to the group outcome. An individual's sense of self-worth is enhanced by the positive distinctiveness of his or her ingroup. However, some experimental research indicates that social identification with a group may actually be increased when the group is threatened or devalued. Overall, research in this area supports the idea that positive ingroup evaluation and collective self-esteem are the products of group identification rather than its cause.

## ETHNOLINGUISTIC VITALITY

---

The objective vitality of an *ethnolinguistic group* (an ethnic group defined by its language) can be defined by factors such as economic status, geographic concentration, and political representation, according to Howard Giles, Richard Bourhis, and Donald Taylor. The greater the group's objective vitality, the more likely it is that group members will learn and maintain their ingroup language. According to *ethnolinguistic identity theory*, which explains language shifts, multilingualism, language attitudes, and media use, perceptions of group vitality are predictive of behavior. This entry looks at the implications of ethnolinguistic vitality for intergroup relations, language shifts, multilingualism, and social attitudes.

#### Language and Intergroup Relations

*Objective vitality* enables a group to survive as a distinctive and thriving collective entity. Groups with higher vitality survive and prosper; groups with lower vitality eventually cease to exist. Three factors combine to determine objective vitality: *status variables*, which include economic, social, and historic status as perceived from within and from outside the group; *demographic variables*, which include territory, population numbers, rates of birth, mixed marriages, immigration, and emigration; and *institutional support variables*, which include formal and informal representation in the mass media, education, government services, industry, religion, and culture. Objective vitality provides the sociostructural context for ethnolinguistic phenomena, but individual people's subjective beliefs about relative group vitality are predictive of behavior. *Subjective vitality* has been measured across cultures, usually as a single dimension, and has been found to vary between contexts and in the way it is structured—for example, depending upon what groups are being compared and the relative weighting of different facets of vitality.

Ethnolinguistic identity theory builds on and elaborates social identity theory and combines with communication accommodation theory to make predictions about language use in intergroup settings. Following social identity theory, it is

assumed that people are motivated to maintain a positive social identity and that groups with higher vitality confer more positive identity than groups with lower vitality. Following communication accommodation theory, it is assumed that people use language to psychologically accommodate to or differentiate themselves from others, and that doing so reflects beliefs about relative vitality.

There are three social strategies that people can use to create a positive social identity. The first is *social mobility*, in which people in subordinate groups can disown their group and converge upon the language of a group that possesses higher vitality. This happens when people have little commitment to their group and see the possibility of passing into a dominant group as feasible. Social mobility is endorsed by dominant groups that aim to assimilate minorities.

The second strategy is *social creativity*, in which people in subordinate groups may organize collectively, but they avoid direct competition with a dominant group. Examples include diglossic languages such as those spoken in Switzerland, where there are High German and (low) Swiss German forms. Speakers of the low form are viewed more favorably on solidarity (e.g., friendliness and kindness) than status (e.g., wealth and intelligence), whereas the reverse is true for those who speak the high form. This happens when people have a strong commitment to their group, when group boundaries are considered impermeable, and when status relations between groups are highly stable. Members of dominant groups will endorse social creativity when their status advantage is unstable.

The third strategy is *social competition*, in which people in subordinate groups aim to equalize or reverse their group's low-status position by promoting linguistic revival movements. This occurs when people are highly committed to their group, see group boundaries as impermeable, and see the status relations between groups as unstable and/or illegitimate. Members of dominant groups are likely to engage in social competition when aiming to prevail over competitive subordinate groups. Endorsement of majority-only language policies is likely in this circumstance.

### Language Shifts

Linguists estimate that there are 6,000 languages in the world, and that at the current rate of loss,

50% will become extinct in the next generation. This massive loss of languages is reflected in a comparable growth of languages such as Mandarin, English, Hindustani, Spanish, and Arabic. As a social indicator, the number of speakers predicts language survival. There is evidence, however, that people will fight against the loss of a language despite the low objective vitality of that language. Linguistic maintenance and revival movements are a case in point. Hawaiian, Gaelic, and Catalan have all declined dramatically in objective terms but have been saved from the brink of extinction by language preservation movements driven by concerns about subjective vitality.

Such psychological concerns may prevent "invented" languages from taking hold. The most successful of these languages, Esperanto, was devised by Ludvic Zamenhof in the late 1800s as a universal auxiliary language that would facilitate global communication. The idea was that people would maintain their heritage language but use Esperanto to communicate across otherwise insurmountable group boundaries. Despite being easier to learn than natural languages, it has never really caught on; relatively few people speak Esperanto. Ethnolinguistic identity theory suggests that the failure of artificial languages like Esperanto is in part driven by their failure to produce sufficient ethnolinguistic distinctiveness for speakers. Indeed, Esperanto is largely made up of European vowel sounds and is easily mistaken for other languages.

### Multilingualism

Code switching is the alternating of languages within an utterance or conversation. Well-known examples that have been elevated to the level of incipient languages include Spanglish and Hinglish—a respective mixing of Spanish and Hindi with English. On the one hand, these mixtures can be thought of as forms of social creativity that exist within speech communities. Those who mix language in this way differentiate themselves from other, "less sophisticated," monolingual ingroup members by using a second language such as English, and they can thus promote a positive identity for themselves. On the other hand, code switching may be perceived as leading to cleavages within a speech community. Those who maintain the heritage language without mixing in others'

codes may come to see themselves as the conservators of a language that is threatened by a dominant group, and hence engage in social competition to maintain their language. Finally, code switching between Spanish and English in the United States can be regarded as a linguistic precursor to cultural assimilation and a form of social mobility.

When relatively high-vitality language groups come into contact, the result is typically positive. For example, nowadays when Anglo-Canadian children take immersive French-language instruction, research shows that these children are equally proficient in English and French and show no evidence of language loss or deficits in general intelligence—a pattern of additive bilingualism. When groups that differ sharply in language vitality come into contact, however, the process of second-language learning is typically detrimental to the members of the low-vitality language group—a pattern of subtractive bilingualism. This has been proven to be the case with Inuit speakers who have been schooled in English or French. In this case, these children lack second-language proficiency and even perform less well in their heritage language than those given heritage language instruction.

### Language Attitudes

People typically view individual speakers through the lens of their group's language, which in turn reflects the relative linguistic vitality of groups. In the 1960s, Wallace Lambert devised the matched guise technique. Naïve subjects listened to tape recordings of different speakers and evaluated their personalities. In reality, the tape contained recordings of the same bilingual speakers using different languages, so any evidence for differences in evaluation were attributable to the language spoken. In the first study, Anglo-Canadian and French Canadian respondents downgraded speakers who used the French guise relative to the English guise. This pattern is understood in ethnolinguistic identity theory as a pattern that occurs when groups are defined by marked differences in language vitality. The lower vitality language group at the time, the French Canadians, were subjectively assimilating to the Anglo-Canadians. Since the rise of the Quebecois movement, however, this pattern is likely to have equalized, if not reversed as the Quebecois shifted from a social mobility to a social competition strategy.

Patterns of social creativity are also evident, as a typical finding is that speakers from high-vitality language groups are considered high on status variables (e.g., wealth, intelligence) but low on solidarity variables (e.g., friendliness, kindness), whereas the reverse is true for speakers from relatively low-vitality language groups. This pattern is extant in the North and South of England as well as in Italy, and it seems to reflect the division into historically competitive groups that no longer engage in outright hostility. Finally, patterns of mutual downgrading can be found in groups that are socially competitive. Further research by Lambert and his colleagues in the 1960s, for example, showed that Palestinian and Israeli linguistic guises were seen in ways that reflected the group membership of the social perceiver.

### Current and Future Work

The concept of vitality, which as described above was originally tied to ethnolinguistic groups, has been broadened and is now applicable to nonlinguistically defined groups. Research on aging has shown that the elderly are typically perceived as possessing higher vitality in Western cultures (e.g., United States, Canada, Australia) than in Eastern cultures (e.g., Japan, South Korea, China), and that the middle-aged are viewed as possessing the highest vitality across cultures. Most recently, research has shown that Blacks who are more ethnically committed avoid television and have decreased perceptions of group vitality. It is likely that future research will continue to expand the concept of vitality to explain intergroup behavior in nonlinguistic contexts.

## EUGENICS

---

*Eugenics* was a political and scientific movement that sought to improve humanity by using the study of heredity to design programs aimed at guiding human reproduction. It was based on an assertion that socially important traits are genetically determined and that steps should therefore be taken to ensure that future generations are descended from individuals with the best traits. Many eugenicists claimed that social categories such as race show inherent differences in intellectual and moral worth. The eugenics movement originated in England and was most influential in the United States in the first half of the 20th century. Eugenics also played a role in other countries. For example, in 1940s Germany, eugenics was used to legitimize the Holocaust. Eugenics has had a lasting influence on several issues relevant to group and intergroup processes today, including racism, anti-immigration politics, and group differences in intelligence. The history of eugenics and its current importance are reviewed in this entry.

### History

Although some ideas and practices related to eugenics can be traced back to ancient Greece, the founder of the eugenics movement is generally considered to be Francis Galton, who first published his ideas in 1865. Galton was impressed by the writings of his cousin Charles Darwin on evolution by natural selection. This led him to suggest that it would be possible to take control of human evolution by influencing who would reproduce and who would not. In this way, he argued, one

could ensure that future generations would be the descendants of the best members of society. These ideas resonated with Victorian fears about moral decline and the associated perception that the most criminal and degenerate people were also the most prolific breeders.

Galton felt that, for humanity to take control of its evolutionary future, a more developed science of heredity was needed. To this end, he attempted to quantify the extent to which various traits, such as criminality, drunkenness, and sexual promiscuity, were inherited. The British eugenics movement acquired the support of scholars and activists from across the political spectrum.

The establishment of eugenics as a political force in the United States owes much to the work of Charles Davenport, who published *Heredity in Relation to Eugenics* in 1911. Davenport claimed that there were genetically determined tendencies toward violent and criminal behavior among certain races. He saw the U.S. population as threatened by the “inferior” blood and “excessive” breeding of southern and eastern European immigrants and others with “undesirable” traits, including Black people. These threats were to be countered by restricting immigration and denying “defectives” such as criminals and insane people the chance to reproduce, perhaps by forced sterilization. Davenport’s ideas, spurred by the panic over the social problems that came with increasing urbanization, became central to the political agenda of the eugenics movement in the United States.

Intelligence testing allowed eugenicists to quantify their vision of human worth in an apparently pure measure of innate intellectual ability. This interpretation of the tests was contrary to that of their originator, Alfred Binet, but it suited the eugenics agenda perfectly. Within the military, White people were found to score higher on the tests than Black people. This was taken as evidence of the biological inferiority of Black people. It led to the conclusion that trying to equalize opportunities in education was worthless because some groups simply lacked the potential for educational achievement.

Eugenics involved both “positive” interventions, which aimed to optimize reproduction among the genetically fit, and “negative” interventions to restrict it among the unfit. Positive interventions involved public awareness campaigns and

programs such as the “Fitter Families” competitions, whereby supposedly genetically fit people were identified and encouraged to produce offspring with one another rather than with the unfit. “Fitness” was evaluated in terms of various criteria, including educational success and physical health, which were assumed to be genetically determined.

The negative eugenics interventions are understandably more infamous. Forcing or persuading those with what were seen as undesirable traits to be sterilized was a common eugenicist strategy. Throughout the world, there have been official and unofficial programs to sterilize criminals, the mentally ill, the mentally or physically disabled, and the poor. Wendy Kline has recently linked U.S. sterilization programs in the early 20th century with an attempt to control female sexuality. Many women were sterilized simply because they transgressed conservative norms of sexual morality, which was assumed to be evidence of feeble-mindedness. The Norwegian government recently admitted to sterilizing hundreds of “gypsies” without their full knowledge or consent from 1932 to 1977. In Nazi Germany, sterilization of “defective” individuals later became racialized, so that Jews and “gypsies” were seen as inherently defective. These efforts intensified and ultimately led to the murder of millions in the Holocaust.

Negative eugenics also took the form of agitation against immigration, which had a major impact on policy. In Britain, the Aliens Act of 1905 was directed against diseased and “idiot” immigrants, while the U.S. Immigration Restriction Act of 1924 was designed to severely restrict the number of immigrants from Asia, eastern Europe, and the Mediterranean, whose presumed low intelligence and high fertility were feared to threaten the “racial purity” of the U.S. population.

Despite considerable political influence at its peak, eugenics did not go unopposed. Some of the strongest criticism came from geneticists who objected to the distorted version of their science. Social scientists also sought to undermine the basic logic of eugenics by arguing that religious, ethnic, and other groups share social and cultural similarities rather than genetic ones. As such, they argued, efforts at improving society should be made by social and cultural means rather than through managing reproduction. It is important to

note, however, that the greatest damage to the eugenics movement is likely to have come from its association with the Nazis. When the full extent of the Holocaust came to light, few wished to be associated with the eugenicist ideology that the Nazis had pursued so brutally.

## Contemporary Importance

### *Scientific Racism*

The 1994 book *The Bell Curve: Intelligence and Class Structure in American Life* by Richard J. Herrnstein and Charles Murray was a clear sign that the central claims of the eugenics movement remain influential in the United States, although it provoked intense debate both within and beyond academia. *The Bell Curve* combines a resolute genetic determinism, claiming that races differ substantially in inherited potential, with an associated political agenda. It therefore echoes the leading voices in the U.S. eugenics movement from 80 years earlier. This is not the only example of the continued assertion of genetically determined racial differences in intelligence. The Pioneer Fund, which was founded by eugenicists in 1937, still exists and continues to fund research to support the basic claims that were central to the eugenics movement.

This interpretation of the relationship between intelligence test scores and social status is important to understanding the legacy of eugenics as a political movement. If intelligence tests are seen as direct tests of inherited ability, then observed differences between class and racial groups can be taken to imply that social hierarchy is based on a natural hierarchy of merit, rather than on injustice. This leads to the conclusion that attempts to improve living conditions and educational opportunities for low-status groups are futile; these groups occupy a low status because they are genetically predisposed to be unintelligent. Indeed, some argue that intelligence tests remain so popular, despite continuing uncertainty about their meaning, because they help to reconcile existing social stratification with the egalitarian values and meritocratic ideology that now prevail in some societies. Thus, a genetic deterministic interpretation of intelligence test scores is closely connected with ideological ways of viewing race and class that serve particular

political agendas. It can be seen as a form of rationalization and legitimization.

There are many reasons to reject the genetic determinist account of group differences in intelligence test scores. Even at the height of the eugenics movement, it was noted that racial differences in the test scores were smallest in northern U.S. cities, where the economic disparity between White and Black people was smaller than in the South, and intelligence scores of immigrant groups increased as these groups became more established in America. Both observations suggest that intelligence test scores reflect the social and economic conditions of the groups being tested. This would be unlikely if intelligence tests were a direct measure of some genetically determined quantity.

Recent social psychological work on intelligence also contradicts the genetic determinist account. For example, research on the threat of stereotyping in relation to intelligence testing suggests that group-based differences are contingent on the testing situation, such that the standard testing procedures systematically inflate the scores of high-status groups and depress those of low-status groups. The differences do not appear if participants are told that their test results have no diagnostic importance.

### *Anti-Immigration Rhetoric*

Since the eugenics movement first became fixated on immigration at the turn of the 20th century, immigration has not ceased to be a salient political issue. On the contrary, it has become the foremost issue in political debates around the world, and recent years have seen an increase in public opposition to immigration in many countries. Anti-immigration rhetoric has, in a sense, diversified. Immigrants are now seen in all sorts of ways, including as terrorists, welfare scroungers, threats to public services, threats to cultural and religious values, and competitors for presumably scarce jobs and housing. Nonetheless, the tone and content of the debate are often remarkably similar to the arguments advanced by Davenport and other eugenicists.

Opposition to immigration is often associated with a fear that the society will be harmed by the admission of people of lesser quality who will propagate undesirable traits. In a recent election in Switzerland, the Swiss People's Party urged voters

to back their initiative to deport immigrants who had been convicted of crimes. Posters showed a group of white sheep grazing on the Swiss flag as one kicked a black sheep off the flag. The headline for the poster read "Bringing Safety." Although the threat posed by immigration tends to be expressed in terms of vaguely defined national "values" or "character" rather than genetics, allusions to race, color, blood, fertility, and other pseudogenetic concepts are not uncommon. Indeed, opponents of immigration still claim that relatively high fertility rates and poor health among immigrants make them a particular threat to the host country.

A return to the kind of organized academic movement of early 20th-century eugenics seems unlikely today; eugenic ideas are too widely opposed in the biological and social sciences. A return to a concerted political movement that relies directly on eugenics to advocate restricted immigration or the sterilization of the deprived, depraved, or disabled also seems unlikely. However, remnants of eugenics seem to survive in some circles of contemporary academic and political debate. There is certainly no shortage of political rhetoric and proposed policy that endorses the view that those with the best genetic profile should be encouraged to reproduce, whereas those with the worst profile should be discouraged. This rhetoric has heightened implications in the light of advances in genetics and the widespread interest in the human genome project. As long as people continue to view important social traits and behavior as genetically determined, eugenic arguments will appeal to those who believe that the regulation of who reproduces with whom is a route to a better society.

## EVOLUTIONARY PSYCHOLOGY

---

*Evolutionary psychology* (EP) is a specific theoretical framework within the evolutionary sciences. The EP perspective toward understanding human functioning and behavior has several unique features and cardinal assumptions that make it different from other major perspectives in the evolutionary sciences such as behavioral ecology and co-evolution. Scholars who adopt an EP perspective, for example, assume that the human mind has been shaped by tens of thousands of years of rather focused selection pressures. Over time, these selection pressures have generated domain-specific cognitive algorithms (i.e., cognitive, emotional, or behavioral responses that reliably occur in response to a specific environmental stimulus or set of stimuli). These mechanisms, on average, helped our ancestors make adaptive choices, judgments, and decisions that in turn promoted their survival and reproduction (i.e., their reproductive fitness).

According to the EP perspective, therefore, our minds are a reflection of the most important selection pressures that our ancestors encountered during evolutionary history and, consequently, our “stone age” minds are sometimes ill equipped to deal with novel features and contingencies of the modern world effectively. This explains why most people are morbidly afraid of snakes and heights (which were recurrent, major threats to the reproductive fitness of people throughout evolutionary history), but they are not afraid of cars or electrical outlets, which kill many more people each year than do snake bites or falls. It also explains why people have such difficulty limiting their intake of salty, fatty, and sugary foods, which are overly abundant in many parts of the world today but

were scarce and valuable sources of needed calories during our evolutionary past.

This entry provides an overview of evolutionary psychology, examining its basic assumptions and its view of intragroup and intergroup processes.

### Basic Assumptions

One of the most controversial assumptions of the EP perspective is that, because there were so many strong and recurrent selection pressures throughout evolutionary history, the human mind contains a host of highly domain-specific cognitive algorithms. Once they had been selected and could be passed on genetically to offspring, these algorithms permitted our ancestors to make rapid, efficient, reliable, and usually fitness-enhancing decisions when confronted with issues and situations that were most relevant to survival and reproduction across evolutionary history. According to the EP approach, the evolution of these genetically based algorithms accounts for much of the cross-cultural consistency that is witnessed in many psychological features, ranging from which features of mates tend to be most attractive cross-culturally to which types of objects or social situations most people in vastly different cultures universally like, dislike, fear, become addicted to, or dread. This cardinal assumption—that the human mind is comprised of many domain-specific cognitive algorithms, shaped by past selection pressures, which helped our ancestors “solve” recurrent problems related to their reproductive fitness with economy, efficiency, and reliability—remains one of the most contentious aspects of the EP framework.

In addition to knowing what the cardinal assumptions of EP are, it is equally important to understand what the EP perspective does *not* suggest. It does not suggest that the environment and what people learn within their cultures or groups is unimportant. In fact, virtually all EP-based models assume that one cannot understand the operation of evolved mental algorithms without also knowing to which kinds of environmental stimuli, events, or learning histories an individual has been exposed. EP also does not presume that natural selection reflects what is “right” or “proper” (that is, it does not fall prey to the naturalistic fallacy), nor does it imply that naturally selected genes that underlie specific mental algorithms invariably

“determine” how people think, feel, and behave in different social situations. Genes cannot express themselves in phenotypes unless they are triggered by and unfold within the context of specific environments.

Across evolutionary history, one of the strongest and most persistent selective pressures on the human mind was other humans with whom individuals had to sometimes cooperate and sometimes compete. Indeed, one of the primary reasons for the rapid and massive development of the neocortex in humans is likely to have been the tremendous selection pressures imposed by the need for early humans to live in groups and work cooperatively when possible. For this reason, it is important to consider how the EP approach can extend and enrich our understanding of intragroup and intergroup processes, topics that are discussed next.

### Intragroup Processes

*Intragroup*, or *ingroup*, processes are interactions within social groups. These interactions often take the form of mutual cooperation to achieve some common goal. In the hunter–gatherer groups from which we evolved, for example, men probably formed coalitional hunting parties to bring down large game, and a successful hunter most likely shared excess meat with others. This sharing carried relatively low costs because a single kill was often more than a single family could consume before spoilage. Furthermore, the benefits of sharing would have been high if others reciprocated when the same hunter was later unsuccessful.

This example illustrates a fundamental tenet of the EP perspective: In order for a behavior to have evolved, the benefits of engaging in the behavior must have, on average, outweighed the costs. If the costs outweighed the benefits, the behavior would have been selected against. Because social exchange within groups is potentially risky, natural selection may have favored cognitive algorithms designed to make accurate impressions of potential exchange partners, maximizing the benefits and minimizing the costs associated with an exchange.

### *Reciprocal Altruism*

Reconsidering the example of the successful hunter, a hunter who indiscriminately shared food

with others in a totally altruistic manner might have gone hungry if the favor was never returned in times of need. It would have been more beneficial for the hunter to share only with those he could expect to reciprocate some time in the future. This pattern of social interaction is known as *reciprocal altruism*, which is the foundation for many forms of social exchange within both human and nonhuman groups. Indeed, this form of exchange has even been found to characterize patterns of blood sharing among vampire bats.

### *Punishing Cheaters*

Traditionally, social exchange research relied heavily on an economic model of motivation in which people were expected to maximize their own outcomes (that is, rewards minus costs). An economic perspective, however, fails to account for why people exhibit a strong desire to punish cheaters—those who reap the benefits of cooperation without paying associated costs. Research suggests that (a) this desire is motivated by anger—the less a cheater contributes to the group relative to others, the greater the anger that is felt by the other group members; and (b) the desire to punish can at times be so strong that people will punish cheaters even at substantial cost to themselves. These findings, which cannot be explained post hoc by purely economic models, can be understood from the EP perspective. Punishing cheaters in social exchanges is adaptive if doing so inhibits them from cheating in the future. When cheaters are rare, punishers have to punish infrequently and, thus, bear sporadic and minimal costs.

Too many cheaters in a group, however, may result in very high costs for the punishing individual. Accordingly, individuals should also have evolved to prefer those who are cooperative and trustworthy group members. Various studies have demonstrated that, across a range of interdependent group types, people consistently value trustworthiness and cooperativeness in other people above and beyond nearly all other characteristics, including intelligence and physical attractiveness. People also prefer group members who are familiar and highly committed to the group, both of which are cues of more or better social exchange opportunities in the future and, therefore, a higher chance of reciprocation.

### Threats to Security

One final important component in the selection of group members is the ability of others to reciprocate. Simply possessing or demonstrating a willingness to reciprocate is not sufficient. Sometimes individuals involuntarily extract benefits without contributing to or reinvesting in the group (e.g., due to age or disability). Punishing such people would invoke costs to the punisher without benefits. Thus, the perceived reason for others' cheating should theoretically influence whether or not they are punished. Recent research shows that people are less likely to punish someone whose cheating is outside his or her control, especially if this lack of control is attributable to a temporary infirmity. Instead of feeling angry toward such "cheaters," most people experience feelings of empathy and/or pity.

Infirmities, however, can pose a threat not only to the ability of fair exchange ability within a group but also to the safety of group members. The intense sociality of most human groups increases the likelihood of pathogen exchange between group members. Being social, in other words, typically leads to increased physical proximity, which can facilitate the transmission of infectious agents. As a result, adaptations may have evolved to minimize exposure to and maximize distance from individuals who appear to be contagious. In this regard, physical disgust tends to be elicited by those who exhibit signs of disease, such as open sores and discharged bodily secretions. This suggests that a disgust response may have evolved to protect people from contagion.

In sum, empirical evidence supports EP-based predictions that (a) people are drawn to partners with whom interactions tend to result in relatively greater benefits than costs, (b) people punish those who threaten the equity of exchange within social groups, and (c) people avoid contact with those who are perceived to pose a physical threat to group security. EP-based theories of ostracism and stigmatization of group members who are perceived to pose a threat to ingroup cooperativeness (e.g., cheaters) and safety (e.g., persons with disease) have increased our understanding of intergroup processes, especially prejudices, which are discussed next.

### Intergroup Processes

*Intergroup processes* are interactions between social groups. Traditional social psychological perspectives toward prejudice, discrimination, and intergroup conflict have examined how and why intergroup clashes occur. Several psychological processes that might be responsible for intergroup conflict have been studied, ranging from ingroup versus outgroup categorization processes, to social learning processes, to perceived competition for limited resources, to the motivation to enhance one's views of the self or one's group. These approaches, however, have relied exclusively on domain-general cognitive processes and mechanisms that fail to make important distinctions between specific stereotypes associated with specific groups, different patterns of emotions and behaviors that are typically elicited by members of different groups, or contextual and personality factors that are likely to evoke or inhibit these stereotypes, emotions, and actions.

Why, for instance, in the United States, do Native Americans often elicit pity from people and motivate them to establish community-outreach programs? Why, on the other hand, do Blacks often elicit fear and the desire to protect oneself? And why, more globally, are individuals concerned about contracting infectious diseases especially prejudice against people who are physically deformed or disfigured, whereas individuals who see the world as a dangerous place are most prejudiced against members of ethnic outgroups?

Steven Neuberg and Catherine Cottrell have developed a new evolutionary conceptualization of the origins of intergroup prejudices and conflict based on the assumption that many modern-day prejudices may be by-products of adaptations that were originally designed by natural selection to manage threats to intragroup processes. This new approach can answer questions, including those posed above, that traditional approaches struggle to explain.

Because interracial contact is too recent a development to have evolved genetically, the EP perspective does *not* argue that there should be an evolved prejudice against a given race or group of people. Although ancestral tribal groups might have come into contact with other tribal outgroups, geographic limitations during evolutionary history probably limited most contact to racially similar others. Instead, EP theorists argue that humans evolved the capacity to perceive threats

that could be posed by outgroups and, thus, to attend to cues linked with outgroup membership. In contemporary society, physical differences between races serve as one such cue, so individuals in multiracial societies such as the United States learn to classify others based on race. Traditional explanations of racial prejudice, such as the need to enhance self-esteem or group esteem, fail to explain why *different groups* elicit *different types* of prejudices, why these prejudices are often contingent on the personality of the perceiver, and why they are evoked by different kinds of situational cues.

### *Cultural Influences*

According to the EP approach, evolved responses are not genetically determined. Instead, they are environmentally contingent and activated by specific contextual information. In the case of racial prejudice, an individual's cultural environment is likely to shape the specific threats that are attributed to members of a specific racial group. Such threats, however, are of evolutionary significance and, therefore, they should trigger evolved adaptive responses designed by natural selection to avoid or eliminate the perceived threat.

For instance, in the United States, people are exposed to the stereotype that Black men (but not women) are dangerous and more likely to commit violent crimes. Regardless of its accuracy, this stereotype leads to the perception of threatened physical safety. This threat perception, in turn, is associated with greater reported fear and a strong desire for self-protection. Gay men, in contrast, are stereotyped as spreading disease (e.g., AIDS) and are thus perceived to threaten health. Instead of fear, this threat perception evokes physical disgust and motivates health-protecting behaviors such as avoiding direct or indirect physical contact.

According to the EP perspective, there is not an evolved prejudice against Black men or gay men; rather, there is an evolved prejudice against those who are believed to threaten safety or carry disease. To the extent that cultural stereotypes portray Black men as being dangerous or gay men as carrying disease, prejudicial responses associated with protecting oneself from physical harm or disease should follow. In both examples, cultural stereotypes generate perceptions of threat and elicit specific emotional and behavioral responses that serve to reduce the threat. Unlike traditional social

psychological approaches, which fail to fully explain these differences in prejudice, the EP perspective anticipates that prejudicial responses ought to differ in response to the specific *type* of threat linked to the stereotype associated with an outgroup.

### *Situational and Dispositional Influences*

In addition to explaining how broad environmental contexts, such as culture, influence perceived threats and group-based prejudice, the EP approach also predicts that more immediate situational and dispositional contexts should influence perceptions of threat. For example, if prejudice against Black men is based on a perceived threat to physical safety, situations that pose a greater risk to safety ought to elicit stronger prejudicial responses against this group, but not against groups that are not stereotypically associated with this form of threat. Likewise, the EP perspective would anticipate that people who are chronically concerned about physical safety should be more biased against a group perceived to threaten physical safety than people who are less concerned about this threat. These predictions have been supported by recent empirical evidence. Once again, such evidence cannot be explained by traditional social psychological theories, yet it was predicted *a priori* by evolutionary theorists.

Findings such as these have significant implications for interventions intended to reduce or eliminate between-group prejudice. Neuberg and Cottrell argue that, because situational, dispositional, and cultural contexts all interact to form different stereotypes of different groups held by different people, different interventions may be needed to combat and reduce these prejudices. One cannot presume, for instance, that an intervention designed to reduce the fear directed toward Black men will also reduce disgust often elicited by gay men. Current interventions could be appreciably improved by incorporating evolutionary principles and findings.

## EXPERIMENTATION

---

Social scientists have a plethora of ways to gather information about group processes. To describe how groups operate, researchers can observe groups in action, examine archival data sources, and use interviews or questionnaires to ask individuals about their beliefs and motivations. All of these techniques are useful, but none allows firm statements about causality. For this reason, researchers often utilize experiments, which, if properly conducted, allow strong inferences about the factors that produce various group behaviors. Because of this ability, experimentation is the most widely used methodology in group research.

Experimentation involves the manipulation of one or more independent variables to investigate the effects on one or more dependent variables. Experimentation is a powerful method because it allows the researcher to draw causal explanations about the “hows” and “whys” of group processes.

This entry provides an overview of the experimental method, describing how experiments are conducted and the basic issues and dilemmas researchers face when designing an experiment.

### Overview

An experimental investigation of group processes begins with the formulation of a *hypothesis*, a formally stated expectation about how certain independent variables will affect certain dependent variables. Hypotheses may be formed on the basis of prior research or assumptions about how the world operates. Once a hypothesis has been formed, it is then tested in a controlled study.

In 1968, an experiment conducted by Bibb Latané and John Darley on bystander intervention hypothesized that the more individuals who ostensibly witnessed an emergency, the longer it would take for any one individual to intervene in the emergency. In an experiment designed to test this hypothesis, Latané and Darley placed an individual participant in a room containing an intercom and told the participant that one or more other participants were seated in different rooms. Participants were led to believe that they would engage in a group discussion with one other person, two other people, or five other people. During the subsequent discussion, the participant heard a fellow group member ostensibly having a seizure (in actuality, participants heard a taped recording of an actor faking a seizure). The researchers then measured how long it took the participant to seek help for the person who was in distress.

Besides manipulating independent variables and measuring dependent variables, experiments such as the one conducted by Latané and Darley involve random assignment of participants to experimental conditions and control of extraneous variables that might affect the dependent variables. In the Latané and Darley study, the number of persons ostensibly present while the participant heard the seizure was the *independent variable*. It is the independent variable that is believed to cause a change in the *dependent variable*, in this case the length of time it took the participant to seek help.

As hypothesized, the researchers found that the larger the group, the longer it took for participants to seek help. The researchers were confident that the changes they observed in the dependent

variable were not a result of preexisting differences in the participants because these people had been *randomly assigned* to different levels of the independent variable. In social science research, participants inevitably bring unique individual differences, such as personality traits and life experiences, into a study, and these in turn may affect their response to the dependent variable regardless of their experimental condition. Randomly assigning participants to different levels of the independent variable minimizes the impact of such factors on the dependent variable. By ensuring that each participant has an equal chance of being assigned to each of the experimental conditions, any systematic differences between participants is randomly distributed across conditions.

In addition to participants' individual differences, other factors may also affect how they respond to the dependent variable. For example, if one condition were run in a setting characterized by frequent interruptions while another condition were run in a setting without such interruptions, the level of interruptions might influence how the participants responded to the independent variables. For this reason, experimenters strive to create conditions that are as similar as possible, except for the independent variable of interest. By holding constant such extraneous variables, the researcher gains confidence that the independent variable of interest in fact caused any change in the dependent variable.

## Types of Experiments

### *Laboratory Experiments*

The classic group experiment is conducted in a laboratory setting. This setting has several advantages. First, random assignment of participants to conditions is fairly easy to accomplish. Second, the laboratory setting allows precise manipulation of independent variables, as well as a high degree of control over extraneous variables. Finally, laboratory researchers can use precise dependent variables. Taken together, these characteristics yield studies that are high in *internal validity*—the extent to which cause-and-effect statements can be made on the basis of the results of the study.

But there are also some downsides to laboratory experiments. Because participants in such experiments are aware that they are being observed,

a number of subject effects can threaten internal validity. *Subject effects* are aspects of the experiment that produce “artificial” behavior on the part of participants. These may take the form of demand characteristics, which are features of the experiment that appear to require specific responses from participants and hence bias how they respond. For example, when an experimenter is aware of the hypotheses, he or she inadvertently may express subtle cues that cause the participant to respond in a way that confirms the hypotheses. Experimenters can minimize this issue by using a procedure in which they remain ignorant of which participants are assigned to which conditions (e.g., by having others assign participants to conditions and employing techniques, such as recorded instructions, which mask condition assignments during the experiment). In addition, participants may want to portray the best possible image of themselves, which can cause them to act in socially desirable ways that interfere with a spontaneous and natural response to the experimental manipulations. In all of these situations, the experimental manipulation may not be the only variable affecting participants' response on the dependent variable. Therefore, experimenters must be sensitive to threats to internal validity and make serious efforts to avoid them.

### *Field Experiments*

As noted, the major advantage of laboratory experiments is the substantial control they provide to the researcher. However, the results of laboratory experiments may not generalize to situations that exist outside the laboratory. To circumvent this drawback, field experiments can be conducted in more naturalistic settings. In contrast to laboratory experiments, field experiments are often high in *external validity*—the extent to which the results of the experiment can be generalized to different settings, participants, and times.

Inspired by the Darley and Latané's bystander intervention study, Irving Piliavin, Judith Rodin, and Jane Piliavin examined helping behavior in the tumultuous context of a New York subway train. In their study, a team of researchers staged an emergency situation, in which an apparent victim collapsed in full view of the train passengers, then members of the research team, acting as passengers,

measured the time it took for bystanders to intervene. The independent variables in their study were the type of victim (drunk or ill), the race of the victim (Black or White), and the presence or absence of a helping model. A major strength of field experiments is that researchers can take advantage of preexisting settings to introduce systematic variations and determine their effects. Thus, because participants in field experiments are generally not aware that they are participating in a study, field experiments are low in subject effects. However, field experiments are vulnerable to threats to internal validity. One drawback of such experiments is the difficulty of randomly assigning participants to different conditions. In addition, in contrast to laboratory settings, where situations can be created that are identical except for the independent variables of interest, such control is more difficult to attain in real-world settings. For instance, Piliavin, Rodin, and Piliavin could not control the number or demographic characteristics of the train passengers in each condition of their study.

It is extremely difficult to design an experiment that is high in both internal and external validity; therefore, researchers typically must choose one over the other. In so doing, they have to weigh the pros and cons of the two kinds of validity and seek an optimal trade-off between control and realism. Deciding on the appropriate methodology depends largely on the research question—whether it is process oriented or problem oriented. Process-oriented questions focus on understanding the underlying causes of a phenomenon, while problem-oriented questions focus on solving a specific problem. Of course, these two kinds of questions are often interdependent, because in order to solve a specific problem one needs to understand the mechanisms that underlie it. Nevertheless, process-oriented questions, which deal with basic mechanisms such as perception, motivation, and emotion, are best addressed using laboratory experiments, whereas problem-oriented questions, in which the social context is key to developing a solution, are best addressed using field experiments.

### Ethical Concerns

By working with human participants, social scientists face a unique ethical dilemma between gathering scientifically valid evidence and maintaining

participants' dignity. As an aid to researchers, the American Psychological Association has established a set of guidelines for ethical conduct of research involving human participants. These guidelines are based on five principals: (1) protecting participants from harm, (2) maintaining participants' right to privacy, (3) minimizing deception, (4) obtaining informed consent from the participants prior to a study, and (5) fully debriefing participants at the conclusion of the study.

Experimenters must take great care to ensure the welfare of participants and protect them from physical and psychological harm. While physical harm to participants is not difficult to assess, psychological harm is often harder to measure. For this reason, experimenters must make substantial efforts to ensure that participants do not experience undue stress either during the experiment or afterwards. This is particularly important when experimenters gather information of a sensitive nature, such as strongly held attitudes and beliefs about sexual orientation, race, and so forth. In such cases, researchers must ensure participant confidentiality by removing personally identifying information from data.

A controversial topic in group research is the use of deception. In some cases, deception is necessary to study a particular phenomenon. For example, both the Darley and Latané and the Piliavin, Rodin, and Piliavin studies led participants to believe that they were witnesses to an emergency situation when in fact they were not. Because deception raises ethical concerns, group researchers go out of their way to avoid it unless it is absolutely essential.

Two final ways to safeguard the rights of participants are to obtain informed consent prior to participation and to fully debrief participants after the experiment. As thoroughly as possible, researchers should describe the procedures used in the experiment before the study and obtain participants' consent to take part. Participants should be informed that they have the right to withdraw from the study at any point without repercussion. At the conclusion of the experiment, researchers should debrief participants. By offering a detailed explanation of the experiment and its broader implications, any use of deception can be explained and justified. In addition, participants can leave the study with an increased understanding of the phenomenon being studied.

### Conclusion

In an experiment, through random assignment of participants to conditions and the control of extraneous variables, the researcher creates an environment in which only the independent variables could plausibly influence responses on the dependent variables. For this reason, the experiment, whether conducted in the laboratory or the field, is a powerful tool for investigating group processes.

## EXTENDED CONTACT EFFECT

---

According to the *extended contact effect*, merely knowing that a member of our group has a close friend from another group can improve our attitudes toward that group. This means that even a relatively small number of cross-group friendships can have a wide impact on prejudice and thus can influence relations between groups on a large scale. The extended contact effect is an expansion of the contact hypothesis, which has a longer history.

Sixty years of research has convincingly demonstrated that positive interactions with people from another group, under the right circumstances, can reduce prejudice and create feelings of warmth and respect toward that group. In 1947, R. M. Williams

authored one of the earliest statements of this hypothesis. However, it was Gordon Allport who in 1954 provided the most influential account of the circumstances under which contact across groups can effectively reduce prejudice.

His hypotheses inspired an enormous volume of scientific research. However, there are many good reasons why most people cannot, or do not, enjoy friendly contact with members of other groups. Thus, the power of cross-group contact to create tolerance and respect might appear quite limited. However, social psychologists have shown that cross-group friendships can have positive effects not only on those actually involved, but also on others who are aware of them—thus the extended contact effect. This entry reviews supporting evidence of this effect and possible explanations for its occurrence.

### Supporting Evidence

The extended contact effect was formally introduced in 1997 with evidence from a series of studies. Two studies were surveys of Whites, Latinos, and Blacks. Respondents indicated how many people they knew from their own ethnic group who had a friend in one of the other ethnic groups. They also answered questions measuring their attitudes toward the two other ethnic groups. Both surveys showed that compared to people who knew of fewer cross-ethnic friendships, people who knew about more friendships between members of their own group and another ethnic group had more positive attitudes toward that other ethnic group.

Subsequently, surveys have shown the same positive effect of extended contact for numerous other groups, including both Catholics and Protestants in Northern Ireland; German adults toward “foreigners” and Muslims; German school children toward Turkish children; heterosexuals toward gay men in both Vancouver, Canada, and in New York; White and South Asian high school students in Britain; and White, Chinese, and South Asian groups in Vancouver, Canada. In every case, the more friendships that a person knew about their own group and another group, the more positively they felt toward the other group.

However, in these survey studies, extended contact and attitudes toward the other group are measured at the same time. Therefore, it could be that knowing

about more cross-group friendships leads a person to hold more positive attitudes—the extended contact effect. However, the causal influence behind these results could just as well be in the opposite direction: Perhaps people with more positive attitudes seek out situations where there will be more interactions between the two groups, so they find out about more cross-group friendships. To be certain that extended contact *causes* improvements in attitudes, controlled experimental studies were required.

Two different types of experiments have been done. One type has been carried out in the field and involves direct interventions with schoolchildren. In one study, for example, British elementary school children were randomly divided into groups. The researchers then read stories about friendships between British and refugee children to one of the groups. The other group heard the same stories, but the friends were both British. Sometime later, the children's attitudes toward refugees were measured. The results were that the group of children who listened to the cross-group friendship stories had more positive evaluations of refugees than the children who heard stories about friendships between the two British children.

Other experiments have shown that these procedures can improve children's attitudes toward immigrant groups and toward children with disabilities. Similar effects were found for a group of adolescents in Finland, where reading stories about cross-group friendships led to improved attitudes toward "foreigners."

A second type of experiment has been carried out in laboratory settings, where new "artificial" groups are created. In one such study, university students were told that overestimators and underestimators differed in a number of important personality characteristics and then asked to perform a task where they made a series of estimations. All of the participants were told they were overestimators and were given a blue shirt to signal their group membership. They then watched as two other students, one in the blue shirt of the overestimators and one in the red shirt of the underestimates, worked on a puzzle.

What the observers did not know was that these other students were actors in the experiment. They enacted one of the following three scripts: (1) they were close friends, (2) they were strangers, or (3) they disliked each other. Consistent with the

extended contact effect, those who watched a cross-group friendship later gave more positive evaluations of the other group (the underestimators) than did those who watched a cross-group interaction between strangers or hostile enemies.

### Underlying Processes

Why does observing the cross-group friendship of others reduce our prejudice? Several explanations seem to have merit. First, there is considerable evidence that cross-group interactions can be a source of anxiety and concern, and these feelings can strengthen negative attitudes toward the other group and lead us to avoid these interactions. Observing cross-group friendships can reduce this anxiety. The friendly interaction experienced by a member of our group may make us more confident that we can also have positive, friendly relations with members of the other group, and this facilitates positive feelings and evaluations.

In addition, extended contact can change our beliefs about what is normal and appropriate for our own group. When other members of our group have friends from another group, we may come to believe that members of our group generally think positively of that group. We come to think that positive thoughts and feelings are the normal and expected response of people in our group to the other group. If we want to be good members of our group, we should adopt these same positive attitudes.

A recent study investigating the attitudes of White and Chinese Canadians toward South Asian Canadians found that those with more extended contact believed that other members of their ethnic group had more positive attitudes toward South Asian Canadians, and this belief about the feelings of others in their group was an important predictor of their own positive feelings toward South Asian Canadians. Thus, extended contact can influence attitudes by shifting the observers' beliefs about what is normal and expected for members of their group.

Finally, there is evidence that extended contact works because it creates meaningful connection between oneself and someone in another group—a connection described as *the inclusion of the group in the self*. The idea is that other people's cross-group friendships provide a conduit that connects one's self-concept (one's knowledge and feelings about oneself) to the other group. When

we feel connected to a member of our own group who has an outgroup friend, his or her connection to the other group can also connect us to that group. Most people have a strong tendency to see things that are connected to themselves in a positive light. Thus, if the other group and its members are now to some degree connected to us, we extend the positive feelings that are reserved for things that are connected to us to that group.

### Conclusion

It appears that simply knowing about friendships between members of one's own group and members of another group can improve one's attitudes toward that group. This extended contact effect can occur as a result of at least three processes: It can reduce anxiety associated with the other group; it can change beliefs about what is normal and appropriate for members of one's own group; and it can connect one to the other group and its members in ways that lead to extending a positive attitude toward the self to the other group.

The extended contact effect provides a basis for real optimism about the possibilities for improving relations between groups. It means

that even a few cross-group friendships may have the power to improve the attitudes of many, and it can thus explain how intergroup attitudes are improved even when direct contact between groups is uncommon.

## FADS AND FASHIONS

---

*Fads* are objects or activities that are popular with a group of people over a short period of time. Fads are also known as *crazes*. *Fashions* are a related phenomenon and are defined as objects or activities that become popular within larger groups over longer periods of time. Fashions are also known as *trends*. Researchers argue that people follow fads and fashions as a result of both *informational social influence* (where they incorporate useful information from others about what is acceptable and desirable) and *normative social influence* (where they adopt the acceptable behavior or desired object so that they themselves are accepted and liked by others). By following fads and fashions people can also assert their identity.

### History and Background

During the 17th century in the Netherlands, the demand for tulip bulbs reached such a peak that astronomical prices were charged for a single bulb, and people were prepared to pay an enormous proportion of their earnings to own this most desired object. The most famous example of this tulipomania was a bulb reportedly sold for fl. 6,000 in the 1620s, when the average annual income of the time was fl. 150. While this is an extreme example, it is illustrative of the phenomenon we popularly know today as a fad. Tulipomania lasted for a short period of time, but during this period it caused a craze that swept

through a society and left many people financially ruined.

In the 20th and 21st centuries, many more familiar and less dramatic examples of fads have existed. For example, most children in the 1950s owned a hula hoop, but these are rarely seen in the playgrounds of the 2000s. In the early 1980s, many children owned a Rubik's cube. Fads can also be seen outside the realm of consumerism. For example, the social networking site Facebook is rapidly growing in popularity, with over 70 million visits recorded in a single month in 2008 and hundreds of thousands of new users joining each day. Also, the discipline of psychology is not immune from research fads that last for a short period and then fade in popularity as new research topics take their place.

The two concepts of fad and fashion are often difficult to tease apart, and there appears to be little consensus amongst psychologists concerning where a fad ends and a fashion begins. Indeed, one dictionary definition of a *fad* is a temporary *fashion*, idea, and/or behavior assumed by a group. Generally, though, it is accepted that fads are short-lived, and that the process of adopting the object or activity of a particular fad over alternatives is rather arbitrary. For example, why were hula hoops, and not some equally fun alternative, the most popular toys of their time?

In contrast to fads, fashions are seen as having a sustained influence on society and a broader reach, often across multiple societies. For example, the hippie fashions lasted for a significant period of time during the 1960s and '70s and were followed by

people throughout the world. In addition, fashions, unlike fads, are characterized by people in a group sharing a look or style. In other words, a clear trend is noticeable among group members, who alter their appearance to reflect what is collectively perceived as appropriate and stylish at any given time. Although fashions can last for extended periods of time, they are inevitably replaced by new fashions that render the old ones outdated—at least until they return when the fashion industry again proclaims them fashionable. This is not uncommon, and it is another important feature of fashion. Although some fashions run their course and disappear forever, some return from obscurity after several years and become part of the “cycle of fashion.”

### Fads, Fashions, and Social Influence

People are influenced by fads and fashions through two processes of social influence: informational social influence and normative social influence. *Informational social influence* occurs when people’s choice to follow a norm is informed by the choices and decisions of others. *Normative social influence* occurs when people’s choice to follow a norm is driven by the desire to be part of a group (and avoid rejection and exclusion) or to achieve a positive social outcome such as being liked or accepted by a desirable group.

#### *Informational Social Influence*

Informational social influence is the mechanism by which people gain important information from others that subsequently guides their behavior. If as a result of informational influence people follow fads or fashions, it is because the behaviors of others have convinced them that doing so is a good choice.

A study by Matthew Salganik, Peter Dodds, and Duncan Watts in 2006 illustrates informational influence in making fashionable music choices. Salganik and his colleagues simulated an online center for downloading music. After agreeing to take part in a study of musical preferences, participants were assigned to either a control condition, where they chose which out of a list of 48 songs they wanted to listen to, or an experimental condition, where they chose the songs they wanted to listen to after seeing the number of downloads

each song had received from other people who had visited the site. It was found that in the experimental condition, visitors to the site paid attention to the download activities of others, and their choices were influenced by the choices of others. Popular songs were more popular in the experimental condition than in the control condition, and less popular songs were less popular. Participants in the experimental condition therefore used informational social influence to navigate the site and increase their chances of finding the good songs.

#### *Normative Social Influence*

People can also follow fads and fashions when they want to “go with the crowd” or feel part of a group. Following trends is one way in which people can gain the approval of others who are important to them. For example, decorating one’s house in a particular fashion might make it easier to be accepted into a desirable social circle. Similarly, wearing particular clothes at school might increase a student’s chances of being accepted by a desirable peer group.

Also, conforming to normative social influence means that people can avoid some of the negative consequences that might result from standing out from the crowd. Resisting group pressure can lead to disapproval from others, negative interactions with other group members, and ultimately rejection or even ostracism by the group. If membership in the group is important, then conforming to the fashion norms of the group is one way for individuals to retain the group’s good opinion.

#### *Fashion and Identity*

Related to the notion of conforming to group norms, adhering to particular fashions can also be a way for people to signal their group membership to others. This is particularly the case for widespread fashions that are adopted by specific groups, or *subgroups* of individuals. Such conformity can evoke positive feelings in people, in that identifying with a personally valued group is good for self-esteem. In displaying their identity through fashion, people also become associated with a particular group membership, and other people then make judgments about them based on their membership in that group.

For example, wearing Goth clothing and makeup signifies to outsiders that a person is most probably a Goth. Identifying him- or herself as a Goth might improve a person's self-esteem. At the same time, others will make judgments about this person based on his or her Goth attire—for example, that he or she is morbid and likes “dark music,” because this fashion is an identity marker associated with a specific set of norms and values. In cases like these, where a fashion is shared by a small group of people, the people adopting the fashion can even be seen as nonconformists. However, some psychologists would argue that this is still a case of normative group influence—in this case, however, people are conforming to a subgroup norm instead of a mainstream norm.

### Organizational Fashions

A good example of how trends fluctuate and how fashions spread or diffuse can be seen in fashions in the promotion and use of particular management techniques within and across organizations. In 1999, Eric Abrahamson and his colleagues studied how the popularity of trends in management practices (collective beliefs about the effectiveness and appropriate use of cutting-edge management techniques) is determined by the discourse surrounding such techniques. They argue that the success and life of an organizational fashion is also determined by the discourse surrounding it. This idea explains why some fashions might be successful and long-lasting, and some may not. It also explains how some fashions may be institutionalized or adopted in the first place, and why some may be dismissed as mere fads.

In particular, Abrahamson and his colleagues argue that variability in when advocates begin, continue, and stop promoting organizational fashions can explain variability in the fashions' lifecycles. Also, combinations of forces both within and outside the management-fashion market can trigger, promote, and diffuse management fashions. Finally, the success and longevity of management fashions can be determined by the emotionality of the discourse surrounding them. Emotionally charged, unreasoned, and enthusiastic discourse characterizes the upswings or successes of fashions. On the other hand, unemotional, reasoned, and qualified discourse characterizes

the downswings or lack of success of organizational practices.

### Fads, Fashions, and Body Image

Another good example of fluctuating trends can be seen in women's and men's responses to social norms concerning body image. In a study conducted in the 1980s, Brett Silverstein and her colleagues examined the standard female body size/shape in American magazines from 1901 to 1981. Their results show significant changes in the female body shape over the years. For example, in the 1940s and 1950s the images were characterized by curvaceous women like Marilyn Monroe, whereas in the 1960s the images of women changed to the reed-thin ideal exemplified by British fashion model Twiggy.

It is important to note, however, that like all fashions, ideal body weight is culture-specific. A study of 54 cultures, conducted by Judith Anderson and her colleagues in the 1990s, illustrates this point clearly. Across these cultures, Anderson and her colleagues measured people's ideal female body (heavy, moderate, or slender). They also analyzed how reliable the food source was in each culture. Interestingly, body size varied according to the reliability of the food source. Specifically, in cultures where food resources were stable, a slender female body shape was preferred. However, in cultures where the food supply was unreliable, a heavier shape was preferred—perhaps because it indicated that the woman was likely to be healthy and fertile.

Men are not exempt from the change in the physical ideal over time. Harrison Pope and his colleagues found some evidence for a changing ideal male body in their analysis of GI Joe dolls' bicep, chest, and waist measurements from the 1960s to 1990s—these showed a significant increase in muscularity over the four decades. In another study, Pope and his colleagues asked men in the United States, France, and Austria to alter computer images of male bodies to match their actual body shape, their ideal shape, and the shape that women would find most attractive. While they were accurate about their own shape, participants' ideal and most attractive shapes differed significantly from their own body shape—overall they chose more muscular body shapes.

There is a great deal of concern about the fashion for certain ideal body shapes. Some studies show that young women perceive themselves as overweight when they are not, and that these women are dissatisfied with their normal (or even slim) body shapes because they do not conform to the thin ideal portrayed in the media. Likewise, the muscular ideal for male figures has been linked to feelings of pressure in adolescent and young adult males. Some study results suggest that young men are changing their eating habits in order to “bulk up” to meet the muscular ideal, which sometimes also entails the use of substances such as steroids. Following fashion therefore does not necessarily have positive consequences.

## FALSE CONSENSUS EFFECT

---

People tend to overestimate the extent to which other people share their opinions, behavioral inclinations, and preferences, a bias known as *false consensus*. In a typical study, participants might be asked whether or not they agree with a statement (e.g., “use of the death penalty is appropriate

in some cases”), after which they are asked to estimate the percentage of their peers who would also endorse the statement. Investigators then compute a score that represents the difference between the estimate given by those who endorse the statement and those who do not. For example, suppose 70% of individuals in a sample endorse the death penalty (and thus 30% do not). If the 70% who endorse it estimate that 60% of their peers agree with them, whereas the 30% of those who disagree provide an estimate of 50% regarding their peers’ agreement, there will be a false consensus effect of  $60\% - 50\% = 10\%$ . Note in this example that participants can exhibit the false consensus effect even if they underestimate the percentage of their peers who agree with them. The key requirement for false consensus is that estimates about others are pulled toward one’s own opinion, irrespective of where they are on an absolute scale. This entry provides a historical background for research on false consensus, lists explanations for this phenomenon, identifies similar psychological constructs, and finally, considers the implications of the effect.

### History and Background

In one of the earliest demonstrations of false consensus, Lee Ross and his colleagues asked Stanford undergraduates to wear an unattractive sign promoting a local restaurant and found that those who agreed to do so gave higher estimates of the number of students who would agree than did students who initially declined the request. The false consensus effect has now been observed in a wide variety of attitudes and behaviors, such as political opinions, health-related behaviors, and social perceptions, and it appears even when incentives to make accurate judgments are present.

Research shows that people are particularly likely to demonstrate false consensus effects for strongly held attitudes and when judging consensus among members of their ingroups rather than among members of outgroups. Other work shows that false consensus is more likely to appear where there are differences of opinion (e.g., whether capital punishment is appropriate) than where there is wide agreement (e.g., whether stealing is acceptable). Of note, George Goethals and his colleagues have shown that people are less likely to

demonstrate false consensus for abilities and predispositions that are a source of personal pride; for example, people see their morality and abilities as being particularly unique, thereby leading instead to a *false uniqueness* bias.

### Explanations

There are many possible reasons why false consensus effects occur. First, it is likely that people surround themselves with others who share their values, attitudes, and preferences. Research on the availability heuristic shows that people make judgments based on information that is most memorable and accessible; given that their peers are more accessible than those who are not their peers, it makes sense that people's estimates of universal opinion will be biased in the direction of their own opinion. Because ingroups typically contain relatively more similar others, false consensus is exacerbated among members of ingroups.

A second explanation is the fundamental attribution error, or correspondence bias; a tendency for people to overestimate the consistency between other people's behaviors and their underlying attitudes. Other people might convey particular attitudes in order to appear socially appropriate, whereas their true attitudes might be quite different. Nevertheless, if their outwardly expressed attitudes are consistent with our own, we may overestimate the consensus of our opinion.

A third reason is that people tend to seek out confirmatory information for their opinions. Research shows that people notice confirmatory information more than disconfirmatory information, which suggests that people will be more likely to remember cases in which their opinions were validated than cases in which others expressed an opposing point of view. A related explanation is that when people are asked to estimate how consensual their opinions are, they might focus more attention on their own opinion than on possible alternative opinions—a focalism bias. Many studies show that people are less likely to consider alternative perspectives if those perspectives are not cognitively accessible. For example, if people are asked how much they like one food, they may report higher ratings than if they make ratings in the context of several other possible foods they might consume.

All of these explanations suggest a cognitive bias in how people encode and recall information about others, but people might also be motivated to perceive consensus in order to avoid ostracism and a lack of social acceptance, as well as to maintain self-esteem. They may be particularly concerned about matching the values of their ingroups. Perceiving consensus can facilitate smooth social interactions; indeed, people expect consensus more when they expect to interact with the other individuals with whom they are estimating consensus. These and other motives could partially explain why people overestimate agreement.

A review of the false consensus literature by Gary Marks and Norman Miller suggests that no one explanation fully accounts for false consensus effects, but rather, that two or more of these processes could be operating at the same time (depending on the topic). Also, some investigators question whether the false consensus effect should necessarily be called a bias. According to these investigators, one's own standing is an important piece of information—often a well-known piece of information—that should be used when projecting beliefs in the aggregate. We know less about others' opinions than we do about our own, and we therefore are less confident in our knowledge of their opinions. Thus, our own opinions might be considered a reasonable anchor.

### Related Constructs

It is useful to distinguish the false consensus effect from other, related phenomena that also address the nature of people's social comparisons. People display the *uniqueness bias* when they *underestimate* the percentage of their peers who could or would engage in positive behaviors, and *overestimate* the percentage of their peers who would or could engage in negative behaviors. For example, individuals who engage in community service may believe that most of their peers would not engage in such moral and self-sacrificial behavior. However, citizens who act in some negative way (e.g., pollute) may believe that most others do likewise. Research by Goethals and his colleagues shows that the uniqueness bias is more likely to emerge for beliefs about one's creative abilities and moral proclivities than for academic skills, a tendency called the "Muhammad Ali" effect because

the famous boxer once quipped, “I only said I was the greatest, not the smartest.” The uniqueness bias is also more likely to appear for general abilities (e.g., intelligence) than for specific ones (e.g., ability to complete a *New York Times* crossword puzzle).

Importantly, the uniqueness bias is not synonymous with false uniqueness nor is it the opposite of false consensus, both of which are measured differently. The uniqueness bias is demonstrated simply by comparing the estimated percentage of individuals who would or could engage in a behavior to the actual percentage. If 70% of participants in a given sample indicate that they would engage in a moral behavior, but members of the sample estimate that only 20% would, the sample as a whole has demonstrated a uniqueness bias of  $70\% - 20\% = 50\%$ . As a result, it is possible to display both the uniqueness bias and the false consensus effect in the same sample. For example, suppose 60% of the members of a group report that they would donate blood and that these individuals estimate the donation rate to be 20%, whereas the 40% who would not donate blood estimate the donation rate to be 10%. This would result in a false consensus effect of  $20\% - 10\% = 10\%$ . However, both groups are greatly underestimating the percentage of their group who would donate, which is quite high (60%), representing a uniqueness bias.

A second, related phenomenon is *pluralistic ignorance*. This occurs when a group of people are engaging in similar behavior, yet the members of the group attribute their own behavior and the behavior of other members of the group to different causes (see the entry on pluralistic ignorance for other definitions of this phenomenon in social psychology). For example, college students at a party may drink excessively because they want to fit in, yet believe that other students at the party are drinking excessively because of a desire to do so. In another example, research on bystander intervention in emergencies shows that people misperceive others’ interpretations of the event from their behavior (i.e., they believe that others do not consider the event an emergency because those others are failing to act). It would seem that such misperceptions run counter to false consensus effects, because in the case of pluralistic ignorance, people are *underestimating* the similarity between their own and others’ opinions. Perhaps in these contexts

the motive to “do the right thing” (and associated concerns about being accurate when judging others’ opinions) overwhelms the motive to seek out validation of one’s own opinions. People can also misperceive consensus and consider their own motives to differ from those of others; as an example, supporters of a political issue may overestimate consensus yet believe that their support originates from “purer” social concerns than does the support of their political comrades.

An interesting field study demonstrates how each of the phenomena described above can co-occur. The authors, Benoit Monin and Michael Norton, capitalized on a water shortage at the Princeton University campus. A showering ban was instituted over a 3-day period to conserve water, and students were surveyed throughout the ban regarding their actual shower use and their perceptions of others’ use. On the day after the ban was instituted, the investigators found that bathers offered a higher estimate of the number of students who were showering (63%) than did those who were not showering (39%)—a false consensus effect of  $63\% - 39\% = 24\%$ . As it turned out, only 33% of the students were actually showering. Across both groups, the average estimate of the percentage of students bathing was 47%, leading to a uniqueness bias of  $47\% - 33\% = 14\%$ . These biases were sustained throughout the ban until it was lifted, at which point the false consensus effect remained, but a uniqueness bias then appeared in the reverse direction (i.e., students *underestimated* how many of their peers were showering). Finally, the investigators found that bathers believed they cared about the community more than the other bathers did—in other words, they believed that their own bathing was justifiable (e.g., because they engaged in intense workouts), whereas others’ bathing was due to immorality. At the same time, nonbathers believed that they cared more about the community than other nonbathers did. Thus, both bathers and nonbathers believed their actions were caused by different factors than those influencing their peers’ behavior—a clear example of pluralistic ignorance.

### Conclusion

False consensus is likely to have important consequences. To the extent that people overestimate the magnitude of social support for their opinions, they

may become less open-minded, less persuaded by alternative perspectives (in part because such perspectives will be perceived to be in a relatively small minority), and more convinced of the moral and social grounding for their own perspective. In turn, this resistance to alternative perspectives can promote intergroup hostility, much like the illusion of unanimity in groupthink. False consensus also has the potential to underlie faulty decision making in a host of consequential domains; examples include career and spousal choices, medical decisions, and political behavior. Although some research shows that asking people to take the perspective of others makes them less egocentric—and perhaps less susceptible to false consensus and other biases—research has not yet identified systematic ways of reducing the bias across multiple domains.

## FAMILIES

---

The family is the child’s first group. However, defining the family is not an easy matter given today’s diversity of family types, some of which have only recently become possible as a result of advances in reproductive technology. At a minimum, scholars agree that the family is a social unit in which members identify with one another and share economic responsibilities, social and emotional commitments, memories of common experiences, and expectations for continuity over time and a common future. These elements characterize many nonfamily groups as well.

Families are a unique kind of group because the members of typical families—parents and children—do not choose their group members and do not typically leave the group. In most families, unlike other groups, members are also biologically related. Like some other groups, family members differ in both age and power, and they occupy prescribed roles when the group is formed (i.e., when the first child is born or adopted). Well-functioning families are hierarchical, with children relatively powerless compared to parents until the balance of power begins to change as children enter adolescence. Families also serve unique functions, the most basic of which is to provide protection and support until children are capable of providing for themselves.

Because families serve as the first and primary source of children’s socialization, much of the research on families focuses on how they socialize their children. Historically, theories held that parents were the primary shapers of children’s personalities, values, and social and emotional competence. In recent years, however, it has become clear that family socialization is far more complex than simple unilateral, parent-to-child influence and that all

family members contribute to family social processes, including children themselves. Theoretical perspectives now reflect this complexity.

### Family Socialization Processes

By studying family members with different degrees of genetic relatedness (e.g., identical vs. fraternal twins), researchers have been able to show that some of the similarities among children raised in the same family are a product of their common family socialization, as traditionally assumed, but some are because children and parents share half of their genes. Because individuals' genes influence their reactions, judgments, and interpretation of experiences, children uniquely affect their parents' and siblings' behavior, and thus their parents' and siblings' influence on them in return. This research has also shown that the children in each family differ from one another partly because parents treat each child in the family as a unique individual, partly because each child interprets and responds to the same family experiences differently (e.g., younger and older children respond to divorce differently), and partly because each child has singular experiences outside the family. Thus, family environments and children's genes interact in complex ways to mold development. For example, children with a genetic history of anxiety disorders who grow up in stressful, conflict-ridden family environments are more likely to develop anxiety-related problems than children without such a family history, or than children with the same genetic propensity who grow up in more typical families.

### Attachment

Socialization in the family begins with the special relationship that forms between parent and child during the first year of life, known as parent-infant *attachment*. In landmark studies by Harry Harlow, John Bowlby, Mary Ainsworth, Alan Sroufe, and their students from the 1950s through the 1970s, it became clear that children become attached to their parents not because parents feed them, as had long been thought, but because of a biologically based need for contact, comfort, and safety that is characteristic of all mammals. By the end of infants' first year of life—in every culture

studied, from hunter-gatherer to urban industrial—they have established an intense and long-lasting emotional bond with their parents and other regular caregivers that is unlike any other interpersonal bond or relationship.

Importantly, research has also shown that it is this unique emotional bond that opens children up to parental socialization influence. One- and two-year-old children listen to and comply with parents' requests not because they fear punishment, but because they want to maintain their parents' love, approval, and protection. One might expect, therefore, that children with more secure, high-functioning attachment relationships would be more compliant, cooperative, and eager to please their parents, and research has confirmed this.

Attachment research remains a thriving area of inquiry. Ongoing questions include how attachments vary by culture, how parenting quality and child characteristics such as emotional reactivity shape the developing attachment relationship, and how early childhood attachment relationships influence later developing social and emotional competencies. It is especially difficult to address the last question because it is not possible to manipulate children's attachment relationships experimentally. For example, children with more secure attachment relationships in infancy have been found to be more successful in the peer group in middle childhood, more likely to be group leaders, and more well-liked by their peers. One prominent theoretical perspective credits these associations to a relationship prototype, called an *internal working model*, which is held to derive from the child's attachment relationship and to influence all subsequent relationships in which the child participates. Scholars with another perspective have argued that continuity in children's general socialization experience in the family is a more likely explanation. Large-scale longitudinal studies in which a significant number of children experience changing family environments, and who can then be studied for several years to examine their subsequent development, hold promise for elucidating these fundamental questions.

### Parenting Styles

Much of the research on family socialization concerns how parents convey and enforce rules

and expectations for children's behavior. Based on influential studies by Diana Baumrind beginning in the 1960s, scholars have identified four common parenting styles. These are based on two distinct dimensions of behavior that have sometimes also been found in research on nonfamily groups: warmth/responsiveness and control/demandingness. *Authoritative* parents score high on both dimensions. They are attentive, affectionate, and accepting. At the same time, they establish clear routines, rules, and limits; expect age-appropriate behavior; and communicate and enforce expectations consistently. *Permissive* parents score high on the warmth dimension, but low on the control dimension. They are affectionate and responsive, but also indulgent, with few rules or limits on behavior or expression and few demands for age-appropriate behavior. *Authoritarian* parents score high on the control dimension, but low on warmth. These parents have many, often rigidly enforced rules, seldom consider the child's point of view, and typically expect their children to behave with greater maturity than the children are capable of. They tend to be intrusive and coercive, as well as harsh, critical, and rejecting. *Disengaged* parents score low on both warmth and control. They are generally detached and uninvolved with their children. They are either indifferent to their children's feelings or thoughts, or rejecting and critical. They have few or no routines or rules, and their expectations for maturity and age-appropriate behavior are inconsistent or inappropriate.

As one might expect, research has shown that the developmental outcomes are quite different for children growing up in families with these different parenting styles. Children of authoritative parents were found to be the most socially and emotionally competent from early childhood through adolescence, with correspondingly low levels of maladjustment. Permissive parenting was shown to be associated with impulsivity, aggression, and less initiative and self-reliance in children. Children of authoritarian parents tended to have little general social competence, and were moody and unfriendly, with low self-esteem. Finally, children of disengaged parents were found to have the least social and emotional competence and exhibited a variety of behavioral and adjustment problems. This research, however, was conducted with a relatively homogeneous population. More recently, researchers have

been working to specify the particular components of each style that produce these differences, as well as whether these styles and their associated outcomes hold up across different family types and cultures. For example, research suggests that both Chinese American and Black American families are more likely to use the authoritarian parenting style, but the outcomes for their children are more like the outcomes for White American children reared in authoritative families. This suggests that parenting styles possess different meanings in different cultural contexts, and that culture serves as an important moderator of family socialization effects.

### *Other Family Socialization Processes*

Although research on parenting styles has been influential and informative, it has largely neglected the role of children in family socialization. Therefore, scholars have begun to extend the study of family socialization beyond disciplinary contexts, and to other mechanisms of influence besides control. Research has focused on *gatekeeping and monitoring*, in which parents manage children's exposure to adults and peers who model (or fail to model) culturally valued behavior; *scaffolding and coaching*, in which parents create structures and routines, and provide help and feedback so that children learn age-appropriate values and behavior through supported participation in a variety of social contexts; and *mutual reciprocity and affect sharing*, in which parents and children establish and share common goals in pleasurable, affectively positive social settings. Notably, none of these involves disciplinary encounters, direct imposition of control over children's behavior, or conflict and disagreement between children and parents.

The trend in family socialization research has been especially influenced by the recent conceptualization of families as groups. This theoretical perspective places more emphasis on family practices and norms, the child's interpretation and acceptance of parents' communication of norms and expectations, and the child's own efforts to behave in accordance with perceived family norms. For example, parental monitoring of children's activities and companions in early adolescence is associated with more positive emotional adjustment and greater social competence, but only when children are honest with their parents about

their whereabouts and accept their parents' authority in monitoring them. One interesting but unstudied question is whether children's socialization in the family establishes some of the basic phenomena that characterize nonfamily groups in adulthood, such as ingroup attachment and positivity.

### The Family as a System

The most complex conceptualization of families considers them as holistic systems of interconnected alliances and relationships that are constantly shifting, and that both affect and are affected by external relationships, including those in the workplace, the community, and the culture. For example, the marital relationship is affected by and affects each child's relationships with each parent, and each child's relationship with his or her siblings. Likewise, the marital relationship is influenced by each parent's workplace relationships. Family relationships are also affected by cultural norms and practices. For example, some cultures value strong extended family ties; children in these cultures are likely to grow up in households that include grandparents, aunts, uncles, and cousins as well as parents and siblings. The family system also develops, with the nature of its relationships changing as each member ages and as the world itself changes. Maternal employment, for instance, has increased dramatically over the last few decades in Western industrialized nations, with concomitant changes in family dynamics and children's experiences. Viewed as a dynamic system, the family provides critical physical and psychological resources for all of its members, and can be characterized by its degree of interconnectedness, stability, and support.

### Dysfunction Within the Family System

The family can also be the source of interpersonal stress and conflict. Traumatic life events, social disadvantage, mental illness, and substance addiction can contribute to a breakdown in the smooth functioning of the family system. In some extreme cases, parents not only fail to provide for their children but actively harm them through physical or emotional neglect or abuse. Moreover, adult children of abusive families are more likely to replicate such abuse with their own children.

Thus, a dysfunctional family system can perpetuate itself across generations.

Contemporary theory acknowledges the importance of the family as a system in adapting to each member's behavior, including mental health difficulties. The tendency for psychological disorders to run in families can lead to significant stress on the family system, particularly if there is a lack of fit between family members' problems. For example, a father who struggles with attention deficit hyperactivity disorder may find it difficult to inhibit a harsh reaction to the misbehavior of his impulsive child, whose inherited tendency to impulsivity is further exacerbated by his father's responses. Family therapy, built on the conceptualization of the family as an interdependent system of relationships, has been found to assist in preventing relapse of significant mental illnesses such as schizophrenia, and it is a promising method by which to treat adolescent problems such as eating disorders. In sum, whether socializing children or providing important resources for the healthy functioning of all members, family members influence one another's development and adjustment in multiple, complex, intersecting ways.

## FAULTLINES

---

Groups have *faultlines* when group members' personal characteristics align with one another, so

that distinct, unique subgroups are recognizable within the larger group. These alignments provide the basis for conflict, especially between the subgroups, and especially when issues arise that are related to the subgroups' differences. This entry provides a specific definition of group faultlines, a variety of examples and implications of these faultlines, and some recent research findings.

### Defining the Concept

The concept of group faultlines uses a geological metaphor: The surface of the earth is covered by layers of rocks, huge rocks. Among, between, and beneath the layers are *faults*, that is, fractures within the earth's crust. As long as things are calm and external forces don't appear, faults can be dormant for many years without being noticed.

In like fashion, we can think of the surface of a group of people as being covered by their demographic characteristics, which hide the more important, underlying personal characteristics that we normally associate with those demographics. Thus, if we could look down at the earth and see below its vegetation, we might see its layers and its faults. Similarly, if we look at a group of people and see their surface characteristics, like race, age, and gender, we also understand that they have deeper characteristics, like preferences, inclinations, and values. At the same time, we have lay theories about how individuals' surface characteristics relate to these deeper qualities. We go even further when we form conclusions about the deeper interrelationships of group members based on their array of demographic characteristics.

As noted, groups can have faultlines, much like the earth has faults. Faultlines occur when a group's members differ on the basis of one or more attributes and their differences align. When more attributes are intercorrelated, they can create the potential for a schism in the group's interpersonal structure (e.g., gender faultlines can divide groups into male and female subgroups). Faultlines increase in strength when the entire group can be divided into a small number of subgroups, each of whose members are similar to each other but are markedly different from the members of the other subgroup.

For instance, a group with two teenagers and two elderly people will experience stronger faultline

effects than a group with two members in their 20s and two members in their 30s. Faultlines also get stronger as multiple attributes align. Thus, a group that includes two older Hispanic men and two young Caucasian women would have a very strong faultline, as gender, age, and ethnicity all align. Faultline strength is strongest when a large number of individual attributes align with each other and create a small rather than a large number of subgroups. The strongest faultlines occur when a large number of attributes that differ widely align themselves consistently and result in two distinct subgroups. In contrast, if a group's members are extremely diverse (i.e., they all differ from each other in many ways), diversity may be high but the possibility of a faultline becomes unlikely. Thus, faultlines, and particularly strong faultlines, tend to surface in groups that have a moderate range of diversity.

Faultlines and diversity are related but different concepts. Diversity refers to the dispersion of group members' personal characteristics. For instance, a group may be homogeneous with respect to gender but diverse with respect to personality or cultural values. Groups are diverse when members are different on any single attribute. Thus, a group that includes members who all have different occupations is obviously diverse in occupations, and more diverse than a group that includes two engineers and two clerks. Diversity is a characteristic of groups that can depend on individual attributes, considered one at a time.

Group faultlines, in contrast, depend on multiple attributes, considered simultaneously. Faultline models suggest that the members of a group that is tremendously diverse on many dimensions may get along very well with one another because the group has no faultlines. The models also suggest that another group that is less diverse may have internal turmoil and conflict if many of its group members' personal characteristics align to form a strong faultline. Faultline models emphasize the formation and action of subgroups: Faultlines can form the basis for difficult interactions within a group, especially when the topic being discussed is related to the characteristics that have caused the faultline. Thus, faultlines use the concept of diversity and build on it by focusing on the microcomposition of a group's members.

### Examples and Implications

An example may help to clarify the different dynamics that can emerge from diversity and faultlines. Consider two groups that encompass similar levels of diversity but different faultline strengths. A group with two female accountants and two male engineers has a stronger faultline than a group with a female accountant, a male accountant, a female engineer, and a male engineer. While the groups have similar diversity in gender and occupation, the former group has a much stronger faultline and, theoretically, may have more difficult interactions—especially if the company budget can send only two people to a professional conference this year, and the group must decide between an accounting conference and an engineering conference.

Among the many attributes that can form potential faultlines, social context plays an important role in deciding whether a particular faultline will be activated. For instance, differences in political ideology in parliament, the home country of parent companies in international joint ventures, and geographical locations in global virtual teams may be more salient than demographic faultlines, such as gender and race.

When faultlines split a group into subgroups, increased internal conflict is a logical result. Recent research indicates that this may be the case even when the issues that a group is addressing are not related to the nature of their faultline. When issues are related to the group's faultline, however, the potential for considerable conflict may increase even more. Thus, if our example group of older Hispanic men and young Caucasian women was discussing the establishment of a day care center at their organization, they might have significant conflict—and it would be easy to predict who would line up on which side of the conflict.

Over time, group members learn about each others' personal characteristics, and their similarities and differences in values and philosophies may become more important than their demographic similarities and differences. In other words, as group members get to know how the other members stand on a variety of attitudinal issues, what they learn can become the basis for either harmony or conflict. Different political preferences, for instance, which are not easily

seen by just observing a person, may lead to political faultlines within a group—and the potential for accentuated political conflict. When conflict is intense, groups with strong faultlines may actually break into two or more groups along their faultlines.

Another effect of faultlines, if they are activated, is that group members may identify more with their fellow subgroup members rather than with the group as a whole. When subgroup identification is strong, members within the same subgroup enjoy highly trusting relationships, but they may be suspicious of the members of the other subgroup. Similarity among subgroup members also creates a psychologically safe environment for team learning. However, the benefits created within subgroups are sometimes created at the expense of the whole group.

### Recent Research

Recent research has indicated that strong faultlines influence the effectiveness of communication with a group: When faultlines are weak, communication across subgroups tends to be effective; when faultlines are strong, increased communication actually seems to decrease performance. Research also has found that members' identification with the group was lower in groups with strong faultlines than in those with weak faultlines. Decision accuracy also suffered in groups with strong faultlines, because these groups failed to process information efficiently and effectively.

A study that is an excellent application of the idea of faultlines investigated the characteristics of firms that were forming a total of 71 international joint ventures in China. Each firm had at least two expatriate managers and at least two local managers. The managers' nationalities were an important characteristic that could have created "factions" (or subgroups) in the management teams: It was to be expected that local managers might find it easier to work with other local managers, and that expatriates might find it easier to work with other expatriates. The research clearly indicated that the presence of such strong faultlines led to task and emotional conflict, less "behavioral integration" (i.e., information exchange, collaboration, and joint decision making), and, ultimately, reduced performance.

The bottom line: Faultlines can be a particularly important structural force in the dynamic interactions within groups.

## FEMINISM

---

The concept of *feminism* is not universal and has many forms (e.g., liberal, radical, womanism) and definitions. However, there are three characteristics that are shared by most, if not all, forms of feminism. First is the recognition that women are treated differently than men, and are in the subordinate role in society. Second, feminists view gender and gender roles as socially constructed (and thus capable of change) and as differentially valued within society. Third, feminism holds that women can be autonomous and self-reliant. The main goal of feminism is gender equality.

### Brief History

Discussions of women's position relative to men's go back at least as far as the 12th century, although "feminism" did not emerge until the mid-18th century. Mary Wollstonecraft's *A Vindication of the Rights of Women*, published in 1792, is considered the first feminist text. Early North American feminists struggled with competing loyalties: family vs. self, abolition vs. suffrage, and change vs. comfort, among others. In 1869, John Stuart Mill published *The Subjection of Women*, which distinguished between women's biological abilities and social construction; for example, it differentiated

between the ability to bear children and the need to stay at home. It is a critical text because it was written by a man and therefore considered more credible by a male-dominated society.

Modern feminist movements are referred to as "waves." The waves of feminism in the United Kingdom and the United States have similar timelines, although other countries have their own progressions. The first wave in the United States lasted approximately 60 years, from 1860 to 1920, and focused on gaining the vote for women. The second wave, in the 1960s and 1970s, is often prominent in definitions and descriptions of feminism. While many actions of the second wave were attempts to make family life more equitable for women, there were also extreme changes in society, both within and outside the feminist movement. The movement of the 1960s left out many women of color, often focusing on White, middle-class issues such as the right to employment and the distribution of household labor. The U.S. Supreme Court's ruling in *Roe v. Wade* in 1973 made abortion legal, granting women control over their own bodies, and sparking a debate that has continued for over 30 years. Extreme actions covered by the media (e.g., marches, bra-burning, single-issue protests) managed to alienate more moderate feminists, distancing more women from what became a very political label. The political climate during the 1980s and 1990s was difficult for feminism, and women continued to avoid the label "feminist" into the next decade. This is the era during which the third wave of feminism began.

### Relevance to Intergroup Relations

Women constitute half of the world's population, and the majority hold a socially subordinate role to men. Compared to men, women experience inequalities in social, political, economic, and domestic realms. Feminism has brought to the forefront several issues relevant to intergroup relations, including (a) feminist identities; (b) stereotyping, prejudice, and discrimination against women; (c) rejection of dominant ideologies; and (d) collective action and social change.

### Feminism as Identity

Females today may believe in feminist ideals but disavow the label "feminist." This is part of the

third wave battle, in which women are fighting to maintain the rights achieved during the second wave, but still struggle against many of the obstacles of 50 years ago. While women may have achieved much success in the workplace, their roles at home may resemble those of their grandmothers. During the 1980s and 1990s, conservative groups tried to undermine the achievements of the second wave, portraying feminists as angry, antimale, bra-burning, home-wrecking, lesbian, and so on. Consideration of this negative portrayal is key to understanding why many feminist women choose not to label themselves as such.

### *Stereotypes, Prejudice, and Discrimination*

Societal attitudes toward women are mixed, encompassing both positivity and negativity. Researchers have identified two key characteristics on which women, and social groups in general, are judged: warmth (or likability) and competence. Women who fulfill traditional gender roles, such as housewives and mothers, are consistently viewed as very warm but not very competent. People view them as having low social status, and the common emotions felt toward these women are pity and sympathy. However, people feel more positively toward traditional women and tend to help and protect them. In contrast, women who fulfill non-traditional gender roles, such as career women and feminists, are viewed as not very warm but very competent. Society views these women as having high social status and in competition with men. Thus, emotions commonly felt toward these women are envy and jealousy, but people tend to cooperate and associate with these groups due to their high status.

Women who are highly identified with their gender are more likely to be aware of discrimination against women. However, many women recognize sexism toward women as a group but deny that sexism affects them personally. Part of this denial may be due to the fact that sexism, like racism, has become more subtle and difficult to detect.

Social psychologists have identified two distinct forms of sexism, hostile and benevolent. Hostile sexism is the traditional form in which people hold openly negative attitudes toward women. Hostile sexists view women, particularly feminists, as competitors with men for jobs and power. In

contrast, benevolent sexism reflects a consistent research finding termed the “women are wonderful” effect. Benevolent sexists view women as pure and deserving of men’s protection. Women are viewed as complements to men, as men’s partners in heterosexual relationships in which women fulfill their traditional gender roles of wife, mother, and nurturer.

Women are less likely to endorse hostile sexism than men, but women are equally likely to endorse benevolent sexism, especially in highly sexist cultures. On the surface, benevolent sexism appears to be positive and provides women with protection and domestic power. However, benevolent sexism actually enforces inequality between women and men. Benevolent sexism in a sense keeps women “in their place” and prevents their mobility in employment and attainment of economic and social power.

Benevolent sexism rewards women who maintain traditional gender roles by providing them with affection and protection. Women who violate traditional gender roles often are subject to the effects of backlash. The backlash effect occurs when stereotype violators are penalized for their violating actions. Women who appear masculine in any way can be seen as violators of gender norms, and they may be sanctioned for it—for example, by being excluded from a social group. Feminists often face the backlash effect as they work toward autonomy and independence.

Women who experience backlash are faced with the dilemma of whether to claim discrimination and seek justice. Research has shown that women pondering whether to report discrimination worry about retaliation and being seen as troublemakers. These fears are reasonable, as research suggests that women who claim discrimination are viewed as complainers, are derogated, and are blamed for their situation. Further, women have reported anger toward other women whose claim of sexism makes their gender group look bad. The negative social consequences for reporting discrimination may prevent women from doing so, which further perpetuates inequality.

### *Feminism and Dominant Ideologies*

Identification with feminism involves rejecting some dominant ideologies or belief systems. Thus,

feminism commonly involves disidentification with some of the core values and standard practices in U.S. society. A fundamental ideology in the United States and many other cultures is that of meritocracy. A meritocratic system is defined by the assumptions that people who work hard will get ahead in life, that people get what they deserve, and that anyone can succeed in life regardless of their circumstances. A meritocratic worldview conflicts with feminism because it does not recognize societal barriers, such as discrimination, as an influence on life outcomes. Further, people who endorse a meritocratic worldview regard victims of discrimination and inequality as deserving these outcomes. Feminism as a belief system recognizes that inequality exists and not all people are treated equally or have the same opportunities; thus, being successful is not due just to hard work. Feminists understand that women have less economic and social power and fewer resources because of unequal opportunities, sexism, and discrimination.

Endorsing a meritocratic worldview has consequences for women's well-being. First, women who endorse a meritocratic worldview are less likely to perceive discrimination. Thus, women who may have less life success due in part to discrimination may blame themselves for their inability to get ahead in life. In contrast, women who reject a meritocratic worldview are more likely to perceive discrimination and recognize it as one cause of their inability to get ahead.

Cultural belief systems, such as meritocracy, serve to justify the status quo. That is, people endorse the system and see the world in its current form as fair and just. A meritocracy places the cause of events internally, as due to a person's own actions. If society believes people are responsible for their own life outcomes, then social change is not needed and inequalities continue. An example of a self-harming consequence of women's endorsement of a meritocratic system is women's perception of entitlement to pay. Women can feel less entitled than men to a high salary for comparable work.

Another dominant ideology in the United States that is relevant to feminism is romantic idealism. U.S. society continues to endorse traditional gender roles in romantic relationships, where men pursue women in courtship and women play a passive role in sexual intimacy. Many women implicitly believe that their ambitions can be fulfilled

through their romantic partner, and women's endorsement of the male "hero" is linked to their attainment of less leadership and lower achievement in education and work. Thus aspects of romantic relationships between heterosexual men and women may be challenged by feminist beliefs, and research has shown that heterosexuals do not equate beauty and romance with feminism.

### *Collective Action and Social Change*

Attitudes toward women have steadily become more positive since 1970, showing more support for women's employment and education, as well as for the sharing of household duties by husband and wife. In the United States this is consistent for conservatives and liberals, and does not vary by region—except in the southern United States, where people show less agreement with these attitudes than is shown by those in other regions. It should be noted that in some parts of the world improvements are less evident.

Feminism is not exclusive to women, although the media would portray it as such. Men have the same ability as women to recognize the societal disparities between genders, realize that such inequality can be changed, and know that women can survive without men. Studies have shown that women's relationships with feminist men have resulted in healthier romantic relationships for both men and women. Both men and women report greater stability and sexual satisfaction with feminist partners. Thus men can serve as allies and partner with women to work for gender equality.

After the second wave of feminism there was a "postfeminist" movement that rejected some feminist ideas as having no merit. Postfeminism encouraged personal choice, and implied that women could have a career, beauty, motherhood, and a good sex life without any sacrifice. Besides ignoring political issues, it romanticized domestic life while not addressing the issues of women across the nation. However, continuing the work of the women before them, women have been waging small battles to change their corner of the world, and this could be considered the heart of the third wave of feminism. While they may not accept the label "feminist," women around the world are working to better their lives and the lives of others in a way that acknowledges and tries to lessen the disparity

between the positions of men and women in society. This humanistic movement may be the new feminism, bound by the fight against oppression.

## FESTINGER, LEON (1919–1989)

---

Leon Festinger is known for his contributions to the study of group behavior, self-evaluation, and attitude change. Many scholars consider Festinger to be the person most responsible for moving the experimental study of social processes to the center stage of social psychology.

### Background

Festinger graduated as a psychology major from the City College of New York in 1939 with a senior honors thesis on factors affecting how people set goals. Despite a passion for all kinds of games (initially chess, later Go, pinball, and cribbage), he was persuaded to study at the University of Iowa with Kurt Lewin, who was known for his studies of motivation. However, Lewin was increasingly interested in group behavior. Conducting

research on complex social processes in the laboratory to test theories and solve applied problems was Lewin's mission. Festinger remained interested in people's level of aspiration and decision making, but he was drawn to Lewin's striving for conceptual understanding and intellectual enthusiasm. Lewin conducted research meetings very informally so that everyone had a voice, and debate was encouraged. In these meetings, Festinger was known for his aversion to sloppy thinking and a fondness for counterintuitive findings, attitudes he held throughout his career.

Festinger's early research concerned the effects of motivation and group standards on goal setting, decision making, taste preferences in the rat, and statistics. He obtained his PhD from the University of Iowa in 1942, remained at Iowa as a research associate for 2 years, and then moved to the University of Rochester to work for the Committee on the Selection and Training of Aircraft Pilots.

### Social Pressures in Informal Groups

In 1945, Lewin moved to the Massachusetts Institute of Technology to found the Research Center for Group Dynamics, and Festinger joined him as an assistant professor of social psychology (although neither he nor Lewin had ever taken a course in social psychology). The center was committed to the application of psychological concepts and methods to solve social problems, and it attracted many talented students. At the time, Festinger's credentials as a social psychologist might have seemed questionable; he later said that he became a social psychologist by fiat.

His first project was based on attitude surveys of residents in married student housing. This study yielded a textbook phenomenon—friendships were more likely the closer the people were physically in proximity (even by just a few yards). Similarity in attitudes was also critical—attitudes of residents tended to converge, but residents who held deviant attitudes were social isolates.

Festinger thought group members acquired similar beliefs and opinions because of social pressures toward uniformity, but this idea remained to be tested experimentally. In his informal communication theory, he proposed that people are susceptible to social pressure when they are attracted to a group. This attraction occurs because some goals

can be pursued successfully only with the cooperation of others or because groups provide validation about social reality, which is necessary since some opinions and beliefs cannot be tested directly or objectively (e.g., “Should abortion be legal?”; “Who is the greatest baseball player of all time?”).

Assuming people are attracted to a group, they could strive for group uniformity or agreement by trying to change other people’s opinions (communication), modifying their views to match those of the other group members (opinion change), or rejecting divergent others as appropriate references (rejection). Such pressures should increase in attractive groups, or as an issue becomes more relevant to a group’s goals.

To test the theory, Festinger and his students conducted a series of laboratory experiments. Groups (or clubs) were formed of previously unacquainted individuals who were asked to discuss various issues. Factors such as types of goals, need for social reality, attractiveness, issue relevance, and so on were manipulated. In some experiments, accomplices posed as subjects and played scripted roles as group members with deviating or consensual opinions. The precedents for this ambitious research program were Muzafer Sherif’s and Lewin’s earlier work, but Festinger magnified the experimenter’s role as playwright and stage director.

For brevity’s sake, only one study will be described here. For his dissertation, Stanley Schachter, under Festinger’s direction, placed accomplices in groups. One group adopted the majority view (i.e., the “mode”) from the beginning, another initially voiced a deviant view but over the course of the discussion adopted the consensual position (i.e., the “slider”), and a third (the “deviate”) maintained the opposing view. Observers coded group discussion behaviors. The actual subjects tried to persuade the other discussion partners. The mode was readily accepted, as was the slider after adopting the majority view. Initially much communication was directed at the deviate, but when the deviate proved impossible to convince, communication declined, and the deviate was nominated for the most undesirable club assignments. Consistent with the theory, group goals or social reality were achieved by striving for group consensus, the pressures to obtain uniformity were manifest via different behavioral routes, and deviates were rejected.

This experiment reflects several features of the “Festinger research style.” Festinger realized that progress in any science required methods appropriate to that field. Social psychology needed its own experimental approach, following Lewin’s lead—a kind of experimental theater, with covers stories, accomplices, and deception to control for confounding factors and to create a situation that was perceived as psychologically meaningful to the subject.

### Social Comparison

After Lewin’s death in 1947, the Research Center for Group Dynamics, with most of its remaining faculty, moved to the University of Michigan where it remains today. Faculty salaries at the center relied on grant support, however, so in 1951 Festinger moved to a tenure-track position at the University of Minnesota where Schachter was already on the faculty.

At the University of Minnesota, Festinger developed his second major theory, social comparison theory. Informal social communication theory was about the power of the group over the person, but in “A Theory of Social Comparison Processes” Festinger emphasized how individuals use groups to fulfill the informational need to evaluate opinions and abilities. The new theory focused only on the need for social reality, and abilities were considered as well as opinions. As with beliefs and opinions, there often is no objective standard available to assess abilities. People must rely on social consensus.

Social comparison theory posited that people evaluate their abilities and opinions by comparing them with those of others when it is not feasible to test them directly in the environment. Comparison leads to pressures toward uniformity (i.e., similarity), but the tendency to compare will cease if others are too different in dimensions that are related to the ability or opinion at issue. For opinions, agreement with others who presumably also are motivated to hold correct views should make us feel more confident. For abilities, observing those with similar abilities should allow us to learn our possibilities for action in the environment, which should be identical or very similar to theirs.

Social comparison theory also recognizes a distinctive feature of abilities. People want to be slightly

better than everyone else because the desire to be better or to improve is emphasized in Western cultures. This means that complete opinion agreement may be satisfactory to everyone, but completely equal abilities will not—implying that “a state of social quiescence is never reached,” as Festinger put it.

### Cognitive Dissonance

While at the University of Minnesota, Festinger read about a UFO cult that believed the end of the world was at hand. A housewife, “Mrs. Keech,” reported receiving messages from extraterrestrial aliens that the world would end in a great flood on a specific date. She attracted a group of followers who left jobs, college, and spouses, and gave away money and possessions to prepare to depart on a flying saucer that, according to Mrs. Keech, would rescue the true believers. Given the believers’ serious commitment, Festinger wondered how they would react when the prophecy failed. He and his colleagues, posing as believers, infiltrated Mrs. Keech’s group and kept notes on the proceedings surreptitiously.

The believers shunned publicity while they awaited the flying saucer and the flood. But when the prophecy was disconfirmed, almost immediately the previously most-committed group members made calls to newspapers, sought out interviews, and started actively proselytizing.

Festinger was unsurprised by the sudden proselytizing after the prophecy’s disconfirmation; he saw the cult members as enlisting social support for their belief to lessen the pain of disconfirmation. Their behavior confirmed predictions from a theory of his whose premise was that people need to maintain consistency between thoughts, feelings, and behaviors.

The theory proposed that inconsistency among beliefs or behaviors causes an uncomfortable psychological tension (i.e., cognitive dissonance), leading people to change one of the inconsistent elements to reduce the dissonance, or to add consonant elements to restore consonance. Mrs. Keech’s followers actively enlisted new believers to obtain social support (and thereby add consonant elements) to reduce the dissonance created by the disconfirmation.

In 1955, Festinger left the University of Minnesota for Stanford, where he and his students launched a series of laboratory experiments testing

cognitive dissonance theory and extending it to a wide range of phenomena. Like the experiments in group dynamics, the studies were carefully crafted and involved cover stories, complex manipulations, and deception. One of the best known was the forced compliance paradigm, in which the subject performed a series of repetitive and boring menial tasks and then was asked to lie to the “next subject” (actually an experimental accomplice) and say that the tasks were interesting and enjoyable. Some subjects were paid \$1 for lying, while others were paid \$20. Based on dissonance theory, Festinger predicted and found that the subjects who were paid \$1 for lying later evaluated the tasks as more enjoyable than those who were paid \$20. The subjects that paid a large amount should not have experienced dissonance because, after all, they were well rewarded and had ample justification. The subjects that paid \$1 had little justification for lying to a stranger and should have experienced cognitive dissonance. To reduce the dissonance, they reevaluated the boring task as interesting and enjoyable. The forced compliance paradigm generated much interest because more attitude change was associated with a small rather than a large incentive—contrary to reinforcement theory. This experiment also illustrates the appeal of cognitive dissonance theory—it combined cognition and motivation and showed how that combination led to nonobvious predictions.

Festinger conducted much research on cognitive dissonance processes and even extended the theory to animal learning, showing that a limited version of dissonance could explain why a rat who worked harder during acquisition resisted extinction longer than a consistently rewarded rat. The former animal reduced its dissonance by finding extra attractions in the situation. Festinger is best known in psychology for his research in cognitive dissonance, and the term *cognitive dissonance* has become a part of popular speech.

He received the Distinguished Scientific Award of the American Psychological Association in 1959 and the Distinguished Senior Scientist Award of the Society of Experimental Social Psychology in 1980. He was inducted into the National Academy of Sciences in 1972 and the Society of Experimental Psychology in 1973.

In 1964, Festinger moved from social psychology to research on visual perception. Although

this seemed like a radical departure, it was a continuation of a theme. Festinger's work on visual perception concerned how people reconcile inconsistencies between visual perception and eye movements to see coherent images. His social psychological research concerned how people resolve conflict (group dynamics), ambiguity (social comparison), and inconsistency (cognitive dissonance) all manifestations of pressures for uniformity.

### Psycho-Social-Archeology

In the late 1970s, Festinger turned to questions about human nature based on archeological data. He read the relevant literature, talked to specialists, and visited archeological digs, work that resulted in a monograph, *The Human Legacy*. His ex-student Schachter referred to it as "psycho-social-archeology."

A general theme of this work was that humans often bring about problems unwittingly as a function of their intellectual and creative talents to create new technologies without being fully able to foresee their long-term consequences. Initially, Festinger's "archeology" was perceived to be at the margins of social psychology, but now it can be seen as prescient of current developments in evolutionary and cultural psychology.

### Mentoring

Festinger was described by an ex-student as "a tough character who did not suffer fools gladly." Others testified to his voracious curiosity, extraordinary memory, incisive intellect, and powers of concentration—more than a little intimidating. However, he mentored dozens of students, his office door was always open, and he was on a first-name basis with his students, something quite rare in the 1950s. Meetings at his home where ideas were discussed over beer and pretzels and dinners with students and other faculty members were common, and everyone played games in his lab. Something of Kurt Lewin's benign nature and charisma rubbed off on Festinger. Both charisma and intellect contributed to the "Festinger legacy" in experimental social psychology.

## FREE RIDING

---

*Free riding* refers to enjoying the benefits and rewards associated with membership in a group without making full contributions to that group. Free riding can occur in a range of group and team contexts varying in size, membership type, and purpose. For example, individuals can free ride in a larger group or societal context by failing to make contributions to shared resources and public goods, such as libraries, blood donation centers, recycling units, and public broadcasting networks. However, they can also free ride by withholding their efforts from a small project team and relying on the work of others. Free riding (also sometimes referred to as the *free-rider effect* or the *free-rider problem*) may undercut a range of group, collective, and societal initiatives intended to benefit multiple parties. This entry describes the background of thinking in this area, looks at a sampling of research, and briefly discusses related social concepts.

### Historical Background

Although analysis of the relationship between individual action and societal outcomes has a long

philosophical tradition, economists and sociologists such as Vilfredo Pareto, Paul Samuelson, and Max Weber were among the first modern scholars to formally articulate the potential for free riding, as well as other similar forms of social inaction, to undercut various societal and market processes. In an influential 1965 book, Mancur Olson provided an economic analysis of how large collectives can lead individuals to view their contributions to the collective as mostly or entirely unnecessary, leading to disinterest and apathy.

Specifically, individuals are likely to view their own contributions to an outcome or public good that is provided by many such individuals as at best minuscule, and perhaps as entirely unnecessary. Stated differently, individuals may reason that if they do not provide the requisite effort or resources, others are likely to sustain the resource anyhow; thus, they may therefore simply choose to “let George do it.” The likelihood of being able to continue to benefit from a pooled resource with many contributors may be nearly as high when one makes little or no contribution as when one makes a full or even exceptional contribution.

Olson noted that such free riding becomes increasingly likely as the size of the group increases, both because individual actions are less immediately noticeable in larger groups and because individuals are likely to view their collective actions as being efficacious in larger groups. As group size increases, the costs of organizing individual contributions or efforts are also likely to increase, providing another possible mechanism for individual inaction. Other factors influencing individual action include the level of public interest about specific causes, the presence of coercion or special incentives to participate, the nature of the task, and individual differences in factors such as value orientation (a habitual tendency to value the self or others) and fairness perceptions.

Consider a political election as an example. As the potential voting base increases in size, it becomes increasingly likely that each individual voter will have less impact on the outcome, that each individual will see less efficacy to his or her vote, and that it will be increasingly difficult logistically to organize voter participation in an effective manner. Yet, if public interest in the election and in issues central to the election is high, if the anticipated outcome is expected to be very close (thereby increasing the

potential value of each vote), or if voters are influenced by potential rewards from friends, political organizations, or community groups (or otherwise fearful of negative reactions from these sources that could result from not voting), individual inaction will be less likely. Similarly, individuals with a vested interest in specific election-related issues or who view themselves as socially responsible might also be more likely to participate.

Free riding is not restricted solely to very large groups or societal collectives, but can also occur among smaller units, including organizations, small groups, and project teams. Indeed, recent research by economists, political scientists, sociologists, social psychologists, organizational psychologists, and industrial relations scholars has implicated free riding as an important phenomenon in a wide range of behaviors and contexts, including cooperative learning in the classroom, the provision of public resources, voting behavior, restaurant tipping, community vaccination, charitable and blood donation, energy conservation, and raw material preservation.

### Research Findings

Robert Albanese and David Van Fleet did an analysis in 1985 of the implications of free-riding theory for business organizations and teams within such organizations. They concluded that the most effective means for countering free riding in organizations is to create organizational task and team structures conducive to individual accountability and responsibility. They highlighted several strategies, include building communication systems and cultures that broaden individuals' views of self-interest to also incorporate organizational goals, more closely monitoring individual contributions, making individuals more accountable, allowing individuals to make more unique contributions, and building organizational commitment.

At the small group level, Norbert Kerr and his colleagues have conducted a programmatic series of studies on free-riding effects and related phenomena. In these studies, participants were asked to pump as much air as possible through a hand-controlled device both individually and with others, and the task type and ability level of participants relative to their partners or teammates were manipulated. Several of these studies showed that

when working with a highly capable teammate on a disjunctive task (in which the group performance is determined by the strongest performer within the group), individuals reduced their efforts, free riding on the work of their teammates. Kerr and his colleagues noted that in these conditions, participants' efforts are more dispensable, or unnecessary for satisfactory group performance. Thus, free riding doesn't just occur in large groups or societal collectives, it also occurs in small work groups when individuals believe their efforts are not obviously needed.

Some of these studies also documented that when working with a highly capable member who consistently performed poorly, individuals often choose to also withhold their own effort from the task to avoid being played for a fool, a phenomenon that was called the *sucker effect*. However, the news was not all negative with regard to individual effort. Some studies also documented conditions under which team members with little ability showed very high motivation levels when working on conjunctive tasks (in which the group performance is determined by the weakest performer within the group). In this latter case, called the *Köhler effect*, participants' efforts were highly indispensable and crucial to team performance, creating the potential for enhanced motivation.

### Related Processes

Free riding has a close relationship with some other social processes. Specifically, in the case of withholding effort from a group, free riding constitutes a form of social loafing. *Social loafing* is the tendency for people to reduce their efforts when working in groups. Thus, free riding represents a type of social loafing in which people take advantage of the efforts of teammates in order to minimize their own efforts—when they perceive that their own efforts are likely to have little or no impact on the group outcome. Because free riding in small groups often emerges in situations where the nature of the task or of the expected contributions of teammates makes a person's own efforts seem dispensable, it may represent a more consciously aware or strategic type of social loafing.

Free riding is also an inherent problem in all types of social dilemmas. *Social dilemmas* are situations in which actions that are beneficial to an

individual, if taken by most or all such individuals, would be detrimental to the group as a whole. In the case of free riding, it may benefit individuals to refrain from contributing their time or money to a public resource (such as a community service organization, symphony orchestra, library, or public television station), but if most or all such individuals were to similarly free ride, the public good in question would be seriously diminished in quality and might even become unable to sustain its existence. Hence, as many scholars have acknowledged, the literatures on free riding and on social dilemmas are largely compatible with one another, especially with regard to the subclass of social dilemmas known as public-good dilemmas, in which individuals are likely to make less than their fair share of contributions to collective resources that are reliant on many individuals.

## FRUSTRATION-AGGRESSION HYPOTHESIS

---

The frustration-aggression hypothesis is an attempt to explain aggressive behavior by linking

it to frustration, in particular frustration of goals. One important application involves scapegoating, where it is suggested that as sources of frustration accumulate—during an economic crisis, for example—the frustrated groups might unleash their aggression against a convenient social target, often a minority group. This entry discusses development of the theory and its major assumptions, applications to intergroup relations, and critiques.

### Background and Assumptions

The frustration-aggression hypothesis was introduced by a group of Yale University psychologists, John Dollard, Leonard Doob, Neal Miller, O. H. Mowrer, and Robert Sears. These authors published an important monograph in 1939 entitled *Frustration and Aggression*, in which they sought to integrate ideas and findings from several disciplines, especially sociology, anthropology, and psychology. In terms of intellectual history, the work is notable for its eclectic use of psychoanalysis, behaviorism, and Marxism. It became one of the most influential explanations in the history of social science for the origins and expressions of aggressive behaviors.

The point of the frustration-aggression hypothesis was to identify a universal, parsimonious set of testable assumptions that would apply to virtually all situations of violence in humans and other animals. According to the original, strong version of the hypothesis that appeared in *Frustration and Aggression*, “the occurrence of aggression always presupposes the existence of frustration, and, contrariwise, frustration always leads to some form of aggression.” Thus, frustration, which was conceptually and operationally defined in terms of goal interference, was seen as both a necessary and sufficient condition for aggressive behavior.

The hypothesis was soon modified by the Yale group, however, and in 1941 it was proposed that frustration might lead to many different responses, one of which is aggression. Whereas the original formulation explained the lack of overt aggressive behavior in certain situations in terms of inhibition due to the fear of punishment (which would not diminish the aggressive drive), the subsequent version made clear that some responses to frustration could reduce the instigation response to such an extent that the aggressive response did not occur.

It is important to point out that Dollard and his colleagues believed that their account of frustration and aggression was valid for human as well as nonhuman (i.e., animal) actors, and for groups as well as individuals. That is, we should expect aggressive inclinations to result whenever a person or animal experiences frustration. The logic of the frustration-aggression hypothesis was applied to the context of intergroup as well as interpersonal relations.

### Applications to Intergroup Relations

In the realm of intergroup relations, the frustration-aggression hypothesis was used to shed light on the dynamics of stereotyping, prejudice, and outgroup hostility. The theory of scapegoating is probably the most well-known application of the frustration-aggression hypothesis to the study of prejudice. The general idea is that as economic or other sources of frustration accumulate, people tend to seek out convenient social targets, or scapegoats, on whom to unleash their aggression.

Drawing in part on Freudian concepts of displacement, projection, and catharsis, the theory held that once frustration and the impetus for aggressive behavior have occurred, it makes relatively little difference who receives the brunt of the violence. In some cases, aggression naturally takes the form of retaliation against the initial source of frustration. In other cases, situational constraints can prevent a person from being able to react against the actual source of frustration (such as when the frustration was caused by a very powerful person or group). In still other cases, such as natural disasters, there may be no one to blame, but the frustration can still produce aggressive inclinations.

Under these latter two sets of circumstances, it was predicted that people will engage in scapegoating, that is, selecting relatively weak, vulnerable targets for aggression (such as members of low-status minority groups, who cannot fight back effectively). For example, it was suggested that during the Great Depression, many Germans blamed Jews and many Southerners in the United States blamed Blacks for their economic frustrations. However, recent research suggests that the connection between economic conditions and hate

crimes is more elusive than frustration-aggression researchers once assumed.

According to the theory, the displacement of aggression onto a socially sanctioned (i.e., convenient) victim group serves several purposes. First, and most important, it channels the expression of aggressive impulses and creates cathartic relief once the aggression has been released. Second, it is socially undesirable to behave violently toward others in the absence of justification, but prejudicial attitudes can be used to justify (or rationalize) the expression of hostility. In this way, members of disadvantaged groups can be blamed for their own plight as targets of hostility and prejudice. Finally, in accordance with psychoanalytic thought, the theory of scapegoating suggests that victim blaming is exacerbated by the projection of (typically unconscious) guilt that frustrated parties feel as a result of their own prejudice and violent activity.

The occurrence of stereotyping, as discussed by Gordon Allport and Bernard Kramer, is explained by the theory of scapegoating as another manifestation of rationalization tendencies. Rather than simply rationalizing an aggressive posture directed against one person, stereotypes are effective rationalization devices that would seem to legitimize hostility against a social group in its entirety. Consequences of the scapegoating dynamic include overgeneralization of stereotypical traits to an entire social group and the exaggeration of similarities among group members, especially with respect to stereotypical qualities. Finally, because stereotypes are ingrained in the culture, they tend to signal which social groups are appropriate targets for relieving one's frustration.

### Criticism and Modifications

The frustration-aggression hypothesis was extremely influential with respect to subsequent decades of empirical research on aggression and violence. Nevertheless, the hypothesis was severely criticized on the grounds of theoretical rigidity and overgeneralization; clearly, it was necessary to limit the scope of the hypothesis to establish its validity. For instance, the initial hypothesis failed to differentiate between hostile forms of aggression, in which the actor's goal is to inflict harm, and instrumental forms of aggression, in which aggression is simply a means to attain other goals

(such as control or domination). This criticism can be dealt with rather easily by confining the frustration-aggression hypothesis to cases of hostile aggression alone.

Critics also challenged the premise that any interference with ongoing goal-directed behavior would evoke frustration. According to Abraham Maslow and others, legitimate (or justified) interferences do not necessarily produce frustration. Only forms of interference that seem illegitimate (or arbitrary or otherwise unjustified), they argued, should lead to frustration. Research on attribution processes indicated that aggressive behavior is indeed a prevalent response to deliberate and unfair efforts to interfere with an individual's goal-attainment opportunities.

Finally, the nature of the connection between perceived frustration and the display of violence also turned out to be more complicated than Dollard and his collaborators realized. In the most empirically successful modification of the original frustration-aggression hypothesis, Leonard Berkowitz suggested that frustration is a psychologically aversive state that can create a predisposition to behave aggressively. His model was a reformulation of the frustration-aggression hypothesis that integrated subsequent theorizing on the antecedents of aggression and addressed many of the criticisms directed at earlier versions of the hypothesis. According to Berkowitz, frustration will lead to aggression to the extent that it elicits negative emotions. Moreover, frustration is only one form of unpleasant negative affect that can provoke violent responses.

The general idea was that aversive experiences produce negative emotions and feelings, as well as related thoughts and memories of past reactions to negative events. Berkowitz noted that these negative emotions and thoughts lead automatically to the fight-or-flight response. The choice between "fight" and "flight" responses was theorized to depend on the intensity of the negative emotion as well as the subjective appraisal and interpretation of the situation. A key factor was whether or not goal interference was expected, and Berkowitz regarded this as a more important factor than its legitimacy (although illegitimate interferences are also frequently unexpected). To the extent that unexpected interferences are more psychologically aversive than expected interferences, they were theorized to lead more

easily to aggressive behavior. Although Berkowitz's model has also been criticized for being overly simplistic, it has received substantial empirical support and is generally considered to be the most useful and valid reformulation of the classic frustration-aggression hypothesis.

Other researchers have focused more on the concept of frustration, asking questions about the nature and causes of frustration and whether different forms of frustration can produce different behavioral outcomes. Their focus has been on feelings of relative deprivation, especially the notion that these feelings are experienced very acutely when expectations are suddenly thwarted, particularly when expectations have been rising. It has been suggested that feelings of deprivation under these circumstances can often lead to violence, as in "revolutions of rising expectations."

Still other researchers have distinguished between interpersonal (or fraternal) deprivation and intergroup deprivation. Such research suggests that interpersonal deprivation (i.e., an individual feeling that he or she is deprived relative to another individual) can lead to low self-esteem, a lack of motivation, and even depression, whereas intergroup deprivation (i.e., members of a group feeling that they are deprived relative to the members of another group) can lead to social protest and collective mobilization. However, it has often been pointed out that such acts of shared rebellion are

far less common than a straightforward application of the theories of frustration aggression and relative deprivation would suggest.

## GANGS

---

Used originally to refer to a group of workmen, the term *gang* is now most often applied to groups distinguished by their involvement in criminal activities. This entry provides a brief history of research on gangs, describes methods of inquiry in this field, and outlines types of gangs and their forms of organization. It then examines the relationship between gangs, crime, and victimization.

### History

Scholarly interest in gangs can be traced at least as far back as 19th-century journalistic accounts of adolescent males growing up in areas of high population density and economic disadvantage. Charles Dickens's fictionalized gang in *Oliver Twist*, for example, was based on accounts of London street urchins.

More systematic and scientific study of gangs began in the 1920s in the United States with Frederic Thrasher's massive investigation of more than 1,300 gangs in Chicago. He concluded that young people seek out gang membership from a desire for excitement, and he painted a picture of gangs as stable, coherent, and highly structured, with well-defined roles such as war counselor, armorer, and treasurer.

Thrasher's account of gangs did much to define the questions dominating subsequent research: How stable are gangs, and how large are they? How coherently are gangs structured? What are their core or defining activities? In answer to each

of these questions, research in the following decades, mostly in the United States, provided a mixed picture. Regarding stability, an early study in Los Angeles suggested that many of the city's gangs had histories extending back as much as 50 years. This and other work noted that enduring gang identities are often based on locality, underlining another recurring theme in gang research—the significance of territoriality. Many other studies, however, failed to find such long-term stability or even to find gangs at all.

The issue of stability is difficult to separate from that of size. Gang members often provide unreliable, uncertain, and highly inflated estimates. Sometimes, as Yablonsky found in a study of New York gangs, they estimate membership in their gangs in the several hundreds. More systematic observation points to much lower numbers, though this work has also revealed the importance of distinguishing core from peripheral members. In the 1960s, studies of patterns of association in gangs over spans of 6 months to a year pointed to core memberships of less than 10 as typical, but there were exceptions.

### Methods of Studying Gangs

What are the consequences of being a group in which criminal behavior is normative, perhaps even its “core business”? A challenge to answering any questions about gangs is posed by the difficulty of collecting valid evidence.

Research on gangs involves the study of naturally occurring rather than ad hoc groups. There

are significant challenges in securing information from and about gangs, because they are involved in illegal activities. Questionnaire methods are attractive, given the low cost of collecting data from large samples. The particular difficulty in using questionnaires with gang members relates to credible guarantees of confidentiality, which limit the researcher's options for checking the validity of responses. Interviews potentially generate richer data but at much higher cost. Many interview studies in this field have relied on sampling young offenders while they are detained or incarcerated. Participant observation would appear to offer the most accurate picture of gang life but contains its own challenges, the most obvious but not necessarily the most serious of which is the ethical position of the observer. One notable example of such an approach, described by James Patrick in his 1973 book *A Glasgow Gang Observed*, was achieved through the researcher's temporary membership in the gang. A more recent example is the 10-year relationship between sociologist Sudhir Venkatesh and a Chicago gang trading in illegal drugs. The rich detail and high ecological validity of such research is offset by the problem of generalization, in that each study is effectively a single case study. Researchers have also drawn on out-group perspectives—those of community workers or criminal justice agencies, for example—to develop a picture of gang characteristics. But the goals and perspectives of the various outgroups inevitably color their accounts and perceptions.

For these various reasons, solid evidence on gangs—their prevalence, formation, size, composition, organization, activities, and consequences for members—remains limited.

### Gang Composition: Organization and Types

While Thrasher's work described what appeared to be highly organized and stable gangs with clearly defined roles and positions, more recent work has portrayed gangs as loosely organized, flexible, and short-lived. It is now generally accepted that the organization of gangs falls along a continuum defined by the respective extremes of organized–stable and flexible–transient, and though the continuum has also been partitioned into types of gangs—such as the typology distinguishing organized, street, and wanna-be gangs

described below—in reality there are no sharp discontinuities between types. However, it is convenient for researchers to focus on the extremes and the middle of the continuum as “ideal types.”

*Organized gangs* are criminal business organizations, primarily composed of adults engaged in criminal activity for economic reasons. The members of such gangs are commonly from the same ethnic background, have poor job skills and opportunities, and group together for social support and financial survival. They are secretive in their membership and engage in profitable forms of organized crime (e.g., selling drugs, prostitution, human trafficking, protection rackets). They are also highly organized and hierarchical, with a quasi-formal career structure. Such gangs tend to be very stable, and their memberships tend to be long-lasting, often spanning generations.

*Street gangs* are primarily composed of youth and young adults who see the gang as a surrogate family and a source or support, friendship, and protection. The members of such gangs proudly advertise their gang affiliation and may engage in crime for economic reasons as well as in organized violence against similar gangs seen as rivals. Street gangs are semistructured, and individual roles in these gangs are loosely defined. The groups are somewhat stable but exhibit a pattern in which they appear and disappear in waves, over time.

*Wanna-be groups* are formed by adolescents who band together from time to time to engage in social activity as well as criminal and antisocial activities in order to find excitement and diversion rather than obtain economic gain. The small number of female gangs that have been reported fit into this category. Organization is minimal, and the groupings involved are quite transitory, based more on convenience and availability than effort or commitment. It is not clear that such groups invariably aspire to be gangs in a more identifiable sense. At least some research suggests members of such gangs are adolescents hanging around with their friends. By virtue of their visibility in public places, however, they are at risk of being perceived, identified, and labeled as gang members by others.

### The Relationship Between Gangs and Crime

Gang membership is associated with criminal activity, but an important question concerns the

source of this association. This question is frequently answered in one of two ways: (1) joining a gang can turn a young person into a criminal or (2) gangs are groups of young people who individually are criminally active. Neither of these answers captures the whole truth.

Consider the potential routes into gang membership. At least three have been distinguished, though in practice it is likely they overlap and combine in varying degrees of relative importance. First, joining a criminal gang may be a pragmatic career decision. In some localities and for some social groups, criminal gangs are the primary and perhaps the only providers of employment. Second, young people who become homeless often band together to form surrogate families and provide solutions to shared problems. At least one authority on homeless youth, John Hagan, has argued, however, that there are important differences between these groupings of street youth and delinquent gangs, differences the group members emphasize.

The third route begins with individual inclination and the common tendency for young people to join groups in pursuit of companionship and fun. Such groupings reflect already established inclinations. This is important, as inclinations toward antisocial behavior and crime predate group membership. Young people are more likely to form or join delinquent gangs, and not other groups, to the extent that they are already disposed to such activity. There is little evidence that young people not so disposed succumb to pressure to join gangs. However, gang formation is also favored by certain social and environmental conditions, including economic deprivation and residential instability. This route into gang membership, in other words, is a combination of inclination and opportunity.

Associating with like-minded peers increases the likelihood that individuals' shared inclinations will translate into more consistent habits of behavior. The group nature of juvenile offending is well established. For routine involvement in more serious crime during adolescence, the group context seems almost to be a necessary condition. Thus opportunities to affiliate with other youth inclined to be delinquent increase the likelihood of a young person's committing crimes.

The more organized the gang, the greater the likelihood of its members committing more serious

and more violent crime. More organized gangs are also more likely to deal in drugs. Supplying and selling illegal drugs requires coordinated activity, and if a group moves into drug trafficking this may set up a feedback loop—a higher degree of organization will support more extensive and profitable drug-based trafficking.

The more organized the gang, the more visible it will be, and the more likely it will be defined and treated by those outside it as a group. In addition, more visible gangs attract more police attention, increasing the possibility of arrest and conviction. Labeling, whether as gang member or through more formal criminal proceedings, in turn increases the likelihood of further and more serious offending.

Basic group dynamics reinforce these feedback loops. Gangs that are more organized are more likely to form and adhere to shared norms and shared views. And their decisions about which actions to take are more likely to polarize in the direction of already shared inclinations. Intergroup dynamics further reinforce the distinctive identity of the group, the deference of its members to ingroup norms, and the emergence of leadership.

### **The Relationship Between Gang Membership and Victimization**

Research on delinquency shows a clear link between victimization and offending, but there is uncertainty surrounding the causality underlying the relationship. Some recent work supports the view that victimization comes first, often in the family or in an institution that has substituted for an absent or nonexistent family.

Insofar as victimization disposes individuals to offending, it may increase the possibility that they will become gang members. One plausible line of argument is that those who suffer victimization, and so lose confidence in conventional forms of protection, join gangs as alternative means to secure protection and redress for grievances. Ironically, however, gang membership increases the likelihood of further victimization. And the more organized the gang, the higher the risk of violent victimization of its members. Much of this victimization is a product of the intergroup conflict characteristic of relations between gangs, but some reflects social control within gangs.

### Institutionalization of Gangs

The link between gang membership and violence relates to what is perhaps most distinctive about gangs as social groups. Almost all other social groups, whatever the strength of the group dynamics that sustain their particular norms, operate within a more general normative framework enforced by the state. Gangs, to varying degrees, operate outside this framework—and violence, whether potential or actual, becomes a substitute instrument of social control.

If a sense of exclusion from the protection of the state system is a feature of involvement in delinquency, and thus in delinquent gangs, under certain circumstances this sense of exclusion is shared by entire subpopulations. Defining features of these populations are urbanization, poverty, and some combination of minority ethnic, religious, and racial status. As John Hagedorn has observed, these circumstances favor the institutionalization of gangs—a process in which their gang identity survives leadership changes and membership turnover, they become larger and develop more complex role structures, they have the capacity to adapt to changing conditions, and they become more embedded in a host community. This last circumstance reflects gangs' involvement in provision of economic, security, and other needs not met by the mainstream. They may also be the focus for identities in opposition and resistance to the dominant culture. But violence, or the capacity for it, is integral to their functioning, and such gangs are characteristically male dominated and armed.

## GENDER AND BEHAVIOR

---

Gender is a subject of much interest to social scientists who study groups, and there are a number of reasons for this. First, much of our daily life is spent in mixed-gender groups. For example, a family—a group in which much of our social behavior occurs—usually contains members of both genders. Thus, most of us are required to interact with members of the other sex on a regular basis. Second, gender seems to hold an important place in our conception of ourselves and other people. One of the first questions we ask about a new baby is, “Is it a boy or a girl?” We are uncomfortable when someone’s gender is ambiguous. And third, gender affects behavior both within and between groups in a variety of social locations.

A number of social scientific perspectives exist on the mechanism by which gender affects social behavior. This entry reviews a few of the primary perspectives and discusses some of the social locations in which gender most affects behavior.

### Perspectives on Gender and Behavior

Gender scholars have espoused a variety of conceptualizations of gender and gender differences in behavior. These vary from very individual and person-oriented (gender is an integral part of an individual’s self-concept) to interactional (gender is a learned behavior) to structural (gender is a system of social practices and cultural beliefs) conceptualizations. Gender as identity, gender as role, and gender as a structural system of practices are discussed in this entry.

#### *Gender as Identity*

Gender holds an important place in how we categorize individuals. In fact, cognitive psychologists have shown that gender is the usually first

category by which we classify others upon meeting them. Further, this process is automatic and unconscious.

At least as important for the study of behavior, gender is a large component of our definitions of our own identities. Most children define themselves in terms of their gender—"I'm a boy" or "I'm a girl"—during their preschool years. When researchers think of gender as an identity, they can examine how this sense of meaning plays out in social behavior and what it means to an individual to be male or female.

When people interact, they bring these identities to the group. An identity is a component of the self and, as such, is a standard to which individuals hold themselves. With regard to gender, this means that people bring with them an idea about their own gender identity, or how masculine or feminine they believe themselves to be. Researchers who examine the effect of gender identity on behavior thus see interaction as the place in which these meanings are made and maintained for individuals. Generally, they see interaction as reproducing general patterns of social meaning regarding gender, femininity, and masculinity. However, viewing gender strictly as an identity makes gender an individual trait rather than a part of the larger social structure. To fully understand the place of gender in group processes and group relations, an understanding of the broader processes that differentiate men and women is required.

### *Gender as Role*

Another important way in which gender is conceptualized by scholars is as a social role. A gender role is a set of structured social expectations attached to the position of "male" or "female." People's gender role represents both the sum of the ways in which they express their gender identity and also the kinds of activities that are seen as appropriate for their gender. Through socialization, children are taught—by their elders and by each other—what kinds of behavior are appropriate for a person of their gender.

Alice Eagly has proposed a social role theory which suggests that social roles develop from the sexual division of labor. The theory distinguishes between communal and agentic types of behaviors, defining *communal behaviors* as those that require

nurturance and emotional expressiveness and *agentic behaviors* as those that require assertiveness and independence. In our culture, communal behaviors are associated with women, and agentic behaviors with men.

At the elementary school level, gender socialization usually takes the form of what Barrie Thorne calls *borderwork*, which is interaction that serves to heighten the differences between the genders. This interaction separates the genders and perpetuates gender stratification (e.g., as expressed in "boys have cooties" and "no girls allowed"). For older children, the socialization process centers on learning (primarily from peers) about how to conduct romantic relationships with members of the other gender. This socialization also serves to reinforce stereotypes about appropriate masculine and feminine behavior. In adulthood, this socialization often continues. However, at times interaction is created to teach less stereotypical gender behavior, such as in women's consciousness-raising groups.

Once socialized, people take the received ideas of what constitutes "right" or "proper" behavior for each gender into their social interactions, and these ideas guide their behavior. Thus, in groups, people tend to enact their gender, no matter what else they are doing. Candace West and her colleagues have labeled this interactional process "doing gender." Gender is thus a set of behaviors people perform, rather than just a way that people think about themselves.

### *Gender as a System of Practices*

Recently within the social sciences, there has been more thinking about gender as a set of social practices rather than as an individual trait or a socialized role. These practices exist at the level of the social institution. They serve to organize social behavior on the basis of gender and bring with them a set of social relations of inequality that distinguish men (as privileged) from women (as not privileged). There are two mechanisms by which this occurs: (1) through the exaltation of things generally associated with men, to which women are denied access and (2) through the deprecation of things associated with women. The system of practices affects the patterns of behavior of men and women, and the system of inequality influences cultural beliefs and status effects.

### Cultural Beliefs

Numerous survey and experimental studies show that cultural beliefs about gender, also called gender beliefs or gender status beliefs, exist everywhere. Despite changes in discrimination laws, women's workforce participation, and notions of political correctness, these gender beliefs persist. The content of these gender beliefs can be described using stereotypes: Women are more nurturing and communal while men are more self-interested and instrumental. In addition, men are seen as more competent, worthy, intelligent, and capable than are women. Women are seen as nicer.

These abstracted meanings are held broadly and are roughly consensual. Most people in the culture can articulate them and believe that most other people hold them. The expectation is that most people will behave in a manner consistent with these beliefs and expect others to behave that way as well. Given the distinction that privileges men, people generally enter social interaction believing that men will act in more competent ways than will women and that men are more deserving of opportunities to exert influence in the group.

These cultural beliefs affect social interaction markedly. They provide the underlying structure and set of practices that shape group and intergroup interactions. One way in which this happens is through the activation of status effects.

### Status Effects

Status effects occur when a characteristic, such as gender, carries differential levels of privilege and this difference affects social interaction. Status effects result in things like estimations of competence, opportunities to contribute to a group task, influence, and leadership.

Many (but not all) cases of gender inequality are better understood as status effects than, for instance, effects of gender socialization patterns. This interpretation has been confirmed and elaborated in theoretical and empirical studies in varied settings. For example, men control about twice as much of a group's participation time as women, men counterargue more and women agree more than vice versa, and men are five times more likely than women to assume leadership roles in initially leaderless groups. Research also shows that nonverbal

power cues are displayed in accordance with a gender status conception.

These studies, while demonstrating the privileged position of men, also attribute that position to status effects rather than to socialization or identity. When women are put in high status positions through experimenter manipulation, they display the same types of high status behavior as do men. In other words, it is the status position that produces the behavior, not a person's gender per se. Given our culture's gender beliefs, however, it is men who receive the benefits of status effects in the current system of practices.

### Locations of Gender Differences in Behavior

Gender differences in behavior exist, regardless of the perspective taken on them. Examples can be found across many arenas of social life. This entry focuses on intimate relationships, household labor, work, and other organizations.

#### *Intimate Relationships*

A number of scholars have studied differences in how men and women approach intimate or romantic relationships. Differences have been identified in the ways men and women talk to each other, the ways they interpret what others say, and the amount of talking they do. One oft-cited notion is that women talk at home, whereas men talk in public. While the veracity of that notion can be questioned, there certainly is evidence that men and women have somewhat different experiences in intimate relationships.

The popular notion is that women want intimacy, while men try to avoid it—at least as long as it is socially acceptable to do so. However, as the work of Lillian Rubin shows, the case may be that men simply do not need to express the desire for intimacy, which may be due to socialization (i.e., males learn it is not manly to express a need for a partner) and/or social position (i.e., men's authority does not require them to express their feelings of intimacy verbally). In addition, women often create barriers to intimacy through their behavior, even as they claim to want more intimacy. The ways men and women behave in intimate relationships is not as black and white as the stereotypes portray.

### *Household Labor*

One issue that can impinge on intimate male–female relationships is housework. With women’s increased participation in the paid workforce, it is often argued that unpaid work at home in the form of cleaning, shopping, cooking, caring for children and the elderly, and outdoor chores should be distributed equally between men and women. Nevertheless, the results of studies on the time men and women spend on housework are mixed. Some studies show that women still do more of this kind of work than do their male counterparts, even when other variables like time availability and resources (i.e., who works more/less and who makes more/less) are statistically eliminated. However, other studies indicate that as women have increased their paid work hours, they have decreased the time spent on housework, such that men’s and women’s total work hours (combining paid and unpaid work) are about equal.

Arlie Hochschild was the first researcher to study dual-career families in depth to see what really happens to the housework when both partners work outside the home. He used the term “the second shift” to refer to the burden of household work carried by women, who put in a full day at work and then many more hours of unrewarded, often unfulfilling work at home. This is also sometimes called women’s double burden.

### *Workplace*

As noted above, one way in which the system of practices privileges men is by exalting things they do while denigrating activities associated with women. Nowhere is this more clear than in the workplace. On the whole, men’s jobs involve higher prestige, better pay, and more autonomy than women’s jobs.

Studies of comparable worth, the idea that work of equal value and difficulty should be rewarded with equal pay, indicate that the pay difference is due, at least in part, to discrimination. Even when studies statistically control for issues such as job interruption, education, time on the job, and job performance, they still find that men are paid more than women in similar jobs. The system of practices is influenced by status processes as well, as illustrated by the following examples.

Cecilia Ridgeway showed how status differences often perpetuate gender inequality in business organizations through gender labeling of jobs, misattribution of results, constructing people as gender-interested actors, and other processes. Those status effects usually carry across interactants and situations, so they diffuse and perpetuate gender stereotyping and gender-based hierarchies in organizations.

Rosabeth Moss Kanter conducted an analysis of the social organization of corporations. She examined how particular social structures constrain or create opportunities for people, particularly minorities, who are in a similar situation to women when they first entered the workforce in large numbers during the 1970s. Kanter focused on social structural characteristics of businesses, such as hierarchy, distribution of power across positions, and social networks. Then she examined how an individual’s position within the social structure in combination with his or her role and its power constrains that individual’s choices. Women in particular were found to be isolated in low-level, low-power positions, disconnected from others, and therefore unable to engage in behavior that would lead to promotion.

### *Other Organizations*

It has been posited that “gender is everywhere.” In fact, gender differences in behavior have been identified in such diverse places as schools, religious organizations, and voluntary organizations. While more women than men graduate from college, fewer women are represented in graduate programs and among faculty. Many religious organizations prohibit women from participating in various roles within religious institutions and support organizations. Women tend to belong to voluntary organizations that are smaller, focused on community or youth, and more peripheral. Men belong to voluntary organizations that are larger, more connected to other organizations, and more focused on economics and business. Clearly, gender has wide-ranging effects on behavior in a multitude of contexts.

## GENDER ROLES

---

*Gender roles* consist of shared expectations that apply to individuals on the basis of their socially identified sex. The sharing of gender roles refers to the tendency of expectations associated with men and women to be consensual in society. At an implicit or explicit level, most people endorse expected behaviors as appropriate for men or for women. Therefore, as Eagly's social role theory argues, membership in the female or male social category subjects people to social expectations that affect social interaction in group situations and influence the intergroup behavior that transpires between women and men. This entry defines gender roles and discusses the consequences of deviation from them, their effect on self-concepts, theories about their origin, and their impact on individuals and society.

### Concept of Gender Roles

The definition of gender roles derives from the concept of social role, which refers to the shared expectations that apply to people who occupy a certain social position or are members of a particular social category. At an individual level, roles are schemas, or abstract knowledge structures, pertaining to a group of people. To the extent that role schemas are shared among members of a society, they are important structures at the societal level as well as the individual level. Roles are thus aspects of social structure, which consists of persisting and bounded patterns of behavior and social interaction.

Social roles foster characteristic ways of behaving among people who have the same social position within a social structure or who are classified in the same general societal category (e.g., as men, as elderly). Encouragement to act in particular ways arises from the shared role schemas that people in a society hold. For example, people who have a particular occupational role (e.g., as an accountant or a plumber) are subjected to a set of expectations concerning the work they should do and the manner in which they should do it.

Gender roles apply to people in the extremely general social categories of male and female. These roles, like roles based on qualities such as age, social class, and race/ethnicity, have great scope because they apply to all aspects of people's daily lives. In contrast, more specific roles based on factors such as family relationships (e.g., father, daughter) and occupation (e.g., nurse, police officer) are mainly relevant to behavior in a particular social context—at work, for example, in the case of occupational roles. This general applicability of gender roles means that they influence behavior, even though specific roles simultaneously constrain behavior. For example, because gender roles are present in the workplace, people have somewhat different expectations for female and male occupants of the same workplace role.

### On Stereotypes

The importance of gender roles is revealed in research on gender stereotypes, which documents the differing beliefs that people hold about the typical behaviors of women and men. The content of many of these beliefs can be summarized by

differences on two dimensions, which are frequently labeled *communal* and *agentic*. Women, more than men, are thought to be communal—that is, friendly, unselfish, concerned with others, and emotionally expressive. Men, more than women, are thought to be agentic—that is, masterful, assertive, competitive, and instrumentally competent.

Gender stereotypes also encompass beliefs about other personal attributes, including physical characteristics, typical roles, specific skills, and emotional dispositions. Research on gender stereotypes has shown that merely classifying a person as male or female automatically evokes these expectations, or mental associations, about the characteristics that are typical of men or women. These associations are pervasive and influential even when people are unaware of them.

Beliefs about the typical characteristics of women and men are not sufficient to demonstrate gender roles because roles are composed not merely of expectations about how people *do* behave, but also of expectations about how they *should* behave. Social roles are thus prescriptive (or injunctive) as well as descriptive. Research has demonstrated the prescriptive quality of gender roles by showing that stereotypical ways of behaving are perceived as generally desirable for people of each sex—at least insofar as researchers have examined the evaluatively positive aspects of gender stereotypes.

To identify desirable behaviors for women and men, some studies have investigated beliefs about ideal women and men. These beliefs about ideal behavior tend to parallel beliefs about typical behaviors of women and men. Such findings show that people tend to think that women and men ought to differ in many of the ways that they are perceived to differ. This oughtness transforms gender stereotypes into gender roles. And these descriptive and prescriptive beliefs define what is considered masculine and feminine in a given society.

The descriptive aspect of gender roles specifies what is considered normal or typical for each sex and thus provides guidance concerning what behaviors are likely to be effective in a situation. People refer to others of their own sex to find out what sorts of behaviors are usual for individuals of their sex in a particular situation. They tend to imitate these sex-typical behaviors, especially if a situation is ambiguous or confusing. The prescriptive

aspect of gender roles describes what is desirable and admirable for each sex, providing guidance concerning what behaviors are likely to elicit approval from others. People thus refer to what is desirable for persons of their sex when they endeavor to build and maintain social relationships. In summary, the power of gender roles to induce role-consistent behavior derives from these roles' descriptions of what is typical of men and women and what is desirable for them.

The idea that expectations about male and female behavior are shared implies a social consensus about typical and appropriate behaviors as well as people's awareness of this consensus. This consensus is evident in stereotype research, which has shown generally similar gender beliefs among people who differ in attributes such as sex, age, ethnicity, social class, and others. Moreover, social cognitive researchers have maintained that virtually everyone acquires the stereotypical beliefs that are associated with important social categories such as sex, race, and age. In addition, awareness of the society's apparent consensus about the characteristics of men and women is demonstrated by respondents' ability to report on the stereotypes held in their own cultures.

In summary, the power of gender roles to affect behavior derives not only from their description of typical and desirable behavior of women and men but also from their tendency to be relatively consensual and for people to be aware of this consensus. People thus believe that the typical other person holds these beliefs and consequently would react favorably to role-consistent behavior and unfavorably to inconsistent behavior. Therefore, social approval and a smoothly functioning social interaction in group settings generally follow from behavior consistent with gender roles. Consequently, it is not surprising that, following from social psychological concepts such as normative influence and self-fulfilling prophecy, research on the behavioral confirmation of gender stereotypes has shown that, under many circumstances, men and women act to confirm the stereotypical expectations that others hold about their behavior.

### Deviation From Gender Roles

A key assumption of a gender role analysis is that behavior inconsistent with gender roles is often

negatively sanctioned and tends to disrupt social interaction. The sanctions for role-inconsistent behavior may be overt (e.g., losing a job) or subtle (e.g., being ignored).

Social psychologists have produced many demonstrations of negative reactions to deviations from gender roles. For example, in one study, men who behaved passively and women who behaved assertively were rated less favorably than men who behaved assertively and women who behaved passively. Also, in small group interaction, women's competent, task-oriented contributions are more likely to be ignored and to elicit negative reactions than identical contributions from men. Moreover, women tend to lose likability and influence over others when they behave in a dominant style by expressing clear-cut disagreement with another person, using direct speech, or displaying assertive or extremely competent actions. Group members thus elicit conformity to gender-role norms by dispensing rewards such as liking and cooperation in return for conformity to these norms and by dispensing social punishments such as rejection and neglect in return for nonconformity.

In general, gender roles regulate social interaction because people judge the value and appropriateness of others' behavior according to its conformity with gender roles. Because people often sanction behavior that is inconsistent with gender roles, these roles have a generally conservative impact by exacting costs from people who deviate from norms concerning male and female behavior. Weighing these negative outcomes in a cost-benefit analysis, people do not deviate from their gender role unless nonconformity produces benefits that outweigh the costs. Part of these perceived benefits for women, as members of a subordinate group in society, may be having some chance to gain access to rewards and opportunities formerly reserved for men.

### Gender Roles and Self-Concept

Gender roles can produce differences in males' and females' behavior not only by affecting the rewards and punishments received from others but also by affecting the self-concepts of women and men. Psychologists have often focused on the extent to which individuals define themselves by the attributes that are associated with being male or

female. These self-definitions constitute an internalization of societal gender roles. The term *gender identity* refers to these self-definitions in terms of masculinity and femininity. Individuals of each sex differ in their gender identity, and men and women differ on the average. Gender identity is only one of many possible social identities, with each identity representing the individual's psychological relationship to a particular social category (e.g., race, social class, religion).

Studies of gender identity have shown that women, more than men, ascribe communal qualities to themselves, and men, more than women, ascribe agentic qualities to themselves. In addition, women's construals of themselves are oriented toward interdependence, in that their representations of others, especially those to whom they are linked in close relationships, are treated as part of themselves. In contrast, men's construals of themselves are oriented toward separation and dominance, albeit incorporating a collective focus on membership in larger groups such as teams and organizations.

The internalization of gender-stereotypical qualities results in people adopting these qualities as personal standards for judging their own behavior. They tend to evaluate themselves favorably to the extent that they conform to these personal standards and to evaluate themselves unfavorably to the extent that they deviate from these standards. One study found that to the extent that gender role norms were personally relevant to participants, experiences that were congruent with gender norms (i.e., involving dominance for men and communion for women) yielded positive feelings about the self and brought participants' actual self-concepts closer to their desired self-concepts. However, despite evidence of gender roles acting as self-standards, people raised in culturally atypical environments may not internalize conventional versions of gender roles and thus may have atypical gender identities. Research has thus shown that people who have self-concepts that differ from those that are typical of people of their sex are less likely to show traditionally sex-typed behavior.

### Origins of Gender Roles

Gender roles form an important part of the culture and social structure of every society. Although the

ascription of agentic qualities to men and communal qualities to women is widely shared across world cultures, beliefs about the proper relationships between women and men vary widely. Traditional ideologies endorse the dominance of men over women, whereas modern ideologies endorse more egalitarian relationships. Gender ideology is generally more modern in more developed, urbanized nations.

According to Wood and Eagly's biosocial model, even though gender roles are products of the culture, they are not arbitrary cultural constructions but are rooted in a society's division of labor between the sexes. The differing distributions of men and women into social roles form the basis for gender roles. Thus, the typical division of labor in industrialized nations assigns a disproportionate share of domestic activities to women and of other activities to men. Mainly women occupy the domestic role, somewhat more men than women occupy the employee role, and women are more likely than men to be part-time employees. Although most women are employed in the paid labor force in the United States and many other industrialized nations, women and men tend to be employed in different occupations in a somewhat sex-segregated labor force.

The link between gender roles and the male-female division of labor follows from the principle that men and women are expected to have attributes that equip them for their sex-typical roles. People are expected to accommodate to their family and employment roles by acquiring role-related skills, such as women learning domestic skills and men learning skills that are useful in paid occupations, particularly in male-dominated occupations. Also, women's association with the domestic role and female-dominated occupations favors interpersonally facilitative and friendly (i.e., communal) behaviors. In particular, the assignment of the majority of child-rearing to women leads people to expect and prefer nurturing behaviors from women.

In contrast, men's association with the employment role, especially male-dominated occupations, leads people to expect more assertive and confident (i.e., agentic) behaviors from them. In addition, expectations about the personal qualities of each sex appear to be shaped by their typical paid occupations. In support of this idea, research has shown that to the extent that occupations are male

dominated, success in them is perceived to follow from agentic personal qualities, whereas to the extent that occupations are female dominated, success in them is perceived to follow from communal personal qualities.

Roles that entail the greatest amount of power and status remain male dominated. Thus status differences between the sexes foster expectations that men are assertive and directive and that women are supportive and cooperative. These expectations arise from people's observations of inequalities between the sexes. Traditionally, men have interacted with women who have lower status than they do—for example, male executives interacting with female secretaries. Until relatively recently, it was unusual for men to interact with women who are equal or superior to them in income and prestige—for example, male executives interacting with female executives.

The inequalities that individual men and women experience are transformed into widely shared beliefs not merely in men's greater status and power, but also in their greater ability and worthiness. It follows that men more readily exercise influence over women in new encounters, even outside of workplaces, and women more readily accept this influence. The expectations that flow from men's higher status shape interactions even when a man and a woman are objectively equal in status. Nevertheless, relatively recent changes in the status of women have moderated this aspect of gender roles in many contemporary societies.

### Impact on Individuals and Society

Gender roles can have powerful effects on individuals who take these roles into account as they strive to reach important goals, enhance their self-esteem, and gain approval from others. Even without conscious awareness of gender roles, people have mental associations about men and women that guide their thoughts and behaviors and help maintain traditional arrangements. Because masculine and feminine associations are elicited automatically by cues related to gender, these associations influence virtually all social interaction.

In all social settings, people must negotiate social interactions as men or women and therefore must contend with their own and others' expectations concerning the behaviors that are typical and

appropriate for individuals of their sex. Violating others' expectations about male or female behavior can bring negative reactions, whereas meeting their expectations can bring rewards of social approval and cooperation. In addition, living up to one's own personal gender identity can yield rewards of self-esteem and satisfaction. Yet, this view that conformity to gender roles yields social and personal rewards is overly simple in societies in which women's position in the social structure is changing and therefore gender roles are in flux. Although these changes can loosen the constraints of traditional norms about how men and women should behave and thus allow more behavioral flexibility, other consequences include ambiguity, confusion, and debates concerning the proper place of women and men in society.

---

## GENOCIDE

---

As defined by the United Nations, *genocide* involves “acts committed with the intent to destroy, in whole or in part, a national, ethnical, racial, or religious group.” Although human beings have been victims of genocidal assaults throughout history—and prehistory—the word *genocide* itself is of relatively recent origin. A word from the Greek *geno* (meaning “race” or “tribe”) and Latin *cide* (meaning “killing”), it first appeared in print in 1944 in the book *Axis Rule in Occupied Europe*, written by Raphael Lemkin, a Polish lawyer. Lemkin had already been studying the causes and consequences of mass slaughter when he witnessed the annihilation of his own community, Eastern European Jewry, during World War II. After the war, he dedicated himself to raising awareness of genocide. His efforts were directed toward lobbying for the establishment of international treaties to prevent genocides and punish those who carried them out. His efforts culminated in the 1948 United Nations Convention on the Prevention and Punishment of the Crime of Genocide. This entry provides a general definition of genocide, and then looks at the phenomenon from the viewpoint of perpetrators, victims, bystanders or witnesses, and heroes and resisters.

### Definition

In Lemkin's view, genocides did not necessarily entail intentions to murder every member of a group. Nor was killing of any kind absolutely essential. Trying to wipe out a group's cultural existence, making it essentially disappear, was enough. The UN genocide convention focuses on physical destruction of a group's members—that is, mass murder—but it still leaves room for interpretation. Indeed, the issue of how best to define genocide has been very contentious.

At one extreme, some reserve the term for efforts to exterminate every last living member of a group. By that definition, few events would qualify—perhaps only the Holocaust, the Nazis' attempt to exterminate all Jews who fell into their hands. At the other extreme, some argue that any armed assault on civilian noncombatants is genocidal. Attempts to develop a finer grained language of mass brutality have been no more successful. For example, the term *ethnic cleansing* is sometimes used to label actions against civilian populations that are allegedly less extreme than genocide—specifically, attempts to forcibly displace or transfer a group rather than directly destroy it. Arguably, however, *ethnic cleansing* is simply a term perpetrators use to downplay the severity of their crimes. Few if any “ethnic cleansings” do not also involve mass murder.

Despite these ambiguities, *genocide* can be defined as an organized effort to brutalize, kill, or otherwise eliminate people who are targeted simply because of their social identities, and not because they pose any objective threat. Although genocide can involve spontaneous explosions of mob violence, it requires planned and organized group activity. Murder is central to genocide, but other acts of violence and cruelty that characterize it are also important to acknowledge and understand.

In addition, there are other ways to try to eliminate groups—by preventing births, for example. Also important to note is that although any civilian casualties during armed struggles are tragic, not all such civilians are genocide victims. During an episode of genocide, all members of a group—men, women, children, senior citizens—are explicitly targeted for violence. Finally, perpetrators of genocide almost always believe they are doing the right thing and do not believe that their victims are

blameless. By any reasonable standard, however, genocidal killings cannot be construed as acts of self-defense.

Besides the Holocaust, recent history's most notorious genocides include the slaughter of the Tutsis in the African nation of Rwanda in 1994, the expulsion and murder of Turkey's Armenian population shortly after the outbreak of World War I, the killings of large segments of the Cambodian population by the Khmer Rouge in the late 1970s, and the rape, pillage, and slaughter of inhabitants of the Darfur region in Sudan that began in 2003.

In addition to the systematic annihilation of large numbers of people, two other aspects of genocide inspire particular horror. One is how genocide becomes a project in which members of the perpetrator group from every level of society become involved—including politicians, the military, police, business owners, educators, clergy, and members of youth movements. The second is the barbarous and diabolical nature of the killing. In Rwanda, in the space of a few weeks, hundreds of thousands of people were cut down with machetes, often by their own neighbors. The Armenians were subject to months of rape, assault, and robbery as they marched to their deaths. And the Holocaust culminated in the establishment of assembly line-style death factories in which Jews (and others) were exterminated in poison gas chambers (which the victims were led to believe were shower rooms).

### Conditions Leading to Genocide

Organized genocidal killings do not develop spontaneously. They are inspired, directed, and sanctioned by powerful and influential instigators—typically, political leaders. But some circumstances facilitate instigators' efforts to mobilize people for genocide.

Genocides are most likely to occur when people in a society perceive themselves to be experiencing difficult life conditions or some sort of social crisis. While some societal problems lend themselves to relatively straightforward solutions, others do not. Thus, when a bad situation seems out of control and is causing widespread fear and frustration, as in wartime, people become increasingly desperate for answers. At such times, they are receptive to

simple analyses of their problems—including the idea that those problems have been caused by the evil machinations of another group of people and that the solution is elimination of that group.

Groups experiencing a collective sense of humiliation are especially prone to lash out at scapegoats to avenge perceived slights. In early 20th-century Turkey, people were acutely aware of the Ottoman Empire's eclipse, and early military reversals during World War I further eroded Turkey's status as a major world power. Later in the century, the German people believed that they had been unfairly blamed for World War I, and they felt burdened by what they perceived to be the vindictive provisions of the Versailles treaty. Just as individuals lash out at others when experiencing a threat to their egos, so do groups, as the Turkish government did with the Armenians and Nazis did with the Jews.

### How People Become Perpetrators

Although genocides are group-level phenomena, individual human beings carry out the killings—that is, they are the ones who chop off people's heads with machetes, drive them over cliffs, shoot them at close range, and herd them into gas chambers. How people bring themselves to do such things, which under normal circumstances would violate their moral standards, is a complex issue.

Research by social psychologists has vividly demonstrated the surprising ease with which people can be led to engage in harmful, destructive behavior, especially when people perceive the authority figures directing their behavior to be powerful and legitimate. In Stanley Milgram's obedience studies, for example, participants administered what they believed to be deadly electric shocks to a protesting person simply because an experimenter told them it was expected and required of them.

Brutality also comes easier to people when they are in large groups. Being part of a crowd, and less identifiable as an individual, can lower a person's normal inhibitions. People who are just blurry faces in a mob become less attentive to their normal standards of behavior. This phenomenon, known as *deindividuation*, undoubtedly played a role in scenes such as those witnessed in Rwanda, where large groups of people assembled to urge

machete-wielding Hutus to decapitate their Tutsi neighbors.

First-person accounts of genocide reveal that over time, the lethal and often shockingly brutal behaviors of perpetrators are not typically direct responses to orders from above, nor are they triggered by any other sort of immediate social pressure. Instead, perpetrators' activities are usually self-initiated, self-directed, and carried out with enthusiasm and even creativity. Ervin Staub has characterized the increasing brutality of perpetrators as a progression along the *continuum of destructiveness*. Perpetrators, like bystanders, need to rationalize and justify their behaviors. Often, this involves convincing themselves that their victims deserve the treatment they are receiving. That can be accomplished by *dehumanizing* members of the victim group. It is easier to terrorize and kill others when one believes that they are so evil, debased, and generally inferior as to no longer even qualify as human beings. The end result of this process is that perpetrators become convinced of the moral justification of extermination, and need no prodding to participate.

In addition, a perspective on intergroup relations known as *social identity theory* describes how simply identifying strongly with a perpetrator group can transform individuals by leading them to embrace attitudes (such as prejudices), beliefs (such as stereotypes), and behaviors (such as discriminatory practices) they see as being prototypical of their group.

A disturbing implication of this discussion of how people become perpetrators is that it involves normal psychological processes. In other words, normal people become participants in genocide. Not all people are equally promising candidates for the role of mass killer, but perpetrators are not necessarily characterized by extreme personality characteristics. Indeed, research by behavioral scientists has not revealed any traits that are necessary or sufficient for explaining why people become perpetrators.

### Which Groups Become Victims

Victims of genocide are generally members of minority groups that have long been the targets of prejudice. But not all minority groups—not even all those perceived unfavorably by the majority—are

equally at risk. Particularly vulnerable are ethnic (and other) groups that are seen as competitors for resources (and thus viewed with hostility), and at the same time, as being clever, competent, and successful. Such groups are the targets of *envious prejudice*. They are believed to be motivated to make life difficult for the perpetrator group and capable of carrying out sinister plans to get their way. In other words, people can convince themselves that these groups are plausible causes of the difficult life conditions in a society. As a result, members of these groups become scapegoats. Armenians in the Ottoman Empire, Jews in Germany, and Tutsis in Rwanda were all targets of envious prejudice.

Also at risk are groups that are seen as being not only hostile, but also so intellectually and culturally inferior as to be less than human. Such groups are the targets of *contemptuous prejudice*. Members of these groups are slaughtered not because they are believed to be plotting against the perpetrator group but because, at crucial junctures in a society's development, they are seen to be dangerous—and expendable—impediments to progress. Native Americans, the Roma people in Europe (often called “Gypsies”), and the original inhabitants of Tasmania were targets of contemptuous prejudice.

#### Acquiescence to Evil: Bystanders and Supporters

Most members of perpetrator groups are not actively involved in the killings. Few, however, speak out against the evil being perpetrated in their names. Many bystanders undoubtedly support the violence, as victims of genocide are typically targets of preexisting prejudice. Even were this not the case, and even if large segments of the perpetrator group opposed the killing, a number of psychological factors would work to mute their objections.

The first is *diffusion of responsibility*. Even when people believe an injustice is taking place and they are capable of intervening in some way, they feel less obligated to do so if they perceive that many others are also witnesses and could act instead of them. In such circumstances, people might not be willing to bear the costs of coming to the aid of other people, even if those costs are not great.

People will be even more inhibited from intervening if they believe that most other people, unlike themselves, support the assault on the victim group, even if that belief is false. Groups are often characterized by *pluralistic ignorance*, a state of affairs in which individuals assume that other group members have different attitudes or beliefs than they do despite that fact that those attitudes and beliefs are more similar to their own than they realize. Pluralistic ignorance prevents people from expressing their objections to unjust or even genocidal policies. This is especially true when people fear that their opinions might suggest a lack of courage, strength, or patriotism. Thus, people often conform to group norms that are privately endorsed by only a small minority of group members.

Few people are comfortable with passively observing the unjust victimization of others. To resolve this tension, bystanders rationalize or justify their inaction. A common method involves *just world thinking*, the tendency to believe that those who experience misfortune deserve their fate. The more people justify genocidal policies, the more they become supporters of those policies. And supporters, of course, can eventually become active participants in mass killing.

#### Nations as Bystanders

It is easy to understand how individuals might not believe they have the power to intervene effectively to stop genocides. The same cannot always be said, though, of other nations. Nonetheless, those nations also usually are passive bystanders. Governments are rarely willing to incur the costs (financial, political, and human) of a military intervention or rescue operation. They typically rationalize their inaction, often by downplaying the magnitude of the violence. Otherwise, they argue that there are no effective means of intervention available to them or that any attempt to intervene will only make matters worse for the victims.

#### Heroes and Resisters

Just as it is impossible to define a specific perpetrator type, those who actively oppose genocide do so for a wide variety of motives. Some act not so much out of sympathy for the victims, but as a

way of expressing animosity toward the perpetrator group. Others assist potential victims or otherwise subvert the perpetrators' plans as a result of the social influence or even active encouragement of esteemed authority figures (for example, local religious leaders). Certainly, though, many people have engaged in resistance and even made heroic efforts to save those targeted for death because of deeply held values and beliefs that are incompatible with genocide. One of the most commonly cited characteristics of helpers is an extensive (i.e., inclusive) view of people—that is, a belief that people should be first and foremost categorized as human beings, and not in terms of race, ethnicity, or nationality. “Extensivity” is associated with feelings of responsibility for others' welfare.

Case studies of heroic helpers reveal a common pattern. Such people typically start with limited acts of resistance but over time become more committed in their opposition and bolder in their actions. In other words, they progress on a *continuum of benevolence*. Major acts of heroism usually represent the final stage of a process that starts with small acts of kindness or bravery.

Nations can behave heroically too. During World War II, Danes organized a rescue operation that allowed most Jews in their country to escape to Sweden. Bulgaria was also notable for having shielded most of its Jews (especially native-born ones) from the Nazis. The country's leaders, in their deliberations and in communications with the public, emphasized the primacy of the Jews' identity as Bulgarians. Consistent with social identity theory, this led other Bulgarians to perceive themselves and the Jews as sharing a common fate.

### The Aftermath: Collective Guilt and Forgiveness

Perpetrator groups are often loath to admit that they carried out genocidal killings. Simple denial is usually untenable, however. Instead, perpetrators might argue that the number of deaths has been grossly exaggerated; that most victims died from disease and starvation, despite efforts to sustain them during a chaotic period of upheaval and violence; that those who were killed died as a side effect of normal military operations; that the

killings occurred during a civil war in which members of the perpetrator group also perished in large numbers; or some combination of these excuses.

Other groups have openly admitted to their former genocidal policies and have attempted to come to terms with the past. Contemporary Germany is a prominent example. Holocaust education is a part of the regular school curriculum, and many prominent public memorials to the Nazis' victims have been constructed.

Individual members of former perpetrator groups can experience collective guilt—that is, guilt due to actions taken by members of their groups, even if they themselves did not take part in those actions (perhaps because they were not born yet). Collective guilt can be constructive, for example by inspiring reconciliation with survivors of the killings and support for the payment of reparations. Collective guilt is far from universal, however. To experience it, people have to subjectively identify with the group that committed genocide, but not too strongly. People for whom group membership is the most salient and important aspect of their self-concept will find it difficult to admit that there is cause to feel guilt. In other words, they will be motivated to deny that a genocide took place or to explain it away.

Survivors of genocide often demonstrate remarkable psychological resilience. Some, however, experience psychological difficulties, including guilt at having lived when so many others were killed. These internal struggles can complicate their interpersonal and family relationships. Although no one can reasonably demand that genocide survivors forgive their former assailants, reconciliation is more likely under certain conditions. The first is some expression of collective guilt by the perpetrators. The second is that survivors frame what happened as an example the terrible things that *people*—as opposed to Germans, Turks, and others—do to other people. Coexistence after a genocide is difficult but not impossible.

*Leonard S. Newman*

## GRADUATED RECIPROCATION IN TENSION REDUCTION (GRIT)

---

*Graduated reciprocation in tension reduction* (GRIT) is a behavioral strategy designed to reduce hostilities among conflicting parties. It is a unilateral strategy under which the adopter initiates a system of conciliation and reciprocation and at the same time signals a willingness to cease the process if the other party attempts to exploit the goodwill. GRIT is applicable to both intergroup and intragroup conflict.

GRIT was proposed in 1959 by Charles Osgood in response to the escalation of the Cold War and the wave of strategic models being advocated, all of which took, in Osgood's view, untenable perspectives on U.S.–USSR relations. Military strategists advocated a preventive or preemptive first strike (“getting it all over with in an angry burst of hell-fire,” in Osgood's words). Pacifists argued for unilateral disarmament by the United States, on the assumption that the USSR would not attack a defenseless country and would eventually follow suit (“passively hoping for the best from an aggressive opponent as we lay down our arms”). Think-tank

experts advocated a buildup of far more nuclear weapons than would ever be needed and simultaneous recognition of the impossibility of completely shielding the country from nuclear attack. Their logic was that such a strategy would both convince the USSR of the United States's ability to annihilate them and produce extreme reluctance within the United States to actually launch such an attack, because a counterattack could not be completely defended (“erect[ing] stabilized deterrence on the shifting sands of human fallibility”). Negotiated disarmament was also advocated in some quarters, though Osgood believed any such negotiations were doomed by biased perceptions, distrust, self-fulfilling prophecy, and inflexibility.

The catalyzing event for Osgood, however, was a debate between the philosophers Bertrand Russell and Sidney Hook over whether it was preferable to live under communism or be killed in a nuclear war (Russell preferred the former, Hook the latter). This convinced Osgood that people were viewing the conflict as a conquer-or-be-conquered situation, and he refused to believe that only two outcomes were possible. GRIT was his response.

### Basic Principles of GRIT

The essence of GRIT is quite simple. One combatant unilaterally announces and performs a concession and indicates expectation that the opponent will reciprocate. If reciprocation occurs, the initiator announces and makes a second, larger concession, hoping it will be reciprocated. This process continues until the combatants arrive at common ground. An occasional failure to reciprocate is tolerable, but if a series of concessions are not reciprocated, the initiator revokes the last action to bring the relationship back into balance, and makes no further changes. Even if such an unsatisfactory outcome occurs, the environment will be improved relative to the pre-GRIT atmosphere, unless it is the initial concession that is rebuffed.

Osgood's analogy for GRIT was of two people standing at opposite ends of a seesaw. The seesaw is balanced, but very wobbly, and it would not take much for one person to tumble off, which would cause the other to come crashing to the ground and both to be injured. Under GRIT, one person would take a small step toward the center of the seesaw and indicate that the other should do

the same. If the other person did so, the seesaw would come back into balance and be a little more stable than it was previously. Repetition of this process would eventually lead to the two people standing in the middle of the seesaw, with the seesaw balanced and very stable. If at any point one person failed to mimic the steps forward of the other, the initiator would need to back up to the last position in order to bring the seesaw back into balance, and here the process would end.

Within each step, there are a number of caveats and details that must be addressed. The concession should not be so major that it cripples the initiator's ability to retaliate if abused. The magnitude of the concession should match that of any concessions made by the opponent. Thus a large concession should be followed with a large concession and a token one with a token one. Concessions should ultimately be made across a variety of issues. It is not helpful to give in on one issue and hold firm on everything else. The initiative should be unforeseen, so that the opponent has no time to distort or propagandize the offer. The concession must be publicly announced, and the initiator must actually follow through on the announcement. Finally, the actual behavior must be clear and unambiguous so that even a biased observer will agree it is truly a concession, and the quality of the concession should be independently verifiable.

Osgood saw GRIT as accomplishing four goals: (1) reduction and control of tension, (2) creation of a trusting atmosphere, (3) empowerment to take initiative, and (4) alteration of future relational processes. When Osgood proposed his model to reduce international tension, his discussion of these goals focused strictly on that arena. That is, as examples of unambiguous concession, he presented actions such as reduction of trade barriers, reduction of troops in disputed territory, and provision of food to impoverished regions supported by the opponent. And the last chapter of his book was devoted to rebutting imagined arguments against GRIT by policymakers.

### Applications of GRIT

To date, there has not been a complete application of GRIT at the international level. The closest approximation is President John F. Kennedy's June 1962 Strategy for Peace initiative, under which the

United States and USSR announced and traded concessions over the course of 15 months. However, this initiative is often criticized as disingenuous because the concessions were largely valueless (e.g., the U.S. offered to halt atmospheric nuclear weapon tests, but held a 2-year backlog of unanalyzed data when the offer was made), and Kennedy stopped the process when public criticism of his actions grew large enough to concern Democratic strategists. Some have pointed to this latter event as evidence that GRIT will never work because the public will not tolerate seemingly endless giving to an enemy. This is speculative, however.

Although developed to deal with international conflict, GRIT was rather quickly recognized as being applicable to interpersonal conflict as well. In fact, most of the subsequent research on GRIT has focused on reducing interpersonal tension. It is important to understand that, because of its complexity, a comprehensive test of all aspects of GRIT at once is not possible. Even if such an experiment could be designed, the number of study subjects required would be so large as to be prohibitive. Instead, researchers have examined particular pieces of GRIT and then assembled those pieces into a larger picture. In general, this work has supported Osgood's arguments for clear communication of intent, adherence to an announced concession, verifiability of the concession, willingness to overlook occasional lapses in reciprocation, and the need for balanced power.

Some other arguments are less well supported, however. For example, so long as one matches the frequency of concession performed by the opponent, matching of the magnitude seems unimportant. One could thus always respond to a concession with a smaller concession, so long as one always does respond. More critically, direct invitations to reciprocate are often perceived as devious rather than attractive. People tend to see the inviter as having an ulterior motive and the invitation as an attempt to set a trap. As the invitation is a crucial part of GRIT, this raises serious questions about how to convey one's expectation of reciprocation without inducing suspicion. Finally, some aspects of GRIT, most notably the recommendation to diversify concessions, have received no systematic research attention.

Some research has tried to identify who is most likely to employ GRIT. The clearest indication is

that users are highly confident individuals with an internal locus of control. Reflecting back on the Kennedy example, it is also clear that the strategy needs to have majority support within the group to be effectively applied. For reasons that remain vague, it appears difficult to persuade even neutral individuals to adopt a conciliatory position. Thus, the GRIT supporter who hopes to win converts is unlikely to succeed.

It is important to note that the body of literature summarized here is not large. In some cases, the conclusions drawn are based on one or two studies. Therefore, GRIT needs more, and more systematic, investigation. Unfortunately, research on GRIT has tailed off considerably since the mid-1980s, as conflict theorists have shifted their attention to mutual-gain models of conflict resolution (e.g., integrative bargaining) and to third-party mediation of conflicts. Undoubtedly, many researchers were disillusioned by the difficulty of testing more than one or two elements of GRIT at a time. GRIT is still cited by theorists with some frequency, but it is usually represented as a well-understood approach that is appropriate for some situations but not for others. This is unfortunate because, as we have seen, much remains unclear about the dynamics and limitations of the strategy.

## GREAT PERSON THEORY OF LEADERSHIP

---

Dating back at least 2,000 years, the *great person theory of leadership* (GPTL) is one of the cornerstones

of traditional academic and lay understandings of leadership. This is because it provides a straightforward answer to the question, “Are leaders born or made?” Answering that great leaders are “born,” the GPTL suggests that these leaders are superior to other people by virtue of their possession of innate intellectual and social characteristics. In short, leaders are simply people who have “the right stuff.”

This stuff is commonly conceptualized in terms of distinctive personality traits that are believed to make those who possess them inherently more adept at directing, managing, and inspiring others than lesser mortals. Either implicitly or explicitly, these leaders are typically assumed to be men, which is why the theory is also often referred to as the “great man theory of leadership.” Different analyses place emphasis on the importance of different traits, but these typically relate to qualities such as intelligence, decisiveness, insight, imagination, and charisma.

This entry examines the origins of the GPTL and some of its empirical and practical limitations. It also looks at how the theory has been refined over time and at some of the ways in which it has been challenged. A key point is that while the empirical validity of the theory is highly suspect, this has not stopped it from being enormously influential.

### Historical Context

The origins of the GPTL are often traced to Plato’s *Republic*. Written in 380 BCE, the *Republic* presented ideas on leadership in the form of a tutorial in which the student (Adeimantus) learns from the master (Socrates) that only a rare class of philosopher-ruler is innately fit to lead the uneducated and brutish majority and that, without such leaders, democracy is in peril. For Socrates, the key characteristics of such a ruler quickness in learning, a good memory, courage, and breadth of vision. Important, too, is that the person needs to be gifted physically as well as mentally.

Although embryonic, Plato’s analysis set the stage for the large body of subsequent leadership research that focused attention on the psychology of the individual and argued that leaders’ distinctive and exceptional qualities mark them out as qualified not only for responsibility and high office

but also for universal admiration and respect. Particularly important in this respect were Thomas Carlyle's 1840 lectures titled "Heroes and Hero Worship," which argued that the history of civilization is effectively the history of the great men whose leadership made civilization possible.

Examining the historical trajectory of such ideas, there is a clear lineage that progresses from John Stuart Mill's notion of the genius whose pleasures are of a higher order than the animalistic gratifications of the majority, through Friedrich Nietzsche's "superman" who would let nothing stop him from satisfying his appetites, to Gustave Le Bon's notion of the hypnotic crowd leader.

These ideas were carried into the 20th century by Max Weber—in particular through his writings on the historical significance of charismatic leaders who possess superhuman powers not accessible to the ordinary person. Weber argued that such people—and only such people—have the capacity to deliver enlightenment and salvation to the masses. This analysis became less popular in the wake of World War II, after people had become terrifyingly familiar with the capacity for charismatic dictators to deliver the very opposite. Nevertheless, the idea of charismatic leadership has recently been rehabilitated and revitalized by James McGregor Burns, whose work focuses on the special properties of an individual that allow him or her to articulate a vision that inspires large-scale group action and transformation.

Along similar lines, numerous popular organizational texts advance slightly different versions of the view that the key to effective organizational and political leadership lies in a peculiar constellation of traits and abilities that set the chosen few apart from the undifferentiated mass. In this vein, hagiographic profiles of business leaders typically encourage attempts to discover the secrets of business success within the psychology of the exceptional individual—their unusual habits, their unique tastes, their extraordinary drives.

### Critiques

Despite the enduring popularity of such work, many researchers and commentators, dating back to Herbert Spencer at the end of the 19th century, have questioned the wisdom and utility of preoccupation with the individual leader that the GPTL

embodies. At a practical level, a series of influential reviews (e.g., by Gibb) failed to find a strong or reliable link between a person's possession of particular psychological or physical traits and his or her subsequent success as a leader. Observers often claim to be able to identify leader traits retrospectively, but prospectively, it is very difficult to specify traits that will cause some people to be more effective leaders than others.

At a political level, observers have argued that the GPTL is pernicious because it disempowers the general populace by leading its members to believe (a) that they are ruled out of contention for high office due to their lack of a suitable leadership profile and (b) that it is people who possess this profile who bring about all forms of worthwhile progress and social change. In this vein, one of the key functions of the GPTL is to encourage the acquiescence and passivity of followers who, if they accept the view that social change is brought about by the actions of distinguished individuals, become resigned to their lowly role and are deterred from seeking to stimulate collective change.

These arguments are supported by historical observations that the cult of the individual leader was promoted particularly vigorously in 19th-century Europe (e.g., through portraits, statues, and biographies) to nullify the threat to the ruling elites that was posed by the prospect of popular revolution. It is possible to see profiles of powerful and wealthy CEOs as a modern manifestation of the same status-preserving motivations.

In the last decade, critiques of the GPTL have had a significant impact on mainstream theory in social and organizational psychology, which has developed a range of approaches to leadership that either adapt or challenge the GPTL in various ways. The most popular adaptations take the form of contingency models, which see leadership as the product of an interaction between the person and the situation. According to such formulations, leadership is not just about having "the right stuff" but also about being in "the right place at the right time." Again, though, researchers have questioned the predictive power of these models and their individualistic conceptualization of the person—in particular, the view that the psychology of the individual leader is stable, static, and immutable.

Important strands of work have argued that the focus on the leader that is encouraged by the GPTL

needs to be balanced by consideration of the importance of followers to the leadership process. In different ways, this alternative emphasis is found in work by Robert Lord and Edwin Hollander, which emphasizes the importance of followers' perceptions and actions (followership) to the success of leaders, and in work by James Meindl, which argues that leadership is a reflection of followers' (often faulty) attributions for the causes of group success.

Taking such critiques even further, social identity researchers argue that successful leadership is achieved not by individuals who are different from others in the way that the GPTL suggests, but rather by leaders who exemplify what the group stands for in any given context. Rather than directing attention toward the leader in isolation, this perspective focuses on the status of leaders as representatives and mobilizers of shared group values, goals, and identities. It argues that successful leadership is not a product of great individuals set apart from ordinary mortals, but rather ordinary mortals who embody and promote their groups.

---

## GROUP BOUNDARIES

---

*Group boundaries* are used to determine who is included in a specific group and who is not. Such boundaries play a central role in human perceptions and behaviors. Sometimes group boundaries refer to concrete and objective criteria that determine group membership (as in the case of gender). Sometimes the crossing of group boundaries is a special event that is readily apparent and even ritually celebrated (as when new fraternity members are initiated, or a new national citizenship is awarded). More often, however, group boundaries are defined in a *metaphoric* or *symbolic* way. They indicate which individuals are most likely to experience a psychological sense of inclusion or exclusion in relation to a particular group.

### Origins and Functions of Group Boundaries

Group boundaries are used to help define the social roles of the self and others. Group boundaries indicate who you are, how you are expected to behave, and how you are seen by others. Group boundaries may evolve naturally and organically (as when new members are added to the family through marriage or birth, or existing family members drift apart and disconnect) or they may be defined with reference to strict criteria that sometimes have legal implications (e.g., through legally certified admission to certain professions). Group boundaries may connect individuals who are similar to each other in terms of a central characteristic that they share (such as their ethnic origin) or they may bring together people who can complement and help each other because they are different (as in work organizations).

The term *group boundary permeability* is used to indicate the extent to which boundaries are fixed (impermeable boundaries) or flexible and easily crossed (permeable boundaries). Because of the symbolic and metaphoric way in which group

boundaries tend to be defined, permeability does not simply reflect whether it is possible to acquire or discard defining group characteristics (such as gender or ethnic origin). Instead, the permeability of group boundaries indicates whether merely belonging to a certain (e.g., ethnic or gender) group prevents people from moving freely within a social system, for instance to achieve positions of higher social status.

Group boundaries have two main functions. The *meaning-seeking* function of group boundaries means that they can be used as a tool to acquire information about specific individuals (including the self), the way those individuals relate to each other, and the way they are likely to behave. The *strategic identity expression* function of group boundaries means that people can define them (and who is included in or excluded by them) in ways that best fit their own self-image. This is the case, for instance, when someone who studied at a prestigious university but did not earn a degree there claims to be an alumnus of that university.

### Group Boundaries and Meaning Seeking

Group boundaries help us define who different individuals are and how they relate to each other. Even when personal relationships seem to be the primary basis for social interaction, events that make group boundaries more salient can have dramatic consequences. This happened, for instance, in the former Yugoslavia. Friends, neighbors, and even spouses felt alienated from each other and sometimes harmed each other because ethnic and racial group boundaries became the central defining feature of their social and political reality.

The psychological mechanism by which people structure and define their social world through group boundaries was illustrated in a classic experiment by Tajfel and Wilkes. They demonstrated that objectively defined stimuli (lines of different length) were perceived differently, depending on whether they were presented as a set of individual stimuli with gradually increasing length or as two separate groups, one with “short” lines and the other with “long” lines. In the latter case, the differences between the lines that were categorized into the same group were minimized. At the same time, the differences between adjacent lines that were separated by a group boundary were exaggerated.

Even when group memberships are flexible and subject to change, group boundaries can be used as a point of demarcation in a more gradual and ambiguous area of transition between different groups. Especially for people who find themselves at or near this demarcation area, group boundaries may help determine how they should see themselves in relation to others around them. In this case, the knowledge that one is included in or excluded from a particular group can result in the adoption of group membership markers, such as language use (e.g., regional dialect, professional jargon), preferences for certain foods or dress styles (e.g., when male students cut their hair and buy a business suit after graduation), and adaptation to specific behavioral norms (e.g., when immigrants attempt to show politeness in locally approved ways).

As a result of such group boundary transitions, many groups are characterized by a continuous flow of new members entering and current members leaving. In this process of changing commitment to the group, individuals can also experience role transitions within the group—for example, from new member to full member to marginal member. This process is described in group socialization theory, developed by Richard Moreland and John Levine. Sometimes the crossing of group boundaries is marked as a meaningful event at which an aspiring group member qualifies to enter the group or a long-standing member formally takes leave of the group (e.g., by going into retirement). In other cases, however, people repeatedly move back and forth across group boundaries. These *boundary spanners* can facilitate networking and integration between different groups. In work contexts, boundary spanners are seen as an important source of information exchange and innovation that can improve work team performance.

### Strategic Identity Expression

Group boundaries are not always defined by concrete membership criteria (such as gender). When group boundaries are more ambiguous, they can be adapted or redefined to strategically include or exclude specific individuals. Such strategic identity expression is likely to occur when people come to the conclusion that their group is devalued by others. This may prompt them to self-present and

behave as if they belonged to another, more highly valued group.

In social psychology, a basic assumption is that people generally want to achieve and maintain a positive sense of self, and a theory that explains how this basic motivation affects the way people perceive groups is social identity theory, developed by Henri Tajfel and John Turner. This theory argues that people tend to self-present and behave in line with norms of groups that can yield them a positive identity. As a consequence, people who belong to groups that have a positive image are motivated to guard their group against the inclusion of individuals who can spoil the group's favorable image. Indeed, research has shown that people respond quite negatively to those who aspire to be included in a group but do not meet the criteria for membership (i.e., impostors). Likewise, people tend to be highly critical of current group members whose characteristics or behaviors reflect negatively on the rest of the group (i.e., black sheep).

When people belong to a group that does not contribute to a positive identity, they can use a range of strategies to cope with this situation. One possibility is to blur the boundaries between different groups. Members of groups with low status, for instance, tend to emphasize differences among individual group members to convey that not all individuals in the group necessarily have the same characteristics. This is intended to lessen the meaningfulness of their (devalued) group membership as a way for others to acquire information about individual group members, including themselves. Alternatively, when the significance of group boundaries cannot be denied, or when these boundaries cannot be crossed, members of stigmatized groups (such as the mentally ill, handicapped, or homosexuals) may simply hide this stigmatizing condition in an attempt to avoid social exclusion.

### Threats of Inclusion and Exclusion

Because of the subjective and symbolic nature of many group boundaries, the way they are drawn can imply a source of (identity) threat, to which people can respond with strategic identity expression. When people are seen as members of a negatively stereotyped group, the resulting stereotype threat can limit their ability to present themselves positively to others or to perform well on certain

tasks. But there also are other more subtle forms of threat that directly relate to group boundaries. These forms of threat occur independently of the group's social standing. The threat in this case is implied in the fact that the way people are seen by others does not necessarily converge with the way those people prefer to see themselves.

*Categorization threat* refers to the threat that is evoked when someone is regarded as a member of a particular group but does not see this as desirable, or thinks it is inappropriate to refer to this group membership in a given situation. Thus, even when inclusion in the group is not disputed (e.g., a woman cannot deny her gender), or when the group reflects positively on the self (e.g., women are socially sensitive), people may still object to being defined in terms of specific group boundaries *in a particular context*. In fact, research has shown that when women think their gender is not relevant to a particular work context, they object to being categorized on the basis of their gender, even if that categorization leads to positive outcomes (e.g., attractive work assignments).

Conversely, *exclusion threat* is the fear that others will define group boundaries in such a way that one is not included in the groups that are seen as appropriate for the self. This is the case when immigrants, seeking to adopt a new national citizenship, are not seen as full citizens by those who were born in the host country. Once again, the threat is not primarily about the attractiveness of one group or the other or about whether people meet formal membership criteria. Instead, people feel threatened when their preferred self-definitions are not respected or accepted by others.

## GROUP COHESIVENESS

---

The term *cohesiveness* derives from the Latin word *cohaesus*, which means “to cleave or stick together.” This may be the one aspect of cohesiveness on which all scholars agree. However, as is the case with many theoretical constructs, it is difficult to reach consensus about the nature of cohesiveness (or cohesion) and its proper measurement.

First scientifically and operationally defined by Leon Festinger and his colleagues in 1950, the scientific concept of cohesiveness has been marked by debate. Indeed, in a 1985 publication, Stuart Drescher and his colleagues suggested that the definition and empirical understanding of cohesion lack both clarity and consistency. And after examining the history of research on cohesion, Peter Mudrack concluded in a 1989 publication that it has been “dominated by confusion, inconsistency, and an almost inexcusable sloppiness in defining the construct.” One promising approach to cohesion is Michael Hogg’s 1992 application of John Turner and colleagues’ self-categorization theory. Hogg distinguished between two types of attraction/liking that occur in groups (and help bind group members together)—an interpersonal form called *personal attraction*, and a group-level form called *social attraction*. The individual group member can experience each of these types of attraction. Further, both may or may not be present at a given time.

Personal attraction varies in strength in different dyadic relationships within a group (e.g., “I like Mary a lot, am ambivalent about George, and

actively dislike Bill”). Conversely, social attraction is a “depersonalized” form of liking based on the extent to which you believe that a person is a prototypical member of a group to which you both belong. Prototypical members are those who possess essential defining characteristics of the group (e.g., “We are a hardworking group”).

Another promising theoretical approach to cohesion was published in 1998 by Albert Carron, Lawrence Brawley, and Neil Widmeyer. They defined cohesion as “a dynamic process reflected in the tendency for a group to stick together and remain united in the pursuit of instrumental objectives and/or the satisfaction of member affective needs.”

Carron and his colleagues identified four major characteristics of cohesiveness. First, cohesion is *multidimensional*. Although task and social factors are the primary binding properties of most groups, there are numerous reasons for group members to stay united (e.g., the stigma associated with leaving the group, contractual constraints).

Second, cohesion in any group (e.g., sports team, family, work group, army platoon) is *dynamic*. Cohesion—and the factors that contribute to it—in a group can change over time. In a marriage, for example, the perceptions of unity and closeness that any couple experiences typically do not remain static over a lifetime. Instead, feelings of closeness, unity, and togetherness fluctuate over time.

Third, cohesion is *instrumental*. Most groups have a *raison d’être* that includes sticking together, and this represents the instrumental basis of the group. For a book club, for example, the *raison d’être* may be mostly social or some combination of task (reading the book) and social (being with friends). For a committee, the *raison d’être* may be exclusively instrumental (achieving committee objectives).

Finally, cohesion is *affective*. In 1995, Roy Baumeister and Mark Leary proposed that humans have a fundamental need to affiliate—that people need frequent interpersonal contact with others in situations characterized by stability and affective concern. Membership in any group satisfies the affiliation need. Cohesion certainly provides a “feel good” property to groups. Lack of cohesion, in contrast, contributes to feelings of anxiety, depression, and alienation.

Carron and his colleagues also proposed a conceptual model of cohesion. A foundation for that model is that each group member develops beliefs about the group as a *whole* (i.e., the similarity, closeness, and bonding among members), as well as about the group's ability to satisfy *personal* needs. The former beliefs are labeled *group integration*; the latter are labeled *individual attractions to the group*.

Carron and his colleagues suggested that there are two fundamental orientations associated with group members' perceptions of cohesion: (1) a *task* orientation, which represents a general motivation to achieve the group's instrumental objectives and (2) a *social* orientation, which represents a general motivation to develop and maintain social relationships and activities within the group. Consequently, four manifestations of cohesiveness were suggested: group integration–task, group integration–social, individual attractions to the group–task, and individual attractions to the group–social.

### The Development of Cohesiveness

How and when does cohesiveness form in groups? This question can be examined using the *minimal group paradigm*. In this paradigm, strangers are assigned to groups randomly and then informed that they share some trivial characteristic (e.g., a preference for one artist over another). Immediately, this shared characteristic leads to bonding (a sense of unity) and “group members” begin to exhibit ingroup favoritism and outgroup bias. According to Henri Tajfel and John Turner's social identity theory, the underlying mechanism is social identification with the group (or self-categorization as a group member), which accentuates perceived or assumed similarities among members of the ingroup and perceived differences between the ingroup and an outgroup.

If categorization into “us” (the ingroup) versus “them” (the outgroup) occurs as readily as it does in the minimal group paradigm, then it is hardly a surprise that distinctions between “us” and “them” are especially strong in groups to which individuals choose to belong and to which they develop strong feelings of cohesion. We now consider some of the cognitive, affective, and behavioral antecedents, consequences, and correlates of group cohesion.

## Group Cohesion and Ingroup Relationships

### Ingroup Favoritism

A common correlate of ingroup favoritism is *sacrifice*—the willingness to place the needs and goals of the group above one's own needs. In research conducted with sports teams, for example, Harry Prapavessis and Albert Carron found that athletes holding the strongest perceptions of team cohesiveness showed the greatest propensity to make sacrifices for their teams—to accept less playing time, adapt to a personally unfavorable style of play, and accept and carry out unpleasant duties.

### Group Success and Group Cohesion

A question of long-standing interest has been whether cohesion is associated with group success. Popular wisdom has been that it is. For example, as early as 550 BCE, Aesop concluded that “union gives strength.” Research in the 20th century, however, produced results that seemed to contradict Aesop's conclusion. For example, in a narrative review of research on group productivity published in 1972, Ivan Steiner concluded that evidence does not support a positive relationship between group productivity and cohesion.

In 1991, Charles Evans and Kenneth Dion conducted a meta-analysis (a statistical integration of results from many different studies) to reconcile the apparently mixed results of prior studies on cohesion and performance. Based on their analyses, these authors concluded that a positive relationship between group cohesion and performance does exist, though they cautioned that these results should not be generalized to work settings where performance criteria are complex.

In 1994, Brian Mullen and Carolyn Copper conducted another meta-analysis to investigate the relationship between cohesion and performance. Their sample of studies represented a broad spectrum of research from sociology and psychology—dealing with military units, sports teams, work groups, and social groups. Mullen and Copper found that, overall, there was a positive relationship between task cohesion (but not social cohesion) and group performance. Interestingly, they also found that the cohesion–performance relationship was stronger for “real groups” than for artificial groups. With regard to sports teams,

Mullen and Copper found that higher cohesion was associated with enhanced team performance across all types of sports, regardless of the amount of group interaction required.

In 2002, Carron and his colleagues conducted a meta-analysis focusing solely on sports teams. They found that social and task cohesion lead to team success, and task cohesion and social cohesion early in the season contribute to team success later on. And, as in the meta-analysis by Mullen and Copper, Carron and his colleagues found that group success produces increased cohesiveness. Thus, groups that have strong social and/or task bonds perform well, and groups that perform well develop stronger social and/or task bonds.

### *Individual Satisfaction*

Group member satisfaction is also entwined in the cohesion–performance relationship. Research has revealed that perceptions of cohesion contribute to group performance, which in turn produces greater member satisfaction. Member satisfaction then leads to the development of greater group cohesiveness.

### *Jealousy*

Platoon commanders, office managers, coaches, and other leaders spend a great deal of time and effort trying to develop sacrifice behavior, successful performance, group cohesion, and member satisfaction in their groups. Within many groups, there are various issues that can be toxic, if not properly addressed. These can create an unfavorable atmosphere within the group and weaken its cohesion. One such issue is jealousy. Jealousy is a common phenomenon in many groups. For example, one group member might be jealous about the amount of attention that another receives from the group's leader. Or within a family, one sibling may harbor jealousy toward another with regard to his or her appearance, personality, popularity, or some other attribute. In a 2005 study of Division I athletes, Cindra Kamphoff and Diane Gill found negative relationships between both task and social cohesion and the presence of jealousy within a team. Moreover, jealousy was more strongly related to task cohesion than to social cohesion.

### *Shared Beliefs*

Until recently, theorists assumed that group members have similar beliefs about the level of cohesion in their group. Researchers typically measure group cohesion by asking members to (independently) complete a questionnaire pertaining to the group's level of task and/or social cohesion. Members' responses are then combined to create an aggregated score that represents a group-level characteristic.

However, researchers have begun to ask whether it is always appropriate to combine individual perceptions of cohesion. If one group member sees the group as highly cohesive, another as completely lacking in cohesion, and a third holds an intermediate view, then an aggregate score is misleading—members of the group do not possess similar beliefs. Some researchers therefore assess the degree to which shared beliefs are present in a group using an *index of agreement*. With regard to cohesion, the index of agreement provides a statistical measure of the extent to which group members show consensus in their perceptions of the group's level of unity. Assuming there is sufficiently high agreement among members, the index of agreement can be used to justify the aggregation of individual scores.

Recent research with sports teams has shown that group members are more likely to share beliefs about their team's level of cohesion when they perceive that cohesion is strong. That is, individuals tend to agree about cohesion when they are part of a close-knit group, but often disagree about cohesion when their group is more divided. In addition, team members are most likely to possess shared beliefs when judging the team's level of unity around group tasks and least likely to possess shared beliefs when they evaluate the team in terms of how well it satisfies their social needs. This is not surprising because sports teams are task oriented, in that the majority of members' interactions relate to the group's common task, and group success is a high priority.

### *Group Norms*

John Turner, in his referent informational influence theory, has suggested that social identification develops through a three stage process: (1) Social categorization occurs such that individuals perceive themselves as part of a distinct category or

group; (2) Individuals' behavior is strongly influenced by the expectations, attitudes, and behaviors of others in that category or group; and (3) Individuals conform to the expectations (i.e., group norms) and stereotypes associated with the group. Typically, the third stage—conformity to group expectations—is strongly related to the presence of group cohesion. Groups that are strongly united have the potential to exert more influence on their members. A classic study by Stanley Seashore in 1954 illustrates the relationship between group cohesion and productivity standards in work settings. Seashore gave a questionnaire to more than 5,800 employees (in 228 work groups) in a machinery factory. He found that highly cohesive work groups showed less variation in productivity than did less cohesive groups. Highly cohesive groups also had higher or lower group productivity (in comparison to the factory norm for productivity), depending on the extent to which group members perceived the company to be “supportive.”

### *Group Diversity*

Laboratory studies using the minimal group paradigm have shown that stronger ingroup cohesion can produce greater bias toward an outgroup. Of course, it is possible that ingroup and outgroup categorizations also can be applied to members of the same group. Birds of a feather may flock together and produce more cohesion when they do, but many groups require that birds of *different* feathers flock together. Sports teams, military units, and work groups, for example, are often composed of individuals of varying ages, ethnicities, and races—demographic factors that have been shown to be sources of conflict among group members.

As Elizabeth Mannix and Margaret Neale suggested in their 2005 report on workplace diversity, “the optimistic view holds that diversity will lead to an increase in the variety of perspectives and approaches brought to a problem. . . . However, the preponderance of the evidence favors a more pessimistic view: that diversity creates social divisions, which in turn create negative performance outcomes for the group.”

A popular conception is that sports is one place where racial and ethnic conflicts do not exist. The rationale for this conception is that an athletic

self-identity (e.g., “I am an athlete”), coupled with cultural beliefs about the sports context (e.g., “The team’s welfare comes first”), diminish the salience of race and ethnicity. Research with college athletes has provided some support for this conception. Both Black and White college athletes with a strong athletic identity strongly endorse the proposition that racial discrimination is not a problem in sports. Popular media have also supported this notion. In 1971, an award-winning television drama called *Brian’s Song* documented the real-life friendship of professional football players Brian Piccolo, a White running back eventually stricken with cancer, and Gale Sayers, a Black teammate who supported Piccolo during his courageous battle against the disease.

### **Negative Consequences of High Levels of Group Cohesion**

Despite the benefits associated with high levels of cohesion, it has some disadvantages as well. For example, in his classic 1972 work on “groupthink,” Irving Janis described situations in which members’ needs to maintain “groupness” and consensus negatively influence their abilities to consider and critically evaluate alternative ideas or viewpoints. In other words, maintaining a high level of group cohesion and conforming to group norms become more important than paying attention to all the facts. Poor-quality decisions are often the result. Janis noted that involvement in highly cohesive groups is the primary cause for groupthink, although the presence of other variables (e.g., group isolation, directive leadership) contributes as well.

More recently, the potential disadvantages of strong group cohesion were explored within the context of sports. In a 2005 study, James Hardy and his colleagues asked more than 100 athletes (from a number of sports and various competitive levels) about the potential disadvantages of high task and social cohesion in sports teams. More than half of the athletes reported possible disadvantages of high social cohesion, whereas a third reported potential disadvantages of high task cohesion. Some of the reported negative consequences of high social cohesion were at the group level, such as time wasted socializing and failure to communicate information that was less than positive. Others

were at the personal level, such as social isolation of individuals who were not in the core group. Potential disadvantages associated with high task cohesion at the group level included damage to social relations because of an extreme focus on the task at hand. A personal-level disadvantage was that high task cohesion leads to increased pressures to perform well so as not to disappoint teammates.

### Conclusion

Human beings have a fundamental need to affiliate. This need is manifested in nearly every group, no matter how minimal. Even on the basis of arbitrary criteria, individuals quickly develop perceptions of “us” and “them” and then favor the ingroup over the outgroup. So, it is hardly surprising that members of real groups form cohesive bonds around their task and their relationships with one another. In turn, the relative degree to which cohesiveness is present in a group is related to group maintenance (activities associated with the development of the group) and group locomotion (activities associated with the achievement of group goals)—the two fundamental tenets of group dynamics identified by Kurt Lewin. Thus, it is not surprising that some group theoreticians believe that cohesion is the single most important group variable.

## GROUP COMPOSITION

---

A key feature of every group is its composition—the number and types of people who belong. *Group composition* has been studied extensively, though in much of that work, it was studied mostly because of its role in other group phenomena, not as a phenomenon in itself. In any event, much research has been done, and several efforts have been made to review and analyze this work.

One way to organize research on group composition is to focus on the characteristics of group members who were studied. Thus, some researchers study *group size*, which involves the simple presence or absence of group members. Other researchers study the *demographic characteristics* (e.g., race, sex, or age), *abilities* (e.g., knowledge or intelligence), *opinions* (e.g., conservatism or religiosity), or *personalities* (e.g., traits or needs) of group members. Unfortunately, researchers seldom view group composition broadly enough to encompass more than one member characteristic. Researchers who study the sex or racial composition of groups, for example, rarely consider one another’s theories or research findings, even though work on one of those topics might well inform the other.

Another way to organize research on group composition is to focus on measurement issues. How can one compute a single number to capture the composition of a group? Some researchers measure the central tendency among group members, examining their mean score on some characteristic that can vary continuously (e.g., intelligence, conservatism, or emotionality), or the proportion of group members who have some characteristic that is categorical (e.g., Blacks, females, or Republicans). Other researchers are more interested in the variability among group members—the group’s level of diversity. They might examine the range or variance in continuous characteristics (e.g., weight, batting average, sociability) or the distribution of members across the levels of categorical characteristics (e.g., college major, religion). Finally, a few researchers have measured special configurations of characteristics among group members. There has been considerable interest, for example, in the unique problems that can arise in groups containing a “token” member (e.g., a work group of men containing just one woman).

Finally, research on group composition can be organized by focusing on the general conceptual orientation that is taken. Three such orientations can be identified. Most researchers conceptualize group composition as the *cause* for other group phenomena. One might study, for example, the effects of group size on levels of conflict among group members. Other researchers conceptualize group composition as a *consequence* of other factors. One might study, for example, whether groups tend to be especially homogeneous for a particular member characteristic, and if evidence of homogeneity is found, then one could ask how that homogeneity was achieved and is maintained. Are the work groups in an organization mostly made up of White men? If so, then why are there not more women and people of color in those groups? Finally, a few researchers conceptualize group composition as a *context* within which other phenomena can occur—a context that can shape those phenomena. One might study, for example, how the number and ages of a family’s children influence the intellectual development of each child. Do children from larger families, or from families in which many children were born at about the same time, grow up to be less intelligent? If so, then why? This last method of organizing the

literature, by conceptual orientation, is probably the most informative, and so the next sections pursue it further.

### Group Composition as a Consequence

Most groups are rather small. Several researchers have done observational studies of natural groups that people form for various activities (e.g., shopping at a mall, working on a task), and the results are clear and consistent—people prefer smaller groups, often containing just a few members. Why? Several possible answers have been proposed.

First, if we assume that people want to keep track of the ongoing personal relationships (who likes whom) within a group, so that they can use that knowledge to guide their own interpersonal behavior, then larger groups may be more confusing and thus aversive. As the number of people in a group increases, the number of possible relationships (not only between individuals, but also between individuals and subgroups, and between subgroups) obviously increases too, but at a startling, exponential rate. In fact, a group that contains more than just a few members may already exceed the limits of short-term memory (seven plus-or-minus two pieces of information) when it comes to the number of possible relationships. Thus, people may prefer small groups because they are easier to understand.

Another possible explanation why people prefer smaller groups is that bad things happen less often in such groups. Research has shown that larger groups are more likely than smaller ones to experience a variety of negative outcomes, such as deviance, social loafing, and internal conflict. Of course, some of these outcomes can be avoided by strengthening a group’s structure (e.g., status systems, norms, roles), or by devoting more resources to monitoring and controlling members’ behaviors. But such changes can make membership in the group less satisfying and may alienate some members, which strengthens their preference for smaller groups.

Finally, evolutionary psychologists have noted that in the animal kingdom, creatures that are inherently social often seem to organize themselves into groups of a particular size. For example, a given species of birds will form flocks that are all about the same size. This “species-specific group

size” may reflect the optimal balance point between membership in smaller versus larger groups when it comes to such issues as feeding, reproduction, nurturance, and defense. A larger group, for example, might offer more opportunities for possible mates, but it would also entail greater competition for such mates. Maybe humanity, as an inherently social species, has “discovered” across long periods of evolutionary history that smaller groups have greater survival value. As a result, such groups are preferred in general and without much thought.

The fact that people prefer smaller groups means that efforts to create or maintain a large group are unlikely to succeed. What often happens is that a large group will break apart into smaller cliques, which may or may not like one another, work together well, and so on. Special tactics may be needed to avoid these problems.

What about diversity in groups? Several studies have shown that groups are usually homogeneous, rather than heterogeneous. Why? Maybe it is because homogeneous groups are less likely than heterogeneous ones to experience various problems, such as miscommunication, mistrust, and lack of cohesion. This might be why people are less committed to more heterogeneous groups, put less effort into such groups, and are more likely to quit them. Another possible explanation is that homogeneity is a natural by-product of group socialization practices. Because similarity is an important source of interpersonal attraction, people are more likely to join (and remain in) groups whose members are more similar to themselves. And groups are more likely to admit (and try to retain) people who are more similar to their members. Diversity is thus rare, unless outside pressures (e.g., affirmative action programs) are brought to bear. Even when diversity does arise in a group, it often “corrects” itself over time through attrition. The people most likely to leave a diverse group are those who are most different from the other members.

The fact that people prefer more homogeneous groups means that efforts to create or maintain more heterogeneous groups are also unlikely to succeed, unless special tactics are used. The members of heterogeneous groups must be led to accept, appreciate, and make productive use of their differences from one another. This is necessary not only for reasons of social justice (people should not be excluded from work groups, for

example, just because of their sex or race), but also because a few studies have shown that diversity can improve group performance, especially on tasks that require creativity.

### Group Composition as a Context

Few researchers have studied group composition as a context, which seems a shame, given that almost every psychological phenomenon can occur in groups of many types, whether they be families, neighbors, coworkers, or others. So, if the composition of a group can indeed shape the way a phenomenon unfolds, then we should explore how and why such shaping occurs. Consider, for example, a study done several years ago on the relationship between scholastic aptitude (as measured by the scores of high school students on the SAT) and academic performance (as measured by those students’ grades later on, during their first semester in college). This phenomenon is well understood, of course—students with greater scholastic aptitude tend to perform better academically. And that is exactly what was found in this study, but what made it special was that the researchers examined students who were living in different settings at college—at home, in a dormitory, or in fraternity or sorority houses. Although the impact of SAT scores on college grades was always positive, it proved to be strongest among students living at home, somewhat weaker among students living in college dormitories, and weakest among students living in fraternities and sororities. Why? Maybe because the values of those people students lived with in those different settings were dissimilar, suggesting that group composition effects were occurring. Students’ families probably valued their academic achievement more than did students’ dormitory roommates, who probably valued achievement more than did the student’s Greek “brothers” and “sisters.” Put another way, the scholastic aptitude of a student was converted into actual academic achievement more thoroughly when the student lived in a setting where others thought that achievement mattered.

### Group Composition as a Cause

Most researchers who study group composition think of it as a cause for other group phenomena

of interest. The underlying premise of their work is that if we understood more about group composition, then it might be possible to create groups that were just the right size, or that contained just the right kinds of members, to ensure that various positive outcomes occurred (or that various negative outcomes did not occur). Consider, for example, all the effort that the coaches, managers, and owners of sports teams put into drafting the right players. What about all the trouble that lawyers go to when selecting the right jurors for a murder trial, or all the concern that has been voiced by both politicians and voters about how many conservative and liberal justices (whose other qualities, such as gender, age, and ethnicity, are debated as well) ought to sit on the U.S. Supreme Court? Finally, consider attempts by therapists to create groups that contain the right kinds of patients—people whose interactions will have the greatest possible therapeutic value for everyone involved.

There are many theories (each with associated research findings) that reflect the conceptualization of group composition as a cause, but this work tends to be narrow—researchers seldom consider more than one member characteristic, even though there could be parallels in how composition effects involving different characteristics occur. In an attempt to take a broader approach, Richard Moreland and John Levine developed a “generic” theory of group composition efforts, one that spans different member characteristics. They began by asking three broad questions that such a theory ought to be capable of answering. First, of all the characteristics that the members of a group possess, which characteristics will matter most in a given situation? Will race be important? What about intelligence? Second, once some characteristic has been identified as important, which group members (each of whom possesses some level of that characteristic) will be most important? Does one person’s intelligence, for example, matter as much for the group as another person’s intelligence, and if so, why? Finally, how do members’ characteristics combine to affect the group? That is, what kinds of transformations (from the individual to the group level) are possible, and when will transformations of each kind occur?

Moreland and Levine’s answer to the first question involved the notion of *salience*. A particular member characteristic, they argued, becomes

important to the extent that group members notice it in one another and believe that it matters. Demographic characteristics, such as age or race or sex, should thus produce stronger composition effects than other member characteristics, because they are inherently more salient and because people generally see them as more important for their social interaction. Moreover, composition effects that involve these “surface” characteristics should occur earlier in the life of a group than composition effects that involve “deep” characteristics, such as abilities, opinions, or personality traits, because the latter require more time for members to assess. A characteristic can also gain or lose salience depending on various situational factors, such as the distribution of that characteristic among group members, the task on which a group is working, or the outsiders with whom a group must deal. For example, sex is a more salient in groups that contain a token female member, camping skills are more salient to groups about to go on outdoor retreats, and political beliefs are more salient to groups whose members have political axes to grind. In all these cases, increases in the salience of the characteristic would make relevant composition effects more likely to occur.

Moreland and Levine’s answer to the second question involved the notion of visibility. A particular group member, they argued, is visible to the extent that others can tell what his or her characteristics are, and the more visible someone becomes, the more impact that person’s characteristics will have on the group. What makes some group members more visible than others? Visibility can arise from higher status in the group, from more frequent (or intense) participation in group activities, or from longer membership in the group (seniority). Someone who has played an especially important role in the life of the group may also have a lot of visibility. For example, a group’s “founder” can sometimes imprint his or her personality on the group (consider Steve Jobs and Apple). It is also possible for someone to gain or lose visibility because of situational factors like the kind of task the group must perform. If an engineering group is asked to solve some complex design problem, for example, and only one of its members has been trained to solve such problems, then that person will suddenly become more visible to the rest of the group.

To answer the third and final question, Moreland and Levine evoked the notions of transformation rules and social integration. Transformations of member characteristics into group characteristics can follow two rules, one simple and the other complex. The *additive rule* is relatively simple—the more of some characteristic that exists among the members of a group, the more that group will be shaped by it. A basketball team whose players are better at making 3-point shots, for example, will probably win more of its games. A work group containing more men will probably take more aggressive action toward competitors. And the Supreme Court is probably more likely to make abortion illegal if some future president appoints additional conservative justices. Under the additive rule, each member affects the group independently of every other, so it hardly matters what the other members are like. This implies a corollary, namely, that any particular person will affect every group to which he or she belongs in about the same way.

The *interactive rule* is more complex, corresponding to what many people call “chemistry” in groups. Sometimes individual characteristics combine in strange, often unexpected ways. A team of mediocre football players, for example, surprises fans by winning most of its games, or a team of star players fails to win many games, enraging fans. Under the interactive rule, the effects of different members on the group are interdependent—one member’s impact depends a lot on what the other members are like. And again, there is a corollary, namely, that any particular person can affect every group to which he or she belongs in a quite different way.

When do these different transformation rules operate? Based on a review of the literature on group composition effects, Moreland and Levine argued that the additive rule always operates, even in laboratory groups, where strangers meet briefly to carry out a trivial task. It is not difficult, in fact, to find published accounts of additive composition effects. But the interactive rule seems to operate only in groups that have higher levels of social integration—groups that are more “real,” because they operate out in the world, exist for longer periods, carry out more important tasks, and so on. Published accounts of interactive composition effects are difficult to find—chemistry in groups, for better or worse, appears to be a rare thing,

something that newly formed or temporary groups are unlikely to experience.

We are still a long way from understanding group composition effects well enough to create ideal groups—groups that are the perfect size and contain exactly the right kinds of members. But interest in this topic has been growing, leading to some valuable new theories and research findings. Optimism is thus justified.

## GROUP DEVELOPMENT

---

Whether there are predictable patterns of development in small groups has been of interest to group scholars and practitioners for some time. Theories of *group development* differ in what and how many levels of analysis they focus on. Some mostly stick to the group level, treating the group as a whole unit and its members and their experiences as relatively homogeneous. Others focus on the development of individual members into, through, and out of groups. Still other theories focus on how groups develop in the context of their embedding environments. Recent theories attempt to incorporate all three levels of analysis by considering the interplay among the group, its members, and its context over time.

### Group-Level Theories

Theories that focus on the group as a unit consider the different stages of interaction the group moves through over time. Some of these theories propose sequential stages, envisioning groups as moving from one stage to the next in a given order. Other theories propose flexible stages, envisioning groups as skipping or repeating stages as needed.

Group-level theories of development have been largely based on studies of groups that have been assembled to accomplish a particular task and have little or no member attrition or replacement. For example, Bruce Tuckman's famous review was based largely on studies of therapy and training groups with stable memberships, and the pioneering work of Warren Bennis and Herbert Shepard was based on groups with fixed memberships that attempted to improve their internal communication.

Theories of group development typically identify up to three aspects of development: (1) task activity, (2) member experiences, and/or (3) group norms. Theories also identify three or more stages of group development: (1) a beginning, involving formation and orientation; (2) a middle, involving coordination and performance; and (3) an end, involving task completion and/or the dissolution of the group.

One of the first theories of group development was proposed by Robert Bales and Fred Strodbeck

in 1951 to address phases of group problem solving. These researchers divided into thirds the interaction time of eight groups of men engaged in a variety of decision-making tasks (e.g., planning a thesis, making arrangements for a Christmas party, devising strategy for a chess game) and then tallied the number of acts of orientation (providing or requesting information, repetition, clarification, or confirmation), evaluation (providing or requesting evaluation, analysis, emotional expression, and wishes), and control (providing or requesting direction and autonomy) in each third. Orientation, evaluation, and control occurred in all three phases of problem solving, but orientation peaked in phase one, evaluation in phase two, and control in phase three. Bales and Strodbeck concluded that problem-solving groups move from an emphasis on problems of orientation to problems of evaluation to problems of control.

In 1956 Bennis and Shepard, who studied groups that were trying to improve their internal communication systems, proposed that groups face two major and competing obstacles: (1) members' orientations toward how power should be handled and distributed in the group and (2) members' orientations toward each other. Based on these obstacles, Bennis and Shepard proposed that groups undergo two major phases of development: (1) preoccupation with authority relations and (2) preoccupation with personal relations.

Echoing similar themes of authority and intimacy in groups, in 1958 William Schutz proposed the Fundamental Interpersonal Relations Orientation (FIRO) model of human relations based on studies of U.S. Navy groups. Schutz proposed that all human interactions move from resolving issues of inclusion (being with, belonging to, and receiving attention) to resolving issues of control (having power, influence, and authority) to resolving issues of affection (sharing feelings and inner thoughts). Schutz proposed that human interaction defaults to an earlier stage if issues in the next stage are not successfully resolved.

In 1965, Tuckman proposed what has become the best known theory of group development. Based on a review of studies and theories of groups over time, Tuckman proposed a four-stage model of group development with the rhyming labels of forming, storming, norming, and performing. Tuckman and Mary Ann Jensen later added a fifth

and final stage, which they called adjourning. Tuckman discussed both the interpersonal and the task processes of the group during each stage. When the group is forming, members look to others to provide guidance, information, and feedback about what interpersonal and task behaviors are acceptable in the group. While storming (which Tuckman suggested might be skipped by task-focused groups), members attempt to express their individuality and resist the formation of group structures. During norming, members accept the group and the idiosyncrasies of other members and begin to interact harmoniously and openly to avoid conflict. In the performing stage, members constructively try to complete the group task. Finally, when the group is adjourning, members struggle to accept the end of the group.

Subsequent group-level models echoed earlier ones. In 1974 Rosemary Sarri and Maeda Galinsky proposed three dimensions of group development: (1) social organization (the structure and pattern of member roles in the group), (2) task activities, and (3) group culture (the norms and expectations that characterize the group). They also specified seven stages of group development: (1) origin (composing the group), (2) formative (seeking mutual interests), (3) intermediate (moderate group cohesion), (4) revision (challenges to existing group), (5) intermediate phase 2 (cohesion after revision), (6) maturation (stabilization of processes), and (7) termination (dissolution and/or goal attainment). In 1980 Roy Lacoursier proposed a five-stage model of group development that resembled Tuckman's model—his stages were labeled orientation, dissatisfaction, resolution, production, and termination.

In the 1990s extensions of prior models were proposed that combined stages or made them more flexible. Susan Wheelan proposed five stages of group development: (1) dependency and inclusion, when members worry about being accepted and included in the group; (2) counterdependency, when members experience conflict over group goals and procedures; (3) trust and structure, when norms and roles are more established and secure; (4) work and productivity, when members focus on task accomplishment; and (5) the final or termination stage, which groups with distinct end points experience. Stephen Worchel proposed a cyclical model with six stages: (1) discontent, before members strongly identify with the group; (2) group

identification, when a precipitating event motivates group identification and coordination; (3) group productivity, characterized by collaborative work; (4) individuation, when members want individual recognition for their contributions; and (5) decay, when the group begins to return to discontent.

Though stage models of group development appear to suggest that groups move linearly from one stage to the next over time, most theorists have allowed exceptions to this rule (e.g., Tuckman suggested that groups may skip storming or revisit it) or back-and-forth cycles between stages (e.g., Stephen Worchel's cyclic model). Many scholars have criticized stage models of group development for treating groups as closed systems that are largely impervious to their embedding environments and for being descriptive without outlining the processes underlying group transitions between stages.

## Multilevel Theories

### *Member–Group Relations*

Taking a different perspective on group development and focusing on the member–group relationship over time, Richard Moreland and John Levine proposed a model of group socialization in 1982 that provides a flexible template for studying member movement into, through, and out of groups. Unlike other theories of group development, the model of group socialization can be easily applied to study ongoing groups experiencing membership change.

Based on a social exchange approach to the member–group relationship, Moreland and Levine's model of socialization assumes that groups and individuals exercise influence over each other and that the relationship between them changes in a systematic way over time. Three psychological processes are at work in the model: evaluation, commitment, and role transitions. The individual evaluates the extent to which a group will meet his or her needs, and the group evaluates the extent to which an individual will contribute to attaining group goals. These evaluations result in individual and group levels of commitment to one another, which are related to a number of important outcomes. A group that is committed to an individual is likely to work to satisfy that individual's needs and retain that individual as a member, whereas individuals who are committed to a group are

likely to work hard at achieving group goals and maintain their membership. Changes in commitment are also important because they lead to role transitions in the group. Through this process, individuals pass through five phases of membership in groups (investigation, socialization, maintenance, resocialization, and remembrance), which are divided by four role transitions (entry, acceptance, divergence, exit).

### *The Group in Context*

Rather than looking inward at members' experiences within and movement through groups, models that focus on how the group develops in relation to its context look outward to the group's embedding context to predict group development. Connie Gersick's "punctuated equilibrium" model of group development suggests that deadlines shape group development. Through an in-depth observational study of eight naturally occurring work groups, whose life spans ranged from 7 days to 6 months, Gersick discovered that the first half of a group's interaction was characterized by an approach to accomplishing the group task that was adopted without explicit discussion. At the halfway point between the first group meeting and the task deadline, however, a group often reevaluated its original approach, developed a new one, and then executed that approach to meet the deadline. The punctuated equilibrium model thus proposes two major stages of group development: one before the middle of a group's life span and a second after its midpoint, both driven by the group's task deadline. Gersick's model is unique compared to previous ones, which largely propose that groups pass through stages of development in a predictable and sequential fashion. The punctuated equilibrium model instead proposes that groups undergo long periods without change, followed by sudden change caused by "revolutionary events," such as reaching the temporal midpoint of a project.

Artemis Chang and her colleagues later suggested that the punctuated equilibrium model and other stage models of group development (such as Wheelan's integrative model) could be viewed as complementary, in part because the integrative model outlines the lower level processes at work within Gersick's two phases. When studying

simulated work groups in a laboratory setting, Chang and her colleagues observed patterns of both punctuated equilibrium and linear progression in groups.

### *Member-Group-Context Dynamics*

Recent models of group development incorporate all three levels of analysis to explain group adaptation to context, members' needs, and interpersonal dynamics in the group over time. For example, Deborah Ancona and her colleagues have studied the roles that different work group members play while managing the group's relationship with the embedding context (usually a work organization). Mary Waller and her colleagues have examined the mutual adaptation of members' work rhythms in groups, based on their preferences for pacing and planning and the task demands placed on groups by their environments.

Others have theorized about what stimulates change in groups over time. Scott Poole and his colleagues proposed four sources of change in groups over time: (1) life cycle change, or group development as it is traditionally conceived of as a prescribed sequence of stages imminent within, or imposed on, groups; (2) teleological change, or purposeful movement toward group goals that adapts to feedback from the group's environment; (3) dialectical change, which emerges from conflict between opposing viewpoints and forces; and (4) evolutionary change, which emerges from repeated cycles of variation, selection, and retention of group members, goals, and strategies.

Holly Arrow, Joseph McGrath, and their colleagues proposed typologies of groups and development trajectories over time based on the complex interaction among local, global, and contextual group dynamics. At the local level are members, tasks, and tools (i.e., group resources and procedures) and their characteristics; at the global level are emergent structures and norms in the group that emerge from and subsequently constrain local dynamics; at the contextual level are aspects of the group's environment, such as deadlines, the organizational environment, and threats and opportunities. Arrow, McGrath, and their colleagues propose possible trajectories of development for various aspects of groups. These trajectories include (1) robust equilibrium, in which an aspect

of a group converges on a stable state and remains there; (2) multistability, in which an aspect of a group alternates between two or more equilibria over time; and (3) instability, in which an aspect of a group demonstrates instability or a chaotic pattern over time. Aspects of groups that may follow one or more of these trajectories include (1) commitment levels between members and their groups (from Moreland and Levine's model of group socialization), (2) project output and performance, (3) division of labor and roles within the group, (4) information sharing, (5) conflict, and (6) group norms and procedures.

As this entry indicates, there is a good deal of scholarly interest in group development. A variety of theoretical perspectives have been offered to describe and explain how groups develop over time, and each of these perspectives has both strengths and weaknesses. Recent theories that consider the interplay among the group, its members, and its context over time appear to be particularly promising.

## GROUP DISSOLUTION

---

*Group dissolution* is a topic that has attracted much attention recently. Scientists are interested in theoretical issues, such as how and why groups dissolve, whereas practitioners are interested in more pragmatic issues, such as how to delay the dissolution of groups that are helpful (e.g., self-help groups) and how to hasten the dissolution of groups that are harmful (e.g., youth gangs, terrorist cells).

One way to organize work on group dissolution is to distinguish between two general scenarios. The first involves the dissolution of groups that were not expected to last for a long time (e.g., juries, therapy groups, task forces, health care teams, and negotiating teams). Members of such groups know right from the start that their groups will someday dissolve. They may even know (if only roughly) when that will occur. A second scenario involves groups that could, at least in principle, last indefinitely (assuming things go well). Many groups are of this sort, though turnover among members (and other changes over time) can be viewed as part of a continual “dissolution” process, in which the current incarnation of the group keeps disappearing and is replaced by newer incarnations. Dissolution is a somewhat different phenomenon in these two scenarios, so they are considered separately in this entry.

### Expected Dissolution

How are groups affected by the knowledge that they will surely dissolve? Research on how anticipated future interaction affects relationships shows that people who expect to continue interacting with one another often behave in ways that produce interpersonal attraction. For example, they (a) disclose more information about themselves, (b) gather more information about others and

remember such information better, and (c) act more cooperatively. Interpersonal attraction within a group should strengthen its cohesion. All of this suggests that there might be less cohesion, and perhaps more conflict, in a group that members expect will dissolve. Ironically, these effects might hasten the group's demise.

Another possible effect of expected dissolution involves group development. In 1988, Connie Gersick published a study of groups that were working on projects with definite deadlines (after which the groups were expected to dissolve). She found that knowledge about the dissolution of a group structured its members' activities. In the groups that Gersick studied, members began their projects quickly, without much planning, and worked hard until about half their time was gone. Then, suddenly, they paused to reconsider what they were doing. As part of that reflection process, the group members often sought more information. Then they began to work hard again, but often in different ways, reflecting changes in their strategies. Gersick did not study any groups that did not expect to dissolve, but her findings imply that such groups might not have stopped to reflect and change strategies, or at least that they might have done that only as needed rather than at any particular point in time.

There has been considerable research on how members react just before a group dissolves that was always expected to dissolve. Some of this work was summarized in a 1977 article by Bruce Tuckman and Mary Ann Jensen. They proposed that a new stage of group development ("adjourning") be added to the four stages already proposed by Tuckman (forming, storming, norming, and performing). Much of the work that Tuckman and Jensen reviewed involved counseling or therapy groups, but other researchers, such as Joann Keyton and James Krantz, have studied reactions to the impending dissolution of work groups, like those embedded in organizations that are going out of business. Some common themes can be found in all of this work. People in groups that are about to dissolve struggle to complete whatever group tasks remain, but that is often difficult, in part because they feel sad, discouraged, and anxious about the future. Special events (e.g., parties) may be held, at which group members reminisce about the past, exchange contact information so

that they can keep in touch, and plan possible future "meetings" of the old group. But people who once were in a group together often find it difficult to maintain any meaningful relationships with one another.

### Unexpected Dissolution

Many groups don't expect to dissolve, so their members do not think about it unless serious problems arise that make the group's possible dissolution more salient. Those problems can be internal or external in origin. A major internal problem for many groups is conflict among members. Although conflict has some benefits, it can also damage a group in serious ways. To the extent that group members are fighting with one another, for example, they have less time and energy to accomplish the group's tasks. As a result, the group begins to fail, which weakens both the commitment of its members and support for the group among outsiders. As conflict intensifies, some members may leave the group, and prospective members may be reluctant to join because the group seems so unpleasant. As a result, the group shrinks and may eventually disappear. Several kinds of external problems are possible. For example, a group may lose support from stakeholders, who withdraw resources that the group needs to survive. Or a group may antagonize authorities or competitors, who decide that it ought to be weakened or even destroyed. Paradoxically, attacks from outsiders often backfire—according to K. L. Dion, group members naturally resent such attacks and react by becoming more cohesive and working harder to keep the group alive.

Whether a group's problems are internal or external, they may not always be clear to group members. A process of problem identification, described by Richard Moreland and John Levine, is often required. A problem must first be detected and diagnosed, then the group must develop possible solutions for it, and finally the "best" solution must be chosen and implemented. Research suggests that groups do not do any of these very well—they are often slow to detect problems and may diagnose problems incorrectly. As for developing solutions, many groups decide that the only solution needed is to simply keep on doing what they have been doing, but with more intensity.

And even when groups admit the need for change, they often prefer to “borrow” solutions for their problems (solutions that have been used before, by themselves or other groups) rather than trying to develop new solutions. Borrowed solutions, of course, do not always “fit” the problems they are meant to solve. Finally, when groups try to choose the best solution for a problem, they often limit their options to just a few alternatives, even when more solutions are available.

These and other mistakes force many groups to cycle back through the process of problem identification repeatedly, wasting time and energy. This contributes (along with several other factors) to a general trend toward failure. Large problems often cannot be solved, and small problems frequently grow larger and larger, until they cannot be solved either. Many groups that never expected to dissolve thus reach at some point the realization that they will soon dissolve.

When that point has been reached, some of the activities and emotions described earlier (for people who expect their groups to dissolve) are likely to occur again, but with two differences. First, members of these groups want to understand *why* their groups are dissolving. What went wrong? Who is to blame? Could anything have been done to preserve the group, and if so, then why was it not done? Considerable sense-making activity thus occurs among members, much of it involving attributions for the failure of the group. Outsiders are likely to be blamed, if that makes any sense at all, but if not, then leaders and other high-status members of the group are targeted. A second difference is emotional in nature. Besides feeling sad, discouraged, and anxious about the future (like people who expect their groups to dissolve), members of these groups often feel angry as well—not only with others but often with themselves. That anger can sometimes lead to aggression.

### Conclusion

Maybe the issue of group dissolution is less important than it seems. Social identity theorists have long argued that a group exists and can influence people’s behavior whenever those people simply think about themselves as group members. If that is correct, then a group could survive almost indefinitely, so long as people remember the group and

categorize themselves as members. That is either a comforting or a disturbing prospect, depending on the group.

## GROUP ECOLOGY

---

Ecology is a branch of biology that analyzes the relationship between an organism and the setting where it lives. Groups can be analyzed in this way too. Every group occupies some setting, and no group can be fully understood without analyzing that setting. Analyses of the settings that groups occupy reveal a variety of environmental factors, ranging from the physical to the social to

the temporal. Although researchers usually study the effects of environmental factors on groups, attempts by groups to control those factors are sometimes studied as well. That is, a setting can be both a cause and an effect of group activities.

### Physical Environments

The physical environments of groups have been especially interesting to researchers. One popular research area is crowding. The effects of crowding on groups are studied in residential areas, college dormitories, and prisons, as well as laboratories. As people feel more crowded, they exhibit greater stress, worse performance (especially on more complex tasks), and more negative social relations. These effects are believed to be mediated by several factors, including loss of control, cognitive overload, and behavioral constraints. Some researchers have found that groups, rather than being the reason why people feel crowded, can sometimes provide solutions to crowding problems. In a crowded dormitory, for example, a friendship group might form and "take over" several rooms or a lounge area. This could restore group members' sense of control, reduce their cognitive overload, and weaken some of the constraints on their behavior.

A related area of research involves groups that work in "exotic" environments, such as outer space, underground, underwater, or at the poles. These environments are generally dangerous, confining, and impoverished in terms of stimulation. Common responses by groups to such environments include increased cohesion, greater pressure on members to conform, and the development of strong leadership. Groups apparently adapt in these ways to eliminate or control any problems that are internal to the group, so that the group's external problems can be handled more effectively.

Another area of research on physical environments involves groups that work in factories or offices. Underlying this research is the assumption that working conditions affect job satisfaction, which in turn affects how productive workers are. Temperature, lighting, floor space, noise, and provisions for privacy have all been shown to affect workers, but individual reactions to such factors may well be shaped by groups. Judgments about working conditions are often made collectively, rather than individually. Several theorists, including

Gerald Salancik and Jeffrey Pfeffer in a 1978 publication, have argued that various social processes can influence workers' opinions about whether their jobs are interesting, their salaries are adequate, and so forth. For example, members of work groups may call attention to some factors more than others, evaluate some factors more positively than others, "explain" why things are the way that they are now, or predict whether and when things might get better or worse. It would not be surprising, then, if judgments about the work environment were affected in these ways as well.

The computerization of offices has led researchers to study the impact of technology on workgroups. A wide variety of computer systems have been studied, including (a) simple word-processing or accounting programs; (b) complex collaborative writing/editing programs; (c) electronic mail, bulletin boards, and chat rooms; and (d) support systems for group decision making. E-mail has been studied most often. The evidence suggests e-mail can affect workgroups in several ways, such as reducing overall communication, equalizing participation levels, weakening status systems, emphasizing informational rather than normative influence, and encouraging deviance. There is little evidence that e-mail improves group productivity.

The research described so far has focused on how the physical environment can affect a group. But there are also several ways in which a group might try to control its physical environment. Some groups, for example, have the resources and mobility to seek out pleasant environments or avoid unpleasant ones. And some groups can alter their environments in ways that make them more pleasant. Finally, it is often possible for a group to interpret its environment in ways that make it seem more pleasant.

Few researchers have studied how groups move from one environment to another. A more popular focus of research is on how groups try to alter their environments. Much of this research involves territoriality. Many groups, such as youth gangs, mark territories and then defend them against outsiders. Primary territories, which are owned by groups and used by them often (e.g., family homes), are the ones most likely to be marked and defended, but secondary and public territories are sometimes treated that way as well. Secondary territories (e.g., a corner bar or certain tables in a dormitory cafeteria) are not

owned by groups, but are used often by them. Public territories (e.g., a picnic table, camping space, or spot on the beach) are neither owned nor used often, but still may be viewed by groups as their “possessions” for periods of time. Some groups also apportion their primary territory among members, usually on the basis of status. This occurs in families (e.g., mothers and fathers “own” different parts of the house), work groups (e.g., the boss has an office with lots of space, windows, and special furnishings), and even college classrooms (e.g., good students often sit toward the front and center and poor students often sit toward the back and sides).

Territoriality is alleged to serve several purposes for groups. A territory could help a group to (a) protect valuable resources, (b) improve living/working conditions, (c) gain a sense of privacy, (d) control social interactions, (e) become more cohesive, and (f) express a social identity. And when certain members take or are given special areas of a group’s territory for their own, they could enjoy some of these same benefits at a more personal level. However, there is little evidence that territoriality actually produces benefits like these for groups or their members.

Although group territories are usually fixed in space, it may be possible for groups to create portable territories that can be transported from one location to another. There is considerable research on the “personal spaces” of individuals—invisible “force fields” that people carry around with them in order to buffer themselves from the world. When someone “invades” another person’s space, that person is likely to back away until the space is restored, and if the invader does the same thing again, then the person may well react angrily. Do “group spaces” exist too, and if so, then are they like the personal spaces of individuals? Two types of research suggest that the answer to both questions is “yes.”

First, *invasion studies* examine how groups react when outsiders try to pass through them (e.g., someone walks through the middle of a group of several people talking together in the hallway). Research has shown that outsiders try to avoid doing this, and when it must be done, they seem embarrassed and may even apologize to the group, as if realizing they have misbehaved. The group, in turn, is likely to be annoyed and may glare at the intruder or say something hostile to him or her.

These reactions vary with characteristics of both the group and the invader. For example, a larger group, or one whose members have higher external status or are interacting more intensely (e.g., arguing), is less likely to be invaded and will react more negatively if its space is invaded. And if situational constraints (e.g., a narrow hallway) “force” someone to invade a group, or the invader has a higher external status, or apologizes for his or her misbehavior, then a group is likely to react less negatively to a violation of its space.

A second type of research on group spaces involves *deflection studies*. Imagine an area in which sight lines prevent people from seeing a group until they are almost upon it. For example, a group may be doing something in an alcove located just off a hallway. This hides the group for a while from people walking down the hall, until they come close enough to discover that the group is there. If “group spaces” indeed exist, then a deflection ought to occur in these situations—the people walking by should change their course suddenly, as though they were “bouncing” off a kind of force field. This is exactly what happens, and some of the same individual and group variables that affect behavior in invasion studies operate in deflection studies and with similar effects.

A few theorists have tried to analyze how groups interpret their physical environment. For example Daniel Stokols argued in a 1981 paper that when a group has occupied a place for a long time and conducted many activities there, that place will acquire special meanings that become shared among members. Those meanings may be functional, motivational, or evaluative and can produce *place dependence* and other important consequences. Place dependence means that moving the group to another place, even one that seems to offer similar or better resources, can be very unsettling to the group and might cause unforeseen and unwelcome changes in its structure, dynamics, or performance. For example, moving a family from one house to another might alter the relationship between a husband and wife or the relationships between parents and their children.

### Social Environments

The social environments of groups have been studied less often. The most popular research area is

clearly intergroup relations. Several other entries in this Encyclopedia are about intergroup relations and related issues, so there is little need to explore that topic here. A few points are worth noting, however. First, many researchers seem to assume that groups relate to one another in a social vacuum. Usually, only two groups are studied, and they have no connections to one another. Yet nearly all groups are bound together in some way, because they share members, have developed friendship ties that cross group boundaries, or are embedded in the same social network. Also, other groups or individuals often intervene in intergroup relations if they believe that their own outcomes could be affected. As a result, intergroup relations are usually complex, involving many actors related to one another in a variety of ways.

Researchers also seem to assume that intergroup relations are nearly always competitive, yet there is clear evidence of cooperation among groups. Sometimes that cooperation is indirect, as when one group imitates others by importing their procedures or uses other groups for social comparison purposes. More direct forms of cooperation are possible too, as when groups exchange valuable resources, form alliances to attain common goals, or merge to form new groups. These and other cooperative relations among groups often emerge in the context of groups having shared superordinate goals that cannot be achieved by working in isolation or in competition.

There are, of course, other areas of research on the social environments of groups. One of them involves groups embedded in organizations. Most of this research focuses on formal work groups within business organizations. Work groups are often shaped by the organizations in which they operate. For example, work groups in organizations that are failing can adapt to their unfortunate circumstances. Organizations of all kinds offer opportunities for informal groups to form and operate as well. In fact, organizations can be viewed as large social networks that link individuals and groups with one another in many different ways.

Another area of research on social environments involves groups that share one or more members. A single person can belong to several different groups. This produces interdependence among those groups, because experiences in one group can affect the person's behavior in all the others to

which he or she belongs. This phenomenon occurs often in families. For example Urie Bronfenbrenner in a 1986 publication noted that child development, which seems to occur primarily within a family, can also be influenced by other groups to which children and their parents belong. Problems at work that parents experience, for example, may be brought home by them, causing them to neglect or even mistreat their children. And peer groups to which children belong may lead them to misbehave, causing their parents to become angry and mistrusting. Sometimes two groups overlap so much that they are nearly the same group. Family businesses can be both strengthened and weakened, for example, by the merging of family and business affairs. What can a parent who runs a business do about a bumbling worker who happens to be a son or daughter? Family businesses must often develop special procedures for regulating the family-business boundary.

Groups are often influenced by people who are not actually members. These people include prospective and ex-members, friends and relatives, customers and clients, and enemies. An "outsider" can, for example, sometimes change a group's performance, as when a sports fan cheers for the home team and/or mocks the visiting team during a big game, thereby helping the home team to win that game. Outsiders can also change the atmosphere within a group, as when a lone woman enters a bar containing only male patrons. More direct forms of influence are also possible, as when people are recruited into new groups by their friends, or someone persuades a person to leave his or her current group and join that person's group instead.

Finally, all groups are embedded within a culture, whether it be national or regional. At least some of the variability among groups may thus reflect cultural differences, and some of the changes groups undergo may reflect cultural trends. Unfortunately, little research on these matters has been conducted.

The research described so far has (again) focused on how the social environment can affect a group. But groups can and do try to control the social environments that they occupy. Deborah Ancona has studied this phenomenon extensively among work groups within business organizations. She believes that the best groups adapt to their organizational settings through various boundary-spanning

activities, such as negotiation (bargaining for necessary resources), scanning (acquiring valuable information), profile management (impressing powerful others), and buffering (defending against current or anticipated attacks). Ancona has found that special roles (e.g., ambassador, scout, guard) associated with these activities develop within many work groups. More importantly, Ancona has found that work groups perform better if they carry out more boundary-spanning activities, through these roles or in other ways. In fact, she argues that a work group's success often depends less on what is happening inside the group than on what is happening around it.

### Temporal Environments

Several other entries in this encyclopedia examine ways in which time could influence groups (e.g., the formation, development, and dissolution of groups, and group socialization). So, little more needs to be said here about those phenomena. There are other ways, however, in which temporal environments can affect groups. For example, consider how work groups react to time pressures. One interesting example of those effects is *temporal entrainment*. If a work group is given a specific amount of time to perform a task, then its members adjust their behavior to suit whatever time they have. If the situation changes, so that more or less time becomes available, then group members ought to change their behavior accordingly. But, in fact, they do not—they keep on working as if the original time limit were still in place. Why? Maybe this is a specific example of a more general phenomenon, namely, the difficulty that groups often have with changing their routines.

Other interesting work on how time pressure affects groups has been reported by Steven Karau and Janice Kelly in a 2004 publication. They proposed and tested an “attentional focus” model of such effects. According to their model, time pressure leads group members to focus on a restricted range of task cues and to adopt task completion as their major goal. All this changes how group members act toward one another (e.g., less socializing, more impatience) and how well they perform their task (e.g., better at tasks for which quantity of output is more important, worse at tasks for which quality matters more). A narrow focus of attention

seems to affect the recall of information about the task, not the initial encoding of that information. Group members under time pressure absorb just as much information about a task as they would otherwise, but then later on they become more selective than they otherwise would be in their memories of that information. Information that seems less relevant to their goal is likely to be forgotten.

Although time can affect groups in several ways, groups are not helpless time travelers. Research suggests that they often try to control their temporal environment. For example, Gregory Janicik and Caroline Bartel argued in a 2003 publication that work groups control time through allocation (how much time should be devoted to achieving various goals?), scheduling (when must projects relevant to those goals be done?), and synchronization (what should each group member be working on at a given moment?). In a study that tested these claims, they found that when groups spent more time at temporal planning, which included allocation, scheduling, and synchronization activities, their performance improved. Other research on the control of time includes work on “temporal orientations” in groups (members may focus on the past, present, or future) and work on how groups might be strengthened by traditions and periodic rituals.

### Conclusion

The physical, social, and temporal environments in which groups operate are clearly important. They not only influence the groups that occupy them, but they are also the targets of group activities designed to change them. Yet group environments are rarely salient to groups themselves and sometimes not even to observers. They provide a background to group life, unnoticed because they surround a group and are always there. They deserve to be analyzed and studied more often, however—they may be unobtrusive, but they are important.

streets to celebrate when their national team advances in World Cup competition. Company employees exchange congratulatory hugs when their firm wins an important new contract. On the negative side, people experience irritation or anger when they encounter those they perceive as illegal immigrants to their country. And, in all too many cases, extreme rage, fear, and hatred directed at an outgroup (a group to which the perceiver does not belong) are driving forces behind pogroms, policies of “ethnic cleansing,” and even genocide.

Following a brief historical overview of the study of emotions and their relationship to group memberships, this entry will discuss research findings in two distinct areas: (1) emotions that people experience in individual encounters with members of other groups and (2) emotions that people experience when they categorize or think of themselves as a group member.

### Historical Perspective

The exposure of Nazi atrocities in the immediate aftermath of World War II sparked a research focus on the psychological origins of prejudice, which one influential perspective traced to intense inner psychodynamic conflicts resulting in an “authoritarian personality.” This perspective focused on affective processes resulting in extreme hatred for outgroups—in other words, the psychology of the extreme bigot. These emotions were seen as irrational, targeted at convenient outgroups (as the Nazis targeted the Jews) without any basis or justification in actual intergroup experience.

However, this line of research was criticized on both conceptual and methodological grounds, and by the 1960s psychology as a whole began to undergo a “cognitive revolution,” with theories stressing information processing rather than emotion and motivation. At the same time, research attention shifted from the rare and abnormal characteristics of the extreme bigot to the more “normal” prejudices that (all too obviously) are common in large numbers of ordinary people. Influential perspectives in this period stressed that prejudice often resulted from conformity to the norms of one’s own ingroup or from stereotypes (socially shared beliefs) about negative characteristics of the outgroup. Emotions played little obvious role in these models.

---

## GROUP EMOTIONS

---

Many of the strongest emotions that people experience are related to events that affect social groups. Soccer fans throughout a country pour into the

Beginning in the 1980s, research interest turned once again toward emotions, with a focus on people's immediate experience in intergroup encounters. Negative feelings such as anxiety and irritation were found to be provoked by encounters with others who are culturally different or belong to unfamiliar or disliked groups, as described below. Finally, in the 1990s researchers began to link emotions and group memberships in a more direct way, assuming that particular emotions can be experienced when people simply think of themselves as members of particular groups and not only in face-to-face intergroup encounters. In these more recent views, emotions related to group memberships are no longer seen only as irrationally driven by deep underlying personality conflicts. Instead they are seen as more or less adaptive and understandable, arising from such factors as conflicts or competition between groups, cultural differences, or lack of familiarity and experience with cross-group interaction. In other words, emotions are normal, and any of us is likely to experience them when reacting to members of an outgroup. Thus, emotional responses to groups are not the sole property of a few extreme, irrationally motivated bigots.

#### **Emotions in Individual Encounters With Outgroup Members**

When people interact with members of outgroups, they may experience the negative emotion of *intergroup anxiety* stemming from unfamiliarity with the group, lack of knowledge about how to behave, or fear of unintentionally giving offense. This anxiety can disrupt the smooth flow of interaction, producing a self-fulfilling prophecy. Notably, people who experience intergroup anxiety may attempt to avoid interacting with outgroup members. In fact, it is generally true that negative emotions about the outgroup motivate people to avoid intergroup encounters. Intergroup anxiety is special in that the tendency to avoid is not motivated by prejudice in the usual sense (dislike or antipathy for the outgroup) but by relatively benign social motives, such as desires for the interaction to go smoothly and to avoid appearing prejudiced.

A second source of negative feelings about outgroup members is simple cultural difference. Members of one group (especially a majority group

that is culturally dominant) can become irritated or annoyed when outgroup members speak a different language, follow different cultural customs, or otherwise violate the ingroup's cherished and symbolically important norms and expectations. In extreme cases, these feelings of discomfort can fuel demands that outgroup members put aside all elements of their own cultures and assimilate to the majority, even in relatively innocuous areas of difference such as clothing styles.

Negative feelings in intergroup interactions can also arise from the negative images and stereotypes of an outgroup that people absorb over a lifetime through socialization as well as from the media and the popular culture. Many individuals do not consciously acknowledge these negative thoughts because they conflict with more explicit egalitarian attitudes, but this nonconscious conflict still has effects: Like intergroup anxiety, suppressed conflict can disrupt thoughts and feelings and interfere with positive social interaction.

Finally, some people may explicitly recognize that they have negative feelings or stereotypic thoughts about outgroup members they encounter and feel guilty or upset about having such thoughts or feelings. Again, the result of these self-directed negative emotions may be disruption of social interaction.

This discussion has focused on negative emotions, which are frequently part of intergroup interaction, but positive emotions can also occur and in fact can lead to reductions in prejudice, as will be discussed later.

#### **Emotions Based on Identification With a Group**

In a number of ways, emotions can be experienced when people simply think of themselves as members of a particular group, even without specific intergroup contact or interaction. As in the example mentioned earlier, people often feel positive emotions of joy or pride when their nation, sports team, or other group achieves a success or positive outcome. In such circumstances people tend to stress their connection with the group, for example by referring to it as "we" or by wearing clothing with team logos or colors.

Identifying with a group can make events that affect another individual group member (not only

the group as a whole) emotionally relevant to a perceiver. Consider how you would feel on hearing that another member of your religion, nation, or other significant group had been negatively and unfairly treated by the authorities in some far-off place. Although the event does not affect you personally in any way, if your common group membership with the victim is salient, you may react with unhappiness and anger.

The underlying reason that people feel emotions, whether positive or negative, on the basis of group membership is that an important group becomes part of the psychological self, an aspect of *social identity*. As a result, any event or situation that impinges on the group—a success or failure, threat, or hopeful outlook—can generate emotional responses just as if the situation were directly relevant to the personal self. So someone can feel great when his or her team wins because the team identification is part of the self, even though the perceiver personally did not score a single goal. Or, a person can feel threatened by discrimination against a fellow group member because the group is threatened, even though the individual is personally unaffected by the remote event. People can even feel guilty about actions of their group in which they have had no personal participation, for example, events in a nation's colonial past that took place hundreds of years before the individual was even born.

An evolutionary perspective sheds light on this phenomenon by assuming that (a) emotions are generally functional and adaptive in directing responses to threats and (b) because humans evolved in group living situations, emotions are likely to be sensitive to group-level as well as individual-level threats and dangers. This perspective predicts that people have a built-in readiness to respond with distinct emotions not only to threats to themselves (e.g., threats of physical harm or theft of personal resources) but also threats to their group (e.g., threats to the stability of the group's status hierarchy, to group-defining beliefs or symbols, or to the clarity of group boundaries). Outgroups may thus elicit negative reactions because they are perceived as posing group-level threats, even if the individual perceiver is in no way personally threatened.

Another viewpoint holds that the specific emotions that people feel in response to societal groups

are related to those groups' structural positions in society. For a perceiver who occupies the societal "mainstream," some groups are regarded as friendly allies and as high in status or competence, resulting in feelings of respect and admiration. Other groups are friendly but low in status and competence (such as the elderly or disabled), and elicit feelings of sympathy and pity. Conversely, groups that are regarded as dangerous competitors rather than allies, and as high in status and competence, are responded to with envy—this has traditionally been the case for Jews. And competitive or threatening groups that are low in status, such as drug addicts or people on welfare, are viewed with disgust. These emotional responses to groups of each type (allies/competitors, high/low status) in turn have implications for the ways people prefer to act toward those groups.

One theoretical perspective has been developed specifically around the idea that emotions can be rooted in group memberships. Intergroup emotions theory holds that when people identify with a group they tend to appraise objects or events in terms of their implications for the ingroup (rather than for the individual self). As a result, emotions can be experienced with regard to the group membership or social identity, and like any emotions, they will contribute to desires or tendencies to act in specific ways. The resulting feelings and behaviors will be differentiated rather than simply negative in character. Thus, people might view one threatening outgroup with anger and feel desires to confront or attack them, while another rival group is viewed with fear, which generates desires to escape or avoid them. Research has confirmed these and other predictions of the theory.

Most of this discussion of emotions based on group identification has involved emotional responses to specific events or objects (an ingroup victory or a threatening outgroup, for instance). Research inspired by intergroup emotions theory has found that people associate more general or chronic emotional feelings with particular group memberships. These are feelings such as anxiety, irritation, pride, discouragement, and so on that are not direct responses to any particular objects or events, but rather more general emotional feelings tied to particular group identities. So people might feel high levels of pride when they think of themselves as citizens of their nation, or anger

when thinking of their political party membership, even if neither of these emotions is especially characteristic of them when thinking of themselves as individuals. For positive emotions such as pride, satisfaction, and happiness, higher levels of these more general or chronic group emotions are experienced by those who identify more strongly with a valued ingroup. General group emotions also relate to people's general behavioral tendencies toward the ingroup and outgroups, such as desires to affiliate with and support the ingroup or to avoid or confront outgroups. In sum, just as individual-level emotions can be either acute responses to specific objects or events (such as fear at the sight of a wasp) or more general, chronic emotional or mood states (such as happiness, depression, or anxiety), so also can group emotions can be acute or chronic. Both types of group emotions are meaningfully related to people's attitudes and behaviors toward ingroups and outgroups.

### Related Topics and New Directions

Although negative emotions most often arise in situations of intergroup conflict or competition, positive emotions can also occur in intergroup situations, and they can be important in reducing prejudice. Specifically, for over half a century the idea that personal, friendly contact across group lines can reduce prejudice has been tested and confirmed. It is often assumed that the reason is that contact helps debunk inaccurate negative stereotypes about the outgroup, which in turn clears the way for prejudice to diminish. In contrast, the real story appears to be that friendly contact produces changes in emotions—more positive and less negative feelings about the individual outgroup member and hence the group as a whole—rather than changes in stereotypic beliefs. Evidence for this idea includes the fact that contact produces larger changes in affective measures of prejudice than in cognitive beliefs such as stereotypes. Some theorists have been concerned that friendly contact with an individual outgroup member might be relatively unlikely to reduce prejudice toward the group as a whole because the outgroup friend would be seen as exceptional or unrepresentative of the negatively viewed group. However, friendship with an outgroup member does reliably decrease prejudice toward the group as a whole, suggesting that

people see the other simultaneously as an individual and as a member of the group. These findings regarding the effects of intergroup contact reinforce the importance of emotional processes as contributors to intergroup relations in general.

Several important future directions for investigation in the area of group emotions can be identified. Research in this area has relied almost completely on self-reports of emotions, leaving unanswered questions about how “real” or deep group-based emotional experiences may be. However, limited evidence to date suggests that group-based emotions have many of the same consequences as conventional individual-level emotions, including biasing effects on cognitive processes, physiological responses, and activation patterns in emotion-related brain regions. Multiple-method investigations will be able to clarify the relative roles of conscious thoughts, affective processes, facial expressions, and the like in contributing to the totality of an emotional episode.

Although emotions are conventionally thought of as automatic and uncontrollable, phenomena that just “happen” to people, recent research has begun to investigate the ways people intentionally manage and regulate their emotions. Do people regulate group emotions in the same ways as individual emotions? Does the fact that group emotions are socially shared—experienced in consensus with other members of the ingroup—make them more difficult to regulate? Since group emotions are based on psychological identification with the group in the first place, are shifts in group identification viable strategies for emotion regulation in some instances? That is, might people choose not to identify with a group if membership regularly produced negative feelings of guilt, irritation, or discouragement? These questions have scarcely begun to be addressed, although knowledge about emotion regulation might suggest new strategies for changing emotionally based prejudiced reactions to outgroups.

Finally, conventional perspectives on prejudice and stereotypes include the idea that these phenomena are highly stable and difficult to change or reverse. In contrast, emotions are labile, shifting rapidly over time periods of minutes if not seconds. This observation suggests that further examination of the role of emotions in prejudice and intergroup behavior might reveal ways that these

phenomena vary on short time scales, rather than remaining stable over months or years.

of people into more enduring new collectives, and the deliberate assembly of new groups by powerful outsiders. Behavioral coordination among two or more individuals creates an ephemeral acting group. In more persistent groups that come together over multiple interactions, the forming process establishes the roles, norms, and boundaries that constitute group structure. Structure is a feature of standing groups, to which members continue to belong even when the group is not assembled for action. Structures established during group formation guide behavior when members assemble and reassemble over time.

In standing groups, successful group formation creates psychological bonds between members and the group. When groups are deliberately assembled, as when a teacher assigns students to project groups or a manager recruits employees for a committee, choices about group size, membership, and task structure help determine how effectively group members will work together. The formation process is more challenging when we are put together in configurations that differ from those that emerge spontaneously and to which our psychology is adapted.

### Acting Group Formation

Since the 1950s, research by biologists and social scientists has revealed how bands of social primates typically feed, travel, or sleep together in small, temporary, shifting collectives that may form in seconds or minutes and dissolve shortly thereafter. Similar types of ephemeral groups are evident throughout human societies. We readily perceive people as belonging to a group when they act together, especially if they also look alike and are physically close together. Despite their transient nature, short-lived groups that meet only once can still be psychologically meaningful. Ostracism research, for example, has documented the distress people feel when they are excluded from an ephemeral group, even when the benefit of inclusion (e.g., sharing in a game of ball passing to pass the time in a waiting room) seems trivial.

Perception of common threat is one of the strongest triggers for spontaneous group formation, as seen in World War II London, for example, when people preferred to congregate in subway tunnels rather than use small private

---

## GROUP FORMATION

---

*Group formation* includes the short-lived emergence of ephemeral groups, the self-organization

shelters. Social psychology experiments in the 1950s and 1960s also demonstrated that people anticipating unpleasant events seek out the company of others facing the same threat. In addition to defensive solidarity, ephemeral groups may emerge to exploit resources unavailable to individuals, to share and discuss information, to enjoy social activities, and to tackle challenges beyond the scope of a single person. A barn raising, a pickup basketball game, a clump of people gossiping, and a search party are examples. The people involved are drawn together based on shared or complementary needs and cooperate to gain mutual benefits. When the needs are met or the benefits cease, the group dissolves.

Coalition formation, which occurs when two or more individuals temporarily join forces to gain an advantage, is a particularly well-studied form of ephemeral group that is ubiquitous among humans and chimpanzees. Coalitions generate considerable social complexity by making power and status dependent not just on individual size and strength but also on the ability to recruit support from others, a vital defensive resource. In social primate populations, support can be solicited through vocalizations, facial expressions, and gestures such as reaching out a hand to solicit assistance. By observing coalitions that form in public, individuals can track dynamic changes in social hierarchies and relative power. According to the “social brain” hypothesis, which proposes that the cognitive demands of complex human social interaction have been an important factor in brain evolution, attention to coalition tracking has helped spur the development of higher mental capacities in primates.

Because people are attracted to similar others, groups that form spontaneously are more homogeneous than would be expected by chance. Observations of people in public settings indicate that such groups are also typically small, between two and five people. Small group size makes it easier for people to hear each other clearly when conversing, and allows for everyone to have their say. Small size also enables groups to coordinate their behavior in real time (act alike) without negotiating more formal guidelines for behavior (norms), division of labor and responsibilities (roles), and task specifications (standard operating procedures, agendas) that larger groups need.

### Self-Organization of New Standing Groups

When the same people repeatedly come to one another’s aid, this indicates not just a momentary coalition but a more enduring alliance—a standing group with members, rather than simply a set of people interacting. Support cliques—small, tight-knit groups whose members interact intensively and rely upon one another for costly assistance—tend to average around five people. Sympathy groups, which can also be counted on for support but involve relationships that are not as close or demanding, are typically larger, in the range of 12 to 15 people. Standing support and sympathy groups balance out costs, benefits, and risks not only across people but also across time, and rely on the strength of the bonds among members to ensure that members’ needs are met. People also organize into standing work groups to tackle ongoing projects. Musicians form bands, entrepreneurs launch new businesses, and neighbors form community watch groups. When forming project groups, people tend to seek out others whom they already know, who are similar demographically, and whose competence they trust.

The formation of durable new groups occurs via social integration—the strengthening of bonds among people—and group identification, which creates a bond between a person and a group. The incidence of new group formation is affected by the opportunities and constraints offered by the social setting and the needs of potential members. People entering a new social setting, such as a new job or school, will typically have unmet needs for belonging, social support, and other resources, and will be more open to forming or joining new groups. Opportunities for frequent informal interaction allow people to discover needs in common and hence facilitate self-organized group formation. Secondary sources of information from mutual acquaintances or from social networking sites, for example, also help people organize into groups based on shared interests. As successful groups grow, coordination becomes more difficult, so growth tends to spawn new smaller groups. This can happen either because the group splinters permanently or because smaller subgroups form their own identity and agenda under the umbrella of a larger organization.

The emergence of new opportunities in the environment encourages self-organized group formation to exploit resources, whether through the formation of new businesses, activity clubs, or research groups pursuing grant money. The propensity of people to organize themselves into new political, social, and economic groups both ties communities together and allows them to adjust to changing circumstances. This can pose a threat to oppressive regimes and organizations, which may actively counter the tendency of people to join forces by limiting opportunities for unsupervised assembly.

### Formation as a Stage of Group Development

Group formation creates a new collective entity with a boundary that distinguishes outsiders from members. Because standing groups interact repeatedly, they change over time, developing structures not available to newly formed or ephemeral groups that enable them to handle a broader range of projects, to coordinate more effectively in larger groups, and to tackle more complex and difficult tasks.

The duration and difficulty of the formation process depends on the nature, purpose, composition, and expected lifetime of the group. Some new groups hit the ground running. Others require more time to sort out structure and process issues before members are capable of working together effectively. Groups that are small, with a clear goal and a mix of appropriate skills but limited demographic diversity, can form more quickly than groups that are larger, more demographically diverse, and have a poorly defined task. Diversity in background, culture, and associated expectations for behavior can be good for group performance in the long run, but culturally diverse groups take longer to form.

The first systematic observations of group formation as a stage in group development—systematic change over time in groups—began appearing in the late 1940s and 1950s. In 1965 Bruce Tuckman integrated the findings of 50 studies into what is still the most well-known model of group development, with “forming” as the initial stage. Forming involves testing and dependence. Group members seek information on what is socially appropriate

and what their own position in the group will be. If the group has a leader, others depend on him or her to provide guidance; if not, a member who shows early initiative may emerge as a leader. Members try out different actions to see how the group responds, allowing them to either discover or create the boundaries of acceptable action and reduce uncertainty. Members also explore what the task or project calls for, seeking to discover, confirm, or create ground rules for how they will proceed.

Studies of group development since Tuckman’s model was published have supported its validity for a wide variety of groups, expanded insights into the forming stage that he described, and also documented clear exceptions. For example, Susan Wheelan has stressed the anxiety about inclusion and acceptance that members feel in the forming stage, while they are establishing trust and seeking approval. Members’ tendency to be polite and avoid conflict makes decisive group action unlikely at this stage.

Two important exceptions show that groups need not follow this standard forming process. Some task groups come together for a single project and disperse when the job is done. They resemble ephemeral groups in their speed of formation, but complete a task that requires repeated interaction over a longer period. Research has shown that these groups usually get to work immediately, deferring questioning, exploration, and thorough orientation to task demands until later. Members focus on the task, attend to division of labor and task leadership as the key structural features, and often do not identify strongly with the group. Despite their immediate task focus, these quick-start groups perform less effectively and efficiently in the first half of their time together than during the second half of the project.

Also contrary to the standard model, specialized groups such as flight crews are able to perform complex and challenging tasks effectively within minutes of forming. Crews can form quickly because prior training and extensive knowledge of what their own and other members’ roles require removes the uncertainty that generates testing and dependency. Structure does not need to be developed because it is imported, and crew members fit together like pre-engineered modules. Even in such crews, however, a short period spent reaffirming

the structure and orienting members to one another helps the group operate smoothly.

When formation fails to bind members together around a common purpose, most self-organized groups will quickly dissolve. Assembled groups whose members are not so free to leave the group may, however, continue to meet even without a sense of shared purpose or commitment. Poor group design increases the risk of failed formation, low commitment, and poor performance. Groups that are too large to coordinate easily, with members who have conflicting expectations or agendas and very different backgrounds, and whose mission is either unclear or not aligned with member needs, will have special difficulty completing group formation and working together for a common purpose.

## GROUP LEARNING

---

Groups and teams have increasingly become a critical component in organizations. Indeed, many organizations rely on groups to carry out both operational and strategic tasks, such as designing and producing new products, delivering services to customers, and developing strategies to respond to changes in the environment. While working on these tasks, learning at the group level occurs when teams change what they know or what they do based on the experience they have acquired working together on the group task.

The topic of group learning has received increasing attention from both researchers and practitioners over the last two decades. Studies across a variety of disciplines have addressed questions such as these: Under what conditions do groups learn? Which factors inhibit or enhance group learning? Which factors explain differences in rates of learning across groups and organizations? The main findings of research investigating learning at the group level is the subject of this entry. The entry discusses the learning process and its main subcomponents, identifies both antecedents and consequences of group learning, and describes why learning in groups is important to organizational effectiveness. Although many researchers use the terms *groups* and *teams* interchangeably, others differentiate between the two terms. In this entry, the terms *team learning* and *group learning* are used interchangeably because this terminology does not affect the findings discussed.

### Research on Group Learning

Group learning emerged as a distinct research topic in the 1990s. Since then it has greatly expanded in both volume and variety. Research on group learning builds on and complements a wealth of studies on organizational learning. Organizational learning has been investigated in many research fields, including organizational behavior, industrial engineering, operations management, and strategic management. Research on both group and organizational learning makes the important distinction that learning at the group or organizational level is different from individual

learning. Not only does group learning involve learning by individuals, it also involves sharing, distributing, and coordinating knowledge across individuals. If an individual group member has learned something, this does not imply that group learning has occurred. For group learning to occur, group members must have access to others' knowledge—either because it has been shared with them by the relevant individuals or because they know that they can access the knowledge by consulting the individuals or a repository such as a database containing that knowledge.

While group learning is critical to an organization's success and survival in a constantly changing environment, assessing it is a challenging task. Two main measures are commonly used to assess group learning: (1) changes in group knowledge that occur with experience and (2) changes in group performance that are associated with experience. Both measurement approaches pose challenges. The difficulty with the first measure is that much of the knowledge group members acquire, share, and use is not coded in formal documentation; is "tacit"; is distributed across members; or resides in repositories other than individuals (such as routines or technologies the group uses to accomplish tasks). As for the second measure, researchers have used changes in the routines the group uses to perform its task or changes in characteristics of task performance (such as quality and speed) that occur as the group gains experience to measure group learning. Yet, there are many factors other than experience that influence group performance. Researchers need to account for such factors or control for them in their empirical research in order to infer that group learning occurred.

Group learning has been investigated in four main streams of research over the last two decades: (1) learning curves in manufacturing or service operations settings, (2) work on group context and group learning, (3) research on how groups learn from different types of experience, and (4) small group research on learning, memory, and knowledge transfer. While a few attempts at synthesis exist across the areas, these research streams have generally flowed in parallel, with little confluence. There are enormous opportunities for these research streams to come together and thereby increase our understanding of group learning.

### *Learning Curves*

Research on learning curves examines the rate of improvement associated with experience in both manufacturing and service operations settings. This research has robustly demonstrated a link between cumulative production experience and operational performance improvement, which is measured by cost reduction, quality improvement, productivity improvement, or completion time. Although research has shown that performance typically improves with experience, it has also documented enormous variation in the rate at which performance improves. Some groups evidence dramatic improvements with experience, whereas others evidence little or no learning. Researchers are beginning to understand factors that explain differences in learning rates observed across groups. For example, research has found that efficiency improvements are enhanced by team stability, knowledge sharing, common ownership, and codified knowledge. These findings point to the influence of the group context on the rate of improvement associated with experience.

### *Group Context and Group Learning*

A second area of research on group learning focuses on the importance of group context in affecting the processes and outcomes of group learning. Studies in this research stream are mainly field based (i.e., done in actual work teams) and investigate how learning processes in groups differ based on contextual factors such as the group's learning climate, leader behavior, and the group orientation or goals. Several antecedents of learning behavior within groups have been identified. Among them there are identification with the group, leader behavior, group climate, shared learning goals and orientation, group structure, and task characteristics. This work has identified important direct effects, such as the influence of context on group learning, as well as variables that enhance or inhibit the impact of context on learning. For instance, a learning orientation (as contrasted with a performance orientation) has been shown to improve performance, but only to a certain extent: If taken too far, a learning orientation can actually hurt group performance. Another important predictor of group learning is psychological safety, defined as a shared belief that a

group is safe for interpersonal risk taking. Research has demonstrated that the effects of team-leader coaching and context support on group learning behavior are due to the effects of the former variables on psychological safety.

### *Types of Experience and Group Learning*

A recent trend in research on group learning is to characterize experience at a fine-grained level and to investigate the effects of various types of experience on learning processes and outcomes. Work in this area has identified different dimensions of experience, such as homogeneous versus heterogeneous experience and direct versus indirect experience. As an example, research has distinguished between learning from direct experience, defined as learning from interactions within a group, and learning from indirect experience, defined as learning by seeking ideas, help, or feedback from outside the group. These distinctions between types of learning are important because different types of learning have different effects on organizational performance variables. For example, local learning or learning from direct experience has been found to positively influence the efficiency of group operations and to be responsible for the effects of group cohesion on efficiency. In contrast, distal learning or learning from indirect experience has been found to positively influence group innovativeness. This stream of research can be productively combined with the second stream to arrive at a deeper understanding of group learning. Examining how dimensions of experience interact with dimensions of the context to affect group learning processes and outcomes is a very promising approach.

### *Group Learning, Memory, and Knowledge Transfer*

A fourth stream of research on group learning examines how members of a group learn either from their own experience or from the experience of other groups, and how they store knowledge in the group memory system. Research in this area is mainly experimental and is thus able to draw causal conclusions on the relationships investigated in a controlled laboratory setting. Through experience working together, group members build a shared understanding and knowledge of the task

they are working on, of the expertise and skills of each group member, and of the resources available to accomplish the task. Groups reach this shared understanding by developing transactive memory systems (TMS), which allow team members to encode, store, retrieve, and share the different pieces of information and knowledge group members possess. When members know what each other knows, both individually and collectively, group performance on interdependent tasks is enhanced. Because of the positive relationship found between transactive group memory systems and group performance, studies have investigated what enhances or inhibits the development of TMS within groups. This body of research has identified features of the group that positively or negatively affect TMS development. For instance, high turnover has been found to inhibit TMS development, while high diversity in group members' expertise and communication has been shown to foster TMS development. Research in this area suggests that storing information and knowledge within groups in a coordinated manner is fundamental to learning processes and leads to better group performance on tasks that involve interdependencies among members.

Not only do groups learn directly from their own experience, they also learn indirectly from the experience of other groups. This later form of learning has been referred to as knowledge transfer or vicarious learning. Personnel movement (the transfer of members across groups) is the primary mechanism through which knowledge transfer has been effected in the laboratory, and it has been shown to be an effective mechanism for transferring knowledge across groups as well as for stimulating the creation of new knowledge among group members.

### **The Learning Process and Its Subcomponents**

Group learning occurs through three main subprocesses: creating knowledge, retaining knowledge, and transferring knowledge. Creating knowledge refers to the development of new knowledge or better understandings of existing information with the group. For instance, as group members work together, they might acquire more information about each other's expertise and skills and, as a

result, develop new understandings or combine their knowledge in new ways. Research on this first subprocess of group learning has investigated when characteristics of members influence the generation of new knowledge. Diversity in the views and perspectives represented in the group has been found to stimulate knowledge creation, and member rotation among groups has been found to have similar effects. The creation of knowledge is also affected by social networks. Specifically, groups with communication ties or links to other groups with different knowledge are more likely to be creative than are groups with dense internal social networks but few ties to external groups.

The second subprocess of group learning is retaining knowledge, which refers to embedding knowledge in various repositories so that it can persist over time and be reused in the future. For example, knowledge might be embedded in individual members, in routines or task sequences, or in member–task networks such as the transactive memory systems group members develop while working together. Depending on where knowledge is embedded, different factors might impair the retention of knowledge. Research has found that turnover is detrimental to a group’s knowledge retention when knowledge is embedded in individuals, especially when the members leaving the group are high-performing individuals. However, it has been shown that group structures can buffer groups from the detrimental effects of turnover. When group members have specialized roles and procedures exist for accomplishing the task, the impact of turnover is reduced. Embedding knowledge in routines or in repositories such as tools or artifacts promotes its retention because interruptions in a group’s work are less likely to have detrimental effects.

The third subprocess of group learning is transferring knowledge. Through knowledge transfer, one group is influenced by the experience of another. Moving members from one group to another has been shown to promote the transfer of both tacit and explicit knowledge. Other factors influencing knowledge transfer are social networks, communication, relationships between work groups, characteristics of the tasks groups perform, and features of the knowledge being transferred. For instance, research has shown that it is easier to transfer knowledge

codified in routines than noncodified knowledge. A shared superordinate social identity has also been found to facilitate the transfer of knowledge between groups.

### Group Learning Consequences

Group learning has important consequences for both the group and the organization in which the group operates. As mentioned earlier, group learning can enhance group creativity and promote group performance. Learning within groups is a key mechanism through which an organization can learn, adapt, and respond to changes in its environment. Thus, group learning can enable the organization to respond strategically to changes and turbulence in the environment. The relationship between group and organizational learning is poorly understood, and more research is necessary to understand how learning at the group level translates into learning at the organizational level. Also, little is known about how patterns of group learning can be created and maintained within an organization so that different groups can learn in their most effective ways but ultimately toward the same organizational goals. Future research shedding light on these questions is warranted and could yield important insights for theory and for practice.

## GROUP MEMORY

---

In psychology, memory often has been defined purely at the individual level. According to this analysis, memories are stored in various parts of the brain and are based on experiences and structured learning of information. However, more recent conceptualizations of groups as information-processing systems have begun to redefine memory to include both the group and organizational levels. To the degree that memory involves the storage and retrieval of information, groups and larger social aggregates perform and rely on such processes on a regular basis. Anthropologists have long viewed memory and recall as sociocultural phenomena. The retelling of stories and myths by parents and group leaders allows all members to share the cultural heritage of the group and helps to reinforce the cultural norms and ideals represented therein. However, only recently has psychology focused on the social or collective nature of memory.

Early empirical work on group memory focused on comparing individuals and groups on memory performance. Similar to findings in other cognitive domains (e.g., problem solving), multiple studies have found that groups recall more information than individuals. Many of the early studies tested a model called *truth wins*—if one member of the group can recall a piece of information correctly, the group will recall the information. Actual group performance tends to be less than this optimal model would predict. For relatively simple types of information (e.g., nonsense syllables, words, etc.), groups perform near the truth wins model, but typically they do better if at least two members recall the information. For more complex types of information (e.g., pieces of evidence for a jury trial, key pieces of information for a strategic planning team), having more than two group members who can recall the information seems important. Thus, although groups remember more than would an average individual, and more than can be remembered by any individual member, their memory rarely achieves what could be considered an optimal level of performance. This entry examines explanations for the superiority of group memory performance, describes the stages in this performance, and reviews current research in the field, including work on transactive memory and shared memory models.

### Explanations for Superior Group Performance

Recent research on group versus individual memory performance has focused on three explanations for the superior performance of groups: information pooling, error correction, and effective group decision making. *Effective group decision making* is defined as integrating all useful information and avoiding decision errors, so both information pooling and error correction are involved. *Information pooling* suggests that groups recall more information because individual group members recall different pieces of information to some degree. The nonoverlapping recall across group members allows groups to recall a greater total number of items relative to any single individual. Research has generally supported pooling as one of the factors underlying the individual–group difference. *Error correction* implies that

group discussion leads groups to reject incorrect items that may have been erroneously recalled by a specific group member. Recent research has confirmed that groups do reduce errors, but only if they are allowed to discuss each item. Nominal groups (groups in which each member contributes to the group product but the members are not allowed to interact) produce considerably better total recall scores than do individuals, but also increase intrusion errors (items recalled that were not part of the initial information to be recalled). Thus, group discussion seems to be an important aspect of both error correction and effective decision making by groups.

### Stages of Group Memory Performance

Group memory performance, much like individual memory performance, involves a number of information processing stages.

#### *Attending to and Encoding Information*

Groups must first attend to relevant information and then encode it (i.e., give it meaning and relevance to the situation at hand). Because groups contain multiple members, each with the ability to encode information, they can encode information in different ways. Each group member may encode a piece of information idiosyncratically based on his or her previous information exposure and currently activated categories. Such idiosyncratic encoding may increase the likelihood that a piece of information will be recalled due to many more contextual cues that may allow at least one member to access the encoded information. Groups can also encode information strategically by assigning certain types of information to specific group members, based on their role in the group or their specific expertise. Thus, information may not be encoded by every member, and the degree of encoding may vary across group members.

#### *Information Storage*

Once encoded, the information must be stored in some manner in the group. Much like encoding, storage can also vary across group members. Different members may have different information demands in terms of the amount of information presented to them. Therefore, the likelihood of a

piece of information being recalled likely will vary across members due to differential rates of storage degradation (forgetting). Research has shown that the greater the number of members who recall a piece of information, the greater the likelihood that the group will recall the information when necessary. Thus, information that is shared across group members is more likely to be recalled. Unfortunately, in information rich environments, greater information sharing also involves a greater cognitive load for each member (i.e., more information for each member to recall). Research on individual memory consistently has shown that recall probabilities for any given item decrease as the number of items increases. Although the issue is not settled, some research supports the notion of some partial information sharing across members as a good strategy for improving group memory. Having information shared by only some group members eases the cognitive load relative to complete sharing but increases the probability of group recall relative to no information sharing. More research is needed on this topic to elucidate the relative trade-offs between reduced cognitive load and information sharing across different task domains.

#### *Information Retrieval*

Retrieval is the final stage of memory. Research findings on encoding and storage reflect information retrieval as the final outcome. However, some research has specifically looked at retrieval at the group level. One aspect of retrieval by a group is whether the group reaches consensus as to whether a specific piece of information should be considered valid, or an accurate representation of the initial information. For the group to have retrieved a piece of information, there must be some agreement as to whether the information was originally present or valid. One of the reasons for superior performance by groups compared to individuals is that invalid information will rarely receive enough support from the group to be included. Similar to other areas of group performance, majority or plurality processes seem to provide a viable description of the group decision process. Incorrect items rarely receive support from a majority of the members and, therefore, are not included in the information recalled by the group. For correct items, plurality or majority support will almost always

lead to inclusion. In addition, occasionally correct minorities will be able to convince incorrect majorities to include a correct item. Thus, item correctness and degree of consensus both play a role in group retrieval.

A second aspect of group retrieval involves cued recall in groups. It seems intuitive that recalling information in groups could help each member recall more information, because items produced by other members will cue a particular item that might not have been recalled without such a cue. Although there is some evidence the group-level cuing process occurs, it comes with a cost that often overrides the benefit—interference. Although hearing information from other group members may cue new items in memory, it can also interfere with ongoing memory processes and prevent items from coming to mind that would have done so without the interference. Unfortunately, in most face-to-face interacting group situations, results tend to show that group discussion interferes with individual memory processes more than it aids them through cuing. However, group members sometimes remember more after being in an interacting, as opposed to a nominal, group. In addition, some recent research shows that technology (split-screen computer-mediated interaction) can reduce interference and still provide opportunities for cuing.

### Transactive Memory

The concept that has garnered the greatest amount of research attention in the past two decades is transactive memory. Initially hypothesized as a mechanism for increasing group memory performance, it quickly became a description of how groups and organizations could, should, and often do structure information storage. A transactive memory system involves both cognitive and metacognitive knowledge at both the individual and group or organizational level. Metacognition involves what people think they know about what they know. Thus, psychology professors may know that they have expertise in psychology but no expertise in chemistry. The actual knowledge they have about psychology and chemistry is located at the cognitive level, but the fact that they know that they know more in one area than another (or at least believe they do) is knowledge

of what they know, or metaknowledge. A transactive memory system is defined by distributed knowledge at the cognitive level in conjunction with shared knowledge at the metacognitive level. Each group member is assumed to have some unique knowledge that the other members do not have. This allows the group as a whole to store (and retrieve) a greater amount of information than would be expected with a random distribution of information across individual members. However, the unique information held by each member is only accessible to the group if each member knows which group member has that unique knowledge. Thus, the metaknowledge is shared by the group members, while the actual knowledge is distributed uniquely across the individual members.

There is now a vast amount of evidence that transactive memory systems aid in group and organizational memory. For example, married couples tend to do better at trivia games than paired strangers, because each member of the couple knows which member is better at certain categories of knowledge. Other research has shown that teams trained together tend to perform better than teams composed of members trained individually, because the team-level training allows members to learn who is good at what. Although groups can be engineered to have a transactive memory system, most groups form such memory systems naturally and within a relatively short period of time. Other research has shown that one of the key issues concerning turnover in organizations is that when a team loses a member, some of the unique knowledge available to the group is no longer present, and the group has to reestablish both the knowledge and the metaknowledge it needs, and then ensure that new members learn the metacomponents of the transactive memory system.

### Shared Mental Models

Another related area of research relevant to group memory involves shared mental models. Groups working on a particular task often need to share a basic understanding of both the task on which they work and the group within which they work. Having all members know what needs to be done, and who should be doing it, allows them to coordinate their actions to reach their performance

goal. The shared task mental model tends to be quite specific to the technology and resource requirements of the particular task. However, the shared group mental model almost always involves, in part, a transactive memory system. Group members must know where information is located within the group in order to efficiently access it. There may be other aspects of the shared mental model of the group (e.g., power relations, the importance of each position, the idiosyncrasies in personality of the other members), but transactive memory is almost always a key component.

Theory and research on group memory in psychology are relatively recent developments, and there is much left to learn. However, the early research has demonstrated the importance of group memory and has changed the way memory is conceived in group and organizational settings.

## GROUP MIND

---

The “group mind” is one of the most ambiguous, most controversial, and most contested ideas in the whole of social thought. It can be traced back to the notion of Atman, or universal soul, in ancient Indian thought. In its modern guise, the concept derives most directly from German idealist philosophy, where it denotes a collective consciousness that is separate from and independent of the consciousness of individuals

### Historical and Philosophical Roots

In broad terms, there are two variants of the concept of group mind. The universalist position, represented in the work of Hegel, suggests that history is the reflection of a universal and unitary spirit (*geist*) that unfolds according to its own internal dialectic. Human beings are merely agents of this *geist*, and the nature of human society reflects its state of development. By contrast, the particularist position proposes that each group (usually conceptualized as a people or nation) has its own *volksgeist*, which unfolds in its own way leading to distinctive histories for different peoples. This approach is represented in the writings of Johann Gottlieb Fichte and Johann Gottfried von Herder, especially as they responded to the invasion of German lands by Napoleon’s armies. The importance of this context reveals the political nature of the group mind concept, which in turn is the source of much of the controversy that surrounds it.

Fichte in particular came to view the “true self” as the political state rather than the individual. Individuals are but elements of the state, he thought, their interests are wholly subordinate to those of the state—indeed, they have no meaning or value outside of their relation to the state. The relationship of individual people to the body politic is conceptualized as much like the relationship of individual cells to the whole human body, which alone is fully conscious. And just as one would cut out any collection of cells to save the body, so individuals must always be sacrificed for

the political whole. Not surprisingly, then, the group mind concept has long been denounced as an apology for (Prussian) absolutism. Such critiques were only intensified by the Nazi usage of *volksgeist* principles.

### Critics in Social Psychology

Group mind concepts entered the mainstream of social psychology in a two-stage process. First, over the course of the 19th century, they spread beyond philosophy to the social and life sciences. In particular, the work of Alfred Espinas on bee communities gave credibility and prestige to such ideas. Espinas argued that, while bees display individual consciousness, they can also form a specialized part of the highly integrated whole, which has its own collective consciousness. In this way individual consciousness can be seen as a constituent part of the consciousness of a higher order unit. What is more, the group mind ensures that the cognitive or emotional state of any one element will automatically spread to all others. Espinas held this to be true even where individuals do not have common parentage. The collective consciousness exists in all parts of the animal kingdom, from protozoa to humans, in this view.

In a second stage, crowd psychologists drew directly on the work of Espinas and others in formulating their own theories. Gustave Le Bon, the most famous of these psychologists, was particularly influenced by the group mind approach. In his book *The Psychology of Peoples*, he suggested that different “races” have irreducibly different “souls,” which means that they feel and think differently and cannot comprehend one another. This idea was then imported into his crowd psychology. Le Bon argued that, in everyday life, people may have developed more sophisticated and individual ways of being. However, when submerged in the mass, all this is stripped away, and people revert to the more primitive “racial unconscious.” This unconscious provides the ideas and emotions that spread uncontrollably among all crowd members, and it explains why even the most refined of individuals can behave like a beast in the crowd.

Le Bon’s ideas were highly influential, and his use of group mind as a supraindividual level of consciousness was employed as the central explanatory concept in a whole series of crowd psychologies in

the early 20th century; among others, those of Wilhelm Wundt, Carl Jung, Theodor Geiger, and Alfred Adler. Jung’s system, which (like that of Le Bon) racializes the group mind concept, is especially well known. He believed that identical ideas occur in members of the same race, independently of any contact, and that these ideas indicate the existence of a psychic commonality. In the crowd, individuals experience a sense of “mystical participation” that reflects their unconscious racial identification. Where the masses behave, said Jung, archetypes take over.

Group mind ideas were also highly influential among the founders of British and American social psychology, including William James, William Sumner, Edward Ross, and William McDougall. Indeed, it is the last of these who is most explicitly associated with the approach through his book, *The Group Mind*, first published in 1920. He almost immediately regretted this title and referred to it as a “tactical error.” McDougall rejects the notion of “some mental entity that exists over and above all individuals comprised in the group.” For him, the notion of a group mind is akin to the gestalt principle that an understanding of the life of the whole must incorporate principles (notably, of organization) that cannot be arrived at by the study of the parts alone.

Yet, equally, these systemic principles affect action through the way that they affect the consciousness of individual actors. Whatever McDougall’s actual position, his title wrought its baleful effects. Despite his explicit repudiation of Le Bon’s claim that crowds revert to a racial unconscious, he and Le Bon were and still are generally lumped together. As such, they generated a powerful reaction, and in this respect, even more than in their own work, they had the most influence on psychology. This is reflected in Floyd Allport’s foundational text, *Social Psychology*, published in 1924, in large part as a riposte to group mind theorists.

Allport makes three claims. First, he dismisses the notion of a group mind and the notion of a collective consciousness as the most flagrant form of this “group fallacy.” For Allport, “there is no psychology of groups which is not essentially and entirely a psychology of individuals.” Second, the behavior of people in group settings is to be explained entirely in terms of individual tendencies. This, claims Allport, reflects a scientific

imperative to explain the complex in terms of the simple, the whole in terms of its parts. Third, he argues that any commonalities of social behavior reflect the convergence of individuals who, due to similarities of “constitution, training and common stimulations, are possessed of a similar character.” Such an approach proved so influential that, 50 years later, Ivan Steiner was forced to ask “what-ever happened to the group in social psychology?”

### The Socially Structured Field in the Individual

Both group mind theorists and their individualist critics conflate *explanandum* and *explanans* (respectively, the phenomenon that requires explanation and that which explains it). Thus, the idea of a group mind goes from assuming that consciousness must be explained at a group level to positing that consciousness exists at a group level. In retort, individualism goes from denying group-level consciousness to denying that consciousness can be explained at a group level. There has long been another position in social psychology, which suggests that consciousness is individual but, in part at least, requires explanation at a group and societal level. This was what McDougall was arguing in his defense of his position. It is reflected early on in the work of Leon Festinger on social norms and in the works of Muzafer Sherif, Solomon Asch, and particularly Kurt Lewin. The task for Lewin is to address the nature of the socially structured field *within the individual*.

Over recent years, such a stance has come increasingly to influence the social psychology of groups through social identity and self-categorization theories. They suggest that we act collectively to the extent that we define ourselves in terms of a collective identity. Hence, the behavior of group members cannot be explained without considering the cultural and historical nature of these identities. Equally, these cultural and historical factors become potent only to the extent that they structure the self-understanding of individuals. In short, rather than positing a group mind beyond the individual, or denying any reality to the group, the task of social psychologists is to investigate the group in the mind of the individual.

## GROUP MOTIVATION

---

When people work together on a task (e.g., group project for class), they influence each other, making the group experience different from working alone in a number of ways. One important type of influence involves task motivation, or the amount of effort exerted to reach a goal. Because groups are frequently assembled to complete tasks, much research has been conducted to explore when and why groups affect their members' motivation.

After a brief review of research on group motivation, this entry summarizes some of the important lessons that have been learned and illustrates how these lessons can help us predict when working in a group will decrease effort (i.e., motivation losses) versus increase effort (i.e., motivation gains). Moreover, knowledge about group motivation can help us make better informed decisions about whether individuals or groups should undertake a task and about how to design and structure group tasks.

### History

Do people work harder in groups or when alone? More than a century ago, Max Ringelmann showed that, for certain tasks, people working in a group were less productive than the same number of individuals working alone. Although it was soon well documented that group performance often differed from individual performance, it was not until much later that researchers demonstrated that these performance differences could be due to changes in task motivation. Given the applied implications of group motivation, research on this topic is conducted within several disciplines, including social psychology, industrial/organizational psychology, and organizational behavior. A number of scholars contributed ideas that were instrumental to advancing knowledge about group motivation, and their influence is still evident in contemporary theory and research.

### Studying Group Motivation

In 1972, Ivan Steiner proposed a valuable set of ideas for understanding and assessing group motivation. Steiner suggested that groups fail to achieve their potential productivity because of losses in coordination and/or motivation. Whereas coordination losses occur when group members do not pool their resources and efforts optimally, motivation losses emerge from reductions in effort. But just how does one determine whether a loss in motivation has occurred?

One approach that has been frequently adopted is to compare the motivation level of a person working on a task alone to the motivation level of a group member working on the same task. For instance, in a classic study by Richard Ingham and his colleagues, participants were asked to pull on a rope either alone or in a group. In the group setting, the other group members were positioned behind the participant so they could not be seen, and, unbeknownst to the participant, were instructed not to pull on the rope. The researchers found that people working alone exerted greater force during the task than did those who *thought* they were working as members of a group.

To date, more than 100 studies have been conducted in a variety of settings (e.g., laboratories, organizations) showing that motivation levels are influenced by working in a group. Many of the

results of these studies can be understood using the Collective Effort Model, which identifies two subjective judgments that determine group members' level of motivation. One is how instrumental their efforts are for reaching a goal, and the other is the value of that goal. Motivation is highest when group members believe their efforts will increase the chances of obtaining a goal and when they also value that goal. Motivation decreases if effort is not seen as instrumental and/or if group members do not place much value on the goal.

### Motivation Losses

Group members frequently reduce the amount of effort they expend on a task when they are working together compared to when they are working alone. Imagine three brothers doing yard work as a group. Suppose they rake and collect twelve bags of leaves in an hour. On average, then, each brother fills four bags. *Motivation loss* in the group would be demonstrated if each brother were given an hour to individually rake and bag leaves and each filled five bags.

Motivation losses (also known as *social loafing*) are one reason each brother may accomplish less when working with others than when working alone. Sometimes these reductions in effort occur in groups because members feel their personal contributions to the overall group product are not discriminable from the contributions of others. For example, if the brothers used a division of labor that assigned each a unique role (e.g., raking, holding the bag, filling the bag with leaves), effort might decline because it would be difficult to make comparisons of their relative effort levels, given the distinct nature of their responsibilities. But even if the brothers decided not to assign unique roles, task motivation would still be likely to decline if all the bags of leaves were piled together so that no one could discern who did what.

Consistent with the Collective Effort Model, research shows that motivation in groups also drops when members believe that their efforts will have little impact on the group's success. For example, if the group is large and its task is disjunctive (that is, requires that only one member solve a problem in order for the group to solve it), then individual members are likely to feel that their efforts are not necessary, and hence they will be

unlikely to exert much effort. This tendency to free ride on the efforts of others is especially likely when the task is not enjoyable or rewarding.

Social loafing can be contagious, spreading even to group members who are diligent and relatively self-motivated. If hardworking group members perceive that others in the group are not trying as hard as they are, they may decrease their own efforts to avoid feeling exploited and being seen (or seeing themselves) as a “sucker.”

### Motivation Gains

Many factors can lead to motivation losses in groups, but are there conditions that encourage people to work harder in groups than when alone? Although motivation gains in groups are not common, they do exist, and over the past few decades there has been an increased focus on understanding when and why working in groups can lead to enhanced effort.

When they are part of the group, members often share a common fate, in the sense that the outcomes obtained by individual members are the same regardless of their personal contributions. When the fate of group members is shared in this way, motivation gains can emerge when some members feel they must compensate for the less capable members with whom they are working. Particularly on tasks that are very important, better performing members may increase their efforts and do more—even more than their fair share—so that the group as a whole can succeed. Such social compensation is especially likely if these group members believe that their performance is necessary to achieve their common goal.

For instance, imagine that three students have been assigned to work together on a group project for their psychology course. The instructor has informed the class that members of a group will all receive identical grades. If one of the group members is struggling in the course, or for some other reason cannot adequately fulfill his or her responsibilities, the other members of the group may increase the amount of effort they dedicate to the project to compensate for this less capable student. While they will probably not welcome the additional work, their task motivation will, of necessity, increase.

It is also the case that, on tasks for which the contributions of the weaker members of the group

determine the fate of the collective, these members will increase the amount of effort they expend. This is due to their realization that their performance will have a strong impact on how well the group performs and how other members evaluate them.

This phenomenon was first demonstrated by the German industrial psychologist Otto Köhler and is referred to as the *Köhler effect*. Research shows that people will work hard when their group is counting on them, in part because they feel that their efforts are necessary for group success and in part because they don't want to face disapproval from others. Another factor is social identity. A central tenet of social identity theory is that when individuals embrace a group and their membership becomes central to their identity, the success and status of the group affect their self-appraisals. If the group is successful, has status, and is perceived positively, the member who identifies with the group derives self-esteem through this association. Conversely, if the group has a negative image, the member who identifies with the group experiences reduced self-esteem.

Thus, group membership and identity can affect motivation in interesting ways, particularly in the context of intergroup competition. When groups are competing against other groups, competitiveness and motivation increase, compared to when individuals are competing against other individuals. When people working on a task feel that they are representing a group and their success or failure will be viewed as an indicator of their group's ability, motivation is likely to increase. Importantly though, whether effort increases or decreases is dependent on whether excelling at the task is something the group endorses or rejects.

In work groups, others' acceptance is often earned by trying hard and doing well. So, when the individual efforts and contributions of group members are identifiable, gains in motivation may occur because members are concerned with how others will evaluate them. It should be noted, however, that the desire to be evaluated positively does not invariably result in enhanced motivation. It will not enhance motivation when the group's norms discourage high levels of effort. Moreover, it is important to recognize that whether heightened motivation facilitates or hinders group performance depends on several aspects of the task, such as familiarity and difficulty.

### Conclusion

Research shows that working in a group can lead to increases or decreases in effort. Although people often conceptualize motivation gains and losses as distinct phenomena, some researchers argue that they share similar underlying causes. For instance, when people perceive their contribution toward the group's product to be unimportant for group success, they will reduce their effort. However, when they perceive their contribution to the group to be important for group success, they will increase their effort. Thus, it is important to understand the basic social psychological processes that underlie why people exert more or less effort in group settings. Such understanding should be very helpful for creating productive task groups.

## GROUP PERFORMANCE

---

*Group performance* is the process and outcome of members' joint efforts to achieve a collective goal. That goal could be nearly anything—to reach a decision, to solve a problem, to generate an idea, to negotiate a contract, to build a house. The scientific study of group performance has been central to several disciplines, particularly social psychology and industrial/organizational psychology (where it is more likely to be referred to as the study of *team effectiveness*). Thus, it is not surprising that a vast amount of research on group performance has been done—literally thousands of studies. There are many reasonable ways to describe and summarize this research literature. This entry considers three questions that have dominated and guided much of this research: (1) Are groups more productive than individuals? (2) What factors affect a group's performance? (3) Why don't groups perform as well as they can?

### Comparing Individual and Group Performance

There are some tasks that only groups can undertake (e.g., certain sports; certain tasks requiring more skills or inputs than any single individual could possess). Most tasks, however, can be performed either by individuals or by groups. Hence, an early and eminently practical question was, “Are groups more productive than individuals?”

Actually, the first topic receiving sustained research attention was a variant on this question, namely, “Are individuals more productive when others are present than when they are not?” Because a common feature of working in groups (although not a necessary one, particularly in this era of virtual work groups) is the presence of others, this is a rather fundamental question. And several aspects of the research on this topic are instructive for the broader study of group performance.

First, it soon became clear that there was no simple and general answer to the question—sometimes individuals performed better in the presence of others (*social facilitation*), and sometimes they performed worse (*social inhibition*). It is also rare for a simple or completely general answer to be found for nearly any question about group performance.

Second, it eventually became clear that the answer to the social facilitation question hinged largely on what the task was. For simple, well-learned tasks, the presence of others was facilitating, whereas for complex, poorly learned tasks, isolated individuals' performance tended to be superior. In much the same way, few if any generalizations about group performance can be made without careful consideration of just what task a group is undertaking. Third, progress in answering this question resulted less from the pattern emerging from a welter of studies than from a theoretical insight (in this case, by Robert Zajonc, who recognized that the presence of others was usually arousing and that such arousal tended to facilitate behaviors that were already likely to occur). Although interest in group performance has always had a very practical bent, Kurt Lewin's dictum that "there is nothing so practical as a good theory" has repeatedly been confirmed in the study of group performance.

One of the first studies directly comparing individuals with cooperative groups was published in 1932 by Marjorie Shaw. She had students in a class try to solve word puzzles either as individuals or in four-person groups. Across three such problems, including one that no individual could solve alone, she found that groups were more likely to solve the problem than were individuals, a result that she attributed to group members catching and correcting one another's mistakes. This and other advantages of groups—members complementing one another's knowledge, pooling their efforts, strategically dividing labor, encouraging one another—might lead one to suspect that groups are generally better problem solvers and decision makers. But even a moment's consideration will suggest that there are many tasks for which a group's disadvantages probably outweigh its advantages. Consider the familiar task of driving a car. With a bit of training and practice, an individual can master the different subtasks involved—steering, braking, using the accelerator, and so on. However, it would be considerably more difficult for a group—one person steering, another braking, and so on—to perform the same task. Clearly, certain forms of coordinated behavior are more effectively accomplished by one person working alone than by several people working together.

Nonetheless, there might still be simple answers to more focused questions, such as, "Does group

performance exceed individual performance in general for certain kinds of tasks?" Reviews of the group performance literature have offered some useful answers to such questions, such as the following:

- Gayle Hill's thorough review in 1981 concluded that group performance is usually superior to individual performance on learning or concept-attainment tasks, vocabulary/word knowledge tasks, idea generation tasks (like brainstorming), and nearly all abstract problem-solving tasks. She attributed this superiority to group members' ability to correct each other's errors and to effectively pool their resources (e.g., knowledge, skills, problem-solving or learning strategies).

- Most studies examining the accuracy of judgments (e.g., judging weights or numerosity, geography judgments) have shown that the average judgment of a group of judges is usually superior to the average judgment of randomly selected individuals. Such research has led some to tout "the wisdom of crowds." However, once again, this conclusion has been shown to depend upon the nature of the judgment being made. Aggregating individual judgments does lead to more accurate judgments as long as individual judgment is unbiased (i.e., the errors of judgment are random). However, if individual judgments are systematically biased (e.g., individuals' weight judgments are mostly too high), then aggregating those judgments will not improve judgment accuracy, even though the variability in judgments will be reduced.

- Good performance on many tasks has several features. For example, a good reader should not only be able to read quickly but with high comprehension as well. So, whether groups do better than individuals may depend upon how we define good performance. One such criterion, on which groups often have been found to be inferior to individuals, is productivity per person. Even when the average group is more productive than the average individual (e.g., can solve a problem more quickly), individuals may still be more efficient than groups (e.g., it would cost more to pay a group to achieve any particular level of productivity than to pay the same number of individual workers). Other popular performance criteria include the quantity and quality of production, how satisfied the performers

and other stakeholders are with the group's work, and whether group members want to keep on working together.

It is only meaningful to compare individual and group performance when there is some agreed-upon standard for good performance (e.g., a correct solution for a math problem or maximum productivity on an assembly line). There are many tasks, however, where no such standard exists (e.g., in most criminal cases, we cannot tell whether the defendant is *really* guilty or not), or there is little agreement about such standards (e.g., which is the "best" brand of champagne). For such *judgmental tasks*, it may thus be difficult to characterize groups as more accurate or productive than individuals. Even with such tasks, though, one can meaningfully compare the relative susceptibility of groups versus individuals to certain biases of judgment. For example, we may not be able to tell whether juries reach the "right" verdicts more often than individual jurors, but we can still see whether juries or individual jurors are more biased by proscribed information (e.g., inadmissible evidence) when they reach their verdicts. Once again, the answer to such questions seems to depend a great deal on aspects of the group's task. If there is widespread acceptance of a bias among individuals, groups tend to accentuate that bias, but when group members can easily recognize a bias, the process of group interaction can correct or mitigate it.

### Factors Affecting Group Performance

Whether groups perform better or worse than individuals, an important question whenever a task must be performed by a group is, "What factors will affect the group's performance?" Of course, the broadest answer is, "Many factors will matter, but their effects will usually depend upon the group's task."

#### *Group Composition*

As every sports coach knows, an important aspect of group performance is how the group is composed. Olympic teams are not representative samples of their nation's populations. Rather, their members are very carefully selected. There is an old saying, "If you want to make chicken soup,

first you need a chicken." Likewise, if you want to have a productive group, first you need productive group members (people with the knowledge, skills, and abilities needed to perform the task and the interpersonal skills required to work productively with one another).

An obvious and basic feature of group composition is the group's size. Clearly, some tasks have specific size requirements (e.g., you can only build a human pyramid with groups of size 3, 6, 10, etc.); for other tasks (e.g., producing a loud cheer at a sporting event), the bigger the group, the better. For most tasks, variations in group size can potentially enhance or undercut group performance. Larger groups have performance advantages in that they tend to have a bigger and more diverse pool of resources (e.g., member abilities, connections with outsiders) and to be viewed (both inside and outside the group) as more legitimate and effective. However, larger groups also can have bigger problems with coordinating and motivating their members, monitoring and sanctioning unproductive behaviors, and meeting the idiosyncratic needs of particular members. And the impact of such size-related effects can be aggravated or mitigated by other actions the group might take (e.g., labeling member contributions might mitigate the adverse effects of member anonymity in large groups). A group's optimal size, then, is that size where such advantages are maximal and such disadvantages are minimal. Given the many factors that influence group performance, it is hard to specify that size a priori. Many particular groups working at particular tasks may only come to identify their optimal size through trial and error.

One aspect of this question is whether more productive groups generally include certain types of people—people in certain demographic, personality, or attitudinal categories. Research on group sex composition is instructive in this regard. In 1985, Wendy Wood reviewed studies comparing all-male and all-female work groups and found that, overall, groups of men outperformed groups of women. However, this conclusion was based on averaging results across all tasks. Many of these tasks required task abilities that favored males (e.g., physical strength). But if one focused on tasks that favored females (e.g., verbal tasks), then the opposite conclusion held—groups of women were more productive than groups of men. Likewise,

groups of men tended to do better at tasks that required their more task-oriented interaction style, whereas groups of women tended to do better at tasks that required their more interpersonally oriented interaction style. The same basic moral emerges from the study of other individual differences: There are few if any individual differences in group member demographics or personality that are consistently related to better group performance. One must carefully consider just what the task requires of the group to begin to identify what a good group member would look like.

Maybe the secret of good group performance lies not in particular individual traits or abilities, but rather in having just the right combination of member characteristics. To take a trivial example, effective American football teams require both burly linemen and smaller, faster backs. Much of the research on this question has focused on the effects of the homogeneity or heterogeneity of group membership and group performance. For example, Patrick Laughlin and his colleagues asked whether a group with homogeneous levels of ability (e.g., three medium-ability members, MMM) would perform a vocabulary task any better than a more heterogeneous group with the same average member ability (HML). For this task, it turned out that the heterogeneous group performed better. In much the same way, other research has asked whether heterogeneity with respect to other characteristics of group members (e.g., gender, race/ethnicity, personality) helps or harms group performance. Some of the interest in this topic stems from widespread interest in the effects of diversity in the workplace, that is, whether diversity in race, ethnicity, gender, and so on improves or impairs work group performance. It appears that certain kinds of diversity (e.g., in task relevant knowledge and skills) can indeed be helpful to groups if they provide a larger pool of resources or help groups to examine issues more critically. When diversity leads to subgroup formation and conflict, however, it can undermine group productivity.

### *Group Structure*

In addition to a group's composition, its structure is also an important factor in how well it performs. A group's structure is the pattern of

links or relationships among group members. These links can refer to a variety of things, including who can communicate with whom, who has authority over whom, and who likes whom.

### **Communication Networks**

Sometimes the nature of the group or its task dictates who can communicate with whom. Sometimes group leaders or managers have the discretion to design their groups' communication networks. Sometimes channels of communication evolve informally in groups. Regardless of their origins, communication structures can have a strong effect on how effectively groups perform. One widely studied aspect of communication networks is their degree of centralization. Centralized networks tend to have a few "central" members who receive information from the rest of the group, process it, and then communicate back to the rest of the group. For example, the highly centralized "wheel" network has everyone in the group able to communicate with a single member at the group's "hub," but with no other members. The highly decentralized "comcon" network permits any group member to communicate with any other group member. Research on communication network centralization has shown, unsurprisingly, that different networks work best with different tasks—with fairly simple tasks, centralized networks tend to be more productive, but with more complex tasks, decentralized networks tend to be superior (in part because they avoid the problem of overloading central group members with more information than they can handle).

### **Authority Structures**

Groups can also differ in their authority structures—who has power over whom. A simple and obvious example is the distinction between hierarchical groups, where power flows from top to bottom, and egalitarian groups, where all members have similar levels of power. Clearly, the optimal authority structure depends on the group's task and even on the members' personalities. For example, John Wilson, Joel Aronoff, and Lawrence Messé showed that a hierarchical structure led to better performance at a model-building task than an egalitarian structure for groups composed of members with high safety needs (who are more

concerned with being in safe and predictable environments). They suggested that this structure provided more structure to members' work, minimized role uncertainty, and reduced the need to take initiative or risks when working on the task, all of which are important to safety-oriented people. However, the reverse was true for groups composed of members with high esteem needs (who are relatively more concerned with demonstrating their competence to others); with this task, the egalitarian structure gave members more of a chance to display their unique individual competencies.

The most interesting aspect of a group's authority structure is leadership. Given that some members have authority over the others, how should that authority be used to maximize the group's performance? Early research on leadership tended to focus on the question of what kind of person is likely to assume or be granted leadership in groups. Such work has shown that members who have status-endowing attributes (e.g., people who are taller, male, belong to higher status social categories), have resources that are useful for task performance (e.g., task ability, intelligence), show strong commitment to the group (e.g., never miss a meeting, talk a lot during group discussion), possess useful social traits (e.g., extraversion), and fit the group's prototypes of a good member (e.g., conform to group norms) or a good leader (e.g., self-confident, decisive) are more likely to emerge as group leaders.

Much subsequent work has focused on the question of what makes one leader more effective than another. An important line of research by Tom Tyler and his colleagues has shown that the procedures a leader follows when making decisions or resolving conflicts in a group are at least as important for evoking support from other members as the decisions the leader ultimately reaches. Most theories of leader effectiveness also have recognized that the nature of the group's task, membership, and norms have as much to do with a leader's effectiveness as does the behavior of the leader. For example, Fred Fiedler's contingency theory of leadership argues that a tough, task-oriented leader is most effective when facing either a very favorable group task situation (e.g., there is little conflict in the group, the task is well defined, the leader has lots of power) or, ironically, a very unfavorable situation. A leader who is less task

focused and more interpersonally focused, someone who works hard to gain acceptance by the group, is more effective when the favorability of a situation is neither good nor bad.

Other research on this topic, initiated by James Meindl, has suggested that leaders actually have less impact on group performance than their followers believe they have. This judgmental bias, called the "romance of leadership," may help satisfy our desire to believe that how well our group or organization performs is really under someone's direct control. In this view, leaders play a rather symbolic role in groups, one that convinces followers that success is possible and meaningful.

#### Evaluative Structures

Another important factor in task groups is how group members evaluate one another and the group as a whole. Methods of sociometric choice (e.g., each group member is asked how much he or she likes or respects each of the other group members) have often been used to summarize and analyze such evaluations. For most tasks, the existence of mutually antagonistic subgroups or cliques will interfere with effective group performance.

One widely studied consequence of mutual positive evaluations is enhanced group cohesiveness. Actually, scholars disagree about what it means to say that a group is cohesive. A common view is that a cohesive group is one whose members like each other and the group as a whole. Another view is that a cohesive group is one with which the members identify strongly. Yet another view is that a cohesive group is one whose members respect one another's task abilities, are highly committed to the group's goals, and are willing to work together (regardless of how much they like each other). These alternative aspects of group cohesion tend to co-occur. More importantly, cohesive groups are generally more productive. A notable exception to this rule is when the norms of a group discourage member effort, as in some industrial settings where there are sanctions for workers who work too hard (i.e., "rate busters").

#### Group Work Environment

There has also been considerable attention given to the effects of a group's work environment on its productivity. Every environment has certain physical

features, for example, that might influence a group's performance. Such features include levels of lighting, noise, and crowding in the environment. It has been shown that the absolute level of an environmental stressor is often less important for group performance than whether workers have some sense of control over that stressor. Of course, a group's social environment (e.g., relationships with other work groups in the organization, group, or organizational culture) and temporal environment (e.g., time pressures) can also affect its performance.

How group members interact with their tools and with one another can also be an important factor. The possibilities for improvement (and deterioration) of work environments have been broadened in the last few decades by striking advances in technology. These include new communication technologies (e.g., e-mail, meeting software) that enable asynchronous and distributed group work, new information technologies (e.g., large databases, the Internet) that expand the pool of readily available sources of information, and so-called group support systems. The latter permit groups to access and share information and to organize their interactions in novel ways. A good illustration is the use of computerized brainstorming, where members of idea-generating groups work at separate but interconnected computer stations rather than talking face-to-face. This avoids some of the inefficiencies of face-to-face interaction (e.g., being unable to contribute an idea while someone else is talking), but still preserves some of the distinctive advantages of group brainstorming (e.g., having access to others' ideas, which spur one's own thoughts).

### *Beyond Group Composition, Structure, and Environment*

The preceding description highlights a few of the more important performance-relevant factors that have been studied and a few illustrative findings, but this only scratches the surface of the group performance literature. This entry could just as easily have focused on other topics, such as, (a) the effects of groups engaging in some planning (it is generally helpful for performance), (b) the effects of groups reflecting on what they do (it appears not to be particularly helpful), (c) the effects of groups setting performance goals (it is generally

helpful, as long as the goals are specific and challenging), or (d) the (generally positive) effects of a collective sense of efficacy. (These topics are explored in the readings listed at the end of the entry.)

Although the focus here is on what affects group performance, keep in mind that sometimes it is at least as interesting to know what group performance affects—what are the consequences (e.g., for member commitment, for the group's future) of particular members or the group as a whole performing well or poorly. Many of the relationships discussed earlier are clearly reciprocal; for example, high group cohesiveness usually enhances group productivity, *and* high group productivity usually enhances group cohesiveness.

### **Actual Versus Potential Group Productivity**

As noted earlier, one informative baseline against which to contrast group performance is individual performance. Other baselines include those defined by some rule or function that predicts how group members combine their contributions. For example, at a task like a group tug-of-war, it might be predicted that group performance will simply equal the sum of the performances by individual members. Other popular combination rules include the average of members' performances, the best member's performance, or the worst member's performance. Such combination rules always make assumptions, if only implicitly, about the process whereby group members work together on their task. So, for example, the simple summative combination rule for a tug-of-war assumes that group members will repeat in the group what they do as individuals, and that they can combine their individual pulls efficiently (e.g., they will all pull together). By comparing actual group performance with the performance predicted by one or more combination rules, researchers can empirically test those process assumptions and thereby learn not only how well groups can perform some task, but also something about the social processes that produced that performance.

In a very influential book published in 1972, Ivan Steiner suggested that for any well-defined task, there was an optimal combination rule. That is, he suggested that given the resources individual members bring to the group (e.g., each member's task-relevant knowledge and ability) and the

demands of the task itself, there is some unique way of combining those resources that will maximize the group's productivity. He referred to that optimal level of productivity as the group's "potential productivity" and argued that this was a particularly interesting baseline against which to compare actual group performance. If the way that group members work together is less than optimal, then actual group productivity will be lower than potential group productivity. Steiner thought this was usually the case, and he called the shortfall "process loss." He suggested that process loss could stem from two things—coordination losses (when the group failed to combine or coordinate its resources in the optimal way) or motivation losses (when group members worked less hard when in the group than when working individually). By identifying and analyzing such motivation losses, one could improve group performance.

This approach is nicely illustrated by research on the Ringelmann effect. In what was history's first social psychological experiment, Max Ringelmann found that as groups pulling on a rope got larger, so did their process loss (i.e., the difference between actual productivity and potential productivity, defined as the sum of the individual members' abilities). Later research showed that this process loss was partly due to coordination losses (i.e., the more people pulling on the rope, the harder it is for them to pull at the same time and in the same direction) and partly due to motivation losses (the bigger the group, the less the average member pulls). The latter finding has led to considerable work on social loafing, revealing a number of aspects of groups that can undercut member motivation (e.g., the difficulty of identifying member contributions for many group tasks). More recently, it has been shown that the opposite can occur under some conditions—people can be more motivated when working in groups than when working alone. For example, research on the Köhler effect has shown that when people learn that other group members are less capable than themselves, or that the group may fail unless everyone does their best, motivation gains will occur.

### Conclusion

Many of our goals are pursued collectively, in groups, organizations, and nations. Given this

dependence on groups to attain so many goals, the study of group performance will continue to be a vitally important area of behavioral science. Although the general topic is extremely complex and there is still more to be learned, a great deal has already been learned in the approximately 120 years since Max Ringelmann first asked groups to grab a rope and pull as hard as they could.

## GROUP POLARIZATION

---

*Group polarization* is the tendency for group interaction to enhance group members' initial inclinations. This group polarization phenomenon, which occurs both in experimental settings and in everyday situations, provides a window through which researchers can observe group influence. Experiments have confirmed two group influences: informational and normative. The information gleaned from a discussion mostly favors the initially preferred alternative, thus reinforcing support for it. This entry begins with a look at how this line of research evolved, describes a variety of examples of group polarization, and discusses two possible explanations.

### The Case of the “Risky Shift”

The discovery of the *risky shift* phenomenon illustrates how an interesting discovery often leads researchers to hasty and erroneous conclusions, which ultimately get replaced with more accurate conclusions. While trying to understand the curious finding that group discussion enhanced risk taking, investigators discovered that discussion actually tends to strengthen whatever is the initially dominant point of view, whether risky or cautious.

A research literature of more than 300 studies comparing individual and group decision making began in 1961 with a surprising finding by James Stoner, then an MIT graduate student. For his master's thesis in industrial management, Stoner tested the commonly held belief that groups make more cautious decisions than do individuals. He invited people individually, and then in groups, to advise imagined characters how much risk to take. Here is an example of the kind of hypothetical scenario Stoner used, created for my own research:

Helen is a writer who is said to have considerable creative talent but who so far has been earning a comfortable living by writing cheap Westerns. Recently, she has come up with an idea for a potentially significant novel. If it could be written and accepted, it might have considerable literary impact and be a big boost to her career. On the other hand, if she cannot work out her idea or if

the novel is a flop, she will have expended considerable time and energy without remuneration.

Imagine that you are advising Helen. Please check the *lowest* probability that you would consider acceptable for Helen to attempt to write the novel. Helen should attempt to write the novel if the chances that the novel will be a success are at least [intervals range from 1 in 10 to 10 in 10].

After making your decision, guess what the average person would advise.

Having marked their advice on a dozen such items, five or so individuals in Stoner's study would then discuss and reach agreement on each item. To everyone's amazement, given popular commentary about the conservatism of groups, the group decisions were usually riskier. During discussion, group members' opinions converged. Curiously, however, the point toward which they converged was usually a lower (riskier) number than their initial average.

Here was an interesting puzzle. The small risky shift effect was reliable, unexpected, and without any immediately obvious explanation. Dubbed the *risky shift phenomenon*, this finding inspired studies of risk taking by individuals and groups. These revealed that the risky shift occurs not only when a group decides by consensus—after a brief discussion, individuals, too, will alter their decisions. What is more, researchers successfully repeated Stoner's finding with people of varying ages and occupations in a dozen nations.

What group influences produce such an effect? And how widespread is it? Do discussions in juries, business committees, and military organizations also promote risk taking? Does this explain why teenage reckless driving, as measured by death rates, nearly doubles when a 16- or 17-year-old driver has two teenage passengers rather than none?

After several years of study, researchers discovered that the risky shift was not universal. They could write decision dilemmas on which people became more cautious after discussion. One of these featured “Roger,” a young married man with two school-age children and a secure but low-paying job. Roger can afford life's necessities but few of its luxuries. He hears that the stock of a relatively unknown company may soon triple in value if its new product is favorably received—or

decline considerably if it does not sell. Roger has no savings. To invest in the company, he is considering selling his life insurance policy.

Is there a general principle that predicts both the tendency to give riskier advice after discussing Helen's situation and more cautious advice after discussing Roger's? Most people advise Helen to take a greater risk than Roger, even before talking with others. Group discussion then accentuates these initial leanings. Thus, group members discussing Roger's dilemma become, on average, more risk averse than they were before discussion.

### Do Groups Intensify Opinions?

Realizing that this group phenomenon was not a consistent shift toward increased risk, researchers reconceived it as a phenomenon in which discussion typically strengthens the average inclination of group members. This idea led investigators to propose what French researchers Serge Moscovici and Marisa Zavalloni in 1969 called *group polarization*, the tendency for group discussion to enhance group members' initial leanings.

#### *Group Polarization Experiments*

This new view of the changes induced by group discussion prompted experimenters to have people discuss attitude statements that most of them favored or most of them opposed. Will group interaction not only lead risk takers to become riskier, but bigots to become despisers, and givers to become more philanthropic? The following are examples chosen from dozens of studies that confirm such group polarization:

- Moscovici and Zavalloni observed that discussion enhanced French students' initially positive attitude toward their president and negative attitude toward Americans.
- Mititoshi Iozaki found that Japanese university students gave more pronounced judgments of "guilty" after discussing a traffic case.
- Markus Brauer and his coworkers found that French students' dislike for certain other people was exacerbated after discussing their shared negative impressions.

- Glen Whyte reported that groups accentuate the "too much invested to quit" phenomenon that has cost many businesses huge sums of money. Canadian business students imagined themselves having to decide whether to invest more money in the hope of preventing losses in various failing projects (for example, whether to make a high-risk loan to protect an earlier investment). They exhibited the typical effect: 72% reinvested money they would probably not have invested if they were considering it as a new investment on its own merits. When making the same decision in groups, 94% opted for reinvestment.

Another research strategy has been to pick issues on which opinions are divided and then isolate people who hold the same view. Does discussion with like-minded people strengthen shared views, and does it magnify the attitude gap that separates the two sides? George Bishop and David Myers investigated this question by setting up groups of relatively prejudiced and unprejudiced high school students and asking them to respond—before and after discussion—to issues involving racial attitudes, such as property rights versus open housing. They found that the discussions among like-minded students did indeed increase the initial gap between the two groups.

#### *Group Polarization in Everyday Life*

In everyday life, people associate mostly with others whose attitudes are similar to their own. Does everyday group interaction with like-minded friends intensify shared attitudes? Do nerds become nerdier and jocks jockier?

It happens. The self-segregation of boys into all-male groups and of girls into all-female groups accentuates over time their initially modest gender differences, notes Eleanor Maccoby. Boys with boys become gradually more competitive and action oriented in their play, while girls with girls become more relationally oriented.

On U.S. federal appellate court cases, "Republican-appointed judges tend to vote like Republicans and Democratic-appointed judges tend to vote like Democrats," David Schkade and Cass Sunstein observed in 2003. That's understandable. But, as these researchers noted, such tendencies are accentuated when judges are among

other like-minded judges: “A Republican appointee sitting with two other Republicans votes far more conservatively than when the same judge sits with at least one Democratic appointee. A Democratic appointee, meanwhile, shows the same tendency in the opposite ideological direction.”

### *Group Polarization in Schools*

Another real-life parallel to the laboratory phenomenon is what education researchers have called the *accentuation phenomenon*: Over time, initial differences among groups of college students become accentuated. If the first-year students at College X are initially more intellectual than the first-year students at College Y, that gap is likely to increase by the time they graduate. Likewise, compared with fraternity and sorority members, independents tend to have more liberal political attitudes, a difference that grows with time in college. Researchers believe this results partly from group members reinforcing shared inclinations.

### *Group Polarization in Communities*

Polarization also occurs in communities, as people self-segregate. Liberal communities attract liberals and become more liberal, while conservative places attract conservatives and become more conservative. Neighborhoods become echo chambers, with opinions ricocheting off kindred-spirited friends. In the United States, the end result has become a more divided country. The percentage of landslide counties—those voting 60% or more for one presidential candidate—nearly doubled between 1976 and 2000. The percentage of entering collegians (in UCLA’s annual survey) declaring themselves politically “middle of the road” dropped from 60% in 1983 to 43% in 2008, with corresponding increases in those declaring themselves on the right or the left.

On college campuses, the clustering of students into mostly White sororities and fraternities and into ethnic minority student organizations tends to strengthen social identities and to increase antagonisms among the social groups.

In laboratory studies, the competitive relationships and mistrust that individuals often display when playing games with one another often

worsen when the players are in groups. During actual community conflicts, like-minded people associate increasingly with one another, amplifying their shared beliefs. Gang delinquency emerges from a process of mutual reinforcement within neighborhood gangs, whose members share attributes and hostilities. If “a second out-of-control 15-year-old moves in [on your block],” surmised David Lykken in 1997, “the mischief they get into as a team is likely to be more than merely double what the first would do on his own. . . . A gang is more dangerous than the sum of its individual parts.” Indeed, “unsupervised peer groups” are the strongest predictor of a neighborhood’s crime victimization rate, reported Bonita Veysey and Steven Messner. Moreover, experimental interventions that take delinquent adolescents and group them with other delinquents actually—no surprise to any group polarization researcher—increase the rate of problem behavior.

### *Group Polarization on the Internet*

E-mail and electronic chat rooms offer a potential new medium for group interaction. By the beginning of the new century, 85% of Canadian teens were using the Internet for an average of 9.3 hours weekly. Its countless virtual groups enable peacemakers and neo-Nazis, geeks and Goths, conspiracy theorists and cancer survivors to isolate themselves with like-minded others and find support for their shared concerns, interests, and suspicions. Without the nonverbal nuances of face-to-face contact, will such discussions produce group polarization? Will peacemakers become more pacifistic and militia members more terror prone? E-mail, Google, and chat rooms “make it much easier for small groups to rally like-minded people, crystallize diffuse hatreds and mobilize lethal force,” observed Robert Wright in 2003. As broadband spreads, Internet-spawned polarization will increase, he speculated.

### *Group Polarization in Terrorist Organizations*

From their analysis of terrorist organizations around the world, Clark McCauley and Mary Segal surmised that terrorism does not erupt suddenly. Rather, it arises among people whose shared grievances bring them together. As they interact in isolation from moderating influences, they become

progressively more extreme. The social amplifier brings the signal in more strongly. The result is violent acts that the individuals, apart from the group, would never have committed.

For example, the September 11, 2001, terrorists were bred by a long process that engaged the polarizing effect of interaction among the like-minded. The process of becoming a terrorist, noted a National Research Council panel, isolates individuals from other belief systems, dehumanizes potential targets, and tolerates no dissent. Over time, group members come to categorize the world as “us” and “them.” Ariel Merari, an investigator of Middle Eastern and Sri Lankan suicide terrorism, believes the key to creating a terrorist suicide is the group process. In 2002, he wrote: “To the best of my knowledge, there has not been a single case of suicide terrorism which was done on a personal whim.” According to one analysis of terrorists who were members of the Salafi Jihad—an Islamic fundamentalist movement, of which al Qaeda is a part—70% joined while living as expatriates. After moving to foreign places in search of jobs or education, they became mindful of their Muslim identity and often gravitated to mosques and moved in with other expatriate Muslims, who sometimes recruited them into cell groups that provided “mutual emotional and social support” and “development of a common identity.” Massacres, similarly, have been found to be group phenomena. The violence is enabled and escalated by the killers egging each other on.

### Explaining Polarization

Why do groups adopt stances that are more exaggerated than that of their average individual member? Researchers hoped that solving the mystery of group polarization might provide some insights into group influence. Solving small puzzles sometimes provides clues for solving larger ones.

Among several proposed theories of group polarization, two have survived scientific scrutiny. One deals with the arguments presented during a discussion, the other with how members of a group view themselves vis-à-vis the other members. The first idea is an example of *informational influence* (influence that results from accepting evidence about reality). The second is an example of *normative influence* (influence based on a person’s desire to be accepted or admired by others).

### *Informational Influence*

According to the best-supported explanation, group discussion elicits a pooling of ideas, most of which favor the dominant viewpoint. Ideas that are common knowledge to group members will often be brought up in discussion or, even if unmentioned, will influence their discussion. Other ideas may include persuasive arguments that some group members had not previously considered. When discussing Helen the writer, someone may say, “Helen should go for it, because she has little to lose. If her novel flops, she can always go back to writing cheap Westerns.” Such statements often entangle information about the person’s *arguments* with cues concerning the person’s *position* on the issue. But when people hear relevant arguments without learning the specific stands other people assume, they still shift their positions. Arguments, in and of themselves, matter.

But there is more to attitude change than merely hearing someone else’s arguments. Active participation in discussion produces more attitude change than does passive listening. Participants and observers hear the same ideas, but when participants express them in their own words, the verbal commitment magnifies the impact. The more group members repeat one another’s ideas, the more they rehearse and validate them. Just privately writing out one’s ideas in preparation for an electronic discussion tends to polarize attitudes somewhat.

### *Normative Influence*

A second explanation of polarization involves comparison with others. As Leon Festinger argued in his influential theory of social comparison, we humans want to evaluate our opinions and abilities, something we can do by comparing our views with those of others. We are most persuaded by people in our reference groups—groups with which we identify. Moreover, wanting people to like us, we may express stronger opinions after discovering that others share our views.

When we ask people to predict how others would respond to items such as Helen’s dilemma, they typically exhibit pluralistic ignorance: They don’t realize how strongly others support the socially preferred tendency (in this case, writing

the novel). A typical person will advise writing the novel even if its chance of success is only 4 in 10 but will estimate that most other people would require 5 or 6 in 10. (This finding is reminiscent of the self-serving bias: People tend to view themselves as better-than-average embodiments of socially desirable traits and attitudes.) When the discussion begins, most people discover they are not outshining the others as they had supposed. In fact, some others are ahead of them, having taken an even stronger position in favor of writing the novel. No longer restrained by a misperceived group norm, they are liberated to voice their preferences more strongly.

This social comparison theory prompted experiments that exposed people to others' positions but not to their arguments. This is roughly the experience we have when reading the results of an opinion poll or of exit polling on election day. When people learn others' positions—without prior commitment and without discussion or sharing of arguments—will they adjust their responses to maintain a socially favorable position? Indeed, they will. This comparison-based polarization is usually less than that produced by a lively discussion. Still, it is surprising that, instead of simply conforming to the group average, people often go it one better.

Group polarization research illustrates the complexity of social psychological inquiry. As much as we like our explanations of a phenomenon to be simple, one explanation seldom accounts for all the data. Because people are complex, more than one factor frequently influences an outcome. In group discussions, persuasive arguments predominate on issues that have a factual element (“Is he guilty of the crime?”). Social comparison sways responses on value-laden judgments (“How long a sentence should he serve?”). On the many issues that have both factual and value-laden aspects, the two factors work together. Discovering that others share one's feelings (social comparison) unleashes arguments (informational influence) supporting what everyone secretly favors.

## GROUP POSITION THEORY

---

The study of prejudice is a cornerstone of social psychological and sociological research. Traditionally, *prejudice* has been defined as negative attitudes toward a person due to his or her membership in a social group. *Race prejudice*, then, is a form of prejudice directed toward people on the basis of their perceived racial group. *Group position theory* is a sociological analysis of race prejudice which posits that its source lies in the structural relationship of racial groups in a given society. Fundamentally, it suggests that the features that make up prejudice are derived from the relationships between racial groups and a group's preferred position in a racialized social order, rather than in the individual feelings and experiences of group members. This entry discusses the historical foundations of group position theory, outlines its core tenets, and highlights empirical research that has investigated the theory. It closes by drawing connections between group position theory and existing lines of research, as well as offering suggestions and implications for future

research. In doing so, the entry integrates and elaborates on the basic premises of the group position theory of prejudice.

### The Theory

In 1958, the sociologist Herbert Blumer published a short essay urging researchers to move beyond a focus on individual feelings, such as antipathy and hatred, as an explanation for racial prejudice. At the time of its publication, the literature emphasized that these individual feelings derived from innate dispositions, such as having an authoritarian personality, and direct social experience. Blumer proposed that scholars should instead examine the positioning of racial groups in a given society and how dominant racial groups come to define and redefine subordinate racial groups.

Race prejudice begins with racial identification: People identify themselves and others as belonging to distinct racial groups. Beyond mere identification, groups form images of themselves and other groups. In a racialized social order, characterizing one's own racial group defines the characteristics of the other group. This ongoing process of definition and redefinition places the racial group in position vis-à-vis the other. For example, in the United States one cannot characterize Blacks without evoking, at least implicitly, a comparison with Whites.

A sense of group position is first set by the initial contact between the groups and later molded by ongoing relations. Factors such as power, skill sets, and opportunity play a role in this process. This arrangement reflects more than a vertical arrangement of groups based on social status—it reflects at least two distinct axes, one marked by domination and the other marked by exclusion. The structural relations of the groups need not reflect objective reality, but instead a subjective sense of where racial groups belong. The sense of group position is common to all who identify with the ingroup and provides a framework for members, acting as a powerful norm that guides its members and provides an orientation of what ought to be. Group position theory argues that it is when this orientation (i.e., the perception of where one's group stands in the social order) is threatened that race prejudice is manifested.

### Core Features

As the definition process suggests, initial conceptualizations of group position theory examined race prejudice toward the subordinate racial group(s) from the perspective of the dominant racial group. For dominant group members, racial prejudice comprises four features. First, the dominant racial group feels a sense of superiority to other racial groups. Second, inferior racial groups are viewed as qualitatively different from the dominant group. Third, members of the dominant racial group feel that they are entitled to certain privileges and advantages. Fourth, dominant group members also possess a basic fear of members of subordinate racial groups—they feel that the subordinate group threatens their dominant position.

Feelings of superiority place the subordinate group below the dominant group and may or may not be manifested in denigration of the qualities of the subordinate racial group(s), for example in the form of negative stereotypes. Categorizing the subordinate group as “alien” allows the dominant group to place it beyond the dominant group. Together, these feelings act to reflect, justify, and promote social exclusion. While superiority and distinctiveness may give rise to feelings of antipathy and aversion, this conceptualization reflects only a limited understanding of race prejudice. Additionally, while dominant groups' sense of proprietary claim and entitlement to important areas of life (exclusive membership in given institutions, claims to positions of prestige and power) excludes the subordinate group, according to group position theory, it does not fully explain racism. For example, within a caste system a sense of superiority, qualitative distinctiveness, and entitlement may be solidified into a structure that is accepted, or at least respected, by all of its members, regardless of their position.

These features point to a positional arrangement of the dominant racial group in relation to the subordinate racial group. With these features in place, race prejudice arises from a fear or suspicion that the subordinate racial group threatens the position of the dominant group. Perceived challenges may arise from a number of different sources—real or imagined attacks on the natural superiority of the dominant group, an intrusion into the sphere of group exclusiveness, or an

encroachment on areas of proprietary claim. Group position theory thus proposes that race prejudice is a defensive reaction to preserve the position of the dominant group.

### Research Examining Group Position Theory

Blumer placed perceptions of group position and the role of competition and threat at the core of racial prejudice. This was a distinct movement away from the literature of the time, which focused on individual processes. Blumer did not, however, conduct an empirical investigation of the premises of the group position theory. The majority of subsequent inquiries into the theory have been restricted to indirect tests of its core mechanisms. Studies that have not employed indirect tests of the model have relied on secondary data analyses with less than ideal measures of core constructs. A number of these empirical investigations reduce the theory to a structural-level claim of objective threat. These lines of research, however, are worthy of note because of their efforts to examine claims embedded in the approach, as well as their efforts to expand the group position theory to consider dominant and subordinate groups.

Lawrence Bobo has examined a number of social situations where dominant group members perceive that they are losing social standing to members of a racial minority group. For example, a heated dispute over the fishing, hunting, and gathering rights of the Chippewa Indians in the state of Wisconsin led to many Whites feeling deprived in relation to the Chippewa with respect to their perceived gains in resources. In this situation, it was not that the dominant racial group perceived the subordinate racial group as inferior or used negative stereotypes to characterize the group but, as Bobo's research suggested, that Wisconsin residents perceived the Chippewa Indians to be gaining resources at their expense.

In an intriguing line of research, group position theory has been expanded to examine race prejudice held by minority groups by looking at feelings of racial alienation. Racial alienation manifests in a profound sense of group deprivation and a weak, or nonexistent, sense of group entitlement. The more group members feel alienated, the more likely they are to regard other racial groups as competitive threats to their social position.

Assuming that members of dominant groups will rarely feel alienated due to their substantial institutionalized privileges, this extension of the group position model implies that alienated minority groups may hold the strongest feelings of racial prejudice.

### Limitations of Group Position Theory

While research highlights many of the components of the group position model, a fully elaborated empirical model of the elements of perceived group position has yet to be provided. Additionally, the process of identifying with one's ingroup and the formation of a group identity are missing from the literature. A number of researchers have argued that the use of statistical analyses of survey data can distort many of group position theory's primary claims, suggesting that quantitative methodologies reduce processes such as race prejudice to basic survey questions that fail to capture the complexities of the original concept. They further argue that race relations are in constant process of formation and variable analysis is too crude an instrument to capture this fluidity.

### Related Theories

Group position theory shares commonalities with other approaches, in particular Muzafer Sherif's realistic group conflict theory and James Sidanius and Felicia Pratto's social dominance theory, but there are clear distinctions. A sense of group position involves elements of realistic group conflict theory. Both theories examine groups that occupy unequal positions within a social order and the interests that attach to those positions. The two theories highlight the role of perceived threats to groups' interests and struggles over access to both real and symbolic resources. Group position theory, however, adds a normative and affective aspect that is not derived from purely material conflicts. Further, while realistic conflict theory stresses the importance of objective competition, group position theory stresses the subjective sense of group position. Both group position theory and social dominance theory share an emphasis on feelings of entitlement, but within social dominance theory perceptions of competition and threat are not clearly articulated.

### Conclusion

In examining the relationship between groups as a source of racial prejudice, group position theory draws attention to the collective process by which one group comes to define, and redefine, another group, as well as the manner in which individuals' sense of their group's position in a social order guides their behavior toward other racial groups. The theory incorporates concepts from both psychological and sociological literature on prejudice, such as attitudes, affect, stereotypes, group identity, and patterns of intergroup contact. By drawing on these sources, group position theory posits that prejudice is not a unidimensional construct. Prejudice involves more than negative beliefs and feelings, and to fully understand this multifaceted force, scholars must recognize that it concerns powerful commitment to a preferred group position.

## GROUP POTENCY

---

*Group potency* is the collective belief within a group that it can be effective. There are two important

aspects of group potency: (1) it is a belief of mutual confidence that is shared by the members of the group and (2) it is a general belief that the group is effective across a variety of tasks or situations, rather than only in a specific context. Group potency is an important concept in fields such as group dynamics, management, and industrial/organizational psychology, because a large volume of research suggests that group potency and performance are positively and reciprocally related. However, when groups are overconfident, or possess too much group potency, their performance can suffer. This entry begins with a brief history of such research, then looks at factors affecting group potency, related characteristics, and applications of the research.

### Background

The notion of group potency stems from the seminal work of industrial psychologist Leonard R. Sayles, who studied work groups in manufacturing plants in the 1950s. Sayles found that “strategic” work groups—those with high levels of collective beliefs about their effectiveness—were successful in their work, and that “apathetic” work groups—those that lacked such beliefs—were unsuccessful. Sayles also noted that in strategic work groups, success breeds success in the sense that prior good performance can build collective beliefs of efficacy that then can lead to subsequent levels of high performance. Similar observations were made in studies conducted in the 1990s by team researchers such as Richard Hackman.

These findings parallel ideas developed by psychologist Albert Bandura, whose social cognitive theory identified self-efficacy and collective efficacy as powerful motivational forces for individuals and groups, respectively. Bandura described self-efficacy as an individual's belief that he or she could successfully complete a specific task, in contrast with collective efficacy, an individual's personal belief that his or her group can be successful in performing a specific task. While self-efficacy is an individual-level phenomenon targeting an individual's ability to meet a specific goal, collective efficacy involves the group's perceived ability to be successful. In each of these cases, in addition to ability, it is the individual's thoughts about himself or herself or the group that can make a critical

difference between being a low performer or a high performer on an individual or collective task.

Building upon this research, Richard Guzzo and Gregory Shea developed the notion of group potency (which involves group members' shared views) in the early 1990s through a series of experiments and field studies. These researchers developed a conceptual framework and a widely used measure of group potency. In addition, Guzzo and Shea demonstrated the distinctiveness of group potency from collective efficacy and other motivational concepts.

### Factors Affecting Group Potency

Group potency stems from factors internal and external to the group. Regarding factors external to the group, research shows that a supportive organizational context goes a long way in building group potency. Organizations that provide rewards, education, information, resources, and goals help to support potent groups. Adequate communication and cooperation among groups within an organization helps group members share information and resources so that they can feel more confident about their group's ability to perform. In line with Bandura's social learning theory, organizational leaders who model supportive behavior for team members encourage them to persist through difficult times, challenge them to rethink their ways of doing things, and coach and mentor them to build group potency.

These leadership behaviors are associated with transformational leadership, which research has linked to the development of group potency in both face-to-face and computer-mediated work groups. Transformational leaders enhance group potency by stressing the importance of group members working together and highlighting the link between group synergy and successful group outcomes. This form of leadership influence can become an internal force that builds group norms and shapes group processes. For example, the repeated emphasis on group members' interdependence and the cooperation–outcome link focuses members' attention on their collective abilities, thereby increasing the value and appreciation of their talents and skills. Such an appreciation builds collective confidence because a group's belief about its ability to be effective is influenced, in

part, by that ability. One study of officer cadets working in groups indicated that group potency was an important factor in predicting performance on a problem-solving task, regardless of the group's actual ability.

In addition to leadership, other factors internal to the group can shape members' potency beliefs. Groups that set clear goals early in the group's life are more likely to feel confident. Groups whose members are aware of and value each others' knowledge, skills, abilities, and life experiences may feel more potent. Prior research suggests that group size may also influence group potency—too few members may limit the knowledge and talent base, thereby decreasing potency, whereas too many members may lead to subgroup formation and conflicts that also can erode group potency. In general, functional diversity is positively associated with group potency. Research also indicates that group members' psychological state, such as experiencing “flow,” or being highly engaged in a task, can elevate group potency. In addition, when groups experience leadership *by* the group (each member shares leadership duties) rather than leadership *of* the group (by one group member), group potency may also increase. Thus, leadership can be an important internal and external force for shaping group potency.

There are also factors that can detract from group potency. One is group tenure. The longer a group works together, the more complacent members can become about their roles and abilities. A sense of confidence can be problematic when the group has performed well over a long period of time, but suddenly things change in the environment and members are too comfortable to adapt to the new situation. This is especially problematic in service industries where customer expectations and requirements for quality are constantly changing. Other deleterious effects of group potency can stem from unexpected changes in group membership, personal conflicts among group members, and free riding or social loafing by some members of the group.

### Correlates of Group Potency

Group potency has been linked to group cohesiveness and outcome satisfaction. Groups with strong bonds between their members appear to have high

levels of confidence in their collective ability to be effective. Potent groups also appear to be satisfied with their achievements. These group characteristics provide process gains that build the belief that the whole is greater than the sum of its parts.

Research suggests that group potency and performance are reciprocally related. In general, increases in group potency lead to increases in performance, thereby increasing subsequent levels of group potency and so on. This spiraling effect results from positive feedback that comes with high levels of performance. Such feedback reinforces group members' positive beliefs about their abilities and effectiveness, and can lead to winning streaks for sports teams.

The relationship between group potency and performance depends on the type of performance measured. Researchers have observed positive associations between group potency and creativity, work outcomes, product quality, and customer service perceptions. In contrast, group potency has been shown to have a negative effect on the profitability of service group operations. This is because the goals of customer service and profitability may be at odds due to the competing values of providing high levels of customer service, which can be costly, and reduce operating profits.

Group potency has been shown to reduce the harmful effects of a group's task conflict (i.e., disagreement about beliefs and/or methods related to tasks being performed) on processes and outcomes in computer-mediated settings. In one study, task conflict was negatively related to group cohesiveness, effectiveness, and outcome satisfaction only in groups with low levels of group potency. It appears that group potency may soften the impact of task conflict and help groups achieve desirable processes and outcomes.

### Applications

Group potency has several potential applications for organizations using groups or teams to complete tasks. Given the increasing use of face-to-face work groups and virtual teams in organizations, managers may consider developing training programs focusing on factors external and internal to the group that can build group potency (e.g., transformational leadership, reward systems). Building on the positive psychology literature, management

development organizations have recently created training programs that emphasize group members' hope, optimism, confidence, and resilience, which represent factors that may be related to group potency. Coordinators of teams may consider exploring the relationship between these positive psychological states and the development of group potency. Support from senior management (e.g., resources), the creation and maintenance of functionally diverse groups, and support from other groups in the organization may also be useful strategies for building group potency.

## GROUP PROBLEM SOLVING AND DECISION MAKING

---

In the broadest sense, a problem is a discrepancy between an actual current state and a desired future state. Examples are the givens in an algebra word problem and the correct answer, the engineering specifications for a new SUV and the finished model, and the clues and the correct answers in a crossword puzzle. Similarly, in the broadest sense, a decision is a choice among alternatives.

Examples are guilty or not guilty for a jury, Mortgage X or Mortgage Y for a homebuyer, and Candidate A, B, or C for voters in an election. Social psychological theory and research on group problem solving and decision making abstracts from these examples by conducting laboratory experiments with simplified tasks, typically with college students. This theory and research distinguishes (a) the group task, (b) the group structure, (c) the group process, and (d) the group product. The group task is what the group is attempting to do. Group structure includes *member characteristics*, such as beliefs, competencies, interests, and preferences; *roles*, such as leader or ordinary member; and *norms*, such as carefully considering the pros and cons of proposed alternatives. Group process entails who says what, when, how, to whom, and with what effect, and the ways in which group members combine their different beliefs and preferences. Finally, the group product is the problem solution or decision of the group, which achieves or fails to achieve the group goal on the task. This entry summarizes the generalizations that have emerged from research on group problem solving and decision making.

### Group Tasks

*Intellective tasks* have a correct solution, such as mathematical problems, logical reasoning problems, or crossword puzzles. On intellective tasks, one or more group members who know a correct answer may demonstrate it to the incorrect members who have sufficient understanding to recognize a correct answer. *Judgmental tasks* are evaluative, behavioral, or aesthetic judgments and preferences for which no objectively correct demonstrable answer exists, such as whether George Washington or Abraham Lincoln was a greater president, blackberry or raspberry a tastier jam, or (absent conclusive evidence) a defendant is innocent or guilty in a jury trial. On intellective tasks, the objective for the group is to obtain the correct answer, whereas on judgmental tasks the objective is to achieve consensus on some response. Although “intellective-judgmental” is a continuous dimension rather than a dichotomy, the tasks used in research tend to fall at one end or the other of this dimension, and so it is convenient to organize research findings in terms of group problem

solving on intellective tasks and group decision making on judgmental tasks.

Group tasks may also be distinguished by the number (or proportion) of group members necessary for a collective response. On *conjunctive* tasks, all group members must succeed for the group to succeed, such as a team of mountain climbers roped together or a team of neurological surgeons removing a tumor. On *disjunctive* tasks, only one group member needs to succeed for the group to succeed, such as three students attempting to solve a geometry problem or a family trying to recall the name of a distant relative. Conjunctive and disjunctive tasks define the endpoints of a dimension of the number of members necessary for a group decision. This number is often formalized by constitutions and bylaws, such as unanimity in jury decisions for capital cases or simple majority to pass a motion using Robert’s Rules of Order.

### Social Combination Processes

Social combination processes map a distribution of group member beliefs, opinions, or preferences to a single collective group response. Examples include members who favor the correct or incorrect answer to a problem, jury members who believe that a defendant is guilty or innocent, and voters who prefer Candidates A, B, or C in an election. To illustrate, consider five people who attempt to solve an algebra problem alone and then as a group. All five members may be correct, four correct and one incorrect, three correct and two incorrect, and so on. Given these distributions of member preferences, do groups follow a majority process such that groups of five, four, or three correct group members will be correct and groups of three, four, or five incorrect members will be incorrect (a *majority wins* social combination process)? Is one correct member necessary and sufficient for a correct group response (a *truth wins* process)? Or are two correct members necessary and sufficient (a *truth-supported wins* process)? Finally, is the probability of a correct group response proportional to the number of correct group members (a *proportionality* process)? These and other plausible group processes may be formalized as social combination models, and the predictions of different models competitively tested against the responses of a number of

groups. Thus, the relationship between the nature of the task and the number of group members who are necessary and sufficient for a group response is an important research question.

### Generalizations About Group Problem Solving

#### *Group Memory*

Evidence indicates that the collective memory of a group is better than the average memory of its members. This has been demonstrated for both recall and recognition memory and for both verbal material and events. Typically two or three accurate group members are necessary for a correct group response. Experiments on mock juries have demonstrated that the collective jury memory is better than the individual memory of the average member and that a quarter to a third of the jury members will suffice for the jury to accurately recall the evidence and judge's instructions.

*Transactive memory* is the capacity of group members to learn and remember different things, which gives them more collective than individual memory. This has been demonstrated in social and work groups. The crucial factors are agreement on who will learn and know what and coordination of the group members to the task demands. For example, task demands may be conjunctive, requiring all members to learn the same thing, or disjunctive, allowing each member to learn and remember different things.

Information sharing has also been studied. Experimenters have distributed information among individuals in different ways and then asked them to make a collective decision. For example, each of three group members may be given two items of information that favor Candidate A (shared information) and a different item that favors Candidate B (unshared information). If the members each mention their unshared information and the group discusses it, they will make an optimal decision (say, Candidate B). However, if they discuss only the shared information, they will make a suboptimal decision (say, Candidate A). The initial experiments using this *hidden profile task* found that the groups tended to discuss the common information and not the unshared information, which led them to make suboptimal decisions. This robust *common*

*knowledge effect* has been demonstrated for various tasks, such as choosing one of three candidates for a position, identifying one of three suspects for a crime, and selecting one of three investment opportunities.

Further research has shown that the common knowledge effect may be overcome in at least three ways. First, the group may be instructed that the decision is an intellectual task with a correct answer rather than a judgmental task that is a matter of preference. Second, the experimenter may instruct each group member to concentrate on learning the evidence favoring a particular response and then tell all the members which person has which evidence. Third, a leader may encourage all group members to express all of the information they possess, even if it is not corroborated by other members.

#### *World Knowledge*

Groups perform better than the average individual on what are referred to as "world knowledge" tasks, such as vocabulary, geography, history, basic science, and verbal analogies. The basic social combination process on such tasks is truth-supported wins, where two correct members who support each other are necessary and sufficient to convince an erroneous majority.

#### *Mathematical and Logical Problem Solving*

Groups also perform better than individuals on mathematical and logical reasoning problems. The usual social combination process is truth wins, where a single correct member is necessary and sufficient for a correct group response. On these problems, a correct answer exists and a single correct member is able to demonstrate the answer to incorrect members, who have sufficient knowledge to recognize the answer.

Most of the research examining mathematical and logical problem solving has involved an equal number of groups and individuals. Such research compares groups and the *average* individual. Some recent research has compared groups and an equivalent number of individuals, for example 40 four-person groups and 160 individuals. This allows comparison of the groups with the best, second-best, third-best, and fourth-best individuals. On some tasks, groups perform at the level of

their best member. On other tasks, groups perform better than their best member.

### *Quantity Estimation*

Research has compared groups and individuals on estimations of quantities, such as the population of cities, lengths of rivers, and revenues of corporations, for which correct answers exist but are generally unknown by ordinary people. In general, groups perform somewhat better than individuals, and at the level of their average member, in quantity estimation. Both groups and individuals make better estimations when given a frame of reference, such as estimating the length of the Ohio River given the length of the Mississippi River or estimating the population of Florida given the population of Texas. These frames of reference convert a raw estimation into a more intellectual task by allowing reasoning from the given information to the estimated quantity.

### *Collective Induction*

Collective induction is the cooperative search for generalizations, rules, and principles. This is the essence of scientific inquiry. One research program has simulated this process using a rule-learning task with ordinary playing cards. The correct rule may be based on any characteristic of the cards, such as suit (e.g., clubs), number (e.g., larger than seven), alternation (e.g., red and black cards alternate), or any combination of these. The problem begins with a known example of the correct rule (e.g., the eight of diamonds for the rule two red and two black cards alternate). On each trial the group members propose individual hypotheses, agree on a group hypothesis, and choose any card to test their hypothesis. Examples of the correct rule are placed to the right of the previous example, and nonexamples are placed below the last card played, so that an array of evidence (examples and/or nonexamples in the order of play) develops over successive trials.

This inductive rule-learning task is both intellectual and judgmental: Hypotheses that do not fit the evidence may be demonstrated to be nonplausible (intellectual), but correct hypotheses may not be demonstrated to be uniquely correct relative to other plausible hypotheses that also fit the evidence

(judgmental). Four generalizations emerge from this research. First, if the correct hypothesis is proposed by a group member, it is virtually certain to be the final correct group hypothesis. However, groups do not form correct group hypotheses that no member has proposed. Second, groups perform at the level of the best of an equivalent number of individuals. Third, multiple examples and nonexamples of the correct rule are more important than multiple hypotheses (proposed rules). In other words, group members are able to generate sufficient hypotheses to determine the correct answer, but they need sufficient evidence to evaluate them. Fourth, positive tests (choosing a card that fits the current hypothesis) are more effective than negative tests (choosing a card that does not fit the current hypothesis), because positive tests are more likely to lead to further examples that make the correct rule more apparent.

## Generalizations About Group Decision Making

### *Mock Jury Decisions*

A large amount of research has studied mock juries making decisions in criminal or civil cases. In this research, individuals typically read a trial summary and choose their preferred verdict (e.g., guilty or not guilty). They then discuss the case as a group and choose a collective verdict. Because the pregroup individual decisions are known, the social combination process that underlies the group decision can be determined.

Several generalizations emerge from the research on criminal cases. First, there are few differences between the verdicts of smaller (e.g., six-person) and larger (e.g., twelve-person) juries. Second, groups follow a two-thirds majority decision process. Third, decisions for groups that do not have a two-thirds majority favor the defendant, a finding known as a *leniency bias*. Fourth, juries seem to follow two different types of deliberation and decision processes. *Verdict-driven juries* quickly divide into factions favoring different verdicts. Each faction proposes only evidence that favors its verdict, and the factions argue and take many ballots until enough jurors change to allow a group decision. In contrast, *evidence-driven juries* collectively consider evidence for and against the

defendant and construct a story of the sequence of events. After they have constructed this story, they consider which of the possible verdicts matches the story. Thus, verdict-driven juries approach the decision as an adversarial process, whereas evidence-driven juries approach the decision as a cooperative problem-solving process. While the decisions resulting from the two types of deliberation are similar, members of evidence-driven juries afterwards are more satisfied with the deliberation process and more likely to feel that both their own and others' views were fully considered. Fifth, the most important individual characteristic that predicts influence in the jury deliberations is world knowledge, which is acquired by education, reading, travel, and occupational and organizational experience.

Research has also investigated damage decisions in civil cases. Here, a rather different pattern of influence occurs. In civil cases, members who are closest to the group median have the most influence on the jury decision.

### *Choice Shift and Group Polarization*

In the early 1960s, an experiment was conducted in which college students considered hypothetical scenarios with two possible actions, one leading to a more desirable but less likely outcome, and the other leading to a less desirable but more likely outcome. For example, they were told that a student has been accepted in two graduate programs in chemistry, a rigorous program in a prestigious university in which few students succeed in obtaining their PhD, and a less rigorous program in a less prestigious university in which virtually all students succeed. Success in the rigorous program was described as leading to a better career, but as a more risky choice. When making group decisions about what odds of success they would accept in order for the student to choose the more rigorous university, participants made more risky decisions than the average group member had previously made as an individual. This result, which was replicated with many hypothetical scenarios and with many different populations, is called the *risky shift*.

However, scenarios were soon written in which groups accepted less risk than their average member in such situations as marriage and investment in an unstable foreign country, which is called the

*cautious shift*. Subsequently, it was realized that groups generally make more extreme decisions in the direction of the prevailing tendency of their members, which is called the *choice shift*. The important generalization is that groups exaggerate the prevailing tendency of their members. The two major theoretical explanations for the choice shift are *persuasive arguments theory* and *social comparison theory*. Persuasive arguments theory emphasizes that group members encounter new arguments during group discussion, which cause them to shift their position in a more extreme direction. Social comparison theory emphasizes that group members desire to look as good as or better than others, which causes them to adopt a more extreme view on the issue under consideration. These member changes are then aggregated by a majority social combination process, resulting in the choice shift.

In a related set of experiments, individuals who made attitudinal judgments alone and then discussed the issue were more extreme in their individual judgments after group discussion than before. This phenomenon is called *group polarization*, although it is more properly *group-induced polarization*. The important generalization is that group discussion and decision exaggerate the subsequent individual judgments of group members. For example, groups of conservative people make more conservative judgments as individuals following group discussion and decision, whereas groups of liberal people make more liberal judgments as individuals following group discussion and decision. This has been demonstrated with many judgmental tasks.

### *Groupthink*

*Groupthink* is the name given to deleterious group processes leading to decisions that turn out to be fiascos, such as the decision of President John F. Kennedy to invade Cuba in the Bay of Pigs and the decision of President Lyndon B. Johnson to escalate the war in Vietnam. According to Irving Janis's original theory, groupthink occurs in highly cohesive and isolated groups with a highly directive leader. These groups consider themselves morally superior to their adversaries and fail to consider all possible alternatives or the reactions of their adversaries. Members who may have doubts yield to the

directive leader and the apparently unanimous group opinion in order to “remain players” in the group. In contrast, analyses of successful decisions, such as that of President Kennedy to impose an embargo in the Cuban Missile Crisis, indicate non-directive leadership, division of the group into independent subgroups, consideration of the pros and cons of alternative scenarios, consultation outside the group, appointment of a devil’s advocate, and a reconsideration of the initial decision prior to the final decision. Experimental research testing this influential theory has shown that the most important factor is directive leadership, whereas group cohesion and isolation are less important.

### Conclusion: “Work the Problem”

In the movie *Apollo 13*, an oxygen tank in the spacecraft explodes on the way to the moon, the moon mission must be aborted, and the lives of the astronauts are seriously threatened. When the flight controllers at Mission Control erupt in angry mutual recriminations, the flight director makes a strong simple command: “Work the problem!” Everyone settles down to devote his or her energies and skills to the paramount problem of saving the astronauts. After a final radio silence, the reentering spacecraft splashes down near the rafts of the frogmen and television cameras. An enraptured world is suddenly unified. Just like the astronauts, the flight director, and the people of Mission Control, we are where we are—with the problems we must solve, the decisions we must make, and the human and material resources we possess. Research on group problem solving and decision making indicates that groups can be highly effective if we cooperate with each other to work the problem.

---

## GROUP SOCIALIZATION

---

The life spans of groups vary widely. At one end of the longevity continuum are groups that exist for minutes, such as several strangers who cooperate briefly to help the victim of an auto accident. At the other end of the continuum are groups that exist for centuries, such as the Society of Jesus (Jesuits), a male Catholic religious order founded in the 1500s that continues to this day. Most groups fall somewhere between these two extremes, with life spans ranging from a few hours to a few years.

Groups that exist over time are not static entities. Instead they change in ways, large and small, that can profoundly affect their members’ interactions and outcomes. Some of these changes, labeled *group development*, involve alterations in the group as a whole. It has been proposed, for example, that many groups move through five consecutive stages in which members exhibit (1) polite efforts to get acquainted, (2) conflict regarding how the group should function, (3) consensus about group procedures, (4) cooperative efforts to achieve common goals, and (5) withdrawal from one another and the group as a whole. Other changes, labeled *group socialization*, involve alterations in the relationship between the group and each of its members. Although development and socialization can influence one another, they are different processes and hence warrant separate consideration. This entry focuses on group socialization, examining how the length and quality of individuals’ relationship with a group affect their thoughts, feelings, and behaviors toward one another.

### A Model of Group Socialization

Most of the work on socialization has focused on organizations rather than small groups. To correct this imbalance, in 1982 Richard Moreland and John Levine developed a comprehensive model of group socialization designed to explain the changes that groups and individuals produce in one another from the beginning to the end of their relationship. Although the model is relevant to many aspects of organizational socialization, it is meant to apply primarily to small, voluntary groups whose members interact on a regular basis, feel emotional ties to one another, share a common perspective, and work together to achieve joint goals. An important hallmark of the model is its focus on *reciprocal influence* between the two parties—not only can the group change the individual, but the individual can also change the group.

#### Basic Processes

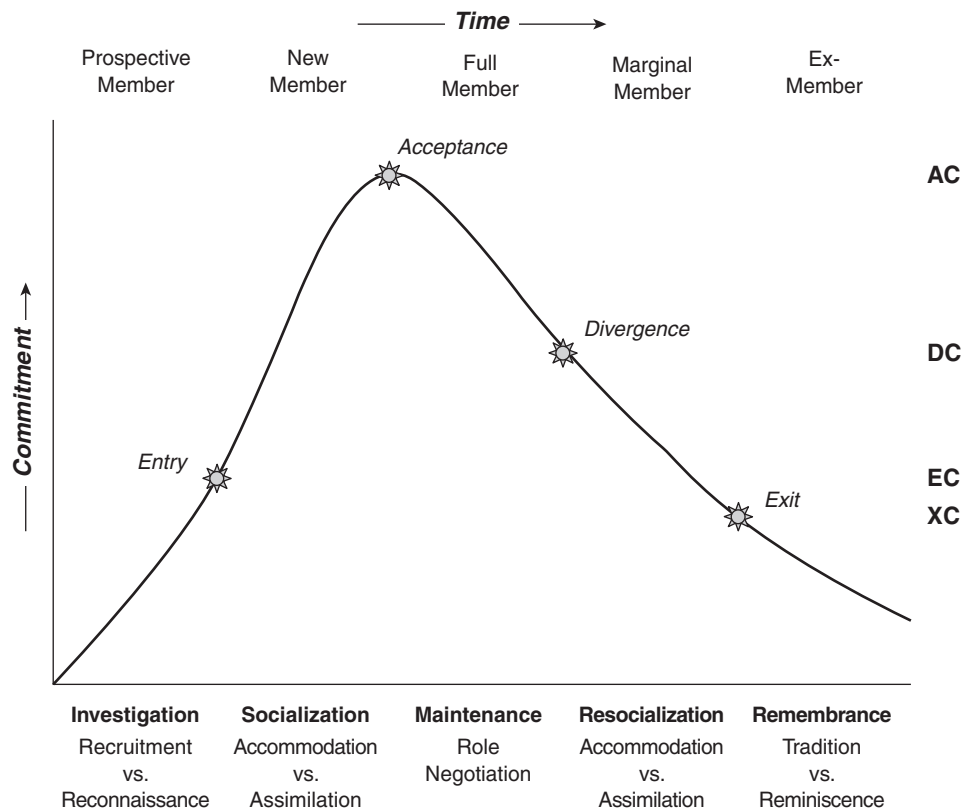

According to the model, three psychological processes underlie group socialization—*evaluation*, *commitment*, and *role transition*. Because groups want to recruit and retain members who will help them achieve their goals, they evaluate individuals in terms of their previous, current, and probable future contributions to these goals. Similarly, because individuals want to belong to groups that will help them satisfy their personal needs, they evaluate groups in terms of their previous, current, and probable future contributions to these needs.

These evaluations, in turn, affect how much commitment the group and the individual feel toward one another. The higher the group's evaluation of the individual, the more commitment it will feel toward him or her. Similarly, the higher the individual's evaluation of the group, the more commitment he or she will feel toward it. When a group feels strong commitment toward an individual, it will experience positive emotions toward the person, try to satisfy his or her needs, and seek to gain or maintain the person as a member. In a parallel fashion, when an individual feels strong commitment toward a group, he or she will experience positive emotions toward it, try to achieve group goals, and seek to gain or maintain membership in the group.

Groups' and individuals' evaluations of one another are typically not static, but instead change over time. When this happens, their commitment also changes, increasing when evaluations become more positive and decreasing when they become more negative. Both the group and the individual develop decision criteria (specific levels of commitment) that indicate when the individual should undergo a role transition signaling movement from one phase of group membership to another. Each party tries to initiate a transition when its commitment rises or falls to its decision criterion, but a transition will only occur if both parties agree that it is appropriate. Because role transitions significantly alter the relationship between the group and the individual, it is important that they both know when a transition occurs. For this reason, transitions are often marked with special a ceremony, or rite of passage. Following a role transition, the two parties continue to evaluate one another, often using different criteria. These evaluations can produce further changes in commitment and subsequent role transitions. Thus, an individual's passage through a group involves a series of membership phases separated by role transitions. Figure 1 illustrates a typical passage involving five membership phases (investigation, socialization, maintenance, resocialization, and remembrance) and four role transitions (entry, acceptance, divergence, and exit).

#### Passage Through the Group

The first phase of group membership is *investigation*, during which the group and the individual decide whether to establish a formal relationship. In this phase, the group engages in *recruitment*, which involves first identifying and then evaluating prospective members. In some cases, identification is assigned to recruitment specialists; in other cases, all members are encouraged to keep an eye out for promising candidates. Once prospective members are identified, they must be evaluated in terms of the likelihood that they will make a positive contribution to the group. This process can be more or less difficult, depending on the ease of assessing the characteristics necessary for effective performance (e.g., knowledge of organic chemistry vs. ability to stay calm under pressure). At the same time, prospective members engage in *reconnaissance*, which involves identifying and evaluating potential groups

**Figure 1** A Model of Group Socialization

Source: Reprinted from Moreland, R. L., & Levine, J. M. (1982). Socialization in small groups: Temporal changes in individual-group relations. In L. Berkowitz (Ed.), *Advances in experimental social psychology* (Vol. 15, pp. 137–192). New York: Academic Press; reprinted by permission of Elsevier.

that they might join. These tasks can also vary in difficulty, depending on the number and visibility of groups in people's environment and their willingness to reveal information about themselves. If the group's commitment to the individual rises to its *entry criterion* (EC), it will extend an offer of membership. Similarly, if the individual's commitment to the group rises to his or her entry criterion, he or she will seek such an offer.

If both parties' commitment rises to their respective entry criteria during investigation, the person will make a role transition from prospective member to new member. The ceremonies that signal entry are designed to both test and increase new members' commitment to the group. Such commitment is important because current members often have doubts about new members' skills and their understanding and acceptance of group norms. In some cases, entry ceremonies involve positive treatment of new members, such as welcoming parties

and gifts. These kinds of ceremonies, which can vary in degree of positivity, are useful because they elicit gratitude from newcomers and motivate them to work hard. In other cases, entry ceremonies involve negative treatment, such as initiations that can vary from mild to harsh. Negative ceremonies are useful because they allow current members to assess newcomers' commitment to the group and also motivate them to rationalize their suffering in a way that increases their commitment ("If this group is so hard to get into, it must be valuable").

Once entry has occurred, the group and the individual enter the second phase of group membership—*socialization*. During this phase, the group attempts to change the individual so that he or she contributes more to the attainment of group goals. This involves providing the new member with the knowledge, ability, and motivation needed to play the role of a full group member. Groups use a variety of tactics in socializing

newcomers, ranging from formal training to informal mentoring. As Levine and Moreland have suggested, groups' success in socializing new members is influenced by newcomers' characteristics and behaviors (e.g., their familiarity with the group before joining and efforts to learn about it after joining), as well as current members' characteristics and behaviors (e.g., their prior experience dealing with newcomers and ability to integrate newcomers into group activities). To the extent that the group is successful in changing the individual, he or she undergoes *assimilation*. During the socialization phase, the individual also attempts to change the group so that it contributes more to the satisfaction of his or her personal needs. This involves providing the group with information about these needs and motivating it to satisfy them. The latter goal is easier to achieve in some cases than others. For example, the more committed the group is to the newcomer (e.g., because he or she possesses valuable skills), the more motivated current members are to satisfy the individual's needs. In addition, compared to a newcomer entering the group alone, two or more newcomers entering together often find it easier to convince the group to address their needs. To the extent that newcomers are effective in changing the group, it undergoes *accommodation*.

If the group's and the individual's commitment to one another during socialization rise to their respective *acceptance criteria* (AC), the person will make a role transition from new member to full member. As in the case of entry, the ceremonies that mark acceptance are designed to both test and increase members' commitment to the group. Although people who have completed socialization generally pose less threat to the group than do those who have just joined, the group is nonetheless motivated to make sure that full members are highly committed. Such commitment is important because full members have more power, status, and responsibility than do people in other phases of group membership. Like the ceremonies that mark entry, those that signal acceptance can be either positive or negative and can vary in intensity. Positive ceremonies often involve sharing secret information about the group and bestowing new rights and responsibilities. Negative ceremonies can range from mild harassment to harsh

punishment in which full members are forced to engage in degrading behavior and suffer physical pain.

Once acceptance has occurred, the group and the individual enter the third phase of group membership—*maintenance*. During this phase, the two parties feel strong commitment to one another and engage in *role negotiation*, during which the group tries to place the individual in a role that maximizes his or her contributions to group goal attainment and the individual tries to define that role in a way that maximizes satisfaction of personal needs. In seeking to fill a particular role (e.g., treasurer), the group looks for candidates who are likely to perform the role well and ask relatively little in return. Once a favorite candidate has been identified, the group must convince the person to accept the role. This can involve offering incentives (e.g., money, power) for taking on the role, making the person's current role less rewarding, appealing to the person's loyalty to the group, threatening the person with ostracism for refusal, and so on. In a parallel fashion, an individual who wishes to occupy a particular role must convince the group to allow this to happen. This can involve making a case that one is uniquely qualified to perform the role, offering to play the role without special incentives, performing one's current role with reduced enthusiasm, and so on. After a full member takes on a particular role, the group's commitment to the individual depends on how well he or she fulfills the role, and the individual's commitment to the group depends on how satisfying he or she finds the role. To the extent that both parties evaluate the situation positively, their mutual commitment will remain high.

However, if the group's and the individual's commitment to one another during maintenance fall to their respective *divergence criteria* (DC), the person will make a role transition from full member to marginal member. Divergence ceremonies vary in negativity, but they rarely have positive features. Their negativity can be influenced by several factors. For example, such ceremonies tend to be harsher when marginal members' behavior is attributed to controllable causes (e.g., motivation) rather than uncontrollable causes (e.g., illness) and when the group is performing poorly and is understaffed. Divergence ceremonies vary widely and

include demotion in rank, reduced privileges and responsibilities, less access to secret information, exclusion from informal cliques, and increased monitoring of one's behavior.

Once divergence has occurred, the group and the individual enter the fourth phase of group membership—*resocialization*. During this phase, the two parties try to repair their relationship. The group's efforts to resocialize a marginal member are more intense when the member's presumed reason for failing to meet group expectations is controllable rather than uncontrollable, when the member previously had high rather than low status in the group, and when the member will be hard rather than easy to replace. To the extent that the group is successful in changing the individual, he or she undergoes *assimilation*. During the resocialization phase, the marginal member also attempts to influence the group. His or her efforts are more intense when the group's presumed reason for failing to meet the member's needs is controllable rather than uncontrollable, when the member's prior status was high rather than low, and when the member has unattractive rather than attractive options outside the group. To the extent that the marginal member is successful in changing the group, it undergoes *accommodation*.

Resocialization can have one of two outcomes, depending on whether the group's and the individual's commitment to one another rise to their respective *divergence criteria* or fall to their respective *exit criteria* (XC). When the two parties' commitment rises, the person will return to full membership via a special role transition (convergence). Of all the decision criteria identified in the model, only the divergence criterion produces a change in membership status when crossed either from above (maintenance to resocialization) or from below (resocialization to maintenance). Although convergence might seem to cancel out the negative implications of divergence for both the group and the individual, this is frequently not the case. Often groups have a lingering distrust of full members who previously "fell from grace," on the assumption that they might do so again. And often full members who previously occupied a marginal status in the group feel a lingering estrangement from the source of their demotion.

When the two parties' commitment falls to their exit criteria, the person will make a role transition

from marginal member to ex-member. Like divergence ceremonies, exit ceremonies vary in negativity, but rarely have positive features. Moreover, the factors that influence the harshness of divergence ceremonies (the perceived controllability of marginal members' behavior, the group's performance and staffing level) have parallel effects on exit ceremonies. Harsh exit ceremonies, which subject marginal members to public humiliation, can take several forms. These include forcing the members to apologize for their misdeeds, requiring them to return membership insignia and previously obtained rewards (e.g., bonuses), and denying them future benefits typically given to ex-members (e.g., pensions). Such ceremonies serve several functions, including punishing deviates for their transgressions, warning other members about what will happen to them if they misbehave, and signaling to outsiders that the group does not tolerate certain forms of behavior. In contrast, mild exit ceremonies remove marginal members from the group while allowing them to save face. These include eliminating the individual's responsibilities (e.g., by downsizing the group), convincing the individual to resign quietly (e.g., by threatening exposure and/or providing a generous severance package), and helping the person move to another group (e.g., by writing inflated letters of recommendation). Such ceremonies may be used because of a feeling of responsibility toward people who once made valuable contributions to the group, fear of retaliation from angry ex-members, or concern that outsiders will think poorly of the group if it has flawed members.

Once exit has occurred, the group and the individual enter the fifth and final phase of group membership—*remembrance*. This phase can vary in length, depending on how long the individual was a member and how committed the two parties were to one another. During remembrance, the group develops a consensus about how much the individual contributed to its goals, and this retrospective evaluation influences its commitment to the ex-member. Commitment can also be influenced by how the person behaves after leaving (e.g., donating money to the group vs. airing its dirty laundry to outsiders). As time passes and the individual becomes less salient to the group, he or she passes into the group's *tradition*. Memories of the ex-member can affect the group's reaction to

current and future members. For example, an ex-member who embarrassed the group may reduce the likelihood that it will recruit prospective members with similar characteristics. In a parallel fashion, during the remembrance phase the individual thinks about how much group membership satisfied his or her personal needs, and this retrospective evaluation influences the ex-member's commitment to the group. Commitment can also be influenced by how the group behaves after the individual leaves (e.g., by including him or her in its activities vs. denying that he or she was ever a member). As time passes and the group becomes less salient to the individual, it is gradually incorporated into his or her *reminiscence*. Memories of the group can affect the person's reactions to current and future groups. For example, past membership in a highly rewarding group may increase the ex-member's expectations for groups that he or she later joins.

#### *Additional Considerations*

In summarizing the group socialization model, an idealized picture was painted of how a "typical" individual might pass through a "typical" group. However, passage through a group can be more complex, as the following examples illustrate. We assumed that group and individual commitment levels change gradually over time, but sometimes they undergo sudden and dramatic shifts (e.g., when a newcomer performs an heroic act that causes a surge in the group's commitment). In addition, we did not discuss the fact that decision criteria may vary in their positions relative to one another, which can have implications for the number of role transitions and membership phases that a person experiences. For example, while the acceptance criterion must be higher than both the divergence and exit criteria, the entry criterion could be either higher or lower than the exit criterion. And the length of a membership phase can vary greatly, depending on whether the two decision criteria that demarcate it are similar (leading to a short phase) or dissimilar (leading to a long phase). In unusual cases in which two adjacent decision criteria are identical (e.g., DC = XC), the phase they would have demarcated will not occur at all! Finally, although the figure assumes that the group and the individual share the same

set of decision criteria and are equally committed to one another throughout their relationship, this is not always the case. And when it is not, the two parties are likely to experience conflict regarding the timing of role transitions.

## GROUP STRUCTURE

---

The discipline of social psychology is rooted in the quest to understand two aspects of how people relate to and interact with one another: stability and change. Regularities that engender observable, stable, and repeated uniformity in social interaction are generally attributed to group structure. Even change—or group dynamics—is often considered to have a predictable logic, which researchers link to *group structure*, defined as the uniform patterns in the relations among group members that are linked to social positions and categories. In this entry, a brief summary of the intellectual history and background of the concept of group structure is given, followed by a discussion of benchmarks in research that have helped scientists understand the nature of group structure and the role group structure plays in group processes.

### History and Background

From the very earliest studies of group dynamics, researchers have recognized that relations between group members play an important role in what people do and what happens to them. Widely recognized as the first social psychological experiment, Norman Triplett's *The Dynamogenic Factors in Pacemaking and Competition*, published in 1898, demonstrated that the physical presence of other people in a competitive relationship enhanced performance over that obtained when people performed alone. While these early studies of *social facilitation* did little to explore the actual nature of the group members' relationships, they firmly established the impact of those relationships, leading researchers to explore different facets of the relationships as well as regularities in them.

Early on, social philosophers and social theorists pointed to norms and values as the fundamental source of regularity in social relations, particularly in small groups and communities. Émile Durkheim, who is associated more commonly with sociology than psychology, offered the concept of *mechanical solidarity*—ties between members generated by shared values and experience—to define social relations. He proposed that mechanical solidarity made cooperation and civil society possible, and that mechanical solidarity

arose naturally from kin relations. As communities grew and individuals migrated from home communities to more urban areas and joined a differentiated workforce and society, family ties were strained. New forms of social patterns emerged, built on the basis of *organic solidarity*—the interdependence of functional positions in society. In the emerging industrial society, characterized by a division of labor, no single individual could survive on the basis of her or his own work. The role one played in any social group depended on the role others played. This interdependence became the foundation for patterned social relations, according to Durkheim.

In a parallel logic examining the structure of social relationships, Ferdinand Tönnies also picked up on the importance of structure as the key to understanding social life. He made an important distinction between community and society—the former is closely linked to the concept of a group. Tönnies referred to the rationality of order in social interaction derived from one's position in face-to-face groups (i.e., communities) whose members share a common purpose and values as *gemeinschaft*. In contrast, *gesellschaft* refers to macro relations born of social class position, interests, and control and formalized through laws and policies.

Concurrent with this early work, Georg Simmel (recognized by some as the father of modern sociology) was developing a theory of social life premised on patterns of association among individuals. Simmel posited that society was best conceptualized in terms of repetitive patterns of activities between individuals across time and place, or “forms-of-sociation.” Simmel's early interest was in patterns of reciprocity, hierarchy, and affiliation.

According to many researchers, Simmel included, norms and values are fundamental building blocks in determining the behavior of people vis-à-vis one another. Yet, it did not take social psychologists long to recognize that expectations for behavior (i.e., norms) and beliefs about appropriate or desirable behaviors and outcomes (i.e., values) were themselves tied to people's position in a social system. That is, for example, behaviors such as deference of one person to another are expected by virtue of people's relative status positions in the group within which they are interacting.

Society is possible, according to Simmel, Durkheim, Tönnies, and other early social theorists, because of such predictability in relationships. Simmel's work became the foundation for the study of social structure—uniform patterns of relationships between members of a society, emanating from the social categories members occupy. As Simmel at least implicitly recognized, those patterns arose in different but interrelated dimensions of interaction (e.g., reciprocity, hierarchy, affiliation).

To summarize, the concept of structure in social relations grew out of early recognition by social theorists that (1) there are recognizable patterns in social interaction, which (2) arise from the positions individuals occupy vis-à-vis one another, and (3) carry with them norms that govern behavior for individuals occupying one position in relation to those occupying other positions. Thus, we can conceptualize group structure as the uniform patterns across multiple dimensions of interaction within and between groups, arising from group members' social categories and the norms governing behavior within and across those social categories. As this conceptualization suggests, group structure defines interaction both among group members and across the boundaries of groups. To date, however, most research on group structure has focused on the effects of group structure on uniformity of behavior among members of the same group, *intragroup structure*, as opposed to patterns in the behavior of members across groups, *intergroup structure*. The following sections provide a brief overview of benchmark research programs in these two lines of research involving group structure.

### Structure in Intragroup Contexts

The vast majority of research on uniformity in the patterns of relationships in groups has focused on within-group analyses. The early work of Jacob Moreno, a psychotherapist, set the stage for the theoretical strategy and methodology of modern analyses of group structure. Moreno argued that individual well-being is rooted in interpersonal relationships. Consequently, documenting and understanding those relationships is the key for successful psychosocial interventions. To facilitate such understanding, Moreno developed a research methodology called *sociometry*, which uses graph

techniques to diagram and quantify relationships between group members along any of a number of dimensions of interaction. Moreno's early work focused on using sociometric methods to identify subgroups and alliances within groups, arguing that these "hidden structures" determined the climate of a group and, through it, the well-being of members. Sociometric methods took rapid hold, became the basis for the journal *Sociometry* (now *Social Psychology Quarterly*), and were the precursors of network analytic methods used in contemporary research on group structure and processes.

As the utility of graph theoretic methods as a means of generating insight on the nature and consequences of group structure became apparent, researchers began to rapidly adopt the strategy to understand a range of group structures. In a series of studies on the relationship between the communication structure of a group and how the group performed on a problem-solving task, Alex Bavelas and Harold Leavitt demonstrated that more centralized structures (i.e., those in which one or a couple of group members were directly allowed to communicate with all or the majority of meetings) generated quicker and less error-prone solutions to a group information-sharing problem, compared to less centralized structures (i.e., those whose members communicated only with one or two others). In addition, the studies by Bavelas and Leavitt revealed that centralized structures were perceived as more likely to involve a strong leader (usually one of the individuals occupying a more centralized position). Members of decentralized groups, however, expressed greater satisfaction with the group than members of more centralized groups. This work suggested that leadership may be differentiated into two roles: task leadership and socioemotional leadership.

Focusing on the socioemotional or affective structure of interpersonal relationships, Fritz Heider's seminal work, *The Psychology of Interpersonal Relations*, posited that perceptions of individuals (like objects) tended toward "psychological balance"—a logical and stable constellation of positive and negative affect within a network of people or objects. While anecdotal examples served to convey the principles of balance, extending them to large groups proved

challenging. Dorwin Cartwright and Frank Harary, however, used graph theoretic methods to formalize and extend Heider's principles of balance. The result was a compelling demonstration of the interrelations between group structure and group dynamics based on a single key assumption: Groups in balance tend to remain in balance, and unbalanced groups tend toward balance. This assumption and the application of network methods to document and track changes in groups led to new abilities to predict such phenomena as exits and entries into groups, changes in affiliations and communication patterns among group members, and the dissolution of groups.

Robert Freed Bales took up the differentiation of leadership roles (i.e., task oriented versus socioemotional oriented) as a part of his larger program of understanding patterns of interaction in problem-solving groups. Using "who-to-whom" techniques akin to network analysis, he examined the different kinds of verbal and non-verbal behaviors exchanged by groups, using this as a foundation for the development of an analytic method for examining groups, Interaction Process Analysis (IPA). Bales's IPA methodology approached groups as networks of actors engaged in act-by-act exchanges. Through analysis of these exchanges, Bales demonstrated that groups are demarcated by identifiable stages in their interactions, which focus on the resolution of problems. The six problems his IPA methodology identifies are problems of orientation, evaluation, control, decision, tension management, and integration. The former four (orientation, evaluation, control, and decision problems) reflect task-related issues that groups must resolve, while the latter two (tension management and integration) reflect socioemotional issues the group must resolve. Consistent with the work of Bavelas and Leavitt, Bales and his colleagues demonstrated that key actors emerge to lead the group through the resolution of these problems (i.e., the task leader and the socioemotional leader) and that the actors assuming these leadership roles could be identified by the pattern or structure of their who-to-whom acts.

Bales's seminal work influenced a host of colleagues and students, including Fred Strodbeck, who adopted the IPA methodology in his famous analysis of juries. His studies showed that patterns

of leadership and influence among members of trial juries could be predicted by the interaction patterns among members, as well as their social characteristics. Bales's work alongside that of Strodbeck, in turn, became an important foundation for research by Joseph Berger and his colleagues in their theoretical research program on expectation states. This program entails a number of theories relating interaction patterns to structural differentiation among group members, including status characteristics theory—a theory that details how states of social categories (such as "male" or "female" states of the category "sex"), which are imbued with greater or lesser social value in accord with the norms of the broader society and are tied to differentiation in the content and amount of interaction engaged in by those assigned to the states. For instance, men tend to be more valued in wider society than women (as reflected, for example, by men receiving greater earnings than women with comparable job types, ability, and experience). This differential social valuing bestows differential status on men and women in social groups. Research over several decades shows that as interaction in groups proceeds, lower status actors tend to be more deferential to higher status actors in group interaction, higher status actors tend to be more dominant and subsequently more influential in group problem solving, even when actual ability is unknown or even runs contrary to the status that social categories engender.

As graph-theoretic methods and social network analysis matured, they began to be applied to a host of other domains. Alongside interests in leadership, researchers gained an interest in the concept of power, or control over valued resources, which structures relationships among members in groups. George Homans viewed power in behaviorist terms, proposing that resources could be used to influence behavior of group members as a reward (positive reinforcement) or punishment (i.e., by denying resources to members). Examining the flow of resources using mathematical and network analytic methods, Richard Emerson offered an insight that served to change much thinking about groups and group structure. Power, he argued, was a characteristic not of a member of a group, but rather of the relations between group members. This key insight led researchers studying

not only power, but a host of other group structures (e.g., influence, communication, affiliation, affect) to explicitly articulate structure in terms of relations between members, as opposed to as emanating from an attribute of members.

A further development in the understanding of power, by David Willer and his colleagues, also served to change the landscape of group studies. Willer proposed that it is not power use that matters in shaping group relations, but rather the potential for power (as perceived by group members) that affects groups. This line of reasoning echoed earlier work by symbolic interactionists who, drawing on William James's work, recognized that "what men perceive to be real is real in its consequences."

The methods of exchange theorists drew upon and matured alongside social network analysis. In the 1970s and 1980s, significant computational and methodological advances by Harrison White, Linton Freeman, and other network analysts forged new paths in not only how structure is theoretically conceptualized, but how it is quantitatively measured. Owing partly to increased availability and growing processing power of computers, social network analysts developed empirically driven conceptualizations of patterns of relations among individuals, operationalizing structure in terms of such concepts as density (i.e., the interconnectedness of group members) and centrality (i.e., the extent to which the relations in a group are focused on one or a few members).

The methodological strategy of social network analysis is founded on empirically examining how relationships between individuals are organized and how that organization affects individual behaviors, attitudes, and interactions. As a result, network analysts tend to avoid a priori assumptions regarding who is or is not a member of a group, unlike other approaches to conceptualizing groups (i.e., on the basis of commonly shared traits or identities). Indeed, one of the most interesting implications of social network analysis is that groups may be best conceptualized as clusters of dense ties among individuals, who, in turn, are tied (albeit less densely) to individuals in other clusters. That is, social network analysis calls into question the notion of a group as a closed system of individuals, instead emphasizing the fluidity of group boundaries.

### Structure in Intergroup Contexts

In contrast to the extensive research on intragroup structure, relatively little work has been done to theorize the structure of relationships between social groups outside that of social network analysts noted above. The work that has occurred, however, has had a profound effect on the study of group dynamics. An early and influential line of work on intergroup structure and relations across group boundaries is the work by Muzafer Sherif and his colleagues, captured in a series of studies on the relations between groups of boys at a summer camp—the renowned "Robbers Cave" experiments. Sherif demonstrated that intergroup attitudes are conditioned by the structure of access to valued resources. When resources are acquired through a zero-sum competition, group members tend to develop hostile attitudes toward members of an outgroup and seek opportunities to undermine the outgroup's pursuit of those resources. In contrast, when resource acquisition requires cooperation across groups, positive attitudes and relations tend to arise across members of the groups.

Another line of research exploring intergroup structure is social identity theory, developed by Henry Tajfel and John Turner. This line of research remains one of the most prolific and influential research programs on group structure and action. Social identity theory is also a multilevel theory, linking self-concept to group membership and to attitudes and behaviors toward ingroup and outgroup members. At the core of this work is the assumption that individuals seek to enhance their sense of self. The self, in turn, is comprised of identities derived from membership in social groups. To the extent that the social groups to which one belongs are viewed favorably (by oneself or others), one's self-concept is enhanced. Furthermore, identities are assessed through a process of social comparison—that is, what matters is the extent to which one's group is viewed more or less positively compared to one or more other groups. Tajfel and his colleagues demonstrated that individuals engage in a variety of behaviors that generate advantages for members of the group to which they belong, including offering exaggerated positive evaluations of ingroup members, overrewarding them, and affording them greater influence in decision making.

In summary, group structure, the uniform patterns in the relations among group members, serves as both an independent and dependent variable in the study of group processes. The dynamics within and across groups can be conceptualized in terms of the way relationships are organized, the content of the relationships (e.g., friendship, communication, identity), and how those relationships affect individual attitudes, behaviors, and interactions.

## GROUP TASK

Groups exist for many reasons—some social (providing settings where we can satisfy our need to belong), some symbolic (contributing to our sense of identity), and some task related (e.g., making a decision, solving a problem, winning a sports competition). This entry deals with the latter reason—performing a *group task*—and considers some of the ways in which aspects of the group's task guide how the group and its members behave. This is particularly important because generalities about groups (e.g., “groups are better performers than individuals”) are all too often asserted as if they held true across any and every task that a group might confront. To the contrary, nearly any assertion about group behavior must take into account the nature of the group's task. With few (if any) exceptions, a statement about group behavior should always have an explicit or implicit qualification—“but, of course, this depends upon the following features of the group's task . . .” This entry gives a few examples of why this is true, describes some of the task distinctions that have been proposed and used successfully to analyze group behavior, and finally describes the most ambitious attempt to classify group tasks, which was developed by the late Joseph E. McGrath in his 1984 book, *Groups: Interaction and Performance*.

Groups often simultaneously work on several tasks or on complex tasks with rather different features. For example, a high school volleyball team wants to maximize student participation and fitness, to represent their school well, to entertain spectators, to win interteam competitions, and so on. Each subtask may place different demands on the group and may affect its dynamics, sometimes in contradictory ways. For example, increasing the size of the team may make it better able to maximize student participation, but may simultaneously undercut its ability to win (by including people who are not highly talented). The game of volleyball likewise is complex, and its different features prescribe and constrain the group's behavior in different ways. For example, composing a team of taller players improves its chances of blocking shots at the net, but may reduce its skill at other aspects of the game (e.g., setting the ball, digging

out low shots). So it is often an oversimplification to suggest that groups have a single, simply defined task. Nevertheless, the performance of a group on a complex or multipart task can often be analyzed in terms of more simply described subtasks.

Our understanding of just how important task features are for group behavior has developed in two rather different ways. Some scholars have proposed rather general theoretical models about how group tasks differ and how these differences might affect group behavior. The task classification, or taxonomy, of McGrath (described below) is a good example. Other scholars did not begin with a theory of group tasks, but rather discovered that focusing on certain aspects of the group's task helped explain apparently confusing or contradictory patterns of findings. Let us illustrate the latter approach first.

### Dependence of Group Behavior on Task Features: The Bottom-Up Approach

#### *Social Facilitation*

One of the first research questions in social psychology and in the study of small groups was, "How does the presence of other people affect a person's task performance?" The earliest studies, done near the beginning of the 20th century, generally found that the presence of others, either as passive observers or as people working at the same task (so-called coactors), seemed to improve individuals' performance. Such results were referred to as *social facilitation*. However, soon additional studies showed the opposite pattern—individual performers doing less well in others' presence than when working alone. One way of reconciling such confusing results was to suggest that they depended on the performance task—but what aspect of the task? Several were suggested (e.g., intellectual vs. physical tasks, simple vs. complex tasks), but none seemed to bring order to the confusion. It was not until Robert Zajonc proposed his drive theory of social facilitation in 1965 that a plausible task feature was identified. Zajonc's theory said that the presence of others increases drive or arousal. Well-established theory suggested that the effect of such drive increases was to make high probability behaviors more likely to occur (and to make low probability behaviors less likely to occur). So, a key task feature was shown to be whether the

correct response was likely or unlikely. For very well learned tasks, where the correct response was highly likely, the presence of others facilitated this response and, hence, improved performance. But for poorly learned tasks, where *errors* were highly likely, the presence of others likewise facilitated these responses, which, in turn, hurt performance. Identifying this key task feature brought order to a confusing research literature and increased our understanding of the effects of others' presence—a basic feature of most task-performing groups.

#### *Group Polarization*

A slightly more recent question to intrigue group researchers was, "Are groups more willing to take risks than individuals?" Societies entrust many important but risky decisions (e.g., whether to declare war or try criminal defendants) to groups rather than to individuals, so this is obviously an interesting psychological question. The results of the first studies, done nearly 50 years ago, were surprising—groups appeared to be more willing to endorse an attractive but risky course of action than individuals. This finding was referred to as the *risky shift* (from a more cautious individual preference to a less cautious group preference). But just as in the case of social facilitation, subsequent research on the risky shift found that sometimes group discussion had exactly the opposite effect, leading to more cautious group preferences than individual preferences—a *cautious shift*. It took some time (and insight) before it was recognized that the direction of shift depended vitally on one feature of the group's decision task—namely, whether individuals were initially generally more favorable toward the risky or the cautious choice. Group discussion served to strengthen or polarize opinion in whatever direction individuals already favored. This pattern of *group polarization* turned out to be very general, applying not just to risk decisions, but to collective attitudes, jury verdicts, and many other judgments.

#### *Contingency Theories of Leader Effectiveness*

A long-standing question has been, "What makes a good leader?" A number of people have argued that a good leader's main job is to keep his or her group focused on the demands of the task, even if this means being somewhat directive and critical,

thereby undercutting his or her popularity in the group. Others argue that one cannot lead effectively without nurturing positive relations with the group, even if such an emphasis on leader-member relations reduces the group's task focus. By the late 1970s, many studies had attempted to see which style of leadership (friendly/relationship oriented versus withdrawn/task oriented) leads to more effective group performance, but there was no clear pattern to their results. Then Fred Fiedler suggested that the answer to this question depended on aspects of the group's task and the leader's relationship with the group. In particular, the more structured the group's task (e.g., group members understand what is expected, the tasks are simple and well understood), the higher the leader's "situational control." Fiedler showed that groups were more effective with a more task-oriented leader when situational control was either very low (strong, directive leadership was essential) or very high (the leader did not need to worry about nurturing the group), but that when situational control was moderate, the opposite occurred (a more relationship-oriented leader was most effective).

### *Social Combination and Group Performance*

One influential approach to studying group performance is the *social combination* approach. It asks, "Can one predict the group's ultimate decision or product from a knowledge of what the individual members bring to the group?" A considerable amount of research has shown that for many group tasks, the answer is "yes"—one can often find a rule, or scheme, that reliably linked individual preferences or abilities and the group's final decision or product. For example, in jury decision making it has been shown that the jury verdict is nearly always predictable from some variation on a majority-wins social decision scheme, which holds that the verdict preferred by a majority at the outset of deliberation will be the jury's final verdict. However, some research has shown that for certain group tasks, majorities routinely fail to prevail. For example, at simple arithmetic problems, an incorrect majority will routinely yield to a correct minority. Patrick Laughlin recognized that the appropriate social combination rule depended on a key feature of the group's task—whether or not it had a solution that could be

widely recognized and accepted by group members. He called tasks with such a solution *intellective tasks* and showed that advocates for the correct solution to these tasks could and did routinely prevail, even when their number was fairly small. However, larger factions usually prevailed at *judgmental tasks*, which have no such correct solution.

### *Summary*

Many more such examples could be given (e.g., whether groups fall short of their potential to generate creative ideas depends on whether one person's generation of an idea interferes or blocks other members' thinking or expression; whether group members socially loaf depends on whether the task permits individual members' contributions to be publicly identified). These and other examples illustrate the basic insight that what a group does depends critically on what it is trying to do (i.e., its task). It should be clear, though, that such demonstrations usually come to narrow conclusions. They tend to implicate particular task features (e.g., how well learned the task is, whether there is a correct answer) as important for particular group phenomena (e.g., social facilitation, social combination processes). Other scholars have taken a different approach by attempting to identify task features that help explain a wide range of group phenomena.

### **Group Task Taxonomies: The Top-Down Approach**

One popular approach to analyzing group tasks is to try to identify key features that differentiate such tasks. This approach starts from an examination of the full variety of tasks groups work on and then seeks to divide them into useful categories or dimensions. For example, Marvin Shaw identified six ways that group tasks differ: (1) their requirements for intellectual versus motor skills, (2) how difficult they are, (3) how interesting they are, (4) how familiar they are, (5) how much they require member cooperation, and (6) whether they have few or many solutions. In another such classification, Richard Hackman suggested that groups usually work on production, discussion, or problem-solving tasks.

Another approach is to focus on a few basic task features, and then link those features to interesting group variables or processes. This approach is best illustrated by an influential task taxonomy proposed by Ivan Steiner, who suggested three basic task features:

1. Is the work required of members on the task divisible? *Unitary tasks* (e.g., solving a math problem) do not have subparts that can be assigned to different group members; *divisible tasks* (e.g., building a house) do.

2. Does the task emphasize the quantity or the quality of the group's product? *Maximizing tasks* (e.g., bailing water out of a ship) emphasize quantity; *optimizing tasks* (e.g., solving a math problem) emphasize quality.

3. How must individual inputs be combined to yield a group product, that is, what are the task's prescribed combination processes? For this latter task feature, Steiner focused on simple, unitary tasks. For *additive tasks* (e.g., a group tug of war), the group product is a simple sum (or sometimes, average) of member inputs. For *disjunctive tasks* (e.g., a unitary math problem), the group must choose one member's input (preferably that of the most able member). For *conjunctive tasks* (e.g., a tethered mountain-climbing team), the group product is defined by the worst member's input. Finally, for *discretionary tasks* (e.g., a group judging how many jelly beans are in a jar), group members can combine member inputs in any way they choose.

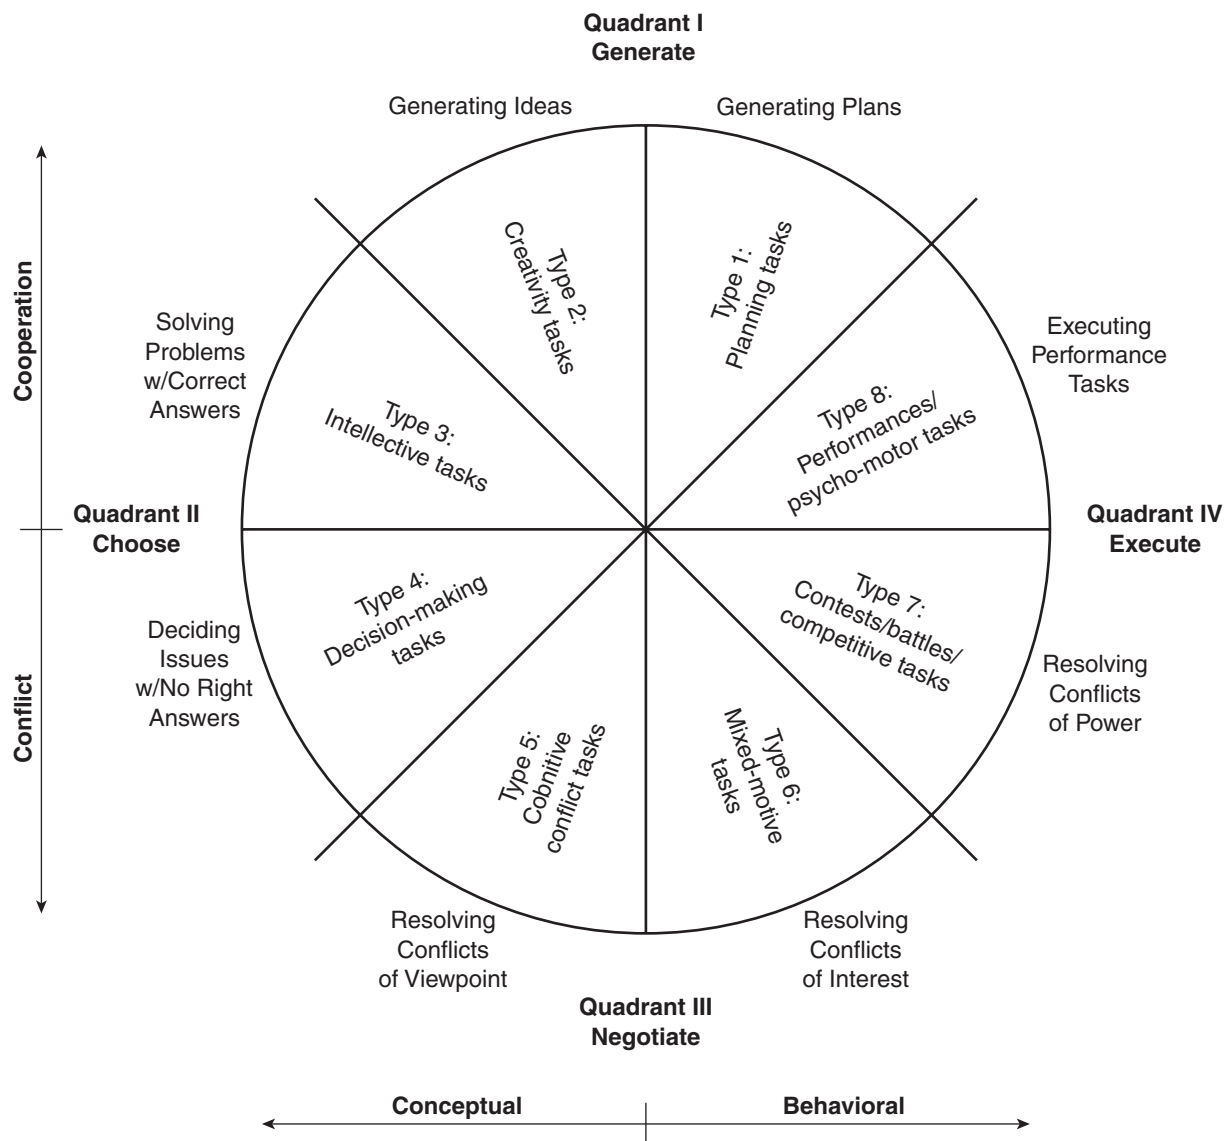

Steiner was then able to show how different variables should affect group performance differently for different types of tasks. So, for example, increasing a group's size or the heterogeneity of member ability should increase group performance at a disjunctive task, but reduce group performance at a conjunctive task.

Joseph McGrath combined the previous two approaches (Shaw's descriptive approach and Steiner's conceptual approach). His taxonomy, the *group task circumplex*, is pictured in Figure 1. McGrath proposed that there are eight types of tasks, which he arrayed like slices of a pie. The slices can first be divided into four quadrants, which distinguish the most basic differences in

what groups do. If one looks at the figure like a map, the two "northern" slices in Quadrant I include tasks where groups have to generate something, either plans (Type 1; e.g., an advertising campaign), or ideas (Type 2; e.g., creativity tasks). The "western" slices in Quadrant II include tasks where groups have to make choices among alternatives, either intellectual tasks with correct answers (Type 3; e.g., solving a math problem) or judgmental tasks without a correct answer (Type 4; e.g., judging a beauty contest). The "southern" slices in Quadrant III include tasks where group members have to negotiate something, either resolving opinion or value conflicts (Type 5; e.g., a group of politicians trying to hammer out a mutually acceptable political platform) or resolving conflicts of interest (Type 6; e.g., labor and management negotiators trying to reach agreement on a contract). Finally, the "eastern" slices in Quadrant IV include tasks where group members need to execute some action, which either involve conflict between groups or group members (Type 7; e.g., a basketball game) or do not involve conflict (Type 8; e.g., a group building a house). McGrath also suggests that there are two basic dimensions underlying these tasks—a vertical dimension dividing tasks that require higher levels of cooperation (those "above the equator") from those involving higher levels of conflict (those "below the equator"), and a horizontal dimension dividing tasks that focus on group members' intellectual or conceptual skills (the "western hemisphere") from those that require skilled overt behaviors (the "eastern hemisphere"). This taxonomy has many admirable qualities. It is comprehensive, potentially describing all the different kinds of tasks groups tackle. It is coherent, showing many of the ways that tasks are similar and different. Most importantly, it is conceptually powerful, in that it incorporates many of the task distinctions that have been shown to be important for group behavior.

## Conclusion

Human beings constantly draw distinctions because such distinctions can be useful in helping us describe, understand, and control the world we live in. Scholars who want to describe, understand, and control how groups function have found it useful to distinguish between the different

**Figure 1** McGrath's Group Task Circumplex

kinds of tasks that groups undertake. Although there is, as yet, no single model that fully describes and explains all the complexities of group life, considerable progress has been made in identifying useful distinctions regarding the tasks that groups confront.

## GROUPTHINK

---

*Groupthink* is the extreme concurrence-seeking displayed by decision-making groups that is predicted to result in highly defective decisions. The groupthink concept was first developed by Irving Janis in 1972 to explain such disastrous incidents as the United States's decision to invade the Bay of Pigs in Cuba, the failure of the United States military to foresee the Japanese attack on Pearl Harbor, Great Britain's appeasement of Nazi Germany in World War II, and the decisions to escalate the Vietnam War and the Korean War. According to this perspective, groupthink is hypothesized to occur when particular antecedent conditions are present. These include high group cohesiveness, insulation from experts, limited search and appraisal of information, directive leadership, and high stress combined with low self-esteem and little hope of finding a better solution to a pressing problem than that favored by the group leader or influential members.

These conditions lead to extreme concurrence-seeking that in turn leads to two classes of faulty outcomes: symptoms of groupthink and symptoms of defective decision making. Symptoms of groupthink consist of the illusion of invulnerability (the group can do no wrong), collective rationalization, stereotypes of outgroups, self-censorship (individuals do not express any objections to the group decision), mindguards (group members who enforce conformity), and belief in the inherent morality of the group. Symptoms of defective decision making include incomplete survey of alternatives and objectives, poor information search,

failure to appraise the risks of the preferred solution, and selective information processing. These two categories of symptoms in turn are predicted to lead to highly defective decision making.

The concept of groupthink has had enormous popular appeal and captured the collective imagination of the public and analysts alike. For example, *groupthink* appeared as a dictionary term just 3 years after it was coined. In the popular press, the term is commonly used to refer to any group that appears to have made a poor decision without regard to existing evidence that conflicted with the group's choice. Researchers have continued to search for new examples of failed decisions that may support the groupthink theory. For example, recent work has used the groupthink concept to analyze the World Com accounting fraud incident, Nazi Germany's decision to invade the Soviet Union in 1941, Ford Motor Company's decision to market the Edsel, Gruenthal Chemie's decision to market the drug thalidomide, the tragedy at Kent State during the Vietnam War, the Challenger and Columbia space shuttle tragedies, the European Union decision about imposing sanctions in the Chechnya conflict, and a city council's decision to ignore state-mandated earthquake preparation procedures.

### Research on Groupthink

Despite the popular appeal of the concept, empirical research evidence provides only equivocal support for the groupthink model. Case studies of decision making by intact groups frequently find inconsistent evidence for the complete model. Following the typical case study methodology, evidence for antecedents, symptoms, and consequences are inferred from archival documents and from interviews with observers and participants. For example, Bertram Raven's analysis of the decision-making processes of the Nixon White House suggested that the group's cohesion depended not on interpersonal liking (a typical definition of group cohesion) but rather on an esprit de corps based on the group members' desires to remain part of a prestigious team.

Similarly, analyses of the National Aeronautics and Space Administration's fateful decision to launch the space shuttle Challenger also question the conceptualization of groupthink and the model

itself. Little evidence was found for the antecedent conditions of group cohesion (as defined by mutual attraction), lack of impartial leadership, and homogeneity of members' backgrounds, but some evidence was found that the launch team was in a highly stressful situation and for groupthink symptoms of illusion of invulnerability, rationalization, illusion of unanimity, pressure on dissenters, mindguards, and bias in processing information at hand. Evidence for other symptoms was inconclusive. In general, evidence supporting the complete groupthink model is limited, with only varying degrees of support for the existence of antecedent conditions and symptoms of groupthink and defective decision making.

Experimental studies have attempted to manipulate multiple antecedent conditions of groupthink while assessing groupthink symptoms and group decision effectiveness. In general, studies using traditional formulations of groupthink and its antecedent conditions have found only limited evidence for groupthink symptoms and no evidence for impaired group decision effectiveness. For example, research examining the effects of cohesion and leadership style (autocratic vs. participative) finds few effects consistent with the groupthink model. Cohesion rarely affects either groupthink symptoms or decision quality. Similarly, measures of decision quality and other symptoms tend to be unaffected by such conditions. However, one consistent finding supports the model's predictions. Groups with directive leaders or who are instructed to limit information sharing and discussion tend to do so.

In sum, research provides very limited support for the groupthink model and its traditional conceptualization. Both case and experimental studies question the causal sequences of the model, failing to document the full constellation of groupthink and defective decision-making symptoms and even the defective decision making that is supposedly the ultimate result of groupthink.

This lack of evidence has raised criticism about the theory that include (a) poor characterizations of the various components of the groupthink process, (b) poor specification of links between antecedent conditions and consequences, and (c) ambiguous definitions of the conditions under which groupthink should and should not occur. Responses to these criticisms and the lack of empirical research

evidence have taken two directions: examinations of other factors that might affect groupthink processes and reconceptualizations of the original model.

### Recent Developments

Several investigations have examined the impact of other variables on groupthink processes and outcomes and on the incidence of groupthink in novel contexts. Once again, results generally question the validity of the groupthink model and the utility of additional variables. Research examining factors such as accountability, certainty orientation, predisposition to conformity, and time pressure has produced limited support for the full groupthink model. In addition to examining the role of additional variables in producing groupthink, research has focused on investigating the incidence of groupthink in new contexts. As with investigations of other factors, only limited support has been obtained. For example, an analysis of archival news articles revealed that some groupthink factors (the salience of group membership, the positive evaluation of ingroup leaders, the negative evaluation of outgroup leaders, and the appearance of self-appointed mindguards) were higher during the Northern Ireland conflict. However, other factors were unaffected by the conflict.

Reconceptualizations and reformulations of the original groupthink model have focused on both refining the concept itself and exploring new approaches to defining the antecedent conditions. The social identity maintenance model of groupthink also was developed in response to the equivocal empirical support for the groupthink model. This perspective underscores the prominence of the group's social construction of its internal processes and external circumstances. According to this model, groupthink then becomes a process of concurrence-seeking that is directed at maintaining a shared positive view of the functioning of the group.

The model suggests that two antecedents of groupthink, cohesion and collective threat, are especially critical in producing groupthink as social identity maintenance. The first condition, cohesion that incorporates a social identity perspective, contributes to the development of a perception of the group as a unique identity, enhances

the development of a shared positive image of the group, and provides the basis upon which threat can operate. The second condition, a collective threat, is the catalyst for the intragroup processes that promote concurrence seeking and defective decision making. This approach has been supported in experimental studies in which the defective decisions associated with groupthink have been obtained and in case studies. However, all of the approaches discussed here require further testing and validation.

### Methods for Overcoming Groupthink

Irving Janis identified nine methods for preventing groupthink in decision-making groups. The methods were generally directed at overcoming the bias of the leader and promoting independent judgments and complete evaluation of all information. These methods included: (1) encouraging members to consult with outside experts to obtain alternative opinions, (2) assigning a devil's advocate (a member who would thoroughly question all group decisions) in each meeting, (3) asking members to consult with trusted associates, (4) assigning the role of critical evaluator to each member during all group meetings, (5) dividing the group into subgroups to pursue the same problem or issue, (6) requiring the group to construct alternative scenarios of any opponent's possible actions, (7) limiting the leader's expression of solutions preferences, (8) holding a second chance meeting after the decision is made to encourage reconsideration of alternative solutions, and (9) assigning independent groups to formulate solutions to the same problem or decision.

Janis noted that none of these strategies is a foolproof method for overcoming groupthink and that most involve significant risks. For example, he suggested that assigning the role of critical evaluator might lead to prolonged debates that would be difficult to resolve and costly in terms of time. It might also require special training for group members who are unaccustomed to such conflict. The use of multiple decision-making groups can diffuse responsibility and accountability. The involvement of large numbers of participants also may be costly in terms of time and money.

New perspectives on groupthink also suggest other drawbacks to these interventions. For

example, the social identity maintenance approach suggests that groups will be motivated to protect the group's identity and its image. In those instances, a group may use the recommended interventions to support its identity rather than enhance its decision-making processes. Thus, the group is likely to consult with outside experts and associates who support its preferred option. The group may also adopt superficial evaluation strategies that mimic true conflict about ideas but actually serve to reinforce and bolster its favored decision.

Other recommended strategies for overcoming groupthink have focused on interventions designed to reduce pressures for identity protection, to change the group's identity, and to stimulate constructive conflict (full evaluation of ideas, tasks, and decisions). Methods for reducing the need to protect the group's identity include the provision of an excuse or face-saving mechanism, the risk technique, and multiple role-playing procedures. Providing an excuse for potential poor performance appears to reduce the group's need to engage in identity-protection tactics and increases the group's focus on problem solving, in turn enhancing performance. The risk technique is a structured discussion situation designed to facilitate the expression and reduction of fear and threat. Finally, multiple role-playing procedures can be accomplished by having group members assume the perspectives of other constituencies with a stake in the decision or of another group member.

Another approach to overcoming groupthink is altering the group's identity. This approach is likely to be used when the identity is firmly entrenched and linked to a failed decision alternative. Procedures for stimulating constructive conflict include structured discussion principles and procedures for protecting minority opinions, as well as linking the role of critical evaluation to the group identity. One method is to provide training in discussion principles for the group leader or, preferably, for all members. A second is simply to expose group members to these recommendations; this approach appears to increase decision quality. Finally, constructive evaluation (as well as other interventions) can be made a part of the normative content of the social identity, as in jury instructions.

## HATE CRIMES

---

The term *hate crime* is of recent origin, dating from the late 1980s. Hate crimes constitute a class of criminal offense, defined by a country's laws, in which violence and other forms of aggression are perpetrated knowingly against members of a stereotyped minority group. While it is assumed that hatred is the principal cause of this aggression, it would be more accurate to categorize these actions as bias-motivated crimes. In the United States, bias crimes have long been recognized, and the Civil Rights Act of 1968 offered protection based on an individual's race, color, religion, or national origin. From a modern perspective, sexual orientation is an omission from this federal list of protection. Any minority group whose members share a detectable attribute is a potential target for hate crimes.

Examples of hate crimes include physical assault, murder, and genocide; attacks on property; bullying and harassment at school or in the workplace; verbal threats or abuse; offensive graffiti, letters, posters, and pamphlets; and malicious complaints (e.g., to a local authority). Target groups include those defined by their ethnicity, nationality or national origins, gender, sexual orientation, and physical or mental disability. The evidence of hate crimes goes back to ancient times, but the widespread use of the term *hate crime* is modern. Popular interest in hate crimes reflects frequent reporting of such crimes in the media and an increased concern at the government and policy-making level to protect members

of minorities in their local, regional, and national communities. To fully understand hate crimes requires a knowledge of theory and research in prejudice and discrimination.

### Historical and Modern Targets

Examples of hate crimes from the past are not hard to find. Anti-Semitism in the pre-Christian era flourished in Egypt and Syria, triggered by the Jewish faith's insistence on monotheism. Similarly, Jews and early Christians were persecuted by the Romans for not recognizing the pantheon of gods. Other examples of anti-Semitism are medieval Christians labeling Jews the killers of Christ, and the Nazi Holocaust designed to obliterate Jews from the face of the earth.

The 20th century has witnessed systematic mass killings of Armenians at the hands of the Ottoman Empire, ethnic cleansing in Bosnia, and genocide in Cambodia and Rwanda. Over the course of two centuries in the United States, bias-motivated intimidation and violence toward Native Americans has been frequent. Hate crimes received more public attention in 20th-century America with the lynching of Blacks, the erection of burning crosses on properties belonging to targeted families, and the painting of swastikas on synagogues.

More recent targets are gay men and lesbians. The United States Federal Hate Crime Statistics for 2006 reported the following order (and numbers) of bias offenses in five categories: race (4,737), religion (1,597), sexual orientation (1,415), ethnicity or nationality (1,233), and disability (94). The

most common targets within these categories were Blacks, Jews, gay men, Hispanics, and those with mental disabilities. Surveys in the United States have revealed that (a) more than 90% of homosexual people have reported being victims because of their sexuality and (b) one quarter of a student sample from diverse ethnic and economic backgrounds admitted that they had verbally abused people they thought were homosexual.

As a hate crime, the murder in 1998 of Matthew Shepard received international attention. A 21-year-old gay college student in Wyoming, Shepard was kidnapped in a bar by two young White men. He was taken to a remote prairie where he was tied to a fence, whipped in the face with a gun until he lost consciousness, and left for dead in freezing weather. He was found a day later, but he died in the hospital. His killers admitted to laughing during the attack. The assailants were convicted, but they avoided the death penalty by plea bargaining and were helped when Shepard's mother appealed for clemency. Described at the time as a crime that shocked the nation, it became a rallying point for gay rights and also for promulgating tolerance of diversity.

### Theoretical Approaches

A key to understanding the origins of hate crimes is to apply what is known from social psychological research dealing with prejudice. The acceleration of anti-Semitism in Europe in the 1930s, which was entwined with Nazi ideology, placed the explanation of prejudice high on social psychology's agenda. Several major theories of prejudice were developed in the decades that followed, in particular, several that offered accounts of why minority groups could become the victims of discrimination, including hate crimes.

#### *The Frustration-Aggression Hypothesis*

One early and elaborate attempt at a theory to explain hate crimes was the frustration-aggression hypothesis. In 1939, John Dollard and Neal Miller and others argued that aggressive behavior arises from a preexisting frustration, with a mediating state of psychological disequilibrium that can be corrected only by aggression. In many cases the cause of frustration is intangible, such as the

economy. Because this hypothesis was a psychodynamic theory, derived partly from psychoanalytic principles, the authors argued that frustration-induced aggression is *displaced* onto an alternative target (a person or even an inanimate object) that can be hurt legitimately, without fear. In other words, a *scapegoat* is found.

Dollard and Miller linked the theory to the presence of prejudice in individuals and also applied it in a more general way to explain large-scale, intergroup aggression against minorities. If the cause of frustration is beyond reach, the need for aggression is displaced onto a weaker group, which functions as a scapegoat. From here, a search began for trends in bigoted violence that could be attributed to frustration arising from economic downturns. Historical examples included anti-Semitism, but Dollard's colleagues, Carl Hovland and Robert Sears, looked for supportive data closer to home. In a 1940 study, they noted that archival records in the southern United States across 50 years contained evidence of a relationship between an economic index (the price of cotton) and the incidence of racial aggression (the number of Blacks lynched). As the price of cotton fell (frustration), more Blacks were lynched (displaced aggression), even though the idea that Blacks were responsible for declining prosperity was far-fetched. However, when time-series analyses in later research were applied to contemporary data to test the link between economic conditions and hate crimes against minorities, there was scant support for the frustration-aggression hypothesis.

#### *The Authoritarian Personality*

There have been other approaches that have looked for the origins of prejudice based on personality characteristics. The most famous of these was a theory advanced by Theodor Adorno and his colleagues. Initially, they used a psychodynamic perspective in an attempt to trace the origins of anti-Semitism to a set of personality traits. As their research proceeded, they extended their argument to cover fascism, and then authoritarianism, since their data suggested that individuals who are prejudiced against one ethnic group were usually prejudiced against all minorities.

Such individuals are bigots and have an *authoritarian personality* that is defined by a constellation

of characteristics: a respect for and deference to authority and authority figures, an obsession with rank and status, a tendency to displace anger, resentment of weakness, an intolerance of uncertainty, and a need for a rigidly defined world. This syndrome of beliefs and behaviors originates in early childhood. Children whose parents adopt excessively harsh and disciplinarian practices to secure emotional dependence and obedience develop an ambiguity in which they both love and hate their parents. This ambiguity is stressful and seeks resolution. Owing to guilt and fear, the hatred cannot be expressed, so it is repressed and finds expression through displacement onto weaker others, while the parents and the power and authority they represent are idealized. This resolution of ambivalence provides an enduring framework for future life and is generalized to all authority figures. According to this theory, extremist groups such as the Ku Klux Klan would have large numbers of members fitting this personality profile, and at different times in their history such people would have little difficulty in carrying out extreme acts of violence against particular minorities, including Blacks, Jews, Catholics, and homosexuals.

### *Intergroup Perspectives*

A different approach to unraveling the causes of hate crimes comes from the field of intergroup relations. In 1972, Leonard Berkowitz applied the concept of *relative deprivation* to understanding how frustration could be retained as an underlying stimulus to collective unrest. The concept refers to people's feeling that their attainments fall short of their aspirations, and has two forms: (1) *egoistic* relative deprivation, where the shortfall is based on an individual making comparisons with other individuals, and (2) *fraternalistic* relative deprivation, where the shortfall is based on making comparisons between one's membership group and other groups.

The second form points to unrest as a consequence of frustration sensed by a whole group. This can be heightened during an economic downturn and could flair quite suddenly into violence against a comparison group. For example, in a context of rising unemployment, the 1992 Los Angeles riots erupted unexpectedly following the acquittal of White police officers accused of beating a Black

man, Rodney King. The assault had been captured on video and played on national TV. Against a background of deepening economic disadvantage, Blacks regarded the acquittal as a poignant symbol of the low value placed on American Blacks by White America. The riot started at the intersection of Florence and Normandie avenues, a relatively well-off Black neighborhood in South Central Los Angeles. A nearby liquor store was looted, cars were damaged, and the police were attacked. The police moved in reinforcements, but later withdrew in an attempt to reduce tension. The intersection was then in the hands of the rioters, who attacked Whites and Hispanics. Reginald Denny, a White truck driver who was driving through, was dragged from his cab and brutally beaten, a crime watched live on TV by millions and which came to symbolize the riots.

South Central Los Angeles is relatively typical of Black ghettos in the United States. However, the junction of Florence and Normandie was atypical, better off than other parts of the ghetto. It was a Black neighborhood where the poverty rate had dropped markedly during the 1980s. That the initial outbreak of rioting would occur there, rather than in a more impoverished neighborhood, is consistent with relative deprivation theories of social unrest.

Other theories do not deal directly with crime, but do address the issue of how prejudice arises. According to Muzafer Sherif's *realistic conflict theory*, stereotyping, discrimination, and prejudice against members of an outgroup, as well as intergroup conflict, follow when the goals of groups collide by competing for scarce resources. Also relevant here is Henri Tajfel and John Turner's *social identity theory*, which is not constrained by focusing on group goals regarding tangible resources. Instead, the theory's main premise is that a group provides its members with a social identity, and in turn this should serve to make an individual member's self-concept more positive. Social comparisons with relevant outgroups do not always succeed in this way. When people perceive that their group has inferior status, believe that this status is illegitimate, and assume that there are viable alternatives, social competition is likely to ensue to create a positive social identity. Direct intergroup conflict often occurs, such as collective action, protests, and revolutions.

In summary, intergroup theories become relevant to hate crimes by pinpointing that individual crimes against members of a target group have their roots in supportive norms and often ideologies, that govern how ingroup members should behave toward minorities.

## HIDDEN PROFILE TASK

---

A *hidden profile task* is a method of distributing information among members of a decision-making group, leaving the optimal decision alternative hidden from members unless they thoroughly pool their unique knowledge. This task is an important tool in understanding when and why groups make decisions that fall short of their potential. Today more than ever, decision-making groups are composed of members with different expert knowledge.

The hope is that group members will thoroughly exchange information in their unique areas of expertise, helping the group to make an optimal decision. Unfortunately, research has shown that group discussion is an ineffective tool for pooling member expertise. Instead, group decisions tend to favor information that all the members knew before the discussion, thereby defeating the purpose of creating a group with diverse knowledge. Research using the hidden profile task has identified conditions under which group members are more likely to share their unique knowledge and help the group to make a better decision than any single member could have made alone. This entry looks at how the hidden profile task is used and discusses what it reveals about poor decision making and its remedies.

### Task Illustration

Hidden profile tasks typically are used in laboratory experiments on small decision-making groups. Groups may be charged with determining the guilty suspect in a homicide investigation, hiring the optimal job candidate, or selecting the best drug to market. In all cases, group members are given a finite set of decision alternatives and information about those alternatives. Some information about the alternatives is given to all group members. In addition to this shared or commonly known information, each member also receives information that no one else in the group receives. This unique knowledge is known as unshared information. A hidden profile task is one in which the shared information supports a suboptimal decision alternative, whereas the totality of information (shared and unshared) supports the optimal decision alternative.

As an illustration, imagine a three-person group choosing between two alternatives for a personnel selection task decision: Candidate A and Candidate B. In the total pool of information there are five pieces that support Candidate A and nine pieces that support Candidate B. Candidate B, therefore, is the better alternative. All three group members read the same five pieces of information that support Candidate A. That is, all information that supports Candidate A, the suboptimal alternative, is shared. In addition to this shared information, each group member reads a different set of three

pieces of supportive information about Candidate B. Individually, each member reads five pieces of information that support Candidate A and just three pieces that support Candidate B. Therefore, each member will enter the group deliberation preferring the same suboptimal candidate. Given that the group is charged with reaching a consensus on the best candidate, and all members already agree, they will have little motivation for discussing the information at length and hence will not discover that Candidate B is the better alternative.

The challenge is for group members to recognize that they have unique knowledge, thoroughly share that knowledge with each other, and be willing to change their initial decision preference. Unfortunately, several factors inhibit the likelihood that group members will share their unique knowledge and reach the best decision.

### Causes of Poor Performance

One reason why groups perform poorly on a hidden profile task is because of a discussion bias favoring shared information. When group members know a combination of shared and unshared information, they are more likely to mention first and later repeat shared than unshared information. Some scholars argue that the discussion bias favoring shared information results from simple probability. If group discussion of information is viewed as a random sampling process in which information is randomly sampled from members' minds, then shared information is probabilistically more likely to be discussed because there are more members' minds from which to select it (compared to unshared information, which resides in a single member's mind).

For the hidden profile task, the discussion bias leads members to give insufficient attention during deliberation to the very information that is critical for determining the optimal decision alternative. The result is poor group decisions. If unshared information supports the same decision alternative as shared information, then failure to discuss unshared information will not harm group choices. Therefore, the hidden profile task is the special case in which neglecting to discuss unshared information will harm group decisions.

Groups also perform poorly on a hidden profile task because individuals favor information that is

consistent with their preferences. In the hidden profile task, information is distributed such that members prefer a suboptimal decision alternative. Because the shared information supports the poor, yet preferred, decision alternative, group members evaluate this information more positively than the unshared information that is not preferred by all the members. If individuals are shown the entire pool of information after forming an initial preference for a decision alternative in a hidden profile task, individuals still positively evaluate shared information that supports their initial preference. The hidden profile task confounds shared information with information preference consistency, such that shared information is consistent with members' preferred alternative and unshared information is inconsistent with their preferences. In this way, the hidden profile task presents members with a twofold reason for avoiding unshared information—it is probabilistically unlikely to be sampled for discussion, and it is inconsistent with members' initial preferences.

Finally, information known or revealed to be shared is judged more important than unshared information, regardless of whether it is consistent with members' preferences. Shared information may acquire its value because it can be validated by others as relevant and accurate. Alternatively, if a member communicates unshared information, others must take the information at face value or question its authenticity. Because of the validation benefit that shared information possesses, those who communicate or know a lot of it (relative to others) are judged to be more capable decision makers than members who mention or know much unshared information. The evaluative benefits bestowed upon shared information and communicators of it (and likewise, the evaluative decrements associated with unshared information) may make it difficult for groups to successfully solve a hidden profile task.

### Remedies

More than two decades of research suggest potential remedies to the hidden profile problem faced by decision-making groups. One recommendation that helps groups is to take more time to discuss and reach a decision. Shared information is favored early in discussion, but it is less likely to be mentioned

later in discussion. Unshared information, in contrast, becomes increasingly more likely to be mentioned as group discussion progresses. If information exchange is viewed as a random sampling process, then unshared information is more likely to be sampled for discussion when group members run out of shared information to sample.

Diversity of opinion also facilitates a hidden profile solution. Despite the potential discomfort of dealing with a deviating opinion in the group, simply having one member who holds a different alternative preference from other members helps the group to reach the best decision in a hidden profile task. Group performance is aided equally when just one or all members of the group disagree on the preferred alternative. Opinion diversity benefits group decisions because it compels members to discuss information more completely and for a longer time compared to when all members initially agree. It also exposes members to information that is inconsistent with their preferences. Therefore, composing groups that have a diversity of opinions can help solve the problems that ensue when members have different information.

Finally, a hidden profile solution is more probable when members know one another's expertise. When group members are told of the domain in which each member holds unique knowledge, then members are more likely to discuss and remember this unshared information. Unshared information communicated by an expert may be more likely to be accepted as accurate and relevant than that mentioned by a nonexpert.

### Limitation

One limitation of the hidden profile research is that it has been conducted on participants in laboratory experiments. Little is known about the prevalence and function of hidden profiles in natural decision-making groups. Organizations are relying increasingly on cross-functional teams to perform work. These teams are composed of members who represent different units (and areas of expertise) in the organization. Often, each member holds unshared information that, if communicated, could help the group to make a better decision than any member could make alone. We can, therefore, speculate that some natural teams experience hidden profile tasks. Because members

rarely know whether their information is distributed as a hidden profile, it is wise to presume that it is and take the time to uncover the team's store of unshared information.

## HOLOCAUST

---

The term *holocaust* derives from the Greek word for “sacrifice by fire” and refers to the systematic, state-sponsored attempt by Nazi Germany to exterminate the Jewish inhabitants of Europe, primarily during the World War II years of 1941 to 1945. It marked the final chapter of an escalating persecution of Jews that began as early as 1933. This entry begins with a brief history of the events and then discusses social psychological research that attempts to explain how the decision to act against the Jews might have been reached and why perpetrators and bystanders participated or stood silent.

### History of the Holocaust

Soon after Adolf Hitler and his Nazi party gained power in 1933, German Jews found themselves faced with a rapid succession of decrees that increasingly stripped them of their civil rights. The Nuremberg Race Laws of 1935 rendered marriage or any sexual contact between Jews and those of

German heritage (Aryans) a crime. State-sponsored violence soon followed the escalating discrimination against Jews. In one of the most massive outbreaks of violence, Nazi storm troopers destroyed thousands of Jewish businesses and burned hundreds of synagogues during the Kristallnacht (Night of the Long Knives) on November 9, 1938. In the wake of this attack, Jews were deprived of the right to own property.

Throughout the 1930s, increasing numbers of Jews were incarcerated in concentration camps initially established for the purpose of detaining political opponents and others deemed enemies of the Third Reich. In the wake of Germany's invasion of the Soviet Union in 1941, mobile killing units (*Einsatzgruppen*) moved behind German lines and, aided by the SS (*Schutzstaffel*), militarized police battalions, and units of Germany's regular army (*Wehrmacht*), killed roughly a million Jews along with thousands of Soviet and Communist party officials. That same year also marked increasing deportations of Jews from countries under German control to recently established concentration camps in Poland. Ghettos in major Polish cities were established to detain those still awaiting deportation.

By 1942, most of Europe and with it millions of European Jews were under German control, making it possible for the Nazis to carry out their extermination with greater speed and efficiency. To that end, a group of undersecretaries of state and officials of the Nazi party convened a conference in the Berlin suburb of Wannsee to plan the "Final Solution of the Jewish Problem in Europe." Europe was to be combed from West to East, and all remaining Jews were to be deported to concentration camps in eastern Europe where they would be "eliminated by natural causes" stemming from a combination of hard labor and starvation. Those who survived this treatment were to be "treated accordingly." The "Final Solution" was carried out with lethal efficiency. By the time allied forces liberated the concentration camps, approximately 6 million Jews—two thirds of the prewar Jewish population of Europe—had perished in the Holocaust.

### Social Psychological Perspectives

An extensive body of scholarship on the Holocaust can be found in a number of academic disciplines,

including history, philosophy, and political science. Social psychological research has addressed three specific and interrelated key issues:

1. The decision issue: How could one group (the German people) become convinced that another group (the Jews) deserved to be killed?
2. The perpetrator issue: How could the perpetrators bring themselves to carry out the systematic killing of men, women, and children, and how could they come to terms with what they had done?
3. The bystander issue: How could so many stand by passively and watch as the Holocaust unfolded?

### *The Decision Issue*

How could the German people become convinced that the Jews deserved to be killed? Most cases of genocide, the Holocaust included, were preceded by a set of difficult life conditions that are experienced by a majority. Whether or not difficult life conditions lead to violence depends on three factors: whether they are perceived as a threat to a group's collective ego and create widespread frustration, the extent and nature of prejudice against an outgroup, and the influence of powerful instigators of violence.

By almost all accounts, Germany felt humiliated by the terms of the Versailles Treaty that formally ended World War I. It called for harsh financial reparations and the ceding of territories historically considered German, as well as the occupation of the Rhineland by France, its former enemy. Many Germans found it difficult to reconcile the feeling of national humiliation with their deep-seated belief that their country was the most sophisticated, culturally refined, and advanced nation in Europe. Many individuals respond to threats to their inflated self with aggression and violence toward others, especially those they perceive as the source of the threat. The political, economic, and social chaos of the Weimar Republic, along with the worldwide economic depression that started in 1929, led to a further deterioration of living conditions and instilled a widespread sense of frustration, another well-known catalyst for aggression.

Neither threatened egotism nor widespread frustration is sufficient or necessary for collective violence to occur. Also, neither predicts which group will serve as the scapegoat to be singled out for violence. At the time of Hitler's rise to power, Jews made up only about 1% of Germany's population. Most of them were highly assimilated, thinking of themselves as Germans by nationality and Jews by religion, and many had records of distinguished military service during the First World War. They did not comprise an outgroup that could be identified based on easily observable features or by virtue of living in different areas than the majority, like most Jews in eastern Europe.

The integration of Jews into German society was so complete that many had attained positions of power and prominence in business, politics, and the arts. However, this may have rendered them subject to *envious prejudice*, a form of prejudice generally directed at high-status groups that are perceived to be in a competitive relationship with the majority. Targets of envious prejudice are often feared, yet grudgingly admired for their competence and achievements. It was all too easy for Germans to accept the Nazi propaganda that the Jews had the power to work in secret to undermine the nation's political and economic institutions for their own gain.

Unlike the virulent eliminationist anti-Semitism some erroneously suspected to have been prevalent among a majority of Germans prior to 1933, envious prejudice provided a form of resentment that was amplified by propaganda and escalating discriminatory policies devised by powerful instigators. The combination of these forces rendered the Jews the scapegoat for Germany's poor social and economic conditions. A simple sharing of this sentiment among the population may further have increased the strength and confidence with which the ingroup endorsed anti-Semitic prejudice by way of group polarization, that is, the tendency of attitudes to intensify as a result of group discussion.

#### *The Perpetrator Issue: The Continuum of Destructiveness*

How could the perpetrators carry out the systematic killing of men, women, and children, and how could they afterward come to terms with what they had done? Genocidal killings are almost

never the result of spontaneous and frenzied outbreaks of violence stemming from strong prejudice against an outgroup. To date, the Holocaust remains the most horrific example of an extermination project that was well planned, organized, and coordinated. It took an opportunistic leader to increase the propensity for violence and further escalate it once it was started, thus creating a continuum of destructiveness that allowed perpetrators to become increasingly brutal in the treatment of their victims. Social psychologists have identified several key processes that help explain how perpetrators may proceed along the continuum of destructiveness. Chief among them are reduction of cognitive dissonance, dehumanization, and action identification.

Cognitive dissonance results whenever individuals' actions conflict with their attitudes. To solve this conflict and reduce the dissonance, individuals frequently change their attitudes to match their behavior (to the extent that the behavior has not been compelled, has already occurred, and cannot be undone). For example, a soldier asked to round up Jews for relocation may have found that he could not do so without being coercive. Although he may initially have been reluctant to handle his victims in a rough manner, if given the assignment again, he may be more willing to be coercive and even violent from the start. The reason is that he may have adjusted his attitude toward his victims in light of his earlier behavior. He may have justified his action by adopting the attitude that his victims deserved the treatment he dispensed.

Attitude change of this sort was likely aided by the pervasive dehumanization of the Jews during the Nazi years. The escalating elimination of civil rights may have been the first step in adopting the view that the Jews were unlike the Germans. Nazi propaganda stressed the nonhuman nature of the Jews by comparing them to a cancer that was growing within Europe. And the infamous 1930s propaganda movie *The Eternal Jew* interspersed images of Jewish businessmen going about their work with images of plague-infested rats squirming through the alleys of German cities.

Just as important, the inhuman conditions of the concentration camps, as well as the similarly inhuman conditions under which Jews were rounded up at gunpoint and herded into railcars

designed for transporting animals, further contributed to the perception that the victims were, indeed, less than human. Ironically, the perpetrators may have been oblivious to the fact that they themselves created the inhuman conditions they subsequently used to justify the inhuman treatment.

At least some perpetrators may have been able to aid in the Holocaust because they were in denial about the meaning of their actions. Generally, individuals can identify their actions on several levels of abstraction. Loading people on trains, for example, could be construed as simply following orders (a low level of abstraction) or contributing to the manifest destiny of the German people (a high level of abstraction). This undoubtedly allowed many perpetrators to think of what they were doing as something other than “killing Jews.” Related to that, individuals’ self-deception about the nature of their actions may have further reduced any reluctance to aid in the killing. The Nazi death machine relied heavily on euphemisms (for example, “relocation for labor duty in the East”), and the highly organized nature of the Holocaust further promoted obedience to a malevolent authority. Thus, even Adolf Eichmann, the architect of the “Final Solution,” could proclaim at his trial in Jerusalem that he never personally killed a Jew.

### *The Bystander Issue: The Continuum of Passivity*

Although the massive scale of the Holocaust required the active participation of thousands of perpetrators, it could not have been carried out without the passive complicity of millions of bystanders who stood by as increased discrimination turned into genocide. Their acquiescence can be best understood through the psychological processes that lead bystanders along the continuum of passivity. Chief among them are dissonance reduction, obedience, conformity, pluralistic ignorance, and a belief in a just world.

Just as perpetrators may have changed their attitudes toward their victims based on their actions, bystanders may have changed their attitudes to match their inaction. Not speaking up against legislation that discriminated against Jews or failing to intervene when neighbors were dragged from their homes could be rationalized by bystanders who

changed their attitudes to justify their inaction. At the same time, many bystanders may have complied with the Nazi policies because of coercive pressures in the form of stiff penalties for failure to obey them.

Although conformity has often been cited as contributing to the widespread apathy, it is perhaps better explained by reference to pluralistic ignorance. Because the Nazis went to great lengths to disguise the Holocaust from the majority of the population, many Germans may have been unsure about what was really going on and may have taken a lack of concern or action on the part of others as an indication that perhaps nothing was wrong (for example, that Jews were merely being resettled rather than sent to their deaths).

Finally, inaction may also have been promoted by an ego-defensive belief in a just world. This belief implies that people get what they deserve, especially when we are unable to help them. To the extent that the Germans, by and large, failed to take action, they may have adopted the view that the Jews deserved what they got.

Although social psychologists have discovered a number of processes among individuals and groups that help explain why and how the Holocaust happened, their attempts in this regard should not be taken as trying to “explain it away.” Rather, understanding these processes may ultimately aid in keeping the promise “Never again!”

## HOMOPHILY

---

*Homophily* is the tendency for there to be higher rates of contact between similar people than between dissimilar people. It is the social process reflected in that old bit of folk wisdom: “Birds of a feather flock together.” Homophily is crucial to the study of group processes because it conditions every interaction. It affects who people interact with, how interactions are structured, the process of group formation, and the course of interactions between groups. This entry describes the basic types of homophily, their origins, and their social implications.

The observation that “like attracts like” is by no means a recent pronouncement. It was Plato who stated that “similarity begets friendship” and Aristotle who noted that some people like those who are like themselves. Stated another way, homophily means that similarity breeds connection. Similarity in the case of homophily refers to *ascribed characteristics*, such as gender, race, and age, and *achieved characteristics*, such as education, social class, and occupation. In essence, homophily organizes society. Because individuals are more likely to interact with those similar to themselves, traits are concentrated in groups.

At this point it is useful to distinguish between homogeneity and homophily. *Homogeneity* is a descriptive term that refers to the degree of similarity within a group or relationship. Thus homogeneity is a way to characterize similarity in groups, while homophily describes the mechanism that leads to homogeneity. In other words, groups become homogeneous due to homophily.

### Types of Homophily

Some of the tendency to associate with similar others is a by-product of our more limited opportunities to interact with people who are different from ourselves. This type of homophily is called induced homophily. *Induced homophily* refers to the tendency for interaction partners to be limited by social structure in ways that generate homogeneous groups and relations. Induced homophily stands in contrast to *choice homophily*, which refers to the tendency of people to choose interaction partners who are similar to themselves.

In naturally occurring groups and relationships, it often is difficult to know how much observed homogeneity occurs as a result of induced homophily and how much results from choice homophily. So, in empirical contexts, researchers often begin by taking account of baseline homophily. We can think of *baseline homophily* as the amount of similarity within relationships that would be expected by chance, given the choices available. For example, taking into account population information only, we would not expect any baseline homophily based on sex, since sex is an equally distributed characteristic. Baseline expectations would be that an individual would have 50% male friends and 50% female friends. Therefore, if 90% of a woman’s friends are female, it indicates that something other than chance is guiding formation of her friendships. That “something” is called inbreeding homophily. *Inbreeding homophily* refers to any amount of homophily over and above what probability would predict based on the relative sizes of the groups in the population. In the example above, we would interpret the difference between the expected and observed rates of similarity (40%) as evidence of inbreeding homophily.

Baseline homophily reflects induced homophily. It tells us about the most basic, population-level constraints on our choices of interaction partners. It is more difficult to isolate choice homophily. Inbreeding homophily *can* reflect choice homophily, or ingroup preferences. However, inbreeding homophily can *also* be induced by social structures.

Consider the example of race in the United States. Taking into account the differential sizes of various racial and ethnic groups in the United States, a baseline model would predict a substantial degree of homophily based on race for members of the largest group (Whites), simply because of higher rates of exposure to ingroup members. In the 2000 census, 74% of U.S. residents self-identified as White only, while 12% self-identified as Black or African American only. Based only on these population distributions, high rates of baseline race homophily among Whites and low rates of baseline race homophily among Blacks would be expected. Whites whose networks are more than 74% White or Blacks whose networks are more than 12% Black would provide evidence of inbreeding homophily. Such inbreeding homophily could not automatically be interpreted as reflective

of choice homophily, however. Individuals interact within families, neighborhoods, schools, religious institutions, and workplaces that are all segregated to various degrees by race and ethnicity. Taking into account the amount of segregation within these various institutional settings, a substantial degree of homophily can be predicted on the basis of race and ethnicity, simply because of higher rates of exposure to ingroup members—well above and beyond the constraints imposed by population-level distributions.

Inbreeding homophily can also reflect the similarity that arises indirectly as a result of (induced or choice) homophily along other social dimensions that are correlated with the dimension under consideration. For example, friendships, romantic relationships, and group associations tend to be homophilous along the dimensions of wealth and education. In the United States, there is a correlation between race and wealth and between race and education. Consequently, when individuals choose interaction partners who are more like themselves in education, this will tend to consolidate relations along dimensions of race as well. In sum, then, inbreeding homophily reflects a variety of processes including both induced and choice homophily.

How exactly does the social environment induce homophily? The primary means is through opportunity structures. The most basic constraint on homophily is proximity. It is easier for us to form connections with individuals and groups that are closer in physical distance. Distance shapes our relationships on a local and global scale. At the most basic level, it is easy to see that a child living in Estonia and a child living in Canada have a very slim chance of becoming close friends. At a more local level, though, proximity remains a powerful constraint on homophily. We tend, in general, to like better those with whom we are more familiar. We feel more positively toward people we see more often at school, at work, where we live, and at businesses and other institutions we patronize. As mentioned above, these environments, along with other groups and organizations (e.g., book clubs, athletic teams, volunteer groups, religious institutions), tend to be already segregated along a variety of dimensions like class, race, religion, and sometimes sex. Therefore, the activities of our daily life tend to put us into more contact, and

often more meaningful contact, with people who are similar to us in a variety of ways.

It is important to keep in mind that homogeneity has sources other than homophily. Over time, we are likely to become more similar to those with whom we interact regularly. We learn things from one another and influence each another's ideas and attitudes and so become more similar in the amount of shared knowledge, attitudes, and values over time. We also have more of the same experiences and become members of groups to which our friends and acquaintances already belong. In these ways, individuals can become more like their friends and associates over time through a process of social influence rather than through homophily. With nonascribed characteristics such as attitudes, values, hobbies, and so on, it can be difficult to distinguish homophily from social influence. Consequently, some of the more compelling evidence for homophily comes from the study of ascribed characteristics. Ascribed characteristics are aspects of individuals, such as gender, race, ethnicity, and religion, that it is difficult or impossible to change in response to interactions with others. Accordingly, when there is homogeneity based on ascribed characteristics researchers can more confidently interpret the differences as resulting from a combination of induced and choice homophily rather than from social influence.

### Bases and Patterns of Homophily

In the United States, a variety of different types of network relations (including romantic relationships, friendships, discussion partners) tend to be homophilous with regard to ascribed characteristics. Race- and ethnicity-based homophily in our culture is observed at rates that are well above baseline expectations. Blacks' networks show higher rates of inbreeding homophily than do Whites' networks. Due to the drastically lower rates of baseline homophily discussed above, however, Blacks nonetheless have much more heterogeneous networks. In contrast, because male and female groups of equal size were observed, it is clear that homophily based on sex is almost entirely a result of inbreeding homophily. Gender homophily becomes visible in childhood and starkly structures friendships and play groups among school-age children. Age is one of the strongest bases of

homophily within friendships in the United States. Our closest friends, especially, tend also to be close to us in age. Our friendship and marriage relations are also homophilous by religion in the United States, as in many cultures. As with race and ethnic homophily, the largest groups (e.g., Protestants in the United States) display less inbreeding, but nonetheless end up with more homogeneous networks than smaller groups (e.g., Catholics and Jews in the United States).

Some research suggests that it is not just similarity, but the right amount of similarity, that is important for forming and maintaining ties. Marilynn Brewer's theory of optimal distinctiveness proposes that a balance is struck between fitting in and standing out. While being too unique may result in expulsion from the group, being too similar may contribute to loss of autonomy. A balance may happen naturally with homophily on one dimension complemented by heterophily on other dimensions.

Research has shown that, as an impetus for structuring networks and guiding interaction, homophily's effects can become more or less important throughout the life course. Gender and race are influential in homophilic processes in peer group formation during childhood. As individuals enter adolescence and adulthood, gender homophily becomes less forceful in structuring relationships. Specifically, most individuals in romantic relationships pursue members of the opposite sex. Research has also addressed how homophilic processes change as individuals adopt new identities and roles. For example, a new mother may seek out social groups where other individuals are also new mothers.

The effects of homophily may also vary over time. While it is true that homophily still rules as a guiding force in many kinds of interpersonal relationships, there is evidence to suggest that its effects are lessening, at least in certain domains. For example, while race homophily is still powerful in structuring intimate relationships, marriage between individuals of different races is becoming increasingly common.

### Consequences of Homophily

Homophily may have some benefits for individuals. Research suggests that people may benefit

most from the social support of network members who are similar to themselves in important ways. People who are going through major life transitions, for example, tend to handle those changes better when they have support from people who have experienced those same changes.

A potential negative outcome for decision-making groups is groupthink. Groupthink is a type of decision making that happens when a group tries to reach a consensus without properly and critically analyzing all possibilities. A cohesive group that is composed of highly similar individuals may reach a faulty conclusion when little or no dissent is expressed.

Homophily is critically involved in the processes described by social identity theory. Social identity theory states that people cognitively place themselves and others into categories. Then, individuals will form groups according to those categories. Finally, a group will compare itself to other groups, in an effort to view itself as superior. Homophily may drive people to categorize others according to their similarity to and difference from themselves. People's need to distinguish between those who are similar to them (i.e., the ingroup) and those who are dissimilar (i.e., the outgroup) and to assign value to these similarities and dissimilarities (i.e., "my group is better than your group") can lead to polarization between groups.

Because homophily increases people's chances of forming bonds with others who are similar to themselves, it tends to localize traits within networks. When people spend more time with those who are similar to themselves in age, gender, religion, and/or ethnicity, they are also spending more time with people who are similar in terms of shared experiences, attitudes, knowledge, beliefs, and so on. This increases homogeneity within networks.

## HOMOPHOBIA

---

The term *homophobia* refers to the fear of or concern about being associated with homosexuality. Definitions used by social science researchers and theorists vary with regards to semantics. For example, some definitions state the fear as irrational; others specify that the fear is directed toward homosexual persons, homosexual behaviors, generalized belief systems, or some combination of these. However, there is overwhelming consensus that the term *homophobia* stems from the notion that homosexuality (actual or perceived) is devalued by society and that heterosexuality is the norm. There is also agreement among sociologists and gender theorists that attitudes and actions that result from this fear are a form of social control that supports intolerance. It should also be noted that this term has no direct clinical or medical association.

### Background and History

Seeking to label the prejudice toward homosexuals, psychologist George Weinberg (1972) coined the term *homophobia* to explain the “irrational fear or hatred of homosexuals.” Consistent with this term, early applications framed homophobia as an individual attribute, in which antigay prejudices are rooted in a person’s psychological makeup, without regard to wider structural sources of antigay prejudices and variations in attitudes held toward gay men and lesbians. Critics of the term argued that its suffix, *phobia*, implies that such fears and attitudes are inherently irrational and dysfunctional.

While earlier scholarship typically employed the term *homophobia* to describe the antigay attitudes of individuals, currently it is more often used to refer to the attitudes, social ideologies, behaviors, and belief systems of groups. At the societal level, the term *homophobia* has been used in congruence with the terms *heterosexism* and *heteronormativity*—all of which refer to the social opposition to same-sex desire. Gender theorists further assert that this opposition is highly associated with patriarchal ties and male dominance.

Homophobia is manifested at both the individual and social levels. At the individual level, homophobia is the fear of being identified as homosexual or as valuing homosexuality. However, the individual level and social level are linked, since society and culture dictate what is considered to be “gay” or “homosexual” and the treatment of certain classes of people. Thus, when homophobia occurs at the individual level it is still nested within the social level.

Attitudes toward homosexuals and homosexual issues are not evenly distributed among individuals and subgroups in society. Empirical research suggests that attitudes toward gay men and lesbians vary based on sex, age, race and ethnicity, social class, education, political and religious affiliation, and whether or not an individual has known a gay person. Cross-culturally, men are generally more homophobic than women. Studies in the United States consistently find that individuals who are older, less educated, and reside in rural areas express relatively high levels of prejudice against gay men and lesbians. Also, those with fundamentalist religious affiliations, those who frequently attend religious services, and those affiliated with conservative and Republican political parties tend to have higher levels of antigay prejudice. Individuals who have personally known a gay person manifest the lowest levels of prejudice, especially if the person is a close friend or family member. Individuals with lower levels of prejudice, such as women and the highly educated, are more likely to experience interactions with an openly gay person. Research exploring levels of prejudice among racial and ethnic minorities is less consistent. It suggests that racial and ethnic minorities are more prejudiced against gay men and lesbians than are their White counterparts. It has been suggested that this difference is due to White women’s

more favorable attitudes toward gay men and lesbians; however, there may also be a spurious relationship with class and education. Research also shows that interpersonal contact may not be as significant in shaping attitudes in all cultures. For example, the belief that homosexuality is a choice is a greater predictor of Black prejudices against gay people in America than the lack of interpersonal contact.

Some cultures view homosexuality as a White or American and European phenomenon. For example, Iran's President Mahmoud Ahmadinejad claimed in a 2007 speech that there are no homosexuals in Iran. This statement followed the 2005 execution of two men for alleged homosexual activity. These actions not only legitimated homophobia in Iran, but also illustrated how social institutions, including but not limited to the media, religion, and governments, perpetuate homophobic attitudes and discrimination against gay men and lesbians.

Gay men generally encounter more pronounced homophobia than do lesbians. However, in societies where social pressures on women to marry are great, such as India, lesbians may be more stigmatized than gay men. In America, homosexuals from racial and ethnic minorities and those with lower levels of education and income encounter greater levels of homophobia. Studies have found that young homosexuals are more likely to experience extreme acts of homophobia than are adult homosexuals. Lesbian, gay, bisexual, and transgender youth are also more likely to use drugs, experience homelessness, participate in sex work, and commit suicide than their heteronormative counterparts.

As with racism and sexism, homophobia is manifested in many forms, including but not limited to malicious gossip, name-calling and bullying, acts of intimidation, vandalism, isolation, rejection, death threats, and physical assaults at the individual level, as well as broad scale discrimination in the workplace, community, or by authority of the government at the societal level. Homophobia can also be internalized, where individuals struggle to resolve social (and often religious) beliefs concerning homosexuality and their own individual desires. This can lead to depression, violence, and even suicide.

Social theorists argue that homophobia and its manifestations not only enforce intolerance toward

gay men and lesbians but also intolerance of anyone not within the dominant culture, and foster a climate of prejudice including sexism and racism. From a micro-level viewpoint, homophobia should then be lessened in individuals through education, and larger scale social change would have to occur to affect homophobia at the macro level.

### Social Distance

In addition to conveying antigay prejudices and attitudes, homophobia is a way to solidify ingroup or outgroup associations and individual identities. Social psychological theories of identity suggest that behaviors can protect identities and indicate individuals' social group while simultaneously distancing members from outgroups. Thus, homophobic actions are a way to socially distance individuals from homosexuals and to reaffirm heterosexual identities in a heteronormative culture. This prevents heterosexuals (or people who want to be identified as heterosexual) from being associated with, labeled as, or treated as a homosexual. In an extension of this concept, a society that devalues homosexuality and associates it with negative (e.g., abnormal or immoral) behavior may have members who seek to socially distance themselves from the devalued behavior in order to reaffirm their identity as good and moral people.

As a category of people, homosexuals are devalued and have a lower status than heterosexuals and as such face greater social scrutiny and harsher punishments. In his work on stigma, Erving Goffman sought to understand how individuals, including homosexuals, gain, lose, and defend claims of status. Overall he found that homosexuals were stigmatized because homosexuality was devalued by society and only when homosexuals could "pass" as heterosexual were they afforded the same status and privileges as heterosexuals. Status construction theories seek to explain how group interaction contributes to structures of inequality. Perceived or actual sexual orientation may be one way in which interaction is ordered, and homophobia is a result of diminished status in that individuals and institutions do not want to be associated with devalued statuses.

Initial definitions of homophobia did not account for why some groups of people are

more homophobic than others. In response to this omission and in seeking to explain why men tend to be more homophobic than women, social and gender theorists began exploring the link between gender and homophobia. The body of literature generated by these theorists asserts that homophobia has important commonalities with sexism—both involve prejudice against gender nonconformity. General feminist thought suggests that what heterosexuals find threatening about homosexuality is that men are not being “men” and that women are not being “women.” Therefore, one way to punish individuals for gender nonconformity is to associate them with homosexuality, which leads to devaluing their status regardless of their actual sexual orientation. According to Suzanne Pharr, homophobia then becomes “a weapon of sexism” and gender conformity.

According to this analysis, in affirmation of the male identity, men must reject what is unmanly. Thus, to be “a man” in contemporary American society is to be sexist and homophobic—to be hostile toward the feminine, toward homosexuals and persons perceived as homosexual, and especially toward gay and effeminate men. R. W. Connell introduces the idea of a “hegemonic” masculinity that is organized around the psychological and social dominance over women, but which also enables the domination of other men. In explaining demonstrations of masculinity and dominance, Michael S. Kimmel asserts that men are under constant threat that they may be discovered as insufficiently masculine and therefore they experience extreme pressure to conform to an ideal masculinity that is unattainable. According to Kimmel, “homophobia” is the fear of being “unmasculine,” or feminine. Work focusing on attitudes toward lesbians seems to fit this fear less well; however, the prevalent suggestion is that men are threatened by the idea that women could live without men.

One of the most cited psychological studies, by Henry Adams, Lester Wright, and Bethany Lohr, found that higher levels of homophobia are associated with greater homosexual arousal in men. It is argued that this study empirically demonstrates Freud’s “reaction formation,” in which socially unacceptable impulses are converted into opposing behaviors as a way to mask the unacceptable impulses from society.

Another important study regarding homophobia, conducted recently by social psychologist Robb Willer, proposes and tests the masculine overcompensation thesis, which asserts that men display extreme demonstrations of masculinity as a reaction to masculine insecurities. Drawing on “reaction formation” and incorporating theories of masculinity, Willer applies theories of identities to show that overcompensation-type masculine behaviors are exhibited by men in an effort to protect their identities as men and indicate their social group while simultaneously distancing themselves from outgroups, such as women and homosexuals. Willer gave randomly determined feedback on a gender identity survey to men and women that suggested they were either masculine or feminine. Participants were then asked to fill out a series of surveys designed to assess measures of masculinity, including attitudes toward homosexuals and homosexual issues. Women showed no variation based on the feedback; however, men given feedback that threatened their masculinity expressed more negative attitudes toward homosexuals and homosexual issues than men given feedback confirming them as masculine.

More research that addresses homophobia has focused on men than on women. In addition, few studies explore why attitudes and behaviors toward lesbians are generally less negative than those toward gay men. There has also been little discussion of intentionality and whether individuals are aware that their homophobic attitudes and behaviors are homophobic.

### Importance

Homophobia influences many of our daily interactions and social identities. Research on homophobia is important because it reveals an important way in which people and social groups are stigmatized and the strength of the stigma to shape attitudes, behaviors, and social interactions. Homophobia is especially powerful because it has a pervasive effect on members of society via gender ideologies. In addition, it affects gay men and lesbians, and those perceived as gay and lesbian, through acts of intimidation, discrimination, and violence. Gay men and lesbians also have less access to social resources than do heterosexuals

and experience higher rates of substance abuse, depression, and suicide. By and large, homophobia provides a basis for unequal treatment, justifications for negative consequences, and support for the status quo.

## IDENTIFICATION AND COMMITMENT

---

Groups rarely have complete control over members and, therefore, need to rely on them to behave in ways that benefit the group even when they are not being monitored. Whether this occurs depends largely on group members' attitudes toward the group. These attitudes are embodied in two closely related psychological constructs, *identification* and *commitment*. Across academic disciplines, researchers as well as practitioners who work with and in groups have investigated the conditions under which group members commit to a group, its work, and its values and the ways in which identifying with a group affects their self-concept. Researchers have viewed knowledge of identification and commitment as essential to understanding how people feel about the groups to which they belong, what they would be willing to do for those groups, and what they receive in return for their loyalty.

People's identification with and commitment to a group corresponds to their performance within it, which is the primary reason why organizational psychologists have been so interested in these phenomena. Typically, researchers have explored the bases for a person's attachment to a group and attempted to predict how it influences the willingness to transcend strict job descriptions to accomplish tasks necessary for the organization's well-being. They also have examined how

attachment influences people's desire to remain with or leave an organization.

Over the years, researchers have developed a variety of approaches to studying people's commitment to groups, resulting in some conceptual ambiguity. This has left lingering questions about the attitudes and behaviors constituting commitment, as well as about the factors that cause some people to be more or less committed to a group and the corresponding consequences of different levels of commitment. This entry discusses the approaches psychologists and group researchers have taken to the concept of commitment and how identification relates to commitment. It then examines the consequences of commitment for group behavior and how groups cultivate commitment among members.

### Dimension Models of Commitment

In 1986, Charles O'Reilly and Jennifer Chatman argued that the myriad definitions of and approaches to commitment contain the unifying premise that a core element of people's commitment is their psychological attachment to a group. Thus committed individuals willingly act in the interest of the group because the group provides them with a connection they need; that is, it contributes to their psychological well-being. Seen from this perspective, commitment is both fundamentally affective, characterized by the bonds that develop between an individual and a group, and motivational, driving individual actions that benefit the group.

Equally important, O'Reilly and Chatman stressed that rather than being unidimensional, commitment consists of multiple dimensions. Drawing on Herbert Kelman's research on attitude and behavior change, they identified three independent dimensions of commitment: *compliance*, *identification*, and *internalization*. Subsequently, John Meyer and Natalie Allen developed a model of commitment with three similar dimensions of commitment: *continuance*, *affective*, and *normative*.

Both the compliance and continuance dimensions suggest the most superficial and transactional form of commitment, in which an individual becomes instrumentally involved with a group to secure specific, extrinsic rewards. Because activities performed in the interest of the group originate from a desire for rewards from the group rather than from any personal, private motives, in compliance-based commitment there may be a discrepancy between individuals' private attitudes and the attitudes and behaviors they exhibit in public on behalf of the group.

Identification-based or affective commitment is more substantive. It involves attachment to the group driven by a desire for affiliation. Group membership implies certain obligations among members. Identification suggests that a person is motivated to act in ways that benefit the group because of a desire to nurture and maintain his or her relationship with the group. With identification, as with compliance, there may be inconsistency between people's private attitudes and their public actions on behalf of the group; however, in identification-based commitment, concerns about group affiliation rather than private attitudes motivate people's behavior.

Finally, internalization or normative commitment occurs when individual and group values converge. Commitment arising out of such internalized values does not need to be motivated by instrumental or affiliative concerns but, rather, originates from private, personal attitudes that correspond to those of the group. In this way, an individual's own preferences can lead to behaviors that benefit the group.

### Cultivating Normative Commitment Through Social Control

Interest in group-member commitment stems largely from the intuition that group members who

feel committed to the group are more likely to behave in ways that benefit the group than are those who do not feel a sense of commitment. Groups that foster a sense of commitment, then, should experience more long-term success. Researchers have focused on two theoretical reasons that commitment should have performance implications for the group. First, commitment helps to create and maintain social control systems that allow groups to regulate individual behavior more effectively than would formal control systems. Second, commitment to the group encourages individuals to align their behavior with the group's interests.

Traditionally, organizational researchers have focused on formal mechanisms used by groups and organizations to coordinate and control members' activities. These formal control systems emphasize surveillance and expectations about positive and negative consequences of different behaviors. Through members' sense of being monitored, as well as rewarded and punished, organizational leaders encourage behaviors that benefit the group and enforce penalties associated with prioritizing personal interests over those of the group. From this perspective, group member commitment is less important than formal mechanisms of control, such as supervisory monitoring, standardized rules and procedures, compensation schemes with explicit rewards and punishments, and planned and budgeted resource allocations.

Formal control systems, however, contain critical weaknesses that can result in a failure to align individual and group interests. First, one weakness is the difficulty involved in specifying ideal behaviors and group member or employee roles, particularly in ambiguous or quickly changing environments. Second, even after these behaviors are identified, it can be difficult to match rewards to these behaviors, and punishments to other behaviors, to produce desired outcomes. Add to this the fact that most jobs have complex or partially unobservable elements, and developing consequences for desired and deviant behavior becomes quite difficult, as does establishing and maintaining legitimate authority over group members. Finally, in relying on individuals' extrinsic motives for behavior that benefits the group, these systems risk undermining the intrinsic value of group membership. Even when formal control mechanisms produce

individual behavior that is perfectly aligned with group goals, these controls can be costly in terms of time, energy, and legitimacy and difficult to maintain over long periods of time. Instead, cultivating strong normative commitment among members can be a highly efficient method of organizing for groups and organizations.

Cultivating normative commitment requires using social, rather than formal, control. Researchers have explored social control systems that use a group's norms and values to achieve these efficiencies. Not only do these norms and values serve a similar function to formal control systems by communicating desirable and undesirable actions, but they do so in an informal manner, drawing attention away from formal group leaders and toward qualities that group members have in common. Thus, these informal mechanisms also increase social cohesion within the group. Strong social control systems, however, depend on group members sharing norms and values regarding important attitudes and behaviors that benefit the group.

#### How Groups Benefit From Members' Normative Commitment

The most striking and robust benefit of cultivating normative commitment among group members is that it promotes organizational citizenship behavior, or members' willingness to transcend formal job or role definitions to perform additional acts beneficial to the group. Because psychological attachment based on normative commitment enables people to take the perspective of the group, rather than just their own perspective, they are more likely to act in the interests of the group. Without such prosocial or extrarole behavior, groups would have to incur additional costs either to have those extra or unanticipated tasks performed or to create monitoring systems to ensure their performance by specified group members.

Substantial research has shown that commitment based on identification and internalization is positively related to prosocial behaviors—behaviors that benefit the group—and negatively related to member turnover. A meta-analysis found that all three forms of commitment led to reduced intentions to exit an organization and decreased overall turnover. In particular, affective and normative commitment predicted better attendance, performance,

and organizational citizenship behavior, as well as lower levels of stress and work–family conflict. Taken together, these studies confirmed that member commitment can have important consequences for groups.

#### Group Identification

Groups benefit from members' commitment, but what do members receive in return for their commitment? Normative commitment based on psychological attachment suggests that those who commit themselves to the group receive psychological benefits from their affiliation with the group. In exchange for their commitment, group members gain membership in the group and satisfy their need to belong.

One reason this belonging can be so rewarding is that it helps to define and enhance a person's social identity. Social identity theorists have argued that rather than just perceiving one, unitary personal self, people actually perceive themselves as having multiple "selves," corresponding to their memberships in various groups. Thus, an individual can perceive him- or herself as having a personal self, a family self, a work self, a national self, and so on. *Social identity theory* refers to the process by which people define their self-concept in terms of their memberships in various social groups. It can be situationally based, because different aspects of a person's self-concept may become salient in response to the distribution of characteristics of others who are present in a situation. When a person identifies with a group, the group's goals and values influence that person's perception and behavior as well as how others treat him or her.

The idea of individuals perceiving themselves as composed of many social selves is important because it means that membership in social groups helps to form one's *self-concept*, that is, how one sees and defines oneself. To the extent that a particular ingroup membership is salient, one's perceived similarity to others in the ingroup is increased. Increasing the salience of ingroup membership causes a *depersonalization of the self*, which refers to perceiving oneself as an interchangeable exemplar of a social category. Identifying with a group can satisfy one's attachment and belonging needs and can also foster pride, accomplishment, and self-esteem.

Researchers have also examined identification at the organizational level. Here the focus is on defining what an organization stands for, and it is typically viewed as the top leaders' role to create clarity for members about the organization's identity. This is the content that is the basis for an individual's level of identification with a group or an organization, and, while it is an important perspective, the psychological impact of such identification is the critical determinant of behavior. Similar to findings on commitment, those who find their organization's identity more appealing behave more cooperatively, are more concerned with the favorability of collective outcomes than with procedural justice, and have better relationships with external groups.

Clearly, there is overlap between the constructs of commitment and identification. Both imply an individual's attachment to the group. While identification specifies the content that is the basis for that attachment and helps people answer the question, "Who am I?" through membership in a group, commitment, as a construct, is broader. Commitment encompasses the expression of attitudes and behaviors that further the interests of the group. Some conceptual ambiguity exists about the construct of identification, with researchers calling for a more rigorous multidimensional conceptualization. But, given the conceptual overlap between commitment and identification, researchers should be careful not to needlessly proliferate redundant constructs rather than clarifying existing ones.

### **Cultivating Commitment Among Group Members**

In considering how groups promote member commitment, most research has focused on normative commitment. This is because increasing instrumental commitment is fairly straightforward, involving allocating sufficient extrinsic rewards to motivate a person to stay, whereas increasing normative commitment is more nuanced. Gradually increasing levels of participation in a group's activities can produce normative commitment, as research using incremental commitment to induce attitude and behavior change has found. For example, the foot-in-the-door strategy has been shown to convince people to engage in a wide range of behavior they ordinarily might refuse to do—from eating an

earthworm to converting religions—by asking them to commit to small acts of participation that gradually lead to larger acts of commitment.

Some companies have learned how to use this incremental approach to building commitment. For example, they use multiple steps to recruiting new employees, leading potential recruits to increase their commitment to the firm with each step, long before these individuals are asked to commit to joining the organization. Other companies avoid discussing salary before an employee is hired, emphasizing the relational benefits of group membership before introducing instrumental incentives such as money.

Rosabeth Moss Kanter has identified several commitment mechanisms used by utopian communities to recruit new members, including requiring new members to abandon their prior lives, move to secluded areas, and live in accordance with unconventional practices at odds with the wider society. Many of these mechanisms require new members to abandon elements of their previous lives through calls for abstinence or extreme austerity. Others asked new members to invest in the community, often in an irrevocable way, or to renounce the outside world, their family, and their prior lives. Many communities took steps to deindividualize new members, stripping them of their previous personal identities through processes of mortification, criticism, and punishment and making their group-based identity more salient. Finally, most communities used rituals, traditions, ideology, and charismatic leadership to help create feelings of communion or belonging within the communities and to reinforce group members' identification with the group. These mechanisms made individuals more likely to commit to the communities and more susceptible to the groups' values. In addition, the successful utopian communities, those that lasted longer, implemented more of these commitment mechanisms than did less successful communities. Interestingly, Kanter argued that while these mechanisms may be exaggerated within these utopian communities, more mild forms of the same mechanisms could regularly be found in other groups and organizations.

These commitment mechanisms have substantial influence on behavior. For example, one study found that individuals who made volitional and irrevocable job choices were more committed than

those who did not, a difference that endured for over a year. Further, mentoring programs for group members were associated with higher commitment and lower turnover of members. In addition, blurring the lines between work and family and strengthening networks among employees increased normative commitment to work groups. These findings suggest that groups can take steps to encourage commitment among their members.

Studying commitment and identification in groups is clearly important to understanding and predicting how people are likely to behave within groups. Research has focused, appropriately, on the underlying psychological bases for this attachment and has usefully clarified our understanding of commitment and identification in groups.

## IDENTITY CONTROL THEORY

*Identity control theory* (ICT) focuses on the nature of people's identities (who people are) and the relationship of these identities to people's behavior. It also focuses on how people's behavior is an outcome of the meanings people attach to the world around them. People not only name and classify the world but also label each other and themselves in terms of the positions they occupy in society, organizations, and groups. Each of these self-labels represents an *identity*, which is a set of meanings a person uses to define him- or herself as a group member (e.g., American), as a role occupant (e.g., student), or as a unique individual (e.g., honest). Moreover, the social structure is a combination of the many role and group positions people hold in society, and these positions carry behavioral expectations that people internalize as their identities.

Each identity is made up of both meanings shared by members of society and each individual's own meanings for him- or herself. The shared meanings allow others in society to understand the identity a person is enacting in a situation, while the idiosyncratic aspect of an identity allows a person to enact the identity uniquely. In addition, people possess multiple identities, each of which is linked to the social structure through these shared meanings and expectations. It is therefore through their identities that people are intimately tied to the social structure.

### Meaning

Central to ICT is the concept of meaning around which identities are formed. What does it *mean* to be a "father" or "son"? What does it *mean* to be an "American"? An identity is a set of meanings applied to the self as a unique individual (e.g., honest), in a social role (e.g., student), or as a member of a social group (e.g., American); together, these meanings define who one is. In ICT, meaning is a response to a stimulus in the situation. In other words, a stimulus in a situation evokes meaning in an individual. A stimulus becomes a symbol when it evokes the same meaning in different people. When people have the same response to a stimulus, they understand each other through this shared meaning.

For example, thinking about oneself as a student (stimulus) calls up a set of responses (meanings) similar to those called up in others who understand what it means to be a student. These responses define what it means to be a student—for example, being studious, responsible, or social. These common responses lead to common expectations and understandings about what a student is, what a student does, how a student relates to a professor, and the position of a student in the university.

### Control of Perceptions

Each identity is a control system with four components: an identity standard, perceptions, a comparator, and behavioral output. The *identity standard* is the set of meanings defining a given identity. *Input perceptions* are of meanings in a situation that are relevant to an identity (mostly feedback from others about how a person is coming across in the situation). The *comparator* is a mechanism that compares the perceived meanings with the meanings in the identity standard and outputs any difference as an error or discrepancy. *Behavioral output* is a function of the discrepancy.

In any given situation, people enact behavior that conveys meanings consistent with their identity meanings but modified by the discrepancy. If people perceive that how they are coming across in the situation (meaning) is congruent with the meanings in their identity standard, the discrepancy is zero and people continue to do what they have been doing. If there is a disturbance to the meanings in the situation and the discrepancy is not zero, people feel distress and change their behavior to counteract the disturbance and reduce the discrepancy toward zero. By changing their behavior, people change meanings in the situation. These altered meanings are perceived and again compared to the meanings in the identity standard. In this way, each identity is a control system that controls perceptions to match meanings in the identity standard.

### Identity Verification

This process of people controlling their perceptions of identity-relevant meanings to produce congruency with meanings in the identity standard is called *identity verification*. The meanings in the

identity standard represent goals or the way the situation is “supposed to be.” People behave in the situation to create and maintain the situation in the way it is supposed to be. By verifying identities, people create and maintain the social structure in which the identities are embedded. Note that by controlling perceived situational meanings, people are bringing about and maintaining the situation, not behaviors. It is the outcome that is important, not the means that accomplish the outcome.

For example, when thinking about yourself as a student, you may see yourself as studious. To verify your identity as a studious student, you may study 12 hours a week, or read all the readings, or talk to your professors. Any of these behaviors can verify your identity of studious student. Perhaps one week you are unable to read all the readings for your class. This would represent a discrepancy because your self-meanings as a student require you to do all of your homework. To fix this discrepancy, you may go back and finish the reading after your class, or you may start reading earlier in the week next week. You will somehow compensate for this discrepancy to align your self-meanings and situational meanings.

### Bases of Identity

ICT distinguishes between three bases of identities. These are *role identities*, based on roles such as father; *social identities*, based on groups or categories such as American; and *person identities*, based on the unique biological individual, such as being honest. Identities formed on each of these bases operate in the same way, adjusting situations to seek verification. If the identity is a role identity, then appropriate role behavior will bring about the changes in the situational meanings to make them consistent with the identity standard. If the identity is a group- or category-based identity, behavior that maintains group boundaries and divisions in the social structure will verify the identity. If the identity is a person identity, then behavior exemplary of how an individual sees him- or herself will verify the identity.

### Multiple Identities

People have many identities, one for each of the many personal characteristics they claim, roles

they have, and groups or categories to which they belong. Each identity has its own perceptions, standard, and comparator. This complexity of the self with its many identities reflects the complexity of society. In ICT, the multiple identities are arranged into a hierarchy of control systems in which some identities are higher than other identities.

Higher level identities act as general principles that guide the programs of lower level identities. The output of the comparator of higher level identities alters the standards (identity meanings) for lower level identities, while the output of the comparator of lower level identities produces behavior that maintains or alters meanings in the situation. Higher level identities include such master statuses as one's gender, race, or class as well as many person identities that are enacted across situations, roles, and groups. One may, for example, be not just a friend, but a female friend; one may be not just an American, but a Black American; one may be not just a student, but an honest student. In each case, the master status of gender or race or the person identity of being honest acts to change the manner in which friend, American, or student is played out.

### Identity Change

The basic rule is that identities act quickly to counteract disturbances to meanings in the situation by altering behavior to bring perceived meanings back into alignment with meanings in the identity standard. However, sometimes people are in situations in which they cannot change their behavior to fix a discrepancy. In these situations, ICT recognizes that the identity standard itself also slowly changes to match the meanings in the situation and reduce the discrepancy to zero. Often, both processes occur simultaneously to verify identities.

### Emotions

In ICT, the verification of identities is tied to emotional outcomes that help guide the process. When the discrepancy between identity relevant perceptions and the identity standard is small or decreasing, people feel positive emotions. When the discrepancy is large or increasing, people feel negative emotions or distressed. Current work in ICT

examines the role of identity verification in the production of self-worth, self-efficacy, and feelings of authenticity. It is also developing predictions about the specific emotions that may be felt when identities are verified and not verified.

## IDEOLOGY

---

*Ideology* is a term widely used in everyday language, in philosophy and literature, and in the social sciences. It is well represented in research in political psychology, and more recently it has attracted attention in social psychology. Definitions of the concept vary considerably. A common theme in the research literature is that an *ideology* is a set of beliefs, shared by members of a group or collective movement, organized into a doctrine that guides thinking and behavior. In social psychology, the term refers to a systematic and integrated set of beliefs whose primary function is explanation. This explanatory function of ideology links the concept to social psychological theories of how people attribute causes to behavior. An ideology circumscribes thinking and entails commitment; hence an adherent will usually find it difficult to escape its grip. Literature dealing with ideology is mainly in the arena of politics, where discussion of ideology usually includes reference to social or political plans and means of putting these plans into action. This entry looks at characteristics of ideology, reviews its expression in politics, and discusses its importance.

### Features of an Ideology

As commonly employed in social psychology, the concept of ideology is connected to discussion of the process of *attribution*, since both are forms of social knowledge and knowledge construction. This connection is clearest in the case of *societal attributions*, the explanations that people give for large-scale social phenomena. Such attributions are located within and shaped by wider, socially constructed belief systems. For example, explanations for poverty can be subject to attributional bias: Both the rich and the poor tend to explain poverty in terms of the way poor people behave rather than in terms of wider economic forces.

There is some overlap between the terms *ideology* and *value*. Both are used in social psychology to denote a higher order concept that provides a hierarchical structure for organizing attitudes. In Norman Feather's view, a value consists of a set of beliefs about desirable behavior and goals, and these beliefs have an "oughtness" or prescriptive quality to them. A value transcends attitudes, and it influences the form that attitudes take. This is partly echoed by Alice Eagly and Shelly Chaiken when they describe an ideology as a cluster of attitudes and beliefs that are interdependent. They add that an ideology is formed around a dominant societal theme. John Jost and his colleagues also emphasize the fact that an ideology is a belief system that is shared by members of a specific group, class, or community. It is also possible that not only beliefs and attitudes but also values can be subsumed by an ideology.

The important influences on the way a person acquires knowledge of the content of an ideology are the same as those that help shape a person's attitudes and values: parents, peer groups, and major reference groups (such as ethnic and religious groups). Although an ideology provides an overarching structure, not all of its detailed content is required before a person has some ideological understanding and commitment.

Perhaps the most interesting aspect of ideologies is that their very existence invites confrontation. If an ideology defines an organized body of beliefs (and attitudes and values) held by its adherents, the chances are great that there will be other available ideologies that are different from and even opposed to it. If an ideology represents a

guiding doctrine for one group, then a different group with a different ideology can be a sufficient condition for intergroup conflict. Indeed, we are very familiar with the political and religious ideologies that serve as rallying points for many of the world's most intransigent factional and international clashes.

### Ideologies and Politics

An early political ideology was Machiavellianism, named after Niccolò Machiavelli, a 16th-century Florentine diplomat considered by some to have been the first social scientist. Machiavellianism is the notion that craft and deceit are justified in pursuing and maintaining power in the political world. The term itself was first used by Destutt de Tracy at the time of the French Revolution and meant "the science of ideas."

The conceptualization of ideology was developed further by the political philosophers Karl Marx and Friedrich Engels, and acquired the connotation of a social structure that enabled a group with power to retain control with the least amount of resistance. According to Marx, an ideology suggests a world system that is in accord with the nature of things. It should be seen as an example of progress, unfolding from history and having the prospect of eternity. The Marxian view is that for an anticapitalist revolution to be successful, people need to understand that the ruling class has an ideology based on domination over subordinate classes. Thus the key to the success of the ruling class prior to the Russian Revolution was that its members had found ways to legitimize the social order.

How is an ideology constructed? This question has been addressed differently by political scientists and by social psychologists. According to John Jost and his colleagues, political scientists argue for top-down processing, in which political attitudes are acquired through exposure to ideological clusters that are established by political elites. Social psychologists point to bottom-up processing, in which people's psychological needs and motives make them receptive to particular ideological positions. In both approaches, an ideology requires that people are taught how to think and how to act and to accept where they fit into society; in other words, the populace is reprogrammed. Historical

examples of mass political education abound. In the 20th century, anti-Semitism was carefully articulated during the rise of Nazism, and Mao Zedong orchestrated a “reeducation” of the populace to provide the basis of his cultural revolution.

From the perspectives of social, personality, and political psychology, there have been three areas of intensive research. The earliest of these was research on authoritarianism. Two modern conceptual developments are social dominance theory and systems justification theory.

### *The Authoritarian Personality*

In their work *The Authoritarian Personality* published in 1950, Theodor Adorno, Else Frenkel-Brunswik, and their colleagues described what they believed to be a personality syndrome that predisposed certain people to be authoritarian. The historical context for this theory was the role of fascist ideology in the Holocaust—Adorno and Frenkel-Brunswik were both Jewish and had fled Hitler’s regime (in Germany and Austria, respectively). The theory proposed that autocratic and punitive child-rearing practices were responsible for the emergence in adulthood of various clusters of beliefs. These included: ethnocentrism; an intolerance of Jews, Blacks, and other ethnic and religious minorities; a pessimistic and cynical view of human nature; conservative political and economic attitudes; and a suspicion of democracy.

With the publication of *The Authoritarian Personality*, Adorno reported that his group had constructed an instrument known as the California F-scale, intended at first to assess tendencies toward fascism, it was eventually purported as a measure of general authoritarianism. Despite substantial methodological and conceptual flaws, this work stimulated huge research interest in the 1960s and beyond. In later years, Robert Altemeyer developed a more restricted but better designed and more useful measure of right wing authoritarianism.

### *Social Dominance Theory*

According to this theory, developed by Jim Sidanius and Felicia Pratto, societies are generally structured as group-based hierarchies, in which dominant groups have higher social status, and more political authority, power, and wealth. Justification for the social structure incorporates

myths and attitudes, fosters particular values, and is elaborated in an ideology that enhances hierarchical social relations and maintains prejudice. A dominant group, such as the rich, is disproportionately advantaged (e.g., by the status or power of its members), whereas subordinate groups, such as the poor, are disproportionately disadvantaged (e.g., by lack of access to health care). A society’s institutions can enhance the existing hierarchy. For example, the criminal justice system may be biased toward harsher penalties for members of socially disadvantaged minority groups.

Social dominance theory also accounts for variation between individuals in the extent to which they accept societal ideologies that legitimize hierarchy and discrimination, on one hand, versus equality and fairness on the other. The underlying motivation is a view of intergroup relations that is exploitative and power based. People who want their own group to be dominant and superior to relevant outgroups have a high *social dominance orientation* (SDO). This encourages them to reject egalitarian ideologies. People with a high SDO are more inclined to be prejudiced than people with a low SDO. The SDO construct is correlated with measures such as ethnocentrism, nationalism, authoritarianism, racism, and sexism; with behaviors such as racial discrimination and the stereotyping of minorities; and with social policies such as death penalty views, welfare reform views, and support for military conquest.

The theory as originally framed was about the desire for the ingroup to be in command—to rule and govern outgroups. Recently, however, social dominance theory has been extended to account for a more general desire of group members for unequal relations between groups, irrespective of whether members’ own group is at the top or the bottom of the status hierarchy. In other words, both dominant and subordinate groups are parties to subordination. The ideologies adopted justify on moral and intellectual grounds the customs and conventions that determine what is valued in a society. This extension makes social dominance theory look more like system justification theory.

### *System Justification Theory*

According to John Jost and his colleagues, most political ideologies are located on a left–right

dimension, with the two poles also often called *liberal*, which calls for social change and rejects social inequality, and *conservative*, which resists social change and endorses social inequality. The basis of a particular political ideology rests on the differences in thinking and motivation that go with being either a liberal or a conservative. Liberals prefer progress, rebelliousness, chaos, flexibility, feminism, and equality; conservatives prefer conformity, order, stability, traditional values, and hierarchy.

Consequently, system justification is more common among conservatives than among liberals. Conservatives justify and protect the existing social system—the status quo—even if this means upholding an unfavorable position for their own group. There is an irony here. Why protect such an ideology when it maintains their position of disadvantage? Jost has suggested that one motivation for this may be to reduce uncertainty—better to live in reduced circumstances and be certain of one's place than to challenge the status quo and face an uncertain future.

### Are Ideologies Important?

Ideologies certainly are crucially important—they frame polarized worldviews and can be the source of intergroup behaviors that are highly conflictual. For example, the cold war spanned almost half a century—a period in which the world was balanced precariously, caught between two diametrically opposed ideologies. Their adherents possessed an arsenal of nuclear weapons capable of destroying life on this planet. One espoused Marxism–Leninism and the other described itself as “the free world.”

More recently an old ideological difference between Eastern Islam and primarily Western Christianity has joined the mix to split the globe in different ways. The “Threat to the West” now extends to China and various “terrorist” nations in the Middle East, whose lethal power is measured in a nuclear currency. As Philip Tetlock has noted, the older bipolar world has evolved quickly into one that is multipolar. It is unlikely that these various nations can be nicely aligned as units on a left–right political continuum. It is more likely that hawks (conservatives) and doves (liberals) will be found in each. The future of humankind is in the

hands of policymakers whose judgments are affected by their ideological commitments.

## IDIOSYNCRASY CREDIT

---

The term *idiosyncrasy credit* was first coined by Edwin Hollander in a 1958 *Psychological Review* article in which he addressed the issue of how individuals gain support for their innovative ideas from other group members. The idea was particularly influential in the field of leadership research where, in light of evidence that those who deviate from group norms are often rejected, a critical theoretical and practical question centers on how leaders encourage followers to support and embrace new practices. Hollander's answer to this question revolves around the idea that to initiate change, individual group members (leaders) need to build up psychological credit with other group members (followers), so that the latter will be open to their idiosyncratic ideas. In this way, idiosyncrasy credit gives individuals latitude to deviate

but also ensures that when they do, their suggestions are taken seriously.

This entry considers the theoretical origins of Hollander's ideas and outlines some of the research that has supported his arguments. It also reviews some criticisms of Hollander's work—notably those that question the theoretical integrity of his analysis and its view that influence flows only from conformity and interpersonal exchange.

### Theoretical Origins

Hollander's ideas originated in theories of leadership and influence that were developed in the aftermath of World War II. Previously, much of this theoretical work had revolved around an appreciation of the “great person”—arguing that those individuals who were able to orchestrate and bring about change were distinguished from others by virtue of their superior character. Within this tradition, research was defined by an almost exclusive focus on leaders themselves.

A key contribution that Hollander made to leadership theory was to challenge the prevailing focus on leaders and throw the analytic spotlight onto followers. If leadership is defined as the process of influencing group members in a way that contributes to the achievement of group goals, then, he argued, the followership of those members should be every bit as important as the actions of leaders. From this perspective, the basis of leadership is seen to lie not in the qualities of the individual leader per se, but rather in the quality of relations between leaders and other group members.

In this way, Hollander advocated a transactional approach to leadership. This approach incorporates principles of interpersonal social exchange, suggesting that effective leadership flows from a maximization of the mutual benefits that leaders and followers afford each other. So, on the one hand, the leader acts in the interests of the group and its members but, on the other hand, the group validates and empowers the leader.

A central notion here is trust, since Hollander argued that before followers are prepared to go out on a limb for their leader, they need first to be confident that the leader is going to act in the group's best interests and take it on an appropriate path. Leaders, Hollander stressed, cannot simply barge into a group and expect its members to

embrace them and their new plans immediately. Instead, they must first build up a support base and win the confidence of followers. That is, leaders need to build up credit—to be understood, respected, and trusted—before they can influence followers to move in a new direction. There are two ways in which leaders typically do this: by displaying competence and by conforming to group norms.

In effect, then, *idiosyncrasy credit* constitutes a line of psychological credit that is built up early in a leader's tenure and then cashed in later in return for influence and license to deviate from established norms. Moreover, like other forms of credit, not only are leaders able to use idiosyncrasy credit for this purpose, but they are also expected to do so. Along these lines, Hollander argued that a leader who has gained credit in the eyes of followers needs to use it to take the group in new directions or else that credit will be diminished. Not only do leaders have to accumulate idiosyncrasy credit, they also need to “use it or lose it.”

### Related Research

Over the last 40 years, a range of studies have examined and tested these ideas. Those reported by Hollander and James Julian in 1970 are probably the best known. These studies showed that leaders who had been elected to their position, and hence had the explicit backing of group members (idiosyncrasy credit), were more likely to challenge poor group decisions than leaders who had been appointed to their position, and hence had no direct mandate from the group. On the basis of such findings, the authors argued that without the backing of followers, leaders lack the security to display genuine leadership when managing the group's interests and that the group as a whole will suffer.

However, even in these studies, it can be seen that the phenomenon of idiosyncrasy credit is not examined directly and is confounded with other potentially important factors (e.g., status, authority, involvement). In line with this observation, it is apparent that empirical research has invoked the notion of idiosyncrasy credit to account for a particular pattern of results more often than it has tested Hollander's ideas directly. Indeed, while Hollander's original article has been cited more

than 250 times (making it a “citation classic”), Web of Science lists only three papers with the term in their title (of which the original article is one).

In this respect, one particular difficulty with Hollander’s ideas pertains to the lack of theoretical specificity regarding the precise source and nature of idiosyncrasy credit. For example, Hollander noted that in organizational settings, men typically have more credit than women, as do those with seniority and status and those who are participative rather than autocratic. He also observed that individuals can have “derivative credit” as a result of their membership in other groups. At the same time, he cautioned that credit is always negotiated and proven in the immediate group context and so is fluid and context specific. These things may all be descriptively true, but what is the explanatory logic that binds them together?

Recently, one answer to this question has been proposed by advocates of a social identity approach to leadership. These researchers have argued that leaders’ capacity to engender followership derives from their capacity to present themselves, and be seen, as prototypical representatives of a salient group membership that is shared with followers. In these terms, idiosyncrasy credit is grounded in group members’ categorization of the leader as “one of us”—a category-based perception that can change as a result of normative and comparative factors that determine the meaning of that ingroup.

The social identity analysis is consistent with many of the observations that Hollander made about the dynamics of idiosyncrasy credit. Critically, however, it argues that the underlying process is not one of interpersonal exchange; rather, it centers on a higher order sense of group identity that leaders and followers share. Among other things, this helps explain how leaders are able to gain support for novel projects outside the small-group contexts in which idiosyncrasy credit is typically studied and where interpersonal exchange is not possible. The capacity for a leader to acquire credit by championing novel social identities (e.g., Nelson Mandela’s vision of postapartheid South Africa) also explains the capacity for individuals who represent minorities and radical groups to bring about change, even under conditions where they have no established credit with the majority. This is a problem that Serge Moscovici

identified with Hollander’s original formulation of the concept, which he faulted for placing too much emphasis on conformity and thereby being too conservative.

These objections notwithstanding, it is apparent that the notion of idiosyncrasy credit has proved to be of enduring value for the study of leadership and influence. Even if it does not fully explain the underlying process, it speaks to two apparent paradoxes at the heart of effective social influence: that deviation tends to be driven by those who are not seen as deviant, and that the capacity to influence others tends to be enhanced by their perception that they have influenced the person leading them.

## ILLUSION OF GROUP EFFECTIVITY

---

The *illusion of group effectivity* is the persistent and widespread belief, despite some evidence to the contrary, that group performance is superior to individual performance. The popular media

and quasi-scientific press often express strong and optimistic beliefs regarding the effectiveness of group-based work, and these beliefs seem widely shared within society. Sometimes, however, the scientific literature clearly shows that groups do not perform well at all and that certain tasks might be better left to individuals. The illusion of the superiority of the group over the individual may persist even when the individual has had extensive experience with a particular task, and therefore, it is not just due to cultural beliefs that are easily falsified through experience.

The illusion of group effectivity has been studied widely within the context of group brainstorming. However, it seems to be a more general phenomenon. It has been argued that group members routinely experience both social-emotional and competence-related benefits from working in groups, and that these benefits lead people to believe that group-based work is particularly effective. This entry discusses research on this illusion in brainstorming groups, examines evidence that the illusion of group effectivity is a more general phenomenon, and considers some implications of this illusion.

### Brainstorming

One of the most robust findings in group research is that people generate fewer ideas and fewer good ideas when they brainstorm in a group than when brainstorming alone. Furthermore, the bigger the group, the less effective each member becomes. For most people, this finding comes as a surprise because they believe that group interaction stimulates idea generation. Research has indeed shown that across different cultures (e.g., in the United States, Europe, and Japan), people strongly believe that brainstorming is best performed in groups. Furthermore, even after people have participated in a brainstorming session, those who worked in groups indicate more satisfaction with their performance than those who brainstormed alone, despite the fact that objective performance measures show that those who brainstormed alone had more reason for satisfaction.

Three different explanations have been suggested for the illusion of group effectivity in brainstorming, and all have received some support. The first suggests that the effect is due to memory

confusion. After a group brainstorming session, group members might no longer recall exactly who has generated which idea and may take credit for a disproportionate share of the group's performance. Consequently, group members think that they have done quite well and come to believe that group interaction stimulates their idea generation. In support for this explanation, it has been shown that group members often are uncertain about the source of specific ideas. Furthermore, group members claim that many of the ideas suggested by others had also occurred to them, whereas people who have brainstormed individually make this claim less often.

The second explanation suggests that the effect is due to social comparison processes. During a group brainstorming session, group members will compare their performance with that of other members. They will, on average, find that they have performed similarly and consequently are quite satisfied with their performance. Individuals generating ideas on their own, however, cannot compare their performance with that of others and therefore might feel insecure and worry that they have not done well. In support for this explanation, it has been shown that providing information about how someone else performed on the brainstorming task has a positive influence on the satisfaction of those who brainstormed alone. For example, just saying how many ideas another person generated reduces the individual brainstormers' uncertainty and leads to higher levels of satisfaction after a brainstorming session.

The final explanation suggests that during a brainstorming session, it will often happen that someone tries to generate more ideas but can temporarily think of nothing new. When brainstorming as an individual, these failures to come up with new ideas are highly salient and may lead people to conclude that they are not performing well. In groups, in contrast, people can listen to others when these failures occur, and failures are consequently not so salient. Because people experience fewer such failures in a group setting, they come to believe that group interaction actually stimulates idea generation (i.e., it appears to be easier to come up with ideas in a group). Consistent with this explanation, group members report fewer failures to generate ideas than do individuals. However, manipulations that increase the number of failures (such as greater

topic difficulty) decrease satisfaction with the group brainstorming session.

### The Romance of Teams

While the evidence for the illusion of group effectivity is strongest in brainstorming research, it has been suggested that the phenomenon is much broader. Specifically, many organizations enthusiastically embrace the idea that teamwork is highly effective, and more and more organizations structure their work around teams. Popular sayings, such as  $1 + 1 = 3$ , two heads are better than one, and together everyone achieves more (TEAM), reflect such beliefs about the benefits of group-based work. However, this contrasts with empirical data from laboratory as well as field research showing quite mixed support for the effectiveness of group-based work.

For example, laboratory results indicate that groups often fail to reap the potential benefits of collaboration when it comes to decision making and problem solving. And field research has shown that the implementation of team-based work leads to modest productivity improvements at best. How might this “romance of teams” (i.e., faith in the effectiveness of team-based work that is not supported by, or even inconsistent with, relevant empirical evidence) be explained?

One explanation is that team-based work is fashionable and that teams are just a passing fad. However, Natalie Allen and Tracy Hecht have proposed that teams provide social–emotional as well as competence-related benefits to their members. These, in turn, make teamwork enjoyable and create the illusion that teamwork is effective. For example, being a member of a team satisfies certain social needs, such as the need for affiliation and belongingness. Teamwork might thus enhance satisfaction and well-being rather than performance. Increased satisfaction, however, might be taken as evidence that group work is effective, while more objective performance indicators do not support this.

Besides these social–emotional benefits, there also are competence-related benefits of working in groups. For example, team members take personal credit for the success of the team, whereas they blame failures on other team members. Further, groups often have a tendency to see their

own group as superior to other groups: Well over 50% of groups agree with the statement “My group is better than most other groups.” In addition, working in a group decreases uncertainty about individual performance. In decision making and problem solving, for example, group members learn about other members’ preferences and problem solutions. When these are similar to their own, group members often take this similarity as evidence about reality; that is, when most members agree about a decision or solution, it is likely to be correct. As a consequence, groups often are quite confident about their decisions and problem solutions, even when objectively they have not performed well at all and have failed to identify the best alternative or solution.

### Implications

Does this imply that groups or teams should not be used at all because performance benefits are merely an illusion? Clearly, this is not the case. For some tasks, it simply is necessary to work together (e.g., shooting a movie can usually not be done alone). Furthermore, working in teams does seem to have certain benefits to team members, such as increased levels of satisfaction. However, simply using teamwork or performing certain tasks in groups does not guarantee high levels of performance. Consequently, it cannot be safely assumed that when people feel good or are satisfied it means that the team is actually performing well—performance has to be shown explicitly.

Further, true performance benefits might only emerge after team members receive appropriate training and have experience in working together, and when they work under conditions that foster high levels of performance (e.g., with good leadership and appropriate feedback and reward structures). It is important to keep all this in mind when one is involved in group-based work arrangements.

---

## ILLUSORY CORRELATION

---

*Illusory correlation* refers to the tendency for someone to overestimate the frequency with which two events co-occur. The correlation is illusory because it is the product of biased information processing on the part of the perceiver rather than an accurate perception of the stimulus environment. An illusory correlation can result from aspects of the events or from biases of the perceiver. When the perceiver overestimates the frequency with which two infrequent and distinctive events co-occur, it is called a *distinctiveness-based illusory correlation*. Conversely, when a perceiver expects certain events to occur frequently, and consequently misremembers the number of times they co-occur, it is described as an *expectancy-based illusory correlation*. With respect to social perception, both types of illusory correlation shed light on the cognitive mechanisms that underlie stereotyping and prejudice. The research demonstrating how illusory correlation can lead to stereotyping pioneered the social cognition approach to the psychology of intergroup relations.

### Distinctiveness-Based Illusory Correlation

Events that occur rarely are more likely to grab an individual's attention than events that happen all

the time. For instance, pervasive social norms for polite and pleasant social interactions make unpleasant, negative social interactions infrequent. A good example of a distinctiveness-based illusory correlation involves the period before desegregation in the United States, when a person rarely interacted with someone of another race. If a White individual experienced or witnessed a negative social interaction with a Black person (two infrequent and distinctive co-occurring events), he or she might have overestimated the frequency with which these events co-occur. In this case, the illusory correlation between Blacks and unpleasantness would become a mental association, or stereotypic belief, about Blacks as a negative group. This type of illusory correlation explains one processing mechanism by which stereotypes about social groups are formed.

The original research to demonstrate the distinctiveness-based illusory correlation simulated group perception in a laboratory setting. The researchers used fictitious groups, A and B, to avoid any influence of participants' preexisting beliefs. Participants read sentences that described desirable and undesirable behaviors of members of Groups A and B. In reading the list, the participants witnessed two infrequently occurring events: There were more sentences about Group A than Group B and more sentences with desirable than undesirable behaviors overall. Importantly, the researchers made sure that Group A and Group B had the same ratio of desirable to undesirable behaviors. If participants relied on proportionality to make judgments in an unbiased manner, they would have rated Groups A and B with equal favor. However, participants overestimated the frequency with which members of Group B engaged in undesirable behaviors. Furthermore, Group B was rated more negatively than Group A on several personality dimensions. This study presented evidence for a cognitive processing mechanism that can result in biased evaluation of groups.

However, it is possible that the results were due to the fact that familiarity breeds liking (called the *mere exposure effect*); that is, increased exposure to Group A could have led participants to think more positively of Group A than Group B. Another study was conducted to rule out this alternative explanation. Participants in this study read a list in which sentences about members of Group B and

sentences about desirable behaviors were infrequent. As a result of this change, the two competing explanations for the previous results—distinctiveness and mere exposure—should have led to different outcomes. The distinctiveness explanation predicts that participants would overestimate the desirable behaviors by members of Group B, leading to more positive feelings about Group B in general. However, if mere exposure were responsible for the differential perception of the groups in the first study, then participants would end up liking the more frequently occurring group (Group A). Indeed, despite the fact that the ratio of desirable to undesirable behaviors was the same for both groups, participants overestimated the frequency with which Group B had performed desirable behaviors. Participants also rated the personality traits of Group B more positively. This study demonstrated that illusory correlation could be formed with distinctive positive events, resulting in positive stereotypes, in addition to excluding mere exposure as the mechanism by which illusory correlation results had occurred.

Further research was conducted to support the *distinctiveness* explanation for illusory correlation. This explanation argues that the co-occurrence of two distinctive events attracts the perceiver's attention, which leads to deeper processing and greater accessibility from memory. As a result of being able to easily remember these instances, perceivers are likely to overestimate how often they actually occur. That is, perceivers will misattribute the ease of retrieval of the co-occurrence to the frequency with which those behaviors occurred. Thus the distinctiveness explanation proposes that differential perceptions of groups result from biased encoding of social information rather than prejudiced memory of it.

Critics of the distinctiveness explanation have argued that perceivers may be accurately encoding the behavioral information, but that the differential group perceptions result from biased memory of that information. To show that the bias occurs at encoding, researchers used the illusory correlation paradigm with one important addition: After reading the list of behaviors (in which Group B and undesirable behaviors were infrequent), some of the participants were shown a frequency table in which the ratio of desirable to undesirable behaviors was equal across groups. If the differential perception of

groups resulted from biased memory of the information, then participants who had seen the frequency table would be able to correct for the memory bias and, consequently, would perceive the two groups as roughly equivalent. However, participants who saw the frequency table persisted in liking Group B significantly less than they liked Group A. This biased judgment of Group B could not have resulted from biased memory of their behaviors, since participants knew from the frequency tables that the groups had behaved equivalently. The fact that participants did not use the frequency information to override their biased judgments of the groups provides evidence that the differential perception of groups was based on biased encoding of the distinctive information. Another study provided further support for the distinctiveness mechanism by showing that the distinctive stimulus events are more easily accessed from memory.

Nevertheless, alternative explanations have been proposed to explain the illusory correlation effect. Some researchers have demonstrated that biases in retrieval from memory can produce the illusory correlation effect. Others have argued that the unequal amount of information alone is the reason that the most infrequent behaviors are overestimated. Because participants will naturally forget some of the behavioral information that they have learned about the groups, they will tend to overestimate the frequency with which the rarest events occurred. By this account, the asymmetry of the stimuli presented, rather than the distinctiveness of certain information, may be responsible for the formation of an illusory correlation. The debate about the process underlying illusory correlation remains unresolved, and it is possible that multiple cognitive processes lead to the formation of illusory correlations. Furthermore, a number of factors can influence whether or not an illusory correlation is formed. Aspects of the perceiver—such as mood, attitudes, and group membership—as well as the nature of the social information affect the formation of an illusory correlation.

### Expectancy-Based Illusory Correlation

Whereas the distinctiveness-based illusory correlation speaks to the formation of stereotypes, the expectancy-based illusory correlation details a

mechanism by which stereotypic judgments are maintained and strengthened. Once stereotypes have been formed, they are resistant to change and influence the individual's processing of new information about the group. In one study, researchers used groups about which people already have stereotypes (e.g., accountants). Participants read a list of sentences that used equal numbers of stereotype-consistent and stereotype-unrelated traits to describe the group members. When they were asked to estimate the number of stereotypic and neutral traits that had been used, participants reliably overestimated the frequency with which the stereotype-consistent traits had been used, compared to the neutral ones. Another study presented participants with equal numbers of stereotype-inconsistent and stereotype-unrelated traits. In this case, participants reliably underestimated the frequency with which the stereotype-inconsistent traits had appeared. These findings speak to the robustness of stereotypes; once they are formed, stereotypes can bias information processing so that the individual continually confirms them.

The studies on distinctiveness-based and expectancy-based illusory correlations demonstrate the ways in which cognitive information-processing mechanisms can produce biased perceptions and evaluations of groups. Illusory correlation research has demonstrated that there is a cognitively based propensity for erroneous judgments in the intergroup context. The findings demonstrate that the cognitive component of prejudice is easy to develop and difficult to overcome.

## IMMIGRATION

---

*Immigration* involves the voluntary and nonvoluntary long-term relocation of people across national boundaries. It may be instigated by a variety of factors, including those that push individuals to leave their country of residence and those that pull individuals toward a new home nation. Immigration levels have reached historically unprecedented levels in recent years, often involving movement from less economically developed countries to more highly developed countries. Immigration has a major impact not only on those who relocate but potentially on both the source and target nations.

When individuals leave developing countries to find new opportunities in more economically developed regions of the world, their countries of origin may lose highly skilled personnel. This is known as the “brain drain,” and it may have a major impact on the economy of these countries. Immigrant-receiving nations differ markedly in their approach to immigrants and in their immigration policies. Nations like Canada see immigrants, particularly those who are highly skilled, as a valuable commodity and accept a large number of immigrants into the country each year on the basis of their potential economic contributions. Others, such as the United States, place more emphasis in their immigrant policies on family reunification. While still others, such as Germany, have historically denied that their country is an immigrant-receiving nation and have defined nationality on the basis of ethnic heritage (formal policies for accepting immigrants have only recently been put into place in Germany).

This entry first discusses the motivations that may lead individuals to migrate, and the forms that acculturation in their new home country may take. It then describes factors that influence the attitudes of members of host societies toward immigrants and immigration. These factors include economic and cultural considerations, perceptions of threat to physical health and safety, and the framing of national identity. Next, the entry focuses on the consequences of discrimination against immigrants, particularly its effects on the contributions that immigrants can make to their new country. It concludes with a discussion of the increasing recognition by developed nations of their need for immigrants, and the resulting shift in the discourse of immigration.

### The Push and Pull Factors of Immigration

One may choose to leave one's country of residence and resettle in a new country for a variety of reasons, some of which may be considered *push factors*—those that drive individuals from their country of origin, and others may be considered *pull factors*—those that attract individuals to a new country. Major push factors include sources of trauma or disaster that migrants wish to leave behind them as they search for a better life, such as life-threatening poverty, natural disaster, environmental degradation, persecution, and war. Individuals who leave their country of origin because of a well-founded fear of persecution on the basis of race, religion, nationality, membership in a particular social group, or political opinion are defined as convention refugees under the United Nations Convention Relating to the Status of Refugees. Less severe push factors primarily include poor economic conditions in one's country of origin, and lack of educational and employment opportunities. In contrast, pull factors are those that attract migrants to a new home country. These may include educational and employment opportunities, a high standard of living, the presence of family members, a safe environment, and political and cultural freedoms.

Not all individuals respond to these push and pull factors in the same way, suggesting that there may be a "migrant personality." For example, it has been demonstrated that individuals who are motivated by opportunities for achievement and

power, and particularly those who consider work central to their lives, are especially likely to desire to emigrate for economic reasons. In contrast, those who are motivated by affiliation, and particularly those who consider family relations central to their lives, are especially likely to desire to stay in their country of origin.

### Acculturation: Immigrants and Members of the Host Society

When immigrants arrive in a new country, they are often faced with two important cultural issues: (1) whether to maintain their cultural heritage and potentially pass it on to the next generation and (2) whether to take on their new country's culture. Models of acculturation were initially developed to examine how immigrants resolve these two issues. Immigrants who wish to maintain their cultural heritage and do not wish to take on aspects of the new culture have been described as endorsing *separation*. In contrast, those who do not wish to maintain their cultural heritage but do wish to take on the new culture have been described as endorsing *assimilation*. Immigrants who strive to have the best of both worlds—those who wish to maintain their cultural heritage *and* take on the new culture—have been described as endorsing *integration*. Finally, those who wish to neither maintain their cultural heritage nor take on the new culture have been described as choosing *marginalization* (separation from both cultures) or, alternatively, as proponents of *individualism* (preferring to focus on the personal characteristics of individuals rather than on cultures).

Recent models of acculturation acknowledge that immigrants are often subject to the conditions of their host society, with both the immigration and integration policies of host nations likely to influence immigrant acculturation. Thus, the acculturation strategies preferred by immigrants are most likely to be successfully practiced when they are compatible with the preferences of the host society. When members of the host society prefer that immigrants give up their cultural heritage and fully take on the new culture, this is described as the *melting pot*. In contrast, when members of the host society prefer that immigrants maintain their cultural heritage and do not take on the new culture, this may result in *segregation*. When the host

society values cultural diversity and immigrants are encouraged to both maintain aspects of their cultural heritage and take on aspects of the host culture, this represents *multiculturalism*. Finally, attempts to prevent immigrants from maintaining their cultural heritage or taking on the new culture can be defined as a form of *exclusion* or as a preference for *individualism*. Of note, not all immigrant groups within a country are treated similarly, with a host society's preference for acculturation depending on whether a particular group is valued or devalued in that society. For example, research has shown that Anglo-Canadians seem to be more supportive of welcoming acculturation orientations (e.g., integration) for British immigrants than for Arab Muslim immigrants.

### Factors Influencing Attitudes Toward Immigrants and Immigration in the Host Society

Attitudes toward immigrants and immigration among members of a host society are important because they may influence support for immigration policies within a nation, the treatment and acceptance of immigrants, the success of immigration policies, the life outcomes for immigrants, and, ultimately, the degree of harmony or discord within a nation. Two important theories that have addressed attitudes toward immigrants and immigration are the *unified instrumental model of group conflict* and the *integrated threat theory of prejudice*. Both have aimed to explain the variety of factors that may influence immigration attitudes, including those discussed below.

#### *Perceived Economic Costs and Contributions*

Over the past few decades, there have been repeated debates as to whether immigrants contribute economically to their new society or are a drain on resources and compete for jobs with those who are native born. Of course, a general answer to this question is difficult to provide because the effects of immigration on a local economy are likely to depend on the immigration policy of the host nation, the concomitant type of immigrants who predominate, and the local economic situation. For example, as described earlier, many immigrants to Canada are accepted under

the economic class of immigration, and are thus specifically selected to be highly skilled and to fill needs in the labor market. Under these conditions, one would expect that immigrants would be more likely to contribute economically to their new society (though underemployment of new immigrants may reduce this likelihood). In contrast, employment-based immigrants do not constitute the majority of immigrants to the United States, so that concerns about the economic contributions of these immigrants may be greater. Thus, when economic times are challenging and unemployment rates are higher, members of host societies are more likely to support restrictive immigration policies.

Irrespective of the *actual* economic contributions of immigrants, an important factor in determining attitudes toward immigrants and immigration among members of the host society is the *perceived* economic contributions and costs of immigration. Immigrants who do not do well economically are likely to be seen as a drain on social services (e.g., welfare), leading to negative attitudes toward immigrants and immigration. In addition, research has shown that immigrants who do well economically may also be seen as a threat to the economic conditions of the host society because their successes may at times be seen as coming at the expense of those who are not immigrants. These “zero-sum beliefs”—beliefs that the more immigrants obtain, the less is available for others—have been shown to lead to negative attitudes toward immigrants and immigration. This means that immigrants may face a dilemma: Whether they fail or succeed economically, they may be perceived negatively by some members of the host society. Fundamentally, it is the belief that immigrants are taking resources from members of the receiving society that drives these negative attitudes. Such a belief may be more or less likely to be part of the dominant discourse within a country, may be more or less likely to be promoted by the media, and may depend on individual difference variables, such as *social dominance orientation*. Research has shown that individuals who score higher in social dominance orientation (i.e., support inequality in society and believe in group hierarchies) are especially likely to see the world in general, and to see relations with immigrants in particular, as zero-sum in nature. As a result, they are especially

likely to hold negative attitudes toward immigrants and immigration.

#### *Perceived Threats to Physical Safety and Health*

Two other types of threats associated with immigrants are (1) threats to physical safety and (2) threats to the health of members of the receiving society. While the former has become particularly salient in the last few years, the latter has a long history of influencing attitudes toward immigration policies and immigrants. Concerns about threats to safety posed by immigrants have become more prevalent since September 11, 2001, due to the salient association of immigrants and terrorists caused by media depictions of the terrorist attacks at that time. Thus, it is now the case that immigrants, particularly those from Middle Eastern countries, are more likely to be viewed with suspicion and even hostility. Concerns that immigrants may bring in diseases that will spread to members of the host society have influenced immigration policies over the last century, despite the fact that immigrants are no longer a major vector of disease (particularly compared to tourism and military travel). Nonetheless, groups that wish to promote negative attitudes toward immigrants, as seen on anti-immigrant Web sites, continue to take advantage of host members' fear of disease by highlighting cases of unhealthy immigrants and those who are stricken with communicable diseases. This results in the dehumanization of immigrants and the promotion of negative attitudes toward immigrants and immigration.

#### *Perceived Cultural and Value-Related Costs and Contributions*

In addition to being seen as a potential threat to tangible resources, immigrants are at times seen as threatening to the culture and values of the host society. Thus when immigrants maintain and celebrate their cultural heritage, some members of host societies may find this threatening. Just as some people under some conditions may see tangible resources as zero-sum in nature, some individuals may also see their nation's culture and values as zero-sum. As a result, they may believe that if immigrants are allowed to maintain their

practices and values, it will weaken the culture and values of the host society. Research has demonstrated that these zero-sum beliefs about culture and values lead to negative attitudes toward immigrants and immigration, particularly toward those who are ethnic and religious minorities and, therefore, more obviously different from the host majority. Just as with tangible resources, the belief that immigrants threaten the dominant culture and values may be more or less likely to be part of the dominant discourse within a country, and may be more or less likely to be promoted by the media. In recent years, the claim that immigrants are a potential threat to the dominant culture and values of host countries has become particularly prevalent within European discourse, resulting in increased support for restrictive immigration policies.

#### *The Framing of National Identity*

How national identity is defined within a particular country and by specific individuals within that country plays an important role in determining whether immigrants are seen as beneficial or detrimental. Two important forms of national identity are nativist/ethnonational and civic/cultural national identity. *Nativist identity* involves the belief that national identity is based on having been born in a country, or at least having lived there for a long time, and on being a member of the dominant religion. This is closely tied to *ethnonational identity*, in which national identity is defined on the basis of bonds of kinship and a common ethnic heritage. In contrast, *civic/cultural national identity* is based on the belief that national identity is based on a voluntary commitment to the laws and institutions of the country, and on the feeling of being a member of the national group. By definition, then, nativist/ethnonational national identity is much more narrow in its construal of who is, and who is not, a member of the national ingroup than is civic/cultural national identity. As a result, countries with a history of promoting a nativist/ethnonational national identity (e.g., Germany) are more likely to have restrictive immigration policies and to reject immigrants as members of the national ingroup. In contrast, countries that have a history of promoting a civic/cultural national identity (e.g., Canada) are more likely to

have relatively open immigration policies and to accept immigrants as members of the national ingroup soon after their arrival.

Definitions of national identity may also change over time. For example, it has been demonstrated that in times of national crisis and threat, the psychological boundaries defining the national ingroup tend to narrow and nativist sentiments tend to increase, resulting in more negative attitudes toward immigrants and immigration. In addition, large-scale immigration, particularly from new and unfamiliar source countries, can increase concerns about national identity and nativist beliefs, so that negative attitudes toward immigrants and immigration become evident. Thus, narrow definitions of national identity and unfavorable views of immigrants and immigration may be mutually reinforcing.

### Discrimination Toward Immigrants

Negative attitudes toward immigrants and immigration are likely to lead to acts of discrimination. Immigrants to new countries have historically experienced a variety of forms of discrimination, including relatively blatant acts of violence and exclusion. Today, the discrimination that immigrants face is often more subtle, but it continues to limit their life choices. This discrimination may affect all phases of the immigration and integration process, from the restrictiveness of immigration policies to limitations on citizenship to more subtle discrimination in everyday encounters. Subtle discrimination may manifest in crucial aspects of immigrants' settlement and integration, including their ability to secure housing, to have their skills and credentials recognized, and to gain access to educational opportunities and social services. As with other forms of subtle bias, this discrimination is most likely to be evident when justifications other than prejudice are readily available. Thus, for example, research has shown that employers may discount the skills of an immigrant applicant due to prejudice, while using the uncertainty of foreign qualifications as a seemingly legitimate justification for this behavior. Whether blatant or subtle, however, discrimination may have a severe impact on immigrants and limit the contributions that they can make to their new country.

### Reciprocal Relations Between Immigrants and Members of the Host Society

The process of immigration has potentially large-scale influences on both immigrants and members of receiving societies. In the process of acculturation, it is likely that immigrants and host members will be affected, with more or less influence on each, depending on the acculturation preferences that predominate. By limiting the life choices of immigrants, discrimination not only affects immigrants and their families, but also affects host societies by influencing the type of society in which both immigrants and host members live and placing limits on the contributions that immigrants can make. Developed nations increasingly have a need for immigrants, particularly highly skilled immigrants, to fill their labor market needs and contribute to their diminishing populations. Thus, the discourse of immigration within these countries is rapidly changing from a discussion of "tolerance" to a discussion of "attraction and retention." That is, immigrants are becoming a commodity for which developed countries must compete. As a result, questions of immigration must now focus on how to best optimize the contributions of immigrants and promote positive relations with members of the receiving society so that immigrants and members of the host country alike fully benefit.

## IMPLICIT ASSOCIATION TEST (IAT)

---

The idea that human thinking and feeling can operate outside conscious awareness and without conscious control is well established. Researchers arrived at this conclusion less from complex theorizing about the nature of the mind than from evidence generated by several unique methods. This evidence revealed that much of social cognition occurs without conscious awareness, control, intentional thought, or self-reflection. Thus implicit forms of preference of both individuals and social groups have come to form a critical component in the understanding of intergroup relations.

One method that contributes to this understanding is the *Implicit Association Test* (IAT). The IAT is a measure of implicit cognition, assessing the relative strength of associations between semantic concepts that may not be consciously accessible. For example, the IAT might provide evidence that, in the person being tested, the category “woman” is associated more with family than with career, while the category “man” reveals the opposite association. Indeed, the presence of such associations can be detected by the IAT even if the person is not aware of them or if the person consciously endorses an opposing belief.

The IAT has been used to study a diverse range of psychological concepts, and its primary use has

been in the analysis of unconscious intergroup attitudes and stereotypes and group identity. Notably, the IAT has been used to study many aspects of implicit intergroup cognition, including its relationship to self-report, its development, neural correlates, and ecologically realistic behaviors.

### Description of the Method

The IAT is a computer-based reaction-time task that measures the relative strength of associations between concept–attribute pairs by instructing participants to classify four sets of stimuli into two superordinate categories using just two response keys. During a typical IAT, participants use two response keys to classify concept stimuli presented sequentially on a computer screen (e.g., faces of Blacks and Whites, representing the concept *race*); for example, pressing the left key to indicate the face is Black and the right key to indicate the face is White. In addition, participants use the same two keys to classify attribute stimuli (e.g., good words such as *happy, nice, pleasant* or bad words such as *terrible, awful, violent*).

For half the trials, a particular concept category (White) and attribute category (good) share the same response key, while the contrasting categories share the other response key. And for the second half of the trials, the pairings reverse so that the opposite categories share the same response key (Black with good, and White with bad). The logic of the IAT is simple: When two concepts are more strongly associated with each other, it should be easier for participants to classify them when they share the same response key than when they share different response keys. In other words, participants should be both faster to respond and more accurate when two closely related concepts share the same response key.

The IAT stimuli can appear in several formats, including pictures and words presented either visually or aurally. Response latencies and errors are recorded and compared to those generated by the first set of trials. The particular pairings described above are counterbalanced across participants to control for potential order effects. (For a sample IAT task, visit <http://implicit.harvard.edu>)

Each participant receives a single score upon completing an IAT, called the IAT score or the D-score. This score is a measure of effect size computed by

calculating the difference between the mean response latency for the two double-categorization blocks and dividing that difference by its associated pooled standard deviation. The D-score indicates the strength of an individual's association between categories and attributes, with larger scores indicating stronger associations. (For more information about how to score an IAT, please see the recommended readings at the end of this entry.)

### Discoveries About Intergroup Cognition

Perhaps because the IAT was first introduced using social groups as the target domain, it has been most heavily used by those interested in the implicit intergroup attitudes, stereotypes, and self-concepts of numerous groups: race/ethnicity, gender, age, nationality, religion, body weight, disability, sexual orientation, and political ideology, to name just a few. As such, the IAT has been instrumental in generating a vast body of descriptive work to document the nature of implicit social cognition in intergroup contexts.

Researchers interested in understanding dual-process theories of social cognition and intergroup relations have used the IAT to measure the degree to which (and the conditions under which) explicitly stated prejudices and implicitly measured associations are consistent. Moreover, the IAT has helped shed light on intergroup cognition by providing key insights into the nature of implicit bias among majority and minority populations, including the developmental origins and neural basis of implicit social cognition as well as the effect of intergroup contact on the reduction of implicit intergroup bias. Notably, the IAT has been implemented online at <http://implicit.harvard.edu>, which serves primarily as an educational site with an attached spin-off research site, allowing data to be gathered from samples well beyond the convenience of college.

### *Dissociation With Explicit Evaluation*

Assessments of bias as measured by the IAT do not always produce results consistent with self-report measures. In fact, a weak correlation or no correlation at all is obtained between the IAT and self-report measures of bias when there is a strong desire on behalf of the participant to self-report

egalitarian views. These results are particularly common in the United States when researchers are studying socially sensitive topics such as race attitudes and stereotypes. Indeed, research has documented that people are reluctant to endorse views that are frowned upon in their culture when anonymity is not assured (e.g., stating a preference for Whites over Blacks or agreeing with a negative stereotype about Blacks).

Thus, while race bias is typically detected using the IAT, such bias is more difficult to detect, if it is detected at all, using self-report measures. Such data relating the IAT to self-report measures of bias support the idea that social cognition derives from two independent pathways, one that is relatively automatic, unconscious, and inaccessible and another that is readily available to introspection and to willful efforts of control. Notably, when the groups involved are not socially charged, the IAT and self-report measures of bias tend to report similar findings.

### Evidence About Bias

#### *Majority and Minority Intergroup Bias*

Research with the IAT has revealed a striking finding among adult participants—only majority group members from socially valued groups exhibit positive implicit ingroup bias. Thus, White Americans consistently show strong ingroup bias, whereas Black Americans do not. Similar observations have been obtained for other majority–minority group contrasts in the United States and in numerous other countries around the world.

#### *Development of Implicit Intergroup Bias*

A child-friendly version of the IAT (Child IAT) was developed to measure the acquisition of implicit associations as they emerge. Collectively, this research has demonstrated that implicit intergroup biases emerge surprisingly early in life at adultlike levels of magnitude, casting doubt on the conventional view that such implicit associations form only over a protracted period of exposure to cultural beliefs. While implicit attitudes emerge very quickly and undergo little change across development, implicit stereotypes seem to take longer to form, appearing to be much more flexible. Ongoing developmental research using the

Child IAT promises to shed light on the cognitive and cultural origins of implicit intergroup bias, while revealing how and when such implicit associations can be modified.

### *Malleability of Implicit Intergroup Bias*

Considerable research has been concerned with understanding the malleability of implicit intergroup bias. Research using the IAT has shown that although the IAT taps an aspect of intergroup cognition that is difficult to control, this implicit cognition, contrary to intuition, is likely quite malleable. Indeed, studies have shown that the mere presence of members of an outgroup (Black) can reduce the degree of implicit anti-Black IAT bias, that imagery exercises can lower the degree of stereotypes of women, and that consistent exposure to women teachers can change girls' stereotypes.

### **Construct and Predictive Validity of the IAT**

Research examining the construct validity of the IAT has demonstrated that it is difficult to produce a desired outcome (i.e., fake the test) and that the strength of implicit associations are often uncorrelated with a person's self-professed beliefs, especially when the domain of interest is susceptible to the common desire to appear unbiased in the eyes of friends, family, and peers. This is precisely the sort of finding one would expect from a measure of *implicit* bias. Categories expected to elicit positive attitudes (e.g., flowers) compared to other categories (e.g., insects) do so. Known-groups tests give further support to the IAT by showing that those expected to have stronger positive associations between concept and attribute indeed show such effects (e.g., members of dominant social groups show greater implicit positivity toward their ingroup than do members of nondominant social groups).

The IAT is also known to be related to several measures of brain activity, with the first studies demonstrating greater amygdala activation to Black faces in those participants who also showed stronger anti-Black IAT bias. Given the strong involvement of the amygdala in emotional learning, such a result (the correlation between amygdala involvement and degree of attitudinal bias) ought to be expected from an attitude measure. Recently,

an identity IAT (measure of association of self with another) predicted activation in the medial prefrontal cortex, showing the activation of different neurons when individuals thought about someone similar to or different from them based on group membership.

The IAT measures the relative strength of association between different concepts. Research has revealed that differences in the magnitude of these associations correlate with differences in actual behavior. In answer to questions concerning the predictive validity of the IAT using real-world samples, a review of all peer-reviewed published papers exploring the predictive validity of the IAT has shown that although both explicit and implicit measures predict intergroup discrimination, the IAT outperforms explicit measures in this context. In particular, implicit intergroup bias measured by the IAT is a better predictor of nonverbal behaviors and decisions made under pressure than are explicit measures of intergroup bias.

## IMPLICIT PREJUDICE

---

Although there is some debate among psychologists as to what implicit prejudice is and how best to define it, *implicit prejudice* is most commonly described as a prejudice (i.e., negative feelings and/or beliefs about a group) that people hold without being aware of it. One can harbor implicit prejudice on the basis of race (implicit racism), sex (implicit sexism), age (implicit ageism), ethnicity (implicit ethnocentrism), or any number of other social groups. Of the various forms of implicit prejudice, implicit racism has probably received the most research attention.

Implicit prejudice is thought to operate automatically, with little intention or control on the part of the person. In addition, people are often unwilling or unable to acknowledge their implicit prejudice. Implicit prejudice can be contrasted with explicit prejudice, which is prejudice of which people are aware and that they agree with and endorse consciously. As discussed below, implicit prejudice can have a wide range of effects on judgments and behavior toward members of different groups. It tends to appear in people's judgments and behavior toward targets of their prejudice both subtly and accidentally. Because it seeps into the behavior of people who see themselves as unprejudiced, it is believed to be a particularly insidious form of prejudice.

For example, consider a White individual who considers himself a relatively open-minded, prejudice-free person. He tries to be fair to everyone and treat people equally. However, imagine he

harbors negative feelings toward, say, Blacks. These are feelings he doesn't readily acknowledge and wouldn't admit to others; indeed, he may adamantly deny them. However, in interactions with Blacks, he appears somewhat distant and aloof. Although he doesn't mean to, he makes less eye contact, smiles less, and generally exudes less warmth with them than he does with Whites.

We would consider this person to be relatively low in explicit prejudice—he would claim, and would perhaps believe, to feel neutrally or positively toward Blacks, and he would certainly disavow blatantly racist notions like racial discrimination in housing and employment. However, he exemplifies implicit prejudice because of his negative feelings and behavior toward Blacks and his lack of awareness of these feelings and behaviors. It is the coupling of unintentional negativity and a lack of awareness that is the hallmark of implicit prejudice. This entry describes the concept of implicit prejudice, explores its manifestations and measures, and summarizes critiques of the idea.

### Origins and Prevalence

Most researchers would agree that, to some extent, socialization processes affect us all. That is, our parents, teachers, peers, television, and other forms of media have an impact on our attitudes and beliefs. Implicit prejudice researchers point to the negative depiction of various groups, particularly Blacks, in popular culture and the media as a primary origin of implicit prejudice. Overhearing prejudicial remarks from our peers and parents is also thought to influence our racial attitudes. These cultural associations are likely incorporated into memory without our awareness or consent, and the process is said to begin in childhood. By adulthood, negative associations in memory involving Blacks (and other stigmatized groups) have become so ingrained that they are capable of being automatically activated upon seeing a Black individual.

While many people are aware of the fact that some minority groups are negatively depicted in society, people tend to be unaware of the impact of these negative associations on their attitudes. In fact, it is common for people to overtly deny that media and other socialization factors influence their attitudes. However, research shows that humans are capable of learning associations implicitly—without

their awareness or intention—in as little as 20 repetitions, and that racial attitudes can form and change implicitly as well.

People also tend to claim that they “choose” their attitudes based on personal experience, facts, and other forms of evidence, but implicit prejudice is a case of a person’s attitudes forming without any consideration of facts or evidence. In contrast to explicit prejudice, which tends to be based on deliberately held beliefs (e.g., that Blacks are violent or unintelligent), implicit prejudice is primarily feeling based. It is the sum of the large number of negative depictions of a given group, not the product of a single fact or negative experience with a given member of a negatively evaluated group. As such, it tends to take the form of “vague feelings” that exist without any specific reason (although after-the-fact justifications can easily be generated to rationalize a person’s prejudices).

An implication of this analysis is that nearly all members of the culture are thought to have some degree of implicit prejudice. Because people—particularly children—are often unaware of the effects of socialization on their attitudes, they do little to prevent socialization processes from influencing them. Thus, most members of a culture that negatively depicts a given group will harbor implicit prejudice against that group. In fact, research designed to measure implicit prejudice indicates that the vast majority of White Americans show implicit prejudice against Blacks. Furthermore, there is some evidence that these socialization processes similarly affect Blacks, leading to implicit prejudice against their own group.

### Manifestations

Because implicit prejudice tends to be more feeling based than fact based, it tends to appear in behavior where emotions tend to manifest. Nonverbal behavior in particular has been implicated as a common outlet for implicit prejudice. In the example mentioned earlier, the implicitly prejudiced individual smiled less and made less eye contact with Blacks than with Whites. Research has shown that implicit prejudice relates to these and other nonverbal indicators of negativity and discomfort, such as body orientation, fidgeting, and the like.

Implicit prejudice is also likely to influence judgments in ambiguous or uncertain situations. One

interesting study demonstrated that Whites who scored high on a measure of implicit prejudice were more likely to interpret a neutral facial expression on the face of a Black individual as angry or hostile than the same expression on the face of a White individual (the faces in this study were computer generated, so we can be certain that the only way in which they differed was race). In another classic study, White participants were more likely to interpret an ambiguous shove on the part of a Black individual as an act of hostility; the same shove performed by a White individual was more likely to be construed as playful. It is likely that implicit prejudice was at work here because people were probably unaware of the fact that they interpreted these behaviors differently based on race.

However, implicit prejudice can also influence people’s deliberate judgments and behavior. This is because people will not attempt to correct their prejudices if they are not aware of them or their biasing influence. For example, in making hiring decisions, employers often take pains to avoid bias and attempt to treat all applicants equally. But if while reviewing applications, the race of an applicant becomes apparent (through a name, photo, or affiliation), implicit prejudice may be activated in the mind of the employer, who would then have to actively correct that bias to maintain equal treatment of the applicants. Given that people are often unable or unwilling to admit to implicit prejudice, it is unlikely that the employer will attempt to correct it. Hence, he or she may inadvertently evaluate Black applicants more negatively than White applicants.

### Measuring Implicit Prejudice

Traditionally, paper-and-pencil-based survey questionnaires have been used to measure prejudice. Such questionnaires typically ask respondents to indicate how much they like or dislike various groups, or their agreement with such statements as, “Blacks should not push themselves where they are not wanted.” This was, and still is, an effective way to measure explicit prejudice because it is a form of prejudice people are aware of and are at least somewhat willing to report to others.

However, researchers cannot effectively use questionnaires to measure implicit prejudice. This is because implicit prejudice is a form of prejudice that

people are either unwilling or unable to report. People are often unwilling to report their implicit prejudice on a questionnaire because they consciously disapprove of their own prejudice and do not wish to appear prejudiced to others, even on a questionnaire. They are sometimes unable to report their implicit prejudice if they themselves are not consciously aware of their own prejudices. So if someone appears to be low in prejudice according to a questionnaire, it could be because they truly are low in prejudice, because they do not wish to confess their prejudice, or because they do not know that they are prejudiced. Questionnaire measures cannot differentiate between these three possibilities.

Owing to the drawbacks of questionnaire measures, researchers have turned to *implicit measures* (sometimes called *indirect measures*) to assess implicit prejudice (see, for example, the entry on the Implicit Association Test). Implicit measures are capable of identifying a person's degree of implicit prejudice without having to ask directly any questions having to do with prejudice. In fact, implicit measures typically do not ask any questions at all. Instead, they assess people's reaction times to various prejudice-related stimuli and infer, based on those reaction times, the degree to which an individual is implicitly prejudiced.

One kind of implicit measure involves prime images that are presented for short durations on a computer screen (typically less than half a second), followed by target words that mean something good (e.g., *excellent*) or bad (e.g., *horrible*). The respondent's task is to identify the meaning of the target word as either good or bad by pressing one of two buttons on a keypad. The image that precedes the target is typically a picture of a person, for example, a White or Black person. A respondent would undergo many such trials of prime image–target word, all the while responding as quickly as possible to the valence of the target word (good or bad). Implicit prejudice would be revealed in the pattern of response times to the target words.

Specifically, people who are implicitly prejudiced against Blacks are relatively quick to identify negative words preceded by Black primes (and positive words preceded by White primes). This is because the racial group “Black” is automatically linked in memory to a negative evaluation; seeing the face of a Black individual activates negativity,

making people quicker to identify other negative items. In other words, quickness to respond on Black–bad trials indicates negative implicit associations to Blacks. By comparing response times to Black–bad, White–bad, Black–good, and White–good trials, researchers can arrive at an index of a given individual's degree of implicit prejudice.

One might ask what a high score on an implicit measure of prejudice might imply in terms of behavior in intergroup contexts. That is, do implicit measures predict behavior? Research has shown that they do. Recall the example mentioned earlier of someone who is high in implicit prejudice but low in explicit prejudice toward Blacks. This individual smiled less, made less eye contact, and exuded less warmth while interacting with Black individuals. Also mentioned earlier was the finding that White respondents scoring high in implicit prejudice were more likely to perceive Black faces as having more hostile expressions. It is precisely these sorts of perceptions and behaviors that implicit measures predict. Specifically, behaviors that are less controllable and less consciously monitored (like many nonverbal behaviors) tend to relate to implicit measures of prejudice; hence, individuals who score high in implicit prejudice smile less, make less eye contact, and so on while interacting with a Black person than with a White person. Explicit measures, in turn, tend to predict more deliberate and thoughtful behavior. For example, people who score high in explicit prejudice are more likely to report not liking a Black individual, and to consciously evaluate that individual negatively.

Much research has examined how explicit and implicit prejudice are related (for example, if someone is high in explicit prejudice, does it mean that person is also high in implicit prejudice?). Interestingly, there is often little relation between the two forms of prejudice. Someone can be high in one or both, low in one or both, or high in one and low in the other. Because of the pervasive impact of socialization processes on implicit prejudice, it is particularly common for someone to be relatively high in implicit prejudice but low in explicit prejudice, as the earlier example illustrates.

### Critique of the Concept

Although implicit prejudice research has received a lot of research attention in recent years, substantial

controversy surrounds it. The debate has centered on three key issues: (1) the prevalence of implicit prejudice (that is, is everyone implicitly prejudiced?), (2) whether people are actually unaware of their implicit prejudice, and (3) whether implicit prejudice and explicit prejudice are truly independent (that is, is implicit prejudice really a different form of prejudice from explicit prejudice?).

Regarding the question of prevalence, many researchers believe that implicit prejudice is an inevitable consequence of socialization, that everyone is at least “a little bit racist” (and sexist, and homophobic, and so on). Corroborating this claim is evidence from some implicit measures, like the Implicit Association Test, indicating that approximately 90% of Whites show evidence of implicit prejudice against Blacks. However, the priming measure described earlier reveals that only 50% to 60% of Whites harbor implicit prejudice. Moreover, as has been described, the variability revealed in implicit measures relates to behavior: People with more negative implicit prejudice scores tend to act more negatively to members of the negatively evaluated groups, and people with more positive implicit prejudice scores tend to act more positively toward members of those groups. Hence, implicit prejudice does vary among people—some have strong levels of it, some none at all, and some show implicit positivity toward groups that most other members of a society dislike.

“Culture” and “socialization” are simply not unitary, one-size-fits-all entities, and people vary in the extent to which they are exposed to negative depictions of various groups. So it is not surprising that although a good number (perhaps even the majority) of members of a culture that depicts some groups negatively eventually come to have implicit prejudices toward those groups, others will not be exposed to (or at least will not be as exposed to) these socialization processes, and hence will not be as affected by them.

The second issue—awareness of implicit prejudice—stems from the many claims that have been made that people are not consciously aware of their implicit prejudice. However, there is no documented evidence that people are, indeed, unaware of their implicit prejudices (and it would be difficult to provide such evidence). In fact, there is evidence precisely to the contrary. For example, some people try to “correct” for their

implicit prejudice, particularly those people who both have a lot of it and are motivated not to be prejudiced; these individuals would not be able to correct for their prejudice if they were unaware of it. Also, people who are particularly *unmotivated* to correct for their prejudice exhibit a similar degree of prejudice on both implicit and explicit measures; they appear to have a good deal of prejudice, and are comfortable admitting it. Finally, evidence from other areas of research shows that when people are implored to be honest, they will report attitudes on an explicit measure that correspond to their implicit attitudes, suggesting that people are aware of their implicitly measured attitudes, but that sometimes they don’t want to report them to others.

The third criticism of implicit prejudice is perhaps the most divisive. Although some researchers who advocate the concept claim that people essentially have two attitudes toward a given group (e.g., Blacks, women, homosexuals, etc.), one explicit and the other implicit, other researchers have wondered whether implicit prejudice and explicit prejudice really do amount to separate and distinct attitudes. Specifically, these researchers argue that prejudice at the implicit level gets at something closer to the “truth,” that is, people’s true feelings about a given group. Explicit prejudice, because of its susceptibility to motivational effects (as when people claim not to be prejudiced out of a concern that they might appear prejudiced), is not really “prejudice” at all, but is really comprised of people’s values or motivations concerning intergroup contexts.

So instead of two attitudes toward Blacks, homosexuals, or whomever, people have one true “gut” attitude, and it is a matter of whether people wish to be honest as to whether their levels of explicit prejudice look any different from their implicit prejudice. From this perspective, implicit prejudice is “true” prejudice, and explicit prejudice is an amalgamation of strategies people employ to appear a certain way in public. The issue then becomes whether to consider this amalgamation an attitude toward a given group. This debate—the relationship between implicit and explicit prejudice and whether they really are distinct—continues in the scientific literature.

## INCLUSION/EXCLUSION

---

*Inclusion* refers to being accepted as part of a group, organization, or two-person relationship, whereas *exclusion* refers to being rejected. Inclusion tends to have positive effects on behaviors, cognitive activity, physical health, and emotions, whereas exclusion tends to have negative effects. Making excluded people feel that they are able to gain inclusion reduces the negative effects of exclusion. This entry discusses the importance of inclusion and exclusion for understanding group processes, reviews the types of inclusion and exclusion people experience inside and outside the scientific laboratory, and discusses the positive and negative consequences of inclusion and exclusion.

### Belonging to Groups as a Fundamental Human Need

People depend on others for much of their well-being. Most humans do not grow the food they eat, make the clothes they wear, or build the shelter in which they live. People obtain these basic necessities from members of their group. To a large

extent, our lives depend on our ability to get along with and feel included by others. In our evolutionary history, exclusion from a group meant almost certain death. It therefore follows that people should be strongly motivated to gain inclusion in groups and avoid exclusion. Roy Baumeister and Mark Leary have suggested that people have a basic desire for positive and lasting relationships. According to this perspective, people try to think, feel, and act in ways that enable them to gain social inclusion and avoid exclusion. Moreover, inclusion is linked to a variety of positive outcomes, whereas exclusion often results in negative outcomes.

### Examining Inclusion and Exclusion Inside and Outside the Laboratory

It is common for members of a group to exclude certain people. People apply for membership in a country club, only to be told that they are not wanted. College students experience exclusion when a desirable college fraternity or sorority rejects their application to join the organization. Children are not picked to join a team for games on the playground or are told they cannot sit next to another person in a school bus. Exclusion is also a common theme in movies and television shows. For example, most reality television shows involve inclusion or exclusion: Some people are excluded because they have terrible singing voices, whereas others are excluded because they do not work well with other members of a group. These examples suggest that inclusion and exclusion are familiar experiences for most people.

Psychologists investigate inclusion and exclusion using several different methods. In contrast to the types of exclusion people experience outside of the laboratory (e.g., not being invited to a friend's party), the methods psychologists use to understand inclusion and exclusion involve exposing people to situations that are less distressing and of lesser importance. The main reason for using mild forms of exclusion in laboratory research is that it would be unethical to expose people to extreme events, such as learning that a loved one does not reciprocate one's feelings, for the purpose of research. Despite the fact that most laboratory manipulations involve rather weak exclusion experiences, the effects of these manipulations tend to be quite strong. In what follows, the six most

popular methods used to study exclusion and inclusion are described. In each method, people who experience exclusion are compared to people who experience inclusion (or some other event), in terms of their behaviors, cognitive activity, physical health, or emotions.

The first method (“lonely future”) involves participants completing a personality test and then learning that they have a personality type that predicts they will end up alone later in life. Other participants learn that they can anticipate a future filled with positive and lasting relationships, whereas still others learn that they will have negative experiences unrelated to their relationships, such as car accidents. The second method (“group exclusion”) involves participants completing a group interaction and learning that no other member chose to work with them on a later task, whereas other participants learn that all other members chose to work with them. The third method (“personal versus impersonal exclusion”) involves participants expecting to interact with a same-sex partner. After exchanging initial information with the partner, some participants are told that the partner refused to work with them, whereas other participants are told that they will not be able to meet the partner because he or she had to leave unexpectedly due to a forgotten appointment. The fourth method (“virtual exclusion”) involves participants playing an online ball-tossing game with two other players (whose actions are programmed by the researcher) and receiving very few tosses from the other players. Other participants receive an expected and appropriate number of tosses from the other players. The fifth method (“think of a time you were excluded”) involves having some participants write an autobiographical essay describing a time when they felt excluded, whereas other participants write about a time when they felt included. Finally, the sixth method (“chronic loneliness”) involves asking participants how much they tend to feel excluded. Researchers then examine the relationships between participants’ feelings of exclusion and their behaviors, cognitive activity, physical health, and emotions.

### Negative Consequences of Exclusion

Exclusion thwarts a fundamental motivation for belonging, and hence the effects of exclusion are

typically negative. This section reviews evidence regarding these negative effects.

### *Behaviors*

Aggression is one of the strongest and most negative consequences of exclusion. Case studies suggest that the majority of students who shoot classmates (such as those at Columbine High School) experienced chronic exclusion. Laboratory manipulations of exclusion produce similar results. In one study, people who were told that no one from a group chose them as a partner blasted a stranger with louder and more intense bursts of white noise than did people who were told that everyone chose them as a partner. Another study found that people who were excluded in a virtual ball-tossing game behaved more aggressively than did people who were included in the game. In this study, aggression took the form of doling out large amounts of hot sauce to a person who expressed strong dislike for spicy foods. Further research indicates that exclusion increases aggression toward both people who are involved in the exclusion experience and people who are not.

Exclusion also tends to influence helping in a negative way. Compared to people who have experienced inclusion, excluded people donate less money to charity, volunteer less, and cooperate less on activities with others. Excluded people cooperate less with others even when it is financially costly to do so and when cooperating will earn them money. Moreover, exclusion reduces helping mostly when the recipient of help does not represent a potential source of social inclusion.

People usually control their impulses because doing so increases their chances of being included in a group. They wait their turn in line, for example, because people who follow rules and act politely are more likely to be included than are people who do not follow rules and act rudely. When people experience exclusion, however, they are much less likely to control their impulses. One reason may be that excluded people do not believe that impulse control will earn them inclusion. Compared to included people, excluded people persist less on frustrating tasks, are less able to control their attention on listening tasks, and eat larger amounts of unhealthy foods and smaller amounts of healthy foods. Although exclusion

reduces impulse control, the relationship between exclusion and reduced impulse control wears off quickly (in less than 45 minutes) for most people. People who have high levels of social anxiety (i.e., are chronically worried about being excluded), however, tend to show poor impulse control for up to an hour after they experience exclusion.

Excluded people are also more likely than included people to behave in ways that allow them to avoid thinking about themselves. Results from one study showed that excluded people sat in a chair that was not facing a mirror (thus avoiding their own reflection) more often than did included people. The implication is that excluded people try to avoid being reminded of personal flaws that caused them to be excluded.

### *Cognitive Activity*

Excluded people do not perform as well as included people on various types of cognitive tasks, including analytical reasoning tests, IQ tests, and reading comprehension tests. Whereas excluded people perform as well as included people on cognitive tasks that do not require much effort (i.e., easy memorization), they perform more poorly on tasks that require large amounts of effort. Just as excluded people do not exert themselves on impulse control tasks, they are also unwilling to use large amounts of mental energy on cognitive tasks.

Exclusion also causes people to interpret other people's actions as aggressive. In one study, people were made to feel excluded or included and were then given vague information about another person. Compared to included people, excluded people were more likely to perceive the vague actions of another person as aggressive. Another study found that chronic feelings of exclusion were related to perceiving others' actions as aggressive. The tendency for excluded people to perceive others' actions in aggressive terms offers one possible explanation for why excluded people behave aggressively.

### *Physical Health and Emotions*

A growing body of evidence links chronic feelings of exclusion to negative health outcomes. Compared to people low in chronic feelings of

exclusion, people who report feeling chronically excluded have poorer immune system functioning, higher resting blood pressure, higher levels of stress hormones, and a lower chance of surviving 30 days and 5 years after heart bypass surgery. People who feel chronically excluded also have poorer sleep quality than people who do not feel chronically excluded.

It is commonly believed that exclusion causes emotional distress, and inclusion increases positive emotions. Indeed, there is evidence that exclusion causes people to feel negative emotions such as anger, sadness, and hurt feelings, whereas inclusion is generally related to positive emotions. When asked how they feel after being excluded, people use words that commonly describe physical injury. For example, excluded people typically report feeling "hurt," "crushed," or "broken-hearted."

Evidence from several studies suggests that describing exclusion as painful extends beyond mere metaphor. In one study using brain-imaging technology, Naomi Eisenberger, Matthew Lieberman, and Kipling Williams showed that the same brain regions respond to exclusion and physical pain. In addition, C. Nathan DeWall and Roy Baumeister demonstrated that excluded participants have lower physical pain sensitivity and higher pain tolerance than do included participants. Excluded participants also show signs of emotional insensitivity, as indicated by reduced empathic concern for another person's suffering and a tendency to predict an emotionally numb response to their favorite football team winning or losing to a rival team. Crucially, excluded participants' numbness to physical pain was related to their emotional insensitivity. Just as the body goes numb in response to serious physical injury, so people become numb physically and emotionally in response to exclusion.

### **Positive Consequences of Exclusion**

So far, we have focused on how exclusion negatively influences behaviors, cognitive activity, physical health, and emotions. There are some findings, however, suggesting positive consequences of exclusion. Most such consequences are due to excluded people wanting to connect with potential sources of social inclusion. Just as hungry people seek out food, so excluded people seek out social acceptance. In so

doing, their behavioral, cognitive, and emotional responses sometimes have positive consequences.

### Behaviors

There is some evidence that excluded people are helpful to others who could be sources of social acceptance. For example, excluded people are more likely than included people to give money to a stranger when they expect to meet the stranger. When no interaction with the stranger is anticipated, however, excluded people give less money than included people. Excluded people also tend to behave in ways that will impress others, possibly as a means of showing that they are worthy of social inclusion. Women who feel excluded, for example, are more likely than other women to work hard on behalf of their group. Exclusion also increases the tendency for people to agree with others, which can be interpreted as an effort to impress others by behaving similarly to them.

### Cognitive Activity

There is evidence that excluded people are more likely than included people to perceive neutral facial expressions as friendly. In addition, people who feel chronically excluded are better at identifying facial expressions and vocal tones than are people who do not feel chronically excluded. Excluded people are also faster than other people at identifying a smiling face (a sign of social inclusion) in the middle of many nonsmiling faces. When presented with a picture of many faces that display various facial expressions (sadness, anger, disgust, smiling), excluded people are more attentive to smiling faces than are people who have not experienced exclusion. In addition, excluded people have more difficulty pulling their attention away from smiling faces than do people who have not been excluded. The implication of all this is that excluded people are motivated to seek out potential relationships. As a result, their attention becomes captured by signs of social inclusion.

### Emotions

Exclusion thwarts a basic human need for positive and lasting relationships, which makes it likely that people will have a deeply ingrained emotional coping response to exclusion. In support of this

notion, there is some evidence suggesting that exclusion activates a coping response in which people seek out positive emotional information in others and in their environment. For example, excluded people are more likely than other people to complete word fragments (*jot*) with positive emotion words (*joy*) as opposed to neutral words (*jot*). When asked to judge which of two words (*cheek, smile*) is more similar to another word (*mouth*), excluded people are more likely than others to choose the option related to positive emotion (*smile*). Excluded people are unaware of this coping response, suggesting that this response to exclusion operates at an unconscious level.

## INFORMATIONAL INFLUENCE

---

What do we do when we are uncertain about how to think or act in a situation? One solution is to look to the attitudes and actions of other people. *Informational influence* (also known as

*informational social influence*) is a type of conformity in which individuals use the attitudes or actions of those around them as cues to correcting their own behavior. It is contrasted with *normative influence*, where people conform in order to be liked or accepted by others. Informational influence and normative influence are the two types of influence outlined in Morton Deutsch and Harold Gerard's *dual-process theory of social influence*.

Characterized as influence to accept information obtained from others as evidence about reality, informational influence is based on a desire to make informed decisions. This influence is most powerful when being accurate is more important, when others are perceived as especially knowledgeable or expert, and when the situation is particularly ambiguous or uncertain. The more uncertain people are about the correctness of their judgments, the more susceptible they will be to informational influence. However, the more uncertain people are about the correctness of the judgments of others, the less susceptible they will be to informational influence.

Informational influence is not irrational; rather, it is a functional way of defining a position in the face of limited information or ambiguity and uncertainty. Indeed, if others have access to more, different, or more accurate information, it may be sensible to adopt their opinions or to be influenced by their opinions. Informational influence is seen as "true" influence, as the individual accepts and internalizes it—that is, conforms because of a genuine belief that others are correct, and it is seen to lead to long-term, private, attitude change. This is contrasted with normative influence, which is seen as leading to public compliance—that is, to conforming to the behavior of others publicly without necessarily believing such behavior is correct. This entry looks at the history of the concept of informational influence and discusses related controversies.

### History and Background

It could be argued that one of the first studies to demonstrate informational influence was Muzafer Sherif's work on the autokinetic effect. The *autokinetic effect* refers to the way in which a pinpoint of light appears to move of its own accord when it is

viewed in a completely dark room where there are no visible reference points. In Sherif's studies, people were placed in a darkened room either alone or in groups and asked to state how much the point of light moved. In this ambiguous situation, people were always influenced by the judgments of other people, even if they first made their judgments alone. The groups converged on a norm that was used to make their judgments. Influence was accepted readily with little awareness and persisted in the absence of the group for long periods of time.

One early account for informational influence was offered by Leon Festinger, who suggested that individuals are motivated to test the validity of their beliefs and prefer to do so through a process of physical reality testing. However, when we cannot rely on our own direct perceptual and behavioral contact with the physical world, as is the case in the autokinetic paradigm, the subjective validity of our beliefs depends on social reality testing and on the consensual validation of our beliefs by other people. In such cases, we will become susceptible to influence from others. If we discover that other people do not share our beliefs and opinions, we will question whether our beliefs and opinions are correct.

Informational influence was also illustrated in Solomon Asch's seminal work on conformity and independence. In Asch's studies, a group of seven to nine young men were gathered together, ostensibly for a psychological experiment on visual perception. Participants were presented with a target line and a set of three comparison lines and told that their task was to state publicly which of the three comparison lines matched the target lines. However, only one person was a true participant; the others were confederates of the experimenter, who had been instructed to give a unanimously incorrect response on certain trials. When alone, participants were able to complete this task with 99% accuracy, confirming that this was not a difficult or ambiguous task. However, in groups, participants conformed to the incorrect response of the group on about one third of the critical trials, a finding that has been replicated in many subsequent studies.

After the studies, participants were asked why they had conformed to the incorrect majority. Many participants reported that they knew that

the group was incorrect but went along with the group anyway because they did not want to stand out from the group and be subjected to ridicule—this is normative influence. However, other participants knew that they were out of step with the group but thought that their judgments were incorrect and the majority was correct, and some participants reported actually seeing the lines as the majority did. This is informational influence.

The distinction between informational and normative influence is associated most closely with the work of Morton Deutsch and Harold Gerard. Deutsch and Gerard argued that prior research on social influence, such as that conducted by Asch, had confounded informational and normative influence. To test this idea, Deutsch and Gerard conducted a study that incorporated a number of modifications to Asch's study. Specifically, Deutsch and Gerard compared levels of conformity in face-to-face situations, in which participants had to state their judgments publicly after hearing the judgments of others, and in anonymous situations, in which participants had to state their judgments privately after hearing the judgments of others. Greater conformity was found in the face-to-face condition than in the anonymous condition, suggesting the presence of normative influence. However, there was greater conformity in the anonymous condition than in the control conditions, suggesting the presence of informational influence.

### Debate and Controversy

The distinction between normative and informational influence has proven useful in a broad range of research fields, including consumer behavior and marketing, persuasion and attitude change, group decision making, and computer-mediated communication. However, a number of researchers have questioned the value of the distinction between normative and informational influence.

Informational influence is seen to be a function of the validity of the information that others provide about reality. A critical question, however, is how the validity of such information is determined. Researchers who are proponents of social identity theory, such as John Turner, argue that our judgments about validity will depend on whether we share a group membership with these other people.

Information provided by members of our own groups will be seen as more credible, trustworthy, and valid than information provided by members of other groups.

Reference group norms establish the validity of information; thus, consensual validation (of social reality) is really normative validation. In *referent informational influence*, the theory of social influence associated with the social identity approach, the focus is not on distinguishing between normative and informational influence, but rather, on a single influence process in which the normative position of people categorized as similar to the self tends to be accepted as valid information.
