### Demographics and a Brief Historical Perspective

ROBERT T. FRANCOEUR

#### A. Demographics

The Republic of Ireland—"Eire" in the Irish language—occupies five sixths of the island of Ireland in the North Atlantic Ocean west of Great Britain. Slightly larger than the state of West Virginia, Ireland has an area of 27,135 square miles (70,280 km<sup>2</sup>). The northeastern corner of the island is Northern Ireland, a part of the United Kingdom. The terrain is mostly level-to-rolling interior plains surrounded by rugged hills and low mountains, with sea cliffs on the western coastline. The climate is temperate maritime, moderated by the North Atlantic Current, with mild winters and cool summers. The island is consistently humid and overcast about half of the time.

In July 2002, Ireland had an estimated population of 3.88 million. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 21.3% with 1 male(s) per female (sex ratio); 15-64 years: 67.3% with 1.02 male(s) per female; 65 years and over: 11.4% with 0.77 male(s) per female; *Total population sex ratio:* 0.98 male(s) to 1 female

**Life Expectancy at Birth:** *Total Population:* 77.17 years; *male:* 74.41 years; *female:* 80.12 years

**Urban/Rural Distribution:** 57% to 43%

**Ethnic Distribution:** Celtic and English

**Religious Distribution:** Roman Catholic: 91.6%; Church of Ireland: 2.5%; other: 5.9% (1998 est.)

**Birth Rate:** 14.62 births per 1,000 population

**Death Rate:** 8.01 per 1,000 population

**Infant Mortality Rate:** 5.43 deaths per 1,000 live births

**Net Migration Rate:** 4.12 migrant(s) per 1,000 population

**Total Fertility Rate:** 1.9 children born per woman

**Population Growth Rate:** 1.07%

(CIA 2002)

**HIV/AIDS** (1999 est.): *Adult prevalence:* 0.1%; *Persons living with HIV/AIDS:* 2,200; *Deaths:* < 100. (For additional details from [www.UNAIDS.org](http://www.UNAIDS.org), see end of Section 10B.)

**Literacy Rate** (defined as those age 15 and over who can read and write): 100% (1993 est.), with 96% attendance in nine years of compulsory school

**Per Capita Gross Domestic Product** (*purchasing power parity*): \$27,300 (2001 est.); *Inflation:* 4.9%; *Unemployment:* 4.3%; *Living below the poverty line:* 10% (1997 est.)

#### B. A Brief Historical Perspective

Celtic tribes invaded what is now Ireland about the 4th century B.C.E., bringing their Gaelic culture and literature. St. Patrick brought Christianity to these Celts in the 5th century C.E. The Norse invasions, which began in the 8th century, ended in 1014 when the Irish King Brian Boru defeated the Danes. English invasions began in the 12th century with bitter rebellions, famines, and savage repressions. The Easter Monday Rebellion (1916) failed, but was followed by guerrilla warfare and harsh repression by the English. When the Irish Parliament (Dail Eireann) reaffirmed their independence in 1919, the British offered dominion status to the six counties of Ulster and to the 26 counties of southern Ireland. The Irish Free State in the south adopted a constitution and dominion status in 1922, while northern Ireland remained a part of the United Kingdom. In 1937, a new constitution was adopted along with the declaration of Eire (Ireland) as a sovereign democratic state. In 1948, Eire withdrew from the Commonwealth declaring itself a republic. The British Parliament recognized both actions, but reaffirmed its control over the northeast six counties, a declaration Ireland has never recognized. Despite recurring violence and political shifts, both the British and the people of Ireland favor a peaceful resolution of the conflict.

#### 1. Basic Sexological Premises

##### A. Character of Gender Roles

The idea that there are definite and separate roles for the sexes pervades all aspects of Irish society. In this division of roles, the feminine is regarded as subordinate to the mascu-

\*Communications: Harry A. Walsh, Ed.D., 1201 Gulf Course Road, #1207, Monticello, MN 55362 USA; [dialeat@msn.com](mailto:dialeat@msn.com).

line. The society is a patriarchal one where social power and control are associated with masculinity. The 1937 Irish Constitution reflected what was considered the main role of Irish women thus: "In particular the State recognizes that by her life within the home, woman gives to the State a support without which the common good cannot be achieved." This provision, and the attitudes underlying it, have been used to deny women equality in all spheres of Irish life.

[*Comment 1997*: The cult of the Virgin Mary is very strong in Ireland. Mary is depicted as a kind of Cinderella—confined to the kitchen with her dreams and fantasies. The model presented to the women of Ireland is seen at the Marian Shrine of Knock in western Ireland. In this vision, she was reported to have worn a long dress with a sash, a veil, and wearing the crown of a rich feudal lady. Yet, one of the best-selling prayer-cards at the shrine is "The Kitchen Prayer":

Lord of all the pots and pans and things . . .  
Make me a saint by getting  
Meals and washing up plates.

[The image of the Virgin Mary held up before the eyes of Irish women reinforces the established cultural attitude: Women can have their dreams, but their place is in the kitchen. (*End of comment by H. A. Walsh*)]

[*Comment 2003*: However, the present generation of young mothers is quite different from their mothers. Getting a career outside the home in place before starting a family is quite common. They may be married, but they are in no rush to get pregnant the first year or, indeed, for several years after marriage. In the "old Ireland," tongues started to wag if a young wife failed to get pregnant within the first year or two after marriage. This, of course, raises the question: How are they avoiding pregnancy? The only reasonable conclusion has to be that they are using some method of artificial birth control. It is hard to imagine that all young couples are employing the natural family planning method of contraception—which suggests that young couples are making conscious decisions that fly in the face of the moral dictates of their Church. The fact that personal conscience is taking priority over institutional conscience is certainly a new feature of Roman Catholicism in Ireland.

[Another small, but significant, sign of the changing times can be seen in a practice that has become quite common today. Young females, when they marry, do not take their husband's name, not even as a second, hyphenated name. So, if Molly Malone marries, she stays Molly Malone. (*End of comment by H. A. Walsh*)]

At the same time, since the advent of the women's movement and Ireland's joining with the European Community in 1973, a number of legal reforms have been brought about, giving women more or less legal equality. But socially, economically, and politically, women are far from equal, although the gap has narrowed somewhat in the past 20 years. Women make up about 30% of the workforce, but in industry, their average earnings are only 67% of the average male earnings. Ireland has the lowest employment rate in Europe for mothers with children under 5 years of age. In 1991, 16.7% of married women were in the labor force, compared with 50% in Germany. There are no publicly funded childcare facilities. Discrimination against women is widely practiced, and as yet, they have no redress in law. The most powerful positions in politics, law, medicine, the military, police forces, industry, universities, and financial institutions are held almost exclusively by men. Although attitudes to equality have changed considerably in recent times, in the social sphere, actual practice lags far behind. For example, in a 1986 survey, 95% of the respon-

dents agreed that men and women should share housework. In reality, women do the lion's share.

## B. The Sociolegal Status of Males and Females

There are no differences between the legal status of male and female children. There are minor distinctions between male and female adolescents. For example, boys may work in bars at age 16 while women cannot work there until age 18. It is illegal for a male over age 14 years to have sexual intercourse with a girl under 17 years of age, but the girl commits no crime in the same situation. Homosexual acts under the age of 17 are illegal for males, but not for females. The government has recently promised legislation that will make discrimination on the grounds of sex illegal.

The social status of males and females is reflected in the gender roles demanded of each. From a very early age, girls begin to learn to prepare themselves for a traditionally feminine role in society and boys learn to prepare for a traditionally masculine role. The feminine role is regarded as having a sense of social value, while men regard themselves personally as superior to women. These attitudes are used as a justification for denying women equality and for the fact that political, social, and economic power is exercised by men.

## C. General Concepts of Sexuality and Love

The socialization process and gender-role stereotyping generally demands that sexual expressions belong properly to the married state of heterosexual men and women. The proper expression of sexuality within the marital union is limited to the act of penile-vaginal intercourse. An inability or lack of inclination to engage in coitus can be grounds for annulment of a marriage. Childless marriages are generally frowned on and the childless couple is considered selfish. Any overt or suggested sexual expression outside the privacy of the marriage bed is, at the very least, disapproved of. Within marriage, women are expected to be sexually available and to play second fiddle to their husband's sexual desires.

Sexual activity outside marriage in heterosexual relationships is tolerated to some degree, especially if it appears that the couple may eventually marry. However, different standards exist for men and women. Males are seen as sexual go-getters with instinctive sexual urges they cannot control. They are neither encouraged nor expected to take responsibility for the consequences of their behavior. Females are seen as sexually passive and in need of a male to awaken their relatively weak sexual desires. Because females are seen as more in control, they are held responsible for both their own and the male's sexual behavior. A further twist to the tale is that women must never undermine the male's dominant role in sex.

Romantic love is idealized and this ideal is perpetuated in all media forms. Romantic novels outsell all other types of fiction. Most people would say they married because they were "in love." People who say they are still "in love" after many years of marriage say so with pride.

The sexuality of children, disabled persons, the chronically ill, the elderly, those who live in institutions, and single persons without an opposite-sex partner is hardly acknowledged, let alone recognized and respected.

[*Comment 2003*: An older, Irish priest recalls the time when married women would confess to experiencing an orgasm when engaging in sex with their husbands. It was assumed that a woman engaged in sex just to satisfy her husband, and that she herself had low or no sexual desire. Consequently, women who experienced orgasm felt that this must have been the working of an evil spirit inside of them; therefore, she needed to confess and be forgiven. The young

people of Ireland today would find it hard to believe that such a mentality existed just a generation back.

["Boys will be boys and girls will be sluts" was an imbedded, male attitude. All examples employed by preachers made it clear that the female was responsible if a couple had sex outside of marriage. Since she did not have any sexual desire worth talking about, she could maintain her composure and control the urges of the aggressive male. (*End of comment by H. A. Walsh*)]

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A. Source and Character of Religious Values

The Irish are an outstandingly religious people. Over 90% of the population are Roman Catholic and 3% Protestant. Eighty percent attend church at least weekly and about 50% express a great deal of confidence in their Church. Among the younger generation, there is less acceptance of orthodox beliefs and religious practices, but the difference between generations is not nearly as great as that found in other Western countries.

Roman Catholicism greatly influences all aspects of Irish life. Since its foundation, the state laws have complemented Catholic Church laws. Until 1972, the Irish Constitution paid homage to the "special position" of the Catholic Church in Irish life. [*Comment 1997*: This resulted, until recently, in an unresolved issue of Church annulments vis-à-vis the constitutional prohibition against divorce. After the constitutional prohibition against divorce was revoked in a November 1995 referendum, it became possible for the estimated 80,000 separated Irish couples to obtain a civil divorce. The Church has, in recent years, granted annulments, dubbed "divorce Irish-style," and permitted remarriage, but annulments were and remain difficult to obtain from Church authorities. (*End of comment by H. A. Walsh*)]

[*Comment 2003*: Since the Irish are enjoying new wealth, the promise of "the grass of a goat and a cow" is ancient folklore to divorcing females today. If the divorcing husband has wealth, women are demanding their fair cut. Also, because of the new wealth of the country, thousands of Irish in America are returning home. Some are returning with second wives. The old put-down about "driving a second-hand car" (marrying a divorced person) has lost its sarcastic bite in today's Ireland.

State schools, which the majority of children attend, are mainly run by religious organizations. [*Comment 1997*: However, because of aging and a decline in vocations, many teaching and administrative positions in schools, once held by religious orders, are now filled by laity. This has caused some tension in recent years as lay educators become more conscious of having political clout. (*End of comment by H. A. Walsh*)] Religious bodies also play a major role in the provision of the country's nonprimary health-care services.

This pervasive religious influence is reflected in the way sexuality is treated on political, social, and personal levels. It is reflected in the type of censorship of books, films, and television programs that prevails. It is reflected in the laws relating to human reproduction, the lack of sex education in the schools, and the absence of the study of sexuality in any academic institution.

On a personal level, sex is associated with fear and guilt for many people, and even in communal, single-sex showers, nudity is unusual. There is evidence, however, of some decline in religious influence over the past ten or so years.

The Irish people as a whole are characterized by conservatism—conservative in religion, in morality, in poli-

tics, and in their views on work, marriage, and the family. Many Irish people are at ease with a republic that is traditional, nationalist, and Catholic. However, a growing number feel alienated in such a society.

[*Comment 1997*: Ease of travel has made the young people of Ireland less insular and more impatient with the insular mentality of the older generation. The youth of Ireland think of London, Paris, Frankfurt, and even Boston and New York, as "neighboring cities," and have exposure to lifestyles and value systems that their parents never had.

[Catholicism and nationalism were synonymous in the minds of the previous generation. To be Irish was to be Catholic. Some of Ireland's greatest writers went into exile because, although thoroughly Irish, they were not seen as Catholic enough. The young Irish today do not see Catholicism as a necessary component of self-identity. They seem to understand where culture leaves off and real faith begins. Consequently, they can discard elements of Catholic orthodoxy with greater ease and feel no guilt about being un-Irish when they do so. (*End of comment by H. A. Walsh*)]

[*Comment 2003*: The Roman Catholic Church in Ireland faces an enormous challenge in today's Ireland. For one thing, the trust level between Church and people has been damaged seriously by revelations of clergy sexual abuse. In the former Ireland, the common thinking was: If you had a doctor in the family, you were blessed; if you had a priest and a doctor in the family, you were saved. Parents are not holding up priesthood as an ideal to their children as they used to do. (*End of comment by H. A. Walsh*)]

For some, the shift towards greater permissiveness and tolerance that began in the 1960s is progressing too quickly, for others too slowly. There is a constant tension between old and new ideologies, between Catholicism and nationalism on the one hand, and liberalism and materialism on the other. Until recently, the battle lines were clearly drawn, but now some are attempting a synthesis of these seemingly contradictory values. Foremost in this attempt is the Irish President, Mary Robinson.

[*Comment 2003*: It is true that the Irish of the last generation packed their churches on weekends. However, the drop-off in church attendance by today's youth would lead one to ask: What brought the previous generation to church in such great numbers? Was it faith or fatherland? There was a saying in Ireland: "It's easier to go to church than to stay away, because, if you stay away, everyone will be talking about you." It was the cultural thing to do. Also, Ireland had been touched by the Reformation Wars through people like Henry VIII, Oliver Cromwell, and Queen Elizabeth I. So, to go to church was a patriotic act, a defiance of English Protestantism. To be Irish was to be Catholic. To be Irish and Catholic was to be anti-British and anti-Protestantism. To say that the Irish packed their churches because of pure faith would be an exaggeration. Faith they had, but not in its purest form, because nationalism was part of the mix. Because faith is a unifying force, the fact that the "faith" of the British and the "faith" of the Irish kept them fighting each other for centuries surely makes one wonder how "faith-ful" either was. So, if Irish youth are not attending church as regularly as the generation ahead of them, it may not indicate a lack of faith but, rather, a search for a faith that comes without the trappings of nationalism and cultural pressures. Church leaders who are crying in their Guinnesses over the fact that youth are not coming to church as faithfully as their parents did, need to understand that the old Reformation Wars have no relevance for young Irish boys and girls today. The biases that still work with some success in Northern Ireland are irrelevant to young people in the Republic. (*End of comment by H. A. Walsh*)]

## B. Source and Character of Ethnic Values

[*Comment 1997*: In the 4th century B.C.E., Celtic tribes invaded what is now Ireland, where their Gaelic culture and literature flourished. The Celtic worldview was dualistic, dividing the world into two opposing subworlds, one of light, good, and spirit, and the other of darkness, evil, sin, and body. In the 5th century C.E., St. Patrick converted the Celts to Christianity. Some anthropologists have suggested that a major factor in the negative and repressive view of sexuality that pervades Irish culture may be traced to the adoption of the original Celtic dualistic philosophy by celibate Christian monks who found it congenial to their own apocalyptic vision. (*End of comment by R. T. Francoeur*)]

[*Comment 1997*: Monasticism introduced an ascetical element into Irish spirituality. To this day, thousands of Irish seek out the barrenness of mountains and islands to do penance for their sins of the flesh. Suffering is seen as meritorious, something to be “offered up” in union with Christ on the Cross or for the release of “the poor souls in purgatory.” Since suffering was seen as meritorious, it was natural that pleasure would be suspect. Sex was “a stolen pleasure.” (*End of comment by H. A. Walsh*)]

[*Comment 1997*: In the 17th and 18th centuries, Irish youth were trained for the clergy in France where they were strongly influenced by another dualistic current, French Jansenism. The Jansenists saw the world torn between two opposing forces of good and evil. Jansenism stressed the corruptibility of human nature and its sinful, evil tendencies, associated the body and emotions with evil, and glorified the ascetic denial of all “worldly” desires (Messenger 1971; Francoeur 1982, 58-60).

[English invasions and colonization started in the 12th century, and the resulting 700 years of struggle, marked by bitter rebellions and savage repressions, have left their mark on Irish culture. English taxation, limits on industrialization, and restrictions on the kinds of crops Irish farmers could raise helped create a society in which marriage of the offspring was delayed to provide manual labor for the farm and support for the parents. In the system of primogeniture, the first-born son inherited the entire paternal homestead, because dividing up the farmland among all the sons would leave none with a viable economic base. With few other economic opportunities available, the other offspring frequently became priests or nuns, or emigrated.

[This combination of religious dualism and economic pressures has resulted in a society strongly dominated by the clergy and religious, with late marriages for those who marry, and a sexually repressive value system that holds celibacy and sexual abstinence in great esteem (Stahl 1979). (*End of comment by R. T. Francoeur*)]

In 1922, Northern Ireland chose to remain part of the United Kingdom, while the Irish Free State adopted a constitution as a British dominion. In 1937, the Irish Free State rejected dominion status and declared itself a sovereign democratic state. In 1948, the Irish Free State withdrew from the British Commonwealth and declared itself a republic.

[*Editor's Note*: John C. Messenger has provided extensive ethnographic observations of “Sex and Repression in an Irish Folk Community” in a small island community of the Gaeltacht he calls Inis Baeg (see Marshall & Suggs 1971).]

### 3. Knowledge and Education about Sexuality

#### A. Government Policies and Programs for Sex Education

Prior to 1984, the government had no formal policies regarding sex education. In that year, a 15-year-old girl and

her baby died during childbirth in a field in the middle of winter. She had not told anybody that she was pregnant. Following this tragic event, sex education became a matter of public and political debate. The Minister for Education planned a reform of secondary level education to include personal and social skills training, including sex education, in the new curriculum. The government's Health Education Bureau began training teachers to teach this new aspect of the curriculum. However, this reform was not implemented because of political, religious, and pressure-group opposition. Nonetheless, over 2,000 teachers have been trained so far to deal with sexuality and personal relationships. A criticism of this training has been that it does not place enough emphasis on how political, religious, economic, and social factors shape sexuality, values, and personal relationships.

In 1987, the Department of Education issued guidelines to postprimary schools recommending that sex and relationship education be integrated into all subjects. These guidelines also recommended that such education should not be secular and would require a religious input. Parents were to be fully involved in the process. Whether or not and how schools implement these guidelines is not known, but it appears that few schools have adopted them. In a *Green Paper on Education* (1992), the government proposed that future curricula will provide for “sexuality education appropriate to all levels of pupils, beginning in the early stages of primary education.”

The government-controlled Eastern Health Board has initiated a Child Abuse Prevention Program in primary schools. The program encourages children to exercise control, to be assertive, and to seek help for any problem. Critics claim that it dwells on negative aspects of sexuality, is too narrow in its scope, and places responsibility for avoiding abuse on potential victims rather than on adults.

It appears that there is wide variation in the ways in which individual schools provide sex education. Some provide none; others set aside a particular day or days and provide expert speakers. More frequently, it is incorporated into one or two school subjects, usually science and/or religion. Surveys reveal that the majority want a more comprehensive school sex education that begins early in schooling and is independent of religious instruction.

No information is available on the provision of sex education in special schools, such as those for mentally handicapped persons.

[*Comment 1997*: Higher education was not available to most Irish in the first half of the 20th century. The priests, schoolteachers, and local doctor, if the town had one, were the only ones with a higher education. This gave the clergy enormous power. Many of them were, for all practical purposes, mayors of the towns. With Irish universities turning out thousands of graduates today, the clergy have to deal with an educated youth. Older Irish people obeyed instinctively when the Church ruled on something. The young Irish today test the pronouncements to see if they make sense or not. If not, they say so. The older Irish were too superstitious to disagree with the Church (“God will get you for that”). The availability of higher education has resulted in young Irish men and women testing the ethical positions of Catholic orthodoxy. (*End of comment by H. A. Walsh*)]

#### B. Informal Sources of Sexual Knowledge

*The Durex Report—Ireland* (1993), designed to be statistically representative of the adult population aged 17 to 49 years living in the Republic of Ireland, found that the following were the main sources of sexual information: own friends, 36%; mother, 23%; books and magazines, 12%; religious teacher, 10%; lay teacher, 10%; father, 5%; and sis-

ters or brothers, 5%. Sixteen percent of this sample believed that the teaching of sex education should be directly influenced by their Church's teachings.

Another nationally representative survey carried out by *The Irish Times* (1990) found that 95% of urban dwellers and 92% of rural dwellers were in favor of providing sex education in the schools. A Health Education Bureau study in 1986 of a national random sample of 1,000 parents found that 64% learned about sex from friends, 37% from books, 23% from mother, 6% from both parents, 2% from father, and 11% from a teacher. Thirty-two percent stated that they had not themselves provided sex education for their children and one in three of these parents stated that they did not intend to do so.

Although sex education is firmly on the political and social agenda in Ireland, consensus has not yet been reached by those who control education on how it should be incorporated into the school curriculum. Meanwhile, the needs of children and adolescents go largely unheeded.

#### 4. Autoerotic Behaviors and Patterns

##### A. Children and Adolescents

The first Irish study of childhood sexual behavior (Deehan & Fitzpatrick 1993) assessed sexual behavior of children as perceived by their parents. It was not nationally representative and had a middle-class bias. More than half of the parents reported that their child had shown no interest in his or her own genitals. Boys were much more likely to show such interest, as were younger children. Thirty-seven percent reported that their child played with his or her genitals. Most parents said this occurred openly in the home. Sixteen percent described such play as self-pleasuring, most regarding this as a comfort habit or "nervous fiddling." It is probable that much childhood autoerotic behavior does not come to the attention of parents.

The impression that autoerotic behavior is common in adolescence comes from the frequency with which it is condemned by the clergy reacting to the frequency with which this "sinful behavior" is confessed, the high proportion of letters to "Agony Aunts" on the subject, and the frequent usage of slang words for self-pleasuring, particularly among adolescent boys.

[*Comment 1997*: Only 50 miles (80.5 km) separate Ireland from England, the home of Victorianism. During Victorian times, Ireland was occupied by England. The Victorian frenzy about masturbation crossed the Irish Sea, and with it much of the inaccurate "scientific" information about the health risks to those who masturbate, the so-called degeneracy theory. Both the Church and the medical profession reflected Victorian attitudes to autoeroticism in Ireland. Even the language of Victorian England crossed the Irish Sea, with masturbation being known as "self-abuse," "the solitary vice," and so on. However, the Irish have a way of molding the English language. While churchmen and physicians spoke of the "solitary vice" and "self-abuse," the native Irish began to speak of "pulling the wire" and "playing the tea pot." (*End of comment by H. A. Walsh*)

##### B. Adults

No studies have been carried out to indicate the extent or diversity of adult autoerotic behavior. There are indications that some men who engage in self-pleasuring during adolescence stop doing so when they reach adulthood because of the stigma of immaturity attached to it. This seems to be particularly so in the case of married men. In contrast, there are some indications that many women engage in self-pleasuring for the first time in adulthood. In recent years, there has been an increasing market for vibrators and other

sex toys in Ireland. Sexually explicit books, magazines, and videos have become increasingly available in recent years, and these undoubtedly sometimes play a part in autoerotic activities. Unusual autoerotic practices sometimes come to light through the work of coroners and doctors. One of these is the use of asphyxiation techniques to heighten sensation during self-pleasuring. Other examples are the use of penile constricting devices, or "cock rings." It appears, too, that drug use is sometimes associated with autoerotic activities.

#### 5. Interpersonal Heterosexual Behaviors

##### A. Children

In Deehan and Fitzpatrick's (1993) study, less than half the parents stated that their child had shown interest in the bodies of others. Where interest was shown, 46% mentioned the interest was in the mother's breasts or genital area; 25% mentioned sibling's genitals as the focus of interest. Sexualized play that involved looking at another child's buttocks or genitals was reported by 23% of parents. However, parents always qualified their answers by adding that this had only taken place in a situation where the child would need to be undressed.

When parents were read a list of possible sex games their child might have engaged in, 7% reported genital touching games and 4% said that their child had been lying on top of another child in imitation of a sexual act. Simulated intercourse or kissing or licking of the genitals was not reported by any parents. Thirteen percent of the children were reported to share a bed, usually with siblings. This was distinguished from children going regularly to the parents' or sibling's bed, which was reported by 64% and 39%, respectively. Bathing or showering with other family members occurred in 78% of 3- to 5-year-olds, 68% of 6- to 9-year-olds, and 33% of 10- to 12-year-olds. These situations provide opportunities for sexual exploration of which the parents would not necessarily be aware.

##### B. Adolescents

###### *Puberty Rituals*

There are no rituals to mark the milestone of puberty in Irish life. In the Deehan and Fitzpatrick (1993) study, parents reported having discussed breast development with 38% of daughters and 20% of sons, menstruation with 26% of daughters and 7% of sons, pubic hair development with 40% of daughters and 20% of sons, erections with 11% of sons and 5% of daughters, and wet dreams with 4% of sons and 3% of daughters. The vast majority of those children were prepubertal. An increasing number of primary school teachers are discussing puberty with their pupils.

###### *Premarital Sexual Activities and Relationships*

The only survey to date on premarital sexual activity in adolescence was conducted in 1991 by Ni Riordain among 2,000 female 12- to 17-year-old students in the province of Munster. It revealed that 25% of the 17-year-olds, 10% of the 15-year-olds, and 1% of the 12-year-olds had experienced sexual intercourse. In the same year, teenage extramarital births accounted for 26% of all extramarital births and 4.7% of all births. These figures suggest that the traditional religious and social taboos regarding premarital sex that were effective for so long are no longer so. It appears that adolescents are sexually active to a degree that would be unthinkable to their parents as adolescents. In addition to the change in adolescents' attitudes towards sex, there is the fact that today's teenagers also have greater freedom to meet and spend time with potential sexual partners. Mixed schools, teenage discos and other social events, trips away from home, and fewer social restrictions by parents provide

sexual opportunities that were not heretofore available. The formation of couple relationships with an understanding of some degree of exclusivity seems to be occurring at a progressively earlier age.

### C. Adults

#### *Premarital Courtship, Dating, and Relationships*

The most common pattern in premarital heterosexual relationships is that of a series of more or less "steady" relationships leading eventually to engagement and marriage. A "steady" relationship usually involves a high degree of mutual affection and sexual exclusivity. Partners usually get to know and socialize with one another's family and friends.

Dances, workplaces, colleges and other postsecondary educational institutions, and social networks, appear to provide the most opportunities for meeting prospective partners, but parents, in particular, are not slow in letting a son or daughter know that they consider a particular person to be an unsuitable partner.

Between "steady" relationships, there may be a series of short-lived relationships, and "one-night stands" seem to be increasingly common. Otherwise, there may be periods of varying length where people show no interest in close heterosexual relationships.

A decision to marry is usually marked by an "engagement," when the couple announce their intention to family and friends. Rings are usually exchanged and a celebration party held. Most couples in steady heterosexual relationships appear to engage in sexual intercourse, though this fact would rarely be openly acknowledged within their families. When such couples spend the night in a family home, they are usually shown to separate bedrooms. More and more couples are choosing to cohabit, often causing considerable conflict with family, particularly for women.

#### *Single Adults*

Little is known about the sexual behavior and relationships of single adults. The cultural imperative to marry is so strong that older single adults, especially women, are often referred to in pejorative terms. Despite this, more and more adults are remaining single. In 1986, 39% of the adult population were single.

#### *Marriage, the Family, and Divorce*

Until the 1960s, Ireland provided an example of a Malthusian population, such that although fertility was high, population growth was controlled through the delaying or avoidance of marriage. Since then, Ireland has moved rapidly toward a neo-Malthusian type of population control, with generally increasing nuptiality and declining marital fertility. In 1961, the crude marriage rate was 5.4 per 1,000 population. This rose to 7.4 in 1973, but has been declining since to 4.6 in 1993. The median age of marriage shows a similar pattern. In 1945-46, this was 33.1 years for grooms and 28 years for brides. This fell to 25 and 23.2, respectively, in 1977, but by 1990 had risen to 28.6 for grooms and 26.6 for brides.

The crude birthrate per 1,000 population remained more or less constant at around 22 until 1980. However, between 1961 and 1981, marital fertility declined 37%, with a corresponding increase in the extramarital birthrate. Since 1980, the crude birthrate has fallen dramatically to 15 per 1,000. The extramarital fertility rate has continued to increase, accounting for 16.6% of live births in 1991, with 28.6% of extramarital births being to teenagers. Marriage has declined in popularity in the past 20 years; women are having fewer children and having them at an earlier age.

As extramarital births increase, so have single-parent families. The 1991 census revealed that at least 16% of

households were single-parent families, with married couples with children making up 48% of the households. The vast majority of single parents are women. On average, they have lower incomes than other women with children and a higher risk of poverty. Most single parents are dependent on the state for their main or only source of income. Single mothers or fathers who cohabit are not classified as single parents.

Within two-parent households, there has been a change from the traditional pattern characterized by a dominant patriarchy, a rather severe authority system, and a generally nonexpressive emotional economy. There was a rigidly defined division of labor, with mothers specializing in emotionally supportive roles. The modern trend is toward a marriage where both husband and wife are expected to achieve a high degree of compatibilities based on shared interests and complementary differences. Rather than being defined and legitimized within closed communal systems, interpersonal relationships are geared toward individual self-development. Part of this trend is that an increasing number of married women are employed for wages, and more married men are assuming childcare and housekeeping duties.

*The Durex Report—Ireland* (1993) included questions regarding frequency of sexual intercourse, change in sexual behavior in relation to the awareness of AIDS, and the number of sexual partners in the previous 12 months. Daily coitus was reported by 2% of married and single adults. Forty-five percent of married and 25% of single people reported intercourse once or twice a week; 13% and 10%, respectively, reported a frequency of once or twice a month. Three percent of married and 36% of single people said they were not sexually active. Married men and women averaged 1.05 and 1.03 sexual partners, respectively, in the previous year. Single men averaged 2.72 partners and single women 1.25 partners in the previous 12 months.

Faithfulness within marriage is highly valued. In the 1983 *European Value Systems Survey*, 98% of the Irish respondents considered it as very important for a successful marriage. In the same study, 12% said they considered marriage to be an outdated institution; less than 1% were cohabiting. In law, a person may have only one husband or wife. Occasional instances of bigamy come to light.

In November 1995, Irish voters approved a referendum legalizing divorce. The original Irish Constitution had stated that "No law shall be enacted providing for the grant of a dissolution of marriage." A 1986 referendum on an amendment to allow divorce was rejected by 63.3% of the voters. Recent opinion polls suggest that the majority would now vote for such an amendment; the government proposed holding a second referendum in 1994. In the 1991 census, just over 2% of adults classified themselves as separated.

[*Comment 1997*: In December 1993, after a Matrimonial Home Bill had been approved by Parliament, the Republic's President, Mrs. Mary Robinson, sent the bill to the Supreme Court for a review of its constitutionality. This unexpected move appeared to be an effort to avoid a protracted battle in 1994, when the people were scheduled to vote again whether to legalize divorce. The matrimonial bill was intended to replace the traditional practice of almost always giving the home to the husband with joint ownership of homes in divorce settlements. After a year's delay, in November 1995, a scant majority of 0.4% of the voters, slightly over 9,100 votes out of more than 1.6 million votes cast in a country of 3.5 million people, legalized divorce. In mid-1996, the Supreme Court of Ireland rejected a challenge and confirmed the pro-divorce vote of November 1995. (*End of comment by R. T. Francoeur*)]

[*Comment 2002*: Divorce was forbidden by the Constitution. The referendum to amend the Constitution in 1996 led to a fight of Irish proportions. Anti-divorce campaigners ran with the slogan: "Hello divorce, goodbye daddy." The Catholic Church threw all its resources behind the anti-divorce campaign. Even the Pope intervened the day before the vote, calling on the Irish people to vote "no." Those favoring a change used some emerging, clerical sex scandals. They showed a picture of a prominent Irish Bishop who resigned after admitting that he had fathered a son in Connecticut. The caption read: "Let the Bishops look after their own families. Vote 'Yes.'" It seems that disgust over clerical sexual misconduct won the day—but not by much. The final vote was 50.3% in favor, 49.7% against. In round body numbers, the margin of victory was only 9,114 out of 1.6 million ballots cast. The one problem with the new Family Divorce Law is that its language is so incomprehensible that the average person will not be able to understand it, and it is so packed with clauses and subclauses, that even attorneys will have trouble interpreting it. It seems that all this padding was inserted to give the impression that a divorce would be difficult to get. Possibly the framers hoped that restrictions would make the bill more palatable. For example, the bill states that couples must be separated for four years before a divorce will be granted.

[Other indications that attitudes have changed in Ireland: It is no longer illegal for Irish women to travel abroad for an abortion; homosexuality was removed from the Criminal Code; between 1974 and 1992, the birthrate dropped by half; and, legal restrictions on the purchase of condoms were dropped. (*End of comment by H. A. Walsh*)]

### *Sexuality and the Physically Disabled and Elderly*

Attitudes about the sexuality of physically and mentally handicapped persons and the elderly are generally negative. In the training of teachers and health personnel who work with the handicapped and the elderly, sexuality is given little or no attention. Institutions in general make little provision for the sexual needs of their residents.

### *Incidence of Oral and Anal Sex*

The incidence of these sexual expressions is unknown. Oral sex appears to be relatively common and anal sex much less so. There are no legal restrictions on any of these activities.

## *6. Homoerotic, Homosexual, and Bisexual Behaviors*

Representation of heterosexuality as the only acceptable sexual expression is directly linked to the wider relationships between the sexes in society. The family, based on marriage, is promoted as the only valid social unit. Homosexual men and lesbian women are seen as a threat, and are marginalized, ostracized, and discriminated against. They can be, and are, dismissed from jobs and denied promotions. In custody proceedings, they can have their children taken from them on the basis of their sexual orientation. They cannot adopt children. They are the targets of pervasive social prejudice, often amounting to open hostility and physical assault.

The societal messages to which young people are exposed almost entirely omit the experiences, desires, and hopes of young lesbians and gay men, as they do with all minority groups. Those images that do occur are almost always negative stereotypes and caricatures. Young homosexuals face an even greater burden of sexual guilt and confusion than is the norm in other societies.

While little or no research has been carried out on homosexual experiences, it appears that these are common in adolescence, particularly for males. It may be just as common for girls, but the greater general tolerance for male sexual expression makes it more likely that one becomes aware of the male homosexual.

Gay men and lesbians tend to meet in particular bars, discos, saunas, and clubs. These are concentrated in cities, particularly in Dublin. Relationships formed can include brief anonymous sexual encounters, a series of sexual friendships, an open relationship with a primary partner, or a closed monogamous relationship. Cruising, in which sexual partners are sought in public places, such as parks and toilets, seems to be limited to gay men. Bisexual married men also appear to favor these outlets.

Telephone support and information lines are run in the major cities by gay and lesbian organizations. They also provide facilities for meetings and social events. Gay and lesbian publications are widely distributed, and publications by the Gay Health Action organization have been in the forefront in keeping all segments of the community informed about HIV infection and AIDS.

In 1993, the government repealed the existing law making homosexual acts between men in public or private illegal, giving all such acts the same legal status as heterosexual acts. The extent of the reform surprised many, since a more limited reform would have resolved a ruling by the European Court of Human Rights in 1988 that Ireland's laws on homosexuality were in breach of the European Convention on Human Rights. The government has also initiated introduction of specific legislation to outlaw discrimination on the grounds of sex and sexual orientation in both employment and social areas.

## *7. Gender Diversity and Transgender Issues*

Transvestism and transsexualism are so marginalized as to be almost invisible. However, people are generally aware of both phenomena and transvestism appears to be quite common. There are a number of transsexual people, but all would have undergone gender-reassignment surgery abroad. It is probable that most hospital ethical committees would not permit the procedure. At present, it is not possible to alter one's birth certificate to change the sex designated at birth. There are no legal restrictions on transvestism.

[*Comment 1997*: Transvestites have a way of acting out their transvestism that is culturally accepted. They can join a fife-and-drum band or belong to a troupe of traditional dancers, and wear kilts. (*End of comment by H. A. Walsh*)]

## *8. Significant Unconventional Sexual Behaviors*

### **A. Coercive Sex**

#### *Sexual Abuse, Incest, and Pedophilia*

In the past decade, there has been a growing awareness that child sexual abuse is common and widespread in Ireland. A 1987 survey of Dublin adults revealed an incidence of 6% for males and females. However, this survey asked only about digital-genital and penile-genital contact. There has been much controversy and some denial concerning child sexual abuse, but there are now signs of official recognition of the problem. An integrated approach involving different disciplines is being developed in an effort to reduce its incidence and to treat victims. Following the success of a recent pilot project, plans are to introduce a full treatment program for abusers. A Child Abuse Prevention Program has been introduced in primary schools, but is not universally sup-

ported. One criticism has been that it places too much responsibility on children for prevention of such abuse.

A 1989 study of 512 confirmed cases of child sexual abuse in a health board area revealed only 55 criminal prosecutions (10.7%). Sentencing ranged from a seven-year jail term to application of the Probation Act. Police statistics for 1991 include only six reported or known incest offenses, a gross understatement of actual incidence. Legally, a male is prohibited from having sexual intercourse with his daughter, granddaughter, sister, or mother, and a female from having intercourse with her son, father, grandfather, or brother. When the victim is under 15 years of age, the maximum penalty for convicted males is life imprisonment and for convicted females, seven years imprisonment. When the victim is over age 15, the sentencing varies greatly.

There is very little public discussion of pedophilia and its incidence is not known.

### [Clergy Sexual Abuse

[Update 2003: In the spring of 2001 and March 2002, documentaries produced and broadcast by the British Broadcasting Corporation (BBC) television and state network RTE reported on the life and 1999 suicide of a priest from Wexford, Ireland, who faced 29 charges of sodomy, sexual assault, and gross indecency, as well as dozens of other cases of clergy sexual abuse. The documentaries shocked the very-Catholic nation, forced the April 1, 2002, resignation of Bishop Brendan Comiskey, the bishop of Wexford, and brought charges against Dublin's Cardinal Desmond Connell, the nation's primate. In 2001, the Catholic Church in Ireland agreed to pay \$110 million in compensation to hundreds of people who were physically and sexually abused by priests and nuns in church-run, state-funded vocational schools. The Church and a special team of police and detectives appointed by the Prime Minister launched two internal investigations and one independent investigation. Early findings put St. Patrick's College in Maynooth, the country's most distinguished seminary, under a cloud following allegations that teenage pupils were sexually harassed by their teachers.

[The core of the scandal was that, despite hundreds of written and in-person complaints to the bishops, no action was taken by the priests' religious superiors. Also, in some cases reported after 1995 by church authorities to the Dublin police, the police took no action on the complaints. In many cases, as has happened in Australia, Canada, the United States, and elsewhere since the mid-1980s, the bishops responded by moving the accused priests to other parishes and jurisdictions. Some of the complaints dated back to the 1930s. In October 2002, the Government Minister for Health and Children said that a national investigation into abuse by Roman Catholic clerics would not be feasible. "How does one cope with the enormity of all of that? It could go on forever." At the same time, the head of the country's Bureau of Criminal Investigation said in an RTE radio interview that "Everything will be looked at, and it will be looked at systematically and collectively" (Lavery 2002ab; O'Brien 2002).

[On the last day of 2002, after a five-hour meeting with representatives of clergy sexual abuse victims, the Roman Catholic Archbishop of Dublin pledged the archdiocese's full cooperation with any police investigation into sexual-abuse allegations against priests. Cardinal Desmond Connell also promised the police full access to Church files, accepted a role for victims in shaping how the Church handles such matters in the future, and their involvement in improving structures for dealing with abuse and complaints (Hoge 2002). (End of update by R. T. Francoeur)]

### Sexual Harassment

Irish legislation does not specifically address the problem of sexual harassment. The Minister for Equality and Law Reform has indicated that such legislation will be introduced. Since 1985, victims of sexual harassment can pursue claims against employers under the Employment Equality Act. A survey of personnel managers, conducted by the Dublin Rape Crisis Center in 1993, found that incidents of sexual harassment had been brought to the attention of management in 40% of the companies. Half of the companies did not have a specific sexual harassment policy and 55% of these had no plans to introduce one.

### Rape

In 1991, 110 cases of rape were reported or known to the police, yet the Dublin Rape Crisis Center was aware of over 300 cases in the same year. Social and professional attitudes to victims of rape often encapsulate in stark form society's pervasive negative attitudes towards women. These very attitudes lead many victims not to report the crime. It is widely recognized that the number of rapes reported to the police represents a minority of the actual incidents.

The 1990 Criminal Law (Rape Amendment) Act extended the legal definition of rape to include penile penetration of the mouth or anus, and vaginal penetration with any object. This act also permits a married woman to charge her husband with marital rape. Conviction on charges of rape or other serious sexual assaults carries a maximum sentence of life imprisonment. Judges, however, possess complete discretion in sentencing, provided they take into account a Supreme Court ruling in 1988 that held that the normal sentence for rape should be a substantial prison sentence. Lenient sentencing is common and causes considerable public outrage.

### B. Prostitution

Female, and to a much lesser extent, male prostitution is practiced in the main ports, cities, and towns. Contact between prostitutes and clients occurs on the street, in massage parlors, and through advertising. Some prostitution is controlled by pimps.

Prostitution is not a criminal offense, but associated activities, such as soliciting in a public place, operating and managing a brothel, or creating a public nuisance, are felonies. The government has recently indicated that it intends to amend the laws on prostitution to make clients liable to prosecution for soliciting and to make "curb crawling" an offense. There is a high degree of tolerance towards prostitution in Ireland, as long as it is out of sight and mind.

### C. Pornography and Erotica

In 1926, the government appointed a Censorship Board with the power to prohibit the sale and distribution of material it considers indecent or obscene. Initially, books were its main focus of attention, and many works of literary merit, such as James Joyce's *Ulysses*, were banned. In 1946, an appeals procedure was introduced, and in 1967, the duration of each ban was reduced to 12 years. Customs and Excise officers are empowered to confiscate material they consider indecent or obscene. Pornographic books, magazines, and videos, mainly imported, are widely available, though they are not openly displayed or easily accessible.

## 9. Contraception, Abortion, and Population Planning

### A. Contraception

Until 1979, the law prohibited importation and sale of contraceptives, despite the fact that, in 1975, 71% of the

adult Dublin population supported the view that birth control was a basic human right. *The Irish Times* survey in 1990 found that 88% of the 18- to 65-year-olds favored the provision of contraceptive information in health education courses in schools. For over 20 years, the discrepancy has been growing between Catholic Church teaching on contraception and the actual practice of many Catholics. Yet, the progressive liberalization of contraception law since 1979 has lagged behind the changing public attitude.

The absence of a comprehensive school sex-education program, combined with the reluctance of most parents to discuss contraception with children and adolescents, means that many young people begin having sexual intercourse with little knowledge, and even less use, of contraception. Little attention has been paid to the needs of adolescents in this regard, mainly because, up to now, the focus has been on meeting the needs of adults.

According to *The Durex Report—Ireland* (1993), the main sources of information on contraception for 17- to 49-year-olds were: books and magazines, 31%; friends, 20%; television and films, 7%; and lay teachers, 6%. The preferred main sources of information were: parents, 35%; lay teachers, 22%; books and magazines; 10%; and government health agencies, 5%.

[*Comment 1997*: Before the advent of “the pill” and condom, the most frequent form of contraception in Ireland was coitus interruptus. Many an Irish woman was shocked to find that she was pregnant even though “he pulled out in time.” Also, men who could not get their hands on condoms were known to fashion their own from saran wrap. (*End of comment by H. A. Walsh*)]

All contraceptive methods are currently available in Ireland, although a person may have to travel a considerable distance for some methods, such as the IUD, diaphragm, or sterilization. Furthermore, the majority must pay for contraceptive services and supplies. Family planning clinics in the main cities and towns are the principle providers of comprehensive family planning services. These receive no government funding except for some educational and research projects. Some clinics have been providing recognized training for doctors and nurses for 20-some years, so that more and more family doctors are now providing fairly comprehensive family planning services.

A recent amendment to the family planning laws allows condoms to be sold to a person of any age with minimal restrictions. Male sterilization is provided in family planning clinics, some private and public hospitals, and by a few family doctors. Female sterilization is carried out in some private hospitals with varying preconditions. Many hospitals will not perform female sterilization for ethical reasons. Some voluntary organizations provide free instruction in natural contraceptive methods, the Billings cervical mucus, and related methods.

Respondents to *The Durex Report—Ireland* (1993) reported on contraceptive use as follows: condoms, 28%; the pill, 24%; natural methods, 9%; vasectomy and IUD, 3% each; female sterilization, 2%; diaphragm and other methods, 1% each. Fourteen percent reported using no contraception, and 12% reported not being sexually active. The condom is particularly popular among 25- to 29-year-olds, upper-social-class groups, and those living in urban areas. By contrast, natural methods are practiced almost exclusively by married couples over age 30 and those in rural areas. The pill is most popular among single women. (See additional comments in Section 1A, Basic Sexological Premises, Character of Gender Roles.)

No comparable survey has been carried out among adolescents. However, surveys in individual family planning

clinics have repeatedly found that a high proportion of teenage, first-time clients had been having unprotected sexual intercourse, sometimes for up to three years.

## B. Teenage (Unmarried) Pregnancies

In 1992, there were 2,435 live births to unmarried teenagers, representing 26% of extramarital births and 4.7% of all births. There has been a continuous rise in both extramarital and teenage unmarried births since 1981, even though the proportion of teens in the population has remained at about 13.3%.

Official statistics show that 700 unmarried teenagers of Irish residence had abortions in England and Wales in 1991. In addition, other Irish teenagers commonly give an English or Welsh address. There is no way of knowing how many unmarried, pregnant teenagers had miscarriages, illegal abortions, or concealed the birth of their babies.

Whatever the actual figures, an appreciable number of Irish teenagers are experiencing unplanned pregnancies each year. In contrast to former times, most pregnant teenagers do not marry. Most have and rear the child themselves, usually with the help of the family and/or partner. About 20% have an abortion and a small number give up the baby for adoption. All unmarried parents are entitled to a means-tested state allowance. In 1984, 42% of Irish teenagers who had an abortion in England or Wales had not used contraception on most occasions when they had sexual intercourse, and 83.4% were not using contraception at the time they became pregnant.

### [*Magdalene Asylums for “Fallen Women”*]

[*Update 2002*: In the 19th century, the Roman Catholic Church opened up what were called Magdalene Asylums as refuges for “fallen women.” Some of the Magdalene women were prostitutes or unwed mothers, but others were committed to the asylums because, in some small way, they had violated the very conservative social mores of the time or ignored the Church’s moral code, bringing shame and dishonor on their families. Operated with state approval by the Sisters of the Good Shepherd and other religious orders of nuns, the Asylums and orphanages were, in fact, self-supporting workhouses, functioning as commercial laundries for schools, prisons, and other institutions. Inmates worked long hours, seven days a week, and 364 days a year with only Christmas Day off. They received no pay, praying nonstop out loud, even while working, to prevent the girls from talking with each other. The women were so completely cut off from the outside world, many stayed in the Asylum until they died and were buried in unmarked graves in prison cemeteries. The babies of unwed mothers were given up for adoption or sent off to orphanages. Over the decades, some 30,000 young women were sent to the Magdalene Asylums. The Asylums were named after Mary Magdalene, the patron of prostitutes who repented and washed the feet of Christ.

[News stories about the 1996 closing of the last Asylum, coupled with the growing scandal of clergy sexual abuse and its coverup by both Church and state, triggered a series of biting exposés of the casual abuse and cruelty that characterized the Asylums, workhouses, and orphanages. One of the most influential of these documentaries was *The Magdalene Sisters*, which received the Golden Lion award for best film at the Venice Film Festival in 2002. The film was seen by over a million people, one quarter of Ireland’s population (Lyall 2002). (*End of update by R. T. Francoeur*)]

## C. Abortion

The Offenses Against the Person Act (1861) makes abortion illegal in Ireland. However, in 1992, the Irish Su-

preme Court ruled that abortion was permissible where pregnancy posed a real and substantial risk to the life of the pregnant woman. Both pro-choice and antiabortion groups campaigned for further action to clarify this ruling. A referendum followed in which the people rejected an amendment to the Irish Constitution that would allow abortion only where there was a real and substantial risk to the life of a pregnant woman, with the exception of a risk of suicide. At press time, legislation by the government was still pending to give effect to the Supreme Court ruling.

In 1983, the people had voted for an amendment to the Constitution that would have prevented any possible future legislation to allow abortion. Ironically, it was the wording of this amendment that facilitated the 1992 Supreme Court ruling.

Following the 1983 referendum, the court ruled that provision of information and counseling services concerning abortion were illegal. Legal opinion also held that a pregnant woman could be restrained from travelling abroad for an abortion. In 1992, an injunction was obtained prohibiting a pregnant 14-year-old alleged rape victim from having an abortion in England. This was appealed to the Supreme Court and led to the latest ruling mentioned above.

In the 1992 referendum, the people also voted in favor of amendments to the Constitution to allow dissemination of information on abortion and freedom of pregnant women to travel abroad for an abortion. Legislation giving effect to these amendments is also awaited. Opinion polls have indicated that the majority of Irish adults approve of abortion where the pregnant woman's life or health is at risk.

In 1991, 4,154 women who gave Irish addresses had abortions in England and Wales. It is not known how many Irish women giving other addresses have abortions each year. The majority of these women go to private, fee-paying clinics. Because of the ban in Ireland on providing abortion information, counseling, and referral, many of these women travel abroad unaware of and unprepared for what is ahead of them. Many have never been outside Ireland previously. Despite the ban, some organizations and individuals continue to provide nondirective counseling and abortion referral, although these sources will be hard to find for many women in need of such information. It is probable that many women experiencing complications following an abortion are afraid to seek help from medical personnel in Ireland.

[*Update 2002:* In March 2002, despite vigorous opposition from the Catholic Church, the Prime Minister, and the majority Flanna Fail party, Irish voters rejected a referendum that would have further tightened Ireland's already strict limits on abortion. This was the fifth time since 1980 that Irish voters have rejected such legislation. This latest referendum would have overturned a ruling that allowed abortion if the woman threatened suicide, and set a 12-year prison term for violations. It also protected existing rights of women to obtain abortions abroad and of women's advocacy groups to distribute information about overseas clinics, where an estimated 7,000 Irish women obtain abortions each year. As of 2002, Ireland and Portugal, both overwhelmingly Catholic, were the only European Union nations with strict laws against abortion (Gerlin 2002). (*End of update by R. T. Francoeur*)]

#### D. Population Control Efforts

The Irish government has no stated position on population growth or reduction. With the exception of the period between 1961 and 1986, the population has been decreasing since figures were first officially recorded 150 years ago. A high emigration rate has more than offset the traditionally

high fertility rates. Almost every family in Ireland has a personal experience with emigration. In the past, most emigration has been motivated by the prevailing economic and social conditions.

### 10. Sexually Transmitted Diseases and HIV/AIDS

#### A. Sexually Transmitted Diseases

##### *Incidence, Patterns, and Trends*

All sexually transmitted diseases are officially reportable in Ireland. However, the number of cases reported to the Department of Health is low and widely acknowledged as representing only a small proportion of the total. A 1979 study by Freedman et al. estimated that reported cases of syphilis represented only 24% of the probable total and reported gonorrhea cases less than 10% of the probable total. The total number of reported STD cases increased from 1,823 in 1982 to 4,619 in 1988 before decreasing to 3,858 in 1991. Overall, there has been a rise of about 400% in the number of cases reported annually between 1972 and 1991. The majority of cases reported are those treated in STD clinics, and these represent a small proportion of all STD cases. Statistics from the STD clinic in the city of Cork show a decline in the number of new cases between 1985 and 1989, with a considerable increase each year since. Genital warts is the most common condition encountered in this clinic, increasing by 63% between 1985 and 1991, while gonorrhea decreased dramatically in the same period.

##### *Treatment and Prevention Efforts*

Treatment for STD is available free of charge at STD clinics in the main cities and towns. Treatment is also available from specialists in private practice and family doctors. Thirty percent of the population is entitled to free medical treatment by family doctors. Until the appointment of a full-time consultant in genitourinary medicine in 1988, clinic services were poorly developed, understaffed, and overcrowded. Since 1988, the situation has improved, but many parts of the country still have no clinical services.

Patients are encouraged to contact partners at risk. If they fail to do so, some clinics will make the contact themselves with the patient's permission. In the 1979 Freedman et al. study, one in five family doctors was interviewed by phone about treatment of STDs. Six percent had seen no STD cases in the previous 12 months. The vast majority had not seen a single case of syphilis or gonorrhea in a woman and a very small number saw more than two cases in the prior 12 months. More than half saw at least one case of male gonorrhea; 4% saw ten or more cases. At the time, the male/female ratio of syphilis and gonorrhea cases was 8.4:1 and 8.5:1, respectively. Over two thirds of the family doctors said they would diagnose and treat cases of STD themselves; 18% would use laboratory tests, and 51% would treat on the basis of clinical diagnosis alone. Unfortunately, there is no more-current data on STD treatment in Ireland.

Only in very recent years has an effort been made to educate the public about STD symptoms, treatment facilities, and prevention. Leaflets on these topics are now produced by the Department of Health, STD, and Family Planning Clinics. STDs are sometimes discussed on radio programs.

#### B. HIV/AIDS

By April 1993, over 70,000 HIV tests had been administered in Ireland. Of these, 0.5% were positive, with intravenous (IV) drug users representing 52% of those who tested positive, with homosexuals 18% and heterosexuals 13%. Among the 341 persons diagnosed as having AIDS, 40%

were IV-drug users, 35% were homosexual or bisexual, 10.5% were heterosexual, 7% hemophiliac, and 2.8% were babies.

All blood donors have been tested for HIV since the mid-1980s. Since November 1992, women attending antenatal clinics and pregnant women having blood tests for rubella status have had anonymous (unlinked) HIV testing. Consideration is being given to similar testing of IV-drug users and those attending STD clinics to ascertain the incidence of HIV infection in these populations.

The vast majority of those suffering from AIDS are treated at a Dublin hospital that is finding it more and more difficult to cope as the numbers increase. Efforts are now being made to concentrate medical care for AIDS patients in primary healthcare settings.

In Ireland, the gay community reacted swiftly and effectively to the AIDS epidemic. A 1989 survey of gay men found that there had been a major swing to safer sex practices, and that this had resulted primarily from education and information campaigns initiated by the gay community. For IV-drug users, the government has initiated a methadone-maintenance and needle-exchange program. This is concentrated in satellite clinics around Dublin. A national AIDS committee advises the Minister of Health on various aspects of AIDS. This has led to wider availability of condoms and government-sponsored advertising about HIV infection in the media. These prevention efforts are supplemented by school sex education programs, but the availability and effectiveness of these, as discussed earlier, is highly suspect. Many nongovernment bodies, such as trade unions, have initiated their own prevention programs.

[Update 2002: UNAIDS Epidemiological Assessment: By the end of December 1999, there were a cumulative total of 691 cases and 349 deaths. Injection drug users accounted for the largest number, 280 (40.5%), of cases of AIDS, homosexual/bisexuals accounted for 237 cases (34.2%), heterosexuals for 92 (13.3%), and the remaining 82 cases (11.9%) was composed of hemophiliacs, children, and others. By mid 2001, a cumulative total of 2,469 cases of HIV infection were reported. The latest breakdown of HIV infection data from the HIV Surveillance System showed at the end of December 1999 that 41.6% of the reported 295 cases were among injection drug users, 22.7% among homosexuals, 18.8% among heterosexuals/unspecified risk, and the remainder (16.9%) was made up of hemophiliacs, children, and other categories.

[The progress of HIV infection and AIDS is monitored through the National System of Surveillance in Ireland. The available data include the AIDS reporting system and the laboratory information on HIV Surveillance. The AIDS reporting system is based on clinical events that are reported by the regional AIDS coordinators to the Department of Health and Children. A number of laboratories throughout Ireland perform HIV testing, and confirmatory tests are carried out in the Virus Reference Laboratory. The HIV Surveillance System is supplemented by an anonymous unlinked antenatal HIV-testing project and a linked antenatal HIV-screening program introduced during 1999.

[The Irish data indicate a relatively low incidence of known HIV-positivity, with approximately 150 new cases per year in a population of 3.6 million (4 per 1,000). It is important that the HIV data reflect the true overall transmission rates, and in this context, the reporting system will include new developments. These include HIV case-based reporting, adjustments for reporting delays, and additional surveillance data, including HIV infection in high-risk groups, including prisons, drug treatment clinics, and sexually transmitted infection clinics. The most recent HIV sta-

tistics indicate that interventions with injection drug users are effective in reducing transmission rates in this group. While Ireland has a low prevalence of HIV/AIDS, transmission has increased significantly in the heterosexual category, and prevention programs are reflecting the new epidemiological data.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	2,200 (rate: 0.1%)
Women ages 15-49:	660
Children ages 0-15:	190

[Less than 100 adults and children died of AIDS during 2001.

[No estimate is available for the number of Irish children who had lost one or both parents to AIDS and were under age 15 at the end of 2001. (*End of update by the Editors*)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

### A. Concepts of Sexual Dysfunction

Irish society defines healthy sexuality differently in many respects for men and women, young and old, rich and poor, and able-bodied and disabled persons. Consequently, cultural definitions of sexual dysfunction depend on who is doing the defining and which people they are talking about. Those who define sexual dysfunctions are often the same people who treat it. In many instances, the definitions current in professional circles in Ireland reflect and reinforce cultural stereotypes of what is considered socially appropriate gender and sexual roles. Those seeking treatment are usually as culture-bound as professionals in their concept of what is sexually dysfunctional or unhealthy.

### B. Availability of Counseling, Diagnosis, and Treatment

Kieran (1993) sent questionnaires to 201 organizations and individuals who appeared to practice psychosexual counseling and sex therapy. Psychologists, social workers, and doctors made up the majority of 75 respondents. Most worked in private-practice settings and doctors were the most common source of referral. The responses are the only perspective on sexual therapy in Ireland.

While there are psychosexual therapists who practice a more psychosomatic approach; they are in a minority. The most common theoretical element shared by the respondents was a behavioral approach.

In the survey, sexual problems were defined in terms of symptoms, for example, vaginal spasms, erectile dysfunction, and early ejaculation. Symptom relief is regarded as a successful outcome in sexual therapy. This symptom-oriented approach is also evident in the enthusiastic manner in which many people have embraced the latest "cure" for "erectile dysfunction," namely, pharmacologically induced penile erections.

Government-funded psychosexual therapy services are not available, except on an ad hoc basis by some public health personnel. Most family planning clinics provide this service, as do organizations such as the Catholic Marriage Advisory Council and the nondenominational Marriage Counseling Services.

There are no legal or other restrictions on who may practice as a psychosexual therapist in Ireland. Although all respondents to Kieran's survey stated that they had undergone training in counseling, no indication of the quality of such training was given. Forty percent of the respondents had received no specific training in psychosexual counseling or sex therapy; 70% were receiving supervision. Training,

professional standards, and accreditation were the most common concerns of the respondents.

## 12. Sex Research and Advanced Professional Education

Little sexological research is carried out in Ireland. No university or other tertiary educational institution has a graduate or postgraduate program on sexuality. Nor is there any formal program for sexological research in any of these institutions.

The only sexological organization working in Ireland is the Ireland Region of the British Association of Sexual and Marital Therapists. Address: 67 Pembroke Road, Dublin 4, Ireland.

## *Demographics and a Brief Historical Perspective*

ROBERT T. FRANCOEUR

### A. Demographics

At the eastern end of the Mediterranean Sea, in the Middle East, Israel is a small nation, long and narrow in shape, about the size of the state of New Jersey. Its western border is the Mediterranean Sea. On all other sides are Arabic, predominantly Muslim, nations—Egypt, Syria, Jordan, and Lebanon, most of which are in a state of war with Israel since its declaration as a Jewish state in 1948. Israel's 7,847 square miles (20,324 km<sup>2</sup>) include a western fertile coastal plain, a well-watered central Judean Plateau, and the arid Negev desert in the south. The climate is temperate, but hot and dry in the southern and eastern desert areas.

In July 2002, Israel had an estimated population of 6.02 million. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.) The 6.02 million population includes about 182,000 Israeli settlers in the West Bank, about 20,000 in the Israeli-occupied Golan Heights, fewer than 7,000 in the Gaza Strip, and about 176,000 in East Jerusalem (August 2001 estimates).

**Age Distribution and Sex Ratios:** 0-14 years: 27.1% with 1.05 male(s) per female (sex ratio); 15-64 years: 63% with 1.01 male(s) per female; 65 years and over: 9.9% with 0.75 male(s) per female; Total population sex ratio: 0.99 male(s) to 1 female

**Life Expectancy at Birth:** Total Population: 78.86 years; male: 76.82 years; female: 81.01 years

**Urban/Rural Distribution:** 90% to 10%

**Ethnic Distribution:** Jewish: 80.1% (Europe/American-born: 32.1%; Israel-born: 20.8%; Africa-born: 14.6%; Asia-born: 12.6%); non-Jewish: 19.9% (mostly Arab) (1996 est.). In 75 years, Israel's population has increased tenfold, while the Jewish population multiplied by fiftyfold from about 85,000 Jews in 1918 to more than 4,140,000 Jews in 1992.

\*Communications: Ronny Shtarkshall, Ph.D., 15 Yasmin St. (Box 1116), Mevasseret-Zion, Israel 90805; ronys@md2.huji.ac.il.

(CIA 2002)

**Religious Distribution:** Jewish: 80.1%; Muslim: 14.6% (mostly Sunni Muslim); Christian: 2.1%; other: 3.2% (1996 est.)

**Birth Rate:** 18.91 births per 1,000 population

**Death Rate:** 6.21 per 1,000 population

**Infant Mortality Rate:** 7.55 deaths per 1,000 live births

**Net Migration Rate:** 2.11 migrant(s) per 1,000 population

**Total Fertility Rate:** 2.54 children born per woman

**Population Growth Rate:** 1.48%

**HIV/AIDS** (1999 est.): Adult prevalence: 0.08%; Persons living with HIV/AIDS: 2,400; Deaths: < 100. (For additional details from www.UNAIDS.org, see end of Section 10B.)

**Literacy Rate** (defined as those age 15 and over who can read and write): 95% for Jews and 70% for Arabs; education is free and compulsory from age 5 to 15

**Per Capita Gross Domestic Product** (purchasing power parity): \$20,000 (2001 est.); Inflation: 1.1%; Unemployment: 9%; Living below the poverty line: NA

Israel is the only country where the society is predominantly Jewish and the Jewish culture dominates. This is a source of difficulty in understanding sexuality in Israel. First, Western cultures do not always appreciate the extent to which Christian teachings differ from Jewish teachings in matters relating to sex and sexuality. (Outside of Israel, large Jewish communities living within dominant Christian cultures have acquired some of the host culture constructs.) This problem is aggravated by a methodological difficulty: Some of the common analytical tools and theoretical frames of reference used to explain sexual issues, especially gender ones, are somewhat lacking, because they are anchored in alien, mainly English-speaking, cultures.

## B. A Brief Historical Perspective

In the southwest corner of the Middle East's ancient Fertile Crescent, the land of Israel contains some of the oldest evidence we have of agriculture and the earliest town life. By the 3rd millennium before the Common Era, civilization had made significant advances in the area. The Hebrew people probably arrived sometime during the 2nd millennium B.C.E. Judaism and the land of Judea prospered under King David and his successors between 1000 and 600 B.C.E. After being conquered by the Babylonians, Persians, and Greeks, Judea again became an independent kingdom in 168 B.C.E. However, within a century, the land was occupied by the Romans. Rome suppressed revolts in 70 and 135 of the Common Era, and renamed Judea Palestine, after the Philistines who had inhabited the coastal land before the Hebrews arrived.

Arab invaders conquered the land in 636. Within a few centuries, Islam and the Arabic language became dominant, and the Jewish community was reduced to a minority. During the 11th to 13th centuries, the country became a part of the Seljuk, Mamluk, and Ottoman empires, although the Christian Crusades provided some temporary relief from Islamic culture between 1098 and 1291.

During four centuries of Ottoman rule, the Jewish population declined to about a third of a million people in 1785. As the Ottoman Empire collapsed in World War I, Britain took over control of the land in 1917; the Balfour Declaration pledged support for a Jewish national homeland there as anticipated by the Zionists. In 1922, the land east of the Jordan River was detached.

Jewish immigration, which began in the late 19th century, swelled in the 1930s as Jews fled the rising tide of Nazi persecutions. At the same time, Arab immigration from Syria and Lebanon also increased. Arab opposition to Jewish immigration erupted in violence in 1920, 1921, 1929, and 1936. After the turmoil of World War II, the United Nations General Assembly voted to partition Palestine into an Arab and a Jewish state. In 1948, Britain withdrew from the country and Israel declared itself an independent state. The Arab world rejected the new state, and Egypt, Syria, Jordan, Lebanon, Iraq, and Saudi Arabia invaded, but were defeated by Israel, which incorporated new territories. In separate armistices signed with the Arab nations in 1949, Jordan occupied the Left Bank of the Jordan, and Egypt occupied the Gaza Strip in the south, although neither granted Palestinian autonomy.

An uneasy truce prevailed until the Six Day War of 1967 erupted when Egypt tried to reoccupy the Gaza Strip and closed the Gulf of Aqaba to Israeli shipping. The war ended with Israel taking the Gaza Strip and occupying the Sinai Peninsula to the Suez Canal, and capturing East Jerusalem, Syria's Golan Heights, and Jordan's West Bank.

Egypt and Syria attacked Israel on Yom Kippur of 1973. Israel drove the Syrians back and crossed the Suez Canal into Egypt. In the disengagement agreement of 1974, Israel with-

drew from the Canal's West Bank. A second withdrawal followed in 1976, and Israel returned the Sinai to Egypt in 1982. In 1979, Egypt and Israel signed a peace treaty, ending 30 years of war. A 1978 terrorist attack from southern Lebanon led to an Israeli invasion. The violence and terrorism has continued, with Israel responding to the 1982 wounding of its ambassador to Great Britain by surrounding and entering West Beirut, and a military occupation by Israel of the West Bank and Gaza Strip.

Civilian unrest and military conflict has intensified in recent years marked by two Palestinian uprisings, called *intifadas* (literally, the shaking off). The First Intifada, 1987 to 1991, was followed by a period of relative quiet and reconciliation from the early to mid-1990s, with hope for a settlement to all Israeli-Palestinian hostilities. In September 1993, the Oslo Agreement was seen by many as groundbreaking and a first step to a firm and lasting peace. But after the 1996 assassination of Prime Minister Yitzhak Rabin by a fundamentalist Jew opposed to Israel giving up any of its occupied territory, the peace process slowed down to a grinding halt. The Palestinians living in the occupied territories did not see their living conditions improve. Additionally, Israel did not begin to withdraw from settlements in the occupied territories, which the Palestinians viewed as one of the largest obstacles for peace. Instead, their population almost doubled in the West Bank, even though few new settlements were constructed. This, along with sporadic attacks from Palestinian militant groups and the retribution from the Israelis, made the situation untenable.

The second intifada, the "al-Aqsa Intifada," began in 2000 with the death of the Oslo Agreement and the failure of a summit between U.S. President Bill Clinton, PLO Chairman Yassir Arafat, and Israeli Prime Minister Ehud Barak. In the wake of the controversial visit of Ariel Sharon to the Temple Mount, renewed violence erupted with a new wave of suicide bombers, and many more deaths among the Palestinians than among the Israelis, as the Israeli army reoccupied the West Bank enforcing strict military law, sealing off the Gaza Strip, and imposing economic and travel restrictions on the Palestinians. The Israeli security forces instituted targeted assassinations of Palestinian militants, and destroyed the homes of suicide bombers' families. With Mr. Arafat isolated by the Israelis, a new Palestinian prime minister was chosen. In mid-2003, with a new "road map" for peace, U.S. President Bush applied very strong pressure on Israel's Prime Minister Ariel Sharon and Palestinian Prime Minister Mahmoud Abbas, even as Palestinian opposition to Mr. Abbas increased and the prospects of peace appeared increasingly remote. At this writing, a new truce seemed at risk over the conflicting need for Israeli security and Palestinian demands for troop withdrawals and the return of prisoners.

## 1. Basic Sexological Premises

### A. Character of Gender Roles

Judaism paints an ambivalent attitudinal picture in regard to women. It is certainly patriarchal in nature. The prayer a man recites three times a day includes a blessing for not being made a woman. On the other hand, the Shabbat blessing includes a praise glorifying the woman of valor. She is described in a traditional role of wife, mother, and homemaker. When a person is commanded to honor his parents, mother and father are mentioned explicitly and not the general form or the masculine one. A man is ordered to leave his mother and father and literally "stick" to his wife, while she is never ordered to leave her parents.

Gender and gender roles are viewed in a more traditional manner in Israeli sociocultural reality than elsewhere in Eu-

rope or North America. Already mentioned are several unique conditions that contribute not only to the perception of gender roles and the division of labor that are the public domain of family life, but also to concepts of intimacy and roles in sexual relations.

Service in the army reserves also contributes to the fixation of traditional roles of men and women beyond the military service at young adulthood. Men serve in the reserve forces a significant part of their adult life, typically 7 to 8%, but some as much as 25% of their time, annually, until they reach the age of 45 to 50. This fact has to be coped with within the family, and essentially exerts its influence on the balance of family life emotionally, as well as on the division of labor within the family balance of power, and the burden of physical and emotional responsibility of women to the children. Many children grow up with the ongoing worry about the danger to the life of the father, but also with stories that include macho and aggressive overtones. The exemption of women from reserve service on their first pregnancy, understandable as it is, only stresses the role division (see also Section 5C, Interpersonal Heterosexual Behaviors, Young Adults).

## B. Sociolegal Status of Males and Females

### *Children*

Legally, the rights of male and female children are fully equal. They inherit equally, are viewed with no distinction in terms of rights for protection by state authorities, and have the same rights for education and welfare in case of need.

Another law that has a bearing on sexual and familial issues is the prevailing legal situation (both in civil code and religious law), that there is no flaw in the legal status of a child born out of wedlock. This is sometimes used by religious authorities as an additional argument against granting abortions for unmarried women.

The only gender difference in the legal status of children is part of the religious family law that favors giving custody over girls to the mothers, while favoring fathers in the case of boys over the age of 6.

### *Adolescents*

During adolescence, the legal status of boys and girls becomes somewhat different, mainly in regard to age of consent for sexual intercourse and the legal age of marriage, while their basic sociolegal rights remain equal.

The differences are in statutory rape laws—a concept that does not exist for boys. This creates an anomalous situation when a boy, who is more than two to three years younger than a girl of 14 or 15, has intercourse with her, opening him to the charge of rape in strict legal terms.

Despite this, the law does not distinguish between minors when it comes to sexual intercourse or molestation by authority figures, such as parents, caretakers, and professionals like teachers, psychologists, or physicians. Both males and females are considered under the protection of the law until age 21.

Another difference is the explicit permission needed to grant a minor girl an abortion without the knowledge and consent of her parents (see Section 9C, Contraception, Abortion, and Fertility Planning, Abortion). The practice is an extension of the rule that allows physicians to give minor girls treatment for preventing abortions, i.e., contraceptives, without the consent of their parents. This widespread interpretation of the law is never challenged in the courts.

### *Adults*

The situation becomes more complicated when females and males reach adulthood. In addition to the complications of family law and the interaction between a predominantly

nonobservant population with state-enacted and enforced orthodox laws and legal system mentioned above, there are several other issues of personal standing in which the issues of gender arise.

Only a few years ago, the income tax laws were changed so that the designation of “head of family” was struck and married women acquired independent standing. Prior to that, women’s earnings were treated as a joint income of the family. The term “head of family” was applied to the husband, unless it was a one-parent family headed by a woman.

An increased percentage of women participate in the labor force. While in 1967, only about 25% of the women worked outside their household, their number passed 40% in 1980 and reached 49% in 1992. Despite their increasing numbers in many economic branches, and higher positions, women still suffer from lower wages for equivalent work, and from lower chances for advancement within a specific area.

The equal opportunity law does not permit discrimination on the basis of gender, and even demands that advancements for work be directed toward both genders.

There is a public campaign now for corrective or compensatory discrimination. Many men and women object to this proposal because they believe that women in Israel do have some offsetting advantage because they do not serve in the reserves, a fact that many employers appreciate.

Another point is the fact that several of the labor laws, especially those dealing with maternal leave, shorter working hours for mothers of small children, and the inability to fire pregnant women burden employers with additional expenses and restrict their ability to compete in an open market. This seems to be a case where what was perceived to be an advanced social law less than 30 years ago may be inappropriate in the new political climate.

Another economic burden and female advantage that both employers and politicians cite is the differences in the pension laws and regulations. Women, whose life expectancy at birth is 79, 3.6 years longer than men (75.4), retire five years earlier than men at age 60. In the public campaign to change the rules, women won the right to choose their age of retirement, but men still have to work until age 65 in order to earn their pensions. Thus, the time that pension funds expect to pay most women is almost nine years longer.

This condition is aggravated by the fact that pension rights to which the surviving member of a couple is entitled are strongly in favor of women, who can receive up to 40% of their partner’s salary, while in the rarer cases of a man surviving his wife, he can receive about 15% of hers. Several advocates of labor reform claim that any such changes will need to deal at the same time with all the structural differences between men and women, otherwise the system will not be able to carry the economic burden, and will also move from one form of discrimination to another, instead of toward egalitarianism.

### *[Issues of Sexual Rights]*

[Update 2002: The national elections of May 1999 and early 2001 illustrated a social phenomenon that has been emerging for a few years, a sectorial fragmentation of the Israeli society and the loss of power of a unifying common core. This is expressed in the political arena by the ideological parties losing their power. About 40% of the seats in the Parliament are held by sectorial parties acting as three large sectorial blocks: Arabs, immigrants from the former Soviet Union, and the religious party of Jews of Middle Eastern origin. On one hand, this has heightened the political power of organized religion; on the other, it has made the secular sector more militant. Nonorthodox religious movements embedded in the U.S.A., namely the reform and conservative

movements, are gaining popularity and power and are using the Supreme Court to force some issues around marriage-divorce laws. This weakens the traditional ties between church and state. On the other hand, the public discourse is currently characterized not only by the intensity of the differences, but by exaggerations and sensationalism in their expression.

[Israel's Supreme Court is also the focus of change around other issues of sexual rights. The most recent case concerning the rights of homosexuals, decided in May 2000, was the registration of a child born to a lesbian woman as the adopted son of her female partner. The boy is now being raised by two official mothers, one biological and one adoptive. In the last two years, the Supreme Court also ordered the military to accept women into some of the most exclusive courses: flight and flight navigation training and navy ensigns. In 1999, two women graduated from flight school and one of them was already flying combat missions early in 2000. On the basis of that decision, a few women applied to be trained in the air force rescue team and to other combat units. This is a conceptual revolution in the military, which since the end of the war of liberation in 1949 excluded women from combat units. Three women are now one-star generals. A retired head of the women's corps was recently appointed to head the prison service. In the civilian domain, the court ordered affirmative action in appointing women as directors to companies which are fully or partially owned by the central and local governments until an equal number of men and women serve as government representatives on the boards of directors. Capitalizing on this decision, several institutions offered courses to train women to serve on boards of industrial, commercial, and public-service companies.

[Another factor in this changing scene is the increasing commercialization of the media and no-holds-barred wars held over ratings in both the printed and electronic media. In a long process, the media, which were mainly ideologically affiliated, are becoming increasingly commercialized. Cable TV was introduced into Israel in the 1990s and, only somewhat prior to that, a second television broadcasting network. Political, social, and, of course, sexual sensationalism are rising in a process that reminds one of the noise level in a restaurant. If the noise level rises beyond a certain point, people who want to talk to each other must raise their voices, which contributes to further increasing of the noise and so on. Thus, issues of rape, harassment, and incest are among the issues discussed and portrayed in minute and hyper-realistic detail in the media. (*End of update by R. A. Shtarkshall and M. Zemach*)]

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A. Source and Character of Religious Values

The term "secular Jew" embodies the problematics and the uniqueness of the Israeli situation. One part of it—Jew—defines the national sociocultural and historical identity. The second part—secular—defines a relationship to Judaism as a religion and religious lifestyle, and the choice of a humanistic or secular democratic frame of reference over a religious one. These two parts can be naturally linked together only within Israel, the Jews' national home.

Only about 30% of the Jews living in Israel define themselves as religious. Most of the other 70% define themselves as secular, while about 17% to 23% define themselves as traditional. The latter observe a few selected rules of observance, mainly ritualistic ones, while living most of their lives according to a secular lifestyle. Despite that, the culture is strongly influenced by traditional Jewish religious values.

Three examples—1. Jewish thought and its vehicle, the Hebrew language; 2. the role of religious values in a predominantly secular society; and 3. religious politics—will illustrate the extent in which Jewish culture influences sexual constructs.

### *The Hebrew Language and Jewish Thought*

Language is the vehicle of abstract and analytical thought and therefore plays an important role in our psychosocial phenomena. Hebrew, the language of Jewish thought, exerts a very strong influence on Israeli Jewish thinking about sex and gender. The first expression of the place and meaning of sex in the world appears in the first chapters of the Old Testament, in a way diametrically divergent from Christian thought. In Genesis, the first time intercourse is mentioned in Jewish literature, the root of the verb used has multiple meanings: knowledge, consciousness, and intercourse. As far as is known, Hebrew is unique in using one root, and thus overlapping meanings, for sexual intercourse: knowledge and consciousness. The common root for knowledge, consciousness, and the verb for sexual intercourse indicates that sex is highly prominent in Jewish thought, and not necessarily in a negative way, especially when one recalls that Jews are known as the "people of the book."

This influence is apparent despite the fact that other layers were added over the biblical language and, until the 20th century, Hebrew was only intermittently used as a spoken language for secular, nonritual, or nonreligious studies. In modern, largely secular, albeit Hebrew-speaking Israel, very few people use the biblical term for intercourse in daily life. Current terminology ranges from the intimate (*make love*) through the neutral (*to perform sex* or *sexual relations, to lie with*) to the aggressive equivalents of *fuck, screw, shaft*, and so on.

Thus, unlike many Christian approaches, traditional Jewish thought views sex as intrinsically neutral. It is a human characteristic with an extremely strong potential (like knowledge and consciousness), which can be turned into either good or evil by three humanly determined acts of choice: the meaning one gives to sex (an act of piety), the context within which it is practiced (marriage), and the way one practices it (rules of conduct, including purity laws). In itself, sex—and the pleasure of sex—is not a sin. The harmony of flesh and spirit, an important tenet of Jewish culture, is expressed in married heterosexual relations. Its consummation on a regular basis, not necessarily for procreation, is a *mitzvah*—a combination of an obligation and a privilege—and pleasure is an important part of it. Those who abstain in marriage run the risk of religious sanctions. As role models, community leaders are to be married with numerous children. There is no monasticism, and abstinence is frowned upon.

Despite this, one can also find strong ambivalence about sex and the expression of sexuality in Jewish thought throughout the ages. Its instinctual nature and extremely high potential for evil needs to be guarded and curbed at all times. Some strong Christian influences are also apparent, especially among the Jews living in Europe for the last two millennia.

Another example of the role of the historical language's influencing modern sexual constructs is the fact that Hebrew is almost a totally gendered language. All the forms of speech—nouns, pronouns, verbs in all tenses, adjectives, and adverbs—take a gendered form. In contrast, English, the language of international research, is neutral, except for a few nouns describing animate objects. A comparative study among children of three different countries found that the gender prominence and dichotomization were ordinal according to the gender differentiation within the language,

Hebrew-speaking children having the highest gender awareness. Thus, Jewish children learn with their first abstractions how important it is to identify the gender of each object/entity and to look for the characteristics that distinguish one gender from the other.

### *The Power of Religious Values in a Secular Society*

The Judaic nature of the society is demonstrated by the role that even secular people ascribe to Judaism in the life of Israel. While most Jews are nonobservant in terms of Jewish orthodoxy, many of them define themselves as traditional. Debates on the relations between state and religion are a constant issue in Israeli politics and public life. Issues, like the definition of the Jew in the law of returning, the opening of public places, or the operation of public transportation on Shabbat (Saturday), support for religious educational systems, and the exemption of women and men studying in religious seminaries from army service, are argued regularly.

In many such debates, many secular people defer to religious demands, not as a surrender to their power politics, but because they view Judaism as having a special role in the life of the state. One of the basic tenets of Judaism is that it is a national religion with a role in both public and private life, with a unique historical role in preserving the Jews as a cohesive people. Sometimes, there is a feeling that in relating to religious demands in public life, secular people place themselves in an inferior position. This closely relates to this topic because marital and gender issues are an important part of the discourse and the complex relationship between state and religion.

### *The Political Power of Religious Parties*

The influence of Judaism on family, gender, and sexual issues is exerted not only through the subtler cultural and indirect sociocultural forces, but also through the political, social, and economic power of the religious minority of the population. While the political platforms of the religious parties are varied, they are united in their determination to preserve the power and lifestyle of Jewish orthodoxy in the public life of Israel. Their political leverage is far greater than their actual electoral power. While the left- and right-wing parties alternated as dominant political powers and formers of governments, religious elements have held the balance of power in all coalition governments because of a proportional electoral system.

In return for support on issues of defense, foreign affairs, and the economy, the secular parties give in to the demands of the religious parties on issues of secondary importance to them in many social areas, including those relating to family, sex, and gender. Thus, the judicial system that determines family matters is religious, although some aspects can be dealt with also in civil court. The religious influence is obvious in the reform of laws regarding abortion, homosexuality, and censorship of pornography.

The combination of religious Halachic canons with a public that is largely secular creates a conflicted situation. The reason for this conflict lies in several religious laws that impose great hardship on men and women, especially on those who do not adhere to the religious lifestyle. These include the law that forbids men who are descendants of the priesthood families of the temple from marrying a divorcee or a widow; a law forbidding an adulterous woman from marrying her partner in sin, even after she is granted a divorce from the husband; and similar laws.

These situations cause hardship also for religious people, but they suffer them because they adhere to the basic religious tenets. For the secular majority who encounter them,

they are an imposition. This is one of the reasons for the strong tensions between the religious and the secular sectors, but the fear of schism is so intense that most people will look for compromise solutions instead of cultural war.

Nevertheless, while the secular and the religious parties have officially agreed to a token truce—the preservation of an ill-defined status quo—in reality, there is a constant political war fought in separate skirmishes on different fronts: in Parliament, the courts of law (especially the Supreme Court of Justice), local governments, and economic pressures. While many secular people feel that religion is gaining ground in public life, most of the religious sector feels on the defensive within the paradox of a secular Jewish state.

## **B. Source and Character of Ethnic Values**

### *An Immigrant Society with Unifying Forces*

Israel is an immigrant society with a common historical background and a melting-pot ethos acting as cohesive forces. The absorption of repeating masses of immigrants since the early 1950s has had a considerable impact on sexual behavior, sexual health, and public involvement in sexual issues. In 1990 and 1991, 400,000 people, 10% of the total Jewish population of Israel, immigrated from the former Soviet Union. Issues of increased rates of induced abortions, relatively low numbers of children, one-parent families, an alleged combination of alcohol consumption and sex, and a seemingly instrumental view of intercourse, quickly surfaced.

Also in 1991, 15,000 Jews immigrated from Ethiopia over one weekend, confronting Israel with issues of traditional medical practices, ritual isolation of menstruating women, and increased incidence of infectious diseases, including STDs and AIDS.

Unlike other societies where immigration leads mainly to social fragmentation, indications suggest that social cohesiveness forces within Israeli society also act in the opposite direction: as integrating agents even within the span of one generation (see below in marriage and fertility patterns). The melting-pot ideology is not just a whim. There are some strong basic and structural needs that contributed to its development: a belief in the continuity and unity of the Jewish people; a sense of threat of either political or physical annihilation or both; and, a sense of revival and modernization of an old culture that was suppressed or dormant by external conditions. Although many people perceive the melting-pot society not as a domination of one group over others, but as a continuous process of the evolution in a new culture, others espouse a more pluralistic approach, advocating the preservation and even the development of ethnic characteristics.

In reality, one can see that many factors relating to dyadic relations and sexual behavior, fertility and fertility regulation, and other characteristics change in a relatively short time, and different studies show the emergence of common phenomena.

### *Israel's Political Situation*

Israel's political situation has a strong impact on sexuality and sexual issues. This small country, with a total population less than that of New York City, has been surrounded by enemy states and hostile populations since its founding. Until the 1979 treaty with Egypt, there was no land border that an Israeli Jew could legally cross. Even in mid-1994 when ongoing political processes set the stage for reducing the siege, Israel required a military service for all citizens that influenced sexual and related issues beyond that requirement.

Siege feelings and the need to keep national unity make many people accept compromises in striving for change, or

at least lower the tone. This often changes the perspectives about priorities and leads to personal inner conflict between personal aspirations and internalized collective ones.

The influence of wars and physical danger on the sexual behavior of people, their marriages, and their fertility patterns are understudied. It is proposed here that, in critically dangerous situations, sex—which is biopsychosocially still connected to reproduction—may serve as a means to symbolically negate personal death. Such a hypothesis was used in attempts to explain diverse phenomena, like the frequently discussed increase in reproduction following military engagement, and the divergence from normative sexual behavior during times of active warfare.

Recent analysis demonstrates that the first phenomenon is only a rumor based on impressions and does not exist in reality. As appealing as the symbolic explanation is, the anecdotally reported departure from normative behavior during times of peace could alternatively be explained by feelings of disintegration during wars and irrelevance of social norms in those times. However, if this explanation were true, one would also expect widespread occurrence of phenomena like rape of the conquered population, which did not materialize in the wars in which Israel conquered land and assumed rule over large Arab populations.

### *Military Service*

Several characteristics of the general military service, which is dictated by the political realities, can affect, directly or indirectly, the nature of Israeli sexual constructs. The role of the Israel Defense Forces (IDF), both as an institution and as a life event for Israeli youth and adults, is larger than in other Western societies. Most people would view it as essential to both their physical and national existence. It is an existential event in the life of most Israelites, and most families are immediately involved with its realities and dangers.

*1. Gender Roles and the Status of Women.* Military service in Israel is general and compulsory for both men and women at the age of 18. Exemptions are granted for physical and mental health reasons, low educational level, criminal record, and religious reasons, but rarely for conscientious objections. However, men serve for three years and continue to serve in the reserves for 25 to 80 days annually until they are 50 years old. Women serve for approximately two years and are retired from reserve service when they bear their first child. This, in itself, is both a reflection and an enhancer of the more traditional role still ascribed to women in Israel (discussed in greater detail below). Other characteristics of the military service tend to accentuate the traditional gender roles.

Despite compulsory service, there is a strong element of volunteering in the army, as youth compete, sometimes fiercely, for service in elite units or prestigious tasks. This entails additional physical and mental hardship during compulsory service and, in many cases, an obligation to serve as many as six additional years. There is a strong element of macho psychology involved here, with both male status and preference by the young women at stake.

Women do not serve in combat, and their choice of professions is not only smaller, but also limited to the less prestigious tasks within the army. Being out of combat service also blocks them from advancing in the army to the higher levels of general staff commands.

As the IDF retires its generals at between the ages of 45 and 53, exemplary service in the army and a top-echelon position is one of the stepping stones to the higher levels of civil service, business, and political careers. This avenue for advancement is closed to women.

The hardships of service, especially in combat units, promote strong male camaraderie and individual friendships; annual service in the reserves to age 45 to 50 tends to reinforce them. These almost-exclusively male interactions can be transferred to civilian life in the form of enhanced networking and alliances.

It seems that the realities of the military can foster traditional gender roles in the minds of both men and women, and also influence their social positions. Other issues discussed below point in the same directions.

*2. Social Mobilization and Meeting Ground.* Sociologists have noted the IDF's role as a unifying factor and as contributing to the relative high mobilization within the Israeli society.

The IDF is involved in absorbing immigrants and in educational projects for women and men who otherwise would be unfit to serve. It also serves as a common meeting ground for people from different ethnic groups, allowing them to mix socially, and in many cases sexually. Many marriages can be traced to relationships formed in the army.

All IDF officers start as rank and file. There is a strong emphasis on advancement based on merit and achievement, and excellence is measured by a combination of mental, physical, and social characteristics. A meritorious service record is viewed as a strong character reference; in civilian life, young men from less-privileged strata have another chance for mobility.

*3. Rite of Passage or Moratorium?* It is hard to appreciate the influence of the IDF on sexual and family issues if one does not understand the role it plays in the general individual psychosocial development of Israeli youth, and its centrality in the life of many individuals. Most Israeli youth leave direct parental control to go into the army. This is only one factor that ties army service strongly to sexarche, choice of mates, and other sexual issues (see Section 5C, *Interpersonal Heterosexual Behaviors, Young Adults*). Developmentally, IDF service has some definite elements of a rite of passage—the physical and mental tests, the demand for initiative and resourcefulness judged by peers and veterans, the formation of group cohesion and social responsibility, the ability to deal with moral dilemmas in extreme conditions—and these serve to separate childhood from adulthood.

While not disputing the rite-of-passage elements in IDF service, or its positive effects, it was recently suggested that, at the same time, the nature of IDF service may also cause a long moratorium on the tasks of real life, and can even be viewed as causing some elements of infantile regression. These may have effects on dyadic relationships and gender roles within them (see below).

*4. Internal Conflicts, Trauma, and Violence.* A possible negative aspect of the military service that may have a bearing on sexuality and family life involves the nature of military engagement in the civilian uprising in the disputed occupied territories during the last six years. This forced the soldiers to confront civilians, rather than enemy soldiers, in a manner previously not experienced. These high-risk confrontations with civilians tend to create strong inner and normative conflicts. Those who raised the issue hypothesized long-lasting effects, among them proneness to violence (including domestic violence) and posttraumatic stress disorders. Claims had been made that, in such discussions, it is difficult to distinguish between political stands and professional opinions.

The possible contribution of these issues on the actual shaping of sexual and dyadic constructs will be discussed in several instances.

### 3. Knowledge and Education about Sexuality

#### A. Government Policies and Sex Education Programs

The educational system in Israel is divided between the general educational system and religious ones. This necessitates separate discussion of the situation in the different sectors. Most of this discussion will be devoted to the secular educational sector.

##### *The Early Years (1930s and 1940s)*

Early attempts at sex education, in the late 1930s and early 1940s, were based on local initiatives. Although coming from two different directions, they converged around the dominant psychoeducational ideology of that period—Freudian psychoanalytical thought. The theoretical concepts, which had little direct field application, were largely that of mental health hygiene of a “preventive” nature, and were concentrated around the Psychoanalytical Institute of Jerusalem and the Public Health Services of a voluntary health service of the Jewish community (Hadassah).

At the same time, attempts were made to develop sex education programs at the educational institutions of the left-wing kibbutz movement “Hashomer Hatzair.” The atmosphere in these institutions was highly experimental, and the issues of sex, sexuality, gender equality, and the control of individual urges and wishes—not only sexual ones—as part of socializing ethos, were central to the life of the movement at that time. For example, not only was the system coeducational, but boys and girls slept together in the same room, four to a room, until age 18, and bathed together until age 12 to 14. Contrary to the expected, this was a society with highly puritan values, at least when it came to youth, and the key concept of sex education and youth sexuality was borrowed from psychoanalytical literature—sublimation. There was high social control over behavior: purity and self-control were expected, not only in the area of sexuality, but also in areas like smoking and drinking. It is interesting to note that these two behaviors are clustered with precocious initiation of intercourse as “problem behaviors” in the modern research literature.

##### *The 1960s*

A revival of interest in sex education came in the early and mid-1960s, when several sex-education “guidebooks” were published by concerned professionals. These were not as yet part of an organized sex-education drive, but their almost simultaneous publication is significant, as was the foundation of the Israeli Family Planning Association in 1966. It seems that the main concerns during that period were the apparent increase of sexual behavior among youth and the alleged contribution of large families to low socioeconomic status (SES) prospects and crime among young immigrants from Middle Eastern countries.

##### *The 1970s and 1980s*

The big organizational change happened in the early 1970s. Dominant among the incentives was the increase in the incidence of sexually transmitted diseases (STDs) among youth, following a wave of youth tourism to Israel after the 1967 war. This also coincided with some changes in the general ethos of the country from communal to individual, which may be attributed to filtration of the youth movements of the 1960s in Europe and North America, and with a relative economic boom following four years of recession.

A national study about sexual knowledge, attitudes, and practices was mandated and carried out in the early 1970s. The outcome of the deliberations of a multisectorial com-

mittee was an outline for a comprehensive general curriculum arranged chronologically by content areas and skill formation, and the formation of a Unit of Family Life and Sex Education at the Ministry of Education.

The original conceptual framework for this experimental unit was a mixture of preventive health (implying a high potential for adverse effects of sexual behavior), a developmental outlook, and normative boundaries. Its mandate was very wide and flexible and included the development of educational programs, the training of sex educators, and the implementation of non-mandatory sex education within the school system.

Two parallel units were formed, one to deal with the issues within the national-religious sector (which dropped the sex education out of its name) and the other one to deal with the same issue within the general (secular) national educational system.

*The National (Secular) Sex Education Approach.* The efforts concerning sex education in the secular (general) system developed in three main parallel directions: 1. the development of programs and educational materials for different content areas, ages, and skills; 2. training sex educators/facilitators; and 3. creating the infrastructure for the implementation of the programs within schools. The development of the programs and the training of sex educators was influenced by the humanistic approach to sex education of the Sexuality Information and Education Council of the United States (SIECUS), the American Association of Sex Educators, Counselors, and Therapists (AASECT), and Society for the Scientific Study of Sexuality (SSSS). Professionals from the United States of America, most notably Lester Kirkendall and Sol Gordon, helped with the first training courses and development programs in the late 1970s and early 1980s.

In 1978, the curriculum for family life and sex education was formally adopted and the unit ceased to be an experimental one. After several years of independent (precarious) existence, it was adopted administratively into the Psycho-Educational Services of the Ministry of Education. The infrastructure for supporting implementation of sex education now includes several regional trainers, with whom teachers can consult.

The appearance of AIDS on the Israeli scene in the mid-1980s was a mixed blessing for sex education. The rise in public interest in sexual behavior, the perception of youth as an at-risk group, and the feeling of inadequacy concerning sex education among many parents, acted together with other factors in 1989 to mandate sex education at least three times within the formal education span. In each stage, elementary, middle, and high school, pupils are to be given 16 hours of sex education. Unfortunately, this mandate was not accompanied by the necessary budgetary or time allotment for this purpose, so that its implementation still depends on local arrangements, the priorities of principals, and the difficulties of the staff in dealing with the subject.

On the other hand, the public interest in sex education took a swing from the developmental-humanistic approach back to the preventive-medical ones. Also, parties less interested in education jumped on the bandwagon and attempted to lead campaigns by playing on the fears of the public.

*The National-Religious Sector Approach (Excluding the Ultra-Orthodox Approach).* This educational system focuses on a moralistic approach and normative behavior within the boundaries of the religious framework. An integral part of this framework is the dichotomization between public and private behavior. While the Jewish practice allows for the fallibility of the individual and mitigating circumstances, it

strongly forbids the a priori consideration or discussion of alternative behaviors. Thus, an educational discussion of the forces leading to premarital sexual behavior, decision making, and alternatives within such situations can be done only within a judgmental right-wrong framework in which abstinence is viewed as the only appropriate alternative.

Several religious educators have been dissatisfied with this approach and expressed their displeasure by participating in training courses for sex educators in the secular sector, contrary to administrative directives. They explain this by their wish to respond to the pressing needs of their pupils beyond the formal and normative guidelines and by a personal need for developing in this area.

*Ultra-Orthodox Educational Systems.* There is only indirect and fragmentary knowledge about sex education within the “Independent Educational System” run by the ultra-orthodox sector, because this system is not accountable to the administrator of the national curriculum (see Section 13B, National, Religious, and Ethnic Minorities, on Ultra-Orthodox Jews [*Haredim*]).

## B. Informal Sources of Information

### *Parents as a Source of Information*

Findings of a national study of youth sexuality from the 1970s, augmented by some later studies using convenience samples and limited populations studies, show that between the ages of 14 through 17: 1. parents in general were viewed as a low source of information on sexual issues; 2. daughters consulted more than sons with parents; 3. mothers are a much more common information source than fathers; and 4. both parents were a very low source of information for sons, although sons also consulted more often with their mothers than with fathers. Finally, the tendency to view parents as a source of information decreased with age—youth in the 10th and 11th grade were less likely to view their parents as a source of information than were 8th and 9th graders. This change was bigger for sons than for daughters. These results are supported by studies of unique populations, such as youth from problem families residing in boarding high schools, kibbutz youth, and by youth general health studies that included sexuality components. Even when similar pictures are different in important details, this can be explained by the unique conditions of the studied populations.

A possible explanation for the findings that girls interact more than boys with their parents, especially their mothers, on sexual issues, can be that the interactions are not initiated by the girls but by the mothers, who are both more concerned with the expression of female sexuality and more comfortable in approaching their daughters.

This finding that daughters consult parents more than sons conflicts with the findings that their objective knowledge is lower when compared to male youth. An explanation might be that the interaction of daughters with their mothers is more on issues of attitudes and consent than on information, or that the higher ambivalence of female adolescents about their sexuality does not allow them to benefit from the higher amount of interactions with adults.

A recent study using a limited convenience sample found a different picture that could be very important, if replicated in a more generalizable form. In a high-middle-class senior high school sample, parents were the second most important source of information for girls and third for boys.

This may indicate that urban middle-class parents are now finding it easier to talk with their children about sex. This may be part of the trend of increased acceptance of adolescent sexuality, or a reduction in the distance between parents and their adolescent offspring.

There is a question whether parents are an appropriate source of sexual knowledge for youth because of their emotional involvement and their heterogeneity in regard to reliable information. Popular sentiments, based on the general assumption that parental involvement in education is desired, regard as problematic the findings that parents are a low perceived source of information. Attempts are being made to change this situation by interventions directed toward both youth and their parents. However, the effort to increase parental involvement may also reflect adult ambivalence over youth sexuality and the desire to control it.

Even if one accepts the belief that increased parental involvement is desirable, these findings are insufficient grounds for designing interventions; many studies need to be deliberately targeted at more-defined specific subgroups before intervention programs are designed. It may be worth investing in programs to help parents to increase their role as a resource for their children and to help fathers talk with and be more available to their sons, only if the recent findings from the urban middle class are confirmed and the explanatory assumptions hold.

The findings from the boarding schools may indicate that in dysfunctional families, a parental substitute may be needed as a reliable source of information, especially for boys whose fathers are either physically or mentally absent and whose mothers find it difficult to interact with male adolescents about sexual issues.

### *Other Sources of Information to Adolescents*

Concern over parents' being a low resource is heightened when other sources of information are viewed. Peers and older adolescents are found to be the main source of information for both male and female adolescents. This may increase parental and adult perception of loss of control, as these are potential sexual partners. In addition, the reliability of this information resource is questionable because of the limited knowledge among older adolescents and because it is biased by the agenda of the resource persons.

While information from peers is in many cases unreliable or incomplete, its language and tone are acceptable to adolescents and young adults. It may, therefore, be beneficial to invest more efforts into developing systems of peer education and peer training.

An important information source is the written and electronic media. Unfortunately, much of the material directed to adolescents is sensationalistic, commercial in nature, and/or caters to the lowest common denominator. Thus, question-and-answer sections in youth magazines rarely deal with ambiguities and some questions that have no answers that are definite or generalizable.

Another source of concern is the fact that more children and youth report exposure to pornographic videos, especially among males, but also females, a result of cable television networks and the popularization of video. (Pornography is discussed in Section 8C, Significant Unconventional Sexual Behaviors.)

### *Extent and Reliability of Sexual Knowledge*

Although knowledge is insufficient to assure healthy or responsible sexual behavior, it is essential for their attainment. Knowledge is also essential during puberty and adolescence to help prevent adverse sequels of sexual behavior, like unwanted pregnancies and sexually transmitted diseases.

It should be noted that, unfortunately, some of the studies mentioned above used what is considered unsatisfactory measures of knowledge, i.e., subjective perception of knowledge rather than measurable objective ones. Studies by

Ronny A. Shtarkshall in convenience samples have shown a marked discrepancy between objective knowledge and the subjective perception of knowledge about contraception; for example, the fact that 90% of adolescents in a large study reported familiarity with at least one contraceptive did not mean that they really had the knowledge they needed to use it.

When objective measures of knowledge were used, a low level of knowledge was found among high school students, many of whom were either sexually active or on the verge of initiating intercourse. Generally, male adolescents demonstrated higher objective knowledge. Female adolescents had higher score on signs of pregnancy and abortions, possibly because of the personal concern with an unexpected pregnancy.

It is unclear why females who reported more interactions with adults demonstrate lower knowledge. As was hypothesized earlier, this could be because their contacts are on issues of conduct, but also because they and the adults are more ambivalent about female sexuality and sexual behavior during adolescence. This hypothesis is supported by limited findings from a high-middle-class study that showed that positive feelings about sex were positively associated with higher objective knowledge.

#### *Sexual Knowledge among Professional Students*

A study evaluating knowledge of professional students in medicine, social work, and law at the Hebrew University in their first and final years revealed rather alarming findings. First, medical school education had almost no effect on the knowledge of medical students; only one of five content areas, the biomedical, showed a positive effect. Second, the level of knowledge was rather low, especially considering the professional needs of physicians and social workers. Third, sexual experience was in marked and significant association with subjective perception of knowledge. Fourth, there were weak and inconsistent associations between sexual experience during adolescence and objective knowledge. The combination of the two findings is alarming. Since it is assumed that awareness of lack of knowledge is better than perceived knowledge that is erroneous, the finding that medical students are largely aware of their lack of knowledge was viewed as a mitigating sign. Finally, even at this stage, age was positively associated with both increased knowledge and a more adequate perception of knowledge. Extrapolating for a younger age, this finding supports the hypothesis that older adolescents are more ready, both cognitively and mentally, to enter into the sexual arena.

Several studies by Shtarkshall evaluated the lack of knowledge apart from mistaken knowledge, assuming that people who are aware of their ignorance are in a better situation than those who do not know, but mistakenly think that they do. The finding that professional students were largely aware of their lack of knowledge was viewed as a positive sign.

#### *4. Autoerotic Behaviors and Patterns*

There are no known sources that document autoerotic behavior patterns in the general population in a quantitative way. Even a publication of a recent general population survey on sexual function and dysfunction does not fill this gap.

Sexual history interviews with a large biased sample of help-seeking individuals and couples show the following patterns. Among the nonreligious, more men than women report masturbating either prior to sexarche or after it. Also, more men than women report direct manual stimulation, while fewer report indirect stimulation, like rubbing the thighs, or thrusting and rubbing against objects. These methods are more favored by women. There is a question

whether this is a difference in practice or a reporting bias, but this question cannot be resolved on the basis of these reports in themselves. Among the orthodox, and certainly among the ultra orthodox, the issue of reporting bias is more pronounced, as male masturbation is a serious sin, while female masturbation is only frowned upon and considered unhealthy.

There are many lay beliefs concerning masturbation that are expressed mainly by adolescents and youth, either as questions or comments within sex education sessions. These are mainly lay beliefs concerning general or reproductive health, and also the ability to identify a masturbating person. For men, the beliefs include depletion of the semen, blindness or shortsightedness, hirsutism on the palms, and an asymmetrical (bent) erect penis. Among women, there are admonitions about weak sight and about giving birth to retarded children as a consequence of masturbation.

### *5. Interpersonal Heterosexual Behaviors*

#### **A/B. Children and Adolescents**

##### *Pubertal Rites of Passage*

See remarks on IDF service as a kind of rite of passage for adolescents under Section 2B, Religious, Ethnic, and Gender Factors Affecting Sexuality, Source and Character of Ethnic Values.

##### *General Lack of Data*

Attempts to elucidate the patterns of sexuality, sexual behavior, dyadic relationships, and other sexual issues concerning adolescents and youth are hampered by sociopolitical restraints. The last study of sexual knowledge, attitudes, and practices in a national sample of youth was done in 1970. In 1991, a proposed study of adolescent sexuality was approved by a review system and then vetoed on educational and moral grounds by the Director General of the Ministry of Education and Culture, a political appointment of a religious minister. Even after the change of government at the end of 1992, a lengthy and tortuous negotiation process about the same study ended abruptly when the psychological services of the Ministry of Education "changed its research priorities" and excluded the survey from them.

Most of the available quantitative information is on secular youth with little on those who define themselves as traditional. All information about religious youth reported here is anecdotal, although it represents the cumulative shared experiences of a network of researchers, counselors, and educators.

##### *Puberty, Adolescence, and Psychosocial Development*

Very little research has been done on pubertal stages. All studies have used convenience samples of Jewish girls. The normal range for the onset of breast development in 1977 was from 8.22 to 12.38 years and the normal (corrected) age for pubic hair development 8.58 to 12.58 years. The normal range for reaching menarche is 11.09 to 15.49 years.

Several interesting effects associating pubertal stages and social class or ethnic origin have been observed. Girls from low socioeconomic class as defined by their fathers' occupations, whose mothers were poorly educated and who came from large families, reach the stages of puberty later than other girls. All three variables are highly and significantly associated with each other and with Middle Eastern/North African origin. Sample sizes did not allow a distinction between the contribution of ethnic origin (genetic) and social conditions (nurture) to this phenomenon.

It is possible that a secular trend is present, since a comparison of menarche in separate studies of similar popula-

tions have shown a drop of almost five months in mean age from 13.75 in the mid 1960s to 13.29 in the late 1970s. (This is not significant because of a large standard error in the more recent study.) During this period, there was a large increase in both the general standard of living and ethnic mixing.

The importance of individual and group differences in pubertal development in relation to psychosocial sexual development is well recognized but very difficult to study. Based on observations and anecdotal information, a hypothesis can be advanced that among Israeli female adolescents, there is an inverted J-curve relationship between age at puberty and the time gap between the onset of puberty and the first sexual intercourse, or sexarche, i.e., girls who develop earlier and later than their peers may go faster through a scale of the stages of sexual behaviors. (Information about male adolescents is insufficient even for development of a hypothesis.)

As for social-class differences in puberty showing that girls of low socioeconomic class reach pubertal stages and menarche at a later age, this may put some stressful pressure on them to act out sexually, especially in integrated schools, because the influence on psychosocial sexual development is exerted not through the abstract national norm, but through interactions with the significant peers. Another pressure on adolescents of low socioeconomic classes in schools, and especially in integrated ones, is the need to excel. There is enough information to suggest that low achievement, in comparison with a significant reference group, is associated with precocious sexual activity.

#### [Ongoing Research on Adolescents

[Update 2001: Several studies are currently in progress on the sexual behavior of adolescents and young adults. Another round of the *Health Behavior in School Aged Children (HBSC)*, a study coordinated by the European Region of the World Health Organization, was scheduled for 2001. This long study contains a very brief section on sexual behavior. The results of the previous round, conducted in 1994 and published in December 1997 (Harel, Kani & Rahav 1997) were limited to the secular sector of the national school system and further limited only to the 10th and 11th grade section of the survey. Other behaviors were also studied among 6th to 7th graders and also in the National Religious Sector of the schools. Adolescents in Israel report having sexual relations to a lesser extent than those in the U.S.A., 27.8% and 13.9%, as compared to 53.5% and 53.1% for American males and females, respectively. The difference between the genders in reporting intercourse during adolescence, on which we reported earlier (in our original chapter in the *International Encyclopedia of Sexuality*), persisted even at the end of the 20th century. Preliminary results from other studies show that this difference continues to be true today. The two other studies are another study in the secular school sector, which focuses on sexual attitudes, norms, and behavior, and a study started in 1995, which looks cross-sectionally at successive groups of young adults. The latter also includes information about orthodox men and women. In the *HBSC* study, the researchers were able to demonstrate that risky behavior, coitus with more than one partner ever or in the last three months, engaging in unprotected coitus, and experiencing coitus under the influence of alcohol or psychoactive drugs is limited to a small subgroup of the adolescents, which may explain the picture of the spread of HIV/AIDS in Israel. (End of update by R. A. Shtarkshall and M. Zemach)]

#### Premarital Sexual Activities and Relationships

This discussion of sexual practices among Israeli youth focuses on two main issues: premarital intercourse and the

context within which it occurs, and on sexarche or age at first intercourse.

The issue of premarital intercourse during adolescence is more complex than that of premarital intercourse in general. It includes adult attitudes toward adolescents' sexual expression and adolescents' response to it, the interaction between adolescents, peers, and significant adults on issues of control and separation. It is very hard to treat these different issues separately, and sometimes even to distinguish between them.

In general, studies up to the mid-1980s showed that attitudes of Israeli youth concerning premarital intercourse, self-pleasuring, homosexuality, and gender are more conservative than those of European and North American youth. Attitudes among adolescents towards premarital intercourse were associated with several independent variables: gender, age, modernity (socioeconomic status of the family of origin), and religiosity.

Degree of agreement with two extreme attitudes toward premarital intercourse—"Intercourse is forbidden before marriage" and "Intercourse is permitted if both partners want it" (not qualified by age, above 18, or by relationship status, in love or engaged)—are detailed in Table 1. In general, younger adolescents are more conservative about premarital intercourse. Both younger boys and girls are more accepting of the forbidding message than older boys and girls, while the situation is reversed for both genders in relation to the permissive attitude.

The findings indicate that, in general, younger adolescents are more conservative about premarital intercourse. 1. As expected, acceptance of the permissive message increases, and that of the restrictive message decreases, with age for both genders. 2. Comparing genders, one sees that in various adolescent age groups, more boys than girls accept the permissive message and more girls than boys accept the restrictive one. 3. Both boys and girls are more accepting of premarital intercourse if there is an emotional commitment, and more so if there is a formal public one, i.e., engagement. The commitment is much more important to girls than to boys. 4. The discrepancy between boys and girls that supports a behavioral double standard is more pronounced when males and females report their attitudes towards virginity at marriage. Both genders express more-permissive attitudes toward males' premarital intercourse. More than two thirds of females believe that girls should be virgins at marriage, while less than half expect this of their prospective partners. Among males, 10% believed that sex is forbidden before marriage, while 43% felt that a woman should be virgin at marriage. 5. There is also a discrepancy between attitudes and behaviors: Males are more permis-

**Table 1**

#### Degree of Agreement in the Attitudes of Adolescents Toward Premarital Intercourse

	Boys		Girls	
	Grades 9-10	Grades 11-12	Grades 9-10	Grades 11-12
Premarital intercourse is legitimate in adolescence if both want it	35.3%	53.3%	14.1%	24.4%
Premarital sex is forbidden before marriage	18.1	10.2	51.1	35.2

*Editors' Note:* Percentages are approximations from the original bar graphs.

sive in their attitudes than their behavior and females are more permissive in their behavior than their attitudes.

These differences in premarital sex attitudes are more pronounced if one compares older boys with younger girls. As this is usually the pattern of pair formation, it can be a source of tension and discontent in dyadic relationships, prior to initiation of intercourse and after initiating it.

Mechanisms like denial and externalization used to cope with these discrepancies can cause difficulties on the individual and social level, including coercive behavior and problems in contraceptive behavior. They can also lead to a reporting bias about intercourse.

In the religious sector, public norms are against any premarital sexual expression, not just intercourse. Many structural and social controls attempt to enforce these norms because of the common belief that, while adolescents have natural urges, they lack the self control of adults—such beliefs are also common among the more conservative elements of the secular sector. The result is sometimes paradoxical: The constant warnings and controls make people more aware of the temptation. The results may be dire when those who transgress do not possess the range of skills that enable them to protect their own needs while doing so. Those who transgress also have very little chance of parental or even peer social support.

#### *Trends in Sexual Behavior, Premarital Intercourse, and Sexarche*

Pooling the results of several different studies, one is able to conclude that the trend from the 1960s to the 1980s is for more youth to engage in premarital intercourse, and that a larger proportion of those who do so start at a younger age. The increase in the reported rate for younger women from the 1960s to the 1980s is three- to sixfold, the highest increase for both men and women of all ages.

Table 2 shows the trend to earlier sexarche among urban women in one study. Caution is needed in using this study, the only one giving data about premarital intercourse among urban Jewish women prior to 1965. This study has all the limitations of retrospective studies; the time span between the occurrence of the events and the reporting point varies, and the reporting may be influenced by a memory bias. In addition, it was limited to married women in their first marriage, and thus it does not represent the whole Jewish population. Both nonmarrying and divorce may be associated in more than one way with the timing of first intercourse.

**Table 2**

**Cumulative Percentages of Women Initiating Intercourse at Different Ages, for Women Reaching Age 16 at Three Different Periods (Cumulative Percentages of Those Who Practiced Intercourse in a Calendar Year Prior to Their Marriage)**

Age at Sexarche (Years)	The Period at Which the Women Reached Age 16		
	1963-1969	1970-1975	1976-1982
14-15	1.5%	3.8%	3.2%
16-17	14.2	23.9	26.9
18-19	50.2	60.1	70.1
20-21	80.2	85.1	93.4
22+	100	100	100

Note: The differences between the three studied periods are significant at the  $p = 0.001$  level.

Editors' Note: Percentages are approximations from the original line graph.

Table 2 also demonstrates an interesting phenomenon. All three groups of women show a sharp rise between ages 16 to 17 and 18 to 19. Since most Israeli youth leave home at that age to go to the IDF, it seems that this is a critical age for the urban women.

In all studies of the urban population, more than 90% of the studied population—secular Jewish youth at high school, at any age more men than women—reported that they had already had sexual intercourse. However, the trend from the 1970s to the 1980s shows that the gender discrepancy in decreasing. The ratio of urban men/women reporting intercourse ranged from more than 8:1 for the 10th grade and 3:1 in the 12th grade in the 1970s, to 3-4:1 in the 10th grade and 2-3:1 in the 12th grade in the late 1980s.

In the mid to late 1980s, between 12% and 30% of urban females and 40% to 55% of males had reached sexarche by the end of grade 12; 2% to 11% of girls and 20% to 35% of boys were sexually active at the end of grade 10.

The discrepancy in proportions between men and women should be a source of concern. The three most widely used explanations in the literature are: 1. the presence of a small group of young women who engage in sex with many young men; 2. The initiation of young men into intercourse by older women; and, 3. reporting bias. As far as is known, the age gap between partners in most of the relationships among adolescents and young adults is either very small or in the opposite direction, the men being older than the women. There are no indications that there is a small group of women who initiate many men into sexual intercourse. Also, the tradition of initiation through sex-for-profit is relatively rare in Israel. It is thus probable that the normative pressures reported above are acting on youth of both genders to create reporting bias in the opposite direction: That is, more boys report having reached sexarche than those who actually do so, with fewer girls reporting it than those who do. An extensive experience with interactive sex education programs dealing with normative pressures and sexual behavior lend additional evidence to support this explanation.

#### *The Context of Sexarche*

In studies of the context within which intercourse is initiated during adolescence, a high proportion of youth reported that intercourse is started within a steady relationship. This is more true for females (95% of those reporting premarital intercourse in a large-scale study) than for males (46% in the same study). The same picture is apparent when comparing the length of relationships: More girls initiate intercourse in longer relationships. Also, girls who were sexually active reported higher frequency of intercourse than boys, which would be the case if intercourse is practiced within a steady relationship.

Despite the general trend of initiating intercourse within a steady relationship, a phenomenon of initiating intercourse with a "sex object" is encountered in significant numbers. Youth of both genders report that they chose a person for the sole purpose of losing their virginity, mainly because "it was time." Sometimes, the chosen person is a different man or woman from the one they are in a current dyadic relationship with. Sometimes, this happens when they play the role of a sexually experienced person in the beginning of a relationship and do not find a way out of the role; at other times, they set out deliberately to find a person "to do it" with. Attention should be paid to this group even if it is small, as they may be considered an at-risk group. Because communications may be hampered by conflicting agendas and pretending experience that is not there, and the commitment between the sexual partners may be lower, it can be hypothesized that protection within this group would also be lower.

Experience shows that youth who are able to consult with parents or other significant adults, more often engage in protected intercourse. Unfortunately, these are a minority, and those who do talk with adults are usually older and less in need of this support than the younger ones.

In looking at the length of relationship within which intercourse is initiated, a seemingly contradictory picture appears. A higher proportion of young women initiate intercourse within a steady relationship of more than 13 months as compared to the young men—41% and 27% respectively.

Several factors, acting separately or in unison, could contribute to this phenomenon. First, the study was done among high school youth, and it is possible that the steady relationship of the young women is with older men who are already out of school. This does not fit with the higher proportion of males reporting the initiation of intercourse during adolescence. Second, the study may be dealing with a double-barreled reporting bias: young women, who feel that it is desirable to initiate intercourse within a relationship, tend to overreport the duration of the relationship, or those who start intercourse early in a relationship refrain from reporting it. An additional contribution to this discrepancy is that a higher proportion of casual relationships are between younger males and older females.

### *Premarital Courtship, Dating, and Relationships and the Prospects of Military Service*

The dyadic and sexual relations are highly influenced by the required military service, even long before they have to enter the IDF. Awareness of this future in the life of each and every youth comes in many ways, encroaching on the daily life of adolescents. Boys and girls are called for physical examinations at age 17. Many of the boys and some of the girls start even earlier on a road leading to one of the elite units or to a desirable military task. Membership in an elite unit means three things: first, a very high physical and mental competition requiring intense and long preparation; second, a much more strenuous and dangerous service; and third, a longer service, ranging from one to six years beyond the mandatory three years. Not all Israeli youth actually espouse this lifestyle; those who do are the pacesetters. The danger of getting killed or wounded in the army is small, higher in the combat units, and still higher in the elite units where even the training can be dangerous. The visibility and psychological impact on everyone are very high and out of proportion to the statistical reality when compared with road accidents or accidents in the workplace.

Working closely with youth and with facilitators of sex education, one frequently encounters two ways in which this reality influences youth in their midadolescence. First, lack of time to grow up and an unsure future are often brought up as reasons for hastening sexarche, mainly by boys, but also by girls who find it hard to face these realities. Girls bring these facts up as looming in their mind even when the boys do not raise them. While it is possible that some young men use these as manipulative arguments, many of them are also strongly concerned. This effect is also documented in fiction and films, especially those by young artists. The summer before army service is part of the cultural terminology that carries with it connotations far beyond the surface.

Also encountered was an effect acting in the opposite direction, to postpone initiation of intercourse. Girls from some conservative environments, especially of Middle Eastern origin, may postpone sexarche in expectation of the time when the family and social controls will be lowered, and also out of regard for their parents' feelings, honoring family values by waiting until they are out of the home prior to initiating intercourse. Most of these girls will not go to college, but

when they come back home after two years, the parents are already resigned to their new status.

### *Age of Consent: Lowering the Social Controls Over the Sexual Behavior of Youth*

In the 1980s, the law of consent underwent a significant reform. Until then, the uniform age of consent—16—applied to women only. While some interpreted this as an expression of the wish to control the sexuality of women, others viewed it as expression of male threat to females' virtue. Toward the end of the 1980s, a change in the legal age of consent took into consideration some of the changes in the behavior of youth. While the age of consent remained 16—again only for women, intercourse between a girl aged 14 to 16 and a boy who was older than her by two years or less would not be considered statutory rape in the context of this relationship. On the other hand, the age of consent was elevated to 21 in cases of intercourse with someone under the guardianship or influence of a professional. The latter section applies to both men and women victims, but it is still not clear whether it applies to perpetrators of both genders.

## **C. Young Adults**

### *Heterosexual Relations and IDF Service*

Life within the IDF strongly influences sexual behavior, the formation of couples, marriage patterns, and gender issues.

By and large, the IDF is an institution of young people, outside regular parental and adult social controls, with its own sets of norms and pressures. Its immediate formal rules, which can be very restrictive, are usually set and administered by people who are between two to seven years older than those obeying them. For most youth, the regularity of military life is highly irregular when compared to their previous lifestyle. On the other hand, outside of defined training and active military duty, life in the military leaves them with unregulated and unsupervised time in the exclusive company of their peers. Despite being a male institution, the IDF includes a high proportion of young women.

There are no formal or social restrictions on fraternization between officers and soldiers, and very little emphasis on military formality and distancing that to outsiders sometimes looks alarmingly like anarchy. Since most youth serve in the army, and all officers rise from the ranks, they are essentially of the same class and traditions.

These circumstances that offer many chances for intimate and sexual encounters, combined with a rite-of-passage situation, tend to give those who are not sexually initiated a chance to be so. This is especially true for those who refrain from dyadic or sexual relations because of external restriction. Many girls growing up in traditional families or communities consciously postpone their sexual debut until the army, as an act of honoring their parents. They view sex away from home as less encroaching on the parental values. It seems that, by mutual consent, the question is not discussed between parents and daughters. Most of these girls will not go to college, but when they return home after two years, the parents are already resigned to their new status, as noted above.

The conditions and situations within the army service are conducive not only to sexual relations, but also to pair formation and to experimentations in relationships (see Section D, Marriage Patterns, below). The IDF environment also creates two specific problems in regard to sexual behavior and gender roles.

First, the permissive environment can impose a strong hardship on youth from traditional backgrounds, especially those with lower educational achievements, who find it

very difficult to deal with the relative lowering of parental control over sexual behavior, coupled with increased opportunities and the company of eligible mates. This is especially true of some young women, mostly from families of Asian/African origin, who put a great value on virginity, and who, finding themselves in an environment much more permissive than their home atmosphere, lack the personal, experiential, and social skills to cope with controlling their own sexual behavior. Add to this the fact that those behaving permissively, including other women, are the ones with the prestigious jobs and high social status, and one gets a problematic situation. To resolve this conflicted situation requires internal controls and social skills that some of these women do not possess because of their traditional sheltered upbringing. For some who feel that once they have lost their virginity they are tainted, the result is promiscuous behavior. For others, it is a contributing factor to their inability to use contraceptives resulting from externalizing what they are doing. Internal conflicts regarding the fact that they are engaging in intercourse are sometimes resolved by the feeling of being repeatedly subjected to it "unintentionally," a solution that also precludes the use of contraceptives. The majority of soldiers applying for abortions through IDF come from this background.

To counter this, the IDF women's corps targets women with low educational achievement as a priority group for sex education programs. These programs attempt to strengthen their self-image and internal controls and to allow those who initiate intercourse to preserve both their self-respect and health.

A second factor is that Israel is a geographically small country. With very strong family ties, most soldiers in the combat units get home regularly every second or third week for a long weekend. It is rare that they will not get home for a month or more. It is thus possible to preserve dyadic relationships and meet with girlfriends on a regular basis. On such weekends, the soldiers, who are both tired physically and under a lot of emotional stress, try to cram in as much eating and sleeping together as they can. Their girlfriends accept the role of supporters and nourishers, a traditional motherly role, because they know how much hardship the boys have to take. There is also a tacit agreement not to raise disagreeable issues. This creates a situation in which the partners establish a pattern of separate traditional roles at the early stages in the relationship. It may also create regressive symbiotic dependence, where one is feeding into the relationship different components and relies on the other to supply the missing ones.

### *Cohabitation*

Unmarried cohabitation has become more prevalent in recent years. Its frequency is unclear, but it is certainly much more visible and acceptable, mostly among middle-class secular youth, either working or in higher education. This is a change from a generation ago when fewer couples cohabited, and then mostly after having decided to get married. Although this phenomenon has been little studied in Israel, the combination of anecdotal data and educational experiences suggest several points of interest:

1. While cohabitation is less binding than marriage and is often perceived as an experiment in dyadic relationships, the partners are expected to be monogamous.
2. Although somewhat more flexible than married ones, cohabiting couples adhere to traditional gender roles.
3. Cohabitation sometimes develops through an interim semi-communal stage, as when two or more boys or girls or a mixed gender group share an apartment for economic reasons. When one of them forms a liaison,

the partner sometimes moves in and shares the bedroom in that communal arrangement. It is only at a later stage in the relationship that the couple sets out to find their own apartment. The initial stage is characterized many times by advertising it only among the peers and not sharing it with the parents, at least not immediately. The movement to the private apartment is usually done with parental knowledge and/or consent.

4. Parental consent, either implied or overt, is no refuge from the feelings of tensions or ambivalence on both sides. When interviewed, several women in such arrangements mentioned that either their father or mother had a difficulty in relating to either the bedroom or the shared bed when visiting their apartment.
5. It is possible that cohabitation is part of the larger phenomenon of extended moratorium that Israeli youth take after IDF service. Cohabitation creates an interim stage between the public announcement of the relationship and creating a formal commitment.
6. Cohabiting young adults who eventually marry, although not necessarily with the cohabiting partner, suggest some ambivalent attitudes to marriage. On one hand, there is dissatisfaction with the parental model of marriage and reluctance to perpetuate a similar pattern. On the other hand, the idealization of marriage and attachment to it as an institution drives them to aspire to an improved version. This may act against the crystallization of traditional gender roles.
7. There are anecdotal indications that cohabiting is, for a growing number of couples, an expression of shunning the rabbinical religious ritual and a rejection of the legal ramifications that it entails. Resolution comes either by using one of the tolerated civil arrangements or in postponing the religious ritual until the last moment when they plan to have children.
8. Breaking up a cohabiting arrangement seems to be more difficult than breaking up a noncohabiting relationship, and the phenomenon of feeling entrapped in a relationship is encountered also by cohabiting couples.
9. When deciding to marry, couples express it as either taking another step along the road or as wanting to formalize the relationship in order to have children. Many cohabiting couples marry when the women are already pregnant.

## **D. Marriage Patterns**

### *Legal Age of Marriage*

The legal age of marriage is distinct from the age of consent. It applies only for women, and currently it is 17. Ronny A. Shtarkshall was involved as an expert witness in an attempt to apply both age of consent and legal age of marriage to men also. This was barred in a parliamentary committee by a representative of a human rights party on the grounds that this will complicate things and that, while women need protection from men, men do not need protection from women.

### *Age at First Marriage*

In comparison to other Western industrial countries, Israelis marry relatively young. This is true even if one looks separately at the Jewish population. In 1990, the median age at first marriage for Jewish brides was 23.2 and for grooms 26.0. It seems reasonable that many marriages at the younger age were initiated by encounters within the service in the IDF. In 1990, roughly 25% of all the men who married for the first time did so between ages 20 and 23, and a third of the women marrying for the first time did so between ages 20 and 22, the years immediately following the service.

Among the Arabs, Muslim women marry for the first time at the median age of 20.0, more than 3 years younger than their Jewish counterparts, while the men marry at 24.4, only about a year and a half younger than Jewish men. Among the Christian Arabs, the median age is only a year younger for women, 22.5, but a year later for the men, 27.5.

In Table 3, we show the changes in age at first marriage of the Jewish population over four decades. It is evident that between the early 1950s and mid-1970s, there was a drop of more than two years in the age at first marriage of Jewish grooms from 27 to 25. Among Jewish brides, the phenomenon is very similar, but smaller, a drop of about one year (23 to 22). This drop is because of the mass immigration from Muslim countries in the mid-1950s and early 1960s. The tradition of these Jewish communities favored early marriage, similar to the Muslim host cultures. This effect on the mean marriage age of brides is less pronounced—and in the median age even nonexistent—because traditionally, brides were younger than the grooms and were married at a very young age, 14 to 16. The Israeli laws forbade such marriages, raising somewhat immediately the marriage age of brides.

Since the mid-1970s, there is a steady rise in both mean and median age of first marriage for both brides and grooms. The rise is larger for women than for men. It is suggested that this rise is the result of educational changes, especially those affecting immigrants from Islamic countries that had a greater impact on women, who were educationally underprivileged in comparison to men. It is also possible that the social acceptance of cohabitation has contributed to the rise in age at first marriage for both genders.

### Marriage Formation

Among the Jewish population, most first marriages, especially those that do not deviate by more than a few years beyond the median age for first marriage, are based on personal choice and attachment. This is true for the secular, traditional, and orthodox segments of the Jewish population, the exceptions being the ultra orthodox and small groups of immigrants from Georgia, Ethiopia, and the Caucasus. Even among the immigrants, the pattern is changing, and many arranged marriages merely formalize previously formed attachments. Youths from some immigrant groups explain that they go through the motions in an attempt to preserve cultural traditions and avoid conflict within their families. The pattern of marriage formation among the ultra-orthodox Jews and among Muslims, the largest group of non-Jews, will be discussed in the special sections dedicated to them at the end of this chapter (see Section 13).

At an indeterminate point beyond the median first marriage, the pressure on the unmarried to conform increases. Participation in family weddings becomes a burden, as many people use the traditional well-meaning but stress-generating blessing, “Soon at your wedding.” This is especially stressful to people with homosexual orientation and those whose self-image keeps them from initiating pair formation. At this point, families, especially mothers, sometimes turn to matchmakers and the young adults agree. The

young adults themselves sometimes resort to meeting people through advertising in the newspapers. It seems that these channels are used by a minority of the population.

### Interethnic Marriages among the Jews

It is estimated that 15% to 20% of the marriages of secular and traditional Jews are among those who originate from different parts of the world, mainly Ashkenazi Jews, originating mainly in Europe, and Sephardic ones, who lived during the last 500 years in Islamic countries. The rate is somewhat lower among the orthodox and lowest among the ultra orthodox. The melting-pot ethos, high mobility of the Israeli society, and the strong mixing effect of the army all contribute to this.

### Marital Variations: Polygamy

Polygamous marriages were prevalent among several Jewish ethnic groups, especially those immigrating from Islamic countries. During the peak immigration years of the 1950s, there was a great outrage about polygynous marriages, mainly from women’s organizations, and they were outlawed almost immediately. This civil law contradicted both the Jewish Halachic law (as interpreted in these Jewish communities) and the Islamic law and tradition.

### Common Law and Civil Arrangements

The courts recognize the status of a “common-law spouse” for the purpose of property division, inheritance, pension rights, and carrying a name. It also recognizes civil marriages enacted in foreign countries by citizens of Israel, and cohabitation contracts enacted according to the civil code, even when the religious courts ban these specific unions. As a matter of fact, these arrangements evolved in order to solve cases that rise from the conflicts that have already been referred to between the Halachic canons and the secular public.

Other patterns of marriage, like homosexual marriages, are not recognized by Israeli law, and single people find it very hard to adopt children.

### Divorce

The Israeli divorce rate is lower than that of the U.S.A. and non-Catholic European countries. Still, the rates of divorce per 1,000 ever-married people aged 15 to 49 rose monotonously by 48% from 1973 to 1983, from 6.5 to 9.6, respectively, for husbands and from 5.3 to 8.2 for wives. In 1983, the denominator was changed to 1,000 married at all ages; comparison between the two periods is difficult. Since 1983, the rate has fluctuated, rising from 5.8 in 1983 to 6.4 in 1991 (new rates), about a 10% increase.

A time series analysis of rates of divorce after a specific duration of marriages reveal that the increase in rates of divorce is only because of an increase in rates of “late divorce.” It is the rates of divorce after nine and 12 years of marriage that are still on the rise. The rate of divorce after two years of marriage did not rise at all since the early 1960s and may even have come down slightly. The rate of divorce after six years of marriage has remained stable since the early 1970s; see Table 4. These findings are somewhat puzzling, as formal marriages are almost universal, the percentage of secular people is similar to most western European countries, and the Jewish religion is more tolerant toward abortion than Catholic Christianity. The relative stability in Israeli marriages supports the claim that the family is a central theme in Israeli society.

One result of the increase of late divorce is an increase in the average duration of marriages that ended in divorce—a rise from 8.3 in the early

**Table 3**

#### Age (in Years) at First Marriage of Jewish Men and Women

	1952	1960	1970	1975	1980	1985	1990
Average male	27.32	26.33	25.02	24.92	25.52	26.40	26.70
Median male	25.68	24.88	24.13	24.21	24.81	25.72	26.01
Average female	22.82	22.20	21.81	22.19	22.61	23.53	23.90
Median female	21.01	21.01	21.40	21.52	21.99	22.82	23.21

*Editors' Note:* Ages are approximations from the original line graph.

1960s to about 11 in the late 1980s and 11.9 in 1991. However, this increase in the duration of the divorcing marriages by almost 4 years was not accompanied by a similar increase of average age of divorce. For men, the average age at divorce for the same periods is 40.0, 38.6, and 39.4; for women, it is 35.1, 35.2, and 35.8, respectively.

This means that the proportion of the couples who marry at a younger age among the divorcing couples is higher than among other couples. This is a sobering observation regarding marriage at a younger age if one regards stable marriages as desirable.

### Extramarital Relations

Another measure for the quality of marriages is extramarital affairs. There is no reliable research evidence about the prevalence of extramarital affairs among married Israeli couples, but anecdotal evidence, the reports in the newspapers about extramarital affairs of celebrities of all kinds, and the citations in divorce cases lead one to believe that the prevalence is rather high. Evidence from counseling, and from extensive education and information work among adults, leads one to believe that extramarital affairs, even known ones, are not in themselves sufficient to destabilize marriages.

### E. Marital Law and the Status of Women

The law in Israel gives authority over personal issues to semiautonomous religious judicial systems of the recognized religious communities. Cases are tried according to the religious laws of each denomination. This is one of the reasons why conservative fundamentalist elements within the non-Jewish religions sometimes support Jewish religious parties, and even vote for them. Opponents of religious rule over personal issues sometimes refer to this as the "unholy alliance."

Marriage and divorce issues of Jews are, therefore, largely determined by the religious Halachic law, although the civil law may also be resorted to in issues of division of property and custody of children. For a secular Jew, the patriarchal nature of the Halachic law creates an asymmetrical and undesirable power balance between the marriage partners.

This situation should not be fully attributed to the power of religious politics. They have at least the passive support

of large segments of the secular majority. Attempts to create a situation in which secular civil marriages will be recognized under the law have been defeated several times under different governments. The claim of orthodox Jews, who are a minority, that this will create a schism within the nation that will end up in a disaster, strikes a chord in the heart of many nonobservant Jews. On the other hand, several developments suggest that the power of the religious establishment is diminishing (see below).

Jewish religious laws and the practice of the religious courts place women in a highly undesirable position for those who do not accept the canonic tenets. They cannot be judges in the rabbinical courts or even testify officially; they can only present their case. According to the Jewish religious laws, the men have more sexual freedom, even within a marriage. The husband is the grantor of a divorce and the wife is the acceptor. Even the religious courts cannot force a husband to receive a divorce against his will. On the other hand, there are several reasons why a divorce can be enforced on a woman, one of them being adultery. As the duty to procreate is placed on the man, he may be granted permission to marry a second wife, when his first one is infertile and refuses to accept a divorce after ten years of marriage.

### F. The Incidence of Oral and Anal Sex

Although anal intercourse was proscribed by law until recently, the restriction was almost never applied to heterosexual couples. A prosecution dealing with a heterosexual couple did result in a ruling by the then-Legal Advisor and Chief Prosecutor, that strongly restricted the legal control of sexual issues (see below).

There is no collected data on the prevalence of these practices, but the experience of counselors and therapists point to the fact that all are practiced by significant numbers of couples. It is interesting to note that several subgroups in the Israeli population, Jews and non-Jews, practice heterosexual anal intercourse as a means of keeping an intact hymen and as a birth control measure, where the loss of one and the appearance of the other can be highly stigmatizing, damaging, or even dangerous.

The approach of orthodox Judaism is expressed in the fact that it frowns upon these practices, but does not proscribe them. A Talmudic story illustrates this approach very clearly, although using metaphorical language. A woman approached one of the sages with a complaint: "I set a table for my husband and he turned it around." The sage answered: "What can I do, daughter, and the scriptures permits him." There is a question whether the story deals with the issue of anal sex or with vaginal rear entry, but at least some of the commentators agree that anal sex is the issue. This can be perceived on one hand as ambivalence, but on the other as a realistic view of human nature.

## 6. Homoerotic, Homosexual, and Bisexual Behaviors

### A. The Legal Situation

Until recently, homosexuality—or rather anal intercourse (sodomy), including heterosexual anal sex—was illegal in Israel. This was an inheritance of the British colonial penal code of 1936. According to gay organizations, victimization of homosexuals on the basis of this law was frequent.

Changes have occurred gradually and evolutionarily, starting in the early 1960s. Despite the illegality of anal intercourse, the then-Legal Advisor to the government and Chief Prosecutor and later Supreme Court Judge, H. Cohen, ruled that sexual intercourse between consenting adults, in private, cannot be a basis for prosecution. Since 1972, five attempts had been made by members of different parties to

**Table 4**

**Couples Who Married in Israel and Divorced, by Year of Marriage and Selected Periods of the Duration of the Marriage**

Elapsed Time: Years Married:	Cumulative Percentages of Divorcing Couples <sup>1</sup>			
	2 Years	6 Years	9 Years	12 Years
1964-1967	2.7	6.0	7.5	8.9
1968-1969	2.4	5.4	7.5	8.8
1970-1971	2.4	5.6	7.5	9.2
1972-1973	2.4	5.8	7.9	9.6
1974-1975	2.6	6.6	8.7	10.4
1976-1977	2.5	6.9	8.9	10.7
1978-1979	2.9	7.2	9.4	11.0
1980-1981	2.7	6.9	9.3	
1982-1983	2.7	7.1		
1984-1985	2.6	6.6		
1986-1987	2.9			
1988-1989	2.2			

<sup>1</sup> The formula used is: Number of couples divorcing after the specified interval from marriage period divided by the number of couples who married in a specific period times 100.

strike this sodomy statute from the penal code. In 1988, a political opportunity allowed its revocation. An amendment to the Equal Opportunity Law passed in 1990 also protects the rights of homosexuals to employment.

The attempts to change the law were accompanied by both public campaigns and many changes in public mood toward homosexuals and homosexuality. Until the mid-1970s, the IDF discharged homosexuals for psychiatric incompatibility and/or for being a security risk. This was changed prior to the 1988 legal change, and the IDF made several arrangements that allow homosexuals to serve without being exposed to undue difficulties.

Currently, several issues are being contested in the courts, mainly rights of cohabiting males that are usually granted to spouses under the rulings of common-law marriages. The issue is not as simple as it looks on first sight, especially when considering the regulations governing the pension rights of spouses when the principal owner of the rights dies. Male spouses have smaller pension rights as survivors than females. In the case of cohabiting gay men, this will give the couple an economic advantage over heterosexual couples.

## B. Public Atmosphere Concerning Homosexuality

Several factors combine to make issues of homosexuality very difficult to cope with:

1. The political power of the orthodox-religious sector within the Jewish population and the opposition/respect ambivalence of the secular sector are major factors. While shifting from viewing homosexuality as a crime to medicalizing it, the orthodox religious still strongly opposes its public sanction.
2. The high sex-role polarization in Israel is part of the perceived centrality of gender differences that have both cultural origin and social importance. Tolerance of Israelis to homosexuality is inversely related to their sex-role polarization, and lower than that of American students living in Israel in proportion to the differences in sex-role polarization. Homosexuality, especially male homosexuality, threatens the world picture of two dichotomized genders.
3. Homosexuality is perceived as incompatible with the familial structure, which is of central importance within Israeli society.

In early 1993, a gay/lesbian conference was held in the Knesset (Israeli Parliament), despite strong protests from members of religious and right-wing parties. Public response to the conference, and to the personalities who discussed their difficulties, created further changes in both attitudes and practice.

A still problematic issue is that of open gay cohabitation. Although possible and prevalent, many people feel uncomfortable about it, and some express opinions that this is part of homosexual activism attempting to influence heterosexuals.

[Update 2002: Jerusalem saw its first "gay/lesbian pride parade" and outdoor party in a public park on June 8, 2002. Despite strong protests from orthodox Jews, approximately 4,000 homosexual Israelis recognized Jerusalem's sanctity to Jews, Christians, and Muslims with a blessing in Hebrew, English, and Arabic, and then marched under rainbow flags and balloons provided by city officials. Similar parades have been held in recent years in the predominantly secular Tel-Aviv, where gays are more accepted and can socialize at an assortment of cafes, clubs, and bars that cater to them. There are only a handful of such gathering

places in Jerusalem, where the first local gay community center opened in 1999 (Greenberg 2002). (End of update by R. T. Francoeur)]

## C. Homosexuality in Sex Education

Despite the fact that homosexuality is part of the sex-education curriculum, and several units deal with homosexuality in general and with homophobia in particular, it seems that both school administrations and sex educators still find it uncomfortable to deal with the issues properly. Many youths, therefore, go through school without encountering issues of homosexuality in sex education, a fact that in itself constitutes a very strong message to both homosexual and heterosexual youth, and especially to those who are still ambivalent about their orientation or wonder about it. Adolescents uncertain of their sexual orientation or gender identity will hardly find support within the school system, as there is no systematic training and recommendations on how to deal with these issues. Normative pressures to conform are high.

An interesting difficulty in facilitating issues of homosexuality in the schools was encountered during the training process of sex educators. Several educators justified their reluctance to deal with homosexuality, expressing fear of their own biases or stereotypical thoughts. Facilitators from the Association for Individual Rights, the Israeli equivalent of a gay task force, supported this position, claiming that only gay people are sufficiently unbiased and sensitive enough to facilitate educational programs on homosexuality.

### 7. Gender Diversity and Transgender Issues

Gender-conflicted persons find it difficult to be evaluated and cared for in an organized and controlled way. There is not one center that has a comprehensive program for sexually conflicted people, and the authors know of several occasions that surgical interventions were accomplished without going through a protocol of evaluation/care/treatment. Other cases, where the psychiatric and psychosocial questions were resolved properly, had to go abroad for the surgical procedures. Professionals may be wary to raise the issues, for fear of invoking restrictive regulations that will even lower the ability to supply the needs of these people.

### 8. Significant Unconventional Sexual Behaviors

#### A. Coercive Sex

The categories in the criminal records of the *Statistical Abstracts* do not distinguish between subcategories of sexual crime and include sexual abuse, incest, and rape under sexual offenses. It is agreed by police, researchers, and activists alike that sexual offenses are probably one of the most underreported crimes. There is some disagreement as to the extent of underreporting as well as to the definition of criminal sexual offenses.

#### Sexual Harassment

The special circumstances of service in the army may create a convenient atmosphere and even stimulate sexual harassment. Since most officers in the three lowest ranks of IDF are not career soldiers, but extending their compulsory service, they are selected from the general mainstream of Israeli youth. Because IDF is in active combat, the selection of male noncommissioned officers (NCOs) and commissioned officers is based on, among other things, aggressiveness, charisma, initiative, and improvisation. These same officers, who are also in the closest working relationship with both men and women of the rank and file, are also older

by two to five years, as compared to the compulsory service women—and in addition, are in a position of authority. Add to this the fact that IDF is organized mainly around values that are traditionally identified as male, and one gets an environment in which women are at a disadvantage. This creates situations that have a potential for sexual harassment on the one hand and manipulative relationships on the other.

There is another situation affecting older male officers of higher rank who are usually married. In combat units, the commanders are in direct daily contact with enlisted soldiers. As one of them phrased it in a group situation: “We grow older all the time, but they always remain at the same age, and we have to compete with them all the time.” The context of this remark clearly indicated that women were part of the competition. It is unclear whether these officers are only in a power position or also in a very vulnerable one. Such environments and motivations have high potential for abuse of power.

The official stand of the army concerning harassment or misconduct is strong, with several structural arrangements that attempt to counterbalance the potential for abuse. First, all women’s dormitories are out of bounds for men, including the officers commanding the camps. On any official supervisory visit, a male officer must be accompanied by an officer of the female corps. All female soldiers have direct access to an NCO or an officer of the female corps whose source of authority comes from an independent chain of command headed by a woman general. Complaints of sexual harassment, or any other issue of a sexual nature, are dealt with independently by the authority under which the woman is serving—the female corps—and if necessary, by the military police and prosecution. A highly publicized case is that of a general commanding the navy who was dismissed from the IDF for misconduct the day after he was acquitted in court of rape charges for lack of supporting evidence.

Despite this, it seems that harassment is prevalent and is a source of concern to both women and the military establishment. In a structurally male, aggressively oriented organization, there is strong ambivalence in treating sexual harassment issues, and there are documented cases of attempted minimizing of complaints, especially when they concern officers with high military potential.

The difficulty lies in what is construed as harassment in the eyes of male and female soldiers. Moreover, many young women find it very flattering, even important, that high-prestige men in the immediate environment are attracted to them. There are also cases where such situations are used manipulatively by the women, this mainly with younger officers.

Several educational efforts are now in process to inform both genders about their rights and about the feelings and points of view of the two genders on this issue. It is believed that legal as well as educational efforts are urgent because, beside the individual aspect, sexual harassment can be used as a means to keep a disadvantaging power balance.

[Update 2001: In 2001, accusations of sexual harassment were brought up by a 23-year-old woman against a government minister and a political leader of his party. The man, a former army general and a Minister of Defense in a previous government denied the accusations. Police investigations prompted two other women to come forward, and a three-count indictment was submitted to the Knesset in order to revoke his immunity from prosecution. The case resulted in a strong public campaign against sexual harassment, especially in the military service.

[The issue of sexual harassment was also raised when several prominent therapists were accused of sexual abuse

by clients. A psychologist was convicted of abusing female patients under a pretext of a treatment method. Accusations were also made in the press against another therapist, an out-of-the-closet homosexual and media expert of marriage and family, two years after his death. The latest case, in which hidden cameras and taping were used by one of the television investigative programs, involved a sex therapist who allegedly used the ruse of training males to become surrogates to sexually abuse them. This case was still pending in early 2001, but it brought into focus, along with the issue of sexual abuse by therapists in general, and sex therapists in particular, the issues of the precarious relationship between the media, the law enforcement authorities, and justice. (End of update by R. A. Shtarkshall and M. Zemach)]

### Incest

In Jewish tradition, incest is such a heinous act that, according to the *Halachah*, it is one of the only three crimes that a person should prefer being killed rather than commit. This may explain the shroud of silence and shame covering the issue of incest. For many years, this was an unheard-of crime.

In recent years, the changes in public climate, the establishment of child/youth investigators, and the change in the rules of evidence allowing the investigator to testify for the child, have increased the number of cases in which incest is reported and prosecuted.

Unfortunately, charges of incest (like battering) are sometimes used as weapons in attempts to get vacating orders and/or custody between divorcing couples.

There are some interesting research questions that need to be clarified, which will have strong bearing on preventive intervention and treatment: first, the differences between the legal definitions of family and of incest in different cultures prevailing in Israel; second, the contribution of the increase in nonbiological parents or siblings living together to the increase in the phenomenon.

### Rape

A marked change in public attitude in Israel toward rape and rapists occurred in the 1980s and early 1990s. This is mainly because of the activities of rape-crisis centers founded by the feminist movement and to their political and public campaigns. These campaigns resulted in changes in the rape and sexual assault laws, mainly the abolition of the need for additional material or other evidence, to that of the victim, in order to convict a sexual offender, an increase in the punishment range given within the law, and a redefinition of grave assaults done with the help of a weapon or gang rape. There were also some changes in the rules of evidence, making it impossible to bring into the trial the previous sexual behavior of an accuser or a witness.

There were also changes in the treatment of survivors. Special examination centers were arranged in emergency rooms in hospitals in each of the big urban centers, in which the staff were trained both by police, by professionals, and by the volunteers of the rape-crisis centers. There are special courses for police investigators, and the volunteers of the centers are allowed to accompany survivors throughout the police investigations.

These changes, which are by and large positive, nevertheless raise some problematic points: first, how to maintain the right to a fair trial and the principle that people are innocent until their crime is proved beyond reasonable doubt; second, the mixing of political and educational work aimed at eradicating rape, with prevention work in a society where rape is still prevalent, with crisis intervention, and with treatment of survivors, which can create some confusion and ambivalent messages.

A study presented at an international conference on victimology found some interesting phenomena that could cause some concern in this direction. The study compared the attitudes of two groups of professionals whose job was to treat rape survivors, police investigators, and emergency-room rape specialists, with those of helping-professions students and those of the volunteers of the rape-crisis centers. It was found that on several scales, the rape-crisis volunteers were more likely to take extreme positions, even when compared only to the women in the other groups. For example, they strongly disagreed with any assertion that there is a possible environmental involvement in the probability of rape, an attitude that seems to be problematic for prevention work. Despite the fact that they were one of the smallest groups, the standard deviation of their opinion scales was the smallest, indicating a very uniform norm. There is at least one case in which a woman who confessed in court that she had made a false accusation of rape against a man cited the pressure by the volunteers as the reason for the filing of the complaint. One has to be careful with such an allegation, because it may be an attempt to lighten the personal load.

Another issue of concern, debated in public, was the slogan that "every man is a potential rapist" proposed for a public service announcement spot. When challenged, it turned out that the intended messages were that one cannot distinguish by appearances a rapist from other men, and that rapists are "ordinary" people. While in itself a political statement open to argument, this is a far cry from the initial message, which was understood by many men and women alike as stating that in every man there exists a potential for rape.

### [*Sexual Commerce and Sexual Slavery*]

[*Update 2001*: For several years, especially since the waves of immigration from the former USSR began, which also brought with it some of the organized and unorganized crime, there were anecdotal reports of women imported from these areas for sexual commerce. As most of these women are illegal immigrants and illegal workers in the country, they are smuggled in as pilgrims to the Christian holy places, tourists, visitors of fictitious relatives, or through other coverups. If caught by the police, these women become victims again, as they are deported back to their countries as illegal employees. In early 2001, a human rights watch organization published a report, which attempted to describe the extent and implication of the phenomenon, and called it, justifiably, sex slavery. The report also condemned the Israeli authorities for not doing enough to eradicate this phenomenon. The authorities claimed that it is the human rights issue that prevents them from taking extreme measures against the perpetrators, because offers of immunity to the women for testifying against their "owners" are rejected by them when these ruthless criminals threaten their families in their counties of origin. (*End of update by R. A. Shtarkshall and M. Zemach*)]

## B. Prostitution

### *The Legal Situation*

Israeli law on prostitution is somewhat complicated. Prostitution itself is not outlawed, but soliciting is, and so are the operating of an establishment used for prostitution and living off the proceedings of prostitution.

As a result, there are several arrangements through which sex workers sell their services and there are "classes" of sex workers. Lowest on the ladder are the "street" or outdoor prostitutes, many of whom also perform the sexual act outside. Higher up are sex workers operating in hotels, especially in tourist hotels, and those operating through some of the escort services that are currently freely publicized

with advertisements on the fringe of legality. So, also, are massage parlors, which became a euphemism for sexual services with allusions to "relaxation."

There have been several media articles describing another kind of arrangement, which is reportedly limited to students, professionals, and middle-class women "supported" by a few men who are regular and exclusive clients. According to the reports, these arrangements are usually temporary, particularly among students.

Several attempts to change the legal situation by licensing prostitutes, putting them under medical surveillance, and allowing them to keep places of business, have failed mainly because of the opposition of the religious parties in the Parliament.

### *Pimping: The Exploitation of Female Prostitutes*

Although the pimps have traditionally belonged to the lower echelons of individual male criminals, they get most of the profits from prostitution. The women under their domination are kept in line by threats and the use of force.

There were several reports of specialists "hunting" young, runaway adolescents around the central urban bus stations, befriending them, and offering them shelter, and gradually moving them into prostitution. A more recent phenomenon in Israel involves importing women from the former USSR under forged papers and employing them in prostitution. This operation has many of the characteristics of organized crime, and the women are totally at the mercy of their "employers," as they are in a strange county with no valid documents.

### *Homosexual Prostitution*

Several areas in the urban centers are known to be mainly or exclusively the territory of male prostitutes. Several reports have shown that, as with female prostitution, many of the sex workers are early or middle adolescents. Apparently, despite the fact that homosexuality is no longer a criminal offense, the police are checking constantly on these areas, and there were some reports of them keeping "pink lists" of male prostitutes. These reports were denied by the police authorities.

### *Transvestites*

Several reports have revealed that some of the female sex workers are really male transvestites who are not gay and who do not cater to a gay clientele. These sex workers, some of whom have undergone hormonal treatment to grow breasts, pretend to their clients to be female prostitutes. They mainly provide fellatio; when asked to perform vaginal sex, they depend on their ability to stimulate the client to orgasm prior to penetration.

## C. Pornography and Erotica

### *The Legal Situation*

Until recently, Israel had at least nominal censorship on the theater and cinema. Written and audio materials were regulated only on grounds of security and not moral ones, and only public pressure created some restrictions. Abolishing censorship on the theater and cinema in 1990, part of an ongoing process of increasing the boundaries of freedom of expression as a basic human right, allows the production and dissemination of explicit sexual acts, and of violent ones, in print, film, and video formats.

Currently, despite the fact that there are fewer restrictions on moral grounds, there is a relatively recent law about displaying offensive materials in public that allows people to sue for damages if their feelings are hurt by specific items. Until now, the attempts to use this law have been restricted to religious issues. It seems that this does not in-

clude films or items otherwise displayed for a fee, especially if the public is warned about the presence of sexual materials. This is still vague, since different aspects of the law have to be tried through a full cycle of litigation before its extent and effectiveness are established.

Restrictions on importing pornographic materials in commercial quantities by customs control are inefficient, and developments in satellite television and videotaping make them obsolete. This, combined with the rise in VCRs during the 1980s and cable television in the early 1990s, expose much wider segments of the population to both soft and hard pornography. Another prominent development concerning the public treatment of sexual issues is the increased commercialization of sex that started in the mid-1980s and intensified in the early 1990s.

### *Response of the Religious Sector*

There is opposition to the increase of explicit materials aired in public from the religious sector. The more orthodox do not allow TV sets in homes and would shun those who do. Their reactions toward the treatment of sexual issues in public range from the economic boycotting of products promoted by what they consider offensive depictions in their advertisements (including dinosaurs!) to the defacing of commercial display windows and the burning down of bus stops. Because the glass/plastic walls of bus stops in Israel are used for displaying advertisements, conservative religious youths mounted a campaign of destroying bus stops displaying "offensive" ads. They later managed to persuade both advertisers and advertising firms, through boycotting, to change their policy and display different ads in areas where there is a large population of ultra orthodox.

### *The Response of the Secular Public*

Secular Jews are mainly concerned with two other aspects of pornography: sexual depictions that are demeaning or threatening to segments of the population and the effects of pornography on children and adolescents.

The influence of pornography on children and early adolescents is a source of concern to some parents, psychologists, and educators. Because sex is a very private matter, children and adolescents who are exposed to pornography have no objective criteria to compare it to and may believe that many or most of the things shown are part of normative behavior of adults. This may cause some difficulties in their emotional reactions to adult and parental sexuality. They are also unaware of the manipulations that are done in making these films, and that can create problems of self-image or fear regarding the sexual organs. There has been speculation that several cases of sexual violence among adolescents, especially those involved with group sex, are related to pornography. Despite the fact that there is no hard evidence to support this assertion, it cannot be ignored and should be researched appropriately.

Two issues are at the core of the secular political discourse. First, which of the following is the most prominent feature of pornography: the commercialized and dehumanized treatment of the human body, the linking of sex and violence, or its use by heterosexual males to dominate women and to perpetuate a sexist and heterosexist society? The second issue focuses on how to counteract the pernicious effects of pornography and whether censorship or social control are a remedy, or a worse disease.

### *Sex Education and Pornography*

Several efforts are being made to incorporate units dealing more effectively with pornography and its impact within the sex education programs in schools. The basic approach is that since there is very little hope of lowering the exposure of

children and early adolescents to pornography unless there is a major social change, it is important to give them the skills to deal with its potential effects. The concern is focused on the explicitness of such units and on the claim that they may raise the interest in pornography or lower the barrier to exposure.

### *Paid Services by Telephone*

Privatization of the telecommunications monopoly in 1990 brought with it many new initiatives for marketing new services. One of these was caller-paid telephone (056) numbers offering medical advice, astrology maps, practical information, and in the sexual area, advice, introduction services, party lines, and sexual-talk bulletin boards. Each of these meets the different needs of people with sexual interests.

At their best, sexual-advice services supply minimal sexual information and a referral service. Callers have no idea of the expertise, knowledge, or training of the persons who provide advice. Some services attempt to do counseling, not the crisis intervention of hotlines, but on a more extensive, sometimes therapeutic level. It is questionable how helpful these procedures are. The service does supply the very strong need of some people who suffer from sexual doubts or problems, the need to get advice without the risk of exposure. If done properly, it could be helpful; however, it can also postpone the time that people will reach out for needed help. Also, lay people exposed to easy access and bad practices cloaked in professional claims may later doubt the ability of any professionals to give help.

Introduction services and party lines, unless they serve minors, have very little potential for damage. They mainly give an opportunity for people to create relationships at a safe distance with as many defenses as they wish. It also allows people some safety measures prior to creating non-mediated interactions.

The sex-talk, fantasy-activated lines operate on a different level, something that many people are unaware of. These services allow people to act out their fantasies in a partial manner, while interacting with a supposedly real person at a distance, allowing the imagination to add the missing elements of reality. For some people, especially sexually distressed ones, this could erode the line between fantasy and reality, creating a few features of virtual reality that may increase the distress instead of alleviating it. Another problematic feature is that commercial considerations demand that the service providers play the stereotypical roles, many of them demeaning and degrading ones, in order to please the customers. Whether these act as cathartic experiences or add themselves into a positive feedback loop is still a question.

Commercial sexual services ignore their potential for harm. They claim they sell a service that no one is forced to buy, and therefore should not be regulated in the name of freedom of speech. It is possible that serious studies undertaken jointly by the service providers and sexuality researchers, followed by self-regulation, will provide an optimal solution. Strong demands are being made by many organizations to limit the access to these services to customers who explicitly request it. Legal efforts are currently being challenged by the industry in courts on the basis of their rights to free speech.

## *9. Contraception, Abortion, and Population Planning*

### **A. Contraception**

Modern contraceptives are easily accessible through several outlets within the health system: mainly the Mother and Child Primary Health Care (MCH) and ob/gyn clinics of the sick funds, including outpatient clinics in obstetrics

departments. There is no legal restriction on the use of contraceptives.

### Adolescents

Despite the availability of contraceptives, several studies have found that the rate of their use by adolescents at first intercourse, and in general, is very low. One found that only half of the sexually active boys and a third of the girls were using contraceptives regularly. Another reported that only 40% of sexually active adolescents have ever used contraceptives. The level of knowledge, as measured in these studies, was not a limiting condition, as it was much higher than the rate of use.

A frequent characteristic of those with early sexarche is that they either use no contraception or rely on the traditional methods of withdrawal or rhythm, and that they are also lower contraceptive users later on. Not only do they start without contraceptives, but they also take longer to achieve adequate protection. Whether there is any causal relationship at all between the two phenomena, and in which direction, is a very important research topic, but it seems to be consistent with the view that many of those initiating intercourse at a younger age do so as acting out or under personal and social pressures, and are therefore more prone to conflicts and their sequels. The fact that kibbutz youth with more egalitarian and permissive attitudes are also better contraceptive users adds support to these interpretations; see Section 13C, National, Religious, and Ethnic Minorities, The Kibbutz Movement, for details.

### Married Women

Use of contraceptives among married Israeli Jewish women is given in Table 5 and demonstrates some of our arguments.

Sterilization is frowned on in the Jewish tradition. While more than two thirds of married Jewish women use medi-

cally prescribed contraceptives, the use of both male and female sterilization is less than 1%, very low compared to other industrial countries with comparable health systems. The demand for sterilization is low because of the importance of childbearing and other issues. But, even when requested, there are many barriers a man or woman needs to overcome to achieve their desire. The reasons given by physicians are the irreversibility of the process and distrust of the ability of people to make irreversible decisions without later regrets.

### Professional Control

The licensing, sale, and fitting of contraceptives are controlled through medical and medicopharmaceutical regulations. This highlights another issue, the power struggle between professions over controlling the availability and use of contraception. While in several Western industrial countries, IUDs and diaphragms are fitted by paramedical professionals, in Israel this is still the absolute prerogative of physicians. Insertion of IUDs is the only invasive procedure that is restricted by regulation to one type of physician, a gynecologist. Thirty years ago, the practice in most clinics was that before being fitted for an IUD, a woman had to have three or four children; later, the number came down to two and even to one. Today, most clinics still refuse to fit an IUD for nulliparous women, especially unmarried ones, on the basis of good medical practice and the wish not to endanger their fertility.

Other social restrictions are also exerted mainly through the medical/health system. A more subtle aspect of the professional power play is the disagreement about the role of psychosocial counseling in the fitting of contraceptives and the success or failure of their use.

### Family Planning

Fertility and family size are mainly a personal and familial decision shaped by normative forces, but they are also part of the public domain and strongly dependent on policy decisions, laws and regulations, authorizations, and financial support or constraints. Family planning and contraception in Israel can be viewed as part of a multidimensional domain built of several axes, of which the most important ones are: modernity, nationalism, and religiosity. While some people view religiosity as belonging to the axis of modernity, this is not always the case in Israel. While among Muslim women, high fertility is inversely associated mainly with modernity (women's education being a major component), in the Jewish population, it is mainly associated with religiosity. Among Jewish women, one finds a defined group of highly educated, professional women who espouse a combination of religiosity with nationalistic ideology, and pride themselves on having more than five or six children.

It is important to note here that while the commandment to "be fruitful and multiply" is taken almost literally, Jewish *Halachah*, which strongly opposes family planning, allows the use of contraceptives on the basis of individual need within the rather wide Halachic formulation of *Pikuach Nefesh* ("danger to the soul"). Moreover, some features of Jewish religious law create unique situations. The fact that many commandments, including "do not spill your semen in vain," bind men only, and allow women to use contraceptives, provided there is no direct damage to the men's sperm. Thus, while vasectomy, withdrawal, condoms, and spermicides are almost universally forbidden, pills, IUDs, and even diaphragms can be used within boundaries.

Apart from the personal position and family decision making, the public stand of Jewish orthodoxy has always

<sup>1</sup> Exposure to contraception was determined by three independent variables: not-pregnant, not trying to become pregnant, and currently engaging in sexual intercourse.

been against organized family planning and the development of fertility control and contraceptive services.

### *Public Policy and the Family Planning Movement*

The movement for birth control or birth planning, and the utilization of modern contraceptives as an integral part of it, are relatively recent in Israel. The Israeli Family Planning Association (IFPA) was founded in 1966. Mother and Child Primary Health Care clinics (MCH), the mainstay of public health in Israel, received an official mandate to deal with birth control issues only in 1972.

The predominant approach to birth control and family planning in the late 1960s and 1970s was a mixture of demographic and health approaches with social/ethnic ideology. The main features concerned the national melting-pot ideology regarding immigrant groups, and the wish to better the situation of the groups with a low socioeconomic status through the control of their family size. From today's perspective, the latter component was not only flawed in its premises, but also parentalistic in its nature (Ronny A. Shtarkshall has coined the term *parentalistic*, as opposed to *pater-nalistic*, because of its less-sexist connotations). This approach was in conflict with two other important axes that strongly influenced family planning—the religious and nationalistic, both of which were pronatalist. Nevertheless, the strong medicalized approach to health in general, and pride in medical professionalism, resulted in one of the first field studies that heralded the introduction of IUDs for worldwide use.

Professionals in several disciplines, including health professionals, were dissatisfied with the medical/demographic framework and favored adoption of a human/family-rights approach. Implementation of this new approach has minimized the authority of the professionals, and focused on enabling the clients to take charge of their own needs and on adapting the counseling process to the need of specific groups. However, responses to recent immigrants from the former USSR and Ethiopia have shown that old habits die very slowly and can be resurrected easily when some service providers decide that they “know better” and intervene without appropriate preparation and adequate concern for sociocultural factors.

### *Client-Oriented Services*

The initiation of special counseling services for youth by the IFPA was also a step toward developing services adapted to the clients' needs. These are not only more accessible services that meet the unique needs of this population, but also a declaration that the sexual experiences of youth are not intrinsically negative. The informal approach, the environment, and the mode of counseling in these advisory centers aim at minimizing the feelings of adult social control of youth sexual behavior. Currently, many municipal services, sick funds, and other NGOs have established such services, so that the IFPA is phasing out direct service to youth and going into an advisory training role for developing such services.

### *Groups at Risk for Unplanned Pregnancies*

Some service providers and organizations view the 19% of the couples who want to postpone or terminate fertility, but use traditional, inefficient methods, as one of the main targets for family planning education. Several studies have shown that most of the married couples belonging to this group really want more-effective contraception, but are hindered from using it by lack of knowledge, suspicion, fear, and subjective difficulties in accessing services.

Unmarried adolescents and young adults, including soldiers in the service, students, and recent immigrants from the former USSR, are also the foci of family planning ef-

forts, because of underutilization or misuse of contraceptives and the high rate of unwanted pregnancies. (See Sections 13A and 13D, National, Religious, and Ethnic Minorities, for issues of family planning and contraception among Muslim women and couples, and among Russian and Ethiopian immigrants.)

As much as the contribution of the family planning services is appreciated, it cannot be ignored that the convergence of fertility rates among the second-generation immigrants was largely achieved, not through their action, but rather through intermarriages of Jews of different ethnic origin, the action of a universal, largely egalitarian, educational system, the unifying force of the IDF, and entry of women into the paid workforce.

## **B. Unmarried Motherhood**

Looking at the development of never-married mothers in the recent years, one concludes that, in Israel, for an increasing number of women, the drive toward childbearing is stronger than the convention that motherhood is only accepted within marriage.

The rate of live births per 1,000 never-married women aged 15 to 44 rose by 70% from 2.3 per 1,000 in the early 1970s to 3.9 per 1,000 in 1989. But the crude rates are not as informative as the age-specific rates: While the rates for the two younger age groups, 15 to 19 and 20 to 24, actually dropped (from 1.4 to 0.8, down 43%, and from 3.4 to 2.9, down 15%, respectively), the rates for the older aged groups increased significantly in the last two decades. In the two decades between 1970 and 1989, the rate has more than doubled for the 25-to-29 age group, from 4.1 to 9.1 per 1,000, tripled for the 30-to-34 group from 6.8 to 20.3 per 1,000, and more than quadrupled for the 35-to-39 group, 5.2 to 21.9 per 1,000.

The drop in the rate of birth of unmarried young women is probably the result of Article 2 in the abortion law that allows legal termination of pregnancy to unmarried women (see under Abortion below). Most abortions of unmarried women are concentrated in the 15-to-24 age group, where a sizable proportion of the sexually active women are still not only unmarried, but also in unfavorable conditions to marry or give birth. Since abortion is also available to unwed older women, the lower rate of abortion and higher rate of unwed motherhood among older women reflects the need of older unmarried women to exercise their right to childbearing.

By Jewish law, a child born to an unwed mother is legal, and there is no stigma attached to his or her birthright. It is the mother who carries the burden of shame, according to the religious ruling and much popular belief, and not the child. Obviously, an increasing number of women are willing to pay the price or do not feel the stigma.

There is no available information on the proportion of unwed women who choose to become pregnant by sexual intercourse or artificial insemination. Some institutions perform artificial insemination by donors with no requirement that the recipient be married, but several court cases reveal that at least some of women prefer impregnation by intercourse.

The issue came into public attention when women sued the fathers, some of them public figures, for child support. Several such cases included signed contracts waiving child support as part of the agreement by the men to impregnate the women. These contracts were declared void by the courts because the court is bound to decide in the best interests of the child even if both parents agree otherwise. In several cases, there were claims that the women misrepresented either their fertility status or the fact that they were using a specific contraceptive. The courts declared this ar-

gument to be irrelevant because, even if proven true, it had no bearing on the interests or the legal status of the child.

Several such involved fathers have formed an organization, "Fathers Not by Choice," and now lobby for the rights of fathers. They contend that the prevailing situation, giving them no custody rights in such cases, and in many cases no other rights, constitutes sex discrimination.

### C. Abortion

Several times in the short history of Israel, abortion has been a major public and political issue, with highly emotional and ideological arguments that embody tensions between different segments of the society, and a discrepancy between public policy and private practices. While playing a prominent role, the element of women's rights to their bodies was not as dominant as in some other countries. This may be because the issue of abortion touches on other issues highly important to the Israeli public: relations between religion and state, national identity and aspirations, and the collective memory of the annihilation of more than half of the Jewish people of Europe in the Holocaust.

Jewish religious laws, the *Halachah*, give precedence to the life of the mother over the life of the embryo/fetus until that moment of delivery when the head is fully out. An abortion because of danger to the life of the mother can be accepted by religious authorities, but only after consulting a Halachic authority. All other abortions are perceived to be murder. Abortion is presented by its opponents as the ongoing denial of life of its future children to a society that had lost one third of its people, 1.5 million of whom were children, and continues to suffer loss of young life by warfare and terrorism.

It has not helped that the professional view of family planning efforts within certain organizations providing abortions was predominantly biomedical. As a result, women seeking abortions were sometimes looked down upon as ignorant or failing to use medically available contraceptives properly. There was a feeling that they should have known better. This view is encountered mainly toward young unmarried women, though in the past it included women of low socioeconomic status who had already had several children. Recently, this attitude was revived in public discussion by the increased demand for abortions from the former USSR immigrants.

It is also possible that some vested economic interests were involved in the opposition to legalizing abortions. Some professionals objected to providing abortions in public hospitals as a waste of public money, while they or their colleagues were performing them privately for a fee.

During the abortion debate, reproductive health data was frequently misused. Those who objected to abortions exaggerated the health risk of abortions—both mortality and the risk to future fertility—as an argument against it. This was mainly done by comparing the mortality and morbidity rates from induced abortions to the successful prevention of pregnancy by contraceptive use, instead of comparing abortion mortality and morbidity with the risk incurred by carrying the pregnancy to term and its delivery. This argument is also facetious because, despite the fact that Israel has a very low perinatal morbidity and mortality, these are still much higher than the risks of abortions performed according to accepted medical standards.

Legally, abortion is still defined as a felony in the criminal code. As with most laws in Israel, abortions continue to be regulated by British colonial laws. For almost 30 years, 1948 to 1978, the only legal reasons for the performance of legal abortions were purely medical. Nevertheless, illegal abortions were widespread. Oddly enough, almost all the il-

legal abortions were performed by licensed gynecologists or general surgeons under accepted medical standards. Extremely few cases were prosecuted, and these only in cases where a woman lost her life.

Since the mid-1960s, several organizations, mainly human rights activists, the Israeli Family Planning Association, the women's segment of the Histadrut, the labor union, the feminist caucus, and organizations seeking to decrease the political power of the religious over individuals, have united in uncoordinated efforts to change the law. The fact that there was a vast difference between the law and the practice, and that the main barrier to seeking abortion was economic, has played a psychological role in paving the way to the change.

In 1977, the Knesset changed the abortion law (enacted January 1978). The main change was the establishment of hospital committees that could allow the performance of induced abortions under five clauses: age (women under 17 or over 40); pregnancy resulting from out-of-wedlock, adulterous, or unlawful relationships; medical conditions relating to the embryo (genetic or developmental malformations); medical conditions endangering the mother physically and/or mentally; and social or economic hardship.

The law stated explicitly that parental consent is not a condition for performing an abortion on a minor and that seeking abortion is free of regional restrictions on the dispensation of medical services. On the other hand, no physician is required to perform an abortion, even a legally authorized one. The establishment of committees in public and private hospitals that were medically authorized to perform abortions was at the discretion of the hospital management. Several hospitals did not establish such committees because of religious or other ideological reasons. The fact that permission for abortion is granted by a hospital committee does not mean that the hospital is required to perform the abortion. The committees are autonomous in determining their procedures and regulating their activities, provided that each committee includes at least one gynecologist, one social/mental health professional, and one woman. In most committees, the woman was also the social worker, thus combining two functions in one person who also has lower status in medical institutions. Some committees demand that the petitioning woman appear before the committee in person and answer questions; others only review a file prepared by the social worker. Some committees convene only once a week, others meet daily; some are known to be "liberal," while others are "hard."

This differentiation became highly important in 1980, only two years after enactment of the new law, when religious parties succeeded in striking out Article 5 allowing abortions for social or economic hardship. Since then, because there are no regional administrative restrictions on where women can seek an abortion, women have preferred to approach the more liberal committees. Thus, the demand for legal abortions among married women, and their performance, has not changed much in the years following abrogation of Article 5 (see Table 6). Only the reasons for which these abortions were granted have shifted. There was a four-fold increase in granting abortions for physical or mental medical reasons (from 8 to 36%).

As of late 1994, privately performed, illegal abortions are still performed largely by physicians under medically accepted conditions. The latest estimate by knowledgeable sources is that their number is 5,000 to 7,000 annually, about 25 to 33% of the total number of abortions performed. This estimate is for the period prior to the arrival of the large 1990-1991 immigrant wave from the former USSR (see Section 13D, National, Religious, and Ethnic Minorities).

In 1990, there was an attempt by religious parties to restrict abortions further by reducing the number of hospitals authorized to have committees and perform abortions, and to limit them to public hospitals only. Since the right-wing government at the time was favorable to this attempt for both ideological and political reasons, a coalition of family planning and health professional organizations, the feminist lobby, and human rights activists was needed to defeat this attempt.

Antiabortion organizations are active, especially among youth and among women seeking abortions. Their propaganda disregards the data and claims that every second or third pregnancy is willfully terminated, while the actual number is less than one in five, even if one counts the illegally performed abortions.

The IDF's attitude toward abortions is consistent with the wider tolerance toward premarital sex in late adolescence. In the past, a pregnant soldier was discharged whether she carried the pregnancy to term or terminated it. This caused many female soldiers who wished to continue their service to hide their pregnancy and have illegal abortions. This rule was changed, and currently a pregnant soldier can seek an abortion through the IDF and stay in the service. The rules still give the IDF an option to discharge a woman on the basis of incompatibility. As far as is known, this option is used only in the case of repeat aborters and if other adverse conditions exist.

As noted in Section 9B on unwed mothers, it seems that the decrease of unwed motherhood in the younger age groups is mainly because of the availability of legal abortions to unwed women. It would have been very interesting to be able to estimate how many "forced marriages" were avoided because of the availability of legal abortions to unmarried women. Research in Israel has shown that among marriages that suffer from abusive patterns, the rate of premarital conceptions is by far the strongest associated variable marking the difference between them and divorcing marriages that do not suffer from an abusive pattern.

A significant aspect of abortions in Israel is their cost. Prior to the 1978 law, abortions were very expensive, creating additional hardship for less-well-to-do women. Since 1978, the prices are between \$250 and \$600, between 40 to 100% of the minimal legal monthly wages. Only abortions performed for medical reasons in one of the public hospitals are covered by the sick funds; the foundation for children run by the Ministry of Welfare pays for abortions for

women under 17; all abortions performed on soldiers are covered by the IDF. In all, an estimated 65% of all abortions are paid for by public funds.

Most abortions in Israel are first-trimester abortions by suction and curettage. Most hospitals use general anesthesia during induced abortion in order to minimize the psychological effects on the woman. Very few institutions perform second-trimester abortions (evacuation), mainly because of staff objections. Mortality and morbidity from induced abortions in Israel is very low.

The large immigration from the former USSR starting in 1989 and peaking in 1990-1991 changed the demand for induced abortions and, possibly also, the conditions under which some abortions are performed. First, it is estimated that these immigrant Jews will increase the demand for abortions by about 10% (over their proportion in the overall population). Second, since most Russian women seeking abortion are married, and the cost of out-of-hospital abortions, privately performed by a licensed physician is rather high, there is both statistical and anecdotal evidence indicating these women seek abortions from USSR-immigrant physicians who are unlicensed to practice medicine or surgery in Israel. They charge less for abortions, are highly proficient in their performance, but sometimes perform them in medically problematic conditions.

#### *[Trends in Termination of Adolescent Pregnancies*

*[Update 2001:* Requests for induced abortions from the hospital authorizing committees, and their outcomes, are reported to the Central Bureau of Statistics. Examination of the trend in the 13 years between 1985 and 1998 reveal that for girls up to age 14 and from age 15 to 19, there is a clear trend of decreasing demand for abortions. Since live births for these age groups have not increased, it is apparent that these youths are protecting themselves with greater success. The conclusion of experts from several fields interviewed for a major series of newspapers articles on this issue was that there is no one cause of this better protection, but an accumulation of several factors: better sex education, the availability of services dedicated to the needs of adolescents, and more social acceptance of adolescents' sexuality, resulting in some adolescents approaching their parents for help in contraception prior to initiating coitus. *(End of update by R. A. Shtarkshall and M. Zemach)]*

## D. Population Trends

### *Uniqueness of the Jewish Population*

The Jewish population of Israel has the highest total fertility rates (TFR, i.e., the average number of live children expected to be born to a woman during her lifetime, as calculated from the age-specific fertilities) among the Western industrial countries—2.6 for 1991. This fertility is far above that of other major Jewish communities, including Eastern Europe and Latin America, even though both populations are descendants of survivors of the Holocaust (as is a large segment of the Israeli population). This is well above the replacement value and reflects the importance of children in the Israeli-Jewish lifestyle, including but not limited to the orthodox and ultra-orthodox sectors. Among secular Jewish couples in Israel, it seems like the birth of the first two children is taken for granted, and family planning considerations are usually reserved for timing and for additional children.

Also, the second generation of Jews immigrating from different parts of the world to Israel change markedly in less than a generation, so that their fertility patterns resemble the Jewish-Israeli pattern more than the patterns in their countries of origin.

**Table 6**

### **Induced Terminations of Pregnancies Performed in Hospitals in Israel (1979-89)**

Year	Total Number of Abortions	Rates per 1,000 Women (Ages 15-49)	Rates per 1,000 Live Births
1979	15,925	17.7	17.0
1980	14,708	18.0	15.6
1981	14,514	17.4	15.6
1982	16,829	19.8	17.4
1983	15,593	17.9	15.8
1984	18,984	19.1	19.2
1985	18,406	18.1	18.3
1986	17,110	16.8	17.2
1987	15,290	16.0	15.4
1988	15,255	15.6	15.2
1989	15,216	15.2	15.1
1990	15,509	14.9	15.0
1991	15,767	15.1	14.9

### Time Sequence of Fertility Changes

Despite the just-mentioned facts, the fertility patterns over the last three decades do show a general drop in fertility among all the national and most ethnic groups in Israel, concomitant with modernization and the rise in both economic and educational level (see Table 7).

Closer analysis of the TFR in various Jewish ethnic groups reveals a more complete picture. While there is a consistent drop in the TFR for Jewish mothers born in Asia and Africa, for mothers born in Israel, and those born in Europe and America, there is a rise in the TFR until the first half of the 1970s and then a decline. The overall rate of increase for both latter groups was similar, 0.3 to 0.4 child per mother. If these trends—the rise in age at first marriage, the delay of age at first birth, and the lowering of the desired number of children—continue, the result can be a continuous decrease of the TFR among Jews in Israel. It is hard to predict to what levels they will go and what will be the forces acting to speed, slow, or reverse this trend. Whatever the situation, the TFR of orthodox and ultra-orthodox Jews will be a factor.

### Factors Shaping Israeli Fertility

Forces shaping Israeli fertility changes in the last 40 years include: modernity, mainly women's education; changes in economic status and perspectives; entrance of women into the labor force; a general downgrading of the collective/national elements within the prevailing ethos; and a concomitant rise in the individualistic achievement-orientation components. Immigration was also a factor: Jewish women from Ethiopia contributed to a TFR rise in 1991, Russian immigrants to a drop in 1990, to where the TFR among Jewish women is below 2.

The pronatalist attitude prevalent in modern Israel explains the socialization toward marriage and parenthood that Israeli adults feel ill at ease to defy. Willed childlessness is not presented as a viable option and childless couples are considered to be in need of help.

### Fertility Services

A direct consequence of this cultural climate is the demand for fertility services, and especially in vitro fertilization (IVF), as aids to married biological parenthood. In 1993, there was roughly one IVF clinic for every 30,000 Israelis, more than in any other country over the world, and lower by

more than a factor of magnitude than the per capita rate in the U.S.A. The research in fertility, and especially in IVF, in Israel is disproportionately high, and several improvements on the methods originated here. Other fertility services are also highly developed in Israel, but the focus is mainly on the biomedical service, with minimal resort to accompanying psychosocial interventions. Several attempts in the latter direction report a marked increase in success rates of the biomedical interventions if they are done in conjunction with the psychosocial ones. Surrogate motherhood is still very rare and complicated by unresolved legal issues.

### Adoption

Married couples who go down the fertility road to its limits without success resort to adoption. In an effort to protect the rights of the adopted children, adoption procedures in Israel are slow and cumbersome. These efforts sometimes backfire, as children drag for years through institutions, foster homes, and the courts without a stable environment and the ability to form lasting attachments. The processes are somewhat easier when older children or physically or mentally challenged children are involved, but in these cases, the adoption process can be much more difficult.

From the side of the petitioning couples, the waiting and procedures are sometimes intolerable, creating a large market in adoption of foreign children. Romania was a source, until government corruption and news of HIV infection in orphanages blocked this option. In several South American countries, what was a legal if costly process turned into illegal trade in forged documents, kidnapping, and extortion.

## 10. Sexually Transmitted Diseases and HIV/AIDS

### A. Sexually Transmitted Diseases

The public awareness of STDs in Israel is low. Syphilis, chlamydia, gonorrhea, and herpes genitalis are reportable diseases, but this regulation is not strictly enforced and not fully observed. A structural reason for this may be that Israel does not have STD clinics specializing in both care and prevention.

In the late 1960s, an apparent doubling in reported STDs, believed to be caused by the influx of volunteers after the "Six Days' War," caused the Ministries of Health and Education to recommend the study of sexual knowledge, attitudes, and behavior. This study, carried out in the early

**Table 7**  
**Total Fertility Rates of Jews and Non-Jews in Israel (1965-1989)**

Period	1960-1964	1965-1969	1970-1974	1975-1979	1980-1984	1985-1989	1990	1991
<b>Jews (total)</b>	<b>3.39</b>	<b>3.36</b>	<b>3.28</b>	<b>3.00</b>	<b>2.80</b>	<b>2.79</b>	<b>2.69</b>	<b>2.58</b>
Mothers born in Israel	2.73	2.83	3.05	2.91	2.82	2.82	2.76	2.70
<b>Muslims</b>	<b>9.23</b>	<b>9.22</b>	<b>8.47</b>	<b>7.25</b>	<b>5.54</b>	<b>4.70</b>	<b>4.70</b>	<b>4.70</b>
Jews (mothers born in Asian and African countries)	4.79	4.35	3.92	3.40	3.09	3.14	3.09	3.27 <sup>1</sup>
<b>Christians</b>	<b>4.68</b>	<b>4.26</b>	<b>3.65</b>	<b>3.12</b>	<b>2.41</b>	<b>2.49</b>	<b>2.57</b>	<b>2.26</b>
Jews (mothers born in Europe, America (N&S), Australia, and Southern Africa)	2.38	2.59	2.83	2.80	2.76	2.66	2.31	2.05 <sup>2</sup>
<b>Druze and others</b>	<b>7.49</b>	<b>7.30</b>	<b>7.25</b>	<b>6.93</b>	<b>5.40</b>	<b>4.19</b>	<b>4.05</b>	<b>3.70</b>

The Total Fertility Rate (TFR) is the total number of live children born to a woman throughout her fertile period. It is based on the sum of age-specific fertilities for women between the ages of 14 to 49 and assumes that women of a specific group have the specific age fertility appropriate for their group when they are at that age.

<sup>1</sup> The rise in TFR among Jewish women born in African countries in 1991 is probably due to the wave of immigration of Jews from Ethiopia.

<sup>2</sup> The rather sharp drop in TFR in 1990 and 1991 among women born in Europe/America is probably because of the large wave of immigration from the former USSR where the TFR among Jewish women is below 2.

1970s, also recommended the introduction of a sex-education curriculum into the schools.

The current prevalence of STDs in Israel for 1993 in annual rates of preliminary notifications were 1.1, 0.0, and 0.3 per 100,000 for syphilis, genital chlamydia trachomatis, and gonorrhea, respectively. This is believed by researchers to be below the actual rate. For example, some estimates of chlamydia infection are as high as 10% of the women of 15 to 49 (2% of the population). Estimates of the prevalence of herpes genitalis are also quite high.

In 1988, a Society for the Study and Prevention of STDs was formed under the auspices of the Israeli Family Planning Association, with the aims of joining biomedical and behavioral efforts, integrating prevention with proper early detection and care, and for increasing the awareness of STDs and their risk to health among health professionals. It holds professional orientation and awareness meetings and formulates guidelines for better detection and care of various STDs. Its educational and public activities are conducted within the general framework of the IFPA.

## B. HIV/AIDS

### Situation Report

Currently, HIV/AIDS has a low prevalence/low incidence in Israel. The documented number of AIDS cases for May 1994 was 292—cumulative incidence of 56 per million—69 of which, 24%, are currently alive in Israel. As of June 1994, there were 1,152 people reported as HIV-seropositive who are not ill with AIDS, a cumulative incidence of 256 per million or 0.026%. It is believed that the reporting of cases is accurate. Tables 8 and 9 summarize the published data about both AIDS and HIV in Israel for June 1993.

The authorities cite the fact that incidence of new AIDS cases within Israel is flat as support for their claim that the situation is under control. They also claim that since half of the new AIDS cases are previously known as HIV cases, the actual number of HIV cases is probably twice the number of AIDS cases reported from all sources.

However, it may be that this perception is only the short-sightedness of politicians and policymakers who do not realize that this may be the lower flat part of an atypical hyperbolic curve, below the threshold of doubling. Several

facts apparent in these tables can be a cause for concern. First, the progression from HIV to AIDS may represent the transmission situation in the past five to ten years. Second, 30% of the HIV cases are of unknown risk factor, and almost 10% of all the people identified as HIV-seropositive are also of unknown gender; among those of unknown risk factor, 25% are of unknown gender. Since HIV testing in Israel is mostly voluntary, and there is no summarized and/or analyzed data about the people who have been tested for HIV, there is no information about over- or undertesting in important subpopulations like age groups or genders. This results in a puzzle with more holes than picture.

### Sociopolitical Issues

There are several troubling questions that relate to HIV/AIDS being a biopsychosocial construct, interlocking with sexuality and other social, political, and cultural issues.

The responsibility for dealing with all the aspects of AIDS has been allocated to the Ministry of Health with its mainly biomedical outlook. The decisions of the National AIDS Steering Committee, which is always headed by a physician, are only recommendations to the director general of the ministry. Thus, decisions to implement policies or actions that may have a strong psychosocial component can be taken up only from its biomedical end, resulting in a distinct bias with serious and unpredictable results.

A second issue is more pervasive. On the one hand, there is the perception that HIV/AIDS and infected persons are marginalized and stigmatized. This perception influences the ways in which people with AIDS or HIV and HIV/AIDS issues are treated. On the other hand, there is a proneness in the responsibility for public health to avoid discussing the fact that, in different situations and under different conditions, it may not only be responsible, but essential to undertake unpleasant or even restrictive measures. (In accordance with the traditional Judaic approach, the application is highly dependant on unique situations that need to be weighed from all sides and in relation to all those who are involved, even though the laws are general and cover everyone.) This chain of bias-guilt-avoidance is hardly suitable to deal with the sensitive issues of HIV/AIDS. It may also be responsible for the fact that Israel has yet to form a midrange plan to deal with the disease.

Another issue is the influence of organizational structures and vested interests on the nature of the efforts to stem the disease. Such phenomena affect the definition of prevention and the perception of appropriate behavioral interventions; they are also the source of the phenomenon that policies are formulated, and interventions designed and implemented, prior to ascertaining the behavioral patterns, psychological, social, and cultural determinants of behaviors involved in this disease.

Vested interests come into play, especially when dealing with allocation of budgets, human resources, control, and research opportunities. Thus, the AIDS centers that are located in eight hospitals, and that are treatment-oriented and medically controlled, strive to retain the overall responsibility for prevention, even of interventions that are community-oriented and those in which the behavioral, and even cultural components, are predominant.

**Table 8**

**Cumulative Adult (Age 15+) HIV+ Cases in Israel (June 1993)  
Presented by Transmission Category (After Slater P.  
Sutton's *Law and AIDS Prevention in Israel*)**

Transmission Category <sup>1</sup>	Males		Females		Unknown		Total	
	N	% <sup>2</sup>	N	% <sup>2</sup>	N	% <sup>2</sup>	N	% <sup>3</sup>
1. Gay and bisexual men	153	100.0	—	—	—	—	153	16.6
2. IV-drug users <sup>4</sup>	97	78.2	14	11.3	13	10.5	124	12.6
3. Homophiliacs	47	97.9	1	2.1	0	0.0	48	4.9
4. Transfusion recipients	7	53.8	5	38.5	1	7.7	13	1.3
5. Heterosexuals	199	58.0	139	40.5	5	1.5	343	34.7
Subtotal (known risk group)	503	73.9	159	23.3	19	2.8	681	68.9
6. Unknown transmission	173	56.3	58	18.9	76	24.8	307	31.1
Total	676	68.4	217	22.0	95	9.6	988	100.0

<sup>1</sup> RS (the first author) would have preferred the use of risk practice or risk behavior to the use of transmission category or risk group. This would have changed the structure of this table. For example, the use of anal sex as risk practice (with subdivision for gay or heterosexual groups) could have clarified the relative role of this practice in heterosexual transmission in Israel, without loss of the ability to calculate the risk to encounter an HIV+ partner in sexual encounters within specific groups.

<sup>2</sup> Percentage of the total number of cases in this specific category.

<sup>3</sup> Percentage of this category in the total number of HIV+ in Israel at that date.

<sup>4</sup> Including drug users with additional risk factors.

Most of the HIV tests are done on these sites in which pre-counseling and post-counseling to the people who test seronegative is limited to printed brochures. The people who test seropositive receive a mixture of medical and social counseling with little organized support and few educational programs. Attempts to alleviate the situation, even with the help of volunteer services, meet with suspicion on the one hand, and financial constraints on the other.

### Priority Groups for Preventive Interventions

The prioritization of groups, and development of educational interventions, have been done without prior behavioral and psychosocial studies or any organized decision-making process. Recently, the topic was discussed in an article with several published commentaries recommending the use of epidemiological data to determine priorities for interventions. This proposal would not be a step forward, because it does not give any consideration to behavioral patterns. It also does not distinguish between risk-group, at-risk group, and risk behavior. Thus, it did not consider hemophiliacs, the highest HIV-seroprevalent risk-group, and failed to notice that they are currently at a very low risk for passing on the infection, that most of them are under constant medical supervision and counseling for their primary disease, and that the at-risk group for infection are their sexual contacts.

The commentaries revealed deep differences between people who deal with AIDS, bordering on a communication gap. Thus, the head of the National AIDS Committee declared a commitment to implement a general AIDS education effort among adolescents in schools, while another commentator pointed out that there were still no behavioral data pointing towards that need, and suggesting that the existing epidemiological data, although scanty, favored the targeting of educational efforts to limited priority subgroups within youth.

The establishing of targeted priority groups is important not only because of the scarcity of financial and human resources, but also because of the need to target the educational messages to the specific needs and conditions of subgroups, if one is to expect to make an impact (see below in AIDS Education Versus Sex Education). The general in-

tervention efforts aim at the common denominators and, therefore, may be too diluted and unfocused.

The balance between targeting priority groups for interventions to lower the transmission within those groups, and support for those who are already HIV-seropositive, and stigmatizing these same groups, is very delicate, especially if the groups are marginalized or stigmatized to start with.

Recently, this issue raised its head when the educational and counseling efforts within an immigrant population suffering from high prevalence and incidence rates, and from a heterosexual pattern of transmission, were sensationalized in the media. The fear and shunning reactions of small segments of the population, combined with the sensitivity and shame within this traditional community, triggered reactions toward the professionals who were in close association with them, and set back some of the preventive efforts.

### Contact Tracing and Educational/Counseling Programs

Epidemiological follow-up and notification, support for people who are HIV-seropositive, and counseling interventions could be highly effective, if implemented professionally, compassionately, and discreetly. This was possible in Israel, as no anonymous testing is available, only confidential ones. Unfortunately, the system did not manage to make the essential accommodations to implement such policies.

In one case, when a whole group of immigrants from a country with a high prevalence of HIV was screened on entry, the recommendation for combined supportive and preventive interventions by case managers working within the community was postponed for more than two years. As transmission within the community continued, while people did not come in readily for voluntary testing, it is questionable whether the intervention can be as effective as if it had been implemented nearer to the screening date.

This immigrant community also posed the challenge of developing culturally appropriate educational programs and training personnel to deliver them. It also challenged the system with the necessity for cultural bridging, and the training of cultural mediators between professionals whose beliefs were embedded in biomedical models, and clients who used a combination of traditional lay beliefs and biomedical models.

This was achieved by creating an alliance between a group of professionals and a group of veteran immigrants who trained to become both educational agents and mediators while they also acted as cultural informants and consultants.

### AIDS Education Versus Sex Education

This question, although general in nature, is especially relevant in Israel, a low-prevalence country in which adolescents can be defined by their moderate prevalence of heterosexual risk behaviors when compared to the U.S.A. and European countries, and very low prevalence of individuals being at-future-risk for HIV infection and not at-immediate-risk.

While today's adolescents do not face the probability of HIV infection, they do face a much more tangible risk of pregnancy and STD infection. In this context, attempts to motivate youth by fear of the small risk of HIV/AIDS or by fear of the future may backfire.

On a more theoretical basis, it is questionable whether it is appropriate to introduce youth to the issues of sex through risks of either a deadly disease, other diseases, or a pregnancy. It is proposed that early sex education, focusing on communication

**Table 9**

Transmission Category <sup>1</sup>	Males		Females		Total	
	N	% <sup>2</sup>	N	% <sup>2</sup>	N	% <sup>3</sup>
1. Gay and bisexual men	110	100.0	—	—	110	45.6
2. IV-drug users <sup>4</sup>	43	84.3	8	9.8	51	21.2
3. Homophiliacs	28	100.0	0	0.0	28	11.6
4. Transfusion recipients	7	87.5	1	12.5	8	3.3
5. Heterosexuals	26	74.3	9	25.7	35	14.5
Subtotal (known risk group)	214	92.2	18	7.8	232	96.3
6. Unknown transmission	9	—	0	—	9	3.7
Total	223	—	18	—	241	100.0

<sup>1</sup> RS would have preferred the use of risk practice or risk behavior to the use of transmission category or risk group. This would have changed the structure of this table. For example, the use of anal sex as risk practice (with subdivision for gay or heterosexual groups) could have clarified the relative role of this practice in heterosexual transmission in Israel, without loss of the ability to calculate the risk to encounter an HIV+ partner in sexual encounters within specific groups.

<sup>2</sup> Percentage of the total number of cases in this specific category.

<sup>3</sup> Percentage of this category in the total number of HIV+ in Israel at that date.

<sup>4</sup> Including drug users with additional risk factors.

and decision-making skills, on responsibility for one's actions and health and also for the health and welfare of one's partner, and on alternative, noncoital sexual expressions, would be both more appropriate for adolescents and, in the long run, more efficient in lowering the transmission rates.

It is also important to note that the differences between cultures are not limited to "esoteric" immigrants, but can also be between "similar" industrial countries. Thus, the concept of "safer sex," which is embedded in the basic premises of a society that is highly individualistic and sometimes adversarial, may be insufficient or inappropriate in a culture that puts more emphasis on the sense of community and cooperation between individuals.

It is also questionable whether egoistic motivations, which are at the roots of safer sex, are sufficient in boundary conditions, where altruistic or secondary motivations are needed to augment the egoistic ones. Such considerations will call for alternative educational approaches. Dealing with issues of mutual protection and responsibility need a much more elaborate educational approach than focusing on barriers to condom use or on the mechanical skills of its use. These should be discussed in the wider scope of sex education.

The decision-making, communication, and protective skills learned in sex education are very similar and can be easily applied to protection against HIV/AIDS.

It is somewhat disappointing that the need for a comprehensive approach to sex education and the urgency of such implementation are wasted, because the interests of some politicians meet with those of educational entrepreneurs. The latter promote the use of shelf programs aimed at the largest possible populations and designed to offend as few people as possible. They are thus focusing on "clinical," nonoffensive, and nonsexual aspects of HIV/AIDS, demand minimal training of the implementers, and minimal hours for delivery. The interest of educational and health politicians is in "magic bullet" interventions that can be put in place speedily and with minimal fuss and objections from vocal political minorities.

Such ready-made AIDS-education programs allow them to shirk their responsibility, while pretending to fulfill it. It is only fair to say that some of these politicians do not know better and believe in what they are doing. The responsibility of the entrepreneurial professionals seems to be graver.

#### [HIV/AIDS Education on the Internet

[Update 2001: In March 1999, the largest educational Internet network in Israel, Snunit, opened a site dedicated to sexuality and the prevention of HIV/AIDS. The site was jointly sponsored by the psychological counseling service of the Ministry of Education and the National HIV/AIDS Steering Committee. Its name, Yachad (Together), is significant, because it reflects the fact that the site is not dedicated to prevention in general or to HIV/AIDS in particular, but to couples and sexual relations (Yachad 1999). The launch of this site was a political event because, in order to be sponsored by the Ministry of Education and Culture, it had to be also approved by the National Religious Educational System. Beside information, chat rooms, and question-and-answer sections, the site includes educational activities through which adolescents can examine their attitudes and values, express opinions about the content of sex education in schools, and examine their exposure to risk through sexual behavior. (End of update by R. A. Shtarkshall and M. Zemach)]

#### [Epidemiology

[Update 2001: Most new cases of HIV/AIDS reported in Israel are still people who were infected abroad, most of

them in one country in which HIV is highly prevalent and from which immigrants are continuously arriving into Israel. At the end of October 1999, there were in Israel 605 cumulative cases of AIDS, out of which 155 were still living, and 2,051 reported cases of HIV, which had not yet progressed to AIDS (National TB and AIDS Unit 1999). The Ministry of Health and WHO estimate that Israel has 50% to 100% more HIV cases than reported. Out of the known cases, about two thirds are men. More than 50% were presumably exposed outside Israel by heterosexual contacts. The proportion is much higher for women than for men, 69% and 31%, respectively. Among those exposed abroad, the proportion of men to women is 1:1.

[Recently, two new phenomena have been emerging: the reporting of cases of HIV/AIDS among migrant workers and among immigrants from the former USSR. While the former are mainly sexually infected, the latter are infected through intravenous drug use, and many suffer also from advanced stages of alcoholism and untreated tuberculosis. Israel is a country with a National Health Insurance, which covers treatment of HIV through the most advanced diagnostics (viral load) and medications (cocktail therapy). Since immigrants are entitled to health insurance from the moment they arrive and are not tested outside the gates, there is an inducement for people from countries that do not supply therapy to move into Israel. Recently, some experts voiced concern whether this may increase the burden intolerably on a health system that is in a chronic financial crisis. (End of update by R. A. Shtarkshall and M. Zemach)]

[Update 2002: UNAIDS Epidemiological Assessment: By the end of 2001, a cumulative total of 3,333 cases of HIV infection were reported. Israel is a country with a low endemicity of HIV/AIDS. With the attribute of being a country of immigration, including significant immigration from African countries, rates of HIV are greatly dependent on the origin of the immigrants.

[An HIV/AIDS registry has existed since the beginning of the epidemic. HIV testing is systematic among blood donors and prisoners and among select groups of immigrants from HIV-hyperendemic countries. Testing is confidential and free of charge for any person requesting the service. Testing is done at all community clinics, all across the country.

[Health education programs are developed for both the general population and for groups with risk behaviors. Treatment and follow-up are specialized in regionally distributed AIDS centers, which can provide adequate follow-up and antiviral HAART treatment to all adherent patients.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	2,700 (rate: 0.1%)
Women ages 15-49:	NA
Children ages 0-15:	NA

[No estimate is available for the number of adults and children who died of AIDS during 2001.

[No estimate is available for the number of Israeli children who had lost one or both parents to AIDS and were under age 15 at the end of 2001. (End of update by the Editors)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

### A. Concepts of Sexual Dysfunction and Therapy

Despite the fact that several of the founders of modern sexology in Germany had either passed through or settled in Israel after the rise of the Nazi regime to power, sexology did not emerge in Israel as a discipline until the early and middle 1970s. Treatment for sexual dysfunctions was limited either to medically oriented interventions or to analyti-

cally oriented psychodynamic therapies, which were imported by members of Freud's Psychoanalytic Institute who immigrated to Israel and founded a similar institute with his blessings in the late 1930s.

The medical approach focused on functional symptoms alleviation as a means to solving the sexual dysfunctions, e.g., the use of dilators for vaginal spasms or numbing creams for early ejaculation. While the psychoanalytic approach recognizes dysfunctions, and issues like orientation and gender confusion as separate diagnostic categories, and is interested in deep causes and their transformation, psychoanalysts did not treat them with the same methods and under similar basic assumptions as medical practitioners.

The development of sex therapy in Israel occurred mainly after Masters and Johnson and is, by and large, an import from the U.S.A. Most of the Israeli therapists are trained there rather than in Europe. Currently, there is a pluralism of approaches to the treatment of sexual dysfunctions, ranging from the purely medically oriented through the combined biopsychosocial approach, and the couple-oriented systemic approach to the psychodynamic.

### **B. Availability of Diagnosis, Counseling, and Treatment**

A World Health Organization (WHO) report counted, at the end of 1988, 13 centers offering sex therapy across the country. This list was not exhaustive even for that date, and since then, more services have opened up in different locations.

Most of the clinics are still located in public hospitals or specialists' clinics of the sick funds. Significantly, few of them have a freestanding status, and most are annexed to departments like Gynecology, Psychiatry, or Urology, depending on the medical training of the head of the clinic or on political considerations. These arrangements are typical of a situation in which sexology and sex therapy are still not considered a full-fledged, professional, and/or academic enterprise.

The clinics, even those in the public hospitals and sick funds, are very heterogeneous. A few have several staff members from different disciplines working full- or part-time with a wide range of services. These can offer a full biomedical and psychosocial evaluation and a variety of therapies. Usually, they will also treat orientation- and gender-confusion issues, including evaluations for sex change, e.g., the sexual function clinics at the Hadassah Medical Organization in Jerusalem and the Sheba Medical Center in Ramat-Gan. Most clinics focus on fewer aspects of the sexual functions or offer a smaller variety of services. Several sex-therapy clinics evolved in nonmedical family and marriage services. These offer mostly psychosocial evaluations and interventions. One of these clinics started in the early 1990s also offers surrogate therapy as part of its services. The male and female surrogates are selected and trained by the staff of that clinic.

Two centers specialize in rehabilitative sexology: Sheba and Beit-Lewinstein Rehabilitative Center. These offer both posttrauma and postdisease treatment of sexual concerns and functions.

A relatively recent development is the appearance of specialized private-enterprise sex clinics that use aggressive publicity and cater mainly to men with erectile dysfunctions. These clinics offer mainly treatment by medication, mostly penile injections. There are several reports that they offer rather poor psychological and dyadic evaluations and interventions, and at least one of them is under investigation by the Ministry of Health.

A national association of sex therapists (ITAM) was formed in the late 1980s in expectation of the therapy-licens-

ing regulations. This is a rather loose association that did not take a public initiative in dealing with defending potential clients against exaggerated publicity claims or misconduct.

## *12. Sex Research and Advanced Professional Education*

### **A. Sexological Research and Advanced Education**

There is not one academic department or academic program that focuses on sexual issues or sexology. All the research and training is done under the names of different "professions," with very little integration and/or interdisciplinary approach. One attempt to form an interdisciplinary group ended when the person who initiated it did not receive tenure and moved to Canada. Despite that, several studies concerning sexual function and dysfunction have been carried out in clinical and limited nonclinical populations. Other studies in the educational, psychosocial, and health fields have included issues of sexuality, sexual behavior, and attitudes. The rise of interest in HIV/AIDS issues has focused some attention to what is defined as sexual risk behaviors.

Only one of the four medical schools includes a course on sexuality and sexual behavior in their regular curriculum. The other three do so only as an elective or intermittently. It is possible to be board licensed in gynecology and urology without any course or internship in the psychosocial and behavioral aspects of sexuality. The only specialization that includes some issues of sexuality in the requirements for board certification is family practice. As a result, at least one of the postgraduate courses in this specialty offers a 32-hour unit on sexuality and sexual issues in the family practice and a 16-hour unit on family planning and contraception.

Several of the universities and colleges offer scattered academic courses on sexual issues within various faculties, schools, or departments. Such are the courses at the School of Social Work of the University of Tel-Aviv, sex education courses at the Kibbutzim teachers-training college, and others.

The Hebrew University of Jerusalem has several academic courses in family planning in various departments. One of them is an interdisciplinary course to train counselors in family planning, contraception, and sexuality-related issues. Although part of the M.P.H. curriculum, this course is considered to be an intervention course in the School of Social Work, and a skills course in educational counseling and psychology. Other courses there are those focusing on the biological, social, and psychological bases of gender differences.

Several courses in sex education are offered within university schools of education. These are nonacademic, in-service training courses held in cooperation with the Unit of Family Life and Sex Education of the Israeli Ministry of Education and Culture. Nonacademic courses, mainly in sex education and family planning, are offered by the Ministry of Education and the Israeli Family Planning Association (IFPA). These take the form of annual courses or concentrated workshops on general issues, on specialized populations (e.g., immigrants and challenged youth), or special issues (e.g., dealing with rape and coercive sex in the educational system, new methods in sex education, and cross-cultural issues).

Recent developments may herald some changes. First, one of the courses in sex education, which is coheaded by Ronny A. Shtarkshall, is currently considered for inclusion in the master of arts degree program by the School of Edu-

cation of the Hebrew University of Jerusalem. This is a 168-hour course for training facilitators for interactive experiential work in sex education. The 56-hour, theoretical-academic component of this course will give, if approved, four annual credits at the graduate level. Second, the IFPA has initiated within the Post-Graduate Training Program of the Sakler Faculty of Medicine of the University of Tel-Aviv an interdisciplinary program in population, family planning, sexual health, and counseling. Third, the IFPA board of directors and council approved criteria for the training and recognition of sex educators. These include academic studies, skills training, sensitization and desensitization to sexuality issues, and supervised experience. It is expected that these developments will create some change in the attitudes toward professionalism in sexual issues.

## 13. National, Religious, and Ethnic Minorities

### A. The Muslims

Muslim Arabs, the large majority of Arab citizens in Israel, constitute 14% of the population of Israel. Their situation is unique: a minority within a Jewish state and culture that has been at continuous war with its neighboring Muslim countries since its founding.

Despite that, some sense of group autonomy that transcends individual rights is recognized by the state, as matters like marriages, divorce, and family law are in the jurisdiction of the Muslim religious courts.

While the national and political aspirations of Muslim Arabs in Israel may be at odds with the mainstream of Israeli society, it is interesting that both the Muslim establishment and the population approve of the Israeli system that allows the religious courts of each denomination to govern its own population.

The religious courts are bound by the civil code, which takes precedence in matters in which the religious courts are at odds with it, like the ban on polygamy and the legal age of consent for marriage. Only recently, the Supreme Court ruled that the religious courts cannot ignore the rulings concerning division of property between husband and wife, which give women more rights than under the religious canons.

This indigenous control also gives the traditional establishment power over younger "upstarts." If there is a movement striving to free the Muslim society from the strong hold of the religious establishment, it is much less visible than among the Jewish segment of the population, perhaps as a result of the value placed on a uniform stance as a minority.

There are several other factors that affect sexual, marital, and familial issues in which the Arab-Muslim society differs from the Jewish mainstream. The Jewish majority is largely urban with an industrial and service-based economy, with high measures of modernity including women's education and their participation in the workforce. The starting point of Arab-Muslim society is largely rural, its economy is based on farming, and the determinants of modernity are rather low. This is rapidly changing, but there is still a wide gap. In

recent years, both academics and some small activist organizations have broken the unified front by publishing studies about marriage patterns, sexual violence, and other disputed issues, and waging public campaigns against phenomena like murder for the honor of the family. These reports provide a good background for discussion of such issues.

### Marriage as a Public Transaction Between Families

The traditional view of marriage in the Arab, mainly Muslim, society is of marriage as a transaction between families, concerned mainly with strengthening the economic and political power of the extended family/tribe, the *Chamulah*. Love and sexual satisfaction have very little to do with marriage, but procreation is very important. This is typical of rural societies, depending on land for wealth and prestige and on unity for its preservation. Marriages are arranged between families, sometimes against the will of the bride or the groom.

Bride payment, *Mohar*, is paid according to the desirability of the bride and the purity of the name of the family daughters and the status of her family. The collection of appropriate *Mohar*, especially for a highly desirable bride from a prestigious family, is a very heavy burden on young men if they do not have the support of their well-to-do families or if they are poor. Thus, the practice of arranged marriages with high *Mohar* has acted not only to preserve the wealth, but to keep the younger men in line and preserve the social status quo. The payment of the *Mohar* has also represented symbolically the fact that the bride's family was losing a labor force, while the groom's family was gaining one, as well as a potential mother of children. Therefore, the fertility of the bride's mother, her aunts, elder sisters, and cousins has been a factor in her desirability and her *Mohar*. This contributes to the fact that the pregnancies and childbearing of each woman in the *Chamulah* is the business of every other woman. Women move into the husband's extended family, but her family of origin is still responsible for her proper conduct.

### Inbreeding

Several mechanisms exist to facilitate keeping the wealth, especially land ownership, within extended families. One is reciprocal marriages: Families exchange two pairs of their offspring, one male and one female from each family. These male-female pairs are often a brother and sister or first cousins. This saves the dowry payments for both families, but also creates double-kinship lines. A second mechanism is the marriage of first cousins, second cousins, uncle and niece, or aunt and nephew, although this is not as common today as in the past. The result is that 45% of all marriages in the Arab society in Israel are between relatives; 25% are of first-degree kin.

This happens despite the decrease in arranged marriages and their transformation into ritual formalization of voluntary pair formation. This seeming paradox can be explained by the fact that, despite modernization, the Arab society is still a closed one with low mobility. The available choices for marriage are limited and usually come from the same village built around extended families.

The health implications of these phenomena can be dire. Several villages, which are socially or geographically isolated, suffer from an extremely high incidence of specific genetic defects. Efforts are being made to lower the rate of genetic defects, even among the married relatives, by appropriate genetic counseling.

One such defect within the domain of human sexuality is the existence of a large number of pseudohermaphrodites of

the dihydrotestosterone (DHT) or 5-alpha reductase deficiency. First reported and studied in the Dominican Republic, this recessive gene mutation has been traced to one family that migrated from the Syrian mountains about 150 years ago and continued to intermarry. A brief attempt to study these people and their environment, while extending them medical help, was cut short by the realities of the Israeli-Arab conflict. It was ascertained that the extended family is aware of the situation and of the peculiarity of these children. Yet, it was never clear whether this is an internal familial terminology or a public one. They almost invariably strive to become men because of the dominance of males in the Arab society. The very few individuals who live as females are servants within their own families.

### *Polygyny*

Another aspect of marriage among Muslim Arabs in Israel is polygyny. The Islamic religion allows a man four wives and as many concubines as his household can support. In reality, it was very rare that a man had more than two or three wives. One of the customs was for the older and dominant wife to choose a younger one for the husband, usually one that she could dominate.

Polygamy is banned by Israeli law. This ban was enacted mainly as a measure affirming women's equality, as a reaction to the custom of Jews who immigrated from Islamic countries. Acceptance of the law by Muslim Arabs in Israel was almost universal until 1967, when it became possible for men to have another wife either from or in the West Bank or Gaza district. Despite this, most Muslim Arabs obey the law and there are very few prosecuted cases of polygamy.

### *Perceptions of Male and Female Sexuality*

In Islamic cultures, the sexuality of men and women is perceived as moving in different directions during a lifetime, a picture somewhat in accordance with some modern sexological descriptions of the early peaking of male and later peaking of female sexual prowess.

According to this Muslim view, men's sexuality is uncontrolled in their youth before they marry. This is the time to keep guard on them, but also to allow them to fool around with women of ill repute. This is also the time to go to war or to forage (where women are seen as the spoils of war). After marriage, as men grow older, their appetites, while undiminished, become more controlled because of their added wisdom. In men, wisdom, cunning, and cool control over situations is usually associated with age.

The sexuality of a woman is believed to be low in her youth and she is perceived as innocent. It is only after losing her virginity that the sexuality of women will grow and may get out of control. Therefore, married women are to be guarded at all times. A man's inability to satisfy his woman or to keep her in line is a very bad reflection on the husband's manhood, in addition to bringing shame to the woman's family of origin.

### *Family Honor*

Two concepts are strongly associated with family honor. The first is the public proof of intact female virginity at marriage; the second is punishment for its defilement. In a traditional wedding ceremony, the family of the bride, usually the mother and/or aunts, are expected to receive the sheet with the signs of hymen blood on it and exhibit it in public. Contrary to popular belief, this is not only a sign for the intactness of the bride's honor, but also proof of the groom's virility.

Sex therapists working with Arab populations encountered the male fear of slighting one's own manhood and family honor by failing to perform. On the other hand, there

are reports that the literary description of shyness and reluctance, signifying a virginal nature that are expected to be conquered by force, are part of the construct of women's perception of the first intercourse. The emerging picture is that of a ritual choreography where each partner has to play his or her traditional role in order to bring it to its full destiny and honor both families.

Even in rural and highly guarded societies where marriages are arranged, young people find their ways to associate with each other. In recent years when schools became coeducational, when there is greater freedom of movement, and when Arab youth are attending universities together with a majority of Jewish students at the age of 18—they do not serve in the army—it is much harder to avoid romance and a certain amount of sexual play between youth. As already mentioned, family arrangements are many times a formalization of self-selection.

Despite this change, the symbolic meaning of virginity is still important. Two sexual practices help young people to keep the hymen intact while engaging in sex: interfemoral and anal intercourse. The first is more risky to the woman as she may become pregnant, and also the man may catch her off guard and penetrate the hymen. The second avoids both, but in the area of HIV/AIDS may be inadvisable. No research has been published on this subject among Israeli Muslims, although there is enough anecdotal information to say that both practices are prevalent.

“When the family honor is shamed, it has to be cleansed with blood.” This is true not only of issues of honor relating to women, but also in other cases of honor, including blood feuds and ritual revenge. Both the annals of the courts and fiction are filled with such stories.

In cases of sexual honor, there are some revealing features. First, when family honor is shamed in matters of sex and marriage, the woman carries the main burden of punishment and men rarely are blamed. One possible reason for this is that killing a man will touch on another matter of honor and start a blood feud that may last for generations. Second, when a transgression is made public, it is the woman's family that carries the burden of cleansing it with blood and killing the alleged transgressor. It was found that in many instances, the women of the family either incite the men to action, or even actively participate in its preparations or the actual deed. This is understandable in the light of the fact that an unpunished transgression reflects mainly on the good name of the women of the family, thus reducing the chances of the unwed ones to marry or to receive a good *Mohar*.

In 1992, a group of Muslim women activists publicly agitated against this practice for the first time. They even demonstrated in public against it, an unprecedented action. It is still unclear whether Jewish female and male activists, by joining in this campaign, will strengthen or weaken it. There is certainly strong expressed sympathy from Jews toward this campaign.

Unlike the practice in some Islamic countries, the courts in Israel do not accept the honor of the family as a mitigating circumstance. On the contrary, they have expressed their lack of sympathy for such customs and followed it with the maximum punishment under Israeli law, which is a life sentence.

### *Fertility Patterns and Their Secular Trend*

The total fertility rates (TFR) of Muslim Arab women in Israel (4.65 in 1993), is the highest among the national religious groups composing its population. Still, it has also undergone the most marked decline in the last three decades (see Table 7). The drop in TFR from 9.23 to 4.65 in 35 years

is proportionally lower than that of the Christian Arab women (50% and 52%, respectively), but in terms of absolute family size, it is much greater. Christian women are having, on the average, only 2.6 children less as compared to 35 years ago, and their TFR is the lowest among the studied groups (2.09 in 1993), while Muslim women are having on the average 4.6 fewer children.

An attempt to study the contribution of different independent variables to this fertility change has revealed an interesting picture involving the cumulative effect of seven independent variables. At the time of the study (1988), the independent variables that were the most strongly associated with both the desired and achieved number of children were the mother's age group, her education, and a traditional arranged marriage with payment of a *Mohar*. Two other independent variables were associated with only one of the studied variables: Urban or rural locality was associated only with the desired number of children, while participation in the workforce was associated only with the achieved number of children.

Education seems to be the strongest of the associated variables, the difference in desired fertility between the two extreme educational categories being almost two children, and between the achieved fertility at a relatively young age (28.5) by one child. The type of marriage is a variable showing the second strongest association. The differences in the desired and achieved fertility between the two types of marriages are 0.6 and 0.5 children, respectively. The other variables, even when significant, showed much smaller differences. Prominent in their lack of association with either the desired or achieved fertility were religiosity and marital lifestyle (who gives up aspirations for the sake of the family).

The combination of the independent variables together show a better overall explanatory power for desired fertility than it did for the achieved fertility. One possible explanation of this discrepancy is the fact that the analysis was done with relatively young women who were still at an interim

stage of achieving their fertility aspirations. Another explanation is that the study was dealing with cognitive conscious variables that associated with the verbal desired fertility, while achieved fertility is more associated with unconscious factors that are not available for this kind of analysis.

#### *Contraceptive Use*

Several studies have demonstrated that the availability and use of contraceptives, in themselves, were only weakly associated with the achieved fertility, the use of contraceptives, as an intermediate variable mediating between the desired fertility and the achieved one, being the behavioral means to space pregnancies or to terminate fertility. Table 10 compares the use of contraceptives among the Jewish population and Muslim Arabs. In order to get a better analysis, the study distinguished between women who do not use contraceptives because they are currently not exposed to additional pregnancies, and those who do not use them for other reasons. The former are pregnant women, women who try to conceive, infertile women, or those who do not practice sexual intercourse.

The first significant fact, in terms of fertility rates, is that the proportion of "non-exposed" women among the Muslims is much higher than among the Jewish women, 29.4% as compared to 20.6% of all the women, respectively. The bulk of the "non-exposed" are pregnant women and those trying to conceive. This means that at any one time, roughly 40% more Muslim women were in the process of having children (see Table 11).

The number of "nonusers" among the "exposed" is also very significant, 21.3% of the "exposed" Muslim women compared with 11.3% among the Jewish women—15.1% as compared to 9% of the total number of women, respectively. This number is very important because it marks the percentage of women among the "exposed" who do not want to conceive, but do not use means of protection from pregnancy. Therefore, these women may be a potential au-

**Table 10**  
**Comparison of the Use and Non-Use of Contraceptives Among Married Jewish and Muslim Israeli Women (Aged 22-44 Years, 1988)**

	Number of Women	Percent of Total	Percent of Exposed
<b>JEWISH WOMEN</b>			
Users of contraceptives	1192	70.6	88.8
Non-users of contraceptives among exposed (non-use for reasons of fear, reluctance, principle, family opposition, no intercourse, or ill-defined)	152	9.0	11.3
Subtotal exposed	1344	(80.0)	100.1
Non-exposed non-users of contraceptives (non-use because pregnant, want to become pregnant, recently delivered, infecund, or no intercourse)	346	20.6	
Total non-users of contraceptives		29.6	
Total number of women	1680	100.2	
<b>MUSLIM WOMEN</b>			
Users of contraceptives	258	55.5	78.7
Non-users of contraceptives among exposed (non-use for reasons of fear, reluctance, principle, family opposition, no intercourse, or ill-defined)	70	16.1	21.3
Subtotal exposed	328	(70.6)	100.0
Non-exposed non-users of contraceptives (non-use because pregnant, want to become pregnant, recently delivered, infecund, or no intercourse)	137	29.4	
Total number of women	465	100.0	

dience for family planning efforts. Another such group not shown here is the women who actually attempt to avoid conception, but who are using inefficient methods. Their percentage is also higher among the Muslim than Jewish women. The conclusion is that when looking only at the women who do not desire conception at a given moment, there is a strong need for family planning efforts among the Muslim Arabs in Israel in order to allow them to realize their desires.

### *Fundamentalist Islam and Women's Status*

In the last ten years, the fundamentalist Islamic movement has gained power among the Muslim Arab population. The change is evident in both social phenomena and in the rise to power of the Islamic movement in the local elections. More women are seen wearing the traditional *chador* covering a woman from hair to toe at both high schools and universities. In previous years, such garb was limited to older rural women. Many mosques are being built in communities, boys and girls are separated in the schools, and there are overt attempts, some of them not so delicate, to bring women "back to their place," ban alcohol, permissive dresses, erotic films, and so on. The Islamic fundamentalists, who are politically most anti-Israeli, are similar in several respects to some Jewish ultra-orthodox groups.

### *Sexual Violence Against Women and Children: The Deep Silence*

The issue of sexual exploitation, coercion, and violence against women and children in the Arab sector has only recently been discussed in public; a first study has been published on the matter and crisis centers have been opened.

Because several characteristics of Arab society, especially in the sexual arena, make it against the self-interest of women, children, and concerned caretakers to make public accusations or seek help in situations of abuse, crisis support is mainly provided by telephone hotlines that allow the caller complete anonymity. A virgin woman who loses her virginity, for whatever reason, has a lower value in marriage and a taint on the ability of the family to guard the virtue of its daughters (which may reflect on the marriage value of other female members of the family). If a married woman is raped, the perception of nonvirgin women as tempters may

cause people to blame her for what happened and not the man (over whom women may have sexual powers). A raped boy or man may keep quiet in order not to raise doubts about his manhood, which is highly valued in that society, and therefore in his ability to marry. Thus, the rape crisis centers that have counseling, intervention, and hotline programs in Arabic report that their contacts in the Arab sector are predominantly by phone, and that fewer callers will agree to identify themselves, make contact, or press charges, as compared to the Jewish sectors.

### **B. Ultra-Orthodox Jews**

The ultra orthodox, or *Haredim*, have an ambivalent existence as non-Zionist Jews, recognizing only divine rules yet living within a Jewish state. In some sense, it is more difficult for them in Israel than in the Diaspora under the rule of non-Jews. Judaism, as a national as well as an individual religion, prescribes rules of conduct not only within the private domain, but also in the public one. These rules do not apply to non-Jews, so it is only among Jews of differing practice that many conflicts arise about public observance of certain rules.

Many of the ultra orthodox live within a defensive spiritual perimeter, trying to isolate themselves and their children from the encroaching influence of secular temptations. They have a separate educational system that, although financed by the government, is totally outside of its educational supervision. Most of their youth do not go to the army, a highly significant experience in the life of secular and orthodox Israeli youth, which has an impact on dyadic, gender, and sexual issues. They also often feel strongly that secular Jews do not understand the importance of their way of life and, being in conflict with them over their own needs, hate or ridicule them. They, therefore, shun strangers, even the ultra orthodox who belong to other sects or communities. As their communities are very closely knitted, their life revolving around the synagogue, the ritual bath, and other public functions, it is very difficult to penetrate into their life.

It is even more difficult to penetrate into issues of sex and marriage that are not discussed in public. A very few windows have been opened into these areas in both fiction and nonfiction, written by people who were formerly ultra orthodox, in a study by a woman anthropologist among religious women, and in sexual counseling and therapy.

[*Comment 2003*: David S. Ribner (2003ab), a professor of social work at Bar-Ilan University in Ramat Gan, Israel, has identified six pervasive influences on the sexual behavior of Haredi Jewish couples, summarized briefly here:

- [*Holiness and sanctifying intimacy*. Because the Haredim see sanctity as infusing every aspect of human experience, all sexual behavior must be intentionally sanctified. By its very nature, sexual behavior cannot be neutral. A Haredi couple must consciously focus on creating an atmosphere of holiness through proper thoughts and some time-and-circumstance limits on behavior—the Sabbath eve is a preferred time for sexual relations which must always take place under the cover of a sheet. As Ribner (2003a, 55) notes, "Attempting to instill a feeling of sanctity while flooded with all the sensory in-

**Table 11**

**Use and Non-Use of Contraceptives among Married Israeli Muslim Women According to Exposure/Non-Exposure to Pregnancy and the Reason Given for the Exposure/Non-Exposure (Aged 22-44 Years, 1988)**

	Number of Women	Percent of Total	Percent of Exposed
<b>Users of contraceptives</b>	258	65.5	78.7
Non-use on reasons of principle	25	5.4	7.6
Non-use because of reluctance, fear, ill-defined	45	9.7	13.7
<b>Non-users of contraceptives among exposed</b> (principles, opposition of family, reluctance, ill-defined)	70	15.1	21.3
<b>Subtotal exposed</b>	328	(70.6)	100.0
<b>Fertility-targeted non-use</b> (pregnant, want to become pregnant, or delivered recently)	115	24.7	
Infecund or no intercourse	22	4.7	
<b>Non-users non-exposed</b>	137	29.4	
<b>Total number of women</b>	465	100.0	

puts of physical intimacy may prove a daunting goal indeed, one often doomed to failure.”

- [*Time and the scheduling of intimacy*. Strict Jewish observance forbids any physical spousal contact during menstruation and the following week. This “two weeks on/two weeks off” pattern of contact characterizes marital life until menopause, with uninterrupted contact permitted during pregnancy and nursing. Intercourse is strongly recommended on the Sabbath eve and the ‘mikve’ night (following the woman’s ritual bath that marks the end of the two-week menstrual-related abstinence.
- [*Modesty in sex as in all else*. Any public contact or display of physical affection is prohibited. This means that Haredi children grow up without ever seeing any examples of parental affection. Sexual thoughts and fantasies about one’s spouse are also forbidden. Sexual intercourse must take place in the dark, although the couple may use some indirect light during foreplay. It is not acceptable for the husband to look directly at the wife’s genitals. The couple should be covered with a sheet during intercourse, but nothing should come between them. These modesty requirements often present major obstacles for newlywed Haredi couples, and even couples married for some time, in shifting from an asexual lifestyle to marital relations with strict modesty requirements.
- [*Being together and becoming sexually active*. The abrupt shift from total abstinence to the initial physical contacts of marriage pose “a daunting challenge fraught with unknowns in a number of areas” for newlywed Haredi. In addition to the total lack of any opportunity to see someone of the other sex not completely clothed, either in person or in print, the little or no information about one’s own sexual anatomy, the spouse’s sexual anatomy, and what to expect in sexual arousal, “can create a potent problem-producing context. Difficulties in their purely physical realm may be as basic and as painfully awkward as neither husband nor wife knowing the location of the vaginal opening” (Ribner 2003a, 58). In addition, with minimal dating and conversation before the wedding, emotional intimacy and sexual communication with the spouse become problematic.
- [*Communications and the language of intimacy*. Everyday life in a Haredi community clearly militates against any exposure to or acquisition of language to describe the sexual parts of one’s own body and the body of the other sex. Haredi women are encouraged to avoid being verbally explicit about their own intimate desires and to use nonverbal clues. Men have more leeway in this than women, but it is difficult for either men or women to be conscious of sexual desires when both have been taught to repress any sexual thoughts or fantasies about their spouse.
- [*Sexual isolation*. With no television, often no radio, no movies, no secular novels, and not even innocuous family or women’s magazines to read, the Haredi couple is protected from any sexual information from the outside during the entire course of their marriage. The rules of modesty practically eliminate any possibility that either spouse will share his or her sexual concerns or questions with a friend, relative, rabbi, or physician. (*End of comment by R. T. Francoeur*)]

### *Arranged Marriages: Potential, Yichus, Health, and Money*

Marriage in the orthodox tradition is one of the most revered institutions. Many if not most of the religious rituals are familial, and it is assigned a most important role in transmitting the Judaic values from one generation to another.

Although Judaism allows divorces, they are highly stigmatizing; striving for the intactness of the family and keeping the peace within it are highly valued.

In the ultra-orthodox tradition, marriages are arranged, either through marriage brokers, or through interested parties in large family circles, or among friends. Four factors are highly important in arranging marriages. They are not necessarily the same for men and women, but they interact in more than one way. First, and probably the most important factor for a man, is his potential in Halachic scholarship. As marriages are arranged around the age of 18 to 20 for men and 16 to 18 for women, a realized potential is rare. The heads of the religious academies or seminaries—the *yeshivas*—will be looking for a suitable match for their most promising students. These will be decided by the second and third qualities: *Yichus*, for which the nearest translation is lineage and financial security. The first *yichus* concern focuses on finding a woman who is herself from a family of Halachic scholars, and thus will not only literally support her husband in his struggle for scholastic excellence, but also increase the chances of bearing and raising children who will be such scholars. This set of *yichus* issues also includes all the qualities of the lineage, not only the hereditary ones, but also ones like the “name” of the family, past divorces of other family members, and other such factors. The second *yichus* concern looked for in women is the ability of her parents to support the continuing studies of the husband in the *yeshivah* for years to come. Such support is contracted for in marriages and may place a heavy burden on the parents, as they can last for three, five, ten, or even more years. During that time, the parents can expect to support not only the young couple, but between three to six children. The quality of *yichus* is also a determinant in the men’s eligibility, but not the financial one, if they are scholars. The financial status is important in men who are not scholars and who are in business or in trade.

Another highly valued factor is health, that of the bride and groom, and the health of their families. Thus, families strive to hide any “problematic” health problems like mental health, developmental disabilities, genetic disorders, or subfertility. They may hide such a son/daughter, even to the point of denying full care because of denial mechanisms.

Many things can detract from the value of a person in marriage, even having a brother or sister who has become less religious. Thus, gossip can be very harmful, and whisper campaigns pernicious. The admonitions against disqualifying gossip about brides and grooms are severe, which attest to the importance of the issue.

Sons and daughters of the big rabbinical families usually marry only within “proven” lines. Sometimes three or four such families remarry for several generations. Such marriages acquire the proportions of almost royal events.

Thus, marriages are viewed mainly not as an issue of the heart, but rational arrangements whose main purpose is to establish a viable, socially, and financially secure unit with a good potential for reproduction, continuations, and excellence.

### *Rules of Conduct Regulating Intercourse*

As stated before, in Judaic tradition, sex is an entity that intrinsically is neither good nor bad, but has a high potential for both. The nature of sex is dependent on its meaning, context, and practices.

For orthodox people, and certainly for the ultra orthodox, the context and practices are highly important and intermingled. The central role of intercourse is procreation in the spirit of the blessing “Procreate and multiply and fill the earth,” although the Halachic basis for the rules and regula-

tions covering the *mitzvah* to procreate are anchored elsewhere. On the other hand, it is important to note that sex is practiced as one of the marriage obligations of the husband, not only for procreation. Thus, contraception may be allowed either for spacing or for ending pregnancies, if one of several reasons recognized by the *Halachah* occur, even before the proscribed number of children is reached. During such periods, when procreation is not its reason, sex continues to be a *mitzvah*.

In terms of meaning, sex, as most other things, should be practiced for the glory of God and his creation. There are several degrees of elevation in practicing it, but if striving for a higher step disturbs one from fulfilling the *mitzvah* itself literally, then that person is really sinning and should change his or her ways. This sometimes has meaning in sex therapy, as the therapist encounters a phenomenon in which sexual dysfunction is explained by the need to strive for an elevation of the sexual act.

The context of practicing sex is restricted to the boundaries of marriage and to the prescribed period of the month that is determined by the woman's menstrual period (see below). The rules of conduct governing the actual act of intercourse are numerous, from the amount of light which is allowed into the room (only indirect), through the place of religious books during the act, through positions that are recommended and acts that are proscribed, to mention just a few. A most-proscribed act is, of course, the spilling of semen in vain, which determines the fact that condoms and withdrawal are religiously banned. There is a discussion whether, if in the course of transgressing other laws, the use of condoms is allowed for protection against AIDS. Another rule of conduct that is perfectly natural and understandable to those practicing Judaism in its ultra-orthodox variation is that women are prohibited from direct verbal initiation of intercourse, although they are allowed other means of initiation, including indirect verbal ones.

It is important to note that pleasure is considered an integral part of the act, and it is the duty of the husband to "please" his wife. This raises several interesting issues, some of which have a meaning in sexual counseling and therapy. First, what is the meaning of pleasing or pleasure in the differing minds of men and women? This will determine if at all, what, when, and how, they ask for something in practice. This also poses a problem for a nonorthodox therapist who may interpret pleasure either in a culturally inappropriate manner, or neglect to include individual variations and needs within the stereotypical interpretation. A second question is what proportion of the couples practice intercourse strictly according to the rules, how prevalent are the private variations to the public norms and how far they go?

#### *Purity Laws: Periodic Abstinence, the Public-Private Dualism of Sexual Intercourse, and the Social Control Over Fertility*

Purity laws restrict the period in which a couple can practice intercourse to about half of the month. The cessation of not only intercourse, but any direct or indirect physical contact between husband and wife is determined by the onset of menstruation; this is called the *Nidah* period. Toward the end of her menstrual period, but not less than five days from its onset, the woman has to check with white cloth at the external opening of the cervix, whether she is still bleeding. When there are no signs of bleeding any more, she has to count seven "clean" days; at the evening of the last day, she has to cleanse herself in the "*mikveh*," literally a pool, which is the public ritual bath. On that same night, her husband is to approach her for intercourse.

This emphasis on purity and the high visibility of the dualism between impurity-purity in women's lives, raise several issues that can be viewed from different aspects.

Writings by religious people directed mainly at non-observant people argue in a mixture of apologetic and aggressive modes that these laws protect the health of women in the time when her body is most vulnerable to infections through sexual intercourse, and that the periodic abstinence creates a healthy sexual tension between husband and wife, and not only increases the bond between them, but also puts some meaning into it. There are also claims that restrictions on intercourse, and the timing of the first intercourse after the abstinence, act not only to increase fertility, but also to the lowering of birth defects. Little evidence has been compiled that will be accepted as supporting the biomedical claim, in fact, and some of the evidence is cited wrongly or out of context. As for the psychological and dyadic claims, this may be true for some couples, but may be totally the opposite for others. Ronny A. Shtarkshall observed in a biased population of help-seeking couples that the purity laws were sometimes the focus of strong suffering on the side of women and a cause for conflict. Some women, for example, complained that the ban of touching was unbearable, especially when in a low or depressed mood or when one is ill or suffering. This was also true when the husband or an adolescent child is suffering. Women also complained that intercourse at the end of the *Nidah* period had a "mechanical" aspect to it, which causes both individual and interpersonal difficulties. The fact that this mechanical aspect of the intercourse—fulfilling a *mitzvah*—may have been only perceived or partially true is unimportant here. The important aspect is that it could cause difficulties and that it has to be addressed.

A highly important point of view is the feminist discourse that includes these laws as one of the determinants of the status of women in the Jewish religious society. Despite the fact that this discourse totally ignores the fact that purity laws also apply to men and to sperm emission, in a highly elaborate way, they point to some very important issues.

First is the issue of fear of contact with a *Nidah* woman unknowingly, which governs the rules of conduct of many orthodox men who will refrain from any casual touch or shaking hands with women. Thus, every woman is suspected to be impure unless proven otherwise. This may be the explanation for grandmothers sometimes being more "touching" than mothers when boys are concerned, and the readiness of the adolescent boys to accept this physical contact.

Second is the heightened awareness of adolescent girls of their bodies, its potential for impurity, and the need to examine it regularly. On the other hand, adolescent boys are introduced to the female issues from a totally "impersonal" point of view, through learning about it in their Halachic studies. The fact that boys also become aware of their own bodies through the need to keep a constant watch over themselves as not to spend semen in vain (which includes nocturnal emissions), and thus be in danger of defiling the religious scrolls, is not alleviating the potential harm that such awareness may impose on the development of girls.

It is important to emphasize that this discourse is mostly limited to nonreligious circles and to religious women of North American origin. Writings about these issues from this point of view, or from related ones, by orthodox women are generally not available.

An important point that is raised by both religious men and women, sometimes from different perspectives, is the public nature of intercourse and of fertility that is dictated by the use of the *mikveh*. Some recent ethnographic/anthropologic literature describe the feelings of women who go

back home after visiting the *mikveh*, feeling in the look of every person in the street, especially the men, the knowledge of the expected intercourse. Thus, a very private act acquires a very public aspect. Both men and women in therapy for either lowered fertility or for sexual issues frequently comment on the fact that going to the *mikveh* is a public proclamation of the failure to conceive in a society where both internal familial and external pressures for procreation are very high, especially on young couples. Men and women commonly comment on the fact that it is public knowledge even before that, when people, especially parents and in-laws, can tell when they refrain from touching each other or making contact, even indirectly, through a dish. This may have several implications (see discussion of therapeutic issues below).

### Fertility Patterns

Although the high number of children born to ultra-orthodox families is obvious and an accepted fact which influences both perceptions and politics, there is little hard data on the fertility patterns of the ultra orthodox. This results from a combination of administrative restrictions and reasons embedded in the ultra-orthodox culture. While the religion of the parents is noted on the birth certificates of newborns, there is no notation of religiosity on documents that are the basis for all the statistical calculations of birthrates, age-specific birthrates, and TFRs. Thus, secular, traditional, orthodox, and ultra-orthodox Jews are in the same category. As the ultra orthodox tend to live in geographically cohesive communities, it is possible to get a handle on their fertility through statistical regions. The TFR for Jews in the city of Jerusalem, which has a high proportion of ultra orthodox (30% by municipal elections), is almost two children higher as compared to the TFR for Jews in the two other big urban centers—Tel-Aviv and Haifa—3.72 as compared to 1.86 and 1.91, respectively.

It is apparent even to naive observers that the fertility pattern is totally different both in spacing and in TFR, as it is common to encounter families with six to nine children and not uncommon to encounter families with ten to 14 children. Young couples usually aim at having the first child as soon as possible, within the first year of marriage. Studies have shown that this is such a prevalent and internalized norm that couples rarely discuss this issue. As a woman's menstruation and pregnancy are public knowledge, loving and concerned pressure is brought to bear on couples early in the marriage. Parents and in-laws are sometimes unaware that such pressures can be devastating both to the fertility and to the sexual functioning of the young couple.

Even in a fertility survey, it was difficult to look at the ultra orthodox separately, because their women tended to avoid being interviewed and were, therefore, underrepresented. The reasons for refusal, especially when the interview touched on issues of children, fertility, and family planning, are perfectly understandable from inside their cultural environment. First and foremost, children and fertility are one of the most precious things in the life of women. In a society where the future and planning for the future are the prerogative of God, any tampering, even a verbal one can be construed as tempting fate or courting punishment. Second, there is the fear of being misunderstood and/or stigmatized by outsiders, especially nonreligious Jews. Third, there is the fear of the evil eye resulting from jealousy.

### Contraception Versus Family Planning

Despite the strong emphasis on procreation, the Jewish *Halachah* allows contraception on the basis of individual

needs and circumstances. As the principles of the *Halachah* do not recognize general rulings, each individual case has to be decided by a Halachic authority on the advice of medical opinion. On the other hand, there is a very strong public opposition to family-planning services. The delicate differentiation between family planning and the use of contraceptives lies in the realm of purpose. While family planning, as such, is a transgression, the use of contraceptives for religiously recognized purposes is allowed.

The religious rules govern not only the use of contraceptives, but also the types of contraceptives to be used. As already mentioned, two types of contraceptives are almost totally banned: male contraceptives and nonreversible contraception, whether male or female. Among temporary female contraceptives, currently the most acceptable ones are combined birth-control pills (for women with breakthrough bleeding), the IUD, and diaphragm. Again, there are personal variations, and medical opinions are sought and listened to.

The public opinion against family planning and contraceptive services is such that ultra-orthodox women, even those with strong need that will probably be acceptable to the Halachic authorities, refrain from seeking help. The tip of the iceberg was seen when women listeners started writing to a weekly radio program, "Not a Children's Game," devoted to reproductive health and family planning issues. A psychosocial analysis of the letters revealed that about half of the women writing in were from the ultra-orthodox community. Half of those were vociferously and almost violently against the program as promoting promiscuity and being antinatal; the other half were women desperately seeking help in dire situations. Religious authorities consulted by the producers assured them that these women could and should receive help according to the *Halachah*. It was also evident that these women will be able to accept help only if it will be within the religious tenets. They were confidentially referred to both medical and religious authorities in the relevant geographical area. This public-private dichotomy is sometimes typical of the religious community.

### Transgressions

The fact that people adhere to many religious rules and live within a religious community does not mean that they do not transgress on any of its laws and rules. Transgressions on an individual basis are varied and should be only recognized and not discussed in such a paper. On the other hand, when cultural, ethnic, or other traditions within a religious community are in contrast with religious rules, or are in contradiction of the rules that these same people profess, these should be looked into.

One such example was mentioned above, when public and spousal pressure prevented women who probably deserved contraception within the *Halachah* from seeking and receiving help.

Another example that relates to contraception was noted in a study that examined the family-planning practices of a very orthodox community of immigrants from Yemen. While the women complained about unwanted pregnancies and the number of children, the husbands claimed that family-planning services should not be approached because of religious reasons. A study by family physicians revealed that the most prevalent family-planning practice in this community, one that the majority of couples used, was withdrawal—a grave sin according to the religious rules.

One can only conclude that, as strong as religious rules are among orthodox groups, cultural traditions sometimes modulate them in unexpected ways.

### Issues in Sex Therapy

Nonobservant therapists working in areas with a concentration of ultra orthodox must resolve several therapeutic, ethical, and personal/professional issues.

First is the difference between the therapeutic paradigm and the basic tenets of the client(s) and their subculture. In essence, one can say that the place of sex in the worldview of the clients differs in some important points from that of the therapist and the therapeutic approach.

While the basic approach of sex therapy to sex is individual- and couple-oriented, hedonistic, and present-oriented, the approach of many of the clients is certainly different. While pleasure and fulfillment are not excluded from the constellation, they are certainly not at its center. The central themes of sex among the orthodox are its function in procreation and the preservation of the family; despite the strong shroud of secrecy and privacy, sex has several "public" aspects to it, especially within the extended families; through the centrality of procreation, sex acquires a strong future aspect to it.

In this domain, one can also include the egalitarian approach of sex therapy, implicit in many of its tenets and interventions. In the ultra-orthodox point of view there is a strong asymmetry in terms of initiative, responsibility, and the duty of husbands for the sexual act and the fulfillment of their wives.

A second issue can be viewed as environmental. While one of the basic means of sex therapy is to lower the burden of performance from the partner who carries it and the introduction of nonperforming sex, among the ultra orthodox, who view procreation as a central aim of intercourse, there is not only an objective criterion for performance, but also a regular almost public viewing of it, at least to other women—the visits of the wife to the *mikveh*.

A third issue is a more individual one. The use of exploration, inventiveness, and flexibility is an important part in the therapeutic intervention. Here the therapist encounters various degrees of rigidity/flexibility as in any other population. The uniqueness is the connection that the clients are making with the religious rules of conduct, a very powerful barrier to possible change. An approach that is embedded in their belief system is that transgression is a matter of choice, and it is an individual choice between sins.

The resolution of these issues lies in the recognition by therapists that any therapy cannot buck the basic belief system of the client and that changes can mostly be effected within that system. In the case of working with ultra-orthodox persons, the therapist must adhere to some self-imposed rules and restrictions. Some of these are harder than others. Such is the agreement to consult rabbinical authorities on issues within the therapy, when the client demands it, and to abide by their specific decision in working with the

specific client for which the question was asked. This raises issues like divided or shared authority and the use of consultations as escape routes. Other issues are the specialized knowledge needed even to ask Halachic questions and the use of the therapist's own rabbinical authority in phrasing them.

The basic rule seems to be the ability to feel true respect from outside and to grasp meanings from inside of a culture that is basically alien to the therapist's worldview.

It is difficult and inadvisable to talk about prevalence of sexual problems, not only because there are no adequate statistics, but because the reasons for seeking help may be totally different from that of the general population. The main complaint is subfertility, which is later diagnosed as a primary sexual dysfunction or the wish to have more children in the case of secondary ones.

### C. The Kibbutz Movement

The kibbutz movement comprises 2 to 3% of the Jewish population of Israel, a seemingly smallish part of the population to be dealt with separately. But this movement of collective communities, the first of which was founded 80 years ago, played an important role in the development of Israeli society. Several features of this subculture are highly important for the discussion of sexuality of youth, fertility patterns, and contraception. The first is that, even with the current changes in lifestyle, and the fact that most kibbutzes have changed sleeping arrangements so that children sleep at their parents' apartments instead of the communal children's homes, kibbutz youth live a life much more independent of adult control in general, and parental control in particular, from early adolescence on than any other group of Israeli youth. Second, despite the fact that the kibbutz society is not as egalitarian as people used to think, it is apparently very much so in many aspects. Third, the kibbutz society emphasizes self-reliance and internal locus of control in many aspects of life by minimizing economic secondary motivations. It is, therefore, not surprising that people take charge of their lives in many aspects, including sexual responsibility and sexual health.

On the other hand, in a seemingly contradictory vein, social pressures to conform are very high within the kibbutzes. It seems that the strongest effects occur when social pressures and the powers of the individual act in the same direction.

### Intercourse During Adolescence and Young Adulthood

When comparing urban to kibbutz youth, it is apparent that beyond 10th grade (age 16), both kibbutz men and women report more premarital intercourse than others; they also start at a younger age. This difference is more pronounced for women than for men—the rate of reported intercourse for kibbutz men is either similar or slightly higher than that of urban young men. In contrast to urban youth, the ratio of kibbutz men and women reporting intercourse, among those who initiated it, was about 1:1 for all grades. Whether this is an egalitarian norm of reporting, or of initiating intercourse or both, needs further studies. These results have been verified in several independent studies over a period of about 25 years.

As reported earlier, it seems that since the mid-1960s, the age of sexarche in Israel is going down for those who practice premarital intercourse (see Table 2). This is true for both youth in both social settings, and is especially marked for urban women. However, as Table 12 shows, there is an interesting difference

**Table 12**

#### Comparison of Sexarche Between Urban and Kibbutz Women Who Reached Age 16 at Different Time Periods

Age at Sexarche (Years)	The Period at Which the Women Reached Age 16					
	1963-1969		1970-1975		1976-1982	
	Kibbutz	Urban	Kibbutz	Urban	Kibbutz	Urban
14-15	0.8%	0.8%	1.8%	1.8%	6.2%	1.9%
16-17	22.0	14.2	41.2	22.0	47.4	26.0
18-19	66.2	48.4	81.8	60.1	86.0	70.1
20-21	89.8	80.1	94.1	85.2	98.6	92.9
22+	100	100	100	100	100	100

*Editors' Note:* Percentages are approximations from the original line graphs.

between urban and kibbutz women. In all three cohorts of urban women, there is a break in the curve and a rise in the slope between ages 16 to 17, and 18 to 19. Among kibbutz women, this is true only for the older cohort, those who reached age 16 between 1965 and 1969. The two younger cohorts of kibbutz women, who reached age 16 in 1970 through 1975 and 1976 through 1982, show a straight line between ages 14 to 15 to 18 to 19 (significant at the 0.01 level for all three cohorts).

The “break” in the curve for urban women can be explained by the lowering of parental/social control for women who leave for the army at the end of 12th grade. There are several possible explanations for the fact that for the kibbutz women the curve is straight: first, kibbutz women may be relying more on internal locus of control and, therefore, are less influenced by the parental/social controls; second, less parental control being exerted on kibbutz youth than on urban youth; and/or more accepting and egalitarian norms of sexuality among kibbutz youth that allow more women both to practice intercourse and to report it. Several indications in the data and in the general structure of kibbutz life indicate all of these factors may be acting together.

### *Fertility Patterns*

A superficial analysis shows similarities between fertility patterns of urban and kibbutz women; closer analysis reveals a much more interesting picture. First, when comparing the TFR of kibbutz women to the segments of the population closer to them in composition, those of American-European origin, one finds that kibbutz women have more children. Second, when controlling for religion and comparing secular urban women with secular kibbutzes and religious (not ultra-orthodox) urban women with religious kibbutzes (a small minority), one can see that in each sector, the kibbutz women have 0.5 more children. Third, the patterns of fertility are different. Kibbutz women marry older, give birth at a later age, and lag behind the urban women in number of children until about age 30, although they continue to have children until a later age.

Another difference is that the interval between giving birth is longer for kibbutz women, when controlled for religiosity, education, ethnic origin, age, stillbirth, and natural or induced abortion. Kibbutz women had intervals two months longer between the first and second child, and three months longer between the third and fourth child. The two latter differences point to a relatively high degree of planning and control of fertility.

When looking at the differences between various types of kibbutz ideologies and diverse lifestyles that emerged during recent years—like young children sleeping at home instead of at communal children’s homes—it was found that the personal differences between women within kibbutzes contribute to the differences in TFR, much more than the differences between kibbutz movements.

### *Contraception*

Does the fact that the kibbutz society: supplies all the material needs of its members, including health needs; shows high prevalence of egalitarian attitudes to sexual behavior of men and women; and puts a high value on planning and control, in fact lowers some of the barriers to family planning and to efficient contraception that are so prevalent among many other groups? If this is the case, then the use of contraceptives among kibbutz women, married and unmarried alike, should be consistently higher than for urban women across all other variables like religiosity, educational level, ethnic origin, and birth order of the children.

As early as first intercourse, kibbutz women show a different pattern from urban youth: 43% of secular kibbutz youth used some kind of contraceptive at sexarche, about half of them—21% of all the women practicing premarital intercourse—used the pill on first intercourse. This number is much higher than the rate for secular urban youth: 27% and 13%, respectively. The significance of this difference becomes more pronounced if one notes that it was already demonstrated that kibbutz women reach sexarche at a younger age than urban youth, and that age at first intercourse is a strong determinant of the ability of youths to protect themselves.

When comparing nonorthodox kibbutz women and urban women during their married life, it is clear that kibbutz women are more efficient and more consistent contraceptors. Only 15% of kibbutz women did not use any contraceptive prior to the first pregnancy, compared to 40% of the urban ones. During that period, only 12% of the kibbutz women relied on withdrawal as compared to 19% of the urban ones. The rates of pill use are reversed, 50% compared to 26%, respectively.

After first pregnancy, the differences are even more pronounced: 90% of kibbutz women contracept and only 8% use withdrawal or rhythm, compared to 28% non-contraceptors and 26% withdrawal or rhythm contraceptors among urban women. These differences remain pronounced in higher birth order intervals. Among variables that might explain differences in contraceptive use prior to first pregnancy within the kibbutzes, the only ones with significance were the birth cohort—older cohorts using fewer contraceptives and less-effective ones prior to the first pregnancy, and ethnic origin—women of Asian-African origin using less-effective contraceptives.

When comparing contraceptive use in 1987-1988, kibbutz women progress from 79% efficient contraceptors prior to the first pregnancy, through 81% after the first and second pregnancy, to 89% after the third pregnancy. Urban women progress from 24% through 62% to 64%, respectively. Not only is there a difference, but the pattern is different. It seems that urban women contact agencies that help them use efficient contraceptives only after giving birth to the first child, while the majority of kibbutz women do so prior to the first pregnancy.

Juxtaposing the patterns of contraceptive use with the patterns of fertility, and taking into account that kibbutz women who start having children at a later age and with longer birth intervals end up with more children over a longer fertile period, it seems that the group is very close to that of the ideal contraceptors—women who use contraceptives effectively to have as many children as they want at the time that they choose. This is also supported by information about much fewer reported unplanned pregnancies, most of which seem to be while using very safe methods.

### **D. Immigrants and Immigration**

Israel is, as indicated, an immigrant society, albeit with some strong internal and external cohesive forces. There are some indicators that demonstrate that these forces are acting toward creation of a common meeting ground, in which some unique characteristics develop.

Nevertheless, two groups of recent immigrants give us the opportunity to look at issues and processes that both immigrants and the host society undergo when faced with the phenomenon of people from an alien culture transplanted into an established one.

One can claim that the immigrants from the former Soviet Union (USSR) and those from Ethiopia have nothing in common. The Ethiopian immigrant group is small even

by Israeli standards, the recent wave arriving since 1991 being 20,000 people and the whole community numbering 50,000. More than half a million immigrants, 10% of the total population of Israel, have arrived from the USSR since 1989. The "Russians" came from a mid-industrial European country with a high literacy rate, mainly from urban areas, having a high rate of academic professionalization, and with many family ties with the established old-timers' society. As a matter of fact, the Mayflower founding parents of the Israeli society and state immigrated from Tsarist Russia and its environments at the end of the 19th century and the beginning of the 20th. The immigrants from Ethiopia came from a country with a rich but isolated culture, non-industrialized, with low literacy rates, mainly from rural-agricultural areas with low mobility, an extended family structure, and very little family ties with the old-timers' establishment.

On the other hand, both groups had undergone, through the dual process of emigration/immigration, being uprooted from one's original culture and transplanted into a new alien one. But the similarities may even go deeper. Both groups came from societies that had very strong external social controls. While among Jews in Ethiopia, the controls were mainly familial and "tribal"—the forces of tradition within a small, isolated, and sometimes persecuted group—those of the USSR were political and institutional. Also, at the time of their immigration, both original societies were undergoing some very strong processes of disruptive transitions. So one is faced with a unique chance of looking at two groups of immigrants undergoing a very similar process, but with somewhat different starting points and cultural contexts.

Interest in the immigrants from Ethiopia and the former USSR is not one of explorers observing exotic cultures with mixed emotions, nor of amateurish anthropologists whose hidden agenda is asserting their own cultural superiority. We are involved and vested participant-observers, with a strong interest in ameliorating the difficult process of immigration and acculturation. Ronny A. Shtarkshall is already an intervener-observer involved in the study and development of integrating interventions.

Because these immigrations are quite recent, the initial processes of cultural integration, some of which are very painful, are still going on. Sensitivities are high and the potential for stigmatization is frightening. Hence, one cannot do more at this time than indicate that careful and sensitive work with these immigrant groups may well in the future provide a rich source for major new insights into the principles and functioning of a cross-cultural sex education program.

### Glossary

These are some Hebrew and Arabic words that are frequently used in the text, mainly for lack of an appropriately equivalent term in English (some of these terms are italicized throughout the text).

*Halachah*: The accumulated body of religious laws, discussions, rules of conduct, interpretations, judicial decisions, and precedents that govern the life of an orthodox religious Jew. Generally, the *Halachah* covers all the aspects of life of a religious Jew from birth to death, religious and secular, public and private. The more orthodox a person is, the more strict is the adherence to the Halachic rules and the more involved are the interpretations.

*Haredim*: A general name given to ultra-orthodox communities by secular people. Most people who use this name do not distinguish even between the major variations of ultra-Orthodox Judaism.

*Mikveh*: Literally, a place where flowing water will collect, the name of the ritual bath that serves for ritual purification of both women and men when this is required according to religious regulations. It is mostly discussed, especially by the secular population, in relation to the purification of women at the end of their impure period—*Nidah*. It should be noted that men should also purify themselves if they spill semen, and that many religious rituals require that men purify themselves in the *mikveh*.

*Mitzvah*: A combination of a religious law, personal obligation, and a privilege. The Hebrew name for the religious rules. The original biblical ones numbered 613 (not a small number in itself), but their development and interpretation in the Talmud increased their numbers several folds.

*Mohar*: Bride payment. Traditionally paid by Muslim grooms to the bride's father. *Mohar* can be paid in money or cattle. It is almost never paid with land.

*Nidah*: A period determined by the menstrual period and seven days after it, during which women are impure and untouchable. The root of the word also means *ban* or *banishment*.

*Shabbat*: The seventh day. Among orthodox and ultra orthodox, it is strictly kept. Not only is no work allowed, but things like lighting a fire or an electric instrument, driving or riding in a car, picking a flower, writing, and tearing paper are banned. Although very holy and strictly observed, one is allowed to do most of the things if the purpose is to save lives. One of the things that is not only allowed, but recommended on Shabbat night, is intercourse.

*Yeshivah*: A high religious academy or a seminary.

*Yichus*: lineage.

## Demographics and a Brief Historical Perspective

ROBERT T. FRANCOEUR

### A. Demographics

Italy is a large peninsula extending into the central Mediterranean Sea. It borders with France on the northwest, with Switzerland and Austria on the north, and with Slovenia on the northeast. The peninsula also contains the two small independent states of San Marino and Vatican City. Italy has a total of 116,306 square miles (301,230 km<sup>2</sup>), including the islands of Sicily with 9,920 square miles (25,700 km<sup>2</sup>) and Sardinia with 9,300 square miles (24,090 km<sup>2</sup>). The alluvial Po Valley drains most of the northern portion of the country. The rest of the country is rugged and mountainous, except for intermittent coastal plains like Campania, south of Rome. The Apennine Mountains run down the center of the peninsula. The island of Sicily, at the southwestern tip of the Italian peninsula, is 180 miles by 120 miles (290 km by 190 km) with a 1992 population of 5 million. A second major island, Sardinia, is about 115 miles (185 km) west of Rome and Naples, south of Corsica, which is a part of France. Sardinia had a 1992 population of over 1.6 million.

In July 2002, Italy had an estimated population of 57.7 million. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 14.1% with 1.06 male(s) per female (sex ratio); 15-64 years: 67.3% with 0.99 male(s) per female; 65 years and over: 18.6% with 0.7 male(s) per female; Total population sex ratio: 0.94 male(s) to 1 female

**Life Expectancy at Birth:** Total Population: 79.25 years; male: 76.08 years; female: 82.63 years

**Urban/Rural Distribution:** 67% to 33%; regionally, the north has 44.5% of the population, central Italy 19.2%, and the south 36.3%

**Ethnic Distribution:** An Italian majority with small clusters of German-, French-, and Slovene-Italians in the north, and of Albanian-Italians and Greek-Italians in the south. In recent years, most immigrants have come from Morocco, the former Yugoslavia, Albania, and the Philippines

**Religious Distribution:** Roman Catholic 78%; Protestant 5%; Muslim and other 10%; 7% profess no religion. The number of those adhering to other religions is increasing, partly as a result of immigration. Identification with a religion does not coincide with active participation: 8.7% of Italians never attend religious services; 39.6% do so only rarely.

**Birth Rate:** 8.93 births per 1,000 population

**Death Rate:** 10.13 per 1,000 population

**Infant Mortality Rate:** 5.76 deaths per 1,000 live births

**Net Migration Rate:** 1.73 migrant(s) per 1,000 population. The natural growth rate of a negative 0.8% per 1,000 population is offset by a positive immigration rate. The total number of immigrants legally present in Italy on January 1, 1999, was 1.1 million, about 2% of the total population. In recent years, family reunifications, mixed marriages, and the increase in the number of children born of foreign parents have led to a decline in the overrepresentation of young, single males among the immigrant population.

**Total Fertility Rate:** 1.19 children born per woman

**Population Growth Rate:** 0.07%

**HIV/AIDS** (1999 est.): Adult prevalence: 0.35%; Persons living with HIV/AIDS: 95,000; Deaths: 1,000. (For additional details from [www.UNAIDS.org](http://www.UNAIDS.org), see end of Section 10B.)

**Literacy Rate** (defined as those age 15 and over who can read and write): 98%; education is free and compulsory from age 6 to 13

**Per Capita Gross Domestic Product** (purchasing power parity): \$24,300; Inflation: 2.7%; Unemployment: 10% (2001 est.)

Since World War II, Italy has changed from a rural society to an industrial or postindustrial society. Agriculture now contributes only 2.9% to the Gross Domestic Product, against 32.1% for industry and 65% for the service sector.

\*Communications: Professor Bruno Wanrooij, Syracuse University in Italy Program, Italian Politics and Cultural Studies, Coordinator, Humanities and Social Sciences Department, Piazza Savonarola, 15 50132 Firenze, Italy; [bpwanroo@syr.fi.it](mailto:bpwanroo@syr.fi.it); [wanrooij@dada.it](mailto:wanrooij@dada.it).

The service sector employs 60.1% of the labor force against 32.5% for industry and a scant 7.4% for agriculture. The per capita income in 1996 was \$21,190, with clear differences in income, higher in the north and lower in the south.

## B. A Brief Historical Perspective

The earliest human settlements within the territory of present-day Italy date almost certainly to some 500,000 years ago and correspond to the Lower Paleolithic period. From the beginning of the 1st millennium B.C.E., there were increasing contacts with Phoenician and Greek colonists, and Italy entered the historical period. While the Greeks settled on the southern coasts of the peninsula, Etruscan civilization developed in central Italy. During the 4th and 3rd centuries B.C.E., the Roman state expanded its territory to the entire peninsula. Expansion continued, and by the end of the 2nd century B.C.E., Rome had become the major military power in the Mediterranean. Territorial expansion was accompanied by the growing importance of commercial activities in addition to agriculture and pastoralism. The following centuries saw a gradual decline of Italy's preeminence in comparison with other provinces of the Roman Empire. With the end of the Western Roman Empire in the 4th century of the Common Era, the Catholic Church sought to take over the authority and prestige of Rome, assuming the government in the territories under its control. In the 11th and 12th centuries C.E., agriculture, crafts, and commerce prospered, the latter two in particular becoming the foundations of an urban economy that was to produce the city states of central-northern Italy. Tuscan and Lombard bankers played an ever more important role in financing the military undertakings of European sovereigns and the papacy, thus increasing their own prestige and political influence. Arts and humanistic studies flourished, and during the Renaissance of the 13th and 14th centuries, Italy became one of the major cultural centers of Europe.

The lack of political stability and the frequent wars among the various Italian states, however, allowed the great European powers to intervene, and by the second half of the 16th century, Spain had established its predominance over Italy. What followed was a slow decline of the political role of Italy in Europe, and of its contribution to cultural and scientific developments. Spanish predominance in Italy, extending over some two centuries, had rather negative consequences for the country, in terms of economic decline and of a growing imbalance between part of the southern regions and other areas of the country.

The period of French rule, which followed the conquest of Italy by Napoleon Bonaparte, saw the reemergence of a sense of national unity among the intellectual and middle-classes. In 1861, after a number of wars of independence against Austria, the Risorgimento resulted in the creation of a United Kingdom of Italy governed by the House of Savoy. Rome was conquered only in 1870. The problems, which the new kingdom had to face, regarded the Catholic Church's refusal to recognize the new state, and, more generally, the integration of the older states, and the gap between the political elite and the lower classes of the population, especially in the rural areas.

After World War I, social tensions and the growth of New Socialist and Catholic Mass parties convinced the ruling groups to help the Fascist movement, led by Benito Mussolini, to take over power. The Fascist regime pursued a policy of repression of the working-class movement while favoring at the same time colonial expansion. Family policies were inspired by the desire to increase the fertility rate and to reinforce the position of the male head of the family. This policy received full support from the Catholic Church

after the Lateran Treaty of 1929, which made Roman Catholicism the state religion until 1984, when a new agreement was signed between the Catholic Church and the Italian government that cancelled most of the privileges enjoyed by the Church.

Fascist family legislation remained valid in Italy even after World War II, and the national government, dominated by the Catholic party, Democrazia Cristiana, opposed changes in family and gender relations. However, developments in the late 1950s and 1960s, including growing industrialization, migration from the rural south to the industrialized north, secularization, and higher standards of education, brought the traditional structures under attack. The youth movement, the feminist movement, and the gay movement also played an important role in promoting profound changes, but maybe even more important was the diffusion of consumer culture.

While Italy in the 1990s has much in common with other European countries, some of the peculiarities of Italian society—the importance of the family, the strong regional differences, and the role of Roman Catholicism, among others—can only be understood in their historical context. For example, in the past in northwest and central Italy, the incidence of patrilocal residence and multiple family households was high. In these regions today, about one third of the population lives for some time in an extended family or in a multiple-family household, and contacts with the husband's family tend to be stronger (Barbagli & Saraceno 1997).

## 1. Basic Sexological Premises

### A. Character of Gender Roles

Sexuality, as we understand it today, is not merely a biological and "natural" fact, but above all a historical construction, resulting from the pressure by manifold forces, and, as such, it is the outcome of complex historical transformations. Gender roles, in particular, are not only based on physical or biological premises, but are primarily the result of the conditions of life of males and females in a given social class, time period, and geographical location.

During the last decades of the 19th century, emancipationist movements in Italy started to question the traditional gender roles, which were based on the identification of males with production and public affairs, and of women with reproduction and private affairs. The prescribed female gender role contrasted sharply with a reality, which—especially in the northern and central regions—saw an active participation of women in the production process. The need to maintain industrial production led to a further increase of the female employment rate in industry during World War I.

The Fascist regime, which came to power after World War I, tried to reinforce the role of the male breadwinner by introducing legislation favoring male employment and by introducing discriminatory measures against female workers. Women received lower salaries and had no access to certain positions in state administration. A quota system was introduced to limit the number of women working for private companies. The government measures failed to reduce significantly female employment, but public appreciation for the female role in the family contributed to strengthen already existing familist tendencies. The desire to conform to the traditional female role of mother and housewife explains the drop in the female employment rate coinciding with the economic boom of the 1960s.

Since this period, new ideals of independence and autonomy have created a trend of growing participation of women in the labor market. Nevertheless, in the 1990s, the female activity rate was still much lower than that of men,

while, partly because of protectionist measures, female unemployment was higher. In addition, women were over-represented on the “black” labor market, where wages are lower, working conditions worse, and social benefits and job security nonexistent.

In 1995, Italy ranked tenth on the United Nations world list of male-female equality. Since the 1960s, the level of education of women has rapidly improved, and today more women than men obtain a university degree. Also, in private business and in public administration, women in Italy have made important progress in the last few years, even though there is still a long way to go for real equality.

The participation of Italian men in household chores is relatively low. While the majority of men—especially in the northern regions—take an active part in the education of children, and a growing percentage is willing to cook, to set the table, and do shopping, very few men participate in activities like cleaning, doing the laundry, or ironing. On the contrary, almost all married women, both housewives and women with full-time employment, participate in domestic work.

### B. Sociological Status of Males and Females

Women received the right to vote in 1945, and in 1947, the Italian Constitution was approved, with Article 3 recognizing equal rights for men and women. According to Article 29 of the Constitution, however, the need to guarantee the unity of the family justified limits to the legal and moral equality of husband and wife. It took several decades to adjust the existing legislation to the principle of equal rights and to change traditional views about the role and position of women. Until 1968, adultery was considered a crime for women, whereas men could be punished for adultery only in special circumstances. Other discriminatory conditions deriving from the male position as head of the family survived until the general revision of family legislation in 1975. The new law, based on the principle of male-female equality and on the recognition of the rights of children, abolished the position of the head of the family, and attributes equal rights and duties to husband and wife in terms of residence, work, education of the children, and so on. Married women in Italy keep their own family name, and can add their husband’s name if they wish to do so. Proposals are in discussion to give couples the choice to transmit to their children either the name of the father or that of the mother.

Legislation regarding crimes of honor—recognizing special mitigating circumstances for those who, enraged by an offense to their personal and family honor, killed their wife, daughter, or sister, or the person with whom their female relatives had an illicit sexual relationship—was canceled in 1981, but had become obsolete in most parts of Italy long before.

Discrimination against women existed also with regard to labor: Women were excluded from many positions and were paid less. This discrimination has been gradually abolished. In 1960, for instance, the Constitutional Court eliminated a law dating back to 1919, which excluded women from many higher-rank positions in the public sector. In 1977, a law was approved which guarantees equal rights for males and females in issues like recruitment and hiring, career, and the like.

### C. General Concepts of Sexuality and Love

In Italy, the prevailing ideology links love and sexuality. Love is presented as a necessary precondition for sexual relations, while happy sexual relations are generally considered necessary for the success of a love relationship. Yet, 60% of women and 74% of men admit sexual desires regarding persons for whom they feel no love (Sabatini 1988). In this case, the fact that the statistics were based on a ques-

tionnaire distributed among the readers of *Duepiu*, a progressive magazine with a clear pro-sex attitude, may have influenced the results. Later surveys, however, confirmed that, especially among young men, sexual relations without love were rather common.

Faithfulness is considered an important value for couples, but a recent survey among young people (Buzzi 1998) shows that about one third of young men and one sixth of young women had sexual relations with persons other than their partner. Adhesion to the values of romantic love and faithfulness thus often is more formal than real.

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A. Source and Character of Religious Values

In Italy, the values of consumer society seem to have replaced religious values in many issues, especially among many young people who refuse to accept the moral guidance of the Catholic Church. In 1996, religious marriages made up 79.6% of the total number, compared to 20.4% of civil marriages. According to a recent survey, the religiosity rate—calculated on the basis of the importance of religion in personal life, and on participation in the activities of the religious community—is close to zero or low for 28.5% of Italians, and high only for 12.3% (Cesareo 1995).

Notwithstanding the ongoing process of secularization, the Catholic religion is still the main source of values affecting sexuality, and the public pronouncements of the Pope are widely discussed in the mass media. Because of the Catholic Church’s opposition to a separation between procreation and sexuality, it has been impossible to introduce clear legislation regarding artificial insemination and other forms of medically assisted procreation. An administrative rule dating back to 1985, which applies only to hospitals and clinics falling under the public health system, admits medical assistance for procreation in case of married couples, but excludes the use of donors. Therefore, medically assisted procreation with the use of gametes from donors takes place only in private clinics, with possible health risks because of insufficient public control. Because of Catholic opposition, a new bill regarding medically assisted procreation, which was approved by the Commission for Social Affairs of the Chamber of Deputies in January 1998, still had not become law by the end of 1999.

### B. Character of Ethnic Values

Immigration to Italy is a relatively recent phenomenon, and as yet the values cherished by immigrants have not had much influence outside the various ethnic groups. In this sense, Italy is not yet a multicultural society. In a medium- or long-term perspective, there is no doubt that the presence of large ethnic groups which do not share many of the views about family values, gender relations, and extramarital sexuality commonly held by Italians, will be a challenge. Contrasting views may lead to greater appreciation of diversity, but may also become a source of growing social tensions and conflict.

## 3. Knowledge and Education about Sexuality

### A. Government Policies and Programs

The introduction of sexual education as part of the regular program of primary and secondary school has met with opposition from Catholics who question both the responsibility of schools in this area and the content of education. Catholics have changed their longstanding view that sexual education could lead to the premature arousal of sexuality

in young people, but still insist that sexual education is, above all, the responsibility of parents. Moreover, they deny the value of an education that focuses on the physical aspects of sexuality if it does not place these aspects in a more general context, and if it ignores moral issues.

For these reasons, and notwithstanding the fact that a majority of Italians favor sex education in school at an early age (Durex 1998), until early 1999, sexual education occurred in schools only on the initiative of individual teachers. Only recently has the Ministry of Education decided to sustain these initiatives formally.

## B. Informal Sources of Sexual Knowledge

Peer-group conversation and the mass media are the primary sources of sexual knowledge. Parents, above all the mother, rank third as a source of information. Magazines and both public and private television offer instructive articles and programs dealing with sexual issues. Moreover, publishers have responded to market demands, and have supplied sexual information both in printed form, in videocassettes, and on compact disks (CDs).

In contrast with the past, sexual education today is less focused on procreation and on genital activity, and tries to explore the relations between gender identity and sexual identity. Moreover, sexual education no longer wants to prescribe sexual behavior on the basis of ideological or religious principles, but rather aims at providing the cultural instruments for self-realization (Cipolla 1998).

Today, young Italians are generally well informed. It should be noted, however, that a high level of information does not automatically translate into sound practices. Knowledge of the risks of sexually transmitted diseases, for instance, does not always lead to the use of condoms.

## 4. Autoerotic Behaviors and Patterns

According to the most recent survey among young people, nine out of ten men, and four out of ten women, admit to masturbating (Buzzi 1998). However, earlier surveys give higher numbers for female masturbation, even though the number of women who never masturbate remains five times higher—20% against 4%—than that of men (Sabatini 1988). Men start masturbating earlier than women: 16.3% before age 12, and 33.3% between age 12 and 13. In any event, the vast majority—both men and women—consider masturbation part of the sexuality of every normal human being. This idea is the outcome of radical changes in the consideration of masturbation.

In the 19th century, masturbation was the object of severe repression, and was said to be the cause of numerous physical problems. Moreover, masturbation, especially if performed in the presence of other people of the same sex as might occur in boarding schools, was believed to lead to homosexuality. In the 20th century, opposition against masturbation was based, above all, on the idea that masturbation undermined the individual's capacity to use sexuality as a form of communication. Alternatively, masturbation was considered a substitute for "real sex," an act which could be performed by young people without stable partners, but which denoted a lack of sexual maturity in the case of adults. Still, in the 1978 sex survey by Giampaolo Fabris and Rowena Davis, 31% of males and 28% of females expressed the opinion that masturbation was unhealthy, while 26% of males and 36% of females expressed their moral condemnation of this activity. Today, even though taboos have not disappeared altogether, masturbation generally is rated more positively as a source of pleasure and as an experience allowing the increase of self-awareness and knowledge of the self (Rifelli 1998).

## 5. Interpersonal Heterosexual Behaviors

### A. Children

In the beginning of the 20th century, expressions of infantile sexuality were considered a form of perversion and were severely repressed. Today, on the contrary, most Italian parents acknowledge the sexual curiosity of children, but at the same time fear that games with a sexual overtone may lead to oversexualization. Moreover, Italian parents are afraid of the sexual abuse of children by adults, which is the object of general severe condemnation and repression.

From a legal point of view, sexual relations with minors under age 14 are considered statutory rape. The age limit is higher, 16, in the case when the adult person cohabiting with the minor is a relative, guardian, or other person with educational responsibilities over the minor. A minor who has sexual relations with another minor is not guilty of any crime, on the conditions that the younger partner is at least age 13, and the age difference between the partners is not more than three years.

### B. Adolescents

#### *Puberty Rituals*

In Italy, no specific rituals exist marking the passage from childhood to adolescence or adult age.

#### *Premarital Sexual Activities and Relationships*

Only a limited number of general surveys about the sexual life of the Italians exist, and most of them were based on the responses of a sample of a preselected population, such as the clients of public family advisory agencies. Most of the information about the sexual life of young people presented here comes from a survey of 1,250 persons aged 18 to 30 by the IARD Institute (Buzzi 1998).

According to this survey, males in contemporary Italy have their first complete sexual relations with penetration when they are 17 to 18 years old; the age of their first sex was not much different from that of their fathers. The average age for females is 18 to 19. The 1998 Durex global sex survey (Durex 1998) does not make a distinction between males and females, and indicates an average age for first sex at 17. The tendency to start sex at an earlier age began with the generation of women born in the 1950s and 1960s.

It is more common for young women aged 18 to 21 from central and northern Italy to have complete sexual relations than it is for males of the same age group (females 71% vs. males 66.3%). The opposite is true for females from the south: Only 51.8% of females aged 18 to 21 had complete relations compared with 64.8% of males from the south. For the age group 26 to 30, the percentages are 84.7% for females and 88.2% for males. Moral values determine why young females do not engage in sexual relations; for males the main reasons are the lack of opportunity or the refusal of the partner (Buzzi 1998).

The first sexual partner for both males and females in almost half of the cases is a person of the same age; the partner of 41.8% of females is somewhat older (21.6% for males), and is somewhat younger for 25.9% of males (4.7% of females). Major age differences are rare. Especially for males, it is very rare that the partner of their first complete sexual relations is their wife (0.8%); it is more common for females to have this experience with their husband (10%).

The "first time" is appreciated positively by 48.7% of males and by 38.6% of females, for whom embarrassment, fear of pregnancy, and pain play a greater role. Young women are also more prone to admit sexual passivity (10.7%), absence of sexual desire (8.8%), and major psychological difficulties (15.3%). Without making a distinction between the sexes, the Durex (1998) survey reports that

first sexual intercourse was disappointing for 32% of Italians, and better than expected for 29%.

First-time intercourse is often at risk for pregnancy and sexually transmitted diseases: Condoms are used on this occasion by about 40% of Italians. Coitus interruptus is used as a method of birth control by 24%. The low incidence of teenage pregnancy in Italy is therefore not a consequence of better contraception, but of the fact that young Italian females start to have sexual relations at a later age than in other countries. [Update 2003: One consequence of the low incidence of teenage pregnancies is the fact that in Italy—contrary to trends existing in other European countries—the number of young unmarried mothers is decreasing. (End of update by P. F. Wanrooij)] Statistical data relating to premarital conception, extramarital pregnancy, and induced abortion showed a radical change in the ten years between 1969 and 1978, when the incidence of these events increased rapidly. The increase affected unmarried females of all age groups. In the following years, however, the growth in the number of extramarital pregnancies stopped, while the increase in premarital conceptions slowed down.

Stable relationships become more common with the increase of age, but a relatively high percentage of young people aged 26 to 30 have no stable partner (38.5% of males and 21.2% of females). Love, physical attraction, and trust are the elements that determine the creation and the duration of a relationship.

### C. Adults

#### *Premarital Courtship, Dating, and Relationships*

[Update 2003: In recent years, American television news magazines like *60 Minutes*, the International Section of *The New York Times*, and investigative reporters “discovered” an Italian premarital lifestyle that lent itself to what might be most accurately called a titillating cross-cultural comparison. The journalists knew that in the last quarter of the 20th century, after the 1960s’ sexual revolution, the number of American unmarried couples living together rose dramatically from half a million in 1970 to 3.7 million in 1994. They also knew that one in seven American children who reported living in a single-parent household actually resided with a cohabiting unmarried couple. Cohabitation had become a part of American culture. “It was the modern way” (Bohlen 1996; Rodriguez 1997/1998; Stanley 1999).

[Young Americans, it seems, place an extremely high value on individual autonomy and the freedom to do what they please. Independence means living on your own or cohabiting without marital ties, and postponing marriage while you find a career and build your nest egg. Leaving home, taking time to live on your own, “helps one grow up, experience life, and be happy with yourself” (Whitehead & Popenoe 1998).

[Then there are young Italian men who find the idea of moving out of the parental home quite unacceptable and unnecessary. They continue living with their parents, into their 30s or 40s, despite being financially independent, and often in a serious ongoing relationship with a woman. In the Italian view, a man does not have to leave home to “be his own person and to do his own thing.”

[This contrast between independent young American men and the Italian *mammoni*—simplistically translated “mama’s boys”—was a bonanza for both Italian and American journalists.

[Personally, I prefer not to speak of *mammoni*, which has a pejorative meaning and suggests a morbid relationship between mother and son, which has little to do with the reality. A more appropriate term would be “long family.” In my view, and that of many Italian men and women, living at

home is not necessarily an indication of a lack of autonomy, unless one refers only to financial autonomy. For all other matters, young Italians are quite successful in negotiating a rather high level of independence while continuing to enjoy the “fringe benefits” of staying at home. In fact, my American students often are amazed by the freedom that their Italian friends enjoy in their families. According to them, American parents would never allow their daughters and sons to invite boyfriends or girlfriends over and sleep with them under the parental roof. Incidentally, I am told that the number of young Americans who return home after college is increasing as it is becoming more difficult to find a job or affordable lodging. I wonder how they will manage to convince their parents to become more accommodating to their personal intimate relationships.

[Which brings up a comment by Barbara Defoe Whitehead and David Popenoe (1998) in their study of unmarried, non-college-educated, young Americans:

[We were surprised by the high number of young adults living with parents. This may be due to the combination of available employment and scarce affordable housing in northern New Jersey. These young men and women are likely to find work close to their families but they may not find affordable rents—thus increasing the attractiveness of living with parents. Also, most of these men and women reported living in intact families at age 15, and perhaps their parents’ marital stability increased the likelihood that they would have the option of returning home. . . . Interestingly, some women said that you had greater freedom living with your parents than living on your own or with a partner. Apparently, this form of dependence on parents is not incompatible with notions of personal independence.

[To make valid cross-cultural comparisons, one needs to avoid the simplistic description and, at the same time, understand and appreciate the subtleties of the social context in both cultures. (End of update by P. F. Wanrooij)]

Although there is no strong social condemnation of the cohabitation of unmarried couples, cohabitation is relatively rare, and marriage is considered the natural conclusion of a stable heterosexual relationship. In 1991, cohabiting couples made up 1.6% of Italian couples. The rate of cohabitation is significantly higher in the northern regions than in the south, for example, 4.1% in the region of Val d’Aosta against 0.5% in the Basilicata.

Notwithstanding a generally positive view of marriage, there is a tendency to delay the time of marriage, and, partly as a result of this, the nuptiality rate in Italy is low: In 1997, it was 4.7 per 1,000 population. The average age at a first marriage in 1994 was 29.3 for males and 26.5 for females; in 1984, it was 27.4 for males and 24.3 for females. Italians in the south are distinguished by a higher nuptiality rate: In 1994, it was 5.6 per 1,000 population against 4.8 in the regions of the north and the center, and at an earlier age at marriage, 25.6 for females and 28.7 for males (Barbagli & Saraceno 1997).

Most Italians leave the parental home only when they get married, and this holds true even for the older age groups: 68% of Italian males aged 35 and over and 63.3% of females who never married live with their parents. Divorce or separation often results in a return to the parental home: About 20% of divorced or separated Italians (25.2% of males and 17.1% of females) cohabit with their parents (ISTAT 1996)

“Long families” are the combined effect of the low cohabitation rate and a relatively late age of marriage: The majority of unmarried young people aged 18 to 34 continue to live with their parents (58.8% in 1998). It is more com-

mon for young men to stay with their family (66.5%) than for young women (50.9%). The percentage of young people living with their family is increasing, especially among young women: In 1983, only 40.4% of them were living with their family.

Economic circumstances, high unemployment among young people, and the difficulty of finding housing also contribute to the incidence of "long families," but do not offer a sufficient explanation for the fact that young people in Italy do not "strike out" on their own. "Long families" are in fact as common in the northeastern region, where unemployment is less a problem, but where 59.5% of young people aged 18 to 34 live with their parents, compared with the south, where economic problems are much more serious, and 59.8% of young people live with their parents. An alternative and more positive explanation of the growing incidence of "long families" is the democratic character of the modern Italian family, where young adults have the possibility to renegotiate their position. In this way, young adults are able to have a satisfactory level of autonomy and independence, while at the same time enjoying the "fringe benefits" of family life in terms of financial advantages and services (Barbagli & Saraceno 1997). For a high percentage of young people (57% in the northeast, 34.2% in the south), the reason for staying is that they are happy to stay and enjoy a fair amount of freedom. Satisfaction increases with age as the reasons for tension decrease (ISTAT 1999b).

The high level of interaction between married adults and their parents is further proof of the importance of the family network in Italy: 3.8% of married Italians under age 64 whose mother is alive live with their mother. Of those who are not cohabiting, 77.8% see their parents at least once a week and one third of them every day. One partial explanation of the high interaction with parents is the low level of geographical mobility: 28% of married Italians live at a distance of less than one kilometer (0.62 mi.) from their parents (ISTAT 1996).

### *Marriage and Family*

According to the 1975 family law, the legal age of marriage is 18 for both partners. Legal courts can give exemption from this requirement, provided that the partners are at least 16 years of age. Generally, the courts do not consider pregnancy a valid motive to grant permission for the marriage of minors. The same 1975 legislation abolished the possibility of reparatory marriage, which in the past had been used by persons accused of crimes like rape and forceful abduction, who could avoid punishment by marrying their victim.

The average frequency for sexual intercourse was 92 times per year (Durex 1998). According to an earlier survey, on average, men and women had sexual intercourse about eight times per month, but there were important differences according to age, with the highest levels of sexual activity in the age group 18 to 25 for women and 35 to 44 for men. The fact that females under 25 showed a higher frequency of sexual intercourse than males of the same age can be explained as a result of their earlier participation in stable relationships and marriage. A similar explanation is proposed for the fact that young women have more sexual partners than men, while the situation is inverted in the higher age groups. In this case also, the higher tolerance of male pre- and extramarital sexual relations may play a role (Fabris & Davis 1978). The more recent survey published by Carlo Buzzi (1998) confirms the higher sexual activity rate of young women, 33.8% of whom have sexual intercourse two to three times a week (against 27.4% for males). Also, the percentage of young women who had no sexual

intercourse during the previous three months turned out to be almost half that of men (12.4% against 23.5%).

According to the 1978 survey, women, more often than men, had sexual intercourse not because they desired to have it, but to please their partner. While 49% of males would like to increase the frequency of sexual intercourse, this was true for only 25% of females, most of whom were satisfied with the frequency (56% against 43% for males). Thirteen percent of females—mostly in the higher age groups—desired to reduce the frequency of sexual intercourse as compared with 3% of males. These gender differences may be explained as the result of a greater pressure on males for sexual performance, but also by the fact that more women found sex less enjoyable. Many of them, in fact, complained that before, during, and after sexual intercourse, men paid insufficient attention to their desires.

The brief duration of foreplay and sexual intercourse, limited almost exclusively to penetration, is more common among the uneducated, among more-religious couples, and among the higher age groups. The average duration of foreplay was about 13 minutes, and that of coitus about 9 minutes (Fabris & Davis 1978). A more recent survey indicates the duration of sexual intercourse, excluding foreplay, is 14.2 minutes (Durex 1998).

It should be noted that the statistical data regarding the frequency and duration of sexual intercourse, as well as other aspects of sexual life, should be treated with caution. Not only do the averages ignore important differences in individual reactions, but it is also possible that the responses are influenced by the desire of those interviewed to satisfy the presumed expectations of the interviewer, or—more generally—by the desire to make a positive impression. For these reasons, it is wrong to use these data as a measure of "normality."

Seventy-six percent of male partners and 72% of female partners in stable couples rated their sexual life "good" or "very good." More-negative judgments were expressed by 3% of males and by 7% of females. The degree of satisfaction with their sexual lives increased during the first ten years of the relationship, and remained the same or decreased thereafter (Fabris & Davis 1978).

According to the 1978 survey, 69% of males and 26% of females always experienced orgasm during sexual intercourse. About one fifth of women never or rarely experienced orgasm. Young, educated, and nonreligious women had a higher orgasm rate. Of the women who experienced orgasm, 29% experienced orgasm as a result of the oral or manual stimulation of the genitals, and 27% experienced it during penetration, whereas for 44% of these women, both activities resulted in orgasm.

At least 41% of Italian males and 14% of females have had extramarital sexual relations. Especially for women, the adultery rate increases with the level of education; it was 20% for women with a university degree. The adultery rate and the number of partners are lower for women, but the extramarital relationship is also characterized by a higher emotional investment (Fabris & Davis 1978). More recent figures indicate that 38% of Italians admit to having been involved in more than one sexual relationship at a time (Durex 1998).

### *Divorce and Remarriage*

Divorce became legal in Italy in 1970, and a 1974 referendum confirmed the existing legislation with a 59.1% majority. Between 1985 and 1996, the number of divorces increased from 15,650 to 32,717. In the same period, separations increased from 35,163 to 57,538. The numbers were highest in the region of Lazio, followed by the more indus-

trial northwestern regions. The divorce rate was much lower in the south. Even though there is a clear tendency toward an increase in the divorce rate, the stability of marriage is higher in Italy than in any other European country. This impression remains true, even when taking into account both separations and divorces: In 1994 in Italy, 16 out of 100 marriages were dissolved as a result of legal separation, and 8 out of 100 because of divorce. In the same year, the divorce rate was 44% in the United Kingdom and Sweden and 29% in the Netherlands. In 1996, the divorce rate in Italy was 0.6 per 1,000 population against a European Union average of 1.8 (ISTAT 1999).

The main reason for the relatively low divorce rate is probably religion. Added to this factor is the importance of the family, not only as a source of emotional support and the context for the development of profound personal relations, but also for many other aspects of social life, from financial support to finding a job. Divorce is seen primarily as evidence of personal failure, and the end of the relationship is considered, above all, the beginning of a difficult period in personal life, rather than as a possible new start and an occasion to regain freedom and independence.

### *Incidence of Oral and Anal Sex*

Oral sex, which in the past was condemned as “unnatural,” is practiced more or less often by 55.2% of young Italians, and only rarely by 26.8%. Earlier surveys indicated that 47% of females and 58% of males experienced oral sex (Fabris & Davis 1978). Oral sex is a common element in the sexual fantasies of Italian males, especially during masturbation; this is less true for women. Both men and women prefer their partner to perform oral stimulation of their genitals, fellatio and cunnilingus, rather than performing these sexual acts themselves on their partners.

While anal intercourse is not part of the fantasies of the majority of women, it is part of the fantasies of 75 to 80% of men. However, the incidence of this practice is relatively low. According to the 1978 survey, 35% of males and 23% of females had experienced anal sex. A more recent survey among young people indicates that 78.6% of females and 62% of males never experience anal sex (Buzzi 1998).

## *6. Homoerotic, Homosexual, and Bisexual Behaviors*

### **A. History**

With the noteworthy exceptions of the Kingdom of Sardinia and the regions under Austrian rule, the Italian states in the first part of the 18th century had no legislation against homosexual acts. After Unification, the repressive legislation of the Kingdom of Sardinia was extended to the other regions of Italy, excluding the territory of the ancient kingdom of Naples. With the introduction of a new penal code in 1889, regional differences in the treatment of homosexual acts were eliminated and homosexuality was decriminalized. Legal persecution of homosexuals continued, however, based on accusations regarding indecent acts, and so on. Especially in southern Italy, however, the general attitude regarding homosexuality was rather tolerant, and by the end of the 19th century, male homosexual communities existed on the island of Capri and in towns such as Taormina. In this same period, Italy attracted a fair amount of sex tourism from countries like the United Kingdom and Germany where existing legislation against homosexuals was applied more severely.

Homophobic attitudes were prominent in the nationalistic propaganda during World War I, which often made references to sexual scandals in the German imperial court, and used accusations of homosexuality against all those who

opposed the Italian war effort, including neutralists and pacifists.

The attitude of repressive tolerance that characterized public reactions to homosexuality continued during the Fascist period, when attempts to introduce more-specific legislation were blocked to safeguard the virile reputation of Italian men. Homosexual communities were thus allowed to survive, but at the same time, police measures were used against homosexuals who dared to “come out.” Especially after 1938, when racist legislation was introduced in Italy, many homosexuals were condemned to legal confinement.

While at the level of legislation, the situation remained unchanged after the fall of Fascism in 1945, during the 1950s, some isolated publications voiced the need to improve the social status of male and female homosexuals. These attempts, however, met with the opposition of medical doctors, and especially the Italian specialists of the new discipline of sexology, who insisted on considering homosexuality a perversion or disease, and advocated anything from sports and sexual encounters with prostitutes to electroshock therapy to cure homosexuals. During the 1960s, members of Parliament tried to introduce legislation against homosexuality, which would punish not only homosexual acts between consenting adults, but also any public discourse in favor of homosexuality. These attempts failed because of the prevailing attitude of repressive tolerance.

Within the context of the sexual liberation movement of the late 1960s, which in the first phase was not sympathetic to the problems of homosexuals, the first Italian group of organized homosexuals emerged. In April 1972, the Unitary Front of Revolutionary Italian Homosexuals (FUORI; the acronym also means “out”) contested the power of medical science at a congress of sexologists. The lack of support from the traditional leftist parties and the radical opposition from the right-wing parties and from the Catholic party, Christian Democracy, convinced the leaders of FUORI in 1975 to establish institutional links with the Radical Party, which had a tradition of civil rights actions. However, the decision led to a split between the reformers and those who considered themselves part of a revolutionary movement; new groups with links to the extreme left-wing parties were then created. In 1982, FUORI was dissolved.

The first nucleus of a new organization of homosexuals, Arcigay, was created in Palermo in December 1980 as a reaction to the tragedy of a double suicide of two gay lovers who had become the victims of public ostracism in the small town of Giarre, when their story became public. The first national congress designed to unite the local groups, created with the support of a dissident Catholic priest, Don Marco Bisceglia, took place in Palermo in 1982. It saw the participation of the most important leaders of Arci, a leisure-time and cultural organization traditionally close to the parties of the left (the communist and socialist parties). The connection between the homosexual movement and the traditional parties of the left, created through Arcigay, was the result of the innovative political strategy of attention for new social groups, feminists and homosexuals, inaugurated by the Communist Party in 1977. This initial connection was followed by a debate on the conditions of homosexuals in the party press (Giovannini 1980). Finally, in 1985, Arcigay was given a more structured national organization, with the election at the second national congress of Franco Grillini as national secretary and Beppe Ramina as president.

The relations between lesbian women and gay men have not been easy, because of, among other reasons, the separatist tendencies of the most radical lesbian groups. In 1990, however, a group of lesbians created Arcigay Donna, and for the first time a woman, Graziella Bertozzo, was elected

national secretary. In 1992, the association itself was rebaptized Arcigay Arcilesbica. In 1996, the association was once more restructured and became a federation of different groups; Arcilesbica chose to become autonomous. The most recent strategy aims at the construction of a gay and lesbian community offering services, institutional support, and the solidarity necessary to allow lesbian and gay persons to express their sexual identity just like non-homosexual persons. [Update 2003: In this context, it is important to note that according to a recent survey carried out by Marzio Barbagli and Asher Colombo (2001), the majority of homosexuals have never openly discussed their sexual orientation with their parents. Coming out on the job is considered even more of a problem, even though only 2% to 5% of those who did come out were confronted with serious acts of discrimination (End of update by P. F. Wanrooij)]

## B. Legal Status

Article 3 of the Constitution of the Italian Republic, approved in 1947, recognizes the equality of all citizens, and condemns discrimination based on sex, race, language, religion, political opinion, and personal and social conditions. The Republic has the obligation to remove social and economic obstacles, which *de facto* limit the full development of the human personality. While this can be interpreted as including the protection of the right of each individual not to be discriminated against on the grounds of his or her sexual orientation, there is no explicit mention of this in the Italian legislation. A campaign to introduce sexual orientation among the conditions mentioned in Article 3 of the Constitution started in 1998.

The creation of Arcigay has given more visibility to the problems of homosexuals in Italian society, and has made it possible to recognize and fight stereotypes, prejudices, and homophobic attitudes. The recognition of the role played by Arcigay in the defense of the interests of homosexuals became clear in 1987, when a group of members of Parliament attended the Third National Congress of the movement. Together with the fight against all forms of discrimination of homosexuals in Italian society, Arcigay has dedicated much energy to the issue of the recognition of the rights of homosexual couples. In 1997, a proposal was presented to Parliament in favor of the public recognition of relations not based on marriage. The proposal defines these so-called “civil unions” as relations between two consenting adult persons of any sex who have led for at least one year a common spiritual and material life. Legal recognition of these unions would entail the possibility of formal registration, and the extension to the partners of these unions of all rights commonly recognized to the partners of traditional couples, including unemployment benefits, compensation for injuries to the partner, priority access to public housing projects, the recognition of the right to reside in Italy for foreign partners, and so on.

A recent survey among Italian Catholics (Inchiesta 1998) indicated a 72.2% majority in favor of giving “*de facto* unions” the same rights as legal families. In this case, an insufficient understanding of the term “*de facto* unions” probably invalidates the results. However, according to a recent survey (Buzzi 1998), 47.1% of young people agree with the idea that “homosexual couples should have the same rights as heterosexual couples,” while only 30% disapproved. The ideas that homosexuality is a disease or a form of sexual perversion that should be illegal obtained, respectively, the support of 17.4% and 8.3% of the respondents.

Notwithstanding this public support, the proposal for the recognition of “civil unions” has made no progress in Parliament, because of numerous groups voicing their objections and the opposition of the Catholic Church and its allies.

According to a 1988 survey, homophobic attitudes are strong, especially among the lower social classes and among the elderly. But 35.3% of all Italians declared that they would simply acknowledge the discovery of a homosexual relative, while 23% would try to help homosexual relatives to express their sexual orientation without anxiety (Fiore 1991). This relatively open-minded attitude at the individual level contrasts with the social rejection of homosexuality. Still, 11.2% of Italians proposed legal measures against homosexuality and, while 48.8% are in favor of the recognition of the equal rights and dignity of homosexuals, 45.3% of Italians see the diffusion of homosexuality as a social peril.

## C. Behaviors

Most males discover their homosexual desires during puberty, between the ages of 11 and 15 (42.6%), or adolescence, age 16 to 20 (20.9%). Females become aware of their desires at a later age. They also start having sexual relations at a later age (22.3% before age 15, against 42.1% in the case of males). Whereas homosexual contacts precede the acquisition of a homosexual identity in the case of males, in the case of females, the first homosexual experiences usually take place after the acquisition of a sexual identity. The main reaction in the case of females is happiness (64.5% against 47.2% in the case of males). However, fear and a sense of guilt continue to play a role. The high number of partners of male homosexuals—12.9% declared sexual contacts with over 400 partners—is in contrast with the declared preference for monogamous same-sex couples. [Update 2003: The number of partners per year is significantly lower for the generation born after 1972 than for those born before 1956. This may be explained in part by the fear of AIDS. However, it might also be the result of a generational change, because those coming of age in the 1980s and 1990s do not share the ideals of free love that were popular both among homosexuals and among heterosexuals in the 1960s. (End of update by P. F. Wanrooij)]

According to Fiore (1991), the most common sexual practices among homosexual couples are: mutual masturbation (practiced in all sexual contacts by 25% of males and 41.9% of females), followed by oral-genital contacts and penetration. Sadosomachistic practices are much less frequent. Generally speaking, sexual practices among homosexuals are polymorphous and depend on the partner, the place, and other specific conditions. [Update 2003: A recent survey by Barbagli and Colombo (2001) shows that similar characteristics apply to lesbian women: mutual masturbation and penetration of the vagina are the most common sexual practices, but practices vary widely depending on conditions like the level of emotional participation. (End of update by P. F. Wanrooij)]

## 7. Gender Diversity and Transgender Issues

During the late 1970s, a group of transsexuals created the Movimento Transessuali Italiani (MTI) (Movement of Italian Transsexuals or MIT). With the support of the Radical Party, this movement succeeded in 1982 in convincing Parliament to change the existing legislation. The original proposal would have made it possible to change one's sex simply by requesting a change in the sex indicators on official documents. The final approved compromise introduced a two-step procedure for changing one's sex. First, a court has to give permission for the surgical adaptation of genitals on the basis of medical and psychological evidence. Certification of the surgical intervention is then needed to change the indication of sex in the documents.

The law is based on the assumption that only two sexes exist, male and female, and, while acknowledging the right of transsexuals to recreate the unity of body and mind, the law offers no solution for transsexuals who intend to change their sex status without undergoing surgical interventions.

## 8. Significant Unconventional Sexual Behaviors

### A. Coercive Sex

#### *Child Sexual Abuse and Incest*

A number of serious crimes committed in Italy and abroad has brought the problem of sexual abuse of children to public attention. The activities of the telephone help service for children, Telefono Azzurro ("Blue Telephone"), have also contributed to making the problem better known to the general public.

Reacting to the increase in the number of cases of sexual abuse of children that have reached public attention, the Italian Parliament introduced in 1998 new legislation against the sexual exploitation of minors in prostitution, pornography, and sex tourism. The clients of prostitutes aged 14 to 16 risk a term of prison from six months to three years, or of four months to two years if the client is under age 18. Similar punishment is attached to the acquisition of pornography involving minors. The main innovations of the law regard more severe punishment for those who produce, sell, or transmit pornography depicting minors, and for those responsible for supporting the prostitution of minors. Those responsible for traffic in minors for prostitution risk a punishment of six to 20 years. The law can also be applied if the crimes are committed abroad, so that travel agencies have the obligation to warn their clients about the risks of sex tourism.

In order to combat sex tourism and the distribution of pornography involving minors, police forces are allowed to work undercover, participate in organized travel abroad, and create Internet sites and discussion groups.

The recent legislation has been criticized for confirming existing stereotypes and for calling for new crusades or "witch hunts." The main criticism centers on the fact that the law tends to focus on persons who are unknown to the child, whereas, in reality, in the majority of cases, those responsible for child abuse are family members or members of the community.

Indictment for incest involving two adults takes place only on complaint and in case of public scandal. Generally, police and judiciary authorities do not take action unless a formal complaint has been filed.

#### *Sexual Harassment*

The majority of Italian women aged 14 to 59 have been the victim of at least one of the following forms of sexual harassment: obscene telephone calls, acts of exhibitionism, physical harassment, and/or sexual intimidation on the job. The persons responsible for acts of sexual harassment are generally outsiders not known to the victims.

Proposals to clarify the legal status of some forms of behavior with a sexual connotation that are clearly offensive came up for open discussion, but early public opinion has resisted all attempts to introduce a more extensive notion of sexual harassment. In many cases, these attempts are considered part of a moral crusade imported from the United States.

#### *Rape*

The Fascist penal code defined rape as a crime that offended public morality and not as a crime against the person. Like many other parts of Fascist legislation, the articles regarding sexual violence remained valid during the first

decades of the Italian Republic. Rape was considered a crime against morality, and no mandatory prosecution existed. The victim had to file a complaint, and often would be as much on trial as the perpetrator, because the defense would insist that the victim had provoked the crime. Evidence of the sexual history of the victim could be presented to the court. Moreover, the fact that the men responsible for this crime could escape punishment if they married their victims, often led to heavy pressure on the victim. In any case, punishment of the crime was relatively mild.

Given this legal situation, and taking into account the psychological problems that still today make it difficult to denounce acts of sexual violence, the statistics have no direct relation with the real incidence of the crime, but are linked with the attitudes prevailing in society, and especially among women. Until the early 1960s, the number of denunciations of rape was highest in the southern regions of Italy, where legal pressure was used to obtain extralegal solutions, like marriage, which could restore the honor of the family (Sabadini 1998).

During the 1970s, changes in sexual mores led to a decline of the number of denunciations in the south. The general increase of denunciations in the 1980s is linked with changes in public opinion, which had grown more aware of the importance of women's rights, while the police forces and judiciary system also changed their attitudes. Women's organizations have played an important role in this change. Already in the 1960s, women's organizations had started to campaign against the existing legislation, underlining the importance of sexual violence against women. The existence of anti-violence centers and of other assistance services organized by women, like the Telefono Rosa ("Pink Telephone"), convinced more women to denounce violence.

Still today, most cases of sexual violence are not denounced, and this is even more true when the person responsible for the crime is someone known by the victim, as is often the case. Only in 21.7% of the reported cases of sexual violence was the person responsible totally unknown to the victim; most other cases regarded friends, relatives, employers, and so on. Friends, relatives, and (ex-)boyfriends are responsible for 54.3% of reported incidents of sexual violence; violence on the job by employers or colleagues accounts for 10.7%. Street violence accounts for 22.5%.

In February 1996, new legislation was introduced. Sexual violence is now considered a crime against the person, and is punished more severely than in the past. By abolishing the distinction between rape (sexual violence with penetration) and other forms of sexual violence, Law n. 66 has eliminated the need for specific medical checks and for a detailed discussion of the acts. According to the new legislation, sexual violence, meaning sexual relations obtained with the use of physical violence, threats, abuse of authority, abuse of conditions of physical or mental inferiority, or deception, is punished with a term in prison from five to ten years. The punishment is six to 12 years if special conditions occur, as in the case of gang rape. Prosecution is mandatory only in special cases, such as when the victim is under age 14. In all other cases, it is necessary to file a complaint within a period of six months from the time of the crime. It is not possible to retract this complaint.

### B. Prostitution

In 1860, the new Italian kingdom followed the French and Belgian example of allowing regulated prostitution in closed houses, where prostitutes were subjected to mandatory medical control and deprived of many civil rights. Notwithstanding the opposition of the abolitionist movement and feminist groups, the system of regulated prostitution re-

mained in vigor, with relatively minor changes, until 1958. The system was justified on the grounds that it gave young men a safe outlet for their sexual desires, and helped to avoid both masturbation and the socially more disruptive problem of the seduction of "honest" girls. Moralistic arguments played an important role as well in the discourse of the abolitionists, who refused to recognize that prostitution could be a choice for poor women for whom the alternatives offered by the labor market often were not much more attractive. Medical science viewed regulated prostitution as a necessary protection against the diffusion of sexually transmitted diseases. Moreover, positivist scientists like Cesare Lombroso (1836-1909), an Italian physician and criminologist, claimed that prostitution was the "biological destiny" of women who shared certain physical and psychological characteristics.

In 1948, Lina Merlin, a socialist member of Parliament, proposed a bill for the abolition of closed houses of prostitution. The proposal, which was not approved until 1958, met with the open opposition of brothel keepers who financed a campaign in the newspapers against the "Salvation Army mentality" of Lina Merlin, and accused her of disregarding male privileges. Protests were expressed also by the national association of venereologists, who warned that the abolition of mandatory medical checks on prostitutes would lead to a rapid increase of syphilis and other venereal diseases. The group of abolitionists was internally divided because some saw the abolition of organized prostitution primarily as a way to reconstruct the moral bases of male superiority, or as part of a more complex effort of moralization, including measures against premarital sex, adultery, and contraception. The main cause of the delay, however, was the silent opposition of the male members of Parliament who simply refused to put the issue on the agenda.

The new legislation, which was finally approved in 1958, did not make prostitution, as such, a crime, but punished only persons involved in procuring and in the exploitation of prostitution. Therefore, those who organized prostitution now ran most of the legal risks, while the prostitutes themselves had little to fear. The result has been that most prostitutes turned to streetwalking; only those prostitutes who could guarantee a high income, and who did not represent special risks of being minors or drug addicts, were employed in illegal brothels.

In the 1980s, prostitutes, or sex workers, started to organize themselves, and the year 1983 saw the first meeting of the Comitato per i Diritti Civili delle Prostitute (Committee for the Civil Rights of Prostitutes), created on the initiative of Carla Corso and Pia Covre. The main aim of this organization was to limit the extensive interpretation of the existing law against the exploitation of prostitution, which was often applied against the husbands and partners of prostitutes. An attempt was also made to reeducate the male clients, and to convince them of the necessity to use condoms.

The presence among prostitutes of drug addicts willing to accept lower prices and not requiring the use of condoms limited the successes of the organizations of prostitutes. In the early 1990s, the arrival of women from Eastern Europe and Africa created further problems. According to a report published by the Ministry of Internal Affairs in September 1997, the total number of women working as prostitutes in Italy is about 50,000. Thirty-five thousand of these women have migrated to Italy from abroad, with the major group coming from Albania. In 1996, 4,387 persons were denounced for the exploitation of prostitution.

Prostitutes can be divided into three categories, depending on differences between the level of personal autonomy, the prices paid for their services, the level of integration in

society, and age. At the top level are the call girls who are autonomous in the organization of their activities; they attract their clients through advertising in newspapers and in specialized magazines. Unlike the call girls, the second group of women, who work officially as actors, dancers, hostesses, strippers, and so on, cannot refuse clients who are procured by agencies or by the owners of nightclubs.

The working conditions of streetwalkers, many of them illegal immigrants, are worse, because their legal situation makes them easily exploited. Moreover, many of these prostitutes, especially those coming from Albania, are minors, and are forced to work on the streets. These young women are often exploited by criminal gangs, who force them to hand over all the money they earn. Moreover, they are the frequent victims of the violent actions of the procurers, especially when they stand up against their exploiters, and refuse to work as prostitutes. Streetwalkers also run more risks in their contacts with clients. Police actions against these forms of violence have been notably inefficient.

The rapid increase in the number of prostitutes and their growing visibility has led to a recent debate about the possible reintroduction of some regulation of prostitution. Proposals have been forwarded to force prostitutes to exercise their profession only in certain locations, and/or to allow them to organize themselves in cooperatives, without being accused of "favoring" the prostitution of their fellow sex workers. In 1998, many city councils introduced repressive legislation, using the existing rules regarding traffic and public order, to force prostitutes and their clients to change locations. At the national level, proposals were discussed to coordinate police actions against the exploitation of women and to create public facilities for prostitutes who want to abandon the streets. Moreover, illegal immigrants are offered the right to reside in Italy in exchange for their help in dismantling the criminal organizations responsible for the "traffic in women."

[Update 2003: In January 2003, the Italian government proposed a bill, which, in its intentions, will combat the increase of prostitution. The exploitation of prostitution by criminal organizations will be punished more severely, and more funds will be made available to assist the women who want to escape from these organizations. Streetwalkers who are not the victims of criminals will be punished with a fine plus a term of prison up to 15 days. Also, their male clients risk a fine. However, prostitution in private apartments will be legal. Moreover, prostitutes are encouraged to undergo frequent medical checkups, even though the bill does not introduce any formal obligation in this sense.

[The conservative government presented its bill as a way of promoting traditional family values, without reintroducing regulated prostitution. Members of the opposition and nongovernmental organizations, however, speak about a return to the system of "closed houses." They claim that the bill merely aims at eliminating the visibility of prostitution, without tackling the problem itself. (End of update by P. F. Wanrooij)]

Transsexuals and transvestites also participate in prostitution, where the two categories are often lumped together under the name *viados*. Male homosexual prostitution, which created Italy's reputation for sex tourism early in the 20th century, is concentrated in the major cities, and takes, above all, the form of streetwalking. As in the case of heterosexual prostitution, some of the prostitutes offering their services to homosexual clients are minors, and a relatively high percentage is recruited among (illegal) immigrants. Male heterosexual prostitution is less common, but according to journalistic sources, there is an increase in the phenomenon. Unfortunately, little research has been done

on this. In recent years, the larger Italian cities have attracted Brazilian and other Latino transvestites, who can earn a much better living as prostitutes than they can in South America.

Not much information is available about the clients of prostitutes. Until 1960, about a quarter of Italian young men had their first complete heterosexual experience with prostitutes. Visits to brothels were considered part of the process of coming of age for young, unmarried men, even though in reality middle-aged married men made up a large part of the clientele.

Today, there is a growing demand for sexual services, which seems to be linked with the more general phenomenon of the commoditization of human relations. About 16% of sexually active Italian males have sexual intercourse with prostitutes, with a higher percentage in southern Italy (Cutrufelli 1996). The increase in the demand, however, has not kept up with the increase on the supply side. As a result, it has become ever more difficult for prostitutes to refuse certain clients or particular sexual acts. Also, the safety risk is higher, as the request to use condoms is often disregarded by clients.

A recent public opinion survey (Buzzi 1998) shows that most young Italians have a more severe judgment about the clients than about the prostitutes. Prostitution, however, is seen above all as a problem of public order, and 64.7% of young people agree with the idea of reestablishing brothels. Moreover, the majority of young men do not exclude the possibility of going with prostitutes.

### C. Pornography and Erotica

While it is difficult to find precise data about the production and commerce of pornography in Italy, there are no doubts about its diffusion. The gradual blurring of the distinction between pornography and other forms of erotica has led to a high level of social acceptance of pornography and opened new markets. In public debate, the anti-pornography position is weak, and pornography is often presented as a form of sexual liberation. Even some Catholic moralists have recognized that pornography can help couples to improve their sexual life as long as it does not replace "natural" sexuality.

The pornography market can satisfy most requests in genres from heterosexual and homosexual to transsexual, and from sadomasochism to sexual acts involving animals, and products including magazines, videocassettes, telephone services, and sex toys. A great diversification exists in the distribution system, which includes normal newsstands, video shops, porno shops, and mail-order services. From the economic point of view, the most important sector of the porno market is the sale of videocassettes, the success of which has been made possible by the wide distribution of videocassette players. With the increase in the sale of videocassettes, the importance of the so-called "red light" cinemas, with their almost exclusively male public, has decreased rapidly, from 122 in 1987 to 85 in 1992. Soft-core magazines, as well, have entered a period of crisis: The October 1991 issue of *Playboy* sold 51,000 copies, whereas during the late 1970s, the average sale had been about 120,000 copies. Hardcore magazines did not suffer the same decline, thanks to the greater diversification of their content. The total yearly sale of porno magazines is about 30 million copies.

Compared to porno cinemas, videocassettes offer the possibility of greater privacy, and cater to the needs of a more mixed public, including women and couples. Pornographic videocassettes are distributed primarily through video shops, where they can also be rented, and at the typi-

cal newsstand. The newsstands have fewer legal problems in selling the hardcore cassettes, which are formally attached to magazines, because, according to a law issued in 1975, the owner of the newsstand is not responsible for the content of the publications that he or she sells. This legal situation has made the newsstands the primary channel for the sale of pornographic cassettes, and has thus determined a high level of visibility for pornography. Video shops, however, offer the advantage of greater anonymity, especially, in the case of automatic dispensers, and the technical quality of the cassettes is usually higher. Estimates of the economic value of pornographic cassettes vary from 250 to 1,000 billion Italian lire per year.

The star system is a characteristic of hardcore pornographic movies produced in Italy, and actresses like Ilona Staller, Moana Pozzi, Jessica Rizzo, and Eva Henger have achieved some popularity also outside the world of pornography, thanks to their presence as guest stars in non-porno television shows. The best-known pornography stars have tried to exploit their popularity also, through the creation of pay sites on the World Wide Web. Not much is known about the consumption of pornography through Internet services, but the growing number of sites in Italian seems to indicate an expanding demand.

Surveys regarding the consumers of pornography (Eurispes 1993) indicate that about 50% of both males and females are sexuality excited by erotic films. However, whereas females prefer erotic films where sexual acts are embedded in a narrative context, males are more easily excited by viewing mere nudity and sexual organs. Earlier surveys (Sabatini 1988) defined the interest for pornography as predominantly male, and suggested that female curiosity increased with age. Moreover, female consumption of pornography seems to take place in the context of the couple, whereas for men it is more linked with solitary sex. The gender differences in the consumption of pornography are probably related to its male focus. Notwithstanding this, generally speaking, there are indications of an increase of the consumption of pornography by couples.

## 9. Contraception, Abortion, and Population Planning

### A. Contraception

According to a 1997 survey (De Sandre 1997), the most common method of contraception in Italy is withdrawal, which is used by 29.2% of women of fertile age with a stable relationship. The incidence of this method is highest among women in the age group 20 to 24 (38.0%), where the contraceptive pill ranks second with 32.9%, and in the age group 45 to 49 (39.6%). Condoms are the most popular method of birth control for women aged 35 to 39 (28.1%); the contraceptive pill prevails in the age group 30 to 34 (30.8%). Nine percent of women with a stable relationship do not use any method of contraception.

The situation is completely different among women without a stable relationship: 48.7% use the contraceptive pill, and 30.8% use condoms. Differences between the age groups are less important for this category, with the exception of women belonging to the age group 45 to 49, whose use of the contraceptive pill is equaled by the use of other modern methods of contraception (both 22.9%). Condoms are used by 7.6% of the 45-to-49 age group, whereas 38.9% of this group does not use any method of contraception. Differences between the age groups are less pronounced among women without a stable relationship. Only the women aged 45 to 49 distinguish themselves: The use of the contraceptive pill is lower for this group (22.9%), and the difference is even

more striking for the use of condoms (7.6%). Thirty-nine percent of women without a stable relationship aged 45 to 49 do not use any form of contraception.

Condoms and other means of contraception were not easily available in Italy until World War I. However, the existing methods of birth control, sexual abstinence and withdrawal, were not popular among men from the higher classes, who often preferred the sexual exploitation of domestic servants and peasant women. The ideals of neo-Malthusianism gained more popularity in the first decades of the 20th century when rubber condoms became available. In 1913, Luigi Berta and Secondo Giorni founded the neo-Malthusian League. The success of this movement was hampered by the advent of World War I, which seemed to show the need of population growth, and gave birth control an anti-patriotic image.

Eager to win the "demographic battle" in favor of population growth, the Fascist leaders introduced in 1930 legislation prohibiting publications and any other form of propaganda in favor of birth control. The production of condoms, as such, was not affected, because they were deemed necessary as a protection against venereal diseases. Subsidies and tax reductions for large families, jobs and better career chances for prolific fathers, higher taxation for bachelors, and healthcare for mothers and children were introduced in this period, but did not convince men, and above all women, to have more children. The main result of the prohibition of contraception was, therefore, an increase in the number of abortions. In addition, there was an increase in the number of illegitimate children, because economic hardship made it difficult to set up new households.

In the years after World War II, there was growing opposition against the Fascist legislation regarding contraception, which had remained valid in Italy even after the fall of Benito Mussolini. In 1956, the Italian Association for Demographic Education (AIED) was founded with the aim of defending the idea and the practice of a voluntary and conscious limitation of the number of children, and of combating the existing legislation against birth control. AIED had the support of the secular lay forces in Italy, of the socialists and of the communists, but its proposals were strongly opposed by the Catholics, who upheld the existing legislation. Still, in 1965, the Constitutional Court declared that detailed information about contraceptives should remain illegal because it offended public morality. In 1971, the legislation forbidding "propaganda in favor of birth control" was declared unconstitutional.

Since the legalization of contraception, the fertility rate has accelerated its decline. Notwithstanding the opposition of the Catholic Church, which has repeatedly reaffirmed its condemnation of contraception in the 1969 Encyclical *Humanae Vitae* of Pope Paul VI, the use of the contraceptive pill has increased, and almost tripled in the ten years between 1985 and 1996.

Some taboos survive, however. In 1997, the installation of condom dispensers in a public high school caused a major outcry in the conservative press. The official newspaper of the Vatican, *L'Osservatore Romano*, spoke about an act of arrogance committed by a minority, even though according to public opinion polls, 79% of the Italians were in favor of the initiative. Earlier, in 1993, an anti-AIDS campaign in high schools was blocked because it endorsed the use of condoms. Furthermore, a recent agreement among private and public television networks excludes publicity for condoms during prime time.

Especially among young people, who seem to be aware of the risks of unprotected sexual relations in terms of STDs and pregnancy, the use of condoms is limited, because it is

assumed that they make sex less enjoyable, because it is embarrassing to buy them, and also because the risk of not using condoms in contacts with occasional partners is judged acceptable. The low incidence of extramarital pregnancies is nevertheless an indication of the widespread use of contraception. The majority of unmarried women above age 20, in fact, have complete sexual relations, but only a few of them cohabit or have children. This is even more significant taking into account the distance between the age of first sex and marriage.

## B. Abortion

Although induced abortion was not allowed during the Fascist period, legal measures against contraception, and the high incidence of premarital sex in certain regions, made abortion a common method of birth control. The first exception in the general prohibition of abortion was made in 1975, when the Constitutional Court ruled that induced abortion should be possible in the case of serious health risks for the woman. After a campaign by pro-choice feminist groups, abortion was legalized in 1978, and women were granted the right to terminate a pregnancy upon request during the first trimester. However, the law contained a number of restrictions: Legal abortion is confined to women whose physical and psychological health are at risk or for whom social conditions, economic conditions, or the family situation make it extremely difficult to educate children. Further limitations regard the obligation to consult a medical doctor, and the mandatory waiting period of seven days between the medically certified decision and the actual intervention. Minors need to obtain permission of a parent or guardian. The male partner of the woman is involved in the decision process only if the woman wishes so.

After the first three-month period, induced abortion is legal only in case pregnancy or childbirth creates serious health risks for the woman, or when the fetus presents pathologies that entail serious risks for the physical and mental health of the woman. All induced abortions have to take place in public hospitals, where the medical staff has no obligation to cooperate if abortion is in conflict with their moral and religious convictions. Partly as a result of the limitations to the freedom of choice, illegally induced abortion has not disappeared in Italy. For obvious reasons, no exact data are available, but the Ministry of Health estimated that 50,000 clandestine abortions were carried out in 1993, 70% of which were in the south.

Attempts to change the existing legislation failed in 1981, when two different referenda, one aimed at eliminating the restrictions, the other designed to severely reduce access to abortion, were voted down by majorities of, respectively, 88.4% and 68%. Abortion remains controversial in Italy, however, and is severely condemned by the Catholic Church. The condemnation was reiterated in a recent Papal Encyclical on ethical questions, *Evangelium Vitae*. The Italian pro-life movement tries actively, but without much success, to convince the political leadership of the need to change the existing legislation. Most of its resources, however, are spent in providing alternative solutions and facilities for single mothers.

After the introduction of Law no. 194, abortion rates rose modestly, increasing from 13.7 abortions per 1,000 women aged 15 to 44 in 1979 to 16.9 per 1,000 in 1982. Since 1984, there has been a steady decline, reaching 9.8 per 1,000 by 1993. A similar pattern was displayed by abortion ratios (the number of abortions per 1,000 live births), which reached 213 in 1996 after having reached a peak of 389.5 in 1984. While the abortion ratios are relatively high because of Italy's low fertility rate, the general trends are similar to other

western European countries. (Salvini Bettarini 1996). Abortion rates and ratios vary considerably according to regions. Since legalization, abortion rates have dropped most in the northern regions, where family planning services are more extensive, but both abortion ratios and rates remain higher in the northern and central regions than in the south.

As far as age patterns are concerned, the abortion rate is relatively low for young women (7.6 per 1,000 women at ages 15 to 19 in 1981, and 4.6 in 1991). This may be, in part, because of legislative restrictions, but it is also linked to the fact that Italian women start to have sexual relations at a relatively late age. Generally speaking, the trend in the distribution of age-specific abortion rates is shifting upward. In 1981, the abortion rate was highest among women aged 25 to 29 (25.3 per 1,000 women), whereas in 1991, the abortion rate was highest among women aged 30 to 34 (16.9 per 1,000 women), with women aged 26 to 29 coming second (15.7 per 1,000 women).

The most recent data (ISTAT 2000) show that the total number of voluntary abortions has stabilized at between 138,000 and 140,000 per year, after a slight increase in 1997 when the number of abortions was 9.5 per 1,000 women of fertile age. Thus, in the years 1980 to 1997, the average number of abortions per woman has diminished by 40.7% against a diminution by 29% of the fertility rate in the same time period. The decline in the abortion rate and in the fertility rate indicate a more frequent, or more efficient, use of techniques of birth control. The decline in the abortion rate is highest among married women in the most fertile age groups, 25 to 28 and 30 to 34. An opposite tendency can be noted among very young women, aged 15 to 19, among whom the abortion rate has increased since the early 1990s, reaching 6.6 per 1,000 in 1998. A more consistent increase regards the abortion rate of immigrant women, which reached the number of 32.5 abortions per 1,000 women in 1998.

### C. Population Programs

Under Fascism, public authorities shared the Catholic Church's positive view about large families, and after the fall of Mussolini, they were slow to change their position. Not until 1971 did the Constitutional Court declare that ideas about population growth dating back to the Fascist period were not sufficient to justify the existence of legislation against contraception. To advance information about contraception and to promote responsible parenthood are part of the duties of the public family advisory agencies created in 1975.

In the postwar period, population planning concentrated on various maternity benefits. The first important legal measure was taken in 1950 when employers were prohibited by law from dismissing pregnant women or mothers of small children. The same law prohibited employing pregnant women in activities that would endanger their health or the health of the unborn baby. Finally, a new law introduced a paid maternity leave of three months before childbirth and two months after childbirth. Mothers have the right to six more months of unpaid maternity leave, during which they retain their position. In the attempt to invalidate the attempt of employers to dismiss women as soon as the possibility of pregnancy increased significantly, a 1963 law specified that marriage was not a valid reason for dismissal. The rules regarding mandatory leave of absence for maternity were reaffirmed and elaborated on in Law n. 1204 of 1971.

Today, Italy's birthrate, expressed in Total Fertility Rate (TFR) is, with that of Spain, the lowest of 227 nations: 1.19 children per fertile woman. A TFR of 0.8 in the northern industrial city of Bologna underscores the social challenges Italy faces. The actions of the Italian governments in the field

of population planning are strongly influenced by the fear that this low fertility rate and a relative decline of the active population will make it impossible to finance pensions for the retired and other welfare projects. Most measures aim at improving the conditions of working mothers, and try at the same time to eliminate gender-specific discrimination, by extending rights, such as leaves of absence for the care of children to men. According to recent proposals, financial compensation for maternity, until now limited to employed women, will be extended to non-employed and self-employed women. Further measures focus on the creation and funding of childcare facilities, and, more generally, aim at reducing the financial burden of families with children.

## 10. Sexually Transmitted Diseases and HIV/AIDS

### A. Sexually Transmitted Diseases

Historically, sexually transmissible diseases (STDs) were seen primarily as a consequence of sexual contacts with prostitutes, and the legal interventions regarding prostitution and STDs were closely connected. The need to control the diffusion of STDs was one of the main arguments for the introduction, in 1860, of regulated prostitution. In 1870, the obligation to notify health authorities of infectious diseases was introduced, together with more specific laws regarding STDs. In 1888, the clinics for the mandatory treatment of infected prostitutes were reorganized and transformed into specialized clinics for the free treatment of contagious venereal diseases. New legislation, approved in 1901, defined syphilis, gonorrhoea, and chancroid (*Hemophilus ducreyi*) as "venereal diseases." According to legislation approved in 1923, venereal clinics had to be created in all major cities. While reaffirming the principle of free treatment, Law 837 of 1956 and successive laws updated existing legislation and established a list of four diseases—syphilis, blennorrhagia (a profuse gonorrhoeal discharge), chancroid, and lymphogranuloma venereum (*Chlamydia trachomatis*)—for which there is an obligation to report. This law is still in effect. Moreover, the terminology used in official documents still refers to "venereal diseases," and has not yet adopted the broader term of sexually transmissible diseases (STD).

While venereologists denounced a rapid increase of venereal diseases after 1958, when the abolition of regulated prostitution made mandatory medical checks on prostitutes impossible, in reality the statistical data could be interpreted in various ways.

In 1972, responsibility for the diagnosis and treatment of STDs was transferred to regional governments. The result has been a growing differentiation in the treatment and operational conditions of various STD centers, with important differences both between regions and within the same region. In the past, venereology was associated above all with dermatology, but recent developments have shown the need for a more interdisciplinary approach.

The precise incidence of STDs is unknown, not only because there is a legal obligation to report only a few diseases, but also because medical specialists tend to disregard this obligation. The Higher Institute for Health (Istituto Superiore della Sanita, ISS) has estimated that the number of unreported cases is at least 100 to 150% higher than reported cases. In September 1991, a national STD surveillance agency was created to collect and analyze data coming from some 48 STD clinics. The aim is not to register the total number of cases, but rather to monitor developments and to gather the data necessary for a better description of STDs (Giuliani & Suligoj 1994).

The results of the first year of the survey confirmed the existence of important regional variations in the registration and/or recourse to STD centers for treatment: 67.4% of the 9,527 STD cases were registered in northern Italy, 19.3% in central Italy, and 33.6% in the south. In order to assist the large number of foreigners involved (10.4%), in 1992, a special project was created for the prevention and treatment of STDs among this group. Heterosexual contacts were responsible for 92% of the cases, and homosexual or bisexual contacts accounted for 8%. The most frequent pathologies were *Condyloma acuta* or venereal warts, 28%; nongonococcal urethritis, 11.2%; nongonococcal vaginitis, 18.6%; and quiescent seropositive syphilis, 10.4%.

## B. HIV/AIDS

The first case of AIDS in Italy was discovered in 1982, and until 1995, there was an annual increase in the number of persons diagnosed as being infected with HIV (see Table 1). HIV infection is unevenly distributed over the national territory, with the highest numbers in the regions of Lombardia, Lazio, Liguria, and Emilia Romagna. Between October 1997 and September 1998, the AIDS rate per 100,000 population was 6.5 in Liguria, 9.1 in Lombardia, 6.0 in Emilia Romagna, and 8.1 in Lazio, against 0.6 in the region of Molise and 1.2 in the Basilicata. In 1997, women constituted 23.2% of the cases.

Among the men diagnosed as being infected with AIDS, drug addicts are the major category (63.6%), followed by men with homosexual experiences (19.7%). Heterosexual experiences are held responsible for 15.2% of the cases of AIDS, but heterosexual contact is the second most important cause (34.2%) for HIV infection in women after the abuse of drugs (59.9%). The average age at which AIDS is diagnosed is increasing: In 1985, it was 29 for men and 24 for women, compared to 37 for men and 34 for women in 1997.

While at first, gay organizations interpreted the alarm about AIDS as an attempt of the medical professions to regain control and use the discourse about health risks to moralize "disorderly sexual conduct," the real dimensions of the problem soon became clear. In May 1985, Arcigay, to-

gether with the Abele group from Turin, promoted the publication of the first Italian book about AIDS, written by Giovanni Dall'Orto (1985). Since then, Arcigay has promoted many public debates and information campaigns about safe sex. Other initiatives included the free distribution of condoms and the creation of homosexual health centers managed by the association itself with the support of the Ministry of Public Health. The success of these actions is shown by the fact that homosexuals in Italy make up a much lower percentage of the victims of AIDS than in most other countries.

[Update 2002: UNAIDS Epidemiological Assessment: The incidence of new HIV cases diagnosed decreased from 19.18 per 100,000 in 1992 to 6.68 per 100,000 in the year 2000. Testing is mandatory for blood donors and systematically proposed in STD clinics and injecting-drug-user treatment centers. There are several regional HIV case reporting systems (e.g., Lazio (region of Rome), Veneto, Friuli, and the provinces of Trento and Modena). Universal Assessment Testing (UAT) surveys have been conducted in newborns in all regions since 1989, showing a mean prevalence of HIV seropositivity of about 1 per 1,000. Prevalence varies greatly by regions. In most of the population tested, prevalence is higher in Lazio, Lombardia (region of Milan), Emilia, and Liguria than most other regions. In addition, prevalence is higher in all regions of the north compared to the south in all populations tested, except blood donors, where the opposite is observed, probably due to the higher proportion of occasional blood donors. Geographical variations are even stronger among injecting drug users, where prevalence in the same region varied from 9% to 48% in 1985 to 86% in small cities. Overall, HIV seroprevalence among injecting drug users decreased from 30.8% in 1990 to 15.8% in the year 2000. Prevalence slowly decreased from 1990 to 1992 in pregnant women nationally, mostly due to a decline in prevalence in Lazio and Lombardia. In Lazio, about 2 of 1,000 women were found HIV infected before delivery, whereas prevalence was at least 2 times higher among those who underwent voluntary abortion.

[About 8,000 patients are diagnosed every year by the STD clinics (however, this number underestimates the burden of disease since STDs are diagnosed by private gynecologists in a large proportion of women). HIV prevalence among STD patients tended to increase from 9.3% in 1991 to 18.8% in the year 2000.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	100,000 (rate: 0.4%)
Women ages 15-49:	33,000
Children ages 0-15:	770

[An estimated 1,100 adults and children died of AIDS during 2001.

[No estimate is available for the number of Italian children who had lost one or both parents to AIDS and were under age 15 at the end of 2001. (End of update by the Editors)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

### A. Sexual Dysfunctions

The notion of sexual dysfunction itself is subject to change, and definitions of sexual dysfunctions often mirror changing attitudes toward male and female sexuality. Thus, inhibited female orgasm (anorgasmia) was not considered a problem in a context where female sexuality was linked almost exclusively with procreation. Premature ejaculation became more of a problem with the emergence of the myth of simultaneous orgasm, and also the idea of (hetero-

**Table 1**

**Annual Distribution of New Cases of AIDS and Mortality Rate**

Year of Diagnosis	New Cases	Mortality Rate
1982	1	0.0%
1983	8	87.5%
1984	37	100.0%
1985	198	93.9%
1986	457	93.4%
1987	1,029	93.0%
1988	1,773	90.4%
1989	2,480	90.8%
1990	3,135	89.1%
1991	3,826	88.7%
1992	4,261	85.6%
1993	4,818	77.6%
1994	5,521	72.7%
1995	5,654	56.9%
1996	4,993	36.7%
1997	3,728	20.7%
1998 (to 30 September 1998)	1,430	13.6%
Total	42,899	67.5%

(Istituto Superiore di Sanità, Notiziario, XI, 11 November 1998)

sexual) sex as pleasure-created pressures and tensions. Finally, the growing resistance to a compulsory idea of sexuality as necessarily linked with orgasm might eliminate the tendency to treat alternative expressions of eroticism as sexual dysfunctions.

About 11% of Italian males have erectile dysfunctions. More widespread are problems regarding orgasm: About one third of Italian males have had at least some experience with problems of early (premature) ejaculation. The most serious problem, however, is a decreased libido. The incidence of physical problems and, above all, psychological factors, like the identification of virility with sexual potency, and the desire to please the female partner, have created a market for new pharmaceutical products. Among women, the sexual dysfunctions with the highest incidence are painful intercourse (dyspareunia), vaginal spasms (vaginismus), and inhibited orgasm (anorgasmia). Also, among women the loss of sexual desire is common.

Recent research among young people aged 18 to 30 indicates that, among males, 10.2% presented erectile dysfunctions, and 30.1% presented problems of premature ejaculation. Inhibited orgasm was mentioned by 13.2% of young females, while painful intercourse was reported by 50.7%. Difficulties in experiencing orgasm were reported by 11.5% of males and 39.8% of females, while 14.1% of males and 28.4% of females complained about the lack of sexual desire (Buzzi 1998).

Other male problems involve fertility. A comparison of the results of sperm analyses of 4,518 men without fertility problems, carried out by the Centro di Andrologia based in Pisa between 1975 and 1994, has confirmed the thesis of a general decline of the number and of the motility of spermatozoa. In this 20-year period, sperm counts went down from 71 million to 65 million spermatozoa per millimeter. The decline of the motility was even more serious, as the number of spermatozoa with progressive motility decreased from 50% to 32%. Oxidation caused by environmental pollution is the main cause of this phenomenon.

## B. Counseling and Therapies

In 1948, the first Italian family advisory agency was opened in Milan by Don Paolo Liggeri. La Casa and its sister organizations functioned as a social movement, where volunteers tried to transmit values and ideals, not as a service agency where paid professionals offered their services to clients. For this reason, the use of American manuals for marriage counseling, with their pragmatic attitude, often created problems. Nevertheless, these Catholic marriage advisory agencies were often innovative, because they underlined the positive role of sexuality in marriage and favored a more active role of fathers in the education of their children. However, as far as the female gender role was concerned, they subscribed to more traditional ideas about the female biological destiny of motherhood, and women's generally more passive attitude in sexuality.

Law n. 405 of 1975 created a network of public family agencies, which were to offer psychological and social assistance to couples and families, and to assist couples in choices regarding procreation and responsible parenthood through information and the distribution of contraceptives. The same law allowed for the public funding of private family agencies. Both Catholic and feminist-oriented advisory agencies thus received funding. The prerequisite of client-oriented, non-directive counseling was satisfied, not by the single agencies, which maintained their ideological premises, but by the system as a whole.

Among the therapies often used in combination to combat sexual dysfunctions, it is possible to distinguish these:

psychotherapies focused on improving the understanding of sexual problems, and thus modifying reactions and behaviors; behavioral therapy using special assignments to modify and improve the perception of pleasure and the idea of sexual pleasure itself; and autogenous training and pharmacological therapies.

## 12. Sex Research and Advanced Professional Education

In 1921, the Società Italiana per lo Studio delle Questioni Sessuali was founded by Aldo Mieli, with the aim to improve the level of information about human sexuality. The journal published by the Society, *Rassegna di Studi Sessuali*, introduced in Italy the themes and ideas developed by progressive German sexologists, and greatly contributed to a more open discussion. The rise to power of the Fascists in 1922, however, reduced the possibilities for reformist action. This was one of the reasons why, in 1928, Mieli submitted his resignation as editor-in-chief of the journal and left Italy for France. By 1931, when Corrado Gini took over control, the journal had become an instrument of the Fascist population policy.

Sexology had to start again in the postwar period. In 1959, a group of medical doctors, headed by Professor Giacomo Santori, created the Centro Italiano di Sessuologia (Italian Center of Sexology, CIS), which is active, above all, in the sector of training and information. The CIS (Via O. Regnoli, 74, 40138 Bologna) promotes an interdisciplinary approach that draws on the results of medical science, psychology, and anthropology, and favors an interpretation of human sexuality that takes into account the biological and medical aspects, as well as the social and relational aspects, without excluding moral aspects. The CIS is a founding member of the World Association of Sexology (WAS), and a member of the European Federation of Sexology.

Aspects of sexology are part of medical training, and specialized schools are attached to some universities. Among these, the Center of Andrology of the University of Pisa, founded by Professor Menchini Fabris in 1975, deserves special mention. Numerous other institutes and associations do research and offer training in sexology, among them:

- Istituto Internazionale di Sessuologia, Via della Scala, 85, Firenze, Italy (founded in 1981).
- Istituto di Sessuologia Clinica, Via Fibreno 4, 00199 Roma, Italy.
- Società Italiana di Sessuologia Scientifica, Istituto di Sessuologia Clinica, Via Fibreno 4, 00199 Roma, Italy; publication: *Rivista di Sessuologia Clinica*.
- Società Italiana di Sessuologia ed Educazione Sessuale, c/o Prof. Gabriele Traverso, Via Circonvallazione 28, 10015 Ivrea, TO, Italy.
- Centro Italiano di Sessuologia (CIS), Via della Lungarina, 65, Rome, 00153, Italy; phone: +39-6-51-245-785.
- Istituto di Sessuologia di Savona, 17026 Noli, Via la Malfa, 5, Savona, Italy; phone: 39-19-748-5687; fax: +39-19-748-5687; Associazione per la Ricerca in Sessuologia (ARS), Via Angelo Cappelletti 1/8, 16126 Genova, Italy.
- The Centro Italiano di Sessuologia (CIS) is the publisher of the *Rivista di Sessuologia* (CLUEB, Via Marsala 24, 40126 Bologna, Italy; www.clueb.com).
- Other publications in the field of sexology are *Rivista di Scienze Sessuologiche* (Edizioni del Cerro, Via delle Orchidee 17, 56018 Tirrenia, Pisa, Italy) and *Rivista di Sessuologia Clinica* (Franco Angeli, Viale Monze 106, 20127 Milano, Italy; www.francoangeli.it; frang@tin.it).

The results of sexological studies often receive great attention in the mass media, and some sexologists—Willy Pasini, to name but one—have gained national popularity as guests on television talk shows and through their articles in the popular press.

## Demographics and a Brief Historical Perspective

ROBERT T. FRANCOEUR

### A. Demographics

It was Marco Polo, a man from Venice, Italy, in the latter half of the 13th century, who wrote a book titled *Le Merveilles du Monde*, in which he introduced the country of Japan to the Western world as *Jipang*, "the land of gold." His book was actually a collection of his experiences and information about his journey through central Asia and China.

Japan is an island country, located to the east of the Asian continent in the northwestern part of the Pacific Ocean. The islands face the Pacific on the east and south sides, the Sea of Japan and East China Sea on the west side, and the Sea of Okhotsk on the north side. The islands form a bow-shaped

\*\**Editors' Note:* Because of time and space constraints, the Editors have converted most of the extensive original bar and line graphs of the original chapter into tables or comments in the text. We have marked the textual material as 2003 comments following our standard notation in square brackets with the end of the comment referencing the original figure or table number and page number in *IES2*, i.e., the original chapter on Japan in volume 2 of the *International Encyclopedia of Sexuality*. Those figures that we have converted to tables contain this reference information in the new tables' footnotes. For those original line graphs that did not contain actual numbers, we have approximated the percentages, which are noted where appropriate. The reader is referred to the original figures in the original volume or on the Web at <http://www.SexQuest.com/ccies/ies2-ref-figures.html>.

(CIA 2002)

string stretching from the northeast to the southwest. In addition to five major islands, i.e., from the north, Hokkaido, Honshu or Main Island, Shikoku, Kyushu, and Okinawa, there are some 320 small islands over a square kilometer (0.39 sq. mi.) each, totaling 145,883 square miles (377,835 km<sup>2</sup>). Japan is slightly larger than Germany or the state of California, and smaller than Spain.

A relatively mild climate prevails, because of the location of most of Japan's islands in the Temperate Zone. With four distinctive seasons, there are variations because of the longitudinal distribution of the islands. Because of the mild climatic characteristics, natural features of the islands, and religious philosophy, the Japanese people have developed a sensitive and cooperative attitude to the relationship between nature and humankind, in contrast to Western culture, which is independent, and often exploitive or in opposition. Such views of nature and humankind may be regarded as characteristic of the Orient.

The landmass of Japan is rather small and approximately 87% of the land is mountainous. As a consequence, fields and basins of rather small scale are divided by mountain ranges. From the beginning, this geographic circumstance has isolated local communities—which in the early days were independent countries—producing different cultures, customs, and religious events in different areas. This situation persisted into the 20th century. Since the Meiji Era (1868-1912), the influence of Western cultures, along with economic growth and the development and popularization of the mass media system in recent years, has promoted an increasingly shared (common) education and culture, resulting in the current unification of the Japanese culture. Cultures imported from China and Korea since the 5th century, and from the Western world since the Meiji Era, have been well absorbed by the Japanese people. The Japanese always kept a flexible attitude in accepting foreign influences to amalgamate traditional and imported cultures, forming their own specific culture.

In July 2002, Japan had an estimated population of 127 million, double what it was in 1925. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 14.5% with 1.05 male(s) per female (sex ratio); 15-64 years: 67.5% with 1.01 male(s) per female; 65 years and over: 18% with

0.73 male(s) per female; *Total population sex ratio*: 0.96 male(s) to 1 female

**Life Expectancy at Birth:** *Total Population*: 80.91 years; *male*: 77.73 years; *female*: 84.25 years

**Urban/Rural Distribution:** 77% urban to 23% rural and small villages, clearly indicating an extreme urban-centered social construction. In the second half of the 1900s, Japan's cities grew into metropolises as the focus of work. At the same time, the number of core (nuclear) families with a small number of children is increasing. As a result, the local community as the basis for human network activities and a humane life is often lost.

**Ethnic Distribution:** Japanese 99.4%; Korean: 0.6%. The government needs to pay attention, though, to the possible problem with minority races, such as Ryukyu (Okinawa) and Ainos, and the forced immigrants from the Korean Peninsula during World War II. At this moment, administrative policies and responsive movements of adherence and preservation of the respective cultures are effectively carried out.

**Religious Distribution:** observing both Shinto and Buddhist beliefs: 84%; others: 16%, including 0.6% Christian

**Birth Rate:** The estimated raw Japanese birthrate in 2002 was 10.03 per 1,000 population, compared with 51.8 in 1980, 63.6 in 1960, and 110.4 in 1950, only 45 years ago. The trend of decreased birthrate and increased longevity is already creating serious problems for Japanese society. Japan has a high-aged society that represents a heavy concentration of aged people in contrast to the working population. The current ratio is somewhere around one retiree for every four workers.

**Death Rate:** 8.53 per 1,000 population

**Infant Mortality Rate:** 3.84 deaths per 1,000 live births

**Net Migration Rate:** 0 migrant(s) per 1,000 population

**Total Fertility Rate:** 1.42 children born per woman

**Population Growth Rate:** 0.15%

**HIV/AIDS** (1999 est.): *Adult prevalence*: 0.02%; *Persons living with HIV/AIDS*: 10,000; *Deaths*: 150. (For additional details from www.UNAIDS.org, see end of Section 10B.)

**Literacy Rate** (*defined as those age 15 and over who can read and write*): 99%; attendance for nine years of compulsory school, although most Japanese children attend at least 12 years of school

**Per Capita Gross Domestic Product** (*purchasing power parity*): \$27,200 (2001 est.); *Inflation*: -0.6%; *Unemployment*: 4.9%; *Living below the poverty line*: NA

## B. A Brief Historical Perspective

According to Japanese legend, the empire was founded by Emperor Jimmu in 660 B.C.E.. However, the earliest records of a unified Japan date from a thousand years later, about 400 of the Common Era. Chinese influences played an important role in the formation of the Japanese civilization, with Buddhism being introduced to the islands before the 6th century C.E.

A feudal system dominated Japan between 1192 and 1867, with locally powerful noble families and their *samurai* warrior retainers controlling local government, and a succession of military dictators, or *shoguns*, holding the central power. This ended when Emperor Meiji assumed power in 1868. The Portuguese and Dutch developed some minor trade with Japan in the 16th and 17th centuries. United States Commodore Perry opened American trade with Japan in an 1854 treaty. Japan gained Taiwan and other concessions following an 1894-1895 war with China, gained the south half of Sakhalin from a 1904-1905 war with Russia, and annexed Korea in 1910. During World War I, Japan ousted the Germans from Shantung and took over the Pacific islands con-

trolled by Germany. In 1931, Japan took over Manchuria, starting a war with China in 1932. World War II started with Japan's attack on Pearl Harbor, Hawaii, and ended with two atomic bombs being dropped on Hiroshima and Nagasaki in August 1945.

In 1947, Japan adopted a new constitution that reduced the Emperor to a state figurehead and left all the governing power with a Diet. In a few decades, Japan quickly moved to become a major world power and leader in economics, industry, technology, and politics.

## 1. Basic Sexological Premises

### A. Gender Roles

In Japan, a strict hierarchy of social classes and clearly defined traditional gender roles have their roots in over 2,000 years of cultural history. In terms of social classes, merchants or *chyonin* were beneath the farmers and artisans. *Samurai*, the social elite, were retainers in the service of the *shogun* and the *daimio*. The *samurai*, who represented the superior male, constituted a bureaucratic and conservative hereditary group. The *samurai* and his sword were more a class symbol than the fierce warrior pictured in American television mythology.

As for gender roles, Karel Van Wolferen (1989) gives a terse picture of the traditional/modern female gender role in *The Enigma of Japanese Power*:

Although in reality Japanese tradition has never frowned on working women, and today the majority of working married women are obliged to help make ends meet in their families, the officially sponsored portrait of "wholesome" family life invariably shows that the proper place for women is at home. In a country where stereotypes are treasured, emphasis on the established proper roles of women is especially noticeable. It extends to demurely polite deportment, a studied innocent cuteness, a "gentle" voice one octave above the natural voice and always a nurturing, motherly disposition. The modern woman in the world of the salaryman [white collar workers] is a cross between Florence Nightingale and the minister of finance (as women are always totally responsible for household finances). Superior intelligence is a liability for girls and women, and must be disguised.

In early 1989, the Welfare Ministry launched a poster campaign to stress that the only difference between males and females is biological. The posters showed two romping, mud-splattered toddlers with the caption *Tamatama otokonoko, tamatama onnanoko*: "He just happens to be a boy; she just happens to be a girl." This notion gained little support from government ministries more closely allied to business and industry, who joined the politicians in upholding traditional gender-role values as a means of continually exploiting the diligence of the people (Bornoff 1991, 452).

In a 1982 opinion poll conducted by the Prime Minister's Office, 70% of the Japanese surveyed agreed with the statement that "Japanese women still believe a woman's place is in the home and that little girls should be brought up to be 'ladylike.'" In a 1989 multinational survey by the same agency on the theme "Men should work and women should stay home," 71% of the Japanese women either completely or somewhat agreed with the premise (see also discussion of Table 28 (*IES2* Fig. 34, p. 814) in Section 5B, *Interpersonal Heterosexual Behaviors, The Sexuality of Adolescents*). Critics suggest that respondents to government surveys may be inclined to give answers they believe the authorities want to hear, so it is important to balance these government survey results with similar surveys in the pri-

vate sector. In one such survey conducted by a noted cosmetics firm, four fifths of the women found working women admirable, and 70% rejected the notion that a woman should quit her job after marriage (Bornoff 1991, 453). Still, the argument that traditional sex roles are strongly valued in Japan is persuasive when one considers that only 20% of Japanese firms offer female employees a year's maternity leave, in most cases without pay, and that daycare facilities are woefully inadequate. (One should recall, however, that the record of American corporations is not much different on these issues, and certainly lags far behind the policies in some European countries.)

Gender roles are clearly defined, although they are also being challenged in modern Japan.

At the two extremes of female and male in popular culture, one finds the geisha and the sumo wrestler: the dainty living doll standing for femininity and the mountainous icon of macho flesh with the little porcine eyes. Between the two bookends plenty of scope lies in a nebulous heaven of make-believe far from the constrictions of daily routine. Segregating the sexes during childhood and defining the contexts and nature of their encounters later on, Japanese society defines gender roles with adamant rules. In the realm of the imaginary, the strict roles encapsulating male and female are broken, being transgressed in fantasies which can be singly and variously violent, sadistic, maudlin, sentimental or comical. Transcending the laws of society, authority and even gender, these fantasies reach apotheosis in the popular imagination with ethereal creatures as blessedly sexless as occidental angels. (Bornoff 1991, 437)

Gender definitions in Japan can transcend the anatomical; masculine and feminine attributes can fade or fuse through conventions. This is most clearly seen in public rituals, for instance, when the emperor becomes a female incarnation of the sun goddess Amaterasu during the *daijosai* enthronement ceremony (See Bornoff 1991, 15-16, for the legend of Amaterasu and Ama-no-Uzume, the Heavenly Alarming Female). Gender reversal is also common in both traditional theater and modern cinema. After centuries of evolution, *kabuki* became a sophisticated form of theater in which the all-male cast plays all roles. *Kabuki* theater has long found a female equivalent in certain *geisha* theatricals comprising dances and playlets in which some of the female cast adopt male roles. In Nobuhiko Obayashi's film *Tenkosei* [*Transfer Students*], a 1983 offbeat youth comedy hit about junior high school lovers who undergo a kind of Kafka-like metamorphosis when the girl's soul enters the boy's body, and vice versa, and are forced to confront their awakening sexuality, the characters adopt the physical and social gender roles of the other. Similarly, the famed Takarazuka Young Girls Opera, founded in 1914, embraces many older male-role superstars, with female actors performing in braided pantomime in military uniforms, tuxedos, cowboy garb, and *samurai* armor, blue cheeks, and mustaches. The Takarazuka Opera is part of a virtuous theme park called Family Land, "a florid world of Tinseltown baroque in pink, a feminine Disneyland with rose-colored bridges spanning artificial water courses." In 1987, when Takarazuka unsuccessfully pushed for recognition as a traditional art form to gain tax exemption, male traditionalists were quick to point out that *geisha* theater provided the proper traditional female counterpoint to male *kabuki* (see also Section 7 on cross-dressing, gender-crossing, and transsexualism; Bornoff 1991, 436-439).

[Update 1997: In ancient times, Japanese women wielded considerable authority. Until the 11th century, it was common for Japanese girls to inherit their parent's house.

The rise of Confucianism and a conservative moral movement that preached the inferiority of women in the early 18th century significantly reduced women's role. In some respects, Japanese women today have less power in society than they did a thousand years ago. Fewer than one in ten Japanese managers is female; women in less-industrialized nations, like Mexico and Zimbabwe, are twice as likely to be managers. Only 2.3% of Japan's key legislative body are women, compared with 10.9% in the U.S. House of Representatives. In this regard, Japan ranks 145 in a list of 161 countries, according to the Inter-Parliamentary Union.

[The public gender roles, however, are reversed when one steps inside the Japanese home. Typically, the wife handles and completely controls the household finances. She gives her husband a monthly allowance and has total control over the rest of the family income. Half of the husbands in one survey reported they were dissatisfied with the size of their allowance, but could do little if anything about it. While the husband and wife may have a joint bank account, and automatic teller machines are available, wives often do not share access to these with their husbands (Kristof 1996b). (End of update by R. T. Francoeur)]

[Update 1997: In the late 1990s, a new phenomenon appeared in Japan's vibrant, big-city nightlife that may echo other signals noted in this chapter suggesting that traditional Japanese gender roles are changing. A 1996 *New York Times* report by Miki Tanikawa focused on New Ai ("New Love"), the largest of Tokyo's estimated 200 "host clubs." The host clubs are a variation of the ubiquitous clubs where businessmen regularly unwind in the company of charming young women, except that the traditional gender roles are reversed and sex is not part of the host-club scene. In the host clubs, it is the women who are flattered and flirted with by attractive men of their choice. The clientele are usually the wives of wealthy men or hostesses at the businessmen's clubs where they spend their working hours pampering male clients. On a busy night, New Ai entertains more than 300 customers in its rooms elaborately decorated with rococo-style furniture, statues, and chandeliers. A band provides music ranging from standard jazz to Japanese love songs. Unlike their male counterparts, the host clubs are strictly for companionship and nonsexual entertainment. Still, an evening of flattery, chatting, drinking, and dancing can cost the equivalent of US\$500 or more. Regular clients may run up monthly bills of \$3,000 to \$4,000.

[Traditional values are, nevertheless, evident in the absence of sexual activity and in the secrecy women are expected to exercise in their visit to a host club. Japanese men can have an open nightlife, including visits to the sexual hot spots known as "soaplands." Japanese women do not have this freedom (see discussion of soaplands in Section 8B, Significant Unconventional Sexual Behaviors, Prostitution). Despite their efforts to defy social conventions, clients of the host clubs often choose a host and remain devoted to him for years, sometimes showering him with expensive gifts to express their affection. (Tanikawa 1996; (End of update by R. T. Francoeur)]

## B. Sociolegal Status of Males and Females

An important insight into the status of women and men in the realities of everyday life and legal statutes can be found in the workplace. Female employees who pass the *tekireiki*, or marriage age, without getting married often encounter discrimination, despite the enactment in 1986 of an Equal Employment Opportunity (E.E.O.) Act. While firing such a female employee is against the law, the atmosphere may become so strained because of inquiries from supervisors and colleagues that the unmarried female may decide to leave the

company. Women who remain employees and unmarried after *tekireiki* must be compensated as they climb, however unwelcomed, the corporate ladder. *Onna dakara* ("Because I am a woman") is a line often heard in the perennially popular and unabashedly sentimental Enka folk songs. Indeed, in a conservative country in which Confucian *samurai* ethics were resuscitated in the 1880s and fomented lucratively ever since in industrial disguise, being a woman can be difficult. Obligatory marriage and motherhood, and subservience to her husband and his family, would seem to have no place in a technopolitan economic supergiant in which half of the work force is female (Bornoff 1991, 452).

The E.E.O. law has been largely ineffectual because large corporations have a strong standing with the government, making enforcement of any measures against sexual discrimination unlikely. From the largest international firms to the smallest businesses, the widespread view is that sexual discrimination is unethical only according to concepts adopted in recent years, concepts that, to some, are quite foreign. The law entitles women to complain, but this more often than not results in "counseling" rather than action, and so few women complain. Even if filing a complaint could theoretically win a woman higher wages and guard her from dismissal, the action of filing a complaint would be viewed as a complete lack of loyalty to the firm and only earn her complete ostracism by her colleagues. Nevertheless, some major firms, including several banks, have recently moved to put ability before traditional stereotypes and hierarchical promotion, and stress greater sexual equality in the workplace. However, even when management gives female employees equality with males, the male business associates the women have to deal with are often uncomfortable or unwilling to deal with a woman as an equal (Bornoff 1991, 452).

[Update 2002: Japanese gender roles are still evident in most female names (which are formed using a word for child), in their limited career opportunities, and in the strong stigma and life of hardship women encounter if they divorce. It is still almost impossible for a woman to use her maiden name after she marries. Many women who are divorced face insurmountable obstacles in achieving financial independence. Even obtaining a credit card in her own name is very difficult. Gender-based restrictions affect women even after death. Under Japan's complex burial customs, divorced or unmarried women have been traditionally unwelcome in most cemeteries, where plots are still passed down through the husband's family and descendants must provide maintenance for burial sites or lose them. About a decade ago, this began to change, according to Haruyo Inoue, a sociologist of death and burial at Japan University. "The woman who wanted to be buried alone couldn't find a graveyard until about ten years ago." In 2002, there were close to 400 new cemeteries that serve single women only. According to Junko Matsubara, a popular writer on women's issues who is credited by many with igniting the trend to separate-sex burials in the late 1990s, "The point isn't simply to avoid being buried with one's husband, but rather to learn how we as women can lead more independent lifestyles."

[Western notions of women's liberation have never taken hold among Japanese women, which gives more social significance to what is quietly becoming one of the country's fastest-growing social trends. In a 2002 TBS television network survey, 20% of the women who responded said they hoped to be buried separately from their husbands.

[In another recent development, eight years after Princess Masako and Prince Naruhito married, and after fertility treatment following a miscarriage, Princess Masako produce a daughter on December 1, 2001. The newborn Prin-

cess Aiko could become a legal heir to the 2,000-year-old Japanese imperial line and Japan's first "test tube emperor," if the governing party decides to change the law of succession, which currently limits succession to the throne of the Sun Goddess to males (French 2001, 2002). (End of update by R. T. Francoeur)]

### C. General Concepts of Sexuality and Love

The Shinto religion recognizes neither good nor evil, so the concept of sin and personal guilt so commonly associated with sex in Western cultures does not exist in the Japanese tradition. The persistence of fertility festivals echoes the acceptance of sex and romance as a natural component of everyday life. Rooted in folk religions and primitive animism, these festivals are celebrated by revelers wearing traditional masks representing the more frankly sexual and comical denizens of Shinto myth and carrying oversized papier-mâché phalli and vulva through the streets (Bornoff 1991, 14-15, 89-90).

Apart from the persistent traditional culture of Japanese sexuality, it is true that Japan has also experienced a rapid modernization, especially in the 1950s and 1960s. As in other societies, modernization in Japan has brought a series of changes in the daily life and lifestyles and hence in human behavior. Table 1 provides a summary of such changes as a model of trends, problems, and issues in lifestyles and human life that are the result of a variety of primary and secondary changes (*IES2* Table 1, p. 771; Hatano 1972).

In general, technological development has resulted in a significant decrease in the amount of physical labor and inconvenient living circumstances. Development of scientific knowledge, along with popularization of education, brought more literacy and freer communications among the common people. The power of the patriarchal structure that originally gave an eccentric, unbalanced character to the family organization decreases as modernization proceeds. In this manner, communication within the family is being ignored. Modern Japanese family life has come to the point where many parents are not taking care of the children and the children are not establishing their self-identity. On the other hand, with only one or two children, parents, and particularly mothers, may be overly protective to the point of rendering their offspring indecisive and inadequate in their interpersonal relationships.

Such changes also cause significant shifts in the way human sexuality is experienced in modern Japan, including the sexual consciousness and sexual behaviors among the people (see also Table 2) (*IES2* Table 2, p. 772; Hatano 1991b). The impact of the scientific development invited marked progress in the knowledge of biology and genetics. This in turn stimulated the development of sexology. For example, much of the mystery in childbirth, especially the superstitions that there are certain relationships between the behavior of the parents in the past and the physical nature of the newborn, has gradually disappeared. The promotion of science education in public schools has helped this tendency.

The next event in this line was the development of sexology and knowledge about sexuality, such as the separation of reproduction and other sexual behaviors, family planning, emancipation from traditional sex roles, and, subsequently, a more liberal attitude regarding sexual activities. Promotion of family planning after the war years played a decisive role in decreasing the yoke of the women in Japan. At some times, abortion was the most frequently used method of family planning, resulting in certain aftereffects on women's health. In these societal trends, religion no longer played a strong role in controlling the code of ethics because of the allergic reaction to the national control of reli-

gion during the dark days of World War II. However, at the same time, modern Japanese have often lost self-identity in terms of development of moral judgment and values.

The pre-modern Japanese had no choice but to accept and follow the lifestyles, behavior patterns, and basic philosophy of life of their parents or leaders in the society. Role models and lifestyle patterns were rather easily found among the family members, as long as one did not attempt to find something new in life. Modern Japanese people, confronted with an explosively large amount of information pouring into their brains, have had to learn how to sort and select this information before they can apply it to actual daily living. It is quite true that during the economic postwar prosperity period, Japan's economic growth almost became the standard of values for society, inviting severe criticism from people in other parts of the world.

Education in information selection systems or value systems—moral education, particularly in relation to sexual activities—has become a major necessity in formal and informal education. Likewise, education in sexual behavior, not in terms of instruction in a behavioral code but in terms of providing understanding of the stages of psychosexual development, will benefit the development of each individual's sexuality. Likewise, sexuality education is expected to enhance education for parenting. All of these needs share a common base as consequences of modernization. The current national *Course of Study* of the Ministry of Education does not include education for either value systems or for establishment of self- and sexual identity. Perhaps these aspects of education belong to the realm of family education. Unfortunately, in contemporary Japan, the national administration of public education is so well developed that the general public has almost forgotten the responsibility of family education. This is causing some serious social problems, particularly when parents expect the

public schools to assume complete responsibility for teaching all the codes of ethics, including sexual behaviors.

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A. Source and Character of Religious Values

According to the latest statistics from the Japanese Ministry of Education, 96.25 million Japanese believe in Buddhism, 109 million in Shintoism, and 10.5 million in other indigenous Japanese religions. A total of 1.46 million are members of various Christian churches. The sum of these statistics exceeds by 75% the total population of Japan. The explanation lies in a characteristic of the Japanese people's attitudes toward religion, which may not be easily understandable for the non-Japanese. The logic of this seemingly illogical trait of Japanese life may be explained in a typical example of Japanese parents who have a custom of visiting a local Shinto shrine to pray to all the 8 million divinities of Shintoism for the healthy growth and well-being of a newborn baby. In the same family, the same parents may have held their wedding ceremony at a Christian church and prayed there for happiness of their newly formed family. The same couple may read the holy scriptures in the Buddhism temple when a family member dies, praying for the dead one to be accepted in the heavenly world safely. Such inconsistency is widely accepted among the Japanese without much friction. Indeed, "three *different* bells ring in the valley," instead of "three bells ring in the valley." Having a mix of various religions in one's daily life is a common way of the Japanese lifestyle. In addition to these well-organized religions, nature worship, which is closely related to Shintoism, is another prevalent religious belief.

Regardless of the mix of religions practiced, which heavily influences the Japanese consciousness on culture, sex, and sexuality, one needs to understand the substantial connection between religion in Japan and the culture, value system, and attitudes toward sexuality. This understanding requires a brief sketch of the history of religion in Japan.

The results of archeological studies in Japan indicate a common practice of burying the dead with certain religious services and rituals during the Jomon and Yayoi culture periods, which ended somewhere around the 3rd or 4th century C.E. During the Jomon period, which lasted several centuries, especially in the eastern part of Japan, remains indicate the special attention the ancestors of the Japanese people then paid to sex and procreation. This is well demonstrated in the artificial designs of the earthed works that are frequently excavated. Throughout the Jomon period, people lived by hunting and gathering, and there was little evidence of any power struggles or the existence of social classes. The Yayoi period arose after the Jomon, around 100 B.C.E., mostly in the western part of Japan. This culture introduced rice crops and ironware from the Korean peninsula and Chinese continent. With these new cultural influences came a disparity of wealth and social

**Table 1**

### Trends, Problems, and Issues in Lifestyles as the Result of Primary and Secondary Changes in Societal Modernization

Primary Changes	Secondary Changes	Trends, Problems, and Issues
		More leisure hours
		Conformism
		Impersonal society
		Leaving hometown
		Extinction of the fireside
		Happy family circle
	Mass media development	Money-first philosophy
Technological development	Freer commuting	Longer adolescence
Industrial development	Less concentric force in family	Lessened family concentric force
Universal education	Less physical labor	Fewer community activities
Decline of agricultural economy	More work outside of the home	Children leaving parents
Decline of patrimonial succession	Materialism	Nuclear family
	Longer school life	Fewer social restrictions
	Emphasis on human rights	Lack of self-realization
		Lack of sincerity
		Lonely crowd
		Lack of communication
		Less emphasis on individuality
		Aimless life
		Generation gap
		Lowered moral code

classes, which gradually spread throughout the society. (See Bornoff 1991, 7-16, for a helpful discussion of the sexual and coital implications of Japanese creation myths.)

Later, in the middle of the 6th century of the Common Era, Buddhism and Confucianism were introduced to Japan from Kudara in the Korean Peninsula. These religions rapidly spread nationwide, combining with the gradual permeation of a central government power ruled by the Emperor's family. Popularization of the new philosophy and new administration proceeded along with the preservation policy of these value systems by the central government. In adopting this new religion and culture, Japan followed a path distinctively different from that pursued in other countries. In most cultures, a religious war has been necessary before a newly introduced religion could gain acceptance. In Japan's case, the local religious practices and customs of the preceding culture were not abandoned; rather both old and new cultures and religions seemed to have coexisted quite peacefully.

From the early years until the end of the 16th century, the prevailing religion in Japan was an amalgamation of Buddhism, Shintoism, which is close to nature worshiping, and local religions. During the Muromachi Era in the 14th to 16th centuries, the Catholic form of Christianity was introduced and propagated to some extent by the Portuguese until 1590, when Toyotomi Hideyoshi issued a national policy prohibiting Christianity. In the next three centuries, during the Tokugawa (Edo) Era, the circumstances surrounding religion in Japan returned to the amalgamation of Buddhism, Shintoism, and local religions as before the Muromachi Era.

In 1868 when the Tokugawa Shogunate collapsed, the Meiji Era began with restoration of the emperor who held power within a new political system that promoted a policy of nationalism and who strengthened the nation's military force so that modern Japan could compete on even terms with other already modernized nations. As the spiritual basis of this strong Japan, the government pronounced that Shintoism would be the national religion. The emperor's family tree, it was claimed, could be traced back some 120 generations through more than 2,000 years of history. Whether or not the historical facts were twisted to some extent, the government goal was to integrate all the religions in Japan into one by national decree. This idea was pursued until the end of World War II in 1945. Aside from the intention of national power, among the common people the concept of traditional Buddhism and citizen's beliefs were substantially followed. This is another proof of the variability of the religion of the Japanese.

In the newly adopted Constitution of Japan after World War II, freedom of faith was promised, and thus the religious control of the national government was abandoned.

**Table 2**

**The Development of Sexology Promoted More Demand for New Sexuality Education**

Events	Contents
Development of science and sexology	Biology and genetics
Broadening perspectives on sexual behavior	Family planning, separation of reproduction and sex, liberation from traditional sex roles, freer sexual activities
More demand for new sexuality education	Transmission of accurate sexual knowledge and information, value judgment education as standard of behavior judgment, education for life planning

At the same time, the chaotic coexistence of various religions leaves the religious thoughts of today's Japanese more or less ambiguous.

**B. Source and Character of Japanese Ethnic Values Affecting Sexuality**

While culture has been variously defined by different researchers, the concept is used here to indicate the complex of phenomena, ideologies, religion, and literature that provide the fundamental orientation for all sorts of behavior patterns of the Japanese people. As was mentioned earlier, deep in the Japanese mind, the structure of cultural consciousness includes a tendency to nature worship and local religions. This may be because of the roots of the Japanese consciousness in an agrarian culture that has been uniquely molded by archeological and historical processes. It can be said that the general belief among the Japanese that children are the natural gift from the divinities is an expression of the sexuality of the Japanese people. In the ancient days of the Nara and Heian periods, the *Man'yoshu*, a late 8th-century collection of 10,000 Waka poems, many of which are love songs, and the 11th-century *Romances of Genji*, 54 volumes of love stories by the woman novelist Murasaki Shikibu, strongly conveyed the attitude and message that love and sexuality were an important part of human thought and everyday behavior as a natural expression of human nature. In other words, sexuality was openly accepted among the early Japanese people.

In Japan's history, an aristocratic culture dominated in the Nara (710-794), Heian (794-1336), and Muromachi (1336-1573) Eras. In the Sengoku (Turbulence) Period, many warlords competed with each other until the Tokugawa Shogunate was established and national integration begun in 1603. Various groups of the military commanders maintained control of the culture and the behavior of the Japanese people during the Sengoku and Tokugawa Eras. Therefore, the cultural construction and sexuality of the Japanese people operated in a double-layer system. More specifically, extremely strict moral ethics and control of behavior were enforced on children and adults in the families of the *samurai* class (soldiers and the commanders), who were influenced by the Confucianism originally introduced to Japan in the 6th century from China. In the feudal value system, as well as its family system, there was no room for any free expression of human passions and natural desires. Thus, not only romantic love, but also immoral and adulterous behavior of any kind were strictly prohibited, and severe penalties, including capital punishment, were instituted for any case that came to light.

While the *samurai* community kept to a strict behavior code of ethics, the commoners and the townspeople did not, except for the upper-class commoners who closely followed the *samurai* code of ethics. Romantic love was freely allowed among the commoners, and often an illegitimate child—a single mother and her child in today's sense—was accepted and reared without any prejudices in the community or tenement commune (Bornoff 1991, 83-149).

All of the *ukiyo-e* and *shunga* (pornographic paintings) by Utamaro, Hokusai, and Kunisada were produced from the commoners' culture. Yoshiwara, the sexual amusement quarter in the city of Edo, painted by Oiran, a prostitute and social entertainer of the highest class, for example, prospered in the middle and later Edo Era. Few examples of erotica in the world tell us as much about the cultures that produced them as the *shunga* tell us about the practices and fantasies of the Japanese. Among the more striking features of *shunga* is the common presence of children, indicating just how very uninhibited and frank the Japanese were about sex (Bornoff 1991, 184-86).

These examples of a dual-layered social and cultural construction during the *samurai* ruling periods produced a double standard of code ethics, each code composed of its own logical but superficial principles and real intention. These two codes are still actively practiced in contemporary Japanese society, making the understanding of the Japanese culture confusing and difficult.

It was during the very last stage of the Edo Era—in fact, only 130-some years ago—when the country of Japan abandoned its three-century-old policy of national isolation, that free trading and cultural exchanges began with the other countries of the world. As has been already discussed earlier, the modernization process of the nation at such an extremely rapid pace produced certain distorted periods in the history of modern Japan. These periods of turmoil and confusion include the collapse of the Tokugawa Shogunate political system, the restoration of the Imperial ruling system in the Meiji Era, the rise of nationalism in the Taisho Era, and the dominance of the militarism that collapsed at the end of World War II in the middle of the Showa Era.

During the Meiji Era, in order for the country of Japan to be able to compete evenly with the other nations in the world, Japan took a policy of economic enrichment based on development of heavy industry, strengthening of the military power, and placing the Imperial family in the sacred order. The value of each individual in this social system was extremely neglected, resulting in the idea that a man is to serve the nation and a woman is to bear children. Any consciousness of sexual equality was thoroughly repressed, and sexual discrimination—the ideas that higher education is not necessary for women or that childless women deserve to be divorced—were commonly expressed and adhered to. Under such circumstances, a very patriarchal sexual culture emerged in which specific male-centered sexual behavior was accepted without any argument. The proxy engagement system, in which it is mandatory for parents to choose the marriage partner of their child, and in which the match-making ceremony takes place only after the parents have chosen the marriage partner (distinctively different from the matchmaking practice seen in the modern times in which the young couple has the right to choose to proceed or not), were typical of such practices.

The cultural structure in the Taisho Era is often called Taisho Liberalism. As a temporal reaction of the Imperial-family-centered social structure of the Meiji Era, some opinion leaders advanced distinctly liberal ideas during this era. This was particularly evident in literary works, as some women writers and cultural leaders proposed the very first expression of the feminist movement in Japan. Others followed by advocating communism and the birth-control movement. The case of Senji Yamamoto, the first sexologist in Japan, was certainly an example of this liberalization trend. Yamamoto had spent some time in America while young and had been influenced by its culture. He was assassinated in 1902, at age 40 years, by an ultra-right-wing terrorist opposed to Yamamoto's promotion of birth control, labor liberalization, proletarian theory, and the anti-Law of Public Peace Maintenance. The national leaders of that time regarded a person like Yamamoto, who recognized the sexual rights of each individual, worked hard against poverty, and had a strong anti-power attitude, as dangerous.

The Taisho Era, which lasted only 15 years, was followed by the militaristic age of Showa, in which Japanese militarists initiated a series of wars, including the invasion of China and military actions in Southeast Asian countries and the Pacific area, leading up to World War II.

In the historical process of Meiji, Taisho, and Showa, Japan's primary national policy consistently focused on eco-

nomical enrichment and strengthening of the military power. Within this societal atmosphere, children were regarded as a national treasure, and thus they were reared comparatively freely. In contrast with contemporary urban life, adolescents in the agricultural community life that dominated the Meiji and Taisho Eras, learned most of the manners and rules that were necessary to spend a normal life in the adult community by spending time together with peers in the local community. A good example of this peer learning was the *Shuku* or "dwelling-together practice."

This *Shuku* community group is roughly classified as either *Wakamono-shuku* for young males and *Musume-shuku* for young females. Within the local community, it was mandatory for each youth to join the *shuku* of their respective sex at a specified age. In the *shuku*, they worked together for the village in the daytime and learned the traditional codes of behavior of the community in the evening. Sexuality education in today's sense was definitely included in this community education system. Within the local community, the freedom of love was widely accepted, as those who fell in love with each other were usually allowed to get married. Children of the ruling-class families, such as village master and landowner, however, were not allowed to enjoy this freedom during their adolescent and youthful days.

In 1945, after World War II, the Japanese people were granted the right to experience democratic and liberal lifestyles because of the cultural influences of the Allied Western countries. The Japanese people have enjoyed this freedom in the subsequent 50 years, and yet, at the same time, the traditional Japanese consciousness of the societal system, moral codes, and fundamental attitude toward life and sex formed throughout the centuries still regulate their thoughts and behaviors today. The highly successful experience of 50 years of newly available pro-Western ways of life visible on the surface of Japanese culture today is definitely overpowered by the centuries-old value systems and views toward sex, human beings, religion, and society at the conscious level and deep in the mind. The sexuality of the modern Japanese is, therefore, formed in a double-layered manner that, in effect, defies clear description or understanding by outsiders. The world has become smaller as the consequence of the vast development in the transportation and media systems. At the same time, however, it is often pointed out that deep in the mind of the modern Japanese people, the national isolation policy is still alive.

### 3. Knowledge and Education about Sexuality

#### A. Historical Perspectives

There are various opinions among the historians regarding the time of the establishment of Japan as a nation, but at least many agree that it was after the 6th century when the political system had gradually formed into a certain style, not in the modern sense, but in a way that was based on and facilitated by organized education run by Buddhist priests from their temples. With the coming of Buddhism in 538 or 552 C.E. (depending on the source cited), numbers of Buddhist priests came from Kudara on the Korean Peninsula. In addition, a likely larger number of Japanese priests went abroad to Korea and China to study. In these temples, education in Buddhist scripts and political administration was provided for the priests and the children of the national administrators.

It is commonly recognized that the first schools in Japan's history were the *Daigakuryo*, or College Dormitories, established in the nation's capital, and the *Kokugaku* or National Schools, which were established in each major city,

in accordance with the *Taihorituryo*, or Great Treasure Laws enacted in 701 C.E.

Subsequently, various educational systems were established to provide education exclusively for the ruling class, i.e., aristocrats, *samurai*, and priests. Even though the political systems and/or power structure changed from time to time, these educational systems persisted because the schools were established by the ruling *daimyo* (feudal lords or landlords) or *samurai* families. Education for the townsfolk and commoners, though not yet institutionalized, was initiated in the 13th and 14th centuries and continued afterwards in the Buddhist temples. During the Edo era (1603-1886), such private schools for elementary education became quite popular and were known as *Terakoya* or temple houses.

Education for women was not available in the rulers' schools, but was available to some extent in the "commoners' schools." Then, in the early 1700s, in the middle of the Edo Era, a unique educational organization developed as a function of the village and town community, for the education of the immature youths for daily life, including education in sexual behavior. These organizations were known as the *Wakamono-gumi*, or young men's activity group, and the *Musume-gumi*, or daughters' activity group. This system of community education was disbanded in the middle of the Meiji Era around 1890 in favor of promoting newly established public school systems.

In 1868, as the shogunate political system collapsed, Japan made its first step into the modern world when Emperor Meiji transferred the capital from Kyoto—formerly Edo, where the Shogunate was located—to Tokyo. In 1872, the new government announced a law known as *Gakusei*, or School System, based on the French school system, and launched a nationwide education for all. This educational law, intended to promote industrial development and the universal conscription system, was ultimately linked with the national policy of enriching the country and strengthening its armament. One may observe in this historic transition the germination of the Japan's militarism in the 20th century.

The Law of Education, enacted in 1879, took a liberal direction in using the American school system as its base. This was quickly amended the following year by the "Revised Law of Education," which put the emphasis on Confucianist morals as the fundamental spirit. This traditional vision was obviously necessary because of strong opposition within the government against Western liberalism. "Catching up with the already modernized nations in the world" was indeed the priority motto of the Meiji government, but in terms of practical education, the goal of producing guns and battleships outranked the education of humans. In 1903, the government took over supervision and authorization of textbooks in order to develop uniformity in people's thoughts and minds. As a result, Japan's education was overwhelmed by the moral and behavior codes of Confucianist ethics based on the emperor system and nationalism.

A short-lived liberal trend developed between 1912 and 1926, when Emperor Taisho was on the throne. This liberal movement, however, was not strong enough to change the government's educational policy, and in the long term, the militarists regained power.

The militarism, and later fascism, grew stronger and matured in the Showa Era beginning in 1926 and climaxing in education's dark period during World War II (1941-1945). After the 1945 defeat, Japanese education was completely transfigured with the adoption of a 6-3-3-4 year sequence, the first nine years being mandatory (six years of elementary school and three years of junior high school). This newly implemented system also brought to Japan substan-

tially equal opportunity of education for boys and girls and all social classes.

The outstanding economic growth of Japan throughout the postwar years is regarded as a contemporary marvel. Along with it, education in Japan also made great progress quantitatively as well as qualitatively. Much of its content will be introduced in the following section. It should, however, be explained here that the Showa Era was closed in 1989 upon the passing of Emperor Showa, and now it is the era of Heisei.

## B. Sexuality Education in Contemporary Japan

### *The Background Education System*

As of 1994, Japan had a total of 65,000 schools of all kinds for its total population of 124.3 million. This includes approximately 25,000 elementary schools (grades 1 to 6), 12,000 junior high schools (grades 7 through 9), 5,500 senior high schools (grades 10 through 12), 1,100 colleges and universities (including two-year junior colleges), 6,700 vocational colleges (mostly two-year), 15,000 kindergartens, and 1,000 special schools for handicapped children. The rate of actual participation in required education has been as high as 99.9% since around 1910, although the length of mandatory education was much shorter before 1945. These statistics exclude some 1,200 heavily handicapped children and an estimated 100,000 prolonged absentees because of illness and unwillingness to participate.

The great majority of those who complete the required education of nine years by age 12 go on to three-year senior high school, specifically 94.3% of the boys and 96.4% of the girls. Advancement to colleges and universities is 36.3% for men and 39.2% for women. This trend to high academic achievement orientation has created stress and mental pressure in the "entrance examination war" all Japanese youths experience. Because of overemphasis on the entrance examination, many recognize the necessity of *Juku*, extracurricular schools in the evenings and on holidays, tutors, and/or correspondence courses to prepare for the examinations. Such practices are common in Japan these days, perhaps more so than in other countries, suggesting the need to discuss the effects and consequences of the *Juku* for the social life of Japanese adolescents and young adults.

The detailed curriculum in each school level, the general objectives of each subject, and aims and contents of each school year for each subject are precisely controlled by the national *Course of Study*. It may seem that the national government limits and controls the contents of education and its teaching methods; however, the *Course of Study* only presents the frame structure of the teaching, and the classroom teacher has the liberty of the details presented. The *Course of Study* is revised once every decade or so.

As in some other countries, the Ministry of Education provides a list of approved textbooks from which teachers select those to be used in their classes. It is true that sometimes court cases have arisen about the suitability of the national policy on textbooks, questioning whether the government is interfering with education, whether the examination/approval system conflicts with the Constitution, or whether the system infringes on the freedom of expression. However, so far the system is functioning well, with individual schools and teachers free to choose classroom content and presentations aside from government approval of texts and teaching materials.

### *Sexuality Education*

There is no distinct sexuality or family-life education course included in the subjects to be taught in the Japanese school system. The *Course of Study* does not require any-

thing to be taught about sexuality, nor does the national government determine any objectives or the content of sexuality education wherever a local school or teacher decides to deal with this topic at any grade or school level. The official statement provided by the Ministry of Education states that "The contents of education regarding sex (and sexuality) are distributed in various respective subjects (relevant to biology, sociology and health, etc.) and sex (and sexuality education) is certainly expected to be integrated in all these subject matters at each school." Therefore, the promoters of sex (and sexuality) education, such as those involved in the Japanese Association for Sex Education (J.A.S.E.), have been advocating school instructional programs by developing and publishing *Sex Education Guidelines* for various school levels and various grades. J.A.S.E. was established and was officially approved by the Ministry of Education in 1972, and has since been the leading nonprofit organization in the field of sex education.

On the other hand, improvement in education for HIV and AIDS is increasing in Japan's schools because of the rapid spread of HIV and AIDS throughout the world since the late 1980s. This in turn has strengthened the importance of sex education in the Japanese schools.

Since 1992, as a result of revisions in the elementary school *Course of Study*, childbirth has been introduced into the science textbook, and physical and psychological changes of adolescence into the health education textbook, indicating that some changes can be made in the *Course of Study*. Any changes in the *Course of Study* automatically means definite changes in the instructional contents at every school. At present, all upper-grade elementary schoolchildren are expected to be exposed to the physiological and psychological aspects of human sexuality. However, so far no textbook describes any aspects of sexual intercourse, which has prompted some criticism from classroom teachers about the incomplete vision and unrealistic attitude of the Ministry of Education.

In the junior high school level, certain topics in sex education are dealt with in health education, science (biology), social studies, and domestic science. However, these are handled less candidly and actively than in elementary schools in the same system or district. The case is similar as well in the senior high schools; the reason perhaps being that classroom instruction is regarded much less as an education for human living than as a preparation for the next entrance examination, i.e., senior high school for the junior high students, and colleges and universities in the case of senior high school students.

"Education indeed is the greatest prevention" is the standpoint of the Ministry of Education regarding HIV and AIDS prevention. Because of this viewpoint, elementary school faculty are strongly encouraged to teach that HIV and AIDS are not transmitted by mosquito bites or by shaking hands with others, and that no person with HIV or AIDS should be discriminated against. It is greatly regretted by many educators and members of J.A.S.E. that sex education in Japanese schools currently needs to be improved so much and that teaching the fact that HIV can be transmitted through sexual intercourse is still not well accepted among the schoolchildren. This has an impact also on a number of cases in which hemophilic patients have become HIV-positive because of contaminated blood transfusions. [*Update 1997*: By 1985, about 40% of all Japanese hemophilic patients, more than 2,000 people, had contracted HIV through contaminated imported blood products. As of 1995, hemophilic patients accounted for 60% of Japanese people with HIV. See Section 10B on HIV/AIDS. (*End of update by Y. Kaji*)] Even these patients are hesitant, because of public ig-

norance, to admit they are HIV-positive. As a matter of fact, voluntary admission of HIV-positive status is almost nonexistent in Japanese society. This is because, for most Japanese people, admitting to being HIV-positive is viewed as a kind of social suicide and societal discrimination is definitely expected.

Because of centuries of a national isolation policy that rejected anything that might endanger cultural and religious harmony, a person with any unusual handicap or disease like HIV was commonly treated as an enemy of society, or at least rejected. It is, therefore, difficult to judge whether appropriate HIV-related education would produce any effects in changing the attitudes of children of any age to HIV-positive persons. [*Comment 1997*: An added problem is the great reluctance, especially among elementary schoolteachers, to mention, let alone discuss, sexuality in their classrooms (*End of comment by Y. Kaji*)] Even in junior and senior high schools, where one might expect teachers to be more open in dealing with sexual issues, and students to be more open to education about discrimination prevention, the effectiveness of education in reducing discrimination against persons with HIV is unclear.

The content of the sex education actually received by students was studied in 1981 and 1987 surveys; Table 3 shows a breakdown in the content of sexuality education by subject (*IES2* Fig. 1, p. 784; J.A.S.E. 1988). When these subjects are clustered into three general categories, 1. physiobiological, 2. psychological, and 3. social, the youth surveyed reported that 29.4%—three out of every ten—had received no sexual education at all (type 0) while an identical figure of 29.4% received an education that covered all three general categories (type III). A little over 20% had sexuality education that covered only the physiological and biological aspects (type I), while 13.5% and 12.8% had instruction that covered the physiological-biological and social (type IIA), or psychological-biological and psychological (type IIB), respectively. In

**Table 3**  
**Subjects Actually Taught in Sex Education and the Percentages of Students Receiving Such Information by Sex, 1981 and 1987**

Subjects	Females		Males	
	1981	1987	1981	1987
Sex organs & functions	63.7%	77.3%	73.2%	83.9%
Menstruation	92.6	98.4	64.9	78.3
Ejaculation	52.9	66.1	68.8	83.3
Secondary puberty signs	75.1	83.7	71.0	84.6
Procreation	64.8	83.3	56.6	75.8
Gender selection & heredity	37.0	50.3	38.3	53.2
Psychological & behavioral differences between sexes	28.4	25.7	27.3	23.1
Sex roles & cooperation	22.6	21.3	25.0	25.6
Male/female friendship	27.5	23.8	27.9	25.2
Adolescent psychology	30.9	40.1	32.6	48.0
Friendship & love	14.1	16.6	16.4	20.8
Marriage meaning & premises	19.1	25.5	18.5	22.3
Population control & family planning	31.0	48.5	26.8	40.0
STDs and misconduct	51.9	41.0	53.5	45.2
Sex and culture	7.1	11.6	12.7	19.7
Sex morals	11.2	11.8	16.7	17.6

(*IES2* Fig. 1, p. 784)

Table 3, the heavy concentration of responses on the top six items, which cover the physiological/biological background of sexuality, supports the conclusion that when Japanese children do receive sex education, it is more often limited to the facts of physiology and biology.

Table 4 presents the percentage of each type of sex education actually given to students of different school levels (*IES2* Fig. 2, p. 785; J.A.S.E. 1988). Naturally, the amount of education, particularly that of type III, increases as the level of schooling advances. In addition, it is shown that in junior high school, the psychological aspects of sexuality are emphasized. This may be an understandable trend since the biological and psychological aspects of pubescent events occur just before or in the early stages of adolescence.

As mentioned earlier, the contents of sex education in Japanese school systems are more or less centered around physiological aspects and are, therefore, cognitive-oriented rather than attitudinal-behavior-oriented. In order for sex education in Japanese schools to become the comprehensive sexuality education it needs to be, more consideration must be given to the psychological and sociological aspects of sexuality. HIV and AIDS education and prevention needs to be incorporated in this framework as a well-balanced education within the national *Course of Study*.

### C. Informal Sources of Sex Education

Teen sex magazines are popular and widely read by Japanese youth. They are noticeably different from their adult counterparts, comparatively wholesome, or at least harmless or insipid. Instead of the violent, sadistic, and degrading content common in adult pornography, teen sex magazines are filled with frivolous, inane, and unabashed boys' club talk and candid cheerleader squat-shots and near-nudist pictorials. Since true sexuality education is absent from Japanese education, and parents and the community no longer communicate this essential information to youths, these magazines do perform an important function, providing limited but basic information about sexual anatomy. Unfortunately, their popularity depends on adolescent titillation that ignores the need to provide information on STD prevention and contraception. Japanese television is also a major informal source of limited sexual information, particularly in the early evening television cartoon programs that cater to adolescent male curiosities about female anatomy (Bornoff 1991, 71).

**Table 4**

#### Types of Sex Education Actually Given and Percentage of Secondary and University Students by Sex Who Received Each

Age Group	Type 0	Type I	Type IIA	Type IIB	Type III
<b>Males</b>					
Junior High Ages 12-14	47.1%	24.0%	3.4%	15.1%	10.4%
Senior High Ages 15-17	24.5	12.5	17.3	6.0	39.6
University Ages 18+	25.6	10.5	19.3	5.5	39.1
<b>Females</b>					
Junior High Ages 12-14	19.2	37.5	3.4	28.5	11.4
Senior High Ages 15-17	8.7	15.0	22.2	8.4	45.6
University Ages 18+	6.1	14.0	26.2	6.0	47.7

(*IES2* Fig. 2, p. 785)

(See Section 8C for comments on the *Roricon* or "Lolita complex" that is so widespread in Japanese sex magazines and can be said to constitute a national characteristic.)

### 4. Autoerotic Behaviors and Patterns

There are clear gender differences in terms of the masturbation fantasies and concrete activity that Japanese boys and girls pursue in their adolescent behavioral development. In reality, the great majority of the senior high school boys practice masturbation, while the majority of girls of ages 20 and 21 years still ignore masturbation after experiencing their first intercourse (J.A.S.E. 1994). The median 22-year-old female has not engaged in masturbation. This may indicate a difference in the degree of sexual drive between the two sexes. But another possible reason that females are not eager to engage in masturbation is the social pressure against the female's self-motivated sexual activities that are unrelated to procreation, although this belief is steadily becoming weaker. The majority of young Japanese women perhaps do not give serious consideration to autoeroticism because of the subconscious expectation that a good Japanese woman should always be modest in any sexual activity. [*Comment 1997*: This may be changing as young Japanese women increasingly reject traditional female roles. (See Section 5C on adult heterosexual behavior, marriage, family, and divorce, below.) (*End of comment by Y. Kaji*)] According to the 1981 survey results, females discover and first experience masturbation as a result of "incidental touching of the genital organ by something" and/or "reading erotic articles." For males, there is an indication that being "taught by some friend" is the more common inspiration.

[*Comment 2003*: In terms of the cumulative frequencies of masturbation experiences of Japanese youths in the 1987 and 1993 national surveys, 16% of the 1987 males had begun masturbating, while about 6% of the 1993 males and the same percentage of both 1987 and 1993 females had masturbated by age 12. For both groups of women, the cumulative totals rose slowly to about 13% at age 17, and then rose to 32% for 1987 females and 35% for 1993 females. After a sharp rise in masturbation experiences between ages 12 and 16, 1993 males held a plateau until age 19. Males surveyed in 1987 leveled off for a year and then moved ahead by 8% over their 1993 peers. At age 21, 92% of 1987 males, 95% of 1993 males, 34% of 1993 females, and 32% of 1987 females had masturbated (*IES2* Fig. 3, p. 786; J.A.S.E. 1994). (*End of comment by the Editors*; percentages are approximations from the original line graph; see note at beginning of chapter.)]

The teen sex magazines mentioned above in Sections 3C, Knowledge and Education about Sexuality, Informal Sources of Sex Education, and 8C, Significant Unconventional Sexual Behaviors, Pornography and Erotica, which are used primarily by young males as a masturbatory stimulant, pose many societal and cultural questions. [*Comment 1997*: The sex magazines and comics targeted to young females are also popular and raise many controversial questions. (*End of comment by Y. Kaji*; see also Perper and Cornog's observations on *manga* in Section 8C, Pornography and Erotica.)] Apart from their relatively healthy content in terms of normal psychosexual development, one controversy centers on the degree to which the staggering amount of these magazines produced and their extensive use by teenagers and older males for masturbation is all that wholesome. Do these magazines promote normal psychosexual development, or do they support and promote an unhealthy, introverted social isolation? Is the plethora of teen sex magazines an unhealthy substitute for many young men who have not developed the interpersonal skills they need

relate to women on a mature and intimate adult level? (Bornoff 1991, 71).

5. Interpersonal Heterosexual Behaviors

A. Childhood Play and Sexual Behaviors

The Threat of a New Subspecies

Since education in sexuality and education for parenting share a common basis, it may be helpful to sketch the possible role and position these two aspects of education hold in the natural developmental sequences of play and sexual behaviors children pass through as they mature (see Table 5) (IES2 Fig. 4, p. 788; Hatano 1991bc). Throughout his or her growth and development, the child is expected to experience certain events and to develop certain skills, so that development of a mature consciousness and behavior will be promoted. Regular mother-child behavior like breastfeeding during infancy is believed to stimulate mental activity of the baby and to enhance a trustworthy relationship between parent and child. Based on this sort of relationship, the time spent in play and fun experiences between the two would promote a sense of playful exploration and form the basis of interpersonal relationships, as well as emotional security. This in turn enhances the ability of a child to play with other children and successfully join in peer-group activities.

Peer-group activities, especially involving play activities among young children, are believed to develop the social aspect of personality. It seems that social development of an individual includes acquisition of communication skills with others, procedures to maneuver human relations, leadership development within a group, and coping skills

between boys and girls, between elders and the young, and between the strong and the weak. As a person grows and becomes ready to engage in heterosexual relationships and sexual behavior, these human relationship skills will become necessary to cope with the opposite sex. Likewise, the above skills are needed when a person becomes a parent.

Together with increasing urbanization and modernization, Japan, especially in recent years, is witnessing the emergence of a new type of young person—what may be termed *Neo homo sapiens*—who often does not accept traditional institutional human relationships and prefers living exclusively at the keyboard of a computer, communicating via networks, and avoiding direct human relations with the others. These young people are often cruel, lacking in interpersonal relationship skills in the sense of human relationships with the others, and unskilled in heterosexual or homosexual relations in later adolescent life. This is evidenced in the increase in older bachelors and in the increasing frequency of *Narita divorce*—divorce upon returning to Narita New Tokyo International Airport from a honeymoon trip outside of Japan—indicating the lack of patience, human relationship maneuvering skills, and inability to maintain a married relationship.

What usually happens [in a Narita divorce] is that newlyweds take a honeymoon in a place like Australia or Hawaii, and the husband is so intimidated by overseas travel that he scarcely wants to leave his hotel room.

The wife, on the other hand, has already taken several foreign trips with girlfriends and is much more comfortable with the idea of being abroad. She wants to spend her days scuba diving and her nights bopping in the disco, and she finds her husband a dreadful bore. So she dumps him at the end of the honeymoon, and they say a final good-bye at Narita. (Kristof 1996a)

The need for sexuality and parenting education is expected to increase as technology continues to transform Japanese society.

The Past and Present Contrasted

According to the latest national statistics, the average married Japanese couple has 1.6 children, definitely one of the lowest rates in the modern world. This tendency to a small number of children is a reflection of urbanization and a high-economic, growth-centered family life with the wife being a highly educated career woman. [Comment 1997: This tendency for Japanese couples to have fewer children may also reflect the lack of sufficient social welfare and public childcare systems, which pressures mothers to stay home and take care of their children. Many Japanese women are reluctant to have more children because of inflexible working hours required by Japanese companies, long-distance commuting to work, the high cost of housing, and the lack of childcare facilities. (End of comment by Y. Kaji)] Apart from the need and preference of each individual family, this trend is not necessarily a healthy phenomenon for society in general, particularly because

Table 5

Human Developmental Stages and Assignments of Play and Sexual Behavior and Positions of Sex Education and Education for Parenting

Developmental Stage	Events and Activities	Resultant Effects
Infant	Breastfeeding (Kinship)	Stimulation of mental activity Parent-child reliance
	↓	
	Parent-child play	Emotional stability and development
	↓	
Preschool child	Peer-group play and activity (Experience of pain, group control)	Cooperation, adjustments, and durability

	↓	
Adulthood	Family life	← Family relations Parent-child relationships

(IES2 Fig. 4, p. 788)

of the consequences of impediments that the individual single child encounters in his or her development (see the third column in Table 5).

In the past, the Japanese family was often situated in a large, family-tree system where several families related by kinship lived together on the same land but in different houses. This arrangement sometimes accommodated different families of three or four different generations. The children learned many important matters from the members of the various families, as well as from their own immediate brothers and sisters. With many children in each family, each child enjoyed excellent educational opportunities within the family community. Indeed, everyday life in the community functioned as the community education. The advent of modernization brought an urban life that forced the extended family and neighborhood community to abandon its educational function. In addition, the daily human exchanges and the network system with the neighbors were lost.

In the pre-modern community, children of similar ages formed peer groups and played together near their farm homes, in a backyard, an open field, or in the barn. The children often obtained interesting and helpful information related to sex from observing the farm animals; in this manner, sexuality education went on in an informal manner. The "doctor/nurse play" they often enjoyed within their peer group in a secret space provided sexual information and fantasy, which in turn helped them form a healthy sexual identity of their own.

Children in contemporary Japan, first of all, now have fewer brothers and sisters in their family so they seldom have opportunities to cope with a small baby, with a younger child, or with an older and stronger child. Some young children of 3 start special training in preparation for the entrance examination for kindergarten. In addition to public school, almost all elementary schoolchildren today attend *Juku*, or special training school, for entrance examination for some junior high school, that may provide a better opportunity for future school advancement. In addition, training in piano, ballet, and swimming, for example, is becoming a common practice among children of all ages. As a result, the children have very little time for spontaneous activities such as playing and spending time together with the children of the peer group. One's ability to live socially and peacefully with other people of different types and capabilities is usually cultivated in these childhood circumstances; however, contemporary Japanese children are not in the position to experience such education. It may not be surprising then to find young grownups today who lack the usual skills of living, playing, and communicating with young people of the same and/or other sex. Human relations require skills in sexuality-related behaviors, such as talking with and obtaining trust from the peers of the other sex, and these are skills that may not be attained by merely reading books or watching television programs.

Contemporary children, who are busy with *Juku* and extracurricular training programs, must watch television programs, play television/computer games, and read comic books during the precious free activity hours, perhaps an hour or so in the late evening, after finishing all the previously scheduled programs. While there is much information related to sex and sexual behaviors on television and in comic books, exposure to this information is not sufficient when they have to use it on their own, cognitively and affectively. They need to perceive this information in the context of actual human relations and experiences. In actuality, most contemporary Japanese children build their knowledge pertaining to sex in a passive manner that results in distortion and inflexibility. The sex-related knowledge should

be actively acquired by each individual with a positive attitude in order for one to handle sexuality in later life constructively and with enjoyment. The reality in Japan today seems to be quite different from what it should be.

This is not to imply or suggest that today's children will grow up to become sexual deviants or criminals. However, it is obvious that attention needs to be paid to the fact that in Japan today, the psychosexual developmental processes of the infants and children are experienced in abstract textbooks rather than in actual experience-oriented activities.

## B. The Sexuality of Adolescents

### *The Results of Four National Surveys*

The office of the Prime Minister sponsored nationwide surveys of sexual development and sexual behaviors of Japanese youths in 1974, 1981, 1987, and 1993. The surveys, conducted by the Japanese Association for Sex Education (J.A.S.E.), mobilized nearly 30,000 youths of ages between 12 and 22 years each time. The reports provide a substantial picture of the sexuality of Japanese youth. The full reports were published in Japanese by J.A.S.E. (1975, 1983, 1988, and 1994) and summarized for the international community on several occasions by Yoshiro Hatano (1988, 1991a, 1993).

[*Comment 2003*: In comparing the ages of menarche in girls and the start of ejaculation in boys, about 5% of all four groups had menstruated or ejaculated before age 10. According to the 1993 survey, a majority of 54% of the 12-year-old girls had already experienced their first menstruation. The menarche curve for girls then quickly declines to a few percent at age 16 and beyond; by age 19, close to 100% of the girls were menstruating. Girls mature a year or more earlier than the boys (*IES2* Fig. 5, p. 791; J.A.S.E. 1994). At age 12, 19% of males had experienced ejaculation. For boys, the peak ejaculation onset occurs at age 13, with about 38% of boys experiencing ejaculation for the first time at that age. At age 15, 76% of the 1993 boys and 64% of the 1987 boys were experiencing ejaculation. By age 21, 96% of the boys surveyed in 1993 and 84% of the boys surveyed in 1987 had experienced ejaculation (*IES2* Fig. 6, p. 792; Shimazaki 1994-95).

[In the cumulative frequencies of the development of "interest in sex" among Japanese youths in the 1987 and 1993 surveys, at age 13, 37% of 1987 girls and 42% of the 1993 girls, and 42% of both the 1987 and 1993 boys experienced an "interest in sex." Between ages 15 and 18 the cumulative total for boys rose from about 78% to 93%. At age 20, 100% of 1993 males and 96% of 1987 males expressed an interest in sex. Between ages 15 and 18, the cumulative male totals rose from 58% to 75%, peaking at about 90% at age 21 (*IES2* Fig. 7, p. 792; J.A.S.E. 1994).

[As for the cumulative "interest in approaching the opposite sex," 25% of 12-year-old males surveyed in 1993 and 34% of 1987 males were interested in approaching a girl, while 55.5% of 1993 girls and 48% of 1987 girls had experienced an interest in approaching someone of the opposite sex. At 16, the cumulative totals were 75% to 80%; by age 21, the cumulative totals for all four groups ranged from 89% for 1987 females to 91% for 1993 girls, and 94% for 1987 males and 96% for 1993 males (*IES2* Fig. 8, p. 793). As for the cumulative frequencies of "desire for physical contact with the opposite sex," the survey results are shown in Table 6 (*IES2* Fig. 9, p. 793). There is a clear difference between an interest in approaching a member of the opposite sex and the desire for physical contact, in that the boys are strongly interested in direct physical contact with the opposite sex while the girls are only interested in becoming closer with the other sex.

[Although these young people, both male and female, seem to start their adolescence with heterosexual “interests” by age 13 or 14, this interest does not have a concrete outcome in social activity, namely dating, for some years. In 1993, 3% of the males and 2% of the females reported dating. Twenty percent of both 1993 males and females started dating at age 14 or 15, and 40% of the Japanese youth, both males and females, surveyed in 1993 had their first dating at age 14 or 15. The tail for the age-of-first-date curve dropped to 7% at age 17 and to 1% at age 21, for both males and females (IES2 Figs. 10 & 11, p. 794; J.A.S.E. 1994).

[In the 1987 and 1993 national surveys, between 5% and 9% of the males and females had experienced dating. From age 13 to age 21, cumulative statistics for males surveyed in 1987 lagged behind their 1993 counterparts by 3% to 8%. Females surveyed in 1993 led in cumulative frequency of dating experience at all age levels.

[Further analysis of these statistics suggests that the girls do not necessarily pursue real love-seeking activities, but prefer spending some time with a friend of the opposite sex. As a matter of fact, they are slow in becoming involved in sexual arousal experiences, while their male counterparts demonstrate a different developmental trend: Sexual arousal comes ahead of dating for males and after dating for the females. Between ages 12 and 14, males surveyed in 1993 have a significant lead of up to 12% over the same-age females in experiencing sexual arousal. At age 14, 1993 females overtake and surpass their male counterparts by about 5% until the two populations match at ages 20 and 21 in their experiences of sexual arousal and first dating.

[As for the onset of dating, nearly equal numbers of males and females surveyed in 1993 reported having their first date at the same ages, being neatly matched from age 11 to 21. Ages 14 and 15 marked the peak years for having one’s first date, with 20% of males and females having their first dates at age 14 and another 20% at age 15. After age 15, the curve for first date gradually declines in the late teens. About 3% of the boys and girls surveyed in 1993 had their first date at age 10 or 11. Ages 14 and 15 were the most common ages for first dates, with 20% of boys and girls having this experience at age 14 and another 20% at age 15. About 6% of boys and girls reported their first dates at age 17.

[For the cumulative frequencies of being sexually aroused reported in the two national youth studies, see Tables 7 and 8 (IES2 Fig. 12 & Table 3, p. 795; J.A.S.E. 1994).

[An examination of cumulative frequencies for kissing and touching the body of the other sex indicates that for boys, kissing and touching the body of the other sex occurs at the same age level, very probably with the two activities occurring as part of the same encounter. In the meantime, the girls are again slower in the physical-contact behaviors, and they perhaps consider kissing itself and their first kissing ex-

perience very seriously. Males and females demonstrate a difference in their developmental trend: Sexual arousal comes ahead of dating for males and after dating for the females (IES2 Fig. 13, p. 795; Shimazaki 1994-95).

[Three percent to 8% of males and females in both surveys reported having their first kissing experience sometime by age 13 (see Table 9) (IES2 Fig. 14, p. 796; Shimazaki 1994-95). (End of comment by the Editors; percentages are approximations from the original line graphs; see note at beginning of chapter.)]

Japanese youths, both male and female, show a remarkably slow development in sexual behaviors in comparison to other societies. There are no clear antisexual activity policies existent in the nation, nor any discouragement of male-female relations in the nation’s limited sexuality education. The most probable reasons behind the slow psychosexual development lie in the traditional societal attitude toward the free sexual activities, particularly when they involve educated, upper-class women, and the society’s strong respect for education, which results in suppression of sexual behaviors among the youths.

[Comment 2003: The 1987 and 1993 males were about even in experiences of touching the body of the opposite sex until age 16, after which the 1993 males reported between 6% and 11% more physical sexual contact with females than did the 1987 males. With some fluctuations, 1987 and 1993 females remained about on a par in touching experi-

**Table 6**

**Cumulative Frequencies of “Desire for Physical Contact with the Opposite Sex” for Males and Females Surveyed in 1987 and 1993**

Age	1993 Males	1987 Males	1993 Females	1987 Females
12	17%	31%	11%	7%
13	33	33	11	7
15	70	60	22	22
17	84	80	37	27
19	84	94	50	30
21	97	97	70	53

*Editors’ Note:* Percentages are approximations from the original line graph (IES2 Fig. 9, p. 793).

ences with males until age 19. At age 19, about 20% of both groups of females reported touching experiences. Between ages 19 and 21, the two female groups diverged with 1987 females, rising to 54%, while only 24% of 1993 females reported touching experiences (*IES2* Fig. 15, p. 796).

[A comparison of cumulative frequencies of petting and intercourse experiences by age progression shows a smooth curve for petting experiences for 1993 males and 1993 females, increasing with age to age 21, where females are about 11% below their male peers. The four curves for intercourse experiences are very similar up to age 16, when 1993 males and females show a distinct increase at age 16, a slowdown at 17, and a second increase from age 18, to 69% for 1993 men and 64% for 1993 women. For the 1987 men and women, the cumulative intercourse-experience curve shows a steady rise to age 17, when the male and female lines continue to rise but diverge (both with an increase at age 20), until the 1987 men reached 59% and the 1987 women reached 36%. Table 10 shows the cumulative percentages reported (*IES2* Figs. 16 & 17, p. 797).

[In comparing the male/female cumulative frequencies of kissing, petting, and intercourse (see Table 11), survey results for males show, as might be expected, an experience gap of 1% to 3% at ages 12 to 15, with the gaps between kissing experiences and petting/intercourse for ages 15 and 19 increasing to 10% to 15%. After age 20, the frequency gaps for all three experiences narrow. For males at all ages, cumulative experiences for petting are a few percentage points higher than for intercourse. There is no crossing over in the cumulative order, i.e., for males, kissing experiences are highest and intercourse lowest at each age. For females, survey results at all ages show a close approximation of the cumulative frequencies for petting and intercourse, with a 2% to 3% edge for petting over intercourse. At age 13, females reported slightly more intercourse experiences than petting experiences. Between age 14 and 15, petting and intercourse experiences were closely linked. At ages 16 and 18, females reported more experience with petting than with intercourse; at age 17, females reported more cumulative experience with intercourse than with petting. Overall, males reported a steady increase in all three experiences from age 12 to 21. Females showed a similar steady increase, with a slight slowdown in the upward curve for all three experiences between ages 17 and 18 (*IES2* Figs. 18 & 19, p. 798; Shimazaki 1994-95).

[Table 12 provides survey data on the total number of coital partners classified by sex and school levels (*IES2* Table 4, p. 799; Shimazaki 1994-95). As with previously cited results, these data indicate more-active behavior for males than for females. Psychologically, the girls seem to develop their interest in the other sex earlier in adolescence: By 12 years of age, 50% of girls already demonstrate a general interest in boys, as opposed to the 14-year-old median-age boy. But such interest in the other sex among the girls is more mental and fantasy-based, and not necessarily accompa-

nied by actual physical activities, such as physical contact, in which the boys are four years ahead of the girls, and sexual arousal, in which boys are five years ahead of the girls (see Table 13) (*IES2* Fig. 20, p. 800). (*End of comment by the Editors; percentages are approximations from the original line graphs; see note at beginning of chapter.*)

The sexual difference in the cumulative experience rate of dating in the age progression does not seem to be very great, but the women's special activeness, far surpassing men's activeness, has been consistently noticed in all of the four surveys. The similarity between the sexes on this behavior very probably occurs because males and females of roughly the same age level are generally dating each other. On the other hand, the increased dating activity of females 15 years and older may have come about because older males start proposing dates to younger females who became more accepting than in earlier times.

In terms of actual heterosexual behaviors, the age differences between the sexes were rather small or nonexistent:

**Table 10**

**Cumulative Frequencies at Age 21 for Petting and Intercourse Experiences**

	1993 Males	1987 Males	1993 Females	1987 Females
Petting	73%	66%	62%	45%
Intercourse	69	59	64	36

(*IES2* Table 4, p. 799)

dating (boys one year ahead), kissing (the same age), petting (boys one year ahead), intercourse (boys one year ahead), and dating (girls one year ahead).

The 1987 data were used to construct a developmental sequence model of sexual events and experiences of the Japanese youths (see Table 13) (*IES2* Fig. 20, p. 800); Hatano 1991). For the median male, experience of ejaculation and sexual curiosity occur within the same developmental year, and related experiences like masturbation and interest in the opposite sex occur in the next year. Indeed, for males, a series of physical and psychological pubescent events suddenly occur within a short two-year period. On the other hand, the social events of adolescence seem to need a certain time to mature, as it took three years after the stormy coming of these pubescent events for these boys to reach the first dating experience. Then three more years are spent before the first petting experience. The time between first petting and first intercourse is usually quite brief; sometimes the two experiences occur simultaneously, in which case both occur with the same partner.

For the median female, the first menstruation is a clear sign of puberty; however, other psychological and behavioral pubescent events are not as concentrated as they are with the male. A Japanese median girl takes about five years after menarche to reach the first dating experience, and another five years before the first experiences of petting and intercourse. In other words, the adolescent time of a boy is three years shorter than that of a girl.

In the case of a boy, sexual curiosity arises together with the ejaculation experience and quickly leads to masturbation. The pubescent male is thus mono-sex-organ-oriented

(phallogentric). In the case of a girl, menarche occurs a good two years earlier than the first sexual development event of boys (i. e., ejaculation), but it does not lead to sexual curiosity for about two years on average, nor does it quickly move to masturbation, which comes towards the very end of female sexual development.

For a boy, the onset of dating leads to a sequence of heterosexual physical behaviors, such as touching the body of a member of the opposite sex, kissing, petting, and intercourse, within the short span of three years after the first date. Girls experience these events in the last three years of the five-year time span that starts with the onset of dating, two years after the average male.

Perhaps because girls traditionally do not initiate dates but rely on the male to take the initiative, and because it occurs one year earlier than in boys, there is a difference between them. At the same time, considering the data, the boy would have to date a different, slightly more mature girl after his first date partner in order for this hypothesis to be supported.

It should be noted that for girls, physical behavior, such as masturbation and touching a boy's body, occurs during the same last stage of development along with intercourse, whereas for a boy it is actually the key mechanism for the progression of subsequent development and is distributed over much earlier stages. The male experiences the series of physical changes and psychological developments in a shorter time span than the female, perhaps because of a strong sexual drive provided by male hormonal secretions. Male maturation is thus centered around more physical and concrete behaviors, and one event hurriedly leads to the

next step. For the male, a sexual behavior means a direct phallic-oriented concrete activity, whether monosexual, such as sexual arousal and masturbation, or heterosexual, such as touching the body of a member of the opposite sex, petting, and intercourse.

Female masturbation, which occurs later than the male, seems to be more possible in relation to the aggressive behaviors of the male. A girl's maturation process is thus centered around vague, romantic loving; it is more psychological and, in the beginning and for some time, devoid of any concrete physical activities. Then, in its later stages, actual loving activities, such as kissing, petting, and intercourse, gradually proceed passively, along with concrete approaches made by the male.

The passiveness of the female in various heterosexual activities is demonstrated by the fact that the physical satisfaction/performance of the sexual activities, such as masturbation and touching the body of a male partner, is experienced at the same developmental time with intercourse and preceded by kissing and petting, which are only possible with a partner. This suggests that the sexually active male should change partners from one stage to the next, because the length of time devoted to the practice of one event varies between the male and female. Consequently, the male tends to seek a more permissive female as he moves rapidly along the developmental sequence. Thus, the typical Japanese male starts by dating a female a year younger than he, experiences the first kissing with a

same-aged female, and experiences his first intercourse with a third female, who is at least a year older than he is.

#### *Acceleration/Deceleration Trends in the Sexual Development Sequence*

Changes in the timing of various sexual events and experiences for the average Japanese male and female in these four surveys, 1974, 1981, 1987, and 1993, are shown in Tables 14, 15, 16, and 17 (*IES2* Tables 5 & 6, pp. 805 & 806; *IES2* Figs. 21 & 22, pp. 803 & 804; Hatano 1991; Shimazaki 1994-95). In the seven-year intervals between one survey and the next, certain changes in developmental ages are observed, although the primary sequential order does not change. In particular, there was a slight acceleration tendency in the latter half portion of adolescence between 1987 and 1993. The steady and noticeable increase in the rate of actual sexual behaviors, like kissing, petting, and intercourse, especially among the college-level students, both male and female youths, is particularly noticeable. This "emancipation" tendency may be a sign of the modernization and Westernization of this age group. At the same time, one needs to consider the possible danger in the spread of STDs and AIDS, even though the latter was not really perceived as a threat in Japan as of mid-1995. (However, comments on the present and future of AIDS must be made with the utmost caution. The results shown earlier in Table 12 on the number of sexual partners, for example, already indicate that more than 60% of male and more than 40% of female college students admitted to having multiple intercourse partners.)

Accelerated physical growth is often observed when more-favorable circumstances are provided, a good example being nutritional improvement. Japanese Ministry of Education statistics suggest a sharp acceleration in physical growth starting in the early 1950s and ending by 1980 (*IES2* Figs. 23 & 24, p. 806; Hatano 1991bc). Apparently, the Japanese postwar growth acceleration because of greatly improved nutrition reached saturation around 1980. More specifically, little growth acceleration was observed in males and females after 1960. Since the changes in the biological phase of sexual maturation ended over three decades ago, the recent accelerating changes in sexual behavior patterns must be because of social changes and new pressures. Likewise, since there was no particular biological deceleration phenomenon during the past 50 years, decelerating behavioral changes can only be explained in terms of changes in social control.

Contemporary Japanese society is enjoying fully its freedom of creeds and beliefs, and rather radical liberal thoughts have been prevalent. As the scientific understanding of human sexuality spreads, people prefer more freedom in sex-related behaviors, as noted earlier in Table 2. This tendency involves college- and university-level students since they are treated as "adults" in Japanese society, and experience little social restriction on their behavior. Under the circumstances, it may be rather natural to find an ongoing behavioral acceleration among the youth of this age level. Changes in the rate of experiences of certain sexual events among university students in these four surveys are shown in Tables 14 and 15.

Contemporary Japan is an overly matured society, and thus certain pathological phenomena may be observed in relation with childrearing and the educational systems. One example is the over-controlling of children by parents, particularly by mothers who overly emphasize academic achievement and sacrifice spontaneous play of the children. Hence, children do not demonstrate autonomous development in their decision-making abilities or their interpersonal human relations. Some observers are increasingly anxious about the possible lack of developments in interpersonal human relations and decision-making abilities among contemporary Japanese children. It would not be a surprise if these children were to show deceleration ten-

\*Students: JHS = Junior High; SHS = Senior High; Univ. = University (*IES2* Table 5, p. 805)

dencies in their sexual behaviors because self-realization and individual independence are so important in the development of sexuality, and hence in the orderly development of sexual behavior.

Another example is the unnecessarily tight pressure of university entrance examinations. Since admission to a university of rank is often considered to be the decisive factor for the whole life of a Japanese, senior high school students are particularly repressed in their sexual behaviors in lieu of preparatory studies. Based on the same logic, parents, and perhaps classroom teachers too, are eager to require that the children concentrate only on schoolwork, and definitely discourage the sexual activity of the children. As a result, the onset of the pubescent developmental sequence, and the adolescent behavioral developmental sequence in general, are being decelerated at certain times. At the same time, because of the freer mode of sexual behaviors, particularly among post-senior high school youth, the last portion of the sexual development sequence is condensed to a shorter period of time.

How Japanese youth can cope with the shorter time span for adolescence and for sexual maturation and more-liberal sexual behavior patterns is an issue of concern for both society and for sex educators and sexologists.

*Thoughts and Attitudes Behind the Sexual Behavior of Youth*

Certain data in the 1987 and 1993 national surveys suggest changes in the sociopsychological background of various sexual behaviors.

Table 18 shows the survey results about the primary initiator of the dating and intercourse behaviors among the Japanese youths in the 1993 survey (IES2 Figure 25, p. 807; J.A.S.E. 1994). Between 40% and 49% of the male and female respondents reported that dating and inter-

course were jointly initiated. In the remaining cases, 46% of the males and 35% of the women saw the male partner as the initiator of dating, while 44% of the men and 60% of the women saw the male partner as the initiator of intercourse. Often, it is assumed that a female wants to pretend that she was forced to follow the male partner in certain sexual behaviors, even though such an attitude relieving the female of responsibility for her sexual behavior may be a reflection of a prevailing lack of self-identity in Japanese women. The ability to make one's own decisions in many important life events is one of the goals of sexuality education, and therefore, the situation is still quite challenging for sex educators.

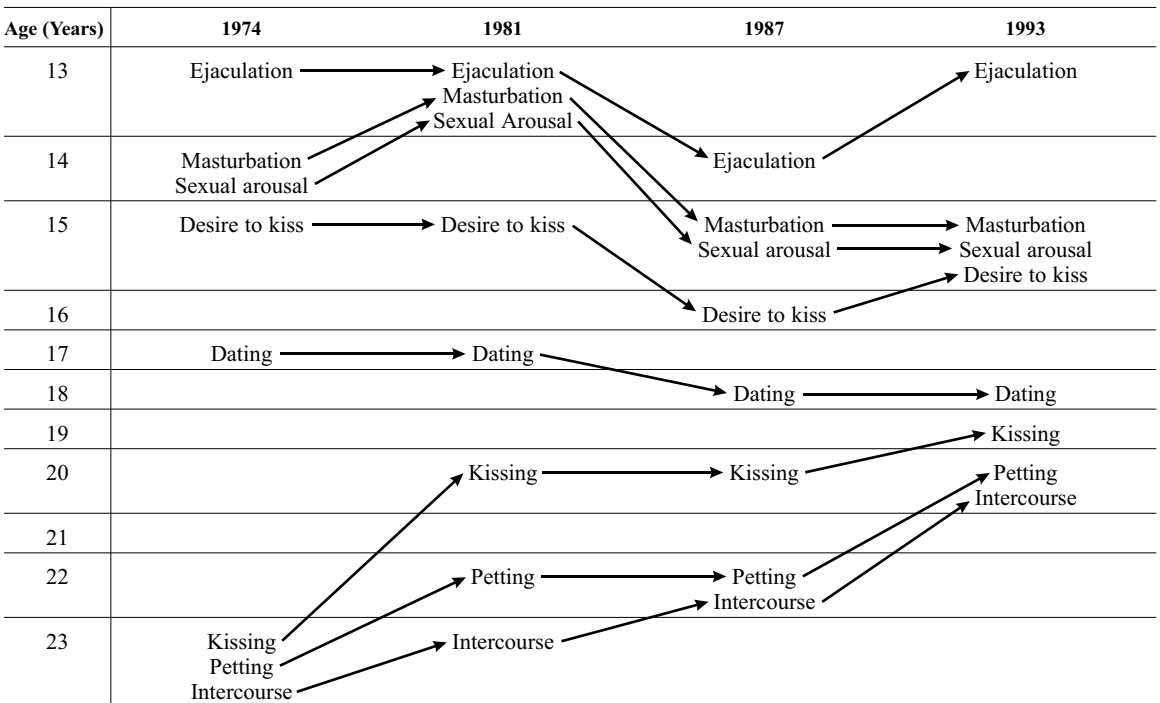

Circumstances for the first sexual arousal experience in the 1987 survey are shown in Table 19 (IES2 Figure 26, p. 808; J.A.S.E. 1988). The main source of sexual arousal for junior high school boys, ages 12 to 14, and to a lesser extent, girls of the same age, is watching sexual material on television and the cinema, 60% versus 45%, respectively. Among university students, on the other hand, 60% reported being sexually aroused—and only 11% by watching erotic visual material; 41% of university men reported being sexually aroused by watching erotic visual material.

The main rationales for the first kissing experience are shown in Table 20 (IES2 Fig. 27, p. 809; J.A.S.E. 1988). Close to two thirds of both males and females found their justification for a first kiss in "liking the person." One in two males reported love or curiosity as their main motive, while significant numbers of women listed love, curiosity, being forced by the male partner, or no reason as their motive.

In terms of the partner's age at first intercourse, roughly equal numbers of university males reported their partner was older than, the same age as, or younger than they were,

**Table 16**

**Sequential Changes in the Developmental Model of Various Sexual Events and Experiences of the Average Japanese Male in These Four Surveys as Seen in the Age of the Median Person for Respective Events**

(IES2 Fig. 21, p. 803)

while more junior and senior high school boys indicated that their partners were either the same age as or older than they were (see Table 21) (*IES2* Fig. 28, p. 809; J.A.S.E. 1988). Regardless of education, about two thirds of the females reported their first sexual partner was older than they. The use of contraceptive devices by both sexes in their first intercourse increased with the level of schooling, reaching 73% and 85% for university males and females, considerably higher than in the United States (see Table 22) (*IES2* Fig. 29, p. 810; J.A.S.E. 1988).

Among the reasons cited for the first coital experience, overall roughly half of the males cited "sexual arousal" and "liking the person," and a third reported "curiosity" or "loving the person." Six out of ten females cited "liking the person" and 38% "loving the person," while 18% were motivated by "curiosity," 15% by "sport," and 13% by "coercion" (see Table 23) (*IES2* Fig. 30, p. 810; J.A.S.E. 1988). In breaking down these motives according to education, six out of ten senior high school and university males cited "liking the person," while junior high school girls mention coercion by the male partner more often than university females do (see Table 24) (*IES2* Fig. 31, p. 811; J.A.S.E. 1988). Table 25 (*IES2* Table 7, p. 811) clearly shows that more females than males think they love their first intercourse partner, and a great many more males than females have intercourse because they were sexually aroused or more curious about the event.

In terms of attitudes regarding premarital intercourse and its connection with anticipation of marriage, the largest number of female university students in the 1987 survey believed that premarital sex is acceptable when there are cer-

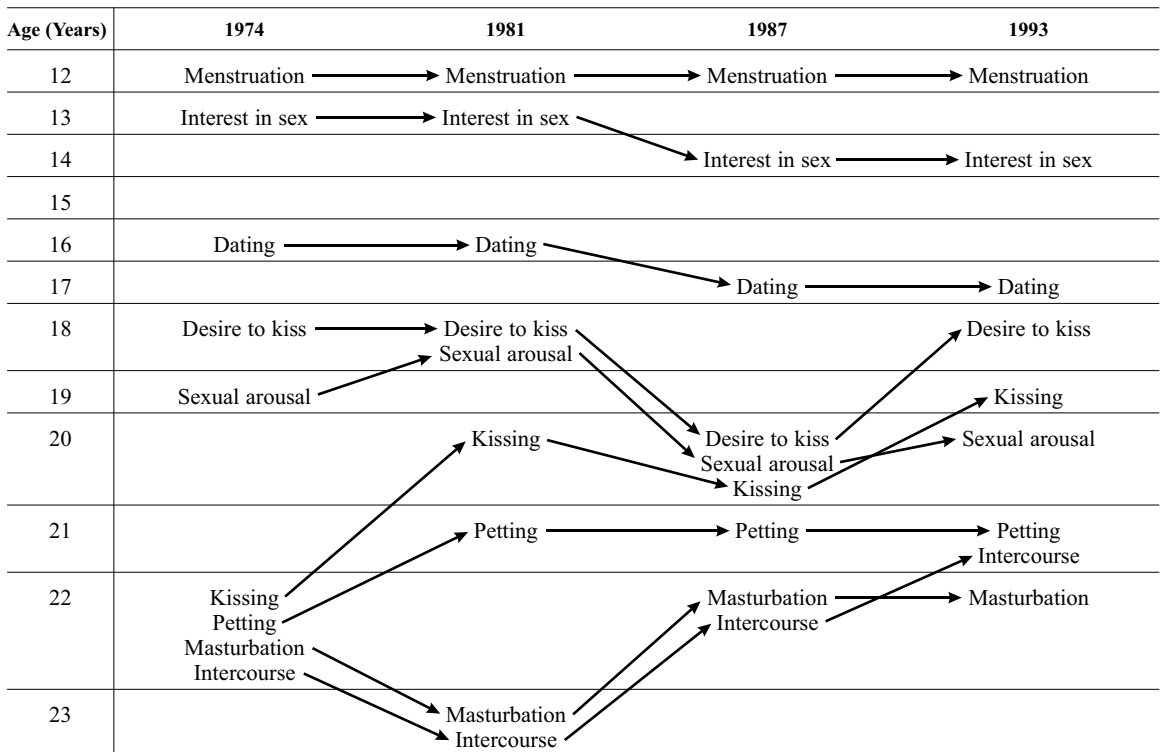

tain agreements between the partners; the second largest group found it acceptable when based on love (see Table 26) (*IES2* Table 8, p. 812).

Table 27 indicates the degree of concern about pregnancy and STD/AIDS reported by sexually active senior high school and university males and females in the 1993 survey (J.A.S.E. 1994). While both males and females expressed strong concern about pregnancy, 51% and 61%, respectively, and 42% and 34% were "somewhat concerned," their strong concern about the risk of STDs and AIDS was significantly less. This might suggest that the threat of STD/AIDS is not as high in Japan as in other countries, or that the youth are not aware of their actual risk (*IES2* Fig. 32, p. 813).

Throughout the four national surveys in these 20 years, sexually active Japanese youth showed a steadily increasing trend in their use of contraceptives from 56% in 1974, to 68% in 1981, to 69% in 1987 and then to 79% in 1993 (*IES2* Fig. 33, p. 813; J.A.S.E. 1994). Along with attaining "behavior emancipation," Japanese youths appear to be taking responsibility for protecting their own health and that of their sexual partners.

Across the education spectrum, Japanese males are more likely than not to agree that a man's role and place is to work outside of the home and a woman's role is to take care of the family. The split is more obvious among university students, with close to 60% agreeing and 40% disagreeing, indicating a conservative trend for more-educated males (see Table 28) (*IES2* Fig. 34, p. 814). Females were significantly more likely than males to disagree with this statement of roles, but university females also showed a clear conservative or traditional trend in their belief on this issue.

**Table 17**  
**Sequential Changes in the Developmental Model of Various Sexual Events and Experiences of the Average Japanese Female in These Four Surveys as Seen in the Age of the Median Person for Respective Events**

(*IES2* Fig. 22, p. 804)

Traditionally, Japanese married by age 25, but this expectation is clearly waning. Regarding their future plans of marriage, Japanese youth keenly reflect the current social trend toward later marriage. About one half of the young people indicated that they want to marry eventually, but are not concerned about the age at which they might marry. Only one in five wanted to marry soon (see Table 29) (*IES2* Table 9, p. 814).

**C. Sex and Sexuality of Japanese Adults**

*Marital Sex*

The Japanese ethical and cultural views of sex could probably be summed up in a few words as something repressed, embarrassing, and simply not talked about. Thus, statistics representing the Japanese concerning frequency of sexual intercourse, sexual positions, and level of satisfaction are still not reported today. Similarly, statistics on oral and anal sex in Japan are not available. One could probably conjecture, however, that the number of Japanese practicing such forms of sex has increased over the past decade or two, because of the influence of more-open conceptions about sex or of adult-oriented comics and magazines.

Loving the person	26	19
Curiosity	25	16
Forced by partner	4	18
No reason	13	16

(*IES2* Fig. 27, p. 809)

In November 1990, *The Weekly Post*, which boasts the largest readership for a magazine in Japan, published the results of a survey in which a random sampling of 2,000 readers took part. Of those surveyed, 33.6% of the men and 23.0% of the women gave complete, valid responses. The average ages of these men and women were 44 and 41 years old, respectively. According to the survey results, which

(*IES2* Fig. 30, p. 810)

may or may not be relevant to our discussion, 85% of the men indicated having had sexual intercourse in the past month. Among these, 55% had had sexual intercourse in the past week. Of all respondents, 15% had not had sexual intercourse in the past month.

Among the men who indicated having sexual intercourse in the past week, 51% had had it once, 31% twice, and 13% three times, making the average number for the previous week 1.7 times.

In other survey responses, 51% of the men indicated that they practice oral sex, and 8% replied that they practice anal sex. Twenty-nine percent of the women said that they always experience orgasm when having sexual intercourse, 30% replied frequently, 24% replied occasionally, and 8% said almost never or never.

While this survey cannot be said to represent the average Japanese, it does provide a general picture of their sexual practices. The results of this survey, when compared to a similar survey conducted by the *Kyodo Press* in 1982, show an increased percentage in every category, which clearly indicates that sexuality in Japan is becoming increasingly more open.

**Marriage and Family**

Dramatic improvement of women’s status in society in the 50 years since World War II has resulted in great changes in the consciousness and attitude of the Japanese people toward marriage and family. Some obvious examples of such improvements are a steady increase in the number of women attending higher education institutions, a remarkable growth of professional and social activities by educated and enlightened women like Nora in Henrik Ibsen’s 1879 *Et Dukkehjem [A Doll’s House]*, and development of a self-sustaining economic strength and expansion of independent life with individual decision making. The daughters of the traditional Japanese families, i.e., the Japanese female dolls wearing pretty kimonos, who used to be educated how to serve and follow the man (husband) and how not to express their own ego, desires, and needs are now nonexistent, having become a part of fairytales. [*Comment 1997: An additional factor, mentioned in Section 4, Autoerotic Behaviors and Patterns, may be the slow-fading expectation that a good Japanese woman should always be modest and not initiate any sexual activity. (End of comment by Y. Kaji)*]

The consciousness and attitude of the men regarding marriage and family life have also been forced to change greatly throughout the time of high economic growth and the current economic stagnation and collapse of the “economic bubble.” The unbalanced economic life between consumer life and insufficient income, and extremely poor housing conditions that come from living in highly concentrated, dense metropolitan communities, are major examples of the forces that have caused changes in attitudes about marriage and family life. In 1950, the average age of first marriage of Japanese adults was 25.9 years for men and 23.0 years for women; by 1990, this was 28.4 and 25.8 years of age, respectively. This rather high age of marriage is not expected to drop in the near future.

According to a recent report from a survey of young adults’ attitudes about marriage, the rate of those who indicated “marriage is not a must

unless one needs to,” and/or “living independently is more important than marriage,” was 41% and 32.8% of women in their 20s and 30s, respectively, and 32.9% and 37.1% of men in their 20s and 30s, respectively.

The youth in older generations used to be concerned with a “get married to have sex and propagate” philosophy that was reflected in the statistical data. [*Comment 1997: Ten years ago, in a survey conducted by the Ministry of Public Welfare in 1987, 91.8% of the males and 92.9% of the females aged 18 to 34 indicated that they wanted to get married. A 1986 survey of university students reported that their cohabitation rate was only 0.3% for males and 0.8% for females. (End of comment by Y. Kaji)*] However, the

Total (percent)	10.5	19.0	29.4	41.1	757	100

(IES2 Table 8, p. 812)

authors of this chapter believe that there is a trend among today's youths to move away from the traditional form of family life and marriage to accept cohabitation as a natural form of living in male-female cooperation. The majority simply hope that when all the conditions are fulfilled, it is not a bad idea to get married. [*Comment 1997: Surveys need to be conducted to support or disprove this interesting hypothesis. (End of comment by Y. Kaji)*]

The traditional matchmaking system as a prelude to marriage is well known. The system was developed under the feudalistic atmosphere and warriors' society in which the preservation of the family was of priority importance.

**Table 27**

(IES2 Table 9, p. 814)

The so-called "middleman in honor" was asked by the parents of the young man or woman to find their child a proper partner in terms of the social level and position of the family. Traditionally, age was not a consideration.

This system is still widely practiced today, although the social status of the family and the respective person is increasingly becoming less important. In the 1960s, a survey analysis reported that 40.7% of all marriages were arranged in the manner mentioned above, and 57.0% were a freely made decision or love-oriented marriage. The rate of arranged marriage in a 1980s survey dropped to 22.8% for arranged marriages and rose to 71.8% for love-oriented marriages, leaving about a quarter of all marriages still arranged by a matchmaker. The newest trend in this system is an increase in the requests for arranged marriages among men over age 30, a reflection perhaps that these older bachelors tend to avoid the rather uneasy attempts to build a love-oriented heterosexual relationship. Marriage is not an easy life event for the young and middle-aged Japanese men these days, particularly considering a 1991 poll by the Asahi Shimbund that reported 60% of Japanese women consider Japanese men "unreliable" (Itoi & Powell 1992). (See also the discussion of the "Narita divorce" phenomenon in Section 5A above.)

*[Multiethnic Marriages*

*[Update 2002:* In the early 21st century, marriage and continuing the family line has become a major problem for many Japanese men. By the time a Japanese man reaches his late 30s or 40s, it is almost impossible for him to find a bride in her 20s or early 30s. Japanese culture celebrates youth as few other cultures do, and the 30- or 40-year-old male is out of the competition. Divorce has been uncommon until quite-recent times, and midlife marriages even rarer. Add in the fact that Japanese women are demanding a higher standard of living from prospective husbands and shunning marriage as noted above.

[As noted in the brief historical perspective, Japan has long been known as the quintessential insular country. Even today, Japan is a near-classless, mono-ethnic nation with 127 million people, of whom a scant 1.5 million are resident foreigners. Less than a million are Korean and Chinese who have lived in the country for generations. But, they are still considered outsiders and remain subject to Japan's exclusive cultural practices and arduous naturalization laws.

However, as more and more Japanese men find it increasingly difficult to find Japanese wives and Japan's population continues shrinking, some new thinking has taken root in recent years: Perhaps marriage with a foreigner is the best answer for these lonely men who want to continue their family line.

[The trend of young Japanese marrying non-Japanese spouses started in the 1970s with more Japanese women marrying foreign husbands. In the 1980s, increasing urbanization left many poor rice farmers with no Japanese women to marry as the women migrated to the cities in search of a more comfortable life. At first, the rice farmers turned to poorer Asian countries,

particularly the Philippines, in their search for brides. In 1990, Korean women were very popular, but as Korea's economy improved, interest in Korean brides declined. In the 1990s, the number of Japanese men marrying Chinese women rose tenfold, despite past animosities and the ongoing political tensions between Japan and China. In 2003, China was the country of choice for foreign spouses, even if the spouse came from a far-western province of China.

[International marriages are now an urban phenomenon, fueled by exchange-student liaisons. And the boom is just beginning. In 2002, over 2,000 international marriage agencies were operating in Japan, with at least 107 specializing in Chinese spouses (see Table 30).

[International courtships usually depend on the Internet, with a few visits by the man to the woman's home and family, which may be several thousand miles distance in some remote western province of China. In many international courtships and marriages, communications are difficult, even after a couple have been together for some time. Communications often depend on an electronic dictionary, fragmentary sentences and phrases written with the Chinese characters that the Japanese and Chinese languages share (French 2002). (End of update by R. T. Francoeur)]

#### [Japan's Changing Family Geometry

[Update 2000: In the traditional Japanese family, the first-born son and his wife are expected to take care of his parents in their old age. A son is also critical for continuance of the family name. With Japanese families having only one or two children, the odds are that the parents may have no son and one or two daughters. In families with only a daughter or two, the future care of the parents depends on whether or not the daughter(s) adopt(s) her husband's family name, and on whether the daughters decide to live in the husband's parents' house or in her parents' house.

[The new family geometries evolving as a response to reduced fertility may involve the daughter keeping her own family name instead of adopting her husband's name, and the husband joining his wife's family and accepting responsibility for caring for her parents in their old age. This pattern of the husband living with the wife's family and assuming the burden of eventually caring for her parents is an arrangement almost unheard of just a generation ago. In "groom adoption," parents with a single daughter may adopt her husband, who will then take her family name, an old custom that is fading in popularity.

[The pressures behind these new geometries include falling birthrates, the world's most rapidly aging population, sky-high real estate prices, the inheritance of parental real estate, and persistent economic uncertainty after a decade-long recession. The result is often an increasingly open and sometimes raw tug of war between the parents of brides and grooms to determine which parents will be cared for in old age by their children, and who will maintain the family gravesite. As the beneficiaries of an economic golden age in the 1960s and 1970s, many of Japan's elderly have huge personal savings and immensely expensive urban real

estate. The contest between families for the allegiance of children has thus become inevitably intertwined with struggles over inheritance rights. Indeed, more and more men are being lured away from their own families to those of their wives by the promise of financial security. These struggles are increasingly eroding the male-driven family structure common in Japan. Ultimately, among the most important consequences of the economic power of the wife's family will be the strengthening of the role of women themselves in Japan and their growing equality with men (French 2000). (End of update by R. T. Francoeur)]

#### [Fading Three-Generation Families

[Update 2002: Despite impressions to the contrary, the practice of an extended Japanese family living under a single roof with the son bringing his wife home to live with him and his parents is relatively new in Japanese culture. It dates back only to the Meiji Era, from 1868 to 1912. Before the Meiji dynasty, most Japanese couples lived apart from their parents. However, as lifespans increased, the Meiji government wanted the household to become the unit of welfare, with the younger people providing all the care of their elders. In this system, the daughter-in-law's role is that of a submissive *yome* (or more politely, a *oyome-san*), who is ruled by her mother-in-law and has no independence of her own. Her main role is to take care of her husband's parents. This system continued after World War II, and began to weaken in the 1960s and 1970s.

[Today, the tradition of parents and children, sometimes three generations, living together has all but disappeared in urban areas of Japan, although it still observed in the rural areas. In 1999, people age 65 and older living on their own or as couples accounted for almost 46% of households, compared with 20% in 1972. In the same period, the number of three-generation families who live together under one roof has declined from 55.8% to 29.7% of all households.

[Among the many factors contributing to the demise of the *yome* are the lure of cities, the desire of more women to work outside the home, the independence of both young and old that comes with financial security, and the fact that increasing numbers of young women do not want to become *oyome-san* and take on the burden of caring for the elderly in their homes. To Japan's credit, the government now offers a huge menu of healthcare services for older people in their homes. The government provides workers to cook meals and bathe elderly family members, and nurses to administer injections. While the elderly have pensions that enable them to live independently, their children are not likely to enjoy this same freedom, as their public and private pension plans are grossly underfinanced (Strom 2001). (End of update by R. T. Francoeur)]

#### Divorce

The attitude of the Japanese people toward divorce has changed as much as their attitude toward marriage. Historically, the divorce rate in the Meiji Era (1868-1912) was higher than the current figure, very probably because men could divorce wives easily, since the social status and human rights of women were regarded as light as a feather. No statistics are available regarding marriage and divorce before Meiji (1868).

In 1946, divorce laws eliminated the old three-line letter whereby a man could dismiss his wife. Before World War II, Japan had one of the highest divorce rates in the world; that high rate is echoed in recent years, following after an all-time postwar low, with the difference that most divorces now are sought by women. Laws still leave alimony rather skimpy, but child-custody now favors the mother instead of

**Table 30**

#### Japanese Men and Women with Foreign Spouses

Year	Japanese Wives with Foreign Husbands	Japanese Husbands with Foreign Wives
1970	4,000	1,800
1985	5,000	7,000
1990	5,500	20,000
2000	7,500	28,000

the mandatory custody by the husband's family that prevailed before 1945.

Like many other democratic practices, the principle of male-female equality was first established throughout the legal structure of modern Japanese society in 1945. The Japanese people used to believe that ending a marriage in divorce for whatever reasons involved a loss of face and honor. Many, particularly among the older generations, still hold to this belief. In this respect, maintaining the marital structure, even when the husband-wife relations are practically broken, is socially acceptable and often the rationale for not divorcing. Considering this background, the divorce rate remained low during the 1950s and 1960s, less than 1.0 per 1,000. By the 1980s, the divorce rate had grown slightly to 1.5 per 1,000. The more recent rate is not much different from the 1980s rate. There are important differences in these general statistics. The divorce rate for couples in their early 20s was 17.0 per 1,000 in 1985, more than ten times the overall average. For couples in their 40s, the rate was 3.6 per 1,000, twice the overall rate. [Update 1997: According to Kristof (1996a), comparative divorce rates in the mid 1990s showed about 24 divorces for every 100 Japanese marriages, compared with 32 per 100 in France, 42 per 100 in England, and 55 per 100 in the United States. (End of update by R. T. Francoeur)]

The increased rate of divorce among the young people may come from their immaturity in the social-perseverance quality, while the rate among middle-aged people may be the result of changes in the male-female social strength relations. For the latter, factors to be considered include a rebellion of the women against the men-centered social structure, expansion of the economic independence of the housewives, and more promotion of women's emancipation. This, in turn, provides the starting point for a discussion about the husband/wife roles in the family life in the modern and future Japanese society.

[Update 1997: In an early-1990s survey conducted by the Dentsu Research Institute and Leisure Development Center in Japan, married men and their wives in 37 countries were asked how they felt about politics, sex, religion, ethics, and social issues. Japanese couples ranked dead last, by a significant margin, in the compatibility of their views. In another survey, only about a third of the Japanese said they would marry the same person if they could do it over. However, this incompatibility might not matter as much, because Japanese husbands and wives traditionally spend little time talking to each other. This is not unexpected, given the primacy most Japanese men place on their work, the disparate social positions and power of men and women in traditional Japanese society, and the suppression of emotions and feeling. The reality in many marriages is the "7-11 husband," so-called because he leaves home at 7 A.M. and returns home after 11 P.M., often after going out for an after-work drink or *mah-jongg* session with buddies. A national survey found that 30% of the fathers spend less than 15 minutes a day on weekdays talking with or playing with their children. Fifty-one percent of the 8th grade students reported they never spoke with their fathers on weekdays. In reality, then, the figures for single-parent Japanese families are deceptive, with the father in dual-parent families more often than not a theoretical presence (Kristof 1996a).

[Divorce, in Japan, has long been a simple matter, requiring little more than the signatures of both parties and filing the papers in city hall. Two major factors in Japanese culture have kept the divorce rate very low despite the lack of couple compatibility, communications, and emotional satisfaction. On the male side, shame is still a powerful social and financial sanction, especially in the workplace,

where many companies are reluctant to promote employees who have divorced or have major problems at home. A divorce is always a negative factor in the employment world.

[Japanese women knew that this simple procedure carried with it many hidden consequences that made divorce psychologically, socially, and financially prohibitive in all but the most abusive situations. Family and relatives are socially embarrassed and shamed by a daughter who has rebelled against a life spent catering to a husband. In a shame-sensitive culture, the whispers of neighbors can be demoralizing. Also, court-ordered alimony was stingy, few jobs were open to middle-aged women, and banks often turned down applications for loans, mortgages, or even credit cards. While child custody goes to the mother in three quarters of all divorces, most Japanese mothers do not have a career or much in the way of financial resources. In the mid 1990s, only about 15% of divorced fathers paid child support (Kristof 1996a). (End of update by R. T. Francoeur)]

### [Divorce among the Middle Aged

[Update 2003: Although the overall divorce rate in Japan appears flat when compared with America and Europe, in the last few years, divorces among older people have been skyrocketing, reflecting profound changes in a traditionally conservative society. Fifteen years ago, middle-aged divorces were almost unheard of in Japan. But in the late 1980s and early 1990s, the divorce rate among younger couples was steadily creeping upward to levels comparable with many European countries.

[Some social-trend observers attribute the explosion in middle-aged divorce to a sort of trickle-up women's liberation, in which grown daughters, often still living at home, prod their mothers to stop putting up with emotionally barren or abusive relationships with their fathers. Concepts novel to Japanese culture, like individualism, materialism, and personal happiness, have been embraced by daughters and are now being picked up by their mothers, breaking down traditional values of the collective good, of harmony, and, above all, of *gaman*, or self-denial. Another factor has been a shift in the content of daytime television and advertising that reflect and energize changing attitudes surrounding middle-aged divorce. Sexy daytime dramas and Jerry Springer-style talk programs, known as "wide shows," have emerged to tutor women in issues like divorce, post-motherhood careers, and sexual freedom. Other roots of this phenomenon are profound social changes, like the demise of lifetime employment, later marriage, the collapsing birth-rate, and a growing number of social-dropout younger adults, who drift between part-time jobs and live with their parents well into their 30s. Taken in combination, these changes are comparable to the seismic cultural shifts seen in the United States in the 1960s and 1970s (French 2003). (End of update by R. T. Francoeur)]

### Sexuality and Older Persons

Recently, surveys in Japan have enthusiastically taken up the topic of sexuality among the middle-aged and aged population. In 1979, Hideko Daikuhara, a public health nurse in Tokyo, conducted Japan's first-ever research on the actual condition of sexual activity among aged persons. Later, Yoshiaki Kumamoto and others at the Sapporo Medical School firmly established research on gerontology—in Japan, gerontology is a branch of andrology. Kumamoto reported the results of a survey on the relationship between sexual activity and aging that was conducted as a part of his research. The survey revealed that 14.2% of men in their early 60s were no longer sexually active. For men in their late 60s, the percentage of inactive males was 22.8, with

32.0% in their early 60s, 50.3% in their late 70s, and 62.6% of men aged 80 or older who were no longer sexually active. Of those who indicated being sexually active, 60% in their 60s, 40% to 55% in their 70s, and 30% 80 or older said they had sex once or twice a month.

Kumamoto's survey was given to 5,500 men. Although it would be difficult to say his survey is representative of middle-aged and aged men in Japan, it is sufficient reference for the trend of sexual activity in these age groups. "Human beings do not lose their sexual drive until they die," has been an expression heard among the common populace of Japan for many years. This is evidence that the Japanese have had sufficient knowledge of the sexual activity made evident in Kumamoto's survey. On the other side of the coin, the popular expression regarding men who are "forever chasing after women, in spite of their age" offers proof that Japanese have both an official and a private stance when it comes to sexuality.

#### [Extramarital Relationships]

[Update 1997: Traditionally, the Japanese male has always had much more freedom for extramarital affairs than the women. In Japanese culture, there is no sin in sex. It is treated as a natural part of life by the Japanese, even more so than in European cultures. Few Frenchmen were upset when the widow and the former mistress of President Mitterand stood side by side at his funeral, because the whole affair was handled with proper decorum. Unlike the United States, Japanese culture has been even more accepting of the private extramarital affairs of high-ranking Japanese politicians, business executives, and ordinary husbands. Extramarital affairs traditionally posed no problem, unless the man either allowed this side of his private life to interfere with his duties or he lost face by not maintaining proper social decorum. One loses face and shames one's family by making public something that should be private (Bornoff 1991, 262-300).

[While no data are available on the incidence of extramarital sex and affairs, the incidence of such behavior is undoubtedly affected by several factors in the changing scene of Japanese male-female relations. While husbands have many avenues for extramarital sex available, with *geishas*, "soap ladies," and the sex workers who ply their trade via telephone clubs, pink leaflets, mobile van services (*Pinkku Shiataru*), lovers' banks, massage parlors, date coffee shops (*deeto kissa*), or on the street, the number of Japanese wives who seek a lover as a way of spicing up their lives with a bit of romance seems to be increasing. In the 1983 *More Report on Female Sexuality*, 70% of the women ages 13 to 60 surveyed reported being sexually unsatisfied. Add to this the fact that Japanese wives control the household finances and have considerably more leisure time than their husbands. Many of the part-time sex workers in Soaplands are female students and frustrated housewives who control their own work schedules and can use the extra money easily available in this work. A 1986 survey conducted by the Prime Minister's Office found that 10% of the 680 women sex workers arrested by the police were housewives (Bornoff 1991, 334). (See also Section 8B, Significant Unconventional Sexual Behaviors, Prostitution.) (End of update by R. T. Francoeur)]

### 6. Homoerotic, Homosexual, and Bisexual Behaviors

#### [A. Homosexuality in Pre-Modern Japan]

[Comment 1997: Masculinity and virility were exalted in the ancient nature religions and in Shinto precepts and rituals that prepared the ground for the warrior culture. In the Shinto winter ritual of *hadaka matsuri*, males of all ages pu-

rified themselves with an icy dip in a mountain spring or waterfall, liberally consumed purifying *saki*, and then formed a pyramid of naked male bodies, a seething mass exaltation of manhood inside the temple. Masculinity was also exalted by the *samurai* and *shoguns* who kept legions of pretty young pageboys in attendance. Even among the Buddhist priesthood, where the injunction of chastity forbade all sexual contact of monks with women, homosexuality was considered an acceptable substitute, as it was elsewhere in Buddhist monasteries throughout the Far East. Each novice pledged himself to an older monk for a number of years. In exchange for tuition, the mentor provided his pupil with instruction in the sacred texts and the spiritual quest. The novice embraced the status of "sworn friend," serving his master, body and soul.

[During the long civil wars, violence and the warrior ethic reigned supreme and women were nothing more than a necessary incubator for progeny. Homosexuality was the ultimate criterion of virility and masculinity. In the stoic way of the warrior and the code of the *samurai*, *nanshoku* (male passion) was not a perversion, but a lofty ideal. Strict conventions limited the passive female role of recipient to youths and boys, while the older male played the active male role of inserter.

[For centuries, the traditional Japanese theater, another male preserve, also had an established current of same-sex behavior and relationships flowing through it. As soon as the female precursors of *kabuki* were banished from the stage in the early 1600s, the overwhelming majority of their male replacements were beautiful catamites and followers of Shudo, "the way of the youth" (Bornoff 1991, 422-433). (See also the discussions of male homosexuality in Section 6 of the chapters on Iran, Morocco, and Turkey.) (End of comment by R. T. Francoeur)]

[Comment 1997: Yanagihashi (1995) has identified four main characteristics evident in pre-modern Japanese homosexual traditions, namely:

1. The relationships are typically between an adult man and a minor;
2. The relationships tend to exist in contexts where contact with the other sex is limited;
3. Female homosexuality seems to be entirely nonexistent; and
4. The relationships were formed exclusively among members of the privileged classes.

[Homosexuality was understood as a substitute or supplement to heterosexuality in a fundamentally heterosexual and male-dominated society. (End of comment by Y. Kaji)]

#### B. Male Homosexuality Today

[Comment 1997: Although Japanese culture has in its history a tradition of sexual love between men, and tolerates the expression of affection for the same sex at most levels of society, the contemporary Japanese attitude toward homosexuality is in general very negative. However, the issue has yet to be discussed as a social issue. For example, according to a nationwide survey of 188 university professors who are teaching subjects related to human sexuality, only 30 (15.8%) have ever addressed the issue of homosexuality in their curriculum (National Survey of Sexology and College Education 1995). Though many lesbians and gay men suffer from the prejudice and insensitivity of Japanese society, most heterosexual Japanese people may be unaware of the negative feelings that drive such prejudice and insensitivity. (End of comment by Y. Kaji)]

None of the larger urban entertainment districts in Japan is without its quota of gay bars and clubs. The laws against

prostitution are fairly nebulous, but especially so when applied to homosexual prostitution. When a gay bar or club comes to grief from the law, it is usually because it employed boys under the legal age of consent or hired exotic youths from other lands who violate the provisions of their visa by working.

Until the specter of AIDS arose in the mid-1980s, many foreign homosexual men found Japan, with its very long, colorful, and venerable gay history, to be a paradise. The fear of AIDS and a touch of xenophobia have closed most gay facilities to foreigners. Exclusion of foreign gays from Japanese gay facilities provides the reassurance of freedom from the risk of AIDS if Japanese homosexuals associate only with other Japanese gays.

[*Comment 1997*: Japanese male homosexuals are called *okama* (august pots), a derogatory colloquial metaphor equating the common cooking pot with the human buttocks. Increasingly popular is the “Japlish” *gei*, or gay. In a 1981 survey, about 6% of male college students reported being active homosexuals; a third of high school boys surveyed reported latent homosexual inclinations. In a similar 1987 survey, both figures declined to 4.5 and 20%, respectively, with a proportionate increase in heterosexual activity.

[Apart from one gay support group with an overwhelming foreign membership, there are no gay activist groups uniting Japanese in coming out of the closet and political advocacy. Gay magazines, such as the famous *Bara Zoku* [*The Rose Tribe*], and gay comics are sold everywhere, but like the many heterosexual erotic publications, their emphasis is more on titillation than information, and certainly not on sociopolitical activism. Gay liberation parties on the political fringe do occasionally surface, especially at elections, but most Japanese gays would rather continue living their erotic lives contentedly in the closet, perusing their gay magazines, and attending gay bars or clubs when they can, rather than become involved in the risky business of political activism (Bornoff 1991). (*End of comment by R. T. Francoeur*)]

[*Update 1997*: This situation began to change in 1991 with the filing of the first court case pertaining to gay issues, the Association for Lesbian and Gay Movement vs. Tokyo Municipal Government. In this case, also known as the Fucyu Youth Activity Center Case, the Tokyo District Court reversed a decision by the Tokyo Metropolitan Government Board of Education that refused to allow homosexual groups to use a youth activity center. Beginning in 1994, the Annual Lesbian and Gay Pride Parade has been held in Tokyo. In 1995, about 2,000 people attended this event, which was cosponsored by 28 groups with predominantly Japanese membership. Also, in 1995, gay professional organizations, such as the Association of Gay Professionals in Counseling and Allied Medical Fields, were founded. (*End of update by Y. Kaji*)]

### [C. Lesbianism

[*Comment 1997*: In ancient times, the neglected ladies of the *o-oku*, the *shogun*'s harem, were well known for taking consolation in lesbian relationships. Unlike the celebration of male homosexuality among the warriors and their pages, however, Japanese culture has preferred to ignore—neither condemning nor celebrating—lesbian relations. *Shunga* with a lesbian theme are relatively rare. There are *resubian sho* (lesbian shows) which are a staple in the modern striptease parlor frequented by heterosexual males, but more as a foreign import than indigenous expression. For a brief time in the early 1980s, Tokyo had a single lesbian bar, but given the contentedness of gay men in the closet and the pervasiveness of female submissiveness, there are even

fewer lesbians anxious to come out in public. While most gay bars exclude all women, some are known to cater to lesbians on certain days, and then only for a couple of hours. In modern Japan, lesbianism is shrouded in comparative obscurity (Bornoff 1991, 433-447). (*End of comment by R. T. Francoeur*)]

[*Comment 1997*: In Japan, as in most other cultures around the world, lesbians have been doubly stigmatized as homosexuals and as women. Lesbians have been typically viewed by Japanese society as a common element in the pornography targeted to men or as “gender-bending” and antisocial. A variety of colloquial terms are used for Japanese lesbians, all of them more or less derogatory. (*End of comment by Y. Kaji*)] [*Comment 1997*: Lesbians are sometimes known as *onabe* (stew-pot) in contrast with the male *okama*, or august pot, or more commonly by the “Japlish” *resz. Rezubian* (lesbian) is the most commonly used term. The *otachi*, or butch, the actress playing male roles, and the *orneko nenne* or *neko* (cat), *Çnue*, or *femme*, mark the two ends of the lesbian spectrum. (*End of comment by R. T. Francoeur*)]

[*Comment 1997*: One uniquely Japanese custom of gender bending is found in the *joshi-puro* (women professional wrestlers). Elsewhere in the world, women wrestlers are shapely Amazons in bikinis intently watched by males. In Japan, women wrestlers mimic their male *sumo* counterparts, with some interesting twists. *Joshi-puro* stars, such as Chigusa, with a boyish hairstyle and tacky, gaudy leotards, serenades her audience of teenage and preteen girls with popular songs before climbing into the ring to attack, gouge, pummel, and drag her mountainous opponent around the rings. Commenting on the adulation Japanese girls show for their heroes in the All-Japan Women's Pro Wrestling Association, the director of AJWPWA has suggested that young girls see women pro wrestlers as very strong, ideal men, a substitute for boyfriends. They feel safe getting close to them because they are female. They provide vicarious thrills for the young girls, and models of aggressive champions of self-assertiveness (Bornoff 1991, 433-444). (*End of comment by R. T. Francoeur*)]

## 7. Gender Diversity and Transgender Issues

Except for the practices of certain ethnic groups in the world, cross-dressing, transvestism, gender-crossing, and transsexualism were, until about 50 years ago, generally considered “diseases” that either required medical treatment or were simply not practiced out in the open.

Reaction in Japan was similar, although there were some exceptions. *Kabuki*, Japan's traditional theatrical art, is one. All parts in a *Kabuki* play are played by male actors. Thus, cross-dressing and transvestism, at least in the theater, has long existed in *Kabuki* roles. One can easily imagine that the actor's psychological state, or mental makeup, walks a fine line between masculinity and femininity, as the actor tries to immerse himself in his role. Actors responsible for female roles were, from their early childhood, compelled to experience first-hand the everyday life, customs, and etiquette of the women they played. Although this extreme practice is not seen in the modern *Kabuki* world, it cannot be denied that an aesthetic sensibility exists in the mental makeup of Japanese in which importance is placed on the beauty of men acting in female roles. As a counterpart to *Kabuki*, Takarazuka Young Girls Opera, which began in 1914, has provided a stage for only female actresses and continues to enchant many women today.

These phenomena may provide a clue when considering gender-crossing, transvestism, and cross-dressing in Japan.

That is, the roles in both *Kabuki* and Takarazuka Opera have come to be viewed as a performance, something one sees only on the stage. Accordingly, occurrences in these fictitious worlds are not always so easily tolerated in the real world. A “drag queen” appearing on television, for example, lives in “television land,” a world from which most people feel detached.

Gender-crossers and transsexuals have not yet been accepted into Japanese society. This is because the majority of people have a dualistic gender bias, believing that a man’s role is to impregnate a woman and a woman’s role is to bear children, while only a minority advocates a society where people are free to choose their gender.

In recent years, gatherings and study meetings on transsexualism and transvestism as a human issue rather than a moral issue have been provided in Japan as well. Saitama Medical School created a stir in July 1996, when its ethics committee approved female-to-male sex-change operations. There is no legal precedent for this in Japanese law and many problems remain concerning how society will accept those people who undergo a sex-change operation.

[Update 2002: In October 1998, five cases of sex-reassignment surgery were performed in Japan (four female-to-male and one male-to-female) by the medical group at the Saitama Medical University. Gender Identity Disorder has gained social recognition in Japan as a status needing medical treatment. A number of transgender support groups have been formed all over Japan. As of March 2000, Trans-Net Japan, a Tokyo-based support group, lists 41 transgender-related support groups all over Japan in their resource booklet. Also, the intersex status has been gaining some social recognition. An Osaka-based support group for the intersexual individuals and their families, PESFIS (Peer Support For InterSexuals) Japan was founded in August 1995 and is now active in Osaka, Tokyo, and Nagoya. In June 2000, Tokyo’s metropolitan government drafted its *Guideline for Human Rights Public Policy Advancement*. Effective at the end of 2000, it became the first policy guideline in Japan to list sexual minorities as human-rights-violated people. While the Governor’s special task force committee was working on the draft, both gender identity disorder and homosexuality were listed as categories of people who need to be protected from discrimination. However, in the final draft, homosexuality was excluded. Gay organizations and their supporters quickly objected to this draft and are trying to make the case for including homosexuality in the listing. (End of update by Y. Kaji)]

## 8. Significant Unconventional Sexual Behaviors

### A. Coercive Sexual Behaviors

#### Rape

Rape, according to Japanese law, is described as having sexual intercourse with a woman through force or against the woman’s will, but there is no clear legal definition for rape. According to Article 177 of the Criminal Code, “if a girl of 13 years or more is forced to have sexual intercourse by means of a violent act or threats . . . or if sexual intercourse is performed with a girl not yet 13 years of age, regardless of the method or whether there was mutual consent,” the offender will be punished. However, the victim or her parent or legal guardian must file a complaint in order for the rape to be recognized as a criminal act.

In 1994, when victims of rape were required to go through this vague and complicated procedure, 1,616 cases of rape were reported. The number of cases actually dropped between 1980 (1,800 cases) and 1990 (1,500 cases), but re-

cent years have seen a slight increasing trend. In Japan, many feel that, because rape is an offense subject to prosecution only upon complaint, few cases come to light. The actual number of cases is sometimes said to be five to ten times the number reported. This is really the problem we should be concentrating on in our discussions, while striving to settle on a clear legal definition of rape. Although sexual crimes, such as indecent assault, sexual abuse, and sexual harassment, were not until recently taken up as social problems, we can at least say that surveys and case studies on these topics are being performed, and that the formation of a nationwide study network is anticipated for the future.

#### [Child Sexual Abuse

[Update 2001: A Child Prostitution and Child Pornography Prohibition Law, effective November 1999, prohibits both buying and arranging prostitution of minors who are under 18 years old. It also prohibits making, possessing, carrying, importing, exporting, selling, renting, and displaying child pornography. (End of update by Y. Kaji)]

#### Sexual Harassment

In 1986, Japan passed an equal-opportunity law for women that was purely advisory and only asked companies to make “an effort” to prevent discrimination against women. The 1986 law provided no penalties for companies that discriminated; it did not even mention the term “sexual harassment.” In December 1996, a Labor Ministry panel recommended putting teeth into the 1986 law by publicizing the names of violators and specifically barring sexual harassment. The panel said that the revised law should expressly forbid gender discrimination instead of simply recommending efforts against it and should ban advertising that describe jobs as “open only to women.” Despite these efforts, protection against sexual harassment in Japan lags far behind American and European standards.

#### Incest

According to Japanese myth, Izanami and Izanagi, the god and goddess couple credited with creating the islands that make up Japan, were in fact siblings who then married. Also, many stories have been handed down from the 4th and 5th centuries concerning consanguineous marriages (incest) in Japan’s Ruling Family (thought by some to be the ancestors of today’s Imperial Family, but this is uncertain). However, since that time, incest has been taboo and avoided in Japan, as in the Christian spheres of America and Europe.

Yet, reports of incest between a mother and son have become a phenomenon in the last few decades. Such reports have come mostly from volunteer groups that provide counseling over the telephone. Frequent situations in the reports include: 1. a mother who sees her son masturbating in his bedroom and begins helping him, which leads to sexual intercourse; and 2. a boy in a stupor or irritated from studying for exams who is embraced by his mother, who feels sorry for him, leading to sexual intercourse. Many psychologists hypothesize that the anonymous nature of the telephone counseling may result in calls that provide an outlet for the expression of fantasies peculiar to young people. However, there is no reason to totally discount the findings from this counseling method. We look forward with great anticipation to future surveys and studies.

### [B. Prostitution

[Comment 1997: Prior to 1948 and the enactment of the Law for the Regulation of Businesses Affecting Public Morals, prostitution was not a criminal offense. The 1956 Prostitution Prevention Law granted the country’s red-light districts a year’s grace, after which the estimated 260,000

sex workers in the 50,000 hitherto-licensed brothels would have to find other means of earning a living. The 1956 law also banned sexual slavery and the practice of selling daughters into the brothel trade. New revisions of the public morals were added in 1984.

[While the commercial sex industry has undergone many changes, it has retained much of its vitality and varied character.

Both before and after the new law, however, the operation of sex-orientated businesses was, and is subject to obtaining "prior permission" from the police and local authorities. This at once casts doubt upon how illegal such things actually are and just what kind of arrangements operators are expected to make in order to open shop. The fact is that bars, cabarets and other concerns employing hostesses are free to operate, provided their services abide by officialdom's favorite old (and sometimes highly coercive) chestnut of "voluntary restraint." "Most of the sex industry is illegal, yet it goes on just the same," the editor of a Tokyo magazine focusing on the *mizu shobai* recently affirmed. "As in the strip theaters, people usually know when the police are coming to raid them. In businesses like these, there's a lot of money changing hands under the table." (Bornoff 1991, 332)

[According to the 1984 *More Report of Male Sexuality*, the majority of men over 30 had their first sexual intercourse experience with a prostitute, whereas those in their 20s tended to have their first encounters with a girlfriend. (End of comment by R. T. Francoeur)]

### [Soaplands

[Comment 1997: It is still quietly accepted and understood that a Japanese husband may join business associates or friends for a visit to a "Soapland" red-light district. The "Soapland" districts in Japanese cities are not an ordinary European or American red-light district. Like the fantasy land of the "love hotels" which provide much-needed romantic privacy for young couples living with parents or with their children in tiny living quarters with no privacy, a "Soapland," like Kobe's venerable Fukuhara district,

leaves nothing to be desired in terms of local color, and works up a merry throng on Saturday nights (the streets are nearly deserted on weekday nights). In Fukuhara's unimaginably gaudy streets, the predominant bordello architecture would put even the most fanciful love hotels to shame. The usual shoguns' castles are dwarfed by edifices with stucco baroque façades arrayed with colorful *son et lumière*, and the odd rickety little old Japanese brothel is eclipsed by adjacent chrome-and-smoked glass pleasure domes and sci-fantasy ferroconcrete extravaganzas from some Babylonian lunatic fringe. Here and there touts in proper *yakuza* uniform lounge in front of the doorways, all short-cropped frizzy hair and neon lights winking kaleidoscopically in their dark glasses. Otherwise pandering seems undertaken entirely by the descendants of the old *yarite*, aging women sitting on chairs and hailing passers-by.

Fukuhara's Soapland foyer interiors have to be seen to be believed. Sprayed fluorescent pink, statuary modeled after Botticelli's Venus rising from the waves stand blushing outlandishly beneath a red roof evoking a Shinto shrine; traditional Japanese cranes in chromium wing their way across a back lit diorama of the Château de Chenonceaux. . . . In the interests of mandatory discretion, the showy façades completely conceal the executrices within. Upon crossing the threshold, it becomes apparent that Soapland ladies join the employees of cabarets and pink salons in a great variety of fancy dress: old-time

courtesans in florid kimono, nurses, airline flight attendants, bunny girls, Suzy Wongs in high-necked mini cheongsams slit up the sides, SM leather goddesses and Buddhist and Catholic nuns (Bornoff 1991, 271, 263-264)

[The leisurely ritual of a Soapland visit, as described by Bornoff, starts with a ceremonial undressing, followed by a relaxing sudsy sponge bath and gentle massage, a rinse, and a lather dance (*awa-odori*) or body-body massage in which the *Toruko-jo* (female) or *Sopu-reedi* (Soap-Lady) massages every part of her client's body with every part of her body on a king-size inflated rubber mattress. Another rinse and a skillful *shakuhachi*, in which the Soap-Lady displays her charms, lead into an artistic performance of sexual arousal that culminates in intercourse. All this occurs with a curious single-minded determination and absolutely no pretense of emotional involvement.

[The old-style, leisurely coital sex play with *geishas* and Soap Ladies, however, is declining in favor of quick, cheaper (and hence, more frequently affordable) masturbation, oral sex, and voyeurism. The equivalents of "fast food," non-coital sexual release for males now account for nearly half of the commercial sex trade. *Herusu massagi* and *fashion massagi*, health and fashion massage, are increasing in popularity. Independent women work in the videogame halls, discos, date coffee shops (*deeto kissa*), mobile van services (*Pinkku Shiataru*), lovers' banks (telephone date clubs), nude photo studios (popular in the 1970s and in decline since), or wait for calls responding to the pink leaflets (*pinkku bira*) they post in appropriate public places or drop in private mail boxes (see Section 8D, Significant Unconventional Sexual Behaviors, Prostitution, in the chapter on the United Kingdom for a British parallel to *pinkku bira*). One factor in this shift is the high-pressure life and lack of leisure in the male business world; most white-collar workers (salarymen) do not have a lot of leisure time or spare money to spend on the traditional commercial sex. Another factor, of course, is a recent growing awareness and concern about AIDS (Bornoff 1991, 282-300).

[According to a 1981 survey, younger prostitutes remained in the trade for three to four years; another small survey of sex workers in the Senzoku-Yoshiwara area in 1988 showed the average age was 26 and careers lasting about 16 months. In the 1986 survey conducted by the Prime Minister's Office, nearly 10% were housewives, another 10% office employees, and 4% students. More than half cited "making a living" as the motivation, 14% were doing it "for the sake of the family," 11% were doing it to pay off debts, while others cited money for clothes, travel, and leisure (Bornoff 1991, 273, 334). (End of comment by R. T. Francoeur)]

### C. Pornography and Erotica

Arguments over the definition of pornography in Japan tend to converge on the issue of what is obscene. The Japanese courts define obscenity as that which "excites or stimulates sexual desire to no purpose, causes harm to a normal person's sense of sexual shame, or goes contrary to a good sense of sexual morality." However, it would be reasonable to say that an interpretation of this correlates with social and cultural changes of the times. In fact, when D. H. Lawrence's novel, *Lady Chatterley's Lover*, was translated into Japanese and published in 1957, it was deemed obscene and banned. Now, in 1996, the same fully translated book is published without problem. In addition, until just a few years ago, photogravures of nude models in which the pubic hair can be seen were never printed in magazines. Now, however, seeing the pubic hair of nude models in Japan's weekly magazines that target adult readers is no longer a novelty.

When discussing pornography in the context of Japanese culture, one cannot leave out the *shunga* genre of the Edo period (1603-1867). *Shunga* is an art form that enjoyed high regard among the people of its time, but at the same time was kept secret. That is telling of the great artistic impact *shunga* had on society and, consequently, the ambivalent state of people's sense of shame, which was attacked by this shocking art form. Even Japanese today are most likely divided in their opinions of whether or not *shunga* is pornographic or obscene.

Turning our attention to modern times, Japanese who live in the big cities frequently come across shops that specialize in "adult goods," similar to what one might see in Europe or America. These adult shops house rows and rows of magazines and videos for the purpose of showing explicit sexual activity, although the sexual organs have been painted black or obscured. The reality is that even a junior high school student, albeit one big for his age, could enter such a store and make a purchase. Thus, one could say that Japan is completely open to pornography.

Japanese are often described as ambiguous, neither black nor white, but in a nebulous state of indecisive gray. They do not denounce the adult stores nor do they speak of them in good terms. They merely let the situation stand in a state of ambiguity. Once a year or once every few years, the police crack down on these stores, at which time the media raises a fuss over the issue for a short time, and then once again the problem is forgotten.

Recently, some mothers' and women's groups began a campaign to banish pornography from the viewpoint that it is degrading to women. How to effect a change in the male consciousness in order for such grassroots activities to take root is now a major topic, albeit one which is only being discussed among women.

### *Sexually Violent Fantasies in Comic Books*

A contribution to a local newspaper in the summer of 1990 complaining that the contents of comic books had become grossly obscene sparked debate between freedom of expression in Japanese comic books and the negative influence these magazines have on young people. This debate has grown into a major social issue. It is certainly true that a great many scenes in the comic books read by young boys and girls would trouble sensible adults. It should be noted that the authors or publishers of these comics have exercised self-imposed control concerning sexually explicit matter. However, there has been apparently no control from either party in limiting scenes containing violence.

This tolerance of violence is because of the norms of Japan's male-dominated society and to its long history in which violence was condoned as a symbol of manliness. As a result, the sexual content of comic books aimed at young people has been curbed, whereas the authors and publishers have been given free rein in depicting violence (Bornoff 1991, 69-71). The past few years, however, have seen an active increase in movements, spurred on largely by women's groups, to denounce sexual violence in the media. As a result, major enterprises, publishers, and television stations have revised their presentations of sexual violence. However, there are always people, in any society, eager to make a profit through work in the underground. It is an undeniable fact that comic books depicting sexual violence can be found in Japan today. Now, many people are crying out that urgent attention be given to sex education, in order to confront the sexism, gender bias, and sexual depravity found in such people as the authors and editors of these comic books. (*Editors' Note:* See also the following two sections on "Ladies Comic Books" and

Perper and Cornog's discussion of Sex, Love, and Women in Japanese Comics.)

### [*"Ladies Comic Books"*]

[*Comment 1997:* One type of popular Japanese erotic comics (*ero-manga*) is the "ladies comic books" that seem to glorify sexual violence and rape. These are not a tiny fringe phenomenon—*Amour*; the leading such comic, has been published for six years and claims a sales circulation of 400,000. *Amour*, *Taboo*, *Cute*, *Scandal*, *Love*, and other similar *ero-manga* have a greater impact than their substantial sales would indicate because copies are often passed around among friends. Even so, these magazines are also not standard fare for the average Japanese woman.

[The paradox of these "ladies comic books" lies in the fact that, although their readers are overwhelmingly women mostly in their 20s and 30s, the cartoon stories glorify sexually passive women, sexual violence, and rape. Ninety of the 316 pages in the December 1995 issue of *Amour*, for example, contained rape scenes. Despite the growing independence of Japanese women, these comics portray passive women being brutalized rather than assertive women who control their own lives. When interviewed by a *New York Times* reporter, Masafumi Mizuno, editor of *Amour*, admitted that "Sometimes we carry stories where the woman takes the initiative, and those kinds of stories have their fans. But most readers seem to prefer when the women are in a passive position." Mariko Mitsui, a former politician and active feminist, finds it puzzling that many young Japanese women really do not want to be liberated. "They want to escape independence, and so for them to be raped seems better" than negotiating their own sexual encounters.

[Another popular comics theme, particularly in those aimed at teenage girls, deals with romances between gay men. These are less graphic and more sentimental than stories of heterosexual romances. They are also erotically engaging without being personally threatening for teenagers who are just discovering their sexuality (Kristof 1995). (*End of comment by R. T. Francoeur*; see a detailed account of *manga* comics in the following section.)]

### [D. Sex, Love, and Women in Japanese Comics]

TIMOTHY PERPER and MARTHA CORNOG

[*Comment 2003:* In this comment, we address the sexual content of modern Japanese comics (illustrated books), an art form known as *manga* ("manga" rhymes with "conga"). *Manga* represent a non-Western, non-Christian, often quite erotic art form widely read in Japan and increasingly popular in the United States. *Manga* are very different from the Western comic book because they are deeply rooted in the Buddhist and Shinto belief systems, and antagonistic to the Neo-Confucian patriarchal social structure, which few non-Japanese readers and analysts understand or appreciate. Hence, Hatano and Shimazaki's descriptions of Basic Sexological Premises (Gender roles, Sociological status of males and females, and General concepts of sex and love) in Section 1 of this chapter and their reflections on religious and ethnic factors affecting Japanese sexuality in Section 2 are vital to our comments on *manga* (Perper & Cornog 2002).

[*Manga* are unfamiliar to many (especially older) non-Japanese readers, and the English-language scholarly literature about it is small (exceptions include Schodt 1986, 1996; Shigematsu 1999; Shiokawa 1999; and a recent monograph of our own, Perper & Cornog 2002). Yet in Japan, *manga* are read by millions of people of all ages and represent some 30% to 40% of Japan's total yearly print output (Schodt 1996). Translated *manga* comprise the fastest-growing component of comics marketed in the U.S. (Boyd 2001). How-

ever, U.S. media coverage quite typically misrepresents the content and meanings of *manga*. For example, the dictionary in the word processing program we are using defines *manga* as “a Japanese style of comic book or animated cartoons, often very violent or erotic” (Encarta 1999). This sort of description is also widespread in newspaper articles (Kristof 1995; Rutenberg 2001), but is nonetheless very wide of the mark. We believe that readers must understand sexuality in *manga* in its own terms rather than as reflected through fundamentally inaccurate media reporting.

[But far more is involved than simply correcting media misrepresentations. *Manga* derives from Japanese aesthetic and erotological traditions, and both are very different from what Westerners may believe is universal about sexuality.

### [The Japanese Cultural Background of Manga

[*Aesthetic Traditions*. Japan has at least an 800-year-old tradition of “serial art”—stories told in sequences of pictures (Schodt 1986). Early examples were drawn on scrolls, and include illustrated romances (*emonogatari*) and illustrated versions of the Tale of Genji (originally written approximately a thousand years ago by Lady Murasaki Shikibu; Hirota 1997). These graphic traditions flourished throughout Japanese history, culminating perhaps during the Tokugawa Shogunate (1600-1868) in the polychrome woodblock prints of Hokusai, Hiroshige, and Kuniyoshi. As a genre, these include prints of cities, markets, and landscapes, as well as pictures of the “floating world” (*ukiyo-e*) and its courtesans, performers, and everyday dramas (Lane 1999). Notable also are sexually explicit *shunga* prints, which achieved mastery of art and eros rarely if ever seen in Western art (Fagioli 1998; Kronhausen & Kronhausen 1978, Vol. 1, pp. 260-312; Vol. 2, pp. 211-270). Iconographies of female beauty emerged, for example, in the work of Utamaro and Harunobu, in which female loveliness is irresistibly compelling, not merely sexy or pretty, but transcendent (Hájek n.d.; Kobayashi 1993; Kondo 1956).

[With the opening of Japan to widespread Western influences in the late 1800s, Japanese artists drew on Western graphic traditions to reshape Japanese art, but these developments were truncated—or even aborted—by the rise of nationalist, militarist, and imperialist power in Japan. With the end of World War II in 1945, Japan rebuilt its state institutions, including virtually complete prohibition of censorship. These factors interacted with the need for public entertainment in the desperate years after the war and with the introduction of Western comics and cartoons into Japan, processes that collectively set the stage for a rebirth of Japanese popular art. One result was the emergence of an ever-increasingly diverse art form today called “*manga*” (for a tabular view of this history, see *Manga* 1999, pp. 158-159).

[*Manga* can be classified by market niche: *shojo manga* for girls, *shonen manga* for boys, *seinen manga* for young adult men, including erotica for male readers, and *redi komi* or *redisu*, romantic/erotic *manga* drawn by women for adult women readers. Each has its own styles, audiences, and popular magazines. Many *manga* for adults—and not a few for adolescents and young adults—deal explicitly with sexuality (Dixon & Dixon 1999; Perper & Cornog 2002; Schodt 1986; Smith 1991). In fact, many *manga* have sexual content, even if not explicit.

[*Erotological Traditions*. Japan has long held beliefs about sexuality and about women that will seem startlingly liberal to Westerners. These combine with Japanese artistic traditions to yield some of the finest erotic art being produced in the modern world. Of particular interest are the roots of *manga* in Japanese erotological and religious traditions.

[Yet it is here that Western, particularly American, readers will have the most trouble. To Americans, sexually explicit depictions fall into either of two—and only two—categories: clinical material or pornography. Clinical material is marked by its emotional detachment, and pornography by its focus on producing sexual arousal. Neither is notable for artistry nor for sensitivity to the array of emotions and social contexts that swirl around sexuality. Indeed, Western pornography excels in decontextualizing sexuality in images of interpenetrating genitals and concupiscent intermingling. For some Americans, such images are unsavory, exploitative, or downright dangerous to individuals and families. To others, they are enjoyable and exciting, partly because the loss of context offers an escape from the sex-negative norms of everyday life. Within these Western social and historical frames for sexuality, it can be difficult—very difficult—even to imagine that a sexually explicit art could exist that does *not* decontextualize, exploit, or escape from everyday reality.

[One result is of considerable importance for understanding how *manga* (and Japanese animated video films) with erotic content have been received in the United States. Erotic *manga* is most often presented in the media, by marketers, and on the Internet as “*hentai*,” a Japanese word meaning “perversion,” but which has become a catchall word for anything sexually explicit from Japan. The outcome can be strange—for example, Yoshiaki Kawajiri’s 1992 animated film *Wicked City* has been called *hentai* even though its basic premise and narrative are religious redemption and motherhood. However, to the American eye, redemption cannot coexist with sexually explicit depictions, and, by default, such images are sluiced into the categories of pornography.

[Yet, Japan is in fact very different from the West. Because the main Japanese islands were never successfully occupied by invaders until the end of World War II, Japanese society retains complex and continuous connections with its ancient historical origins in agrarian life. Japan’s native religion—Shinto—centers on nature and its immediate connections to human existence, mediated through a multiple pantheon of spirits, divinities, and supernatural beings collectively called *kami*. Nor does Shinto or the many forms of Japanese Buddhism have the notion of original sin. Neither religion has a single Deity who acts as Law-Giver and Eternal Judge of human wrongdoing. Japan lacks—and has lacked throughout its history—an organized, hierarchical, and centralized church for which sexuality is thought to be a sure path to damnation. In many ways, modern Japan retains—and aestheticizes—an open “peasant frankness about things sexual” (Adler & Wolf 2000, 227, 469, 569). This is not to say that Japan is a peasant society—it is nothing of the sort. Instead, Japan is the only major industrialized nation that has *not* demonized sexuality under the rubrics of sin, danger, and pollution.

[Japanese sexual traditions and customs have origins in native Shinto beliefs and in Chinese Taoism, which both consider sexuality a positive moral and medical good for men and especially for women. Examples range from the Taoist-derived erotology of the *Ishimpo*, dating from the late 900s C.E. (Levy & Ishihara 1989), to Dr. Sha Kokken’s 1960 illustrated sex manual *Seiseikatsu no Chie [Hints for Sex Life]*, which sold millions of copies (Sha 1964). These traditions are alive and well in *manga*, particularly in *redi komi* or *redisu*, sexually explicit *manga* drawn by women artists for women readers.

[*Women’s Place in Society*. American readers unfamiliar with the complexities of Japanese society tend to think that Japanese women are oppressed, repressed, and disempowered by long-entrenched patriarchal rule. This is the image

of the timid and submissive Japanese woman tip-toeing with eyes downcast behind her husband. But like all media- and movie-derived clichés about Japan, this view is profoundly oversimplified, if not downright inaccurate when viewed within Japanese social and historical traditions (McClain 2002, 93-98).

[The Shinto pantheon includes powerful female *kami*, like the sun goddess Amaterasu Omekami, whose shrine at Ise is among the most beautiful in Japan. In legend, Amaterasu is the foremother not only of the Imperial line, but of the Japanese people themselves. Likewise, Japan's animist traditions have powerful priestesses and shamanesses (Ellwood & Pilgrim 1992, 50-51, 56-58, 72-73, 90). Images of female supernatural and spiritual power appear repeatedly in *manga* and will be incomprehensible if the reader insists on seeing Japan through Western stereotypes of the subordination of Japanese women.

[Likewise, women's literacy. Japanese is written in two native syllabaries—*hiragana* and *katakana*—plus characters called *kana* borrowed from written Chinese. From the 9th century onward, *hiragana* was used by women and was called *onna-de*—"woman's hand" (Japan 1999, 619). Women's literacy was initially the possession of a courtly class, like the Heian-era women writers, Lady Murasaki Shikibu and Sei Shonagon. But as urban merchant classes developed during the Tokugawa period, women's literacy increasingly became the norm, not merely because women worked in shops with their families (the wife or daughter who keeps books and accounts must be literate), but also because women read novels (Beasley 1999, 179). From the mid-1600s on, shrine and village schools began to proliferate, and McClain (2002, 84) shows a contemporary woodblock print of two women teachers instructing a class of children in calligraphy. One little fellow is busily poking his brush into a friend's nose, but another is studiously practicing *hiragana* while the teacher guides his hand. By 1907, the percentage of girls entering school had reached 96% (Kaneko 1995).

[Another factor conducive to gender equality was the development of agrarian small land holdings during Tokugawa Japan and later, in which members of a nuclear family farmed a small plot of land (Smith 1959; on p. 103, a Tokugawa-era print shows two men and a woman working next to each other threshing wheat). In these forms of family labor, men and women worked together in the fields, for example, planting and harvesting rice. The direct involvement of women in farm production seems to have left a powerful egalitarian imprint on gender relations: Planting rice may be back-breaking work, but in a nuclear farming family, the collaborative labor of both women and men was essential for survival. Hayao Miyazaki's beautiful and evocative 1993 animated film, *My Neighbor Totoro*, contains a number of segments showing the essential role—and great importance—of women in farm life as recently as the 1950s, the decade of the film's setting.

[These agrarian traditions are associated with sexual customs. Anthropologist John Embree described open sexual joking and flirtation in village life (1939/1995), and the 1999 Kodansha Japanese encyclopedia notes that "night visiting" and multiple liaisons long continued in the provinces (Embree 1939/1995, 193-194; Japan 1999, 413). In some areas, such as fishing villages in Western Japan, it remained customary for teenage boys and girls to sleep in communal lodges until the young people paired up and married (a custom called *neyado*; Yoshizumi 1995, 191, 197). It follows that traditions of open sexual expression were not merely the prerogatives of a "promiscuous" Heian nobility of a thousand years ago—as Morris (1964/1994, Ch. 8, e.g.,

pp. 225-228) seems to suggest—but have survived as living traditions in Japanese agrarian culture.

[These traditions remained alive as the three great urban centers of Japan developed—Kyoto, Osaka, and Edo (later renamed Tokyo). *Ukiyo-e* and *shunga* prints document not only a widespread urban acceptance of sexuality, but also an aesthetic principle that still reigns in *manga*: Women embody a variety of physical, emotional, and spiritual beauties and powers cohering in one person.

[Against these erotophilic and female-positive social forces have been arrayed a set of beliefs in male superiority and attempts to limit sexual activity. These broadly center on Neo-Confucianism. Neo-Confucianism was not a populist or grassroots movement, but was adopted by the upper and ruling classes, especially during the Tokugawa Shogunate, as providing a warrior- and duty-centered social system for the *shogun* and his high-ranking *samurai* retainers (Beasley 1999, 173; Hall 1968/1991, 181-185). From this vantage point of power, its adherents sought to impose Neo-Confucian doctrines top-down on Japanese society. The late 18th-century Neo-Confucianist ideologue Hosoi Heishu wrote, "When she is young, a girl must obey her parents. When she is married, she must obey her husband. When she grows old, she must obey her sons" (McClain 2002, 95). This social and political philosophy centers on obedience to one's superiors and ultimately to imperial power: The woman owes obedience to father-as-emperor within the family and to husband-as-emperor within a marriage.

[Neo-Confucianism and its underlying principles of male superiority and erotophobia had effects outlasting the fall of the Tokugawa Shogunate in 1868. Its tenets remained central to the militarist, nationalist, and imperialist policies that emerged in Japan of the 1930s. Kimura and Yamana (1999) trace the effects on women's rights, which declined for upper-class (noble) women during the Tokugawa period, then declined in general during the period of Meiji constitutionalism and later militarism, but rose sharply after World War II (see also Yoshizumi 1995). But even so, Westerners living in Japan before and during World War II stress the power and importance of women in local Japanese society, for example, in the village (Maraini 1959, 143, 260).

[It appears that Neo-Confucianist ideology was contested throughout its history and was never fully assimilated throughout Japanese society. Today, Japanese feminist writers stress the need to eradicate the last vestiges of Confucianist patriarchy (Sodei 1995, 216). But despite these vestiges, and despite the misogyny of some Japanese social circles, modern Japan seems much more similar to its pre-militarist traditions about women and sex than to anything that would please the Neo-Confucianist.

[A number of factors, therefore, combine to create a distinctively non-Western view of sexuality in Japan. These include medical and intellectual traditions that consider sexuality a positive good, religious beliefs that bring people into close conjunction with nature and its fruitional capacities, farming traditions that treat sexuality as normal and natural, and, in the cities, urban traditions of entertainment, theater, and the arts that bring sexuality and female beauty to the forefront. Equally important is the absence of religious erotophobia, in particular, the notion familiar to Westerners that sexuality is sinful in all but a very few contexts. Likewise, the failure of Neo-Confucianism to seize the popular mind and, later, the defeat of the militarists in World War II, reopened Japanese traditions of erotophilia and the view that sexuality is a positive good. Combine all these with traditions of sexually explicit art, and the erotic content of *manga* seems inevitable and unsurprising.

### [The Sexual Content of Manga

[Not all *manga* are sexually explicit, but most *manga* we have seen contain material of considerable sexological interest. Sexual representations range from lighthearted love comedy and satire to very serious dramatic fiction, and include virtually all forms of sexuality—romance, flirtation, kissing, courtship, sexual intercourse, oral sex, female and male homosexuality, sadomasochism, prostitution, orgies, transvestitism, hermaphroditism, incest, bestiality, voyeurism, and rape. Throughout these representations, sexuality in its many forms is contextualized by character, plot, and setting, so that it is not isolated from social and psychological meanings contained in the narrative. The result is an extraordinary diversity of content, emotional tone, and drawing styles in *manga* with sexual content.

[The discussion below is summarized from a monograph (Perper & Cornog 2002) in which we described the erotic content of *manga* translated into English and commercially available in the U.S. from 1999 to the present, supplemented by a smaller sample of untranslated *manga* available in Japanese-language bookstores. Readers interested in the details of the sample, together with a complete list of translated *manga* surveyed, are directed to the original paper. In the descriptions below, publishers are given in parentheses, and *manga* are categorized according to how important sexuality is to the narrative. The categories we use overlap more or less, and the reader should not take these categories as a rigid taxonomy. The range of depictions is considerable, from *manga* without any hint of sexual intercourse to stories that focus primarily on sex.

- [Category 1: No sexual intercourse.

Sexual intercourse is neither depicted nor implied. Other content of considerable sexological interest may occur, such as transvestitism or intense emotional depictions of adolescent or adult romance. Occasionally, partial or incidental nudity may occur, but is not the focus of the story. By definition, rape does not occur in this category. (Perper & Cornog 2002, 102)

[Included here are *manga* for boys (*shonen manga*) and for girls (*shojo manga*), plus a variety of specialized *manga*, e.g., about *mah jongg* or boxing (Schodt 1996) or about firefighters in modern Tokyo (Masahito Soda's *Firefighter! Daigo of Fire Company M*, Viz Communications). But also included here are stories about adolescent and young adult romance that deal humorously or seriously with sexuality and its meanings.

[One subgenre is the love comedy, like Rumiko Takahashi's *Lum\*Urusei Yatsura* and *The Return of Lum\*Urusei Yatsura* (Viz) and Ken Akamatsu's *Love Hina* (Tokyopop/Mixx). These stories typically focus on the endless vicissitudes of the protagonists' affections, usually presented as comedies of miscommunication and confused lust. Lum is a very pretty 16-year-old alien princess with a volatile temper and a tiger-striped bikini and matching boots, who comes to Earth as part of an alien invasion. When the invasion fails, she immediately finds herself an Earth boyfriend, Ataru Moroboshi, with whom she lives in his parents' house (Lum and Ataru also attend the same high school). Ataru's gaze and hands are constantly wandering towards other girls, and Lum is equally constantly zapping him with electric rays or throwing things at him.

[In *Love Hina*, the male protagonist, Keitaro, has failed his college entrance examinations and is at loose ends until he inherits a boarding house from his grandmother. It turns out to be a girls' dormitory, and although Keitaro never deliberately makes advances on the young women, he contin-

uously finds himself in compromising positions, like wandering by mistake into the women's side of the hot springs. In another episode, the young women—none of whom have boyfriends—are talking about kissing, and mischievously start kissing each other. But they are all very quick to retaliate against Keitaro if *he* overstrays the boundaries of propriety.

[Stories like these have a comic, even satiric, view of adolescent sexuality and its emerging emotions, embodied desires, and virtually complete lack of social skills. These narratives are comic because they often exaggerate the silliness of adolescence and because they drive the plot to deliberately absurd conclusions. But underlying the silliness is what can be called "selective realism." If the story never explains who feeds these always-hungry adolescents or who pays the rent, it never veers far from the deeper experience of adolescence as a period of genuine uncertainty about sexuality. Below the comedy, an adult reader will sense the fumbling confusion and mixed-up embarrassments of coming of age. Such plots caricature and displace adult sexuality onto the safer and less serious venue of adolescence.

[In another subgenre of young romance *manga*, feelings of anxiety, alienation, and disorientation come to the forefront. Miwa Ueda's *Peach Girl*, Fuyumi Soryo's *Mars* (both Tokyopop/Mixx), and Tomoko Taniguchi's *Aquarium* (CPM Manga) are far from amusing—indeed, they are quite compelling dramas. In depicting loss and anxiety, these narratives center on worlds in which girls bully each other, sometimes viciously, in which boys are never really trustworthy emotionally or sexually, and in which a girl's self-mutilation is not at all impossible (in *Aquarium* and in Mohiro Kito's *Shadow Star*, from Dark Horse Comics).

[Other examples include *shojo manga* such as Naoko Takeuchi's *Sailor Moon* and Clamp's *Cardcaptor Sakura* (Clamp is a group of four women artists from Osaka; both from Mixx). Both have heroines with superpowers, and both are immensely popular as *manga* and as animated videos. Ten-year-old Sakura has obtained her superpowers from a set of magical cards. But together with coming to peace with her magic, she must sort out her feelings for two boys who like her, and a young man, Yuki, who makes her feel "all floaty," a good description of Sakura's growing recognition that perhaps she loves Yuki and perhaps might someday marry him.

[In these stories and others like them, the absence of overt sexuality underscores not a world of asexual children or adolescents, but the reality that genuine sexual involvement is yet ahead of them. These narratives show young people who are still trying to organize and make sense of their sexual feelings, a task made harder because they may not even recognize that their feelings *are* sexual.

[Also of considerable interest are depictions of gender fluidity, including a variety of male-female interconversions. Rumiko Takahashi's *Ranma 1/2* (Viz) and Hiroshi Aro's *Futaba-kun Change* (Studio Ironcat) portray the mix-ups and confusions that attend the magical and repeated transformation of the protagonists, Ranma and Futaba, from male into female and then back. Because these are comedies, transformations always occur at maximally embarrassing moments—for example, when Ranma-female or Futaba-female morph into their male forms in the ladies' bathroom, or when Futaba, now in female form, discovers that "she" is menstruating.

[Transvestitism also occurs in *manga*. Early examples include Osamu Tezuka's *Princess Knight* (from the 1950s and 1960s; Schodt 1986, 95-96, Fig. 114) and Riyuko Ikeda's *Rose of Versailles* (1972-1974), whose apparently

male “hero,” Captain Oscar Franois de Jarjays of Marie Antoinette’s palace guards, is actually a woman (Schodt 1986, 215). *Cardcaptor Sakura* contains a charming example, when Sakura gets to play the Prince in a school performance of “Sleeping Beauty” wearing an elegant doublet, cape, high boots, plumed hat, and sword.

[In Masukazu Katsura’s *Shadow Lady* (Dark Horse), the 17-year-old heroine, Aimi Komori, has an alter ego, the supersexy and superpowered cat burglar Shadow Lady. In one episode, the all-male Anti-Shadow Lady Squad of the police force wears wigs and dresses in an attempt to capture her in a department store late one night. But she is vastly amused by the hairy legs and distinctly unfeminine figures of the “female” mannequins that surround her in the cosmetics section. So she strips to her underwear and gleefully flaunts her real femaleness before the frustrated men, who of course cannot capture her.

[Juniko Mizuno’s *Cinderella* (from Viz; note spelling) is a satiric noir retelling of the classic fairytale, where Cinderella’s father operates a bizarre *yakitori* restaurant (*yakitori* being a kind of skewered chicken dish). He dies but returns as a bright-green zombie with a new zombie wife and her zombie daughters, one of whom complains (or boasts) that she never wears a bra because her breasts are too large. Cinderella tries to cope by making bras for her new stepsister, and *yakitori* sauce for the restaurant (from spider eggs and rice wine). But then she falls in love with a zombie idol singer named The Prince. A helpful fairy disguises Cinderella as a zombie—very pretty, and also bright green with flesh coming off in green blobs. Thus transformed, Cinderella attends a concert by The Prince, who falls in love with her. As dawn comes, Cinderella runs away, losing not a slipper but an eyeball. The Prince mounts a search for the eyeball’s beautiful owner, and eventually The Prince and Cinderella are united, with The Prince now singing at the restaurant. The characters are all very cute—in Japanese, *kawaii*—but overall, the story is an acid satire of the pretensions of love and family.

[Although sexual interactions are not depicted explicitly in these stories, sexuality is always present in one form or another. Rather than artificially desexualizing life, these stories see sexuality as intrinsic to human existence, sometimes funny, sometimes dangerous, but never to be denied.

- [Category 2: Sexuality is an on-going presence, but is as yet not explicit.

Sexual intercourse among the main characters is not depicted explicitly but may be mentioned or joked about. Other sexual dynamics may occur in on-going manner, either jokingly or seriously. Rape may occur. (Perper & Cornog 2002, 102)

[This category blends into the first, but typically the protagonists are older or are more deeply involved with their social settings. A good example is Katsuhiro Otomo’s six-volume *manga*, *Akira* (Dark Horse), which became famous as an animated film. It is an extremely complex story about a post-apocalyptic world in which mutant telepathic and telekinetic children vie with neo-imperialists for the control of a war-devastated Tokyo. The imperial soldiers—little more than teenage thugs—wander through the wreckage, raping and pillaging in desperate drug- and power-induced hallucinations. For the antihero, Tetsuo, the only solace is his sexual liaison with a young woman, but not even sex is an anodyne for the catastrophic destruction of society.

[Yukito Kishiro’s nine-volume masterpiece, *Battle Angel Alita* (Viz), is likewise set in a post-apocalyptic future city, called Scrapyard. Here too rapists abound, as do piles of

junk and trash, dysfunctional cyborgs, insane cybersurgeons, and a deadly game of rebellion and war with a ruling class that lives in the floating city of Tiphares. Alita herself is a cyborg warrior, discovered by cybersurgeon Doc Ito as a half-destroyed body in a junk heap. The story traces Alita’s path of self-discovery from her early love for Hugo, a human who is killed trying to reach Tiphares, to an end in which Alita becomes a *bodhisattva*-like savior of the world.

[Like *Akira*, *Battle Angel Alita* centers on a world that has collapsed into chaos, in which personal epiphanies through sexuality or drugs cannot repair the damage. *Battle Angel Alita* deals with karma, in the sense of a sequence of events set into ineluctable motion as the past reverberates into the future. The almost off-handed presence of sexual themes creates a sense of adult realism in these stories that transcends noir fantasy.

[Clamp’s *Clover* (Mixx) is among the most beautiful *manga* ever drawn. It is apparently unfinished, but centers on Suu, a young woman with immense telekinetic powers, and a soldier, Kazuhiko, who is commissioned by a military council of wizards to bring Suu to an amusement park. Unbeknownst to Kazuhiko, Suu is apparently trying to find a beautiful young singer named Ora, who had been Kazuhiko’s lover before she died. We do not find out if Suu’s quest succeeds, but the depiction of Ora and Kazuhiko is among the masterpieces of erotic art, not for being explicit (it is not), but for its evocation of intense erotic love. Here too, sexuality is woven into the fabric of life.

[Likewise, Hiroyuki Utatane’s *Seraphic Feather* (Dark Horse) is a masterpiece of drawing and design. It is set in a city being built on the moon, where a wrecked alien starship has been discovered. The protagonists are Sunao Oumi, a fretful young man, and Kei Heidemann, a virginally lovely girl whom Sunao rescues from a terrorist bomb explosion in the spaceport. Their growing love arises from Kei’s mysteriously forgotten childhood friendship with Sunao, and is set amidst corrupt corporations and politicians, assassins, plus strange alien robots and their ambitious master, Kei’s brother-in-law, Apep.

[But Utatane’s crowning achievement in *Seraphic Feather* is United Nations Special Investigator Attim M-Zak. She has the augmented powers of body and mind of an “Angel Class” agent, and is simultaneously erotic, beautiful, proud, and inwardly melancholy. Her sexuality glows through her every action, not as consummated sexual intercourse, but as a source of her power and pride.

[Certain themes link *Shadow Lady*, *Alita*, *Ora*, and *Attim M-Zak* together. Their openly powerful sexuality does not weaken them nor make them the helpless playthings of men. None is submissive, and none is passive. Neither does their femaleness make them second-best copies of men—for example, female characters who imitate male superheroes. Instead, in these depictions, femaleness is a self-complete state of being. These women do not need or want men to guide them or rule over them. Attim and her heroine sisters act for themselves, and therein we sense not merely resistance to Neo-Confucianist themes of women’s subordination, but their final demise.

- [Category 3: Sexuality is increasingly important and explicit.

Sexual intercourse is explicitly depicted or clearly implied in the drawings. Other sexual activities, including rape, may also occur. All are significant to the story, but are not its central focus. (Perper & Cornog 2002, 102)

[Once again, the range and diversity of narrative is striking. Naoki Yamamoto’s *Dance Till Tomorrow* (Viz) is an ironic

view of an alienated generation of slackers, *yakuza* gangsters, relatives scheming over an inheritance, and a woman hired to seduce the presumptive heir, all admixed with dry humor, explicit sex, and a crazed roster of characters. By contrast, Hideo Yamamoto's *Voyeur* and *Voyeurs, Inc.* (both Viz) are grimly realistic depictions of a firm of young private detectives. In the first major episode of *Voyeurs, Inc.*, they are hired to spy on a high-school girl who, it turns out, is running a prostitute ring starring the services of her classmates. (The story is based loosely on real-life high-school prostitution that began, it is said, in Tokyo's Shibuya High School; Kimura & Yamana 1999, 75-87.) Matters are much worsened when they discover that her father wants to seduce her. *Paradise Kiss*, by Ai Yazawa (Tokyopop/Mixx), is a stylish and elegant story about high-school senior, Yukari, her decision to become a fashion model, and her love affair with George, a young fashion designer at the Paradise Kiss boutique. Yukari has never even dated a boy, let alone kissed one, when she decides that she will sleep with George—and she does.

[Historical *manga* like Kazuo Koike and Goseki Kojima's *Lone Wolf and Cub* (Dark Horse), Sanpei Shirato's *The Legend of Kamui* (Viz), and Takehiko Inoue's *Vagabond* (Viz) likewise incorporate sexuality into their narratives. Sometimes as rape, sometimes as consensual intercourse, sexuality cannot be avoided in the kind of aesthetic realism sought by these artists.

[But the significance of sexuality is not limited to satire or to aesthetic realism. Picaresque fantasies, like Johji Manabe's *Outlanders* and *Drakuun* (both Dark Horse), portray sexually enthusiastic heroines, for example, sword-swinging Princess Kerula with her lover Dard in *Drakuun*. When Kerula assassinates Emperor Gustav, she starts a major war between the Empire and her homeland, the tiny kingdom of Ledomiam. In the last published episode, a now-pregnant Kerula and Dard, Kerula's sister, Rosalia, and her rifle-toting female lover, Rua, plus a crew of other malcontents, are about to invade the Empire in an effort to topple Gustav's evil successor. In *Outlanders*, Princess Kahm is the daughter of the Galactic Emperor, which does not stop her from finding, bedding, and marrying a young Earthman named Tetsuya. In the end, her Imperial father kidnaps her, causes her to forget Tetsuya with a magical spell, and then orders her to kill him. But her memories return. She turns on her father in fury and kills him, not her husband, as the imperial world collapses into flaming debris. It is hard to imagine narratives better designed for subverting Neo-Confucianist ideologies of women's obedience to father and emperor.

[Rumiko Takahashi's masterpiece, *Maison Ikkoku* (Viz), is a 14-volume study of love, sex, and marriage in modern Japan. Like novelist Jane Austen, Takahashi depicts her characters in finely wrought detail, from Kyoko Otonashi's blinding grief at her husband's death after only six months of marriage, to her suspicious doubts about Yusaku Godai's motivations and protestations of love, and finally to her admission to herself and him that she returns his love. In parallel, Takahashi explicates the intricacies of an arranged marriage between Asuna Kujo, the daughter of a high-ranking and fabulously wealthy family, and Shun Mitaka, a young tennis coach from an equally wealthy family, who also loves Kyoko. For Kyoko and Yusaku, and for Asuna and Shun, the denouement centers on love and sexuality played out through complex machinations of family and class.

[Shun is skillfully maneuvered into marrying Asuna by both their families, who hold dynastic interests above everything else, and by Asuna herself. Asuna makes her marital intentions very clear—she arrives at his apartment one night

ready to sleep with him. Although he is too drunk to respond sexually to her or to remember what happened, and she soon leaves, he certainly understands what it means that she has left breakfast for him in his refrigerator. In delicate but unmistakable symbols of domesticity and food, she has said that they are already married. He cannot ignore her invitation—her chauffeur knew where she was, and therefore so does her family. As rumors start that she is pregnant (she is not), he yields to the social and emotional forces that surround him and soon makes a formal proposal of marriage to her family, which is accepted. Their story ends with the birth of twins and their recognition of their growing love for each other.

[The tapestry of events leading to Kyoko and Yusaku's marriage is different. Overwrought with anxiety about Yusaku's feelings, and having just refused Shun's proposal of marriage, Kyoko accuses Yusaku of having an affair with someone else. Stumbling through his furious denial and through their mutual uncertainties, they end up in a love hotel, only to discover that memories of her late husband prevent them from having intercourse. Painfully, they must set their feelings to rest. The later scene where they triumphantly do make love is one of the most powerful in all *manga*. They too marry, and *Maison Ikkoku* ends with the birth of their daughter, Haruka.

[In stories like these, sexuality and sexual intercourse are depicted as they exist in actual life, within complex webs of feelings, intimacies, doubts, pleasures, and responsibilities. Sex is intrinsic to the narrative because it is inescapable in life itself.

- [Category 4: Sexuality is central.

Explicitly depicted sexual intercourse and other forms of sexuality are a major narrative focus. (Perper & Cornog 2002, 102)

[Virtually all forms of sexuality occur in this category, and their diversity is hard to summarize. However, a few generalizations will be useful.

[Erotophilic consensual intercourse is typically loud, ecstatic, and drenchingly wet, especially for women. Women are often portrayed as erotic, powerful, and very beautiful (we have identified at least five modalities used in *manga* for depicting female beauty and sexual allure; Perper & Cornog 2002). Female sexuality is virtually never a source of shame or punishment, perhaps most notably in the sexually explicit *redi komi* subgenre drawn by women artists for women readers.

[Our sample contains relatively few depictions of male homosexuality, but the fan-drawn genre of YAOI, with its beautiful young men passionately in love with each other, is very popular in both Japan and the U.S. (YAOI-Con 2002). Female-female sexuality occurs more frequently in commercial *manga*. Some are casual encounters, but other stories depict the two women as partners and lovers in long-term relationships (Pamila and Pfil in Kondom's *Bondage Fairies* from Eros Comix, Princess Rosalia and Rua in Johji Manabe's *Drakuun* from Dark Horse, and Sheila and her friends in Ryo Yuuki's *Sheila's Diary*, from RedLight Manga). Sometimes, female-female sexual attraction is only suggested by gazes, touches, and intense emotional bonding, for example, between Utena and Anthy in Chiho Saito and Be-Papas' *Revolutionary Girl Utena* (Viz). However, in Kunihiko Ikuhara's brilliant 1997 animated film of *Revolutionary Girl Utena*, the love affair between Utena and Anthy is not only depicted, but is the heart of the film.

[Because space is limited, we will focus on three themes—comedy and satire, spirituality, and alienation and rape.

[*Comedy and Satire*. Two artists come to mind when writing about explicit sexual humor in *manga*—Toshiki Yui and Haruka Inui. Yui's stories are populated not only by cheerfully erotophilic and very pretty young women, but also by incompetent demons, eccentric gurus, and puzzled young men, all enmeshed in wildly escalating plots. In Yui's "The Contract" (in *Misty Girl Extreme*, from Eros Comix), Misty is hoping for sexual ecstasy when she summons a demon. Although he promises to drive her mortal mind insane with pleasure, he manages only one premature ejaculation, and disappears muttering and mumbling as Misty loudly expresses her disgust at how useless he is. Yui's *Wing-Ding Orgy* (Eros Comix) is a five-part parody about virginal Keisuke, his reluctant girlfriend, Michiko, and two female spirits, Ruki and Mana, who materialize to assuage his sexual desires. After the malfunction of a magical dildo obtained from a lunatic psychic guru, Keisuke seeks the help of a sex therapist, which only makes matters more complex, as Michiko, Ruki, and Mana coalesce into a single ultrasexy female. In Yui's "My Little Darling" (in *Hot Tails* from Eros Comix), a suave demon makes a pass at Miki. When her angry boyfriend, Tetsuya, threatens him, the demon shrinks Tetsuya down to three inches tall and stalks off. Miki and the now-tiny Tetsuya discuss this problem in a coffee shop, and Tetsuya asks to sit on her lap. There he discovers that he can climb into her vagina. While she squirms in embarrassed orgasms, the demon returns and inveigles her to a love hotel. But when the demon's penis enters her vagina, it encounters the now enraged Tetsuya, who bites this intruding monster and sends the demon through the hotel's ferroconcrete wall. He regains his full size in a later episode, but for now, Tetsuya is happy with the advantages of his miniaturization.

[Inui's *Ogenki Clinic* (Studio Ironcat) is a long-running, slapstick parody of sex therapy. Therapists Dr. Sawaru Ogekuri and Nurse Ruka Tatase are sex-positive, but their treatments are unconventional, to say the least. Dr. Ogekuri's penis looks exactly like him, including carefully parted hair and eyeglasses (an example of genital personification, Cornog 1986). Yui and Inui's stories, among others, have female characters with penises and testicles (in Japanese, *shii meru*). In *Ogenki Clinic*, even a *shii meru* woman can have a personified penis, but this one has her face and long hair, and is therefore a female penis (Perper & Cornog 2002, 30). *Ogenki Clinic* was one of several *manga* considered harmful by Japanese authorities during the early 1990s (Kinsella 2000, Ch. 5, notes 1 and 2, p. 211), but from the perspective of the year 2003, it seems more satiric than dangerous.

[In an untranslated example by Oida Cute (from *Penquin Club Comic*, Issue 11, 2001), Hana-chan and her boyfriend are leaving a bar, and Hana-chan is quite drunk (little bubbles keep floating over her head). Once outside, she happily reassures him that she is fine—and then throws up all over him. They end up at a hotel, where Hana-chan falls asleep fully clothed while hugging a pillow. Then she wakes up, decides she wants sex, and begins to masturbate. She and her boyfriend go on to intercourse, but then she throws up again. The story ends with them both taking a shower together and laughing.

[These stories satirize male libido and its blundering desires, the frustrations and complex desires of women, and the vagaries of sex in an imperfect world. The root of the comedy is that sex is constantly running out of control—in the family, in Wolf Ogami's *Super Taboo* (Eros Comix); in the workplace, in Tetsu Adachi's *Weather Woman* (CPM Manga); and in the entire cosmos, in Ai Ijima and Takeshi Takebayashi's *Time Traveler Ai* (CPM Manga). In such goings-on, even the deities are laughing.

[*Spirituality*. Serious spiritual themes are not uncommon in sexually explicit *manga*. An example is *Zashiki Bokko*, by Senno Knife (from *Sepia* No. 2, Studio Ironcat), which opens with a note: *Azashiki bokko* is "a female ghost inhabiting an old inn." Young Masao has just returned to his family's hot spring spa (*onsen*) after graduating from college. The welcoming party is well under way, and someone asks him if he will decide to work here at the inn. And peeking at him from behind a sliding paper wall is a very pretty girl. "Koyuki!" he murmurs. The relatives joke that he has no cousin named Koyuki. "Must be a ghost," they laugh. In a flashback, he remembers years ago when they met in the hot springs, both naked. She stroked his back as he nestled between her legs, and he protested, "It's getting hard. Stop that!" But she pressed her face to his: "Don't be ashamed about it. When the time is right, I'll do it with you."

[Now alone in his bed, he wonders if she even remembers. But she peeks into his room and then enters and takes his hand. Together, they go to the *onsen*. "Do you remember the promise?" she asks as they swim together naked. They make love, entwined in the warm water, kissing and caressing. He wonders who she is, and decides that it doesn't matter. He wants to be with her always.

[Next we see his mother and grandmother talking—Masao has decided to stay and maintain the family inn. "It must be that ghost," says grandmother. "They say when you have a *zashiki bokko* then business will thrive." The final drawing shows Koyuki alone in the *onsen*, naked and beautiful: "I'll protect this inn as long as you are here with me." With her, the inn is protected against fire, bandits, storm, and desolation. She is the *kami* of the *onsen*, not a ghost in the Western sense, but a semi-divine female protective spirit—beautiful, erotic, and powerful.

[There are other examples of explicit sexuality, spirituality, and the supernatural. One is Hiroyuki Utatane's elegantly drawn "Ryu-Ho" (in *Countdown: Sex-Bombs*, Eros Comix), which retells the legend of Ryu-Ho, the first emperor of China's Han dynasty, whose mother was a mortal woman and father a dragon. Another is Jiro Chiba's *Were-Slut* (Eros Comix), about a young woman whose magical sexuality heals her lovers. A similar theme occurs in *Wolf*, by Harumi Shimamoto (in *Space Dreams*, from Studio Ironcat). An untranslated example is Iruka Banto's *Toga-Oi Byakuni* (roughly, "To the Nun, the Harm," from *Cute*, Issue 10, 1999), set in 1910, about the murderous hatred between young and beautiful Yukiji Wakao and her mother-in-law, Ohkura. Yukiji's family is high nobility but presumably impoverished, whereas her husband's family is nouveau riche (*narikin*) but without rank or status. Ohkura poisons Yukiji after learning that Yukiji has been having an affair with one of her husband's business associates. But as the supernatural enters the story, Yukiji returns to life, triumphant and transcendently beautiful, and it is Ohkura who dies.

[*Alienation and Rape*. These themes of spirituality draw on Japanese folklore and religion to create images of sexuality interwoven into the fabric of the universe itself. And yet, sex has a dark side. It leads to art delving not only into sexuality, but also into social chaos and disintegration.

[Such narratives set sex into a grim modernity in which loss of self, identity, and security is the norm. Stylistically, such stories lend themselves to an aesthetic realism recognizable by both content and drawing style—serious themes directly involving social issues and negative emotions portrayed in a gritty, edgy style emphasizing the absence of beauty and prettiness in the characters' lives (sexually explicit examples include the work of Benkyo Tamaoki, Ronin Tenjiku, and Akira Gatjaw, among others). This sort of real-

ism descends from the *gekiga* style pioneered in the 1960s and 1970s by artists like Sanpei Shirato (see Randall 2002ab, for a brief history and examples), but is also influenced by cyberpunk, e.g., William Gibson's 1984 pioneering novel *Neuromancer*; and by film noir, like Ridley Scott's 1982 *Bladerunner*. Now we encounter sexuality set in an alienated and anomic modern world or, more often, in post-apocalyptic worlds of social disintegration (*Akira* is an example). In those worlds, women's sexuality emerges not as pleasurable eroticism nor as passive victimization nor as a source of further chaos, but as *resistance* to death and disintegration.

[Masahi Shibata's *Sarai* (ComicsOne) is set in a post-apocalyptic world of social chaos and genetic disintegration. Sarai is a "guard maid," one of a group of young women who act as bodyguards and warriors. Sarai carries a *samurai* sword, traditionally a man's weapon, a visual trope that Neo-Confucianist masculinity can no longer protect society. But Sarai and the other guard maids can, or can try, to prevent utter chaos, sometimes by dispatching rapists and other vermin, and sometimes by saving the lives of their friends.

[One of the most extraordinary examples of a woman armed with a *samurai* sword is Saya, the protagonist of Benkyo Tamaoki's *Blood* (Viz), which combines themes of alienation, sexuality, and Japanese folklore into a sexually explicit horror story. It has a subplot involving explicit female-female sexuality, but *Blood* centers on the premise that a breeding program has existed for some 150 years for hybridizing human beings and ogres in an effort to obtain for humans the genes that confer immortality on the cannibalistic ogres. The program, ill conceived to begin with, has failed—the hybrids are worse killers than either parent species. Now the terrified human beings have bred Saya as an ogre-hunter, and although her American handlers treat her with great contempt—between assignments they keep her handcuffed and naked in a cell—they are quite willing to use her for exterminating the hybrids.

[Saya locates a motorcycle-riding gang of ogres in Yokohama ("sluts and thugs," someone calls them), and encounters their psychopathic gang-leader. She tracks him down to a wrecked and abandoned hotel, where he transforms into a monster who wants to rape and kill her, and devour her corpse. Saya beheads him with a single, sudden sweep of her sword.

[But she also encounters her counterpart, Maya, who, like herself, was bred from human and ogre stock as an ogre-hunter. But Maya is defective, and she needs human blood and flesh to live. Yet, it is Maya who tells her of their common ancestry and offers herself as a sacrifice for Saya to eat, thereby to fuse with each other and create their own future, independent of human beings. As Maya commits *seppuku*, Saya holds her dying body, waiting to complete Maya's request. Saya escapes, kills her American handlers, and, in the last images, walks through the dark streets of Tokyo seeking her and Maya's future.

[It trivializes the intensity and power of these images to dismiss them as fantasy or science fiction. Instead, we see women and their sexuality as embattled. Subjected to rape or to scientific but utterly wrongful breeding, these women find weapons and use them. When—to give another example—Attim M-Zak uses a sword to cut the arm off a man attacking her, the narrative has moved far beyond clichés of submissive Japanese women. Instead, we are in the territory of open resistance. But Saya's reaction to the rapist and to her handlers is not the resistance of a frightened child, nor even of an angry, defiant child having a tantrum. Saya is an adult, trained in the craft and use of a death-dealing weapon, and her purpose is to kill. Her ability to resist comes not

from a child's fear, but from her status as a mature and powerful woman.

[As *Blood* implies, no situation better illustrates themes of women's resistance and power than *manga* that deal with rape. Many critics of *manga* in the United States and Japan argue that it condones and glorifies rape. However, the data from our sample suggest the exact opposite (Perper & Cornog 2002, 45-54, 80-86). We identified 87 examples of sexual assault or rape in our translated sample. In them, we encounter a theme widespread in sexually explicit *manga*: rape followed by bloody revenge against the rapists. First we give several examples, and then some statistics.

[In "Dead Angela" by Kaz Yamane (in *Verotik 2: Verotika East*, published by Verotik), pretty and blonde Angela is the assistant to Professor Devore, an archeologist who has excavated a hitherto unknown bipedal skeleton somewhere in South America. Local terrorists invade the laboratory and machine-gun Professor Devore and then tie up Angela and repeatedly rape her. The terrorist leader shoots Angela, and her body falls backward against the skeleton. Its eye sockets start to glow, and it extends bony protrusions that surround her naked body. Now standing, its skeleton an armored carapace around her, she hears its voice in her mind: It is a living symbiont. "Master Angela, from now on, we are one. Your life is my life, your blood is my blood, your death is my death." She attacks the rapists, and, with one bloody sweep of her now-armored hand, she rips the head off the man who raped and shot her. The last panel shows her naked in her symbiotic armor, an icon of vengeance. The caption reads, "I am restored to life. We are not alone."

[Yuichiro Tanuma's *Princess of Darkness* (Eros Comix) is similar. It is a complex tale of dreams and demons centering on female art student, Maki Kurohara. In episode 4, she is sexually assaulted by five thugs, but invokes a murderous naked female demon armed with knife-bearing gauntlets who slashes the five men to ribbons.

[One of the most remarkable examples of rape-revenge occurs in Koh Kawarajima's *Immoral Angel* (published by Manga 18). Disgusted with humanity, the gods have decided to destroy the world. A man named Nekozo Kyusu, gifted with supernatural powers, is building an ark to save a selected number of his fellow humans (he contemptuously calls them lemmings). He kidnaps a high-school girl, Reimi, to be his mate and repeatedly rapes her. She resists each time, screaming and fighting, but his strength is too great. Finally, he abandons her, pregnant with his child.

[As the anger of the gods increases, the world is wracked by earthquakes, tidal waves, and other disasters. Nekozo abducts and rapes another young woman, but Reimi seems to reappear, naked. She reveals herself to be his and Reimi's grown daughter Rema, winged and vengeful. As father and daughter battle, his attacks go awry, and Rema taunts him with her mother's hatred and with his own powerlessness. Avowing that her one and only filial duty to him is to destroy him, Rema tears her father to shreds. She then destroys the ark, obliterating him and his life's ambitions.

[*Immoral Angel* deals not merely with rape-revenge, but also is explicitly anti-Confucianist. Earlier scenes of the mother's repeated rapes are balanced by the daughter's revenge. The conclusion, like that of most rape-revenge stories, is that rape is virtually a cosmic crime that demands and receives profound retribution and retaliation.

[An untranslated example is Go Nagai's *Devilman Lady* (KC Comics), about a woman martial artist who is also a demon. A ravaging monster attacks and rapes a woman, but Devilman Lady counterattacks, first castrating him and then killing him. As other monsters attack a group of children, she then destroys them in scenes noteworthy for their bloodiness.

[In the 87 cases of rape in our earlier sample, 80% or 92.0% show the woman or her friends taking violent and most often, murderous revenge against the rapist. An additional five (5.7%) showed rape as criminal, but did not include revenge. This gives  $(80+5)/87$  or 97.7% of the examples that are rape-negative. Only two stories (2/87, or 2.3%) showed rape as something that the woman desires. (See Perper & Cornog 2002, Appendix 2, for a complete annotated list of all 87 cases.)

[Since then, we have located a number of additional examples of rape-revenge, including *Blood*, *Immoral Angel*, and *Devilman Lady*. The occurrence of rape-revenge is a major trope in sexually explicit *manga*. It is not an artifact arising from our use of a translated sample, because the rape-revenge theme occurs in untranslated *manga* and in Japanese film, like Takashi Ishii's 2000 live-action *Freeze Me* and Yoshiaki Kawajiri's 1992 animated *Wicked City*. These conclusions are in line with Diamond and Uchiyama's (1999) well-documented argument that no correlation exists between pornography and rape in Japan, and also with Schodt's suggestion that *manga* may itself help reduce violent sexual crime (1996, 49-53). Rape-revenge *manga* rise in inexorable emotional intensity, which is released only when the rapists are destroyed and balance is restored between sexuality and the cosmos.

### [Conclusions

[The sexual content of *manga* ranges over a wide spectrum of activities, emotions, and meanings. These include cheerful and humorous erotophilia, serious sexual and erotically expressed love, and revenge and resistance to rape. Most often, sexuality is contextualized by character, narrative, and setting, so that it is portrayed as a fully human activity rather than being restricted to genital couplings.

[At its best, *manga* contain some of the finest erotic art in the modern world. Japanese traditions have not been lost in these portrayals. Much *manga* holds the reader's attention not only for the sheer beauty of the drawing, but as comic and dramatic narrative. Modern *manga* continues Japanese erotic traditions in representing sex as a positive and healthful good for both sexes. Strong, powerful women characters, innovative and unconstrained treatment of sexual themes, excellent artwork, and powerful plots make *manga* a force to be reckoned with as the medium gathers more and more readers worldwide. (End of comment by T. Perper and M. Cornog)]

### E. Sadism and Masochism

It is well-known that sadism and masochism (S&M) have been taken up in Japan's literature and paintings. A number of works by Sei Ito on the subject of *shibari* (bondage) are famous examples. One depicts a woman being tortured while a drooling jailer looks on in delight. Another shows a naked woman suspended upside down, while under her an old man is enjoying a drink of *saki*. These are typical of Sei Ito's works. Of course, works such as these are not part of Japan's mainstream literature or paintings, but rather are learned of only in the quiet mania of the back streets.

It is uncertain how many people are interested in this type of sadism and masochism today, but their numbers are not few. Roughly 10,000 magazines dealing in S&M are thought to be sold each month, by which one could estimate the number of interested people to be perhaps two or three times that number.

On the other hand, in the Japanese media's typical fashion of trying to stimulate the reader's interest, some minor weekly magazines print photographs or articles that depict situations with a sadistic mistress and a masochistic man.

Naturally, most of these depictions are contrived, as people who really practice S&M do so in secret, hidden from public view. Both Tokyo and Osaka have nightclubs in their busiest nightspots that make money off of S&M. Still, experts say that the people who go to such places probably realize it is all just an act.

## 9. Contraception, Abortion, and Population Planning

### A. Contraception

Various contraceptive devices became available in the democratic days after the war, including use of the pessary (diaphragm), contraceptive jelly and foams, and so on. Nearly 80% of Japanese people still choose the condom as their most favorable contraceptive device. This choice, however, is conditioned by the government's near-total ban on the oral contraceptive pill. [Update 1997: As of January 1997, only a medium-strength form of the pill was available in Japan for medical (non-contraceptive) purposes. However, some women were using it as a substitute for the low-dose contraceptive pill normally taken by American and European women. Originally, the Ministry of Health and Welfare cited the possible link between the hormonal pill (OCP) and cardiovascular disease, weakened immunity, cervical cancer, and thrombosis as its reason for not approving distribution of the pill in Japan. In 1996, new research studies undermined this objection, and the Ministry of Health and Welfare gave signs that it might remove its over three-decade-old ban on the OCP, perhaps even by the end of 1997. The Ministry admitted to some continuing concerns about removing the ban. There is a fear that, with the birthrate at 1.4 live births per woman, pushing the OCP might drop the birthrate even lower. More realistic is the fear that use of the OCP rather than the condom would increase the spread of AIDS among those who use the pill. More basic to the cultural values of Japanese men and women is the fear that Government approval of the OCP may send a signal of promiscuity and upset the delicate dynamics in male-female relationships. Even married women tend not to discuss contraceptives openly with their husbands. Traditionally, Japanese men are accustomed to taking the lead in relationships, especially when it comes to sex. Japanese women frequently express their awe at the independence of American women who make their own decision to use the pill. Nevertheless, after decades of public and national administration debate, approval of the OCP may be expected in the near future (WuDunn 1996). (End of update by R. T. Francoeur)]

Japanese contraceptive practices naturally reflect this limitation. According to the latest statistics, 77.7% of contracepting Japanese use a condom; one in five, 21%, use the Ogino method/rhythm method/BBT method; 7.1% use withdrawal (coitus interruptus), 7% rely on surgical sterilization, and 3.7% on the intrauterine device. The rather high popularity of condom usage among the Japanese people is because of the strong policy of the Imperial Army Administration throughout the militarist period, when it was consistently used to prevent various venereal diseases.

Margaret Sanger (1883-1966), the American nurse who eventually organized the International Federation of Birth Control, visited Japan early in the Showa Era, the late 1920s, to promote the birth control movement in Japan. At the time, the national administration disliked this idea because of its own policy of promoting childbirth for national security reasons. Thus, the government publicly opposed the birth control movement. Nevertheless, because the military widely promoted use of the condom for prevention of venereal diseases, it eventually was firmly accepted by the common peo-

ple in Japan as an effective method of birth control. Later, in the post-World War II years, this positive attitude of the Japanese people toward the condom functioned effectively in promoting the family planning movement.

Condoms are often sold to housewives by door-to-door "skin ladies." In 1990, moralists were disturbed when, after a marked increase in teen abortions, a condom company targeted the teenage market with condom packets bearing pictures of two cute little pigs or other cartoon animals and names like "Bubu Friend" (Bornoff 1991, 337).

The greatest obstacle in Japan to contraception is the national control of the contraceptive pill (OCP). In the 1970s, the promoters of feminism were openly against induced abortion and thus started a movement to make the OCP available. However, when they recognized that high-dosage OCPs had side effects, they changed their position and strongly opposed its free use. As is widely known now, the majority of current low-dosage OCPs pose little danger. Consequently, some of the current feminist promoters in Japan are not against expansion of choices by making low-dosage OCPs widely available. Nevertheless, the great majority of Japanese feminists still maintain their skepticism about the use of OCPs.

### [*The Female Condom and "the Pill"*]

[*Update 2001*: In June 1999, the 35-year-old government ban on the oral contraceptive pill was finally removed, prompted by serious criticism against the sexual double standard of the government regulatory board that approved Viagra in January 1999, an unusually brief six months after application from the pharmaceutical company. In November 1999, Japan's regulatory body approved the female condom, which clinical tests found to be 97% effective in preventing pregnancy. The female condom also received a very favorable relative overall acceptability rating of 89% (Reuters Health, November 12, 1999). (*End of update by Y. Kaji*)]

### [**B. Unwed Teenage Pregnancy**]

[*Update 1997*: Japan has consistently maintained one of the world's lowest incidences of out-of-wedlock births, well below 5% (Lewin 1995). A 1995 study by the Population Council, an international nonprofit New York-based group, reported that only 1.1% of Japanese births are to unwed mothers, a figure that has been virtually unchanged for 25 years. In the United States, this figure is 30.1% and rising rapidly (Kristof 1996a). (*End of update by R. T. Francoeur*)]

### **C. Abortion**

As has been mentioned earlier, the national policy of Japan after the Meiji Era, when Japan's modern national structure emerged, was to strengthen the nation. Thus, children were considered to be the treasure of the nation, and abortion was naturally deemed illegal.

With the rebounding of the post-World War II social order, the Eugenic Protection Law was implemented in 1948, and induced abortion became a fully legal and allowed method of birth control in Japan. The law set out certain premises to be satisfied for abortion to be permitted, but many accepted it quite readily. Thus, induced abortion became the most popular method of family planning in Japan in the mid-1950s, with 1.2 million abortions a year, an extremely high rate of 50.2 per 1,000 women annually. Later, the rate and the number of the induced abortions declined rapidly, dropping from 1.1 million cases in 1960, to 730,000 cases in 1970, and 457,000 cases in 1990. By 1990, the abortion rate was 14.9 per 1,000 women a year, less than a third of the rate of 40 years ago. This significant and important change came about because of the special effort of advocates of a sound family planning movement and the increased use of

condoms. It should be noted that this reduction in abortion and the popularization of family planning were achieved despite the unavailability of the oral contraceptive pill and a quite-low IUD usage rate.

Even though the current rate of induced abortion is becoming acceptably low, there are still disturbing elements in the statistics, mainly a gradual increase of abortion among teenage youths. In the 1970s, the total number of abortions for teenage pregnancy was approximately 13,000. This number increased to 14,300 in 1970, 19,000 in 1980, and 29,700 in 1990. The rates of abortion among women under 20 years of age increased as follows: 3.2 per 1,000 in 1960 and 1970, 4.7 per 1,000 in 1980, and 6.6 per 1,000 in 1990. Keeping in mind that the sexual activity of young people in this nation is increasing, it is apparent that more-efficient education of the youth for pregnancy prevention is strongly needed. For one thing, sex education within the public education system is far from being well developed in this country. The traditional value systems about sex and sexuality, such as the theory of purity education that prohibits and condemns premarital sexual activities as a crime, for example, creates burdens for the young people, even though two thirds of them accept premarital relations. Such beliefs often affect the sexual behavior of the young and interfere with their acquisition of knowledge and skills about pregnancy prevention.

[*Comment 1997*: Japan has no debate over the morality of abortion, and no politicians taking political stands for or against abortion. In fact, virtually everyone believes that abortion is each woman's own private business. Despite this wide acceptance of abortion, there is ambivalence about abortion among many Japanese women and men that reflects the dualism one finds throughout Japanese sexual attitudes. At Buddhist temples around the country, one finds galleries of hundreds, even thousands of tiny memorial statues dedicated to aborted fetuses, miscarried and stillborn babies, and those who died as infants. These *mizuko jizo* are dressed and visited regularly, sometimes monthly, by Japanese women who have had an abortion or lost a baby and feel a need to atone for their loss. Japanese women, and sometimes men, visit their *mizuko jizo* to express their grief, fears, confusions, and hopes of forgiveness for ending a human life so early, however rational and necessary that decision may have been.

[The concept of the *mizuko jizo* did not develop until after World War II and has since been linked more and more with abortion rather than miscarriages, stillbirths, or infant deaths. Even some gynecologists who perform abortions regularly visit the temples to purify themselves in a special Buddhist ritual. In former times, fetuses and even newborns were not believed to be fully human or to have a spirit or soul until the newborn was ritually accepted into its family and linked with its ancestors, so abortion and even infanticide was accepted matter of factly. The recent tradition of the *mizuko jizo* appears to satisfy many of the emotions and feelings traditionally suppressed in the acceptance of abortion (WuDunn 1996). (*End of comment by R. T. Francoeur*)]

### **D. Population Control**

From ancient times, population control, particularly in each village community, has been maintained publicly perhaps as part of the wisdom of the public welfare. In pre-modern days, the actual method often involved certain techniques related to primitive religions and/or incantations "turning childbirth changing into stillbirth." What in Western culture is termed infanticide was not necessarily considered illegal or unreasonable according to the faith and/or ethics of that era. According to authentic ancient belief and practice, the baby belongs to God until the very moment of

its first cry. Therefore, suffocating the newborn before it cried, before it was “really born,” and returning the incipient life to God was not considered wrong. Western culture would consider this culpable infanticide, but such was not the case in ancient Japanese beliefs; see the discussion of abortion and *mizuko jizo* in the preceding paragraph. [*Comment 1997*: Similarly, in many regions of China, a newborn infant is not considered “fully born” and human until the whole extended family gathers three days after the infant’s birth to celebrate its “social birth” and official recognition by the family’s patriarch and, through him, by the whole extended family and their ancestors. (*End of comment by R. T. Francoeur*)]

By 1995, the Japanese government had become so concerned about its plunging birthrate—1.53 per woman and declining—that the Institute of Population Problems, a part of Tokyo’s Health and Welfare Ministry, sent out questionnaires to 13,000 single Japanese citizens asking them what they thought about marriage, families, and children. In view of the plunging birthrate and a heating up of the war of the sexes, Japan is facing a demographic time bomb. As the population ages and the birthrate shrinks, the tax burden on the Japanese workforce will rise. Economists also suggest that Japan’s famously high rate of savings will increasingly have to support its retired population, and not factories and other productive investments (Itoi & Powell 1992).

[*Update 1997*: With its birthrate plunging to 1.4 in 1996—Tokyo’s birthrate was 1.1—Government projections suggested that within a hundred years, by 2100, Japan’s population will tumble to 55 million, from 125 million today. That would be the same population Japan had in 1920. At 55 million, Japan would have a population density five times that of the United States today, but its position as a global power would certainly be reduced, when in 2050 Japan’s population drops to just one quarter of America’s projected population. By the year 3000, it could drop to 45,000, according to a weekly magazine projection. To counteract this trend, many Japanese cities are paying women residents a bonus, up to \$5,000, when they have a fourth baby. Among the other incentives being considered are: cash upon marriage, cut-rate land for childbearing couples, importing Philippine women of marriageable age, and cash grants to parents when their children turn 3, 5, and 7, which are all auspicious birthdays in Japan. Because of the discouraging cost of childrearing, some have recommended an annual financial bonus. In 1995, when Prime Minister Hashimoto was Finance Minister, he suggested a novel way of encouraging fertility: Discourage women from going to college.

[In 1996, the average Japanese woman marries at 27. Seventeen percent of women in their early 30s are still unmarried. One of the reasons cited by women who chose not to marry was a common negative view of the Japanese male as a desirable mate (Kristof 1996c). (*End of update by R. T. Francoeur*)]

[*Update 2001*: With a 1998 Total Fertility Rate of 1.38 children per fertile woman, Japan is struggling to persuade couples to have more children and help avoid many long-term social problems. Japan’s current population of 126 million is expected to drop to 105 million by 2050. In those 50 years, the median age will increase from 41 to 49 and those age 65 and older will double from 17% to 32%.

[Prior to June 2000, salaried parents with an annual income below US\$67,000 and self-employed parents with an annual income less than US\$43,000 received a monthly \$50 subsidy for each of their first two children, and \$100 monthly bonus for subsequent children under age 3. The \$50 bonus covers 25% of basic monthly expenses for a child under age 3: food, clothing, and utilities. In June 2000, a

new law extended this bonus to children under age 6, more than doubling the number of parents who qualify. Similar past efforts have had scant effect. Social observers suggest that the major factor in Japan’s low birthrate is the increasing number of Japanese women graduating from universities, obtaining well-paid jobs, enjoying their independence, and marrying later in life. Another is the fact that Japanese men traditionally avoid any participation in household work and leave the whole burden to their wives.

[This trend, coupled with the rising number of legal and illegal immigrants attracted by Japan’s shortage of workers, will have serious repercussions for Japan’s future economy and workforce. In 2000, about 1.5 million foreigners resided and worked legally in Japan. But thousands of undocumented aliens are also pouring into Japan, from China, Korea, South America, and Ghana. In 1990, Japan had an estimated 110,000 undocumented immigrants; this rose to half a million in the year 2000. In 1989, 4,159 Japanese who had immigrated to Brazil a generation or two back returned to Japan. In 1998, 222,217 returned from Brazil. In 1989, 864 Peruvian *Nikkeijin* returned to live in Japan; in 1998, 41,317 returned to Japan. In Oizumi, a small industrial town 50 miles (80.5 km) from Tokyo, nearly 12% of the population is Latino.

[As Japan’s birthrate plummets and legal and illegal immigration accelerates, many aspects of Japan’s traditionally insular homogeneous monoculture are already changing, including the context and character of sexual attitudes and behavior. (*End of update by Y. Kaji*)]

[*Update 2002*: In March 2002, the Japanese Cabinet issued a report signaling concern over Japan’s plummeting birthrate and the aging population. In May 2002, Prime Minister Junichiro Koizumi ordered his top aides to draw up policies outlining plans to make parenthood more attractive and affordable for the country’s swelling ranks of childless 20- and 30-year-olds. Echoing the need for new social strategies to promote parenting, Health Minister Chikara Sakaguchi predicted that company employees would have to pay nearly 25% of their salary to pension premiums to maintain the current payout in 2025. Japan’s population is expected to peak at around 127 million as early as 2005. After 2005, Japan’s population is expected to fall rapidly over the next 50 years to roughly 100 million. Meanwhile, the “graying” of Japan will accelerate until, by 2050, 35.7% of Japan’s population will be over age 65, more than double the percentage in 2000. Demographers and economists do not agree on the effectiveness of new policies to encourage more young people to have more babies as a long-term viable solution. Faced with similar futures and failure of efforts to raise the birthrate, European and North American countries have stabilized their populations with immigrants (Greimel 2002). (*End of update by R. T. Francoeur*)]

## 10. Sexually Transmitted Diseases and HIV/AIDS

### A. Sexually Transmitted Diseases

Japan’s Venereal Disease Prevention Law has remained unchanged since it went into effect in 1958. However, venereal diseases (VDs) common at the time this law was established, along with genital herpes, chlamydia, trichomoniasis, and HIV/AIDS, have come to be called sexually transmitted diseases (STDs) in Japan, as well.

Of these STDs, HIV/AIDS excluded, typical VDs of the past, such as syphilis and gonorrhea, have followed a steady decline year after year. The number of gonorrhea cases, for example, reported to the Ministry of Health and Welfare, in line with the Venereal Disease Prevention Law, declined

from its peak of 178,000 cases in 1950 to 4,000 in 1964. Slight peaks in the number of cases reported were seen thereafter, with 12,000 in 1967 and 13,500 in 1984, but between 1970 and 1980, the number hovered between 5,000 and 7,000 cases. As concern for HIV/AIDS began to intensify in Japan in the 1990s, the number of gonorrhea cases showed a steady decline from 3,465 cases in 1992 to 1,724 cases in 1993 and 1,448 cases in 1994. As for the number of syphilis cases reported to the Ministry, a steady decrease can be seen from 6,138 cases in 1970 to 3,635 in 1975, 2,081 in 1980, 1,904 in 1985, 1,877 in 1990, and only 804 cases in 1993.

On the other hand, the actual number of herpes, chlamydia, and trichomoniasis cases is unclear since reporting of these diseases is not required. However, the Ministry of Health and Welfare began collecting data in the late 1980s from selected hospitals, with reports gathered from about 600 hospitals throughout Japan. This data suggests the following trends: Trichomoniasis and condyloma acuminatum have shown a decrease, albeit slight, but the same cannot necessarily be said for chlamydia and herpes. Reports indicate that the number of infections among people in their teens or 20s has become particularly striking. Such reports cannot be said to be unrelated to the increase in sexual activity among Japan's youth. Since sexual activity among these youths is expected to become even more prevalent in the future, it is obviously desirable that we tackle countermeasures for these STDs in earnest.

[Update 2001: The first sentinel surveillance of STD in Japan was conducted in 1998. Woman-man ratios of infection rates per 100,000 persons for each STD, and high woman-to-man ratios for overall STD incidence (1.40), condyloma acuminatum (1.11), genital herpes (2.25), chlamydia (2.31), and nongonococcal and nonchlamydial infection (1.51), challenge the current Japanese common understanding that STDs are mainly a male health problem treated by urologists. STD prevention and treatment in Japan should focus more on female patients (Kumamoto 1999). (End of update by Y. Kaji)]

## B. HIV/AIDS

Japan has not been quick to respond to the HIV/AIDS problem in its own country. Patients showing signs of Kaposi's sarcoma and *Pneumocystis carinii pneumonia* for which no cause could be found began to appear in America in 1981. The following year, the United States Centers for Disease Control and Prevention (CDC) began calling the syndrome AIDS. In 1983, it became known to the world that a virus, named HIV, was the cause.

At last, Japan's Ministry of Health and Welfare was moved to action, forming an AIDS research task force, which began surveillance for occurrences of AIDS in Japan. The first AIDS patient that the surveillance committee found was a homosexual returning briefly from America in March 1985. In May of the same year, they announced that AIDS patients contracting the disease through blood transfusions had been confirmed. In 1996, the country became embroiled in an extremely serious debate, in which the government or several committee members of the AIDS research task force and pharmaceutical companies were suspected of a secret pact to cover up the outbreak of "the real first" AIDS patients who had contracted the disease through unheated blood products. This problem was resolved in July of 1996 when the government and the pharmaceutical companies apologized to these victims and paid them an out-of-court settlement. However, not everyone feels that the agreement reached is a complete solution to the problem.

Turning to the situation of HIV/AIDS in Japan, current as of the end of May 1996, 3,642 people had been infected

with HIV (including those with AIDS symptoms), of which 1,806 contracted the disease through unheated blood products. Although these numbers are extremely low compared to those of other countries, one cannot discount that the HIV/AIDS problem in Japan is a large one. For example, only 13,703 people underwent examinations for HIV in 1995, just one third of the 37,774 tested in 1992, when the number of people taking the examination reached its peak. In Japan, the number of people taking the test has declined over the past three years, from which one could assume Japanese feel the danger of contracting HIV/AIDS is becoming more and more remote.

For those unlucky enough to contract AIDS in Japan, there are 203 AIDS-authorized hospitals throughout the country where one can receive treatment. However, the names of nearly half of these hospitals are currently not being made public. Furthermore, some hospitals, even some of the AIDS-authorized hospitals, refuse treatment to AIDS patients, as reported by the Osaka Plaintiffs in AIDS Litigation Organization.

Of course, not everything about the HIV/AIDS problem in Japan is negative. For instance, until recently, major newspapers and other companies serving the public, such as NHK Television, had not directly taken up sexual problems. However, with the current situation, including the HIV/AIDS problem, even the most straitlaced newspapers and television stations have begun to use such words as condom, homosexuality, and anal sex. Such a trend has engendered the makings of informative reports on human sexuality. This issue is not felt in the media alone; it is also having a great impact on Japan's educational system. HIV/AIDS is clearly introduced in junior high school textbooks on health as an infectious disease. Thus, all children in Japan are now learning about HIV/AIDS.

Furthermore, teachers of social studies, home economics, and homeroom classes are actively educating students about HIV/AIDS in order to dispel any prejudices and discriminations the students may have. Naturally, this education is not only aimed at HIV/AIDS discrimination, but is related to sexual discrimination, as well. Although sex education in Japan is not sufficient in its current state, this education aimed at HIV/AIDS and discrimination may be the breakthrough Japan needs, and perhaps a golden opportunity to firmly establish sex education in the schools. This can certainly be viewed as a positive influence.

[Update 1997: As of August 1995, the reported number of AIDS-related deaths was 626. The cumulative number of reported cases of HIV infection was 3,423 among Japanese persons and 881 among non-Japanese. Among this number were 1,803 hemophiliac patients who contracted HIV as a consequence of the use of contaminated blood products in their daily treatment.

[The incidence of AIDS in Japan is still very low, although some suggest that the official figures underplay the actual incidence and danger. Only 15 deaths from AIDS were reported in 1986 for a population of 120,000,000. By mid-1988, the death toll had risen to 46 with an additional 34 confirmed in hospitals, and 1,038 persons who tested seropositive.

[The initial response of the Japanese gay community to the AIDS epidemic in the early 1980s was misguided. Because the number of Japanese gay men infected with HIV had been comparatively low, many Japanese gay men, like the rest of the Japanese people, found it easier to view AIDS as an exclusively foreign phenomenon. Discrimination against foreign, especially Western, gay men by Japanese gay men was widespread. One consequence of the fear of AIDS is that homosexuals visiting Japan report

that many former gay paradises, particularly the no-holds-barred male sauna, are now closed to non-Japanese. (*End of update by Y. Kaji*)

[*Update 2001*: As of June 2000, Japan had an accumulative reported 5,058 persons infected with HIV and 2,367 AIDS patients. This number included 1,434 HIV-infection cases and 631 AIDS cases where the virus was transmitted by use of tainted blood products. Most HIV/AIDS cases in Japan are because of sexual transmission. Reported HIV/AIDS cases transmitted by IV-drug abuse or mother-to-child transmissions are less than 1% of the total cases. (*End of update by Y. Kaji*)

[*Update 2002*: UNAIDS Epidemiological Assessment: HIV prevalence rates in Japan continue to remain well below 1% for most HIV-risk-behavior groups, except among female sex workers of foreign nationality (2.7% from 1987 to 1999). Most reported HIV/AIDS cases in Japan during the mid-to-late 1980s and early 1990s were because of HIV-infected blood products that were imported for the treatment of hemophilia patients; a third of the AIDS cases (33%) reported in 1988 were in hemophilia patients infected through imported blood coagulation factor products.

[The high percentage of hemophilia AIDS cases is still the distinctive characteristic of HIV infection in Japan and is not seen in other countries in the world. However in 2000, about 78% of newly diagnosed HIV infections appear to have been acquired through sexual contact. One of the characteristics in recent years is that the infection through sexual contacts in Japan is getting higher among Japanese men. Almost all HIV infections in Japan are related to imported infections (including hemophilia infections), and then some limited transmission from these infected persons to their regular sex partners. Behavioral data show low condom use, both in the general population and among female sex workers (6% to 25%).

[Estimates suggest that, by the end of 2001, 12,000 persons were living with HIV, a prevalence of 0.02% among people aged 15 to 49 years.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	12,000	(rate: < 0.1%)
Women ages 15-49:	6,600	
Children ages 0-15:	110	

[An estimated 430 adults and children died of AIDS during 2001.

[At the end of 2001, an estimated 2,000 Japanese children under age 15 were living without one or both parents who had died of AIDS. (*End of update by the Editors*)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

Unfortunately, no compiled information is currently available on sexual dysfunctions in Japan. However, by drawing inferences from many researchers on the subject, certain facts come to light. The most common dysfunction, accounting for about half of all informally reported sexual disorders, is erectile dysfunction. Other common dysfunctions include sexual phobias, sexual avoidance, decreased sexual desire, dyspareunia (painful intercourse), female orgasmic disorder, vaginismus (painful vaginal spasms), homosexuality, and gender identity disorder.

One dysfunction that has become an issue of late is that of sexual inactivity among couples. Dr. Teruo Abe, a psychiatrist who studied under the American Helen Singer Kaplan, defines the term sexually inactive couples as "couples who do not engage in consensual sexual intercourse or sexual contact for a period of one month or longer, despite

the lack of special circumstances, and who can be expected to remain sexually inactive for a long period after that." Abe reports that the number of such sexually inactive couples during the period from 1991 to 1994 increased by 2 to 4 times the number between 1985 and 1990. Yet, over a ten-year period, only 303 patients with this dysfunction came to seek Abe's assistance. Assuming that there are about 50 institutions in Japan that treat this sexual disorder, estimating generously, then only about 12,000 to 15,000 people have visited doctors for this sexual disorder over the past ten years. While there are probably many opinions on whether this number is large or not, the number reflects the current state of the disorder in Japan.

There are no types of sexual dysfunctions peculiar to the Japanese. The most common dysfunctions are treated by such specialists as gynecologists, urologists, and psychiatrists, or clinical therapists and counselors. Unfortunately, these fields of medicine remain too isolated from one another in Japan. It would be desirable, therefore, for the medical institutes themselves to gain an understanding of all aspects of human sexuality.

In 1976, the Japanese Red Cross Medical Center was the first public medical institution in Japan to establish a sexual counseling center. Although before that time, sexual treatment was carried out in the gynecology, urology, and psychiatry departments of private and university hospitals, such treatment was mainly for functional disorders. It was very rare for these hospitals to provide treatment from the perspective of total human sexuality.

Japanese doctors, counselors, psychologists, and sociologists who first became aware of the importance of sexual counseling and treatment met and formed the Japanese Association for Sex Counselors and Therapists (JASCT) in July 1979. The Association welcomed Patricia Schiller, founder of the American Association of Sex Educators, Counselors, and Therapists (AASECT), as honorable chairman and adopted the ideology of her organization. The JASCT proceeded to take charge of sexual counseling and therapy in Japan and continues to do so today. JASCT's objective is to carry out surveys and research with the help of sex counselors and doctors who treat sexual disorders. They do not issue licenses in recognition of qualifications.

From what limited information is available, it certainly seems that Japan is very active in the treatment of sexual dysfunctions, but unfortunately the reality is that a lot more problems remain unsolved. Underlying those problems in Japan is the popular notion that sex is not something you talk about, and the belief that, except in cases of extreme pain, as long as you can tolerate the problem, it will heal in time and you will not have to bother others about it. Recently, however, an increasing number of people in their 40s or younger, who have been exposed to a more sexually open society in their youth, are moving away from this tendency and seeking sexual counseling and treatment.

## 12. Sex Research and Advanced Professional Education

### A. Research and Advanced Education

With the exception of such scientific subjects as reproduction and birth taught in the fields of biology or medicine, Japan's institutions of advanced education have only made sex a direct topic of research in the past two or three decades. Traditionally, sex has not been made a subject of learning in Japan's academic world. Thus, on the rare occasion that someone has pursued the study of human sexuality, that person has been seen as an outcast, and, at times, ostracized, as was the case with Senji Yamamoto, who taught

in the Biology Department of Doshisha University and, early in the 20th century, was Japan's first sexologist.

Although Japan became a democratic society in 1945 allowing for the freedom to study human sexuality, even in institutions of advanced education, a wall remained standing in the academic world inhibiting such freedom, and the wall was high and thick. No reason exists for the academic world to be separated from society. It has become gradually understood that sex education is necessary in higher education in order to address the various problems in Japanese society, such as sexual problems among youth, information on sex provided by the media, the issue of STDs and HIV/AIDS, and the phenomenon of more couples opting to rear fewer children.

Universities for training teachers and departments of education were the first to show an interest in teaching sex education at the university level. Regardless of its quality, sex education in Japan's elementary and junior high schools and institutes of advanced education is usually taken up in the health and science curricula. Therefore, it was natural for sex education to be first taught to those interested in teaching. Recently, an increasing number of departments of human science have been established in Japanese universities, wherein study of basic human sexuality has become abundant.

Still, sex education in universities and other institutions of advanced education cannot be said to be functioning sufficiently. Take, for example, the estimate that only about 5% of Japan's 1,150 universities and junior colleges provide lectures on human sexuality. One can assume that developing more programs on sex education in universities and other institutions of advanced education will become a major issue in Japan's educational system.

## B. Sexological Organizations and Publications

Until mid-1996, the authors of this chapter, Yoshiro Hatano, Ph.D., served as Director, and Tsuguo Shimazaki as Secretary of the Japanese Association for Sex Education (J.A.S.E.).

Japanese Association for Sex Education. Address: J.A.S.E., Miyata Building, 2F, 1-3 Kanda Jinbo-cho, Chiyoda-ku, Tokyo, 101 Japan. Tel.: +81-3-3291-7726; Fax: +81-3-3291-6238. J.A.S.E. publishes *Sex Education Today*, a monthly journal.

In mid-1996, Tsuguo Shimazaki established the Nikon Information Center for Sexology (NICS). Address: N.I.C.S., Hobunkan Building, 6F, 3-11-4 Kanda-Jinbo-cho, Chiyoda-ku, Tokyo 101 Japan. Tel.: +81-3-3288-5900; Fax: +81-3-3288-5387. N.I.C.S. publishes *Sexology Updater* (ten times a year).

Other Japanese sexological organizations and publications include:

Japanese Association of Sex Educators, Counselors, and Therapists (JASECT), JASE Clinic, 3F Shin-Aoyama Bldg (West), -1 Minami-Aoyama, 1-chome Minato-ku, Tokyo 107 Japan.

The Japan Family Planning Association, Inc. (JFPA). Address: Hokenkaikan Bekkann, 1-2, Ichigaya Sadohara-cho, Shinjuku-ku, Tokyo 162 Japan. Tel.: +81-3-3269-4041; Fax: +81-3-3267-2658. JFPA publishes the journal *Family Planning and Family Health* (monthly).

Japan Federation of Sexology (JFS). Address: c/o Nikon Information Center for Sexology (NICS), Hobunkan Building, 6F, 3-11-4, Kanda-Jinbo-cho, Chiyoda-ku, Tokyo 101 Japan. Tel.: +81-3-3288-5200; Fax: +81-3-3288-5387.

Japan Institute for Research in Education, 4-3-6-702 Kozimachi Chiyodaku, Tokyo 7102 Japan. Tel.: 03-5295-0856; Fax: 03-5295-0856.

Japanese Organization for International Cooperation in Family Planning, Inc. (JOICFP), 1-1, Ichigaya Sadohara-cho, Shhijuku-ku, Tokyo 162 Japan. Tel.: 81-3/3268-5875; Fax: 81-3/3235-7090.

Japan Society of Adolescentology (JSA). Address: c/o Japan Family Planning Association, Hokenkaikan Bekkann, 1-2, Ichigaya Sadohara-cho, Shinjuku-ku, Tokyo 162 Japan. Tel.: +81-3-3269-4738. JSA publishes the journal *Adolescentology* (four times a year).

The Japanese Society for Impotence Research (JSIR). Address: c/o First Department of Urology, Toho University School of Medicine, 6-11-1, Omori-nishi, Ota-ku, Tokyo 143 Japan. Tel.: +81-3-3762-4151, extension 3605 or 3600. Fax: +81-3-3768-8817. JSIR publishes the *Journal of the Japanese Society for Impotence Research*.

Japanese Society of Sexual Science (JSSS). Address: c/o Hase Clinic, Shin-Aoyama Building, Nishikan 3F, 1-1-1, Minami-Aoyama Minota-ku, Tokyo 107 Japan. Tel.: +81-3-3475-1789. Fax: +81-3-3475-1789. JSSS publishes the *Japanese Journal of Sexology* (semiannually).

## Demographics and a Brief Historical Perspective

ROBERT T. FRANCOEUR

### A. Demographics

Most African nations, being political artifacts of colonialism, are multiethnic and multilingual. Patterns of sexual behavior are, therefore, quite varied, the result being complexity rather than uniformity. Economic and social factors that have an impact upon sexual patterns, therefore, include traditional cultures (initiation, courtship, and marriage customs), colonial imports (Christian and Islamic values, and education), and contemporary Western influences (consumerism and the media). Nowhere is this more clearly demonstrated than in Kenya, an east central African nation that lies across the equator, with Sudan and Ethiopia in the north, the Somalia in the northeast, the Indian Ocean in the southeast, Tanzania in the southwest, and Lake Victoria and Uganda in the west. With a total area of 224,960 square miles (582,650 km<sup>2</sup>), Kenya is slightly smaller than the state of Texas in the United States. The north is arid, but the land supports large game reserves and contains the fertile Lake Victoria Basin in the west. The climate varies from arid in the interior to tropical along the coast.

In July 2002, Kenya had an estimated population of 31.14 million. These estimates explicitly take into account the effects of excess mortality because of AIDS. This can result in lower life expectancy, higher infant mortality and death rates, lower population and growth rates, and changes in the distribution of population by age and sex than would otherwise be expected. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 41.1% with 1.02 male(s) per female (sex ratio); 15-64 years: 56.1% with 1.01 male(s) per female; 65 years and over: 2.8% with

(CIA 2002)

0.77 male(s) per female; *Total population sex ratio:* 1.01 male(s) to 1 female

**Life Expectancy at Birth:** *Total Population:* 46.2 years; *male:* 46.2 years; *female:* 47.85 years

**Urban/Rural Distribution:** 35% to 65% (1994 est.)

**Ethnic Distribution:** Kikuyo: 22%; Luhya: 14%; Luo: 13%; Kalenjin: 12%; Kamba 11%; Kii and Meru: 6% each; other African: 15%; non-African (Asian, European, and Arab): 1%

**Religious Distribution:** Protestant: 38%; Roman Catholic: 28%; indigenous beliefs: 26%; Muslim: 7%; other: 1%. A large majority of Kenyans are Christian, but estimates for the percentage of Muslims and adherents to indigenous beliefs vary widely.

**Birth Rate:** 27.61 births per 1,000 population

**Death Rate:** 14.68 per 1,000 population

**Infant Mortality Rate:** 67.24 deaths per 1,000 live births

**Net Migration Rate:** -1.48 migrant(s) per 1,000 population

**Total Fertility Rate:** 3.34 children born per woman

**Population Growth Rate:** 1.15%

**HIV/AIDS:** *Adult prevalence:* 13.95% (2001 est.); *Persons living with HIV/AIDS:* 2.2 million (2000 est.); *Deaths:* 180,000 (1999 est.). (For additional details from www.UNAIDS.org, see end of Section 10B.)

**Literacy Rate** (*defined as those age 15 and over who can read and write*): 78.1% (*male:* 86.3%, *female:* 70%) (1995 est.)

**Per Capita Gross Domestic Product** (*purchasing power parity*): \$1,000 (2001 est.); *Inflation:* 50% (2000 est.); *Unemployment:* 40% (2001 est.); *Living below the poverty line:* 22.9% (2001 est.)

One in four Kenyans lives in modern urban areas, notably the capital, Nairobi, which has become a melting pot for all Kenyan cultures, and Mombasa, a tourist mecca on the Indian Ocean. Kenya is the leading Black African tourist destination, with splendid coastal areas, highly developed wildlife-viewing opportunities, and an infrastructure that has been very safe, comfortable, and competently run.

Nairobi, the capital and center of industrialization, has a population of more than one million. Mombasa, Nakuru, Eldoret, Kisumu, Nyeri, Embu, Meru, and Thika are other

\**Communications:* Norbert Brockman, Ph.D.: not available. *Updates:* Beldina Opiyo-Omolo, B.Sc., Department of Health, East Stroudsburg University of Pennsylvania, East Stroudsburg, PA 18301 USA; bopiyo@yahoo.com.

large cities with a diversity and employment opportunities that attract many people from the rural areas, creating the usual urban problems. [Update 2003: In December 2002, Kenya went through a historic election in which political veteran Mwai Kibaki took a lead in landmark elections that marked the end of President Daniel arap Moi's 24-year rule. President Mwai Kibaki, a leader of the National Rainbow Coalition (NARC), defeated Uhuru Kenyatta, who had been handpicked by Moi to be the flagbearer for the Kenya African National Union (KANU), Kenya's long-ruling party since independence. (End of update by B. Opiyo-Omolo)] [Update 1997: In the 1990s, unrest with political tribal clashes have occurred primarily in the Rift Valley region from which the former president hails. Kenya has, since independence, had only one political party. The advent of multiparty politics in 1992 was decried by the president as a Western idea that would divide the people along tribal lines and plunge the country into lawlessness and anarchy. At the same time, legislators from the Rift Valley started preaching and demanding publically a change from the "Majimboism" (federal) system. Many tribes have coexisted peacefully in the Rift Valley for many years. These legislators asked the indigenous people, the people who originally owned the land before it was sold to others, to drive out these other people. With strong backing from the government, this effort resulted in a deadly, indiscriminate massacre of defenseless citizens, loss of property, and increased poverty, because a good percentage of the country's corn and pyrethrum is grown in this area. The children lost out on educational opportunities when the schools were closed and no teachers were willing to work in these areas. Nevertheless, the current situation is calm, and the churches and opposition parties have kept up their significant work for peace, restoration, and reconciliation. (End of update by P. M. Kariuki)]

## B. A Brief Historical Perspective

When the vast Bantu migration of the late medieval period—perhaps the largest human movement in history—turned south at Lake Victoria, it found small groups of well-entrenched Hamitic tribes and a few bushmen. The Bantus also encountered large Nilotic tribes that had arrived from the north, and these racially diverse nations settled into an uneasy relationship around the Lake region. Their descendents number about 25 million in Kenya, which straddles the equator on the east coast of Africa. Arab colonies exported slaves and spices from the coast of today's Kenya from the 700s on. Britain took over the country in the 19th century. In 1959, the Mau Mau uprising swept the country. British colonialism brought half a million East Asians and about a quarter million Caucasians in the early 1930s, both settler families and short-term expatriates connected with commercial, missionary, and international organizations.

[Update 1997: The agenda of the Mau Mau organization was to gain independence from the British, win control of their land and self-rule, and obtain the release of Jomo Kenyatta, then in British detention. Violence was widespread as the Mau Mau forces in the forests fighting the British were supported by a nationwide network involving the majority of Kenyans, both men and women. Defectors, traitors, and those who collaborated with the British were killed.

[For two decades, following Kenya's independence in 1963, the country was politically stable and prosperous, with a steady growth in its industry and agriculture, under Presidents Jomo Kenyatta (1963-1978) and Daniel arap Moi (1978-2002), under a modified private-enterprise system. In 1982, the military Air Force attempted to overthrow the government. Since then, government corruption, top-level scan-

dals, the employment of unqualified people in upper-level positions, serious inflation, and the collapse of government services and systems have resulted in low morale throughout the workforce and an unstable economy. (End of update by P. M. Kariuki)]

## 1. Basic Sexological Premises

### A. Character of Gender Roles

Social reinforcement maintains clear gender roles in all Kenyan societies. Western education has produced a small female professional class, but expansion of women into new spheres of activity occurs only in Western roles that were unknown in traditional society: Western medicine, education, and bureaucracy. The Kenyan government has given strong support to educated women, appointing government officials, diplomats, and leaders from among them.

### B. Sociological Status of Males and Females

Among many Kenyans, there is strong belief in the existence of ancestral spirits. The ancestors assume functions of social control and must be placated when offended. There is a bond between the worlds of the living and the dead, and a mutual interdependence. It is important, therefore, to maintain a balance in populations between the two worlds by having children. The "living dead" need descendants to perform rites in their honor. Add to this the economic incentive of having large numbers of children in order to provide for old age, and the cultural resistance to population control becomes apparent. In the African family, children are received with delight and treasured. The first-born is especially important in the family. The orphaned are taken in by their extended families. [Comment 2003: Institutional orphanages were almost unknown until recently, when the HIV/AIDS scourge has been killing many parents and leaving young children with nobody to take care of them. Most of these children whose parents have died of AIDS end up in the too-few orphanages. (End of comment by B. Opiyo-Omolo)]

Infanticide was practiced in traditional culture, but is now illegal and practiced rarely and surreptitiously. A baby may be killed if it is the result of an incestuous union or, in different ethnic groups, if an albino, triplets, or born feet first. The newborn of an uncircumcized Nandi girl is exposed to die if no one adopts it.

Life from childhood is organized around progress through age sets within a kinship system, each with its own preparation and responsibilities. These stages vary from tribe to tribe, but always include childhood, an initiation period leading to junior adulthood, marriage, family building, and the status of elder.

### C. General Concepts of Sexuality and Love

Sexuality is always a part of the kinship system, controlled within it, and subject to its purposes. Love is recognized and accepted as part of personal relationships. One may choose a marriage partner because of personal attraction, even though arranged marriages continue. Nevertheless, love is not a high value in itself. In polygamous marriages, junior wives will often be chosen by the first wife to meet work needs.

A great deal of sexual freedom for both sexes is allowed within these social controls. Unmarried boys and girls slept communally in many Kenyan societies, and several provide youth huts. [Update 1997: In a number of tribes, the Kikuyus, for instance, young men and women are allowed to dance, play, and even sleep together at certain organized times (*guiko*, among the Kikuyus), but no sexual activity is allowed although it may occur in these situa-

tions. Generally, premarital pregnancy disgraces a girl. Love, as an emotionally expressed feeling, was never valued in the tribal tradition. Today, it is treated as a Western idea and viewed with a lot of suspicion, especially by the older people. However, love as an act of the will has always existed. (*End of update by P. M. Kariuki*)

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A. Source and Character of Religious Values

For Africans, religion is a natural, present, and pervading influence deeply interwoven with culture. Everyday life is nowhere secularized as in the West, and religion as a personal and private activity is quite foreign to African sensibility. This is indicated by the presence of a mere 0.1% atheists and nonreligious persons in the country (see Table 1). The importance of religion for sexuality, therefore, is far beyond the issues of moral behavior so dominant in Western thinking.

Both Catholic and Protestant churches are very conservative theologically and morally, the former because of dependence upon expatriate (Irish and Italian) missionaries, and the latter because of a mass evangelical movement that has dominated Protestantism for several generations. Kenya is a center for the independent church movement, with over 500 groups ranging from African denominations to prophetic cults. Many allow polygamy and permit women prophetic figures, but are intolerant of abortion, contraception, sex education, and social equality for women. [*Comment 2003: President Mwai Kibaki is a member of the Catholic Church, while former President Daniel arap Moi is a member of an evangelical Kenyan denomination, the African Inland Church. (End of comment by B. Opiyo-Omolo)*]

Many Kenyan Muslims are East Asian disciples of the Aga Khan. African Muslims, primarily Swahilis on the coast, follow a moderate, relaxed form of Islam, and their numbers are declining.

### B. Source and Character of Ethnic Values

The ethnic distribution in Kenya in 1995 was: Kikuyu 21%, Luhya 14%, Luo 13%, Kalenjin 12%, Kamba 11%, and the remainder divided among Europeans, Asians, and Arabs. There are essentially two layers of cultural influences in every Kenyan. The first is the traditional tribal value system, and the second consists of Western influences. Sexual values, traditions, and behavior arise from the matrix of these influences, which vary among individuals. One family may speak a tribal mother tongue, continue traditional practices of initiation, bride wealth, and taboos, while another may speak Swahili or English predominantly, take many values from Christianity and the media, and feel free of tribal tradition. Several factors influence these differences: degree of urbanization, tribal intermarriage, religion, and level of education.

**Table 1**

#### Estimated Religious Distribution in Kenya

Religion	Percentage of Population
Roman Catholics	29
Protestants and Anglicans	27.4
African independent churches	21
Orthodox	2.6
Christian Total	80
Traditional animists	12
Muslims	6
East Asian religions	2

Moral strictures within Kenyan societies tend to be based on shame rather than on guilt. Disapproved sexual behaviors cast shame upon one's age group, clan, or tribe, rather than produce feelings of personal unworthiness through guilt. There is a strong social element to all ethical norms, including sexual norms. Sexual behavior in Kenyan societies is significant only in terms of the social realities of childbearing and family alliances. Consequently, where ethnic influence breaks down, as when a Kenyan moves to an urban area outside the tribal milieu, the inhibition of shame may be removed, resulting in behavior that by Western standards seems promiscuous and irresponsible.

There are contrasts in sexual norms among different ethnic groups. In some groups, such as the Luo, women who give birth before marriage are disgraced, while in other groups this is seen as a valuable sign of fertility. Virginity in women is highly prized in some groups, such as the Somali, Maragoli, and Luo, and regarded as unimportant in others, among the Kisii, Kikuyu, and Nandi. Among the Kikuyu, an infertile or impotent husband may provide another sex partner for his wife. Among the Nandi, a married woman can continue to have sex with her former lover or other members of her husband's age set. In contrast, the Maragoli regard extramarital sex as adultery. Therefore, the sexual culture shock in urban areas comes not only from contact with Western ideas and media, but also from interaction with diverse traditional value systems.

## 3. Knowledge and Education about Sexuality

### A. Government Policies and Programs for Sex Education

Sex education is treated with great ambivalence in Kenya. School curricula are nationalized, and there is no curriculum for sex education. Nevertheless, the idea is endorsed, and units of Family Life Education (FLE) are integrated into various curricula. These have been designed by nongovernmental organizations (NGOs), particularly the National Christian Council of Kenya, the Kenya Family Planning Association, the YMCA, the Kenya Catholic Secretariat, and the National Women's Federation (Maendaleo wa Wanawake). All of these organizations also provide various training programs for sex education teachers.

When tested in 1991 on six topics—menstruation, wet dreams, pregnancy, contraception, STDs, and AIDS—80% of the adolescents had received instruction on at least one topic between the ages of 12 and 15. Further testing on specific issues, however, showed that only 23 to 37% had practical knowledge on specific topics.

The government attempted to use television for sex education in the late 1980s, developing a popular soap opera series in Swahili. After several episodes, President Moi ordered the program stopped, endorsing instead traditional sex education by tribal elders. The fact that today, fewer youths live in rural areas or undergo traditional initiation, was never broached. Media such as television, comic books, and now radio and local comedian actors are used well in AIDS education, but this is the only topic systematically dealt with.

[*Update 1997: The issue of sex education has become a major issue in Kenya. As mentioned, the government has made some efforts to introduce it in the schools, but this has met with considerable resistance from religious groups, particularly the Muslims and the Catholic Church. The Boy Scout movement, with the help of pathfinder funds, published a book on family life education for their members. This book discussed topical issues on sex education, human anatomy, and abortion. Subsequently, the government used*

this book as the basis for a sex education syllabus to be taught in the schools. Following much resistance and criticism from the religious groups and parents, the President ordered the book's withdrawal from all bookshops and stores in 1985.

[The issue of AIDS, which is alarming, has complicated the issue of sex education for several reasons. For one thing, the people do not take the AIDS threat seriously. {*Comment 2003*: The Kenyan government did not consider HIV/AIDS a priority until 1999, when the former President Daniel arap Moi declared AIDS a natural disaster. Since then, HIV/AIDS has been put on the priority list, with organizations like the World Bank and UNAIDS funding several HIV/AIDS projects. (*End of comment by B. Opiyo-Omolo*)}. The problem is with the level of information given, coupled with and complicated by the prevention methods advocated. The people in the churches who could be most effective in communicating the needed information believe the information about condom use as a way to reduce the spread of AIDS is scientifically false and that the people are not being told the truth. They are also aware of the economic factors in the sale of condoms: The manufacturers are out to make money with ineffective condoms while the users continue to die as AIDS spreads. There is a widespread belief that the whole issue is linked with a eugenics movement whose aim is to produce a "thoroughbred" race through genetic engineering. Africans are aware that some have classified them as a lower race. This belief in a eugenics-oriented link is supported by the requirement of the World Bank and the International Monetary Fund that 20% of every loaned dollar go to the provision of contraceptives and abortifacients. Government hospitals and clinics like the Maria Stopes clinics are flooded with these drugs, while there are absolutely no other drugs available to treat other ailments. The government preaches ensuring good health for everyone as a national goal. But when the only drugs the people find available are for AIDS and pregnancy prevention, they question the credibility of the government and its policies, and lose faith in anything it tries to advance.

[As a result, the main religious groups organize protest marches through the major towns, where thousands of people, young and old, attend. These marches are climaxed with the burning of condoms and sex education books. These people call for telling the truth about the effectiveness of condoms. They advocate that sex education be left to parents, and that parents be involved in any decision that would affect their children. They also advocate AIDS prevention through abstinence and chastity. For married couples, they call for "zero grazing," strict marital faithfulness. (*End of update by P. M. Kariuki*)

[*Comment 2003*: Sex education for teenagers in Kenya has been largely stymied by the protests of religious groups. Teenagers are not told that condoms can protect against HIV. Instead, they are taught that abstinence is the best method of safe sex, with nothing mentioned about condoms and other contraceptives. Students only learn about AIDS in career subjects like biology, where the basic facts about this killer disease are taught in a very clinical way. (*End of comment by B. Opiyo-Omolo*)

## B. Informal Sources of Sexual Knowledge

Traditionally, sex education was undertaken as part of the initiation process. It began, however, much earlier in the extended family and social structures of particular ethnic groups.

Sex instruction does not often come from parents. In the presence of their children, they are expected to avoid any words, acts, or gestures of a sexual nature. The rules of

shame might allow openness about sexual matters with a grandparent, however, and among the Kisii a grandmother could be the confidante of her grandchildren on their sexual experiences.

A small child will remain with its mother until about age 7. At this point, in some tribes, boys move in with their father or older boys. In other groups (Maragoli and Luo), both boys and girls go into separate huts with older children or into the homes of an elderly couple. These village dormitories provide socialization, sex education, and opportunities for sexual experimentation. The last is conducted in secret, although girls often "fail to notice" a youth visiting in the girls' dormitory. Two lovers might also go into the bush. A father and older sons might build a private hut for a son who reached puberty, especially since initiation ceremonies might be held only every few years. Under these circumstances, young men have free rein to engage in sexual activities. In slang, these huts are sometimes referred to as "the office," and "going to the office" means having a girl over for sex.

These patterns of sex education have continued into present-day society, where studies show that parents are a negligible source of information, while 31% of girls and 38% of boys indicate teachers as the most important source. This does not reflect organized sex education in the schools, but the influence of proctors and teachers in boarding-school settings.

## 4. Autoerotic Behaviors and Patterns

In Kenyan tradition, self-pleasuring is unacceptable among girls, and was part of the motive for clitoridectomy. For uninitiated (uncircumcized) boys, however, self-pleasuring is considered a proper preparation for a mature sex life. Boys in the same age group may engage in self-pleasuring together without shame, but all such activities are to be given up with initiation.

Adult male self-pleasuring is regarded as immature and childish after initiation, even for the unmarried. It is therefore surrounded with taboos. A man who has been circumcized is regarded as unready to assume adult responsibilities if he engages in self-pleasuring.

## 5. Interpersonal Heterosexual Behaviors

### A. Children

Living in the unmarried men's hut, a boy has ample opportunity to listen to sexual conversations and observe older boys with their sweethearts. The degree to which an older boy may "play sex," as youth slang puts it, depends upon social custom. An uncircumcized Nandi boy rarely has an opportunity for intercourse, because of the strict controls of the warrior age set. Maragoli girls often participate in sex play with boys, although intercourse does not take place until after puberty. The Kisii tolerate extensive sex play among smaller children, although shame taboos require that after about age 7, such activities are not to be seen by parents.

Western influences have rendered many of these customs invalid. Many children are sent to boarding schools, where socialization is controlled by older children with little supervision. Nocturnal visits that are manageable in a traditional setting often turn into rape under these circumstances. Older youths who are not part of a tribal social system often feel little responsibility for younger children, and certainly not for female students who include no sisters or members of tabooed clan groups.

The urban family must dispense with age-set socialization entirely and keep their children in the home. Grandpar-

ents are seldom available for counseling or instruction. Other children and youths come from differing cultures, so that peer influences rarely reinforce traditional values.

## B. Adolescents

The sexual world of the Kenyan adolescent is extremely complex, combining traditional initiation rites, Western values and ideas, and a changing set of social expectations.

In traditional society, adolescents were initiated in a clearly defined period and by a series of events. In all cultures, these included instruction in male/female roles within the tribe, marriage customs, morality, and acceptable sexual behavior. Bantu cultures included circumcision for men, and usually for women. The Luo are the largest group not practicing circumcision. Among the Maasai and Samburu, after initiation, the new warrior could take a mistress from among the unmarried girls.

Initiation was done by age sets that were given distinctive names and provided a strong sense of bonding. While there were differences among ethnic groups, the pattern was essentially the same. Age sets went through various stages of adulthood together and shared a common responsibility for one another. In a few cases (Nandi and Maasai), it was not regarded as adultery if a woman slept with an age mate of her husband. Elsewhere, the opposite is the case—adultery within the husband's age set would be incestuous, and there are taboos against the marriage of a son or daughter to one of another age-set member. However different cultures interpreted it, the age-set bond defines sexual and marital relations.

Male circumcision is an important sign of adulthood, responsibility, and bravery. When performed as a part of an initiation ritual, the boys are expected to receive the surgery without flinching, lest they disgrace their families. It is preceded by a cold dip in a river to deaden the senses. Circumcision is such a public symbol, it is not unusual to hear a man say "I have been to the river," to mean "I know what I am talking about." Because of the social significance, youths who do not undergo initiation, either because the family lives away from the tribal area or they are in school, will arrange for private circumcision from a doctor or clinician. After his teens, an uncircumcized male is the butt of ridicule and at considerable disadvantage in finding sex partners. A youth who cries out during the surgery is disgraced for life and will be able to find a wife only among the handicapped, elderly, or those with illegitimate children.

Female circumcision will be discussed under Section 8D, Unconventional Sexual Behaviors.

Although custom severely restricts adolescent intercourse, in reality a certain amount of sexual activity takes place. This is most marked in mixed situations (e.g., in cities and boarding schools), but it is also the case in traditional settings. In several cultures, elaborate sex play is institutionalized. Neither penetration nor touching of the genitals is allowed to either partner. Among the Kikuyu, the girl wears a leather apron during this activity, which is conducted in a special hut set aside to provide privacy to young people. Breast fondling is the main stimulant, as well as frottage. The Luo use a method of interfemoral intercourse. Where intercourse is tolerated, the main technique of avoiding pregnancy seems to have been withdrawal.

Detribalized youths experience considerable social pressure to become sexually active, without balancing social support that might make sexual abstinence a viable option.

Two 1987 studies reported age at first sexual intercourse to be 14 in the cities, and 13.7 for boys and 14.8 for girls in the rural areas. By age 20, 42% of rural females and 76% of rural males had had intercourse. Almost all of these in-

volved multiple partners. Forty-one percent of rural girls have had intercourse with more than one partner (mostly for money from married men), 17% with three or more. The figures for boys are 72% and 51%, respectively. A 1991 cross-cultural study of in-school adolescents reported 48% of primary school males, 69% of secondary, and 77% of vocational to be sexually experienced. The comparable figures for young women are 17%, 27%, and 67%. No studies record preferred sex partners, but the widespread prevalence of prostitution is not to be discounted for the disparity between males and females in comparable settings.

Correlates of sexual activity among adolescents are peer influence (males with sexually active peers are seven times more likely to be active themselves); weak religious commitment; risk-taking behaviors (smoking, disco attendance, and alcohol use); dysfunctional family situations (for females); attending boarding school (for males); and attending a rural school.

Only 5% of the general adolescent population use any form of contraception. In striking contrast, the figure for students is slightly less than 15% who use contraception regularly, indicating that birth-control use is strongly influenced by educational status. It must be remembered that somewhere around 90% (statistics are imprecise) of youths terminate schooling after Standard Eight at about age 14 to 15. Correlates of contraceptive use among school girls are high academic achievement and upper socioeconomic status—each of these triples the likelihood of contraceptive use. There is only one correlate for boys, a sexual relationship with a girl supportive of contraception, which doubles the likelihood of contraception.

## C. Adults

### *Premarital Courtship, Dating, and Relationships*

Traditionally, premarital sex activity was circumscribed and controlled. A youth who impregnated a girl was liable for brideprice to her father, and might be punished in addition. While a few nomadic peoples like the Maasai institutionalized mistress relationships for unmarried warriors, this was the exception. Those practicing female circumcision usually demanded proof of virginity at marriage.

Courtship is dominated by brideprice. All marriages involve brideprice or bride wealth, regardless of whether they are traditional or among the educated elites. The origins of this payment to the father's family is recompense for the lost economic services of the daughter. Brideprice was paid originally in cattle and goats, but today usually involves money. Negotiations are often protracted, and various members of the extended family receive gifts over a period of time which corresponds to the Western engagement period. One Kenyan manufacturer uses a television ad showing the suitability of its blankets for brideprice gifts. A woman with education or skills is highly prized, while someone of low status—a housemaid, single mother, or orphan—might bring only a small bride wealth, and be viewed as appropriate only as a second or third wife.

[Update 1997: The payment of the brideprice has several functions beyond compensating the family of the bride for their investment and loss of the daughter's economic services. Part of the ceremony is to announce to all the intention of the couple to marry. After the traditional goats and bananas are offered, the clan members of the man and woman meet to negotiate issues like who the daughter is, what her skills are, her level of education, and the general duties she will undertake in her new home. The purpose here is to give the visitors, the man's relatives, a general overview of the woman's family, their status, and prosperous attitude as reflected in the daughter. This gives them a

better reason to offer something substantial to compensate for the work done by the family on their daughter.

[The brideprice agreed to is always on the high side. This insures that the ties between the two families will never end. A Kikuyu aphorism states that the brideprice never ends. This underlines the purpose of the brideprice in maintaining the clan/family bond. Other ceremonies, involving a goat slaughter, sharing of the meat, and a traditional liquor between the clans, reinforce this bonding. While the brideprice ceremonies differ from one tribe to another, the principle and purpose remain the same. Among the social elite, the primary function may be the economic benefit, but for most Kenyans this is secondary. (*End of update by P. M. Kariuki*)]

If a marriage is not successful, the bride wealth is to be returned. Kenyan men marry at a later age than women, in part because of the burden of bride wealth. In Kenya, however, difficulties in acquiring bride wealth do not prevent marriage as it has in neighboring Uganda, and the Kenyan government continues to support the practice. Brideprice is a further indication that marriage is primarily seen as the alliance of families rather than an interpersonal commitment based on love. Marriage is cemented by the bride wealth, giving a large number of the bride's family a material stake in the perseverance of the marriage, a form of marital insurance.

### *Sexual Behavior and Relationships of Single Adults*

This area of life has undergone great change. In traditional society, male youths became warriors after initiation, protecting the tribe and its herds. With this function lost, unmarried youths have no clear position in the kinship system. Those fortunate enough to pass rigorous examinations usually attend boarding schools, separated from the influence of their extended families. This has had disastrous results for identity, producing alarming rates of promiscuity, premarital pregnancy, and AIDS. Substantial numbers of women in the university and professional schools drop out because of pregnancy, a tremendous economic loss for the country and a major force holding back the advancement of women. A 1988 government study estimated that 400 to 500 women drop out of normal schools each year because of pregnancy. Pregnancy screening is now a condition for admission to teachers' colleges, and random screening is conducted among students after admission.

Working-class youths suffer similar dislocation. About 90% of young people terminate schooling by the end of Standard Eight, around age 14. [*Update 1997*: While the 90% figure just cited seems high to me, it is clear that the average age of terminating education varies from region to region. Today, the higher percentage of young people end their education by the end of form four (high school) and fewer by the end of Standard Eight (grade or elementary school). In the central region where I worked as education secretary for seven years, the majority ended their education with the completion of high school. (*End of update by P. M. Kariuki*)]

Where traditional initiation has lapsed, circumcision of boys takes place in a clinic or by bribing a clinic worker to perform the surgery at home. Girls' circumcision is now illegal in Kenya. The sexual information imparted at initiation is not given, and sex education is dominated by peers. Youths have evolved an argot of Kiswahili known as "Sheng," a street language seldom understood by adults. Kiswahili has a very restricted, even prudish, sexual vocabulary, but Sheng is rich in sexual slang.

Huge populations live in massive slum areas surrounding Nairobi and a few other major towns, and these have be-

come breeding grounds for prostitution, venereal disease, and sexual abuse. Radically altered social conditions have shattered traditional mores in the cities, while providing no alternative social controls.

### *Marriage and Family*

Most Kenyan societies are patrilineal, meaning that descent is reckoned in the father's line and authority over children rests with the father. In matrilineal societies, children are in the descent group of their mothers, but under the headship of the males in that line. The only significant implication of this presently is in marriage. In matrilineal societies, males are limited in their search for a wife, since they will bear responsibility for children in their sisters' families.

Matrilineal groups usually also practice levirate marriage, in which a man must take his brother's widow and children as his own. If the dead man has left no children, the brother may father children in the dead man's name. This aspect of African traditional law has been accepted into Kenyan jurisprudence in a contentious case involving a deceased Luo lawyer whose widow, from a prominent Kikuyu family, refused to accept Luo traditional law. When she lost the case, the brother's family seized the body to bury it in traditional fashion. By refusing to attend this ceremony, or to accept her brother-in-law as her new husband, she was regarded as divorced, and the deceased was buried as an unmarried man.

Of the five recognized forms of marriage in Kenyan law, three are monogamous—Christian, civil, and Hindu marriages. Islamic marriages are potentially polygynous, and African customary marriages are polygynous. Although the precise word for marriages of single husband/multiple wives is "polygyny," Africans use the broader term "polygamy," and it will be so used here.

### *Polygamy*

A man may take junior wives only if he is able to support them, which limits polygamy. Bride wealth alone inhibits polygamy, but the increasing cost of educating children is equally daunting. A man may take a second wife as a display of wealth or prominence, to provide an assistant in farm work for the first wife, or to begin another family. Each wife has to have living quarters for herself and her children. In practice, men arrange a small plot of land that the wife works to support the children.

A polygynous husband is expected to be sexually active with all his wives. In some groups, she is entitled to a visit between each menstrual period. More commonly in the rural areas, a man will sleep with his wives in rotation, several weeks at a time.

In contemporary society, the husband may take a job in the city, and visit his wife or wives from time to time. It is not uncommon today for a man to live apart from his legal wives for many years in this way.

In some cases, one or more wives may live on the *shamba*, or garden plot, while another stays in the city, caring for her husband. In addition, many men will take a "city wife," a form of concubinage in which the man supports the woman in the city while not having a legal relationship with her. Many wives living on the *shamba* prefer this to another legal wife or the probability of her husband's resorting to prostitutes. Children born to a "city wife" are the father's, and are raised by his wife.

Polygamous marriages were never in the majority, and today are declining under economic pressures. At the same time, other less-formal arrangements have become common. These include the phenomenon of the "city wife" and polyandrous mistresses. This latter arrangement involves

several urban men who jointly support a woman. None of them live with her, but she shares a sexual relationship with each. In one case known to the author, one man paid the woman's rent, another her food bills, and a third paid for her clothing. Her arrangement was known to her peers since she held a professional position, and she was not regarded as a prostitute. Any children born of such arrangements are regarded as fatherless. [Update 1997: I am not aware of this polyandrous relationship involving a wife openly maintaining a sexual relationship with two or more men. However, a wife or mistress may have sexual relationships with more than one man for the purpose of obtaining money from each. When the men eventually learn about the multiple relationships, the result is a breakup that may escalate with a thorough beating of the woman or fighting between the men involved. (End of update by P. M. Kariuki)]

In the tradition, a marriage must be fruitful. The advanced stages of elderhood are marked by fathering children, having them come to the age of initiation, and having grandchildren. Among the Kisii, an impotent husband could recruit an *omoso nyomba*, literally "warmer of the house," to impregnate his wife. He was preferably chosen from descendants of the same grandfather, and any children are the husband's heirs, not the biological father's. A childless widow could also make the same arrangement.

Since childbearing is such a central condition of sexuality, female orgasm is not sought in itself. Nevertheless, it is approved and acceptable. Male orgasm, however, is a sign of potency, and men will seek sexual relief even when abstaining from intercourse. Abstinence is observed from the time pregnancy is obvious until some time after birth, and during menstruation. During this period, if a man has only one wife, he may engage in other forms of sex, including fellatio. Kikuyu men, conditioned to breast stimulation, often center on this activity.

An interesting birth practice is found among the Luo, who are Nilotic and not Bantu. Several days after parturition, when a woman is to leave the birth hut with the newborn, her husband must have intercourse with her. Before this act, she may have no contact with anyone who has had intercourse, including midwives or relatives. To do otherwise would afflict the child with *chira*, a spiritual curse resulting in the child's death or the parents' sterility.

#### [Wife Inheritance

[Update 2003: In August 2000, an Anglican bishop in west Kenya called on the women belonging to his church to reject *joter*, a widespread African tradition with some similarities to the Levirate Law, which in biblical times required the brother of a married man who died without a male heir to have sexual intercourse with the widow to provide the dead brother with an heir. In the African tradition, the widow becomes the wife of another member of her deceased husband's family. The term *joter* may be used to mean "wife inheritance," or it may refer to the male relative who inherits a widow. *Joter* is traditional among the Luo people of Nyanza Province of western Kenya. The Luo people are often polygamous, so several widows may be inherited by a single male family member. Another element of this tradition is the practice of holding a "cleansing" ritual, in which the widow has sex with an outsider before being given to her brother-in-law or other family member. The bishop called for creation of a new ritual of "symbolic inheritance," which would transfer responsibility for the support of the widow to a male relative without giving him sexual access to the widowed wife. *Joter* and other patterns of multiple sexual partners are, along with female circumcision and "salt cuts," a factor in the heterosexual spread of HIV/AIDS.

[Some males, seeking to profit from taking on an extra wife or two, are now becoming professional *Joters*, with offices where they advertise themselves for prospective clients (widows) in return for a small fee. Most of these men now demand payment to *inherit*. Because of this, some widows now demand that these *Joters* undergo a blood test for HIV first before they pay them.

[An early 2003 Human Rights Watch report condemned the traditional African practice of wife inheritance, which is common throughout Kenya, and extends far and wide in sub-Saharan Africa, in which a widow is transferred to a male relative of her deceased husband. Typically, the new husband takes control of the property with or without the consent of the widow.

[Traditionally, according to the report, wife inheritance ensured that the extended family would take care of widows. But critics maintain that it strips women of their property rights and exposes them to sexually transmitted diseases like AIDS. "Wife inheritance is often portrayed as an act of generosity, in that the widow will have a man to 'look after' her and confer the legitimacy of being in a male-headed household. But men clearly benefit, not just from their inherited wife's labor and childbearing potential, but also from the property the deceased husband leaves behind."

[The report found that widows have little recourse to retain family property after the death of their spouses or as a result of separation or divorce. Taking their claims to the judicial system is costly, and judges, relying more on tradition than law, do not necessarily side with the women. "It should be remembered that a wife is married into the husband's clan," a Kenyan judge ruled in a 1997 separation case. "The matrimonial home, in most cases, lies within the clan land. It would, therefore, not be in keeping with our culture for the husband to be made to vacate the clan land for the wife." Husbands may orally will their property to their widows, but they are often reluctant to put this in a written legal form, because they might hasten their death. Researchers for the Human Rights Watch report described many women who found relatives descending on their homes immediately after the burial of their husbands to take everything the widow owned.

[The report called on the government of President Mwai Kibaki, which has pledged better treatment of women, to overhaul the legal system so that women have the same rights to property as men. The report recommends that judges and police officers undergo training on the issue and that a legal aid system be set up to assist destitute victims (Lacey 2003). (End of update by B. Opiyo-Omolo)]

#### Sexuality and the Disabled and Aged

The Kenyan government estimates that 5% of the population is physically disabled, mostly with deformed limbs and eye afflictions resulting from poor birth-delivery conditions. No studies of the sexual adaptations of this group have been reported, but the disabled can be observed in all types of relationships, married and otherwise.

Since childbearing so defines a married woman's importance, later sex is not spoken of. In at least one tribe, parental sex was supposed to stop when the first child was married. A wealthy man might take a young junior wife when his first wife reaches menopause, causing him to cease having sex with her.

#### Incidence of Oral and Anal Sex

Vaginal intercourse is the norm for marital sexual activity, with little foreplay. Anal sex is associated with homosexual rape, not unknown during civil strife, and both anal

and oral sex are culturally abhorrent, though fellatio is acceptable in a few cultures during periods of abstinence, such as the lactation period.

## 6. Homoerotic, Homosexual, and Bisexual Behaviors

### A. Children and Adolescents

Certain types of same-sex activity were tolerated in tribal tradition, but only as childish behaviors unworthy of an initiate. In tribes where initiation involves long periods of separation from female contact along with powerful emphasis on male group bonding (Maasai), situational homosexuality is not uncommon. When limited to mutual self-pleasuring, it is regarded as merely unmanly. Oral or anal intercourse can, however, result in expulsion from the age set, severe beatings, and disgrace. One finds some nonpenetrative homosexual behavior among Maasai *askaris* (guards) who have migrated to Nairobi or the coast.

Urban poverty has created an underclass of abandoned street youth, almost all male, ranging in age from 7 to the late teens. These “parking boys” survive by protecting parking spots, begging, petty crime, and scrounging for garbage. Though the older protect the younger, situational homosexuality is normative.

### B. Adults

Self-identified gay Africans hardly exist in Kenya, although homosexual activity is not unknown. There are no homosexual gender roles, such as the *berdache* in Native American societies, or the effeminate *gà'tuhy* of Thailand. Because homosexuality profoundly violates the traditional social pattern, it has been tabooed to the point that subcultural social norms have never developed.

Kenya has retained many aspects of the colonial British penal code, and homosexuality continues to be illegal as a “crime against nature.” It is regarded with disdain and disgust by the majority of the population, and persons arrested for homosexual activity are treated harshly by the police. In some traditions (e.g., Kikuyu), homosexuality could be punished by death.

Kenyans discriminate against same-sex behaviors. Self-pleasuring with a partner or spouse present is regarded as childish, but relatively harmless, particularly between friends. While socially and legally tabooed, playing the inserter role in same-sex acts does not define a man as homosexual. Accepting insertion, especially in anal intercourse, is regarded with extreme disgust.

There are no gay venues nor any overt gay presence in Kenya. A small white, predominantly British, homosexual society exists in Nairobi. Most expatriate white homosexuals avoid African partners because of the drastic consequences, and confine themselves to sexual activity on trips to Europe.

Male prostitutes are readily available on the streets of Nairobi and Mombasa, usually catering to tourists. They are well dressed in order to be able to enter international hotels. Male prostitution serving an African clientele does not seem to exist. The prostitutes themselves are probably bisexual, many having girlfriends or wives, and consider themselves heterosexual. All religious groups abhor homosexuality and condone its complete suppression. There are no gay activist or support groups in Kenya, nor any gay publications. Foreign gay publications are proscribed.

Lesbian and bisexual relationships are either so rare or so hidden as to be unnoticeable. The “woman-to-woman” marriage discussed in Section 8 should not be confused with lesbianism, even if an occasional sexual exchange may occur.

Homosexuality is often ascribed to the coastal Swahili, Arabs, and Muslims generally as a racist slur, and the few

Africans involved are said to be exploited by these groups. The sexual act in these accounts is always sodomy, which, as an image of rape and political dominance, effectively excludes mutuality in same-sex relationships. Male homosexuality is politically interpreted in terms of racist, anti-black exploitation by whites (former colonial masters) and Arabs (former slavers).

This pattern, both expatriate and African, is typical of sub-Saharan Africa except for the Republic of South Africa. Although the dramatic AIDS pandemic has generated interest in research on same-sex behavior, almost no such research has been done in Africa. A 1995 study indicated that such research is almost unknown in sub-Saharan Africa. In Kenya, all survey research designs must be approved by the Office of the President, a sufficient damper on any same-sex studies. The National AIDS Programme has no literature or outreach to homosexuals in Kenya.

The imposition of Western social notions of homosexual/gay patterns tends to obscure any true picture of same-sex activities in Africa. To say that there is no organized gay community in Kenya does not mean that there is no homosexual activity. There are cliques of men who are predominantly or exclusively homosexual, but who limit their sexual activities to their acquaintances group. In this sense, in urban concentrations such as Nairobi and Mombasa, these serve as homosexual analogs to age-set groups. Occasionally, one finds a group organized as a brotherhood or fraternity, a form of homosexual support group providing casual, although not promiscuous, pairings. A 1995 survey indicated that violent assault was either likely or possible for homosexuals in Africa—at 69%, the highest in the Third World. This helps to explain the closed nature of homosexual society in Kenya and other African countries.

## 7. Gender Diversity and Transgender Issues

Gender-conflicted persons are regarded as homosexuals and treated as criminals. Suppression is so complete as to make such persons, to the extent that they exist, invisible.

Kenyan traditional societies did not provide for special gender roles. During the independence movement, sodomy was practiced by some in the Mau Mau society, with the sole intent of making the participants ritually unclean and thus unable to participate in normal society. This is the only ritual use of homosexual behavior known.

## 8. Significant Unconventional Sexual Behaviors

### A. Coercive Sex Sexual Abuse

Child sexual abuse seems to be increasing, and is part of a generalized child abuse resulting from pressures of social change and loss of the holding power of traditional taboos. An alarming new development, however, has appeared with the rise of AIDS. This is the exploitation of pubescent girls by older men, hoping to find inexperienced partners who are unlikely to be infected. The image of the prosperous “sugar daddy” is a stock figure in Kenyan humor, accompanied by his *ndogo-ndogo* (literally, “little-little”).

### Incest

Incest is as socially condemned in Kenya as in the West, and seems to be rare. The Kisii sometimes excuse it because of drunkenness, but in other societies, it would be severely punished by mob justice. In some cases, children conceived incestuously would be killed.

### *Pedophilia*

True pedophilia, involving sexual contact between adults and prepubescent children, is rare in Kenya, scorned, and severely punished. Girls between 12 and 14 are often objects of older men's attentions, however, even though this is socially disapproved. Peasant fathers may accept bride wealth from men seeking a young wife, and this is not regarded as selling one's daughter. The government has campaigned against the practice, but has not been able to eradicate it in rural areas. In one district in 1988, only one girl completed Standard Eight, all the rest of her class having been married before completing elementary school.

### *Sexual Harassment*

The forms of sexual harassment found in Western society are probably as common among the professional class of Kenyans as elsewhere. There is also a serious problem of sexual exploitation of schoolgirls by male teachers.

Poverty forces many rural girls as young as 10, to be employed as housemaids and child minders in middle-class homes. Besides the economic exploitation they endure, sexual harassment by males in the household is common. Being from rural areas, often speaking only a tribal language, these girls have no power to resist sexual advances. If they become pregnant, they are cast out and often forced into prostitution.

### *Rape*

Reports of rape have been increasing in Kenya, although exact statistics do not exist. Practically speaking, only violent stranger rape is acknowledged as criminal. Neither Kenyan law nor general attitudes accept the concept of marital rape. Rape of such subordinate women as prostitutes or housemaids is regarded very lightly.

Sexual exploitation of girls in boarding schools and universities is common. A young woman who enters into a social relationship with a male student is expected to be available sexually. Because women have been conditioned to serve men and accept their orders from childhood, refusal of sexual overtures is difficult. In 1991, incidents involving mass rapes in secondary schools, in one case leading to several deaths, brought international publicity leading to government attempts at reform.

[*Update 2003*: The concept of sexual harassment is not Kenyan, and there is no vocabulary for sexual harassment in the local languages. So many times, this will be swept under the rug as the issue arises. Yet, there are so many unwelcome sexual behaviors, insults, remarks and jokes, unwanted physical contacts, requests, and even threats that create daily discrimination against so many women, particularly in Kenyan universities. In these universities, harassment occurs all the time. For example, women students are being groped and fondled as they queue for meals at the cafeteria. The result is that women students virtually end up retreating into their residence halls, and hence, their social life on campus is curtailed. They then cook and eat from their rooms, use the library sparingly, attend classes when it is an absolutely necessary, and avoid social functions on campus. Sexual guidelines do not exist on these campuses. (*End of update by B. Opiyo-Omolo*)]

### **B. Prostitution**

Female prostitution is widespread and patronized by both tourists and Kenyans. Technically illegal, it is tolerated by the authorities. Prostitutes tend to come from the less-educated class of women, including single mothers, junior wives driven out of their homes by first wives, abandoned girls, and economically distressed women. A working-class prostitute earns the equivalent of one U.S. dollar

per encounter, less in the poorer slums. Under these conditions, by 1990, almost 85% of Nairobi prostitutes tested positive for HIV. With weak economic inducement for remaining in prostitution, however, church programs such as Maria House in Nairobi teach cottage-industry and market skills that make it possible for women to earn a comparable living outside the sex trade.

Despite Kenyan government disapproval, sex tourism is promoted by German operators, including a "Sun and Sex Safari" that includes an antibiotic injection on return! Sex tourism in Kenya has never approached the exploitive level found in Thailand and the Philippines, but it is an ever-present element.

Male prostitution is a phenomenon of sex tourism, and is found mostly in coastal resort areas, such as Mombasa and Malindi.

### **C. Pornography**

All forms of erotica and sexually oriented publications are illegal in Kenya and not available for sale. This includes publications featuring nudity, which is culturally offensive.

### **D. Female Circumcision**

Female circumcision is practiced by Nilotic and some Bantu peoples. [*Update 2003*: Among the groups that practice female circumcision, it is thought that the procedure benefits girls. There is a widespread belief among those who practice it that ancestors will curse girls who have not undergone the procedures. Many believe that the cut reduces female promiscuity, ensuring virginity at marriage and marital fidelity. (*End of update by B. Opiyo-Omolo*)] It still continues widely among the Somali and Turkhana, and surreptitiously among others. Its purpose is to reduce female sexual pleasure, and make women docile to their husbands and less likely to engage in adultery. Women not circumcised are referred to by traditionalists as "unclean" or as "prostitutes." As a Kikuyu girls' circumcision song concludes, "Now we can make love, for our sex is clean."

The Kikuyu, Maasai, and Meru only removed the clitoris (clitoridectomy) during initiation at puberty. The Turkhana and Somali practice pharaonic circumcision, removing the clitoris and the labia minora. The wound is then sutured (infibulation), leaving a tiny hole for menstrual flow. This is often inspected at betrothal as a sign of virginity. Pharaonic circumcision is performed on girls between the ages of 3 and 7.

The Anglican Church strongly opposed female circumcision, and it has been illegal since the colonial period. The campaign reached a crisis in 1929, when the Church of Scotland Mission made opposition a condition of employment and school entry. This politicized the question and gave rise to the Kikuyu resistance, and the independent church and school movements. In 1930, an elderly female missionary died after rape, forced circumcision, and mutilation. Jomo Kenyatta, the Father of Kenya, made resistance a cornerstone of liberation, declaring that female circumcision "symbolizes the unification of the whole tribal organization."

After independence, Kenyatta permitted female circumcision, but President Moi again outlawed it in 1982 after the deaths of 14 girls. He reaffirmed this in 1990 after a widely publicized tribal ceremony. There are indications that the practice is waning.

[*Update 2003*: The practice is now illegal in Kenya, even though there are people who still practice it secretly in some communities. The government is now cooperating with a dynamic and broad-gauged campaign against the practice across Kenya being waged by NGOs and donor or-

ganizations in those areas where this is still being practiced illegally. There are now organizations that specifically provide protection to women or girls who wish to avoid this practice, for example, the Kenya Maendeleo Ya Wanawake, Federation of Kenyan Women Lawyers (FIDA), and Coalition on Violence Against Women in Kenya (COVAW), among others. Some churches and schools do offer occasional refuge to victims and potential victims of this practice. (*End of update by B. Opiyo-Omolo*)

### [E. “Dry Sex” and “Wet Sex”

[*Comment 2003*: In Africa, as in cultures elsewhere, there are certain sexual practices and topics that Africans simply do not discuss or acknowledge with non-Africans, because they are very sensitive, sometimes taboo, and many times very racially charged. Even within an individual tribal culture, some sexual topics and behaviors are not open for discussion between men and women, or between children and their parents. Unless one lives within a native community and becomes very, very close to the people, Africans balk at discussing these issues, and “dry sex” is one such practice.

[“Dry sex” is not something new. It is a well-established and more or less widespread practice in various subequatorial African cultures. It is very common in Southern Africa, particularly in Zimbabwe, Zambia, Malawi, some parts of Nigeria, some parts of Uganda, in Southern Sudan, and even in Kenya and Botswana. The only difference is in what these women use for drying up their vaginas. However, you will never hear about these practices, unless you are a woman who lives within the community for some extended time and the women learn to trust you.

[In the northwest part of Tanzania and neighboring regions, “wet sex” is widely known and practiced. “Wet sex” consists of foreplay, where there is intense stimulation by the male partner on the woman’s labia and clitoral regions. This stimulation results in copious production of secretions (thought to come from Bartholin’s glands). People talk about it openly, sometimes mixed with a sense of humor and intertribe jokes. Some researchers have blamed this practice for the high incidence and prevalence of HIV and STDs. The implications of this kind of information for action plans (resource inputs and sociocultural issues) are enormous. Now that these behaviors have been brought into public attention, a well-thought-out survey that is representative of different segments of the populations becomes essential for an effective public health policy (Tanzania Personal communication 2003).

[In March 2003, when Dr. Francoeur, editor of this *Encyclopedia*, inquired whether “dry sex” was observed in Botswana, Dr. Ian Taylor replied; “‘Dry sex’ is common in Botswana as well and leads to vaginal tears and lesions which help spread HIV/AIDS, it is true.”

[Personally, as I was growing up in the rural town of Kisumu, Kenya, there were many practices and myths that we were taught by some of our peers and even older women that we were to do to attract men. Some of them were good, but some of those things I do not feel comfortable talking about to this day. We were told that if you want your breasts to grow fast, you had to rub a certain poisonous leaf on your breast or let boys touch them, so that you could have them grow faster and more round. Many African men like women with large buttocks as well. As a result of this, many girls tried to do whatever they could to have big buttocks. One technique to accent the buttocks was to tie their belt so tight that the lower parts of their body stood out.

[Even today, many African men have three to five wives. These women compete among themselves to be the best cook for the man of the house, or the best in bed. This is obvi-

ous and was determined by where the man slept most of the time. Some women consult traditional healers and witch-doctors, who sell them love potions so they can out-do their co-wives. Some of these love potions come in the form of soil mixed with baboon urine, or even salt, that women use before they have sexual intercourse with their husband. It is the traditional healers who teach these women about the importance of drying their vaginas as a way to please their husbands. These concoctions also make their vaginas swell and become very hot, making it tighter so that when a man inserts his penis, he feels “big” and therefore, a “real man.”

[Until recently, very few people knew about these practices. Unless one grew up in the village or became very, very close to the people, you can never know what goes on. As the HIV/AIDS epidemic devastates subequatorial Africa, and non-Africans have become aware of female genital mutilation, taboos about other sensitive sexual practices have weakened. In 2000, Mark Schoofs discussed the implications of dry sex in the spread of AIDS in his eight-part Pulitzer Prize-winning report on “AIDS: The Agony of Africa. Death and the Second Sex.” In the chapter on Nigeria, Uwem Edimo Esiet, a public health physician, and his wife Nike Esiet, M.P.H. (Harvard), a former public relations officer for the Society for Women and AIDS, have raised the issue of “salt cuts.” But these new insights into the complexity of the HIV/AIDS epidemic only came after considerable trust was achieved. (*End of comment by B. Opiyo-Omolo*)]

### F. Woman-to-Woman Marriage

Some 30 Bantu societies provide for marriage between two women, including a dozen Kenyan ethnic groups. Among these are several large tribes—the Kisii, Nandi, Wakamba, and Kikuyu. In other parts of Africa, this was characteristic of status women, such as royals or political leaders, but in East Africa, it ordinarily represents a surrogate female husband who replaces a male kinsman as jural “father.” The wife may bear children for her husband, in whose clan line they then belong. In other cases, women marry women to achieve economic independence, and brideprice is paid. These autonomous female husbands are accepted as men in male economic roles. This dual-female marriage is economic, and illustrates the separation of sex and gender in African societies (Amadiume 1987).

There is no evidence of lesbianism in any of these marriages, and the wife is often provided with a male sexual partner to raise the children. She is not permitted to refuse him when he visits the household for this purpose. The husband figure is henceforth forbidden to have sex with a man, because this would constitute homosexuality because of her legally male status. She may become an elder, and among the Nandi, may attend circumcisions, forbidden for females.

Although Westernization has made female marriages embarrassing, they were confirmed in customary law by the Kenyan courts in 1986, and are subject to divorce legislation. [*Update 2003*: In January 2000, a Kenyan court granted an 80-year-old tribal woman a divorce from her wife on the grounds of cruelty and molesting her daughter. In 2002, a Kenyan woman went to court, demanding the right to inherit a piece of land belonging to her deceased “husband”—another woman. Grace Wanjiru Ndungu, 70, was told by her “husband’s” relatives to leave the farm, on which she had been living with her children for more than 40 years. Ms. Ndungu claimed she was a widow, and the only difference is that her husband happened to be a woman. Traditional inheritance law, her attorney argued, holds that in the event of death, the woman like Ms. Ndungu and her children are entitled to inherit the property of the dead woman “husband.” The lawyer admitted that his client faced a tough legal battle,

because this would be the first time such an argument had been heard in a Western-style court. (*End of update by R. T. Francoeur*)]

### G. Bestiality

Among pastoral groups and nomads, occasional instances of bestiality take place. When they involve uncircumcised youth, they are punished with a beating. Initiated males are treated more harshly. They are so disgraced after the public judgment of the elders that they would most likely go to a city. For a married man, bestiality is sometimes punished by death by mob justice.

## 9. Contraception, Abortion, and Population Planning

### A. Contraception

[*Comment 2003*: Only about one in every five women in Kenya uses at least one method of contraception. This means that a large number of women are open to the risk of unsafe pregnancy. (*End of comment by B. Opiyo-Omolo*)]

Foreign birth-control agencies cooperate with the government population-control program. Condoms are distributed at hospitals and clinics, supplied in large numbers by the U.S. Agency for International Development (USAID) and by such nongovernmental organizations (NGOs) as the United Kingdom's Marie Stopes Institute. The government has forbidden their distribution in schools, and school contraceptive education is severely limited. Condom use runs counter to the common taboo forbidding a wife to touch her husband's penis with her hand.

[*Comment 2003*: There is a strong belief in Kenya that condoms should be used only in sexual contacts outside marriage. The idea of using condoms with a marriage partner is rejected by most men since "Condom use in marriage suggests unfaithfulness, which leads to mistrust." (*End of comment by B. Opiyo-Omolo*)] Because of cultural resistance to condom use, Natural Family Planning (NFP), using the Billings Method, has had some modest acceptance by combining NFP with traditional periods of abstinence, such as during lactation. Operating throughout the country in both mother tongues and Kiswahili, NFP has promotion and training teams made up of unmarried youth and married couples practicing NFP.

Contraceptive methods requiring medical intervention, IUDs and the pill, are beyond the means of most Kenyans, and limited to the elite and expatriates.

### B. Teenage Unmarried Pregnancies

Having a baby outside marriage is unacceptable in much of Kenyan society where tribal customs are very strong. Teenage pregnancies reported among schoolgirls between 1985 and 1990 ranged from 6,633 to over 11,000. These rough figures of only a small segment of the adolescent population indicate a serious problem.

### C. Abortion

Abortion is illegal unless the mother's life is at risk or unless two doctors certify that the pregnant woman is mentally unstable and incapable of caring for a child. It is likely to remain so in the foreseeable future. Former president Moi strongly disapproves of abortion, and no religious tradition accepts it. Under the law, anyone convicted of assisting in an abortion or killing of an unborn child can face 14 years in prison.

With abortion illegal and the widespread practical ignorance about contraception—and cultural proscriptions that prohibit its use—thousands of Kenyan young women and teenagers are forced every year to turn to illegal and unsafe

abortions, which are a lucrative underground business, especially in the sprawling squatter slums of Nairobi.

Statistics are unavailable, but Nairobi's Kenyatta National Hospital with 2,000 beds treats 40 cases of incomplete abortion daily. About 50% of its gynecological admissions are because of complications from induced and incomplete abortions. Dr. Khama Rogo, a gynecologist at the private Agha Khan Hospital, has estimated that at least 187,500 illegal abortions were performed in Kenya in 1993. One third of Kenya's maternal deaths are because of unsafe abortions. With an extensive hospital and clinic system throughout Kenya, this represents only a tiny fraction of botched abortions. [*Update 1997*: Kenya has both government-run and church-managed nursing schools. While the church-run schools do not permit abortion, the state schools require that nurses record and document how many abortifacients they have inserted in patients to pass their licensing examination. In one state school I visited, the principal informed me that if the student nurses do not do this, irrespective of what they believe, they fail the examination. In the same school, a number of back-door abortions were carried out by the students for money. (*End of update by P. M. Kariuki*)]

The Marie Stopes Center, a grassroots organization with 10 clinics, is one of the few to provide counseling and abortion under the mental health provisions. These clinics also provide family planning and medical care (Lorch 1995).

### D. Population Control Efforts

Kenya's population growth rate is among the highest in the world, currently between 3.8 and 4% annually, at the current rate doubling every 17 years. With only 13% of its land arable, there is considerable population pressure. The government endorses population control as a national goal, and foreign-aid donors commonly demand active population-control programs as a condition for full assistance.

Kenya has succeeded in increasing contraceptive use to 27% of married couples, as compared with 10% throughout sub-Saharan Africa. Lifetime number of births per woman went from 7.7 in 1984 to 6.7 in 1989, but this still remains higher than the 6.4 figure for sub-Saharan Africa generally.

[*Update 1997*: The idea of population control has been unpopular among Kenyans for several reasons. Traditionally, children are embraced as a great blessing: They continue the family and clan lineage and also take care of the aged. The majority of Kenyans are firm in their Muslim or Christian faith, and all the religious sects have worked very hard to decry the Western methods of population control, which are viewed with great suspicion. Most Kenyans view the arguments for population control as overstretched and many times exaggerated. Most of the land is underutilized, and the real solution to the country's economic ills is not to reduce the population growth, but to provide good political governance and a sound economic system. With proper government and economy, Kenya can support its current growth rate. (*End of update by P. M. Kariuki*)]

## 10. Sexually Transmitted Diseases and HIV/AIDS

### A. Sexually Transmitted Diseases

Syphilis and gonorrhea are widespread among certain ethnic groups (e.g., the Maasai). Nomadic tribes are heavily infected, as are urban prostitutes, street youth living rough, and the residents of the most degraded squatter slums in Nairobi. Antibiotic treatment is available at all hospitals and clinics, and mobile clinics treat nomadic peoples, who are especially at risk. [*Comment 2003*: However, most people do not seek treatment because of the stigma attached to the STDs. (*End of comment by B. Opiyo-Omolo*)]

## B. HIV/AIDS

Because it borders Uganda and Tanzania, two countries with an extremely high incidence of AIDS, Kenya is vulnerable to AIDS. Since tourism is the greatest hard-currency earner, however, the government downplays the incidence of the disease. The first AIDS case was diagnosed in 1984, but the first death ascribed to AIDS was listed in 1984. In 1992, a powerful party leader argued in Parliament that "it is not in the national interest to release alarming AIDS figures." The Director of Medical Services in the Ministry of Health was dismissed for revealing that 700,000 Kenyans were diagnosed HIV-positive, with 40,000 confirmed AIDS cases, in an estimated population of 28 million. Current (1994) estimates are 800,000 HIV-positive Kenyans, including 30,000 children; an estimated 100,000 have AIDS. Dr. Frank Plummer of the University of Manitoba, who has done fieldwork in Nairobi for several years, calculates the infection rate among urban youth at 12% (see also Section 3, Knowledge and Education about Sexuality). The numbers are about equally divided between males and females, and heterosexual contact is the primary source of infection.

In Kenya, AIDS programs are based on a threefold attitude toward the significance of the disease. It is seen simultaneously as a health problem, a threat to the tourist industry, and as an insult to national pride.

Traditional initiation customs encouraged safe-sex practices among youths and limited intercourse outside marriage. With Westernization and urbanization, these controls have lapsed, however, and promiscuity is widespread. Condoms are readily available in the urban areas, but most traditions do not accept them. Christian and Islamic groups both disapprove, and in 1991, a prominent Muslim leader was disgraced when a condom was found in his luggage during a search by militant Islamic youth. The influence of religious groups is high, especially as Former president Moi was an evangelical Christian. When attempts were made to use television for safe-sex promotion, he personally stopped them. [Comment 2003: The use of condoms to prevent HIV/AIDS among Catholic faithful in Kenya is still out of question. They insist and believe in total abstinence for the unmarried and total faithfulness between spouses. In August 2002, the Anglican Church challenged the stigma associated with HIV as "a sin before God and humankind." They thus ended the silence surrounding HIV/AIDS by supporting the use of condoms in the fight against AIDS. (End of comment by B. Opiyo-Omolo)]

Despite political misgivings, the Ministry of Health has embarked on an extensive AIDS-education program since 1990. Devised by a national committee that has been relatively free of political pressure, it has centered on educating basic health providers and community leaders. This includes professionals such as physicians and nurses, but also herbalists, midwives, ritual circumcisers, and "market mamas," the influential local traders. Consequently, grassroots understanding of the causes of AIDS is high. For the future elites, use is made of the national service period, which is a condition for admission to higher education. Sex and AIDS education (with condom distribution) is included, and given in mother tongues. Studies done by the Marie Stopes Institute have shown that even university-educated youth respond to safer-sex education when it is given in their mother tongue, even though they may be fluent in English and Swahili.

Blood supplies have been screened for HIV since 1985. Despite this, as a further reassurance for the skittish tourist industry, special safari insurance was introduced, providing for air evacuation of injured tourists to Europe if necessary.

The implications of AIDS are very serious for the tourist industry. In 1987, the United Kingdom Ministry of Defense

banned holiday use of recreational facilities on the Kenya coast to British troops. Resultant publicity in Europe caused extensive cancellations at resort areas, with loss of 20 to 50% of all bookings that season. Because of the catastrophic effect of this on the economy, the AIDS question is a delicate political issue.

Kenya, like many African countries, has been deeply offended by speculative Western theories that AIDS originated in Africa. This is ascribed to racism and colonialism, and has prompted denials and a defensive attitude towards AIDS and AIDS research. Conversely, it has spurred support for research leading to an "African solution." The government has strongly supported the work of Dr. Davy Koech of the Kenya Medical Research Institute (KEMRI) on oral alpha interferon (Kemron). Unfortunately, when Kemron was tested by the World Health Organization (WHO) and a Canadian NGO, Dr. Koech's positive results could not be replicated.

U.S. Agency for International Development (USAID) projections in 1993 show Kenya with 1.2 million cases of HIV/AIDS by 1995, 1.7 million by 2000, and 2 million by 2005. The government has acknowledged the problem and admitted that its educational program has not brought about behavioral changes. What seems to have created the crisis mentality in the government is the realization that HIV/AIDS is disproportionately high (and rising) among the best-paid workers, the base of the middle class. This includes urban business and long-haul truck drivers.

The Kenyan government healthcare budget for 1993 was \$60 million in a falling economy, with 20% earmarked for AIDS prevention. Of this, Kenya contributed only \$77,000, the rest coming from foreign donors. The United States doubled its \$2 million contribution in 1994, but Western pressures to reduce foreign assistance make this source an unreliable one for the future.

There has been a recent shift in attitudes in the national leadership. Both former president Moi and current President Mwai Kibaki and his Health Minister, Honorable Mrs. Charity Ngilu, now regularly address AIDS prevention, although they do not speak out with the candidness of President Yoweri Museveni of neighboring Uganda, who openly endorses condom use. Although condoms are available in clinics, the government has not yet allowed them to be distributed to the young in schools. Since the great majority of high school and university students live in dormitories, this effectively removes the largest at-risk group from condom education.

According to a July 1996 report at the 11th International Conference on AIDS, Kenya ranked fifth in the world with 1.1 million people infected with HIV.

[Update 2002: UNAIDS Epidemiological Assessment: HIV information among antenatal clinic attendees has been available from Kenya since the mid-1980s. Nairobi and Mombasa are the major urban areas. In the major urban areas, HIV prevalence among antenatal clinic attendees tested increased from 2% in 1985 to 19% in 1995. In Nairobi, HIV prevalence increased from 2.7% in 1987 to 6.6% in 1990. By 1995, it had reached 25%. In 1999, HIV prevalence among antenatal clinic attendees in Nairobi was 17%. HIV prevalence among antenatal clinic attendees in Mombasa increased from 10.2% in 1990 to 16.5% in 1993 and then 17.8% in 1998. In Kiwi, a periurban area of Mombasa, HIV infection rates doubled from 12.2% in 1989 to 24.1% in 1995; in 1999, the rate was 23%. Information on age-specific HIV prevalences is not available.

[Outside the major urban areas, HIV information became available in 1988 from Machakos and from Kajiado in 1989. By 1990, 12 sentinel surveillance sites were reporting

HIV information. Among antenatal clinic attendees tested in these sentinel surveillance sites, median HIV prevalence increased from less than 1% in 1988 to 13% in 1997. In 1997, HIV prevalence ranged from 6 to 35% among 15 sentinel surveillance sites. In Kisumu, a town near the Uganda border, HIV prevalence plateaued between 1990 to 1993 at about 20%, and then shot up to 30% in 1994, 34.9% in 1997, before decreasing to 27% in 1999. In Busia, another border town, the rates increased from 17.1% in 1990 to 34% in 1999.

[Female sex workers tested in Nairobi were found with an HIV prevalence of 60.8% in 1985 and, by 1992, the rate had gone up to 85.2%. In 1993 to 95, 55.2% of sex workers tested in Mombasa were HIV-positive. HIV prevalence among male STD clinic patients tested in Nairobi increased from 16% in 1985 to 28% in 1991 to 1992, while among female STD patients, HIV prevalence increased from 33.3% in 1991 to 47.2% in 1998. In 1998, HIV prevalence among female STD clinic attendees tested in Nairobi was 29%. Nine percent of STD clinic patients tested in 1994 in Mombasa were HIV-positive.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	2,300,000 (rate: 15%)
Women ages 15-49:	1,400,000
Children ages 0-15:	220,000

[An estimated 190,000 adults and children died of AIDS during 2001.

[At the end of 2001, an estimated 890,000 Kenyan children under age 15 were living without one or both parents who had died of AIDS. (*End of update by the Editors*)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

Professional therapy is a serious lack in Kenya. The University of Nairobi has a post-M.D. psychiatric training program, but it includes very little preparation for dealing with sexual dysfunctions, and has only a few graduates. The services of psychiatrists are also beyond the means of all but the wealthy.

Kenyan cultures exalt the dominant virile male. Erectile dysfunctions are, therefore, considered serious and deeply shameful. Impotence is often a symptom of the pressures on men from traditional backgrounds who attempt to succeed in a competitive, capitalist, and urban milieu. Successful Western therapies that involve progressive levels of sensate and sexual exploration are seldom successful, since men rarely admit impotence to their wives. Male dominance allows them to assert that they have an outside "girlfriend" and, thus, no further interest in their wives. The average Kenyan wife would not challenge this. The level of marital communication is very low.

Male self-pleasuring is regarded as a dysfunction after initiation, but an acceptable release before. It is seen as a symptom of immaturity and sexual failure, and is rarely admitted by adult men.

An American Catholic missionary group has established the Amani Counseling Center in Nairobi, where a wide spectrum of services is available on a sliding-fee scale. The most commonly reported presenting issues of a sexual nature are male impotence, sexual abuse of subordinate women (e.g., maids and students), male self-pleasuring, and fear of homosexuality. Amani also sponsors a weekly newspaper column from letters received from around the country.

The Kenyatta National Hospital has operated a sex therapy clinic one afternoon a week since 1981, treating about

30 patients a year. Presenting problems are: erectile failure, 46%; ejaculatory problems, 25%; and reduced libido, 29%.

With no licensing requirements for therapists, charlatans abound. While witchcraft is illegal and vigorously suppressed, traditional healers and herbalists advertise cures for impotence, AIDS, and homosexuality, and are eagerly sought out.

## 12. Sex Research and Advanced Professional Education

Research on sexual matters is conducted either through the Ministry of Health or the Kenyatta National Hospital. Quality surveys of adolescent sexual behavior have been done, and statistics are kept on AIDS. There are no centers engaged in sex research on a regular basis, and there are no courses at the university level on human sexuality.

Research by expatriates must be approved in advance by State House, the office of the president. This is regardless of topic, and a condition of getting an entry visa. In addition, the results of all approved research may be released only with government approval. Approval for sex research has been rare, and only when of benefit to national policy. A Canadian medical group has been allowed to study the incidence of AIDS among prostitutes.

There are graduate-level programs in counseling (United States International University—Africa, and Catholic University of East Africa), pastoral counseling (Amani Center), and psychiatry (University of Nairobi). All include courses in sexuality or marital therapy, but there is no program devoted to sexuality.

There is no professional association for sexologists, and there are no journals on sexuality in East Africa. However, a related organization, the Family Planning Private Sector Programme, is a possible source of information; address: Fifth Floor, Longonot Place, Kijabe Street, P.O. Box 46042, Nairobi, Kenya. (Phone: 254-2/224646; Fax: 254-2/230392).

## *Demographics and a Brief Historical Perspective*

ROBERT T. FRANCOEUR

### A. Demographics

Mexico, with the official name of United Mexican States, is a country of 761,606 square miles (1,972,550 km<sup>2</sup>) located in North America, bordered by the United States to the north, and Guatemala and Belize to the south. Mexico is bordered on the east by the Gulf of Mexico and on the west by the Pacific Ocean. It is the third-largest country in Latin America, three times the size of the state of Texas, and a republic formed by 31 states and one Federal District. Sandwiched

between the Sierra Madre Oriental Mountains on the west coast and the Sierra Madre Occidental Mountains on the Gulf coast is a high, dry, temperate central plateau. The coastal lowlands are tropical. About 45% of the land is arid.

In July 2002, Mexico had an estimated population of 103.4 million. (All data are July 2002 estimates from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 32.8% with 1.04 male(s) per female (sex ratio); 15-64 years: 62.7% with 0.95 male(s) per female; 65 years and over: 4.5% with 0.8 male(s) per female; *Total population sex ratio:* 0.97 male(s) to 1 female

**Life Expectancy at Birth:** *Total Population:* 71.03 years; *male:* 68.99 years; *female:* 75.21 years

**Urban/Rural Distribution:** 72% to 28%. In 2002, 20 million people lived in metropolitan Mexico City, making it the most populous city in the world.

**Ethnic Distribution:** Mestizo (Amerindian-Spanish): 60%; Amerindian or predominantly Amerindian: 30%; white: 9%; other: 1%

**Religious Distribution:** nominally Roman Catholic: 89%; Protestant: 6%; other: 5%

**Birth Rate:** 22.36 births per 1,000 population

**Death Rate:** 4.99 per 1,000 population

**Infant Mortality Rate:** 24.52 deaths per 1,000 live births  
**Net Migration Rate:** -2.71 migrant(s) per 1,000 population

**Total Fertility Rate:** 2.57 children born per woman

**Population Growth Rate:** 1.47%

**HIV/AIDS** (1999 est.): *Adult prevalence:* 0.29%; *Persons living with HIV/AIDS:* 150,000; *Deaths:* 4,700. (For additional details from [www.UNAIDS.org](http://www.UNAIDS.org), see end of Section 10B.)

**Literacy Rate** (*defined as those age 15 and over who can read and write*): 89.6% (*male:* 91.8%, *female:* 87.4%), with ten years of compulsory schooling (INEGI 1992a)

**Per Capita Gross Domestic Product** (*purchasing power parity*): \$9,000 (2001 est.); *Inflation:* 6.5%; *Unemployment:* 3% in the urban centers, plus considerable underemployment. Among most of Mexico's rural population and urban poor, who constitute by all measures a majority of the population, the standard of living is close to subsistence. In 1990, 63.2% of adult Mexicans reported a monthly

\**Communications:* Eusebio Rubio, Ph.D., Pestalozzi 1204-705, Colonia del Valle, Mexico D.F. 03100 Mexico; eusebio@internet.com.mx, rubioa@servidor.unam.mx.

income below the minimum wage, a measure of income that in 1993 corresponded to a yearly income of approximately \$3,000 (INEGI 1992a). *Living below the poverty line*: 40% (2001 est.)

## B. A Brief Historical Perspective

Mexico was the early site of advanced indigenous civilizations, starting with the Olmecs (1500 B.C.E. to 300 B.C.E.) and the Mayas, who also began as early as 1500 B.C.E. As they moved north from the Yucatan to Mexico, the Mayas brought with them their advanced agriculture. They built immense stone pyramids and invented a very accurate calendar. Classic Mayan civilization collapsed between 790 and 900 C.E. The Aztecs, who overcame and replaced the Toltecs, built their capital city, Tenochtitlan, in 1325 on the site of present-day Mexico City. The Aztec civilization collapsed following its first encounter with Spanish conquistadors under Hernando Cortes, between 1519 and 1521.

After three centuries of Spanish rule, the people rebelled under the leadership of two priests and a general, the latter declaring himself Emperor Augustin I in 1821. A republic was declared in 1823. At the time, Mexico's territory extended into the American southwest and California. In 1836, Texas revolted and declared itself a republic. After the Mexican-American War (1846-1848), Mexico gave up all claim to lands north of the Rio Grande River. French support helped put an Austrian archduke on the throne of Mexico as Maximilian I (1864-1867), but American pressure forced the French to withdraw. Porfirio Diaz headed a dictatorship between 1877 and 1880 and again between 1884 and 1911.

In 1917, rival forces agreed to social reform and a new constitution. Since then, Mexico has developed large-scale social programs of social security, labor protection, and school improvement, although many segments of the population, including the indigenous natives, barely manage to subsist.

## 1. Basic Sexological Premises

### A. Character of Gender Roles

Gender roles are changing. Some 50 years ago, gender roles in Mexico could be easily described as the traditional separation, magnification, and stereotyping of male and female differences. Women were dichotomized into the two double-moral-standard subtypes of the princess and prostitute, and men were instructed to be the impenetrable and insensitive provider who exercised his power over women.

Today this is changing. In a sample of 10,142 high school students representative of the whole country, the National Population Council conducted a national survey on various aspects of sexuality (CONAPO 1988). In 1988, 83.1% of the respondents thought men and women had equal legal rights (as they do), 69.7% thought that authority at home should be shared by men and women, and only 13.2% thought housework to be the exclusive responsibility of the woman. In another survey among 2,983 male and female 15- to 24-year-olds, Morris et al. (1987) found that only 6.6% of females and 13.7% of males thought that a woman who works outside the home is deceiving her husband and not fulfilling her obligations as a wife. In 1984, Rubio et al. (1988) found in a sample of 521 first-year medical students that only 17.7% agreed with the statement that women are naturally passive, and 91.3% thought it is equally important for men and women to pursue professional educations.

The process of recognizing the equality of women and men has clearly begun, although it is also true that, in practice, women have more disadvantages than men. Women are overrepresented in the lower-income levels and underrepre-

sented in the higher levels. Only 19.6% of Mexican women are engaged in paid work compared to 68% for males (INEGI 1992b). It is also a fact that most working women have, in fact, two jobs: the paid one and the housework.

### B. Sociolegal Status of Males and Females

The fourth Article of the Constitution explicitly recognizes the equality of men and women. In 1974, a revision of all legislation was effected to eliminate any gender discrimination, and there are several other laws and a national program aimed at evaluating and promoting the integration of woman in the nation's development. Despite these efforts, there are a number of areas where women are at a disadvantage. The expansion of industrial labor has benefitted males more than women. Inequality also shows in other areas of work: 74.1% of professionals are men, 80.6% of the executive positions in the government belong to men, and only 3.4% of those who work in domestic jobs are men (INEGI 1992b).

Technically, male and female children and adolescents enjoy equal benefits as far as education, healthcare, and social significance go within society and the family. However, gender-dimorphic training begins early. In general, lower-socioeconomic-level families tend to transmit the older values. As the social class and education level of the parents increase, one observes a tendency toward transmitting an egalitarian ideology.

### C. General Concepts of Sexuality and Love

There have been attempts at picturing empirically the constructs people have of sexuality and love. In general, it can be said that both sexuality and love are seen as positive and desirable aspects of life both for men and women, but ambivalent feelings on sexuality are often encountered. Diaz Loving's (1988) nonrandom sample of 300 individuals in Mexico City found that love, although seen positively, has many interpretations. Romantic love is seen as an idealization, passionate love as being vulnerable. Furthermore, there are important differences in how males and females perceive love: Females tend to see love more positively, while men tend to think of it as genital and sexual; men more often than women see it as an unattainable utopian dream.

In the CONAPO (1988) survey, the participating students thought that the aims of sex were: intimate communication 63%, mutual pleasure and satisfaction 37%, and having children 15.5%. In another survey effected in Mexico City with 613 individuals randomly selected from households, De la Peña and Toledo (1991a) found that respondents mentioned the following objectives for sex: enjoyment 48%, physical outlet 29%, and having children 18%. In a subsequent report (1991c), the same authors reported that, of the sexually active respondents, only 3% of males and 6% of females think of sexual intercourse as something unpleasant or have an indifferent attitude towards it. A survey of medical students found that the majority, 69%, disagree with the statement that procreation is the most important goal of sex (Rubio et al. 1988).

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A. Source and Character of Religious Values

There are two sources of religious values in Mexico: European Hispanic Catholicism and the indigenous religions that dominated the area prior to the arrival of the Europeans. Both have blended in the course of almost 500 years of interaction. Religiosity has followed the same pattern of other cultural phenomena in the history of Mexico. Rather than

one system giving up in favor of the other, a complex mixture of both cultures has generated a new and unique culture. In 1990, 90% of the population was Catholic, but the Catholicism practiced is different from the Catholicism of other countries. As with the ethnic blending, religiosity has gone through a process of syncretism. The best example of this is the cult to the Virgin of Guadalupe, which quickly gained popularity because it could be integrated with preexisting cults of Aztec gods.

To complicate the picture, the prehispanic source was not a single one. There were at least four major cultures with important religious differences: Olmec, Toltec, Mayan, and Aztec. The Aztecs dominated much of the land that is now Mexico when the Spaniards arrived, but they were the dominant political power and empire, not the only culture.

The Aztec religion was characterized by a view of the universe where a constant fight for cosmic order took place between the forces of the sun and the forces of the moon and the night. Light, endurance, sobriety, and sexual self-restraint were on the sun's side; cowardice, drunkenness, and sexual incontinence worked for the moon, the night, and the evil forces (Wolf 1975). Sex was seen as something to be controlled, but its value in procreation and as a source of pleasure in both men and women was also recognized. Polygamy was common among the wealthy and divorce rare but regulated.

An interesting aspect in the Aztec religion is the place that childbirth held in the culture. Childbirth was seen as a combat in which the woman was the warrior. A woman who died in childbirth received war honors at burial.

Moderation in every aspect of life, including sexuality, was central in the ideology of the education (Morgan 1982). In other aspects, religion and society were highly repressive: Homosexuality was severely punished, although practiced; the official penalty was death (Lumsden 1991).

The other religious components in this synergistic interaction were the beliefs and behavior patterns brought to Mexico by the Catholic Hispanic conquistadors. Historical documents clearly indicate that the Church teachings were not the norm of behavior among the people. The Council of Trent (1545-1563), a response to Protestantism, served as a basis for the teachings of the clergy in charge of indoctrinating the indigenous population. A document from the 17th century written by Fray Gabino Carta, summarizes the Church's sexual teachings: There were seven ways in which lust could appear, all conducive to mortal sin: 1. simple fornication (intercourse out of wedlock), 2. adultery, 3. incest, 4. ravishment (forcing a woman to participate in sex), 5. abduction of a woman, 6. sins against nature (masturbation, sodomy, which usually meant homosexuality, but sometimes applied also to "unnatural" heterosexual coital sexual positions—different from the man above the woman lying on her back, and bestiality), and 7. sacrilege (Lavrin 1991).

## B. Source and Character of Ethnic Values

The ethnic composition of Mexico is complex. The majority of the population, 55%, is *mestizo* or *mestee*, a mixture of the European, mainly Spanish, with the indigenes that populated the area before the arrival of the Spaniards. Creoles, descendants of persons born in the New World from parents born in Europe, still constitute an important segment of the population, 37.5%. Being European in origin and not racially mixed, they can be considered Caucasian. A third group consists of a very heterogeneous minority called Indians. These indigenes are composed of 56 linguistically differentiated groups. In 1990, the indigenous population was 5,282,347, that is, 7.5% of the total Mexican population (CNP 1989).

It is difficult to pick out a single overriding characteristic in the ethnic values in Mexico. In the background, we have the original cultural sources that still can be observed today in many aspects. However, what is Mexico today only began to constitute itself some hundred years ago. There are many traces of the conquered culture. The resulting culture, best described by Octavio Paz (1950), is hermetic, inscrutable, full of resentment, and searching for refuge and finding it in the Virgin Mother María de Guadalupe-Tonantzin. According to Paz, Mexican culture is also hiding, always behind masquerades like the macho role where men attempt to calm their fears of being penetrated in a sexual way. Yes, but more importantly, Mexicans also hide in their inner self, behind a very sophisticated strategy of simulation and lies. Almost every foreigner soon learns when dealing with people of low social level that words and promises do not mean what they normally mean. When Mexicans lie or simulate they feel protected and safe. The cult of the Virgin of Guadalupe, the macho attitude, the propensity to simulate and to lie are the results of a process lived by a culture that, instead of being eliminated, was dominated.

[Comment 1997: In addition to the value of *machismo* mentioned above, Mexican sexual attitudes and behaviors are strongly influenced by three other values—*marianismo*, *ediqueta*, and *pronatalism*—which are commonly shared with some minor variations across the Latino world of South and Central America. To avoid duplication in several chapters, these four basic values are described in detail in Section 1A, Basic Sexological Premises, in the chapter on Puerto Rico. The reader is referred to that material later in this volume. (End of comment by R. T. Francoeur)]

But the Mexico of 1995 is by no means well depicted by the above comments. The process of the last two-plus decades has exerted a profound impact on the character of Mexican culture. Proximity to American culture is a major factor. The American dream is at the same time desired, hated, and feared, but the shaking of economic structures during the 1980s has led to a new identity search that is currently in the process of being delineated. This is evident in the sexual attitudes and behavior of people, as can be seen below.

## 3. Knowledge and Education about Sexuality

### A. Government Policies and Programs for Sex Education

In the last five to ten years, the need for sex education has been recognized and accepted by most sectors of the population. There are, however, differences about what this education should include and how it should be effected, depending on the ideology of the subsector of the population one considers. Both the government and the Catholic Church have stated that there is a specific need to pay attention to the educative process of sexuality.

Education in Mexico is centralized. The Ministry of Education is in charge of developing programs for all basic school levels—the first ten years of education. This it implements with free schooling in an extensive system of public schools. Official textbooks are provided for these schools and their use is compulsory. Private schooling does exist, but their programs have to cover the official program material.

This situation has facilitated the inclusion of sex education themes. Since 1974, when the official population policy changed from a pro-procreative to a policy promoting low population growth, sex education has been seen as an important element of this policy. A National Population Council was established to pursue actions necessary to implement the new policy. One of the early programs under-

taken was the National Program for Sex Education. As a result of this program, the content of the official programs and textbooks began to include sex education themes.

Initially, the sexual contents were limited to basic biological information. This raised considerable opposition, but after almost 20 years, the general public has come to accept the need for sex education and to demand more completeness in the program.

Most adolescents, especially females, now have access to information about puberty through the school system. The contents of sexual education programs now include psychological, family, and community considerations of sexual development. Meanwhile, sex education has been integrated into a more general framework of population education (Saavedra Arredondo 1986). The major shortcoming is the lack of adequate training for the teachers who apply these programs.

## B. Informal Sources of Sexual Knowledge

In the last ten years, an increase in the role of parents as reliable informants has been observed. Friends, popular literature in the form of comics with stories, and television and radio constitute the alternative sources of information. Popular literature deserves a special comment because it is probably the material more frequently read by Mexicans. Unfortunately, it is one of the means of perpetuating sexual myths and ambivalence towards sexuality. In the last four years, there has been a growing interest in the mass media to include sexuality themes in their broadcasts. In general, this has become a new source of scientific information for most people.

### 4. Autoerotic Behaviors and Patterns

#### A. Children and Adolescents

Children frequently engage in self-pleasuring, but it still causes anxiety in many parents. The exploratory activities of children are well recognized and tolerated, but more explicit practices of sexual arousal are repressed. There are no figures of the incidence of this phenomenon.

Adolescent self-pleasuring is also very common. Reactions to it vary with the social context. In 1984, in a survey of single university students nonrandomly selected for a comparative study with American single students (mean age in both groups 20), Rubio (1989) found an incidence of 50.8% that, interestingly, was not different from the American incidence. In another study among younger students (17 to 19 years of age), Rubio et al. (1988) found a rate of 65% with an important gender difference: 88% for males and 39% for females. In a more recent study among 728 students 17 to 26 years of age, Ordiozola-Urbina and Ibañez (1992) found similar numbers: 83% of males and 22% of females.

Attitudes towards self-pleasuring are not clearly oriented towards accepting or denouncing it, but a tendency to view it as a natural act and not a sick one is clear. Morris et al. (1987) found that 46% of adolescent females and 75% of males said that autoeroticism was OK once in a while, but 34.5% of the females and 49% of the males said that self-pleasuring was bad for the health. Rubio et al. (1988) found less-restrictive attitudes, but the respondents were medical students: Only 29% agreed that self-pleasuring is not a healthy practice.

#### B. Adults

There is less systematic information on adult autoeroticism and attitudes about it. Among Mexico City adults, De la Peña and Toledo (1991b) found that 75% of males and 20% of the participating females said they had engaged in

self-pleasuring. Interestingly, more than half of those who were currently engaging in this sexual outlet at the time of the study said they liked it very little or not at all. My own personal experience with the mass media on this issue indicates that self-pleasuring is still one of the most anxiety provoking of all sexual issues.

### 5. Interpersonal Heterosexual Behaviors

#### A. Children

Sexual exploration and sex rehearsal play occurs very often in children. There are forms, like doctor's play, which are tolerated and understood. More-explicit sex play is not tolerated and is usually repressed by parents and other caretakers, such as teachers.

#### B. Adolescents

##### *Puberty Rituals*

There are no widespread rituals of initiation to puberty.

##### *Premarital Sexual Activities and Relationships*

During early adolescence, 11 to 15 years of age, most adolescents begin to explore in a form of ritualized relationship called *noviazgo*, formally a relationship period prior to marriage. However, during early adolescence, *noviazgos* are commonly established without marriage as a goal. For young adolescents, it is a social way to regulate interpersonal relationships. It appears that the major part of early dyadic sexual exploration takes place in this form, though no formal data exist. At this early age, *noviazgos* are usually of short duration. Once an adolescent has had his or her first *noviazgo*, it is not difficult for either a male or female to continue with subsequent *noviazgo* relationships. Intercourse is usually deferred to a later age.

The possibility of having had the first intercourse increases after 15 years of age: The CONAPO (1988) survey found that the typical age for first intercourse is 14 to 17 years of age for males and 16 to 19 years for females, but only 23% of participants had had sexual intercourse. Figures from other studies are higher: In a 1984 group of unmarried students, Rubio (1989) found a figure of 40%. Also in 1984, among medical students (17 to 19 years of age), Rubio et al. (1988) found 46% had had intercourse (59% of males and 31% of females).

The last decade may have seen an increase in early sexual intercourse, especially in the big cities. In their Mexico City study, Morris et al (1987) collected information from 2,983 youngsters in 1985 and found among the group of 15 to 19 years: 13.4% of the females and 44% of males had had intercourse, with 39% and 85%, respectively, for the 20- to 24-years-of-age group. More recently, Ordiozola and Ibañez (1992) found among 728 university students that 31% and 74% of males had had sexual intercourse.

#### C. Adults

##### *Premarital Courtship, Dating, and Relationships*

De la Peña and Toledo (1991c) studied adults in Mexico City and found that 76.3% of their respondents had had premarital intercourse. In another study by the same authors on adults living in the state of Baja California bordering the United States, the figure for premarital intercourse was 93% for males and 54% for females.

Those who will marry follow a clear set of rules for courtship, with a formal *noviazgo* that includes several assumptions: mutual exclusivity of sexual interaction, regular scheduling of dates, and, when the decision to marry has been taken, many activities to prepare the couple for the common life. Sexual intercourse is common in these adult relationships as the institution of *noviazgo* has gained au-

tonomy in the past 30 to 40 years, and surveillance by an older woman in the family, the *duana*, has declined. In the larger cities, the *noviazgo* often has much less restrictive rules than it did in the past. Economic difficulties may delay or make the marriage plans impractical. One result is that a significant number of persons elect a single life as the style of life, either never marrying or after one or more marriages. These individuals may establish *noviazgos* where marriage in fact is not considered for the future.

Although not prevalent, there are some forms of courtship and premarital sexuality that deserve mention. In many communities, some close to Mexico City, a man and woman may decide to live together, but the man is said to “steal” the woman from her family. Depending on the economic possibilities, the woman goes to live with the man’s family or the couple establishes a home of their own. After some years, and some children, the couple may decide to marry, and a wedding takes place, usually with a long series of festivities that may extend to several days. In some communities of the state of Oaxaca, the tradition of arranged marriages persists, many times in a less definitive form because the opinions of the man and woman are considered. In other instances, the man or the woman may spend some time, usually months, living with the family of the spouse-to-be to gain approval of the family to proceed to marriage.

### Marriage and the Family

Two types of marriage exist in Mexico: civil and religious, and, since one type does not have validity in the other domain, people tend to have both types. The 1990 data of the census indicate 45.8% of those 12 years or older are married, 7.4% live together but are not married, 40.6% are single, 1.9% are divorced or separated, and 3.6% are widows (INEGI 1992a).

Mexican families have varied structures, with the extended and nuclear family patterns dominant. Extended families include father, mother, and children with the addition of some other relatives, such as grandparents, uncles, aunts, or others. One form of extended family, characterized as “unstable” because some of its members, aunts and cousins, spend only a limited time with the family, is also very common. López-Juárez (1982) describes this family style as typical. The extended family functions as a social-support mechanism, substituting for other forms of social support that are nonexistent, or exist on a very low scale, in Mexico (e.g., unemployment insurance and care for the elderly). The extended family used to be the norm, but the frequency of nuclear families, groupings limited to father, mother, and children, increases as social class rises higher and urban living spreads. The mean number of household members dropped from 5.8 in 1970 to 5.0 in 1990 (INEGI 1992a).

As indicated above, cohabitation is frequent but not the norm. Monogamy is the rule and bigamy is penalized with jail. Although some individuals do in fact have two or more concurrent marriages, discovery entitles the concerned ones to send the guilty party to jail, and there are cases of this. While there are no recognized forms of plural marriage, it is important to note that this refers to formal marriage. Informal liaisons that include sexual interaction and forms of economic support, and cohabitation where one or both of the concerned have other concurrent liaisons, are not infrequent.

### Divorce and Remarriage

There are two forms of civil divorce: an administrative divorce, where the couple agrees, and the necessary divorce, where one of the spouses has incurred a legally recognized cause of divorce. Divorce statistics are not reliable,

but a general feeling is that it is becoming more frequent than it used to be some 50 years ago. The fate of the divorcee appears to differ according to gender: Males tend to remarry more than females. A trend observed in my own clinical practice is that the stigma and social barriers associated with divorce have decreased in the last ten to 20 years.

### Extramarital Sexual Relations

Marital sexuality, surprisingly, is not the most frequent form of sexuality, at least in Mexico City. De la Peña and Toledo (1991c) found that, of their respondents who had had sex in the month previous to the survey, only 45% were married. In another report (1991d), the same authors found that among the 613 adult respondents in Mexico City, extramarital behavior was reported by 29.7% (50% of males and 10% of females). In a report on the state of Baja California (De la Peña & Toledo 1992b), the figure was 40% of males and 15% of females.

[Update 1997: A form of concurrent liaison that used to be common occurs between a married man and his female lover who, after some time, acquires a higher status than a simple love affair and establishes herself in a separate household, usually helped or totally paid for by the man, who has a kind of second family with her. This relationship may include children and practically all the elements of a family, except for the legality of marriage and for the daily cohabitation, because the previous marriage is maintained. This phenomenon is known as *la casa chica*, literally, “the small home”—the term is also used to refer to the paramour. In January 1997, a prominent Mexico City politician, president of the Democratic Revolutionary Party, may have witnessed a change in public attitude when he called on his fellow politicians to abandon their widely known, and renowned, custom of maintaining several *casa chicas* and commit themselves to marital fidelity.

[Deterioration of economic standards of living seen in the last two decades appears to have made this pattern of liaison less common today than in the past. Mexico’s economy shrank by 6% in 1995 when inflation was expected to top 50%, banks were charging an astronomical 70% interest on credit cards, and corporate benefits and largess for executives and middle managers dried up, leaving males unable to support their usual number of *casa chicas* and paramours.

[Although this custom is widely practiced and has a long standing in Mexican culture, such relationships usually leave the woman totally unprotected by the law when it comes to inheritance and separation rights (food, pension, alimony, etc.). While most Mexican wives would likely be happy to see the mistresses out of work, economists are greatly troubled by estimates that tens of thousands of single women who have relied on the *casa chica* tradition for much of their livelihood will be added to the swelling unemployment lines. Most of these women have few if any marketable skills.

[The paramours are taking steps to cope, forming support groups, sometimes called *Las Numero Dos*, to help rebuild their lives and find jobs. Although Mexico’s economy remained seriously depressed into 1997 and many middle-class and wealthy males were obliged to reduce the number of paramours they supported in separate houses, the resilience of the tradition and the adaptability of Mexican males is evident in the booming popularity of “pass-through hotels,” which charge couples by the hour. However, Carlos Welti, a demographer who has been studying Mexican sexuality for 20 years, reports that the decline of the *casa chica* has been part of an evolution in sexual mores that has followed fundamental changes in the condition of women, in-

cluding increased education and growth in the number of women working outside the home. Also, because of easy access to birth control, the average Mexican woman today bears about three children instead of the 6.8 average that prevailed in 1976 (Padgett 1995; Dillon 1997). (*End of update by R. T. Francoeur*)]

### *Sexuality and the Physically Disabled and the Aged*

The prevailing attitude is that disabled and older persons are nonsexual and have no need for sexual intimacy. Only recently, and then in very small ways, has this public attitude begun to change with a slowly growing awareness of these special populations' needs.

### *The Incidence of Oral and Anal Sex*

De la Peña and Toledo (1991a, 1992a) have provided some information on attitudes toward oral and anal sex: 44% of Mexico City respondents think oral sex is an acceptable practice, 41.2% think anal sex is acceptable. In the Baja California study (1992b), the corresponding figures were 33.3 and 22.2%.

Behavioral information gives similar rates: De la Peña and Toledo (1991ab) report 45.3% of respondents as practicing oral sex: more than 50% of males but only one third of women in the Mexico City study, and 42% of males and 40% of females in the Baja California study. Among Mexico City students, Ordiozola and Ibañez (1992) found that active oral sex was practiced by 21% of females and 51% of males, while 22% of females and 52% of males had engaged in passive oral sex. In a study of younger single university students, I found a figure of 28% (Rubio 1989).

Anal sex is slightly less common than oral sex: 32% of males and 26% of females (De la Peña & Toledo 1992b); 7.4% of female university students and 13.8% of males (Ordiozola & Ibañez 1992); and 18.5% of participants in my study of single university students (Rubio 1989). There are no legal restrictions to practice oral or anal sex.

## *6. Homoerotic, Homosexual, and Bisexual Behaviors*

### **A. Children and Adolescents**

The values of mainstream Mexican culture are highly homophobic, as would be expected in a culture derived from two homophobic precursors, the Hispanic European and Pre-Columbian cultures. There is little evidence of the incidence of homoerotic or homosexual behavior during childhood and adolescence, but it is my clinical impression that these behaviors occur in an important number of people during development, especially during adolescence when identity formation is helped by closeness to same-sex friends in both males and females.

### **B. Adults**

Homosexual behaviors are infrequently studied by Mexican sexual researchers. The studies of De la Peña and Toledo (1991ab) report homosexual behavior in 3.3% of the respondents: 5% of males and 2% of females for the Mexico City study, and 9% of males and 5% of females for the Baja California study. I found a percentage of 6.2% of single students with some form of homosexual behavior (Rubio 1989).

Attitudinal information is also scarce. A tendency toward tolerating the homosexual person seems to be emerging, but few people think this is an acceptable form of sexual behavior. Only 9.9% of males and 9.7% of females in the De la Peña and Toledo (1992) study thought homosexuality was correct. While I found that 58.7% of medical students do not think legal measures should be taken against homosexuals, 40.3% nevertheless think homosexuality is a

degeneration. Still, 58.2% of female and 56.1% of male adolescents in the Morris et al. (1987) study thought it was no problem to have a homosexual friend.

According to my clinical and professional experience, there are no fixed patterns of selection of one of the traditional gender roles in male and female homosexual persons. Lumsden (1991) notes that Mexican homosexuals do not suffer the degree of loneliness typically experienced by American and Canadian homosexuals, because friends and families stay close to the individual.

The courtship patterns in the homosexual individuals have adopted an American pattern: organizing support groups, well-established spots in the cities, specialized bars, and gathering sites. An important number of homosexual and bisexual individuals, however, suffer from the restrictions of a society that is highly homophobic, and undergo a long period of isolation before integrating themselves in the homosexual social network. There are no legal restrictions for homosexual behavior, although lower-level authorities, i.e., local police, sometimes exert repression against the homosexual individuals, a manifestation more of internalized homophobia than institutionalized persecution.

During the past 15 years, homosexual persons have organized a variety of support groups. There are homosexual groups in almost every city of size. These groups work for the recognition of the legal and human rights of homosexual persons, and with AIDS prevention, education, and support.

## *7. Gender Diversity and Transgender Issues*

### **A. Transvestites, Transsexuals, and Transgenderists**

There is no systematic information on the incidence of transvestism, transsexualism, and transgenderism. The three situations do occur and the number of people who have these conflicts is not small. The following comments reflect my impressions.

Transvestism occurs in four distinct forms. First, the fetishistic transvestite, who is generally a heterosexual who cross-dresses to achieve sexual arousal, usually with complicated rituals forming part of the arousal process. When this situation generates conflict with the partner, the individual may seek treatment, usually on an individual basis with a private professional. One private institution offers help at low-cost rates for these and other sexual problems (see Section 13, Research and Advanced Education, below). Second, the professional transvestite, who may be heterosexual or homosexual, who impersonates females working in transvestite shows. Third, the homosexual who sometimes likes to cross-dress as a means of expression of his sexual preference. Some of these individuals find in prostitution a way of living; other male prostitutes just cross-dress in order to gain more customers. The fourth type is the truly gender-conflicted person who finds relief for an internal craving to express his gender identity/role by cross-dressing for variable amounts of time during his daily life. Psychological adjustment of this last subtype varies. These people usually go through a period of high satisfaction cross-dressing and then suffer from various forms of anxiety that make them seek help from a mental health practitioner.

Transsexuals in Mexico suffer from a lack of systematic attention and knowledge on the part of most health professionals. They are often mistakenly diagnosed as homosexuals in conflict; the usual response from the medical profession is rejection. I have participated in the psychotherapeutic treatment of some transsexual individuals,

but, until very recently, I was without any resource in the official health system to offer any help beyond psychological and behavioral counseling. In 1993, one public hospital agreed to pursue the medical and surgical treatment of transsexuals in collaboration with psychotherapeutic supervision by staff at Asociación Mexicana para la Salud Sexual A.C. (AMSSAC). There are major needs in this area still uncovered by official health policy.

### B. Specially Gendered Persons

Mexican mainstream cultural expectations are very dichotomized in considering individuals either male or female. This is reflected in the difficulties encountered by gender-dysphoric patients described above, and by the lack of any kind of third gender or sex as found in some cultures.

I have one verbal report from a student some 15 years ago that in a region of Oaxaca near the Tehuantepec Isthmus, there are communities where a third gender is considered, with social norms ascribing to the effeminate man activities in the household and prohibiting him from pursuing more-typical male activities. I have not had the opportunity to corroborate this information.

## 8. Significant Unconventional Sexual Behaviors

### A. Coercive Sex

#### *Sexual Abuse and Incest*

All sexual behavior of an adult with a preadolescent (prepubertal) child is considered a crime. Around 1985, the government of Mexico City established special police offices dedicated to working with victims of sexual crimes and to legally prosecuting the perpetrator. Before this change, regular police handled these crimes, and many victims avoided contact with the police fearing further mistreatment. Some other states have adopted this new policy.

Recent information suggests the level of child sexual abuse, although underreporting can be assumed. During three months in 1991 in the Mexico Federal District, 122 cases of sexual crimes where the victim was under 12 years of age were investigated: In 53%, the crime was rape, and in 91%, the aggressor was known previously by the victim (the father was the aggressor in 12% of the cases) (Muñoz Gonzalez 1992).

Incest is a taboo for most of Mexican society. Among some low-level socioeconomic-class communities, it is evident only when the daughter delivers a child fathered by her own father, and this is acknowledged by the neighborhood as one more of the facts of life. Scientific knowledge of this phenomena is very limited and far from satisfactory.

Among some isolated ethnic groups that have conserved their purity of race by not mixing with outsiders, incest may be an acceptable way of organizing and perpetuating society. This is the case, at least, among the Huicholes, a group of some 8,000-9,000 people living in West-Central Mexico. According to Palafox Vargas (1985), various forms of incest are practiced and accepted in the community.

#### *Sexual Harassment*

Sexual harassment is considered a crime only in modifications to the law effected in 1990 after intense participation of feminist leaders. Sexual harassment, both in labor and academic settings, seems to be common, but it has been difficult to document cases. Penalties are possible for sexual harassment, but there is very little experience in applying the law.

#### *Rape*

Rape, forced sexual intercourse with a man or a woman, has long been considered a crime. Recently, the penalty for

rape was increased to seven years in jail, which prevents early freedom for convicted perpetrators. Still, the crime is not adequately or sufficiently prosecuted. In Mexico City between January 1992 and November 1993, 1,645 rapes were reported to authorities (Casorla, in press). This figure of about 900 reported rapes annually in Mexico City is far below the estimates of authorities there of a yearly figure of reported and unreported rapes between 15,000 to 20,000. The figure for the whole country is difficult to estimate, but some authors put the figure at about 60,000 rapes per year (Ruiz Harrel 1979).

### B. Prostitution

Prostitution is a common practice in Mexico. There are no legal penalties for the prostitute, but there are for anyone who exploits her or him. The pattern of prostitute activities has varied with changing policies of the governments. Some 50 years ago, there were zones in the cities where open prostitution was accepted and regulated by authorities. This still is the case for several cities, but in Mexico City, the law now prohibits open acceptance zones. This policy has generated a lack of control of where and when prostitution is practiced.

There are many levels of prostitutes, from the street girl or boy to the sophisticated call girl, and even some specialized services where the contact is established by phone and arrangements made beforehand. Since these more sophisticated and organized forms of prostitution are illegal, it is difficult to find any information on the extent of the business.

In recent years, prostitutes working independently in the streets have organized themselves in groups to fight for their rights. Claudia Colimoro, the leader, now has a full program being pursued in the political arena. She estimates the number of street prostitutes in Mexico City at about 15,000 (Colimoro 1993).

### C. Pornography and Erotica

There are vague legal restrictions to the commercialization of pornographic material, vague because the material has to be considered obscene to be forbidden, and there are no clear criteria for this. Despite restrictions, softcore pornography circulates openly and legally, and hardcore is widely available. Softcore publications are produced in Mexico mainly through joint ventures with large American companies such as Playboy and Penthouse. Hardcore is not produced in Mexico, although American, and sometimes European, videotapes are illegally copied and distributed very efficiently to street markets, making them very easy to obtain. The dimension of this illegal business is unknown to anyone not inside it, but it is certainly a profitable and large business. In the last year, the Playboy subsidiary began mail distribution of legally authorized hardcore videotapes produced in the United States, but for the first time with translations in subtitles.

## 9. Contraception, Abortion, and Population Planning

### A. Contraception

Contraceptives are easily obtained by anyone seeking them. They are offered free of charge through the official healthcare system and can be purchased at any drugstore with few restrictions. This fact speaks about the informal values of Mexican society and the nominally Catholic people: The Catholic Church officially opposes the use of contraceptives, but this opposition is not reflected in the usage rates of the Catholic population. The Morris et al. 1987 study of a representative sample of adolescents in two sections of Mexico City clearly shows that the attitudes of

youngsters do not correspond to Church positions: Only 22.3% of females and 15.5% of males thought God should decide the number of children to be procreated by the couple. The CONAPO survey documented that a majority of youngsters who have had sex actually use contraception: 64.6% of young males and 58.2% of young females, with condoms used by 38.8% and oral contraceptives by 23.8%. Women reported 23.9% using condoms, 23.3% rhythm, and coitus interruptus 21.5%.

Adult use of contraceptives is common. According to the information from the National Survey of Health and Fertility, the percentage of women in a marriage, cohabitation, or other sexually active relationship who use contraceptives is 52.7%, up from 30.2% ten years ago (Secretaría de Salud 1990).

### B. Teenage Unmarried Pregnancies

Adolescent pregnancy occurs frequently. An annual rate of 56 births for each 1,000 women in the 15- to 19-years-of-age group is reported (Urbina-Fuentes 1992). The fate of these pregnancies is not clear. Eskala et al. (1992) followed 189 pregnant unmarried adolescents at one of the main centers of high-risk pregnancy care in Mexico City, reporting that most unwed mothers decided to live with the father of the child. This option was much less popular for mothers with high education expectations. Since abortion is illegal, there is no reliable information on what percentage of pregnant adolescents terminate their pregnancy and what percentage carry through to birth.

### C. Abortion

Voluntary (on request) abortion is not legal in Mexico. The law permits abortion in cases of rape or when the health of the mother is at risk. However, the legal procedure is so complex that in practice it is almost impossible. Illegal abortions are, nevertheless, widely practiced. A source of the Mexican Social Security Institute, a huge social medicine system that provides medical care to everyone who has a formal job, estimated there were about two million during 1989 (IMSS 1990). According to some not-very-systematic reports, abortion is the fourth cause of death, although this does not show up in the official statistics because cause of death is recorded under another category, such as generalized infection (Abasolo 1990). This same source estimated that for each 100,000 babies born, 5.7 women, most of them adolescents, die from abortion complications. De la Peña and Toledo (1991d) reported that a third of their female respondents said they had had an abortion. The National Survey of Health and Fertility reported that 14.3% of Mexican women had had an abortion (Secretaría de Salud 1987).

Abortion is one of the most controversial issues in Mexico. Among the Mexico City respondents of De la Peña and Toledo (1991a), 30.3% approved abortion if there was a medical reason and 28.9% if a woman wishes it for social reasons; 17.1% said they would never accept it. Givaudán and Pick de Weiss (1992a) interviewed 500 persons in two groups in Mexico City and found that most respondents approve the decriminalization of abortion, 60% think abortion is a decision of the woman only, 62% think public hospitals should offer abortions, and 76.2% think legalization would reduce maternal deaths. The opinions of men and women in these studies did not differ significantly. In a second study, Givaudán and Pick de Weiss (1992b) interviewed 300 people representative of the two most important cities in the state of Chiapas where, in 1990, abortion was legalized briefly. After some days, the local congress reversed its position and suspended the new law. While the opinions reported were more divided than in the Mexico City survey,

half of the respondents think abortion is a woman's decision and that the Catholic Church should change its point of view. Half of the respondents also think abortion services should be provided by public hospitals; slightly more than half think depenalizing abortion would reduce maternal deaths.

### D. Population Control Efforts

Official policy is clearly oriented towards reduction of population growth. The policy changed 21 years ago from a pro-growth policy. In 1974, the government recognized that a low population growth would be favorable for national development. As a result, there has been a major campaign to achieve the new goal, and there are many indications that the efforts have been conducive to concrete results. The current population growth rate is 2.6, down from 3.2 between 1950 and 1970. Efforts include actions at many levels: free family planning at public hospitals, education and information programs at many levels, programs for women looking for an increase in the quality of life, and actions to promote a better distribution of population and many others.

## 10. Sexually Transmitted Diseases and HIV/AIDS

### A. Sexually Transmitted Diseases

Evaluation of the available data on the incidence of sexually transmitted diseases is difficult because not all the cases are reported. The data reported by the healthcare system include the following figures for 1991: gonococcal infections: 15,681 cases (18 per 100,000 inhabitants), genital herpes: 3,480 (4 per 100,000), and syphilis: 3,282 (3.8 per 100,000) (Secretaría de Salud 1992). There are no statistics for the other sexually transmitted diseases, except AIDS. Despite the problem of underreporting, investigators have come to some interesting conclusions: The rate for gonorrhea has been declining, from 230 cases per 100,000 inhabitants in 1941 to the current rate of 18 per 100,000. Researchers who have attempted to document prevalence among these diseases consistently report higher figures, suggesting that the problem is much more frequent than the levels reported by official statistics (Del Rio, in press). STDs are more frequently a problem for males between 20 and 24 years of age and women between ages 18 and 24.

### B. HIV/AIDS

AIDS (SIDA) was first diagnosed in 1983 when 17 cases were identified. Since then, the increase in diagnosed cases can be divided into three phases: from 1983 to 1986, the growth was moderate; from 1987 to 1989, a rapid growth period was observed where cases doubled in only a few months with an exponential increase in identified cases; and from 1989 to the present, when there has been a slower, yet still exponential, growth in the number of cases. As of December 31, 1993, the total number of cases reported to the Health Ministry was 17,387 cases. However, estimates of the real number of cases, correcting for late reporting and underreporting, takes the figure to 27,000 cases (Del Rio, in press).

Another alarming point in these statistics is a doubling of the number of cases in women, from 7.9% of all the cases in 1987 to a current 14.8% of all cases. The current male-female case ratio is 6:1 (INDRE 1994). (Table 1 shows the numbers of reported cases from 1983 to 1993.)

Most of the cases are because of sexual transmission. Thus, it is clear that education is the only preventive measure available. The severity of the AIDS epidemic has not escaped officials, but the effectiveness of preventive measures remains under discussion. Early in the epidemic, the

government set up a special office to deal with the problem: the Consejo Nacional para el Control y Prevención del SIDA (CONASIDA). This agency has launched several campaigns in the mass media to increase the awareness of the general public of the risk posed by AIDS, but the campaigns have been criticized by both those who say they are offensive to the moral conscience of people and those who argue the contents of the messages are not clear enough. There has been an upsurge in the number of independent nongovernmental organizations (ONGs) that devote themselves to preventive and educative work, but their efforts are restricted by financial limitations. In the beginning, these organizations focused their work on the gay community, which was the hardest hit in the early stages of the epidemic. In the recent years, many of these ONGs have included actions to reach all the sexual orientations.

Public attention to the problem has increased considerably in the last three years, and the mass media has both responded and been responsible for these. It is common for radio stations, television, and the print media to devote space to discussions and informative programs on AIDS.

[Update 2002: UNAIDS Epidemiological Assessment: There is some information available on HIV prevalence among antenatal women in Mexico since the late 1980s. HIV testing of antenatal women in Mexico City in 1987 resulted in no evidence of HIV infection. HIV test results from ten states in 1990 also showed no evidence of HIV infection among antenatal women. In 1991, HIV testing in 12 states resulted in a prevalence of 0.1% and, in 1994, 0.6% of antenatal women tested were HIV-positive.

[HIV information among sex workers is available since 1986. Among the major urban areas, HIV information is available from Mexico City, Guadalajara, and, in 1987, Monterrey. Between 1986 and 1996, HIV prevalence among sex workers tested has remained below 0.5%. Outside the major urban areas, HIV information is available from Merida, Acapulco, Tijuana, and the states of Chiapas, Jalisco, and Michoacan from the late 1980s and from the 18 states through 1997. HIV prevalence among sex workers tested in the 18 states reached 1% in 1996.

[In 1995, 6% of intravenous drug users tested in Chihuahua were HIV-positive. In 1997, 1% of intravenous drug users tested in Tijuana were HIV-positive.

[In 1999, the information on HIV prevalence among STD clinic patients resulted in a very high prevalence in one site: males having sex with males (30.0%), male IV-drug users (8.0%), male sex workers (48.5%), as results of patient autoselection.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	150,000	(rate: 0.3%)
Women ages 15-49:	32,000	
Children ages 0-15:	3,600	

[An estimated 4,200 adults and children died of AIDS during 2001.

[At the end of 2001, an estimated 27,000 Mexican children under age 15 were living without one or both parents who had died of AIDS. (End of update by the Editors)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

### A. Concepts of Sexual Dysfunction

The concept of sexual dysfunction as a health problem is only recently gaining acceptance in Mexico. The traditional approach ignored the quality of sexual interaction of people. If one interprets the decisions of the official health system on healthcare policies, attention to these problems was considered either unnecessary or a luxury. The assumptions were that problems of sexual dysfunction were always in the realm of psychoanalysis and traditionally outside the realm of possibilities available to the majority of Mexicans because of the high cost of treatment. Also, emotions of shame and undue guilt prevailed among those who had such problems, preventing any search for help. This panorama has changed in the last 15 to 20 years. I have had the experience of people who at 50 years of age ask for help for problems they have been aware of for 30 or more years, and who express their relief at the change they experienced in society. It is now easier to admit that one has a sexual problem and to seek help. The resources to provide effective help are still limited to a few private organizations with limited resources. I have been in the forefront of this change, because the institution (AMSSAC) where I work devotes its efforts specifically to the treatment of sexual dysfunction among economically restricted individuals, and to providing formal training in sex therapy to professionals.

In the minds of lay people, the concept of sexual dysfunction is still very vague. Most people immediately identify terms such as impotence and frigidity with the lack of ability to complete intercourse and to experience pleasure and orgasm. In more-professional settings, increasing attention is being paid to sexual dysfunction. Medical associations and medical schools are beginning to include themes on sexual functioning in their curricula and in their programs for congresses and professional meetings.

As a frame for clinical treatment and research, the following concept of sexual dysfunction has been proposed: a series of syndromes where the erotic processes of the sexual response occur recurrently and persistently in a way that results undesirably for the individual or the social group (Rubio & Díaz, in press). There is no information on the incidence and prevalence of these problems among the general population, but there are a number of indirect indicators that show the problems to be very common. In six years, the sexual dysfunction clinic set up at AMSSAC has been used by close to 700 individuals, around 30% of whom seek help as a couple. This number is surely much lower than the total number of people seeking help at AMSSAC, because patients requesting treatment are requested to wait a long time before their treatment can begin. The data in Table 2, re-

**Table 1**  
New Cases of AIDS per Notification  
Year and Sex, 1983 to 1993

Year	Cases per 1,000,000	Incidence	Ratio Male: Female	Percentage of Cases in Women
1983	6	0.07	6:0	0.0
1984	6	0.07	6:0	0.0
1985	29	0.3	14:1	6.9
1986	246	2.9	30:1	3.2
1987	518	6.6	12:1	7.9
1988	905	10.6	6:1	13.5
1989	1,607	18.3	6:1	15.2
1990	2,588	31.8	5:1	16.2
1991	3,167	37.9	5:1	15.4
1992	3,220	37.5	6:1	15.2
1993	5,095	58.5	6:1	14.8
Cumulative data from 1983-1993	17,387	200.00	6:1	14.8

ported by González in 1993 and based on 195 initial-intake diagnostic interviews during an 8-month period, give an idea of the relative frequency of the sexual problems encountered at AMSSAC. Generalization, however, is difficult, because the center is a specialized center in Mexico City. Comparative information from other regions of the country is not available.

### B. Availability of Counseling, Diagnosis, and Treatment

Specialized treatment for sexual dysfunctions is available, but the few trained professionals and treatment centers severely limit this. This is particularly true in the smaller cities and rural areas. In the big cities such as Mexico City, Guadalajara, and Monterrey, individual professionals who have obtained specialized training both in Mexico and abroad—mainly the United States—offer sexual therapy privately. However, this is far from sufficient for the size of the population. The situation is more critical in the official health system where sex counseling and therapy is not offered in any systematic way. Some professionals working for the official health system have been trained in sexual counseling, and they do provide this service, but with no organized structure.

As mentioned above, AMSSAC is involved in the training of sex therapists, and some already trained professionals offer their services within the sexual dysfunction clinic at AMSSAC. This clinic, although privately run, serves only patients whose economic situation prevents them from seeking help in a private clinic. Much work is needed before it can be said that the Mexican population has the ability to solve its sexual dysfunctions via professional treatment. Unfortunately, one result of the above situation is the proliferation of street therapists and fraudulent remedies to which many people still look for help.

## 12. Sex Research and Advanced Professional Education

Sexual research is conducted as a formal activity by very few researchers. However, their work is beginning to give a panorama of what goes on in the country. This has reduced the need for constantly referring to foreign research and literature.

There are researchers working now at every level of the sciences that deal with aspects of sexuality. Basic physiological research in animals is conducted following state-of-the-art methodologies in highly specialized centers. Psy-

chological research, conducted basically by a group in the Universidad Nacional Autónoma de México, has produced interesting information on the sexual behavior of young people, some of which is reviewed in this article. Anthropology researchers have also produced original work on gender issues in both the Universidad Nacional Autónoma de México and in El Colegio de México. Clinical research on sexual problems is just starting, but some information is beginning to appear. The systematization of these efforts into a body of sexual science, however, is far from being realized. Sexology, as a formal discipline, is only recently being considered, and this with considerable reticence.

Advanced education in sexology has been offered by private institutions for some 25 years, but these efforts have been concentrated in Mexico City. Recently, a number of private and public universities have opened up the possibility of short programs on sexology, focusing on sex-education issues. The list below reflects the efforts and achievements of the main groups that have participated in the construction of the human sexuality body of professionals.

The Asociación Mexicana de Educación Sexual (AMES), a private nonprofit organization, was the first to offer systematic training in sex education, with good foundations in sexology. This organization has offered courses for professionals—usually professionals trained in other disciplines, such as education, psychology, and medicine—courses of approximately 180 hours, since 1974. Other institutions, such as the Instituto Mexicano de Sexología, followed this pattern, although with modifications in length and format of the courses offered.

Then, organizations with a focus on special problems, such as adolescent contraception, and family planning, followed. Among the latter, the Fundación Mexicana para la Planificación Familiar (MEXFAM) has distinguished itself in systematizing the training in sexuality via postgraduate courses in sex education and sex counseling. This organization has promoted the institutionalization of training in public universities in other cities in addition to Mexico City, in what has become known as the Diplomats in Sexuality.

Training in sex therapy has been available since 1987 in our institution, Asociación Mexicana para la Salud Sexual (AMSSAC). Training includes clinical experience and formal lectures and readings over two years, with 650 hours of instruction.

Official institutions have included courses on sexology in the medical and psychological curricula, but no formal graduate courses are offered, with the exception of the aforementioned Diplomats in Sexuality. No formal degrees in sexology are offered.

## *Demographics and a Brief Historical Perspective*

ROBERT T. FRANCOEUR

### A. Demographics

Morocco is situated on the northwestern coast of Africa. It shares its borders with Algeria to the east and south, and with Mauritania to the southwest. It is bordered on the west by the Atlantic Ocean and on the north by the Mediterranean Sea, the two expanses of water being separated by the Strait of Gibraltar, which is situated to the north of Morocco. The area of Morocco is 172,410 square miles (446,550 km<sup>2</sup>), slightly larger than the state of California. About 20% of the land of Morocco is arable. Fertile plains extend the length of the Atlantic coastline: in the regions from the center-north, the plain of Fès-Saïss; to the south, the plain of Souss-Massa; and to the south-southwest, the Tadla. To the east of these plains, the Atlas Mountains, which peak at 4,165 meters (13,665 ft.) (Toubkal), extend from the southwest of Morocco to the confines of the Algerian borders in the northeast. To the north, the Rif Mountains connect the northwest coast of Morocco to West Algeria (l'Ouest Algérien). Of the great wealth of Morocco, along with farming and its human resources, is the mining of phosphate, which is found in great abundance in the central regions of Morocco, the city of Khouribga, and in the Moroccan Sahara. Until 1976, the Mo-

(CIA 2002)

rocan Sahara represented one of the last vestiges of French colonialism in Morocco.

In July 2002, Morocco had an estimated population of 31.17 million. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 33.8% with 1.04 male(s) per female (sex ratio); 15-64 years: 61.5% with 0.99 male(s) per female; 65 years and over: 4.7% with 0.82 male(s) per female; *Total population sex ratio:* 1.0 male(s) to 1 female

**Life Expectancy at Birth:** *Total Population:* 69.43 years; *male:* 67.2 years; *female:* 71.76 years

**Urban/Rural Distribution:** 53% to 47%

**Ethnic Distribution:** Arab-Berber: 99.1%; other: 0.8%; Jewish: 0.2%

**Religious Distribution:** Muslim: 98.7%; Christian: 1.1%; Jewish: 0.2%

**Birth Rate:** 23.69 births per 1,000 population

**Death Rate:** 5.86 per 1,000 population

**Infant Mortality Rate:** 46.49 deaths per 1,000 live births

**Net Migration Rate:** -1.09 migrant(s) per 1,000 population

**Total Fertility Rate:** 2.97 children born per woman

**Population Growth Rate:** 1.68%

**HIV/AIDS** (1999 est.): *Adult prevalence:* 0.03%; *Persons living with HIV/AIDS:* NA; *Deaths:* NA. (For additional details from [www.UNAIDS.org](http://www.UNAIDS.org), see end of Section 10B.)

**Literacy Rate** (*defined as those age 15 and over who can read and write*): 43.7% (*male:* 56.6%, *female:* 31%) (1995 est.); *attendance for nine years of compulsory school:* 95% (education is free and compulsory from age 6 to 16)

**Per Capita Gross Domestic Product** (*purchasing power parity*): \$3,700 (2001 est.); *Inflation:* 1% (2001 est.); *Unemployment:* 23% (1999 est.); *Living below the poverty line:* 19% (1999 est.)

### B. A Brief Historical Perspective

Morocco is rich in Paleolithic remains, particularly in parts of North Africa and the Sahara, which were populated until the Neolithic era. The people who settled in the region soon after that were probably natives of Europe and Asia. They became the ancestors of today's Berbers. In the 7th

\**Communications:* Nadia Kadiri, M.D., Professor of Psychiatry, Centre Psychiatrique Universitaire, Rue Tarik Ib Ziad, Casablanca, Morocco; [nadiakadiri@hotmail.com](mailto:nadiakadiri@hotmail.com) or [n.kadiri@casanet.net.ma](mailto:n.kadiri@casanet.net.ma) or [nadiakadiri@yahoo.com](mailto:nadiakadiri@yahoo.com). Abderrazak Moussaïd, M.D., 38, Boulevard Rahal El Meskini, 20 000 Casablanca, Morocco. Elaine Hatfield, Ph.D., University of Hawaii, Psychology, 2430 Campus Road, Honolulu, Hawaii 96822 USA; [elaineh1@aol.com](mailto:elaineh1@aol.com).

century B.C.E., the Phoenicians laid the foundations of commerce on the Mediterranean coast of North Africa at sites having Berber names that became the great ports of Tingi (Tangier), Melilia (Russadir), and Casablanca. The conquest of Carthage by the Roman Empire in the 1st century B.C.E. assured Roman domination of the entire African Mediterranean coastline to the Straits of Gibraltar. From 25 to 23 B.C.E., Juba II, a Berber sovereign, administered the Berber kingdom of Mauritania (Algeria, Morocco, and a part of Mauritania). Around 42 C.E., the emperor Claudius I annexed the whole empire of Mauritania to the Roman Empire. In 429, Morocco underwent the invasion of the Vandals. The Byzantine general Bélisaire regained the region in 533. After the conversion of the emperor Constantine I the Great in the 4th century, Christianity expanded in the Roman regions.

It appears that Islamic troops reached the Atlantic Ocean in 681 under the command of Oqba Ibn Nafii. The real conquest started later on, between 705 and 707, under the direction of Moussa Ibn Nouisair. The Muslim establishment was in the meantime long and difficult. Many Muslim dynasties, claiming Arabic origins for religious reasons or prestige, ruled in various areas of the country. In 788, Idriss I, descendant of Ali, son-in-law of the Prophet, founded the dynasty of the Idrissides. It is from this age that dates the founding of the city of Fès, which became an important religious and cultural center of the Islamic world under Idriss II. The rigorist Almoravide warriors of Islam went on to dominate the region beginning in 1062, the date at which they founded Marrakech as the crossroads of commercial routes between the Arab world and the Sahara. A new reform movement, the Almohades (the Unities), launched by Ibn Toumart in the first half of the 12th century, put an end to the Almoravide empire in 1147, marking the triumph of the seated Berbers of the anti-Atlas under the aegis of Abd Al-Moumen (1130-1163). The Almohades exercised their authority over what are currently Algeria, Tunisia, Libya, and part of Portugal and Spain.

In 1269, the Mérinides of the Arabic Berbers took over the throne, but they could not maintain the unity of the North African empire of the Almohades. During the reconquest of Spain, which exiled the Arabs and the Jews, the great majority of Spanish Muslims found refuge in Morocco they took over. In 1415, Ceuta (Sebta) was occupied by the Portuguese. In 1497, Melilia fell to the Spanish. The intrusions of the Europeans provoked the rise of the Beni Saâd (or Saâdiens), who became masters of the country in 1554. Moroccan Saâdiens, aided by Moorish and Jewish refugees from Spain, created a prosperous and unified country. In this period, Moroccan architecture and arts flourished. In 1664, Mauly Rachid founded the Alaouite dynasty, which still reigns to this day in Morocco. The Alaouite dynasty knew its apogee under the sultan Moulay Ismail (1672-1727), the builder of the city of Meknès. His reign was followed by a long period of family rivalries. At the end of the 18th century, only the northern third of Morocco remained under the administration of the sultan.

On March 30, 1912, the sultan recognized the French protectorate. Spain, for its part, assumed control of the north of Morocco, from the enclave of Ifni (southwest) and from the Moroccan Sahara (west). The occupation of the country was not total until 1934. After World War II, the Moroccan nationalist resistance forced independence in 1956, opening the era of the constitutional monarchy in Morocco. The last vestiges of European colonialism persisted until the recent past. The enclave of Ifni was not returned to Morocco until 1964, and the Moroccan Sahara was not recovered until 1976 at the end of a popular nationalist march called the "Green March." Two other enclaves, small ports situated on

the Mediterranean coast west of Tangier, Ceuta and Melilia, are still occupied by Spain.

## 1. Basic Sexological Premises

### A. Character of Gender Roles

The traditional family structure remains very faithfully attached to the archaic patriarchal scheme. The father is, in general, a patriarch who inspires respect and to whom one owes obedience and acknowledgment. The mother is the housekeeper "wife-mother" who does everything. She is the one who makes the decisions in the social sphere. But she prepares her own strategy for managing her ecosystem by imposing a strong personality in the household. She reveals herself to be more conservative than the man. When a woman becomes a mother, she is always considered a potential danger, because she is perceived as having a devastating effect on the man. However, our Islamic religion adopts an ambivalent attitude toward women. On one side, she is considered as being more wily than *Iblis* (Satan) whom she incarnates in our collective unconscious; on the other side, the *Hadith* (*Words of the Prophet*) considers woman as a simple being of spirit, whose faith is incomplete. This notion is largely predominant in the rural population, whereas city women have begun to rebel against this state of things (Moussaid 1992; Naamane 1990). [*Update 1998*: In terms of Moroccan cultural change, there are continuing tensions between the people of the *magzken* in the urban organized government and the people of the rural and tribal *bled*. These tensions often focus on the differences between modern Western sexual and marital values and the age-old customs and values espoused by the tribal and rural cultures (Fernea 1998, 63). (*End of update by R. T. Francoeur*)]

### B. Sociolegal Status of Males and Females

In the legal sphere, the rights of the individual man or woman are governed by the penal code, the code of commerce, and the code of family (personal) law (*mudawana*). Morocco's penal and commercial codes are identical in scope, with men and women sharing the same rights and obligations. To the contrary, the code of family law, which regulates man-woman relations in the domains of marriage, repudiation, filiation, custody of the children, guardianship, and inheritance, is far from being equitable (*Statut du Code* 1996).

[*Update 2000*: A first step in reform of the *mudawana* came in the early 1980s, when the Union de l'Action Feminin and other groups gathered over a million signatures in support of a petition urging the King to reform the family law regulating marriage, divorce, inheritance, child custody, and polygamy. There is still no central office to deal with alimony or child support. The new code is known as the *Statut du Code Personnel "Mudawana"* (1996) (Fernea 1998, 106, 113, 120). (*End of update by R. T. Francoeur*)]

If the penal and commercial codes are inspired by French law, the Moroccan code of family law is inspired by the *Chariâ* (*Islamic Law*), especially that of the Malékite rite. Although the *Chariâ* accepts polygamy with up to four legitimate wives, Moroccan law adopts some restrictions with the view of limiting the practice of polygamy, and poses conditions of equality in the treatment of the co-spouses. Polygamy is to be avoided when a disparity is to be feared (Article 30.1).

On the other hand, Moroccan women still have not been able to reach a real emancipation and autonomy vis-à-vis men, despite the important changes observed in our modern society. The Moroccan woman still commonly estimates the man to be superior to her, tolerates work of a temporary nature, judges having children, especially boys, as all important for inheritance, thinks that virginity is of major im-

portance, and accords a great place to the ceremony of marriage. The woman in our society is a woman in evolution, but she remains linked to the group (Amir 1988; Kacha 1996; Moussaid 1992). This woman is opposed to the total transformation of those who might lead us toward an insecure situation. This opposition is because of internal resistance that is linked to the educational and external schemas in the measure where the social milieu brakes this desire for change (Amir 1988; Kacha 1996).

On March 12, 2000, two rival demonstrations by several hundred thousand Moroccans bore testimony to the transitional tensions and evolution evident in our country. The issue of both demonstrations was a government plan for a variety of social and human rights reforms proposed by the new King, Mohammed VI, who came to the throne after the death of his father, King Hassan II, in July 1999. Among other reforms, the government plan would fully replace with a court divorce the practice of repudiation, in which the husband can divorce his wife by a triple verbal declaration. The reform would also provide for equal division of money and property in a divorce, and support a literacy program for rural Moroccan women, over 80% of whom are illiterate. In the capital, Rabat, 200,000 to 300,000 members and representatives of women's groups, human rights movements, and political parties ended their march supporting the reform with a concert. In Casablanca, at least 200,000 men and women marching in separate columns—some claimed twice that number—denounced the reform (Associated Press 2000).

[Update 2000: In terms of judiciary power, Morocco is far ahead of Egypt, with 20% of its judges being women, compared with no Egyptian female judges. On the other hand, whereas Egyptian President Sadat appointed 35 women to his country's Parliament in 1981, Moroccan women had to wait 37 years following independence to have two women elected to the Moroccan Parliament (Fernea 1998, 117). (End of update by R. T. Francoeur)]

### C. General Concepts of Sexuality and Love

In Islam, the love of God occupies a big place in the heart of the believer with regard to carnal love. This has not prevented sexuality from flourishing with the advance of Arab-Islamic civilization, across the different dynasties, in passing through the great sociocultural cities of Damas, Baghdad, and Cairo (Malek 1995). Since those early times, the arts, knowledge, amorous poetry, and sexual culture have not ceased to deteriorate. This degradation puts in relief the contradictions that exist between the religious law and the traditions that are a part of what is prescribed by Islam concerning sexuality and what is forbidden within the family, in the extended community, and in the whole society. While the Muslim religion is more permissive, in contrast to Christianity, it gives primacy to carnal pleasure within the framework of marriage as a means of union with the other and with God. This glorification of sexual pleasure is a necessary ornament to the existence of the believer. Sexual abstention is, consequently, advised against, almost forbidden: "Rahbaniatan: The monasticism that they [Christians] have created has not ever been recommended or enjoined by us," the Koran tells us. The *nikah* (marriage), the religious and judicial framework in which sexuality exerts itself, organizes the sexual connections, their breaks, their changes, and the practical consequences that they entail.

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

[Comment 1998: To understand Moroccan culture, one needs to have some sense of the Spanish, French, Portuguese, Berber, and Arabic influences that have been

blended together to create modern Moroccan linguistic heritage and customs. In Moroccan civil law, we are dealing with Islamic law, local customary law, and the resonance of tribal law, Spanish and Portuguese customs, and the French penal code. Attitudes toward women, for instance, come not only from Islam, but also earlier presences, such as the Tuareg nomads in the south and the mountains. When Herodotus spoke of the "blue men of the desert," he commented on how socially strong the Tuareg women were, and called them Amazons. When the Tuaregs became Muslims, they kept their tribal laws (Fernea 1998, 63-64). (End of comment by R. T. Francoeur)]

### A. Cultural Factors

The sexual behavior of humans is largely influenced by their sociocultural context. In our societies, to bring up the subject of sexuality is *hchouma*. This word is delicate to translate: On the one hand, it means "disgrace," on the other hand, it means "modesty." It is a code to which one conforms without reflecting on it and which legislates all the situations of existence. *Hchouma* presents itself thus like a thick veil that separates two worlds in total opposition: The one is governed by local customs and excludes every possibility for a being to affirm oneself as an individual, except for the social model. The other universe is done in silence and in secret. It is the world of the person beyond the conventions (Naamane 1999).

In the Arab world, sexuality remains a taboo, the oppression of women keeps their appearance more archaic; however, many voices are being raised against this state of things. Thus, many voices are being raised to denounce the situation of women in the Arab world and especially the sexist discrimination: polygamy, the wearing of the veil, and their non-participation in public life (Attahir; Cherni 1993; Kacem 1970).

In Morocco, the role of the woman and her status varies as a function of her ethnic origin, of her rural or urban setting, and of her socioeconomic and intellectual level, among others. Thus, according to the last census (1997), only a quarter of the urban women are illiterate, compared with 89% of rural women. Likewise, with the practice of polygamy, which varies according to the regions. The Berbers and the Fassis are less polygamous than the inhabitants of the Chaouia (region of the center). Women of the Moroccan Rif and of certain regions of the north work in the fields, assuming the rougher tasks, while men are generally passive. However, these women benefit from more experience, the right to education, and the right to work. But despite the recent changes in women's personal status [*mudawana*], more limits are emphasized in the persistence of polygamy, no right to divorce (the husband's prerogative), and no equality for inheritance, where a daughter inherits half of what a son receives.

However, misogyny remains common currency in Morocco; the woman holds a social status of second rank. She often remains less desired at birth than the boy. She frequently has less access to education. If she works, she has to do double work: professional activities and household activities. And she owes obedience to her husband.

### B. Source and Character of Religious Values

Knowing that 99% of Moroccans are Sunni Muslims, a remark must be made immediately: Islam is far from being the religion most repressive of feminine sexuality as it is current to believe; well to the contrary, Islam's view of sexuality takes more of the sense of a sacred duty, where erotic practices are encouraged, pleasure is pursued, and the satisfaction of the woman is indicated. Islam distinguishes itself in this way from the Judeo-Christian culture, where sexual-

ity is a “regrettable necessity,” a moment of victory of the body over the soul according to classical duality (body/soul, good/bad).

In considering woman as an erotic and seductive being, but also deceptive, Islam creates fears of the ominous role she can play in destabilizing society. Thus the prophet said: “I will not let this point be the cause of worse discord for men than for women.”

Mernissi (1983) writes in this framework: For Islam, the woman is an invincible seductress; the undoing of the man is inevitable if he does not have recourse to God. The prophet orders his disciples: “Do not visit the women alone, Satan will seize you” (Berrada et al. 1999). In order to avoid the ominous consequences of that sensual and seductive tyranny over the social equilibrium, the Koran has foreseen the following measures:

- *Prohibition of Coeducation.* However, in Morocco, coeducation in the primary and secondary schools and universities is a current practice. Women have the right to enter any profession or job. Just recently can one find women employed as traffic police.
- *Wearing of the Veil.* In Morocco, one finds great freedom regarding the wearing of the veil. Despite the extremist events that have occurred over the years, Morocco has witnessed a rise of integration and accommodation. Although the number of women who wear the veil has increased greatly, the wearing of the veil is a trivial act, neither rejected nor required.
- *Sexist Discrimination and Oppression of Women.* Islam has attributed to women the status of minors. During all periods of life, it is the man (father, husband, or son), who manages her life. She owes him obedience and submission. She can be beaten in the case of disobedience (*Les Femmes IV: Sourat 38*).
- *Polygyny.* Islam gives to man the right to have four wives at the same time (*Les Femmes IV: Sourat 3*). In defense of this right, the Imam Ghazali explains: “There are some men whose sexual desire is so ebullient, that a single woman does not satisfy them and does not protect them against the risk of becoming adulterous. It is desirable in this case that they marry several women (from one to four)” (Al Ghazali 1992). Thus, on the one hand, for Islam, it is the woman who is a seductress and nymphomaniac. On the other hand, it is the man who needs four women to appease his needs! Mernissi (1983) poses the question whether it is not the dreaded polyandry that is at the base of the conclusions regarding the erotic nature of women. The sexual satisfaction of women is taken into account by such laws that made sexual satisfaction of the woman a conjugal right in the case of polygamy and that authorized divorce in the case of the impotence or abstinence of the husband. Thus, the sexually satisfied woman will not try to look for sexual pleasure in illicit extramarital relationships.
- *Control of Women’s Sexual Practices.* Islam constrains the woman to make love with her husband every time that he wants. In the case of refusal, she exposes herself to the curse of God. The prophet, reported by Boukhari, said: “The woman who refuses to satisfy the needs of her husband is cursed until she accepts.”

Islam gives the woman the right to accept sexual pleasure. Thus, “the preliminary games [loveplay] (*mulaaba*) are warmly recommended by the prophet,” “caress your women until they are tender.” These preliminaries are destined for the satisfaction of the woman, just as the sexual act is not a bothersome duty, but the happiest gift from heaven (Boudhdiba 1986).

The frequency of marital contact has also been regulated. Thus, the Imam Al Ghazali (1992) recommends that Muslims make love with their wives as frequently as possible. He proposes for the polygamous at least one contact every four days.

Sodomy is prohibited. “Cursed are those who take the woman by the anus,” said the prophet (Al Ghazali 1992). Sexual contact during menstruation is forbidden by the Koran (*The Génisse II: Sourat 22*). Masturbation, even though not forbidden, is not recommended. It is permitted only in the case of the risk of adultery or in the event marriage is not possible. Sexual contacts outside of marriage are prohibited.

### 3. Knowledge and Education about Sexuality

#### A. Government Policies and Programs

Sexual education, such as is seen in European and North American countries as part of the programs of academic study, does not exist in either primary or secondary academic programs. What is taught is provided in the form of scientific knowledge of the anatomy of the sexual organs and of the biology of fertilization. This sexual education is centered on procreation and prevention of sexually transmitted diseases.

#### B. Informal Sources of Sexual Knowledge

The expression “sexual education” is part of the multiple taboos that characterize our society. The subject frightens and worries Moroccans, because there has always been confusion between sexual education and sexual freedom. Discussing sexuality with parents remains a strong taboo in Morocco. A certain difference exists between the two sexes. For all young children, boys are encouraged to display their genital organs, whereas girls are supposed to hide their intimacy. At the time of preadolescence, the girl has discussions with her mother, who believes her role is to inculcate in her daughter the obligation to preserve her virginity and to avoid all sexual contact before the bonds of marriage. During these discussions, she prepares her daughter for puberty. The principal role of the mother is to obligate her to preserve her virginity with a talk full of modesty and *hchouma*. On the other hand, the preadolescent boy is left to his own devices, and has no one with whom to talk about his bodily transformations other than his friends and companions. A study in 1992 (Naamane 1999) showed that in 360 Moroccan men, divided equitably between the urban and rural areas, no man had ever gotten information from his father. In one case, the father made an allusion to the puberty of his son to ask him to begin to fast. Thus, in these situations where the young lack total communication about anything sexual with their parents and elders, it remains only to the young of their age, the media, and popular speech.

### 4. Autoerotic Behaviors and Patterns

Autoeroticism, in its broadest sense, is not condemned by the *Fikh* (religious law). Moreover, no Koranic verse mentions masturbation as a prohibited practice, so it is both a quite common and well known sexual outlet. The point of contention concerns the obligation of ablutions after involuntary touching of the genitals (Rissala in Malek, 1995, p. 29). In the rural areas, masturbation, as much as zoophilia, remains the instrument most used in a male youth’s apprenticeship in sexuality. Adolescents masturbate themselves, often in a group, making from this event a competition that consecrates the one that ejaculates quickly and most strongly. If masturbation among adolescents is hushed, ignored, but not tolerated, that of adults is almost a sacrilege. It is a *hchouma*, more than a disgrace, without being truly illicit. In the popu-

lar mind, the fingers of the hand can symbolize the spelling of the word *Allah*: The little finger indicates the letter *A*, the ring and middle finger represents *LL*, and the closed index finger and thumb represents *H*, so the hand symbolizes *Allah* and must not be used as a sexual instrument.

## 5. Interpersonal Heterosexual Behaviors

### A. Children

Infantile sexuality absolutely is said not to exist in our context. Instead, from early childhood, one inculcates an implicit sexual education totally antagonistic to the consideration of the two sexes. The sexuality of a boy is praised and valued. He must forge his virility from his young age; he must be the stallion who must get hard in the presence of a woman (Malek 1995). The sexual education of girls is done traditionally by the women of the family, by mothers, aunts, and older sisters. The older women tell the young girl what is forbidden and what is recommended in terms of repressing their sexuality.

### B. Adolescents

Female adolescence is dominated by the repression of sexuality with the objective of preserving an intact hymen, the symbol of chastity, until the wedding day. The education of the senses of the body is negative and tends to block the personality of the girl on both the physical and psychic planes. The adolescent girl carries the mark [*prégnante*] of *hchouma* (disgrace) and honor, which crystallizes itself in the obsession with virginity (Naamane 1990). This education is perpetuated by the mothers, who make each step of the evolution of the girl a shock lived in anxiety. However, a study in the urban areas observed that “in three decades, the proportion of women initiated in the elementary principles of their sexuality changed from 38% to 55%.” This initiation touches on two essential questions, menstruation and the gaining of knowledge of sexual contact (intercourse) (Naamane 1990). Paradoxically, in the large cities like Casablanca, girls have access to sexual information at a precocious age.

### C. Adults

The sexuality of adults is only conceived of within the framework of marriage. The couple is then an inescapable notion and an obligation that brings one to social conformity. However, the stakes of control in this institution are varied. Contrary to the apparent patriarchy, there are many households that are managed by women with strong personalities. This reality is reinforced by the number of children: The more children a woman has, the greater is her power. And it is not by chance that polygyny is predominant in certain regions more than others.

[*Update 2001*: In the northern coastal region of the Rif, patterns of authority in the traditional Moroccan family are changing because of a major economic reality. Local unemployment has drawn 60% of the fathers and sons in the Rif to Europe in search of employment, leaving many households headed by women. At the same time, Morocco is witnessing an increase in the number of young and middle-aged women choosing to remain single. Almost invariably, these singles by choice are economically self-sufficient and well educated (Fernea 1998, 104, 116)

[The preliminaries to a traditional Islamic marriage negotiation are concerned with class, family histories (blood), and the dowry. Marriage in Morocco today involves new concerns about common goals, joint religious faith, educational background and career potential, and love and romance. In the High Atlas Mountains, the Ait Haddidou tribe follows a very different set of marriage customs. During the annual *moussem* or festival season in Imilchil, men and

women arrive looking for mates. The divorced, single, young, and middle-aged come in hopes of finding true love or at least a suitable partner. The village notary publics register the couples, so there is some record, but it is commonly understood that the couple can split up after a day or a month or a year, with no cost, no hard feelings, and no religious stigma (Fernea 1998, 64, 88-89, 104). (*End of update by R. T. Francoeur*)]

[*Comment 2003*: In Morocco, as in other cultures in which traditional tribal rural customs come into conflict with Western urban values, one of the most frequent and often-complex conflicts finds the family and older generation expecting the traditional arranged marriage, while the younger generation is being influenced by contact with the romantic marry-the-one-you-love view of marriage. Coping with this conflict of expectations and values requires some kind of compromise if the individuals and families involved are to avoid a major tragedy. (The reader is referred to Section 13 of the chapter on Sweden where the Editor summarizes the 2002 tragedy of Fadime Sahindal, a 26-year-old Kurdish woman who fell in love with a Swedish man and became the victim of an “honor killing” by her father.) Here we provide an abbreviated account of a Moroccan-tribal versus modern-marriage conflict that ended in a compromise. (The original 1987 account can be found in Roger and Terri Joseph’s *The Rose and the Thorn*.) The Josephs’ vivid descriptions of Moroccan family life make it clear that, even in Morocco, compromise is often required. In most of the world today, prospective brides and grooms, parents, elders, and the extended family have to consult with one another before arranging a marriage. Even in the most traditional of societies, parents and husbands have generally been forced to balance conflicting interests.

[The Moroccan tribal world, for example, is definitely a man’s world. Men possess absolute authority over their wives and children. They have the power to take several wives. They often promise their sons and daughters to potential allies at very young ages. Yet, if you think of your own family, you will surely observe that things do not always go as they are “supposed” to. Some fathers are impossible. Eventually, family members learn that it is easier to give in than to try to argue. Some aunts are strategic geniuses—they can enlist an army of relatives to plead, threaten, and haggle on their behalf.

[Hamadi and Fatima, for example, were going along, happily married, when Hamadi decided that it was time to acquire a second wife. Within days, everyone in his immense, extended family was squabbling. Fatima threatened to divorce Hamadi if he married again. She refused to share her house with another woman. Fatima’s brothers warned Hamadi that if Hamadi and Fatima got a divorce, they would reclaim all the land she had brought into the marriage. (Hamadi had spent years planting fruit and nut trees on the property.) Fatima threatened to take their twin daughters to her brother’s house as well. Technically, Hamadi’s family “owned” the infants, but because they were still nursing, he would have to wait two years to collect them. In Morocco, twins are considered to be *baraka* (good fortune); if Hamadi’s daughters left, people might conclude that good fortune had left Hamadi’s house. To add to Hamadi’s woes, Fatima issued a final warning. If Hamadi divorced her, she would march bare-breasted to the weekly market. This left him badly shaken. Things got worse. One of Fatima’s brothers had married Hamadi’s cousin. He announced that if there was to be bad blood between the two families, he would divorce his wife. Hamadi’s mother complained that the money Hamadi had saved for a second wife should be spent on Hamadi’s son, Ali, who had just turned 15. He needed money for his wedding. Finally, a tired Hamadi surrendered. He concluded, “Women are to be

gotten around, but I guess I won't get around these" (Joseph & Joseph 1987, 55).

[When other "all powerful" Moroccan fathers tried to force their children into unappealing marriages, sympathetic family members employed an avalanche of strategies to thwart them. Young lovers persuaded mothers, uncles, brothers, neighbors, and business partners to plead on their behalf. One fond mother slyly hinted that a prospective bride her son secretly disliked was bad tempered, lazy, and had a bad reputation. When his father forced Abdallah to marry a woman he disliked, Abdallah claimed his wife was a witch. He divorced her and married the woman he had been attracted to in the first place. After that, his poor father's alliances were really in shambles.

[One young woman threatened to kill herself if she were forced to marry. Many relied on witchcraft or magical charms to get their way. One woman warned an unappealing suitor (Haddu) that she had visited a *dhazubrith* (witch) and obtained a spell that was guaranteed to make him impotent. The marriage took place, but the hapless Haddu was unable to "become stiff" (p. 49). He tried counter-charms, but to no avail. He finally agreed to dissolve the marriage. Sometimes, these desperate stratagems worked; sometimes they did not. (*End of comment by Hatfield & Rapson, 1996, 47-48*)]

As for extramarital relations, they are illicit. But socially, the "treachery" of the woman is much more condemnable than that of the man. In reality, after 30 or more years of marriage, the woman often becomes much more demanding with regard to her husband and does not hesitate to get involved with extramarital relations. In urban areas, despite the traditional norms and ideals, marriage is more and more inaccessible because of material constraints, particularly, the high cost of living and high unemployment, which make marriage impractical for many young men. The "detrribalized" urban space creates intense sexual needs, but offers very few possibilities to satisfy them (Dialamy 1995).

In 1971, the average size of households was over 5.6 persons; this rose to 5.9 persons in 1982. In the same year, 1982, the rate of occupation was 2.3 persons per room. Many couples do not have a private bedroom. Thus, the beginning of a couple is hypothetical because of the absence of this exclusive and independent space that permits the spouses to isolate themselves during their sexual play, the condition imposed by the *Chariâ* and tradition.

Divorce by "repudiation" is an absolute weapon available only to the man, who can use it when he desires, even though the last modifications of the code of family law (1993) tend to humanize it more. The custody of children remains the full right of the mother, who to receive it should remain single until the boy is 12 years old and the girl is 14, the age at which a child has the right to choose the parent with whom he or she wants to live. When the mother remarries, the custody of the children returns automatically to the father (*Statut du Code* 1996).

Access to sexual pleasure is an inalienable right, prescribed by our religion, for both spouses to the same degree. Consequently, pleasure opens the path to all sexual practices. Only sodomy is prohibited by all the theological traditions. Instead, according to irrational popular ideas, the missionary position alone is well accepted. The other positions are seen as being generators of disorders and diseases.

## 6. Homoerotic, Homosexual, and Bisexual Behaviors

### A. Homosexuality

Homosexuality (*liwat*) derives from the name of Lot, whose person and tribe is mentioned on numerous occa-

sions by the sacred books (Malek 1995). In Morocco, male homosexuality is considered a punishable offense by both the *Chariâ* and the civil penal code. This attitude pushes homosexual practice into a clandestine realm, with all the obvious consequences associated with such social denial. Conformity to all-important social rules requires a male, regardless of his sexual orientation, to get married and have children. Within this façade of social conformity, homosexual males create well-closed spaces, cafés, cinemas, nightclubs, and so on, where they can meet other like-minded males without endangering their façade. They are completely sealed to all who come to these places for encounters.

Female homosexuality or *sihaq* is not mentioned in the Koran. It is prevalent in certain regions of Morocco, particularly the north, but remains hidden, unmentioned, and unstudied.

### B. Homoeroticism

Westerners consider certain behaviors of Arabs in general as signs of latent homosexuality. It is a matter of certain completely acceptable male behaviors, like holding hands, putting an arm around another man's shoulder, embracing the face, bathing together (Moorish bath), and masturbating in a group during adolescence in rural areas. From our point of view, these behaviors have nothing to do with being sexual. They are part of our everyday culture.

## 7. Gender Diversity and Transgender Issues

No scientific work has been performed in the transgendered field. The real transsexual subject is rarely seen as anything other than an isolated entity. They are generally confused with homosexual persons or persons with other deviant behavior. Casablanca has been known for a long time as a city where transsexuals came from all over the world for sex-change surgery. Although available, these operations were always practiced in a clandestine way.

However, cases do arise in the course of psychological consultations, in which the young behave in school or during everyday life in a manner opposite their sexual identity. In the course of follow up, some of these persons experience depression syndromes because of this conflict between their sexual identity and their social identity. Management of such cases is difficult in Morocco, where there is a complete legal void concerning this clinical entity. (See Section 8D below for transvestism.)

## 8. Significant Unconventional Sexual Behaviors

Sexology in our context must take account of sexually deviant or perverse behaviors. The particularity comes from the fact that what is perverse for us in the East may not be considered so in the West and vice versa. In this framework, it is the conformity to the prevailing social rules that sets the criteria for normality. All behavior that does not obey the said social criteria, is considered in our society as an offense. The question that is posed then is: Why are we seeing many transsexuals and transvestites in the West and very few in our Islamic countries, and then only in very specific and close circles? In our point of view, the answer lies in the close relationship between behavior and the system (society and power) in which we are living. If the social system is too liberal, too permissive, it will favor easy access and freer expression of more sophisticated "perversities." At the same time, a too rigid and repressive system will favor the appearance of a meager, weak, and repressed sexu-

ality (Moussaid 1997). See also the discussion of transvestism in Section 8D, Paraphilias, below.

### A. Sexual Abuse of Children

The sexual abuse of children seems to be frequent, but is usually hidden by the families. In the legal field, these abuses are very seriously punished whether that abuse involves a male or a female child.

### B. Prostitution

Prostitution or *zina* has always existed in our Arab-Muslim landscape, as it has in all historical civilizations. In the recent past, at the time of the French protectorate, prostitution was regulated and supervised in brothels. Today, it is repressed and constitutes an offense, which leads to other negative effects and risks. In effect, there is a “sexualization” of different social factors, which are becoming more obvious in our country. This “sexualization,” evident in the prostitution relationship (giver-receiver), is generated by the material concerns and the crushing weight of the entire social system, which neglects the woman to the point where she is reduced to her body and to her sexual appeal, and is forced to rely on prostitution to survive. Prostitution may sometimes be ignored, because it is occasional, but even then, it does raise some problems. This appearance of sexual freedom is in fact a kind of slavery of the young girl who has affairs with many men, some old, some rich, some strangers, some unfaithful spouses, and some dissatisfied husbands (Moussaid 1997; Naamane 1990).

### C. Pornography and Erotica

The pornographic industry, *khalâa*, as it exists in the West, is not present in Morocco. Instead, consumer spending has become more and more widespread, even while it is limited to certain social classes that are in contact with the Western world. The intrusion of the media, particularly satellite television and videocassettes, in our audiovisual field, has changed the previous situation by giving all levels and social classes access to pornographic images and materials. Meanwhile, the possession of pornographic documents, films, magazines, and so on, constitutes a criminal offense. On the other hand, Morocco was unique in the Arab world, being the only Arab country where the ancient works of Arab erotology of the 14th century, *The Perfumed Garden*, and so on, were available. These books, which deal with sexual behavior and erotic pleasures, are now perceived as true pornographic documents, especially by young adolescents.

### D. Paraphilias

#### *Frotteurism*

Frotteurism is a very prevalent behavior in our country, generated by the great frustration of the citizens. This frustration is a consequence of the years of repression, which censures all sexual relations outside the bonds of the marriage. The favorite place for this practice is the crowded public transportation system.

#### *Zoophilia*

In rural areas, zoophilia is still very widespread and not blameworthy. With masturbation, it constitutes an obligatory passage in the adolescent male’s apprenticeship of sexuality. Although this practice has never been mentioned in the Koran, it is prohibited without question by the *Chariâ*: “He who has copulated with a beast, kill him and kill the animal.”

#### *Transvestism*

*Takhanout* is more or less tolerated, insofar as in the past, women were absent from the artistic scene, and cross-dressing men played the role of women. This practice has always existed and exists still in certain domains where

women have not yet gained access. These transvestites are, in general, homosexuals who practice without any impunity, as long as there is no public act.

## 9. Contraception, Abortion, and Population Planning

### A. Pregnancy Outside of Marriage

Pregnancy outside of marriage is prohibited and remains punishable by law and religion. It appears that such pregnancies are more frequent in the urban than the rural areas, but no statistical study has touched this problem. However, there exist a not insignificant number of abandoned infants born out of wedlock, of which the state takes temporary charge in anticipation of their being adopted by welcoming families.

### B. Abortion

Only therapeutic abortions are authorized and practiced in a hospital setting. Non-therapeutic abortions are practiced secretly by physicians in private practice following standard medical methods. There are no accurate official statistics. Moreover, considering that contraceptive methods are not taught to young girls who get involved with illicit sexual relationships, their pregnancies are candidates for the voluntary interruption of pregnancy (IVG, *interruptions volontaires de grossesses*). These IVGs are also frequent among married women who utilize IVG in case of undesired pregnancies.

### C. Family Planning

Family planning is a program integrated within the healthcare system. It is based on the spacing of births and not on their limitation. It has contributed to reducing considerably the risks of morbidity and maternal and infant mortality. It is also an essential component of the strategy of the socioeconomic development of the country. The principal actors are the state in the public sector, the private sector, and the ONGs (*organisations nongouvernementales* or non-governmental organizations, NGOs), in particular the Moroccan Association of Family Planning. The latest study documents the results of their efforts: 99% of married women have heard of at least one contraceptive method, and 92% know where to obtain information or services for at least one method.

By decreasing order, the best-known family planning methods are the pill, the intrauterine device, tubal ligation, condoms, the injectables, and the vaginal methods. The pill remains the contraceptive method the most used, with 64% in 1995 compared to 68% in 1992. The rate of contraceptive use has increased significantly since 1980. In effect, in 1995, 50% of married women utilized some contraceptive method compared to 41.5% in 1992, 35.9% in 1987, and 19.4% in 1980 (all methods combined).

The principal objectives of Morocco’s family planning program are:

- To respond to the expressed and potential needs of the population concerning family planning and contraception;
- To attain a contraceptive prevalence in favor of the long-term methods;
- To modify contraceptive use in favor of the long-term methods;
- To involve the societal agents of the different agencies in our society—youth, sports, social affairs, agriculture, etc.—to participate in the promotion of the concept and methods of family planning; and
- To augment participation of the private sectors in the supplying of contraceptives to attain a balance between both

private and public sectors, a kind of social marketing project. At the present time, the private sector accommodates 38% of the demand for contraceptive products.

## 10. Sexually Transmitted Diseases and HIV/AIDS

### A. Sexually Transmitted Diseases

The sexually transmitted diseases (*maladies sexuellement transmissibles, MST*) and AIDS (*SIDA*) are illnesses known all over the world, and Morocco and the Arab Muslim countries are not exceptions.

At the present time, there is the Program to Fight Against STD and AIDS under the direction of the Epidemiology and the Fight Against Illness Division of the Ministry of Health, which organizes those activities in coordination with elected leaders, the local authorities, and the ONGs (NGOs). Table 1 lists the incidence of several STDs since 1991.

The incidence of STDs is progressively increasing; it increased from 50,567 cases in 1991 to 189,021 cases at the end of 1997 and 100,827 cases in the first half of 1998, despite the underreporting of cases in the public sector and its almost complete absence in the private sector.

The incidence of vaginal discharges (leukorrheas) is much higher than that of urethral discharges. In the early 1990s, syphilis outranked chancres (*Hemophilus ducreyi*), but this has been reversed in recent years. Eighty percent of the cases reported occur among 15- to 44-year-olds, with females accounting for 71% of the cases.

A variety of factors have contributed to the increase in STDs in Morocco, including:

- More than half the population is young;
- Tourism jobs in the country;
- The proximity of Europe and the important number of Moroccan nationals returning from abroad;
- The low socioeconomic level;
- The delay in the average age of marriage, which now approaches 30 years old;
- Self-medication by carriers of STDs;
- The anarchistic, unregulated prescription of antibiotics; and
- The poor use of condoms among those with extramarital relationships.

In 1999, the Ministry of Health launched a new public policy and strategy for taking charge of the STDs. This strategy adopts the syndrome approach, based on treating the patient at paraclinics without waiting for the results of biological tests. This approach, which seeks to intervene immediately to break the chain of transmission of these diseases, is based on epidemiological public health considerations, fol-

lowing the USAID project strategy, with the contribution of AIDSCAP and the University of Washington. In coping with the STDs in Morocco, one should not ignore the fact that half of the carriers of STDs self-medicate with antibiotics. This poorly advised and unregulated use of antibiotics is the cause of atypical and asymptomatic, highly contagious forms of STDs (*Note Ministérielle No. 26 1997*).

### B. HIV/AIDS

The first case of AIDS was diagnosed in Morocco in 1986. Its appearance was one of the elements that has allowed the very wide development of programs for the prevention of STDs using all the latest approaches. Tables 2 and 3 summarize the AIDS statistics in Morocco.

The age group predominantly affected is from 15 to 40 years old (69%). Ninety percent of the HIV-positive children are infected perinatally. Males account for 70% of the cases. The other particulars of AIDS in Morocco are: 42% are bachelors; 35% are married women; 85% were infected while living in Morocco; and 15% are recent immigrants.

Transmission modes include: heterosexual, 61%; homosexual, 10%; intravenous drug use, 9%; multi-risk, 8%; transfusion, 4%; perinatal, 4%; and unknown, 4%. Before the 1990s, the main modes of transmission were homosexual contact and IV-drug use; at present, the dominant mode of transmission is heterosexual intercourse.

In 1995, males with AIDS outnumbered females by three to one. The age distribution of AIDS cases was: 15 to 29, 24%; 30 to 39, 43%; and 40 to 49, 12%. STD patients, tuberculosis patients, and pregnant women showed an approximate seroprevalence of AIDS of 1 per 1,000. Eighty-three percent of the cases were urban, with the most cases reported in Oujda, Rabat, and Tangier. The transmission by blood products has noticeably diminished thanks to the screening by the Centers of Transfusion of the Kingdom, from 11.4% to 4% in 1998. However, the prevalence rate of HIV among blood donors, which was 1.3 per 10,000 in 1996 and 2 per 10,000 in 1997, had changed to 8 per 10,000 at the end of June 1998.

The actual prevalence rate of AIDS disease is 0.02%, which places Morocco among countries less touched, at the same level as the countries of the Maghreb in the western extremity of the Islamic world (northern Africa) and the Middle East.

In April 1998, the Ministry of Health adopted a national strategy to take charge of the HIV/AIDS challenge (*Circulaire Ministérielle No. 7 1998*). This strategy defines the modalities of the diagnosis of HIV, the prescription and utilization of the antiretrovirus (ARV) medications, the biological follow up, and the reporting of cases. The program is

**Table 1**

**Statistics on STDs in Morocco, 1991-June 1998**

Disease	1991	1992	1993	1994	1995	1996	1997	1998 (June)
Yeast/fungal	26,646	68,176	69,119	102,214	106,621	108,621	133,716	72,886
Urethritis	14,402	23,207	19,948	27,012	28,260	32,397	35,603	17,916
Syphilis	4,952	5,506	5,635	5,226	5,015	5,084	5,226	2,507
Chancere	2,161	2,981	3,153	3,720	4,742	4,289	5,807	3,081
Condyloma	761	775	429	451	804	1,138	662	285
Hepatitis	792	1,594	1,195	1,367	948	1,138	2,008	1,024
Genital herpes	598	651	477	502	458	574	561	220
Other STDs	225	544	1,108	2,013	3,793	2,722	5,438	2,902
Total	50,567	103,434	101,065	142,505	150,541	156,722	189,021	100,821

(*Note Ministérielle No. 491 1996*)

financed in its majority by the Ministry of Health, as well as by certain ONGs (NGOs).

The new program is based on two major, well-equipped facilities, the Hospital Ibn Sina in the capital city of Rabat, which serves the north of the country, and the Hospital Ibn Rochd in Casablanca, which covers the southern part of the country. These two centers work in close collaboration with referring centers at the regional level. Reporting cases of HIV/AIDS is obligatory in accordance with the 1995 decree of the Ministry of Public Health. In Morocco, because the country has endemic tuberculosis, the early pursuit of the *Koch bacillus* bacterium is systematic among seropositive patients.

Another aspect of the campaign against HIV/AIDS are sensitization and education programs, especially those for women, which are reinforced every year on December 1, on the occasion of the worldwide day of the fight against AIDS. Sensitization programs have also been implemented for healthcare professionals. HIV-detection equipment at all centers for blood transfusions has clearly improved the quality of donated blood. At the same time, a considerable effort was made to educate all professionals traditionally at high risk, such as barbers and dentists. More basic in the prevention of STDs and AIDS is the improvement of the socioeconomic level of the country.

[Update 2002: UNAIDS Epidemiological Assessment: According to the HIV Sentinel Surveillance, in 2001, the HIV-prevalence rate in Agadir, Marrakech, and Casablanca was high compared to previous years. But these latest data were not confirmed by the HIV Sentinel Surveillance conducted in 2001. So, we cannot conclude that the infection rate has considerably increased in these areas.

[The results of the HIV Sentinel Surveillance in 2001, in pregnant women were: in Agadir 0.20%, in Marrakech 0.00%, and in Casablanca 0.37%.

[At the end of 2001, the number of AIDS reported cases was 963, of which 69% were because of heterosexual transmission and 6% because of injection drug use in all cases. Among 963 AIDS cases reported, 620 were in males, of which 59% were because of heterosexual transmission and 9% because of injection drug use.

[Concerning STDs, 600,000 new cases of STDs are estimated, but had not been registered. The number of STD new cases registered in 2000 was 307,040, and in 2001 was 347,655. Of the STD registered cases in 2000, 39.6% were young adults between ages 15 and 29, and 44.2% were among those 30 to 44. In 2001, of the STD registered cases, 39.4% were young adults aged between 15 and 29, and 44.8% were among those 30 to 44.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	13,000	(rate: 0.1%)
Women ages 15-49:	2,000	
Children ages 0-15:	NA	

[No estimate is available for the number of adults and children who died of AIDS during 2001.

**Table 2**

**The Epidemiology of AIDS in Morocco, as of June 30, 1998**

Cumulative number of cases of AIDS disease	510
Number of declared cases in 1997	92
Number of declared cases (June 1998)	46
Number of adults affected (15-40 years)	351
Number of children affected (age < 15 years)	21
Cumulative number of deaths from AIDS	139

[No estimate is available for the number of Moroccan children who had lost one or both parents to AIDS and were under age 15 at the end of 2001. (End of update by the Editors)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

### A. Female Sexual Dysfunctions

Although female sexual dysfunctions are frequent in our society, they are usually concealed by society. Vaginismus represents the most frequent motive for a sexological consultation, because it puts the life of the couple's relationship in danger. Women who suffer from vaginismus do not consult a professional counselor or therapist until they are driven to do so by the partner and/or the family. In Morocco, the causes of vaginismus are, most often, a restrictive religious education, negative beliefs relative to the anatomy of the hymen, misconceptions about the mechanism of penetration, and sexual assault traumas (rapes and attempted rapes), which, unlike in the West, are rarely reported.

Anorgasmia, or inhibited female orgasm, is also frequent, but rarely constitutes a motive for a sexological consultation. Here, as with vaginismus, the causes are restrictive education, negative beliefs relative to female sexuality in general, the awkward behavior of the man, a lack of the development of fantasies [*agénésie fantasmatique*], and the prohibition of childhood and adolescent masturbation.

### B. Male Sexual Dysfunctions

Erectile dysfunctions (ED) are very frequent among men and affect all ages and all social classes. An epidemiological study in the general population with a representative sample ( $N = 651$ ) showed that globally, 54% of the men presented some erectile dysfunctions, distributed as mild in 38.8% of men, moderately troubling in 15.1%, and severely troubling in 1.1% (Berrada et al. 1999). But only a small minority of males who admitted to ED were willing to take responsibility and seek treatment. That is because of their socioeconomic conditions and certainly because of the feeling of disgrace and devaluation that the patient experiences when he sees in the therapist a rival who will judge him. Also keeping the patient from seeking help for ED are the irrational folk ideas that accompany sexual impotence, which suggest that it is because of *tqaf*, a form of sorcery, which is treatable by a faith healer (*marabout*). Apart from the well-known organic causes of diabetes, high blood pressure, cardiopathies, cholesterol, iatrogenicity, smoking, and so on, the psychogenic causes are more frequent for men over 40 years old. These may include conjugal monotony associated with the lack of fantasizing, and may be aggravated by performance anxiety. In effect, the process of fantasizing, in our society, is associated with adultery, and accordingly, are

**Table 3**

**The Incidence of AIDS over Time**

Year	New Cases	Accumulated Cases	Year	New Cases	Accumulated Cases
1986	1	1	1993	44	172
1987	9	10	1994	77	249*
1988	14	24	1995	57	306
1989	20	44	1996	66	372
1990	26	70	1997	92	464
1991	28	98	1998	46	510
1992	30	128	(June)		

\*19 of the 77 new cases reported in 1994 had been previously counted as ARC (AIDS-Related Complex)

prohibited and inhibited for the majority of men. Among young adults, the relationship of circular causality, where various psychogenic factors—for the most part, religious and educational—interact, is a common cause of erectile dysfunction (Bonierbale 1991).

Premature ejaculation is beginning to become a very frequent symptom and a motive for consultation, more than before, when it was considered an indication of virility that one learns in the course of the collective masturbation during adolescence. At the present time, men are becoming more and more conscious of the frustration of their wives, and are thus beginning to take responsibility for it. A very frequent symptom in our cultural context is an association of premature ejaculation with the feeling of having a small penis. Constrained to conceal his assumed handicap, the subject will ejaculate quickly in a hurried sexual encounter.

### C. Therapies

The therapeutic modalities available for male and female sexopathies are varied. Therapy is available from general practitioners, urologists, psychiatrists, endocrinologists, gynecologists, and so on, as well as by sexologists and andrologists, who are a small minority in the healthcare community. However, almost all of the patients will consult first, if not in an exclusive way, with the traditional faith healers (*marabouts*). The therapeutic arsenal from which medical personnel can draw is rather rich. The most recent products, intracavernous injections (IIC), Viagra, and aphrodisiacs, were available in Morocco before the majority of European countries made them available in the market.

## 12. Sex Research and Advanced Professional Education

The domain of teaching and of sexological research is still timid in our country. The Moroccan Association of Sexology (L'Association Marocaine de Sexologie, AMS) began an ambitious program in this domain after 1994. This program rests on the organization of an annual congress, with the participation of numerous experts in the sexological world, and of roundtables on a particular theme. Meetings and congresses of the AMS are organized in a different city and under the aegis of a different university each year. Among the objectives of the AMS is the installation of a program of teaching or a course of sexology within a university framework, and the organization of fundamental research oriented especially toward anthropological, psychological, psychoanalytic, sociological, neurological, biological, judicial, medicolegal, physiological, pathological, experimental, and therapeutic aspects of sexual behavior. This research should result in a conceptualization of sexology that is adapted to our Moroccan context. Given that the actual sociopolitical climate is not favorable, the AMS has decided to limit this discipline to the medical domain (sexual pathology). This adoption of sexology by the medical sciences may be only beneficial in the short run. The focusing on sexual behavior, in the long term, needs a reaffirmation and an acceptance of this science by society and by the medical community. Because sexology carries at the present time a pejorative connotation, research on sexual behavior is marginalized (Moussaid 1997).

Three professional organizations deal with sexological issues in Morocco:

The Moroccan Association of Family Planning (Association Marocaine de Planification Familiale, AMPF), 6, Rue Ibn El Kadi Casablanca, Morocco.

The Moroccan Association of Sexology (L'Association Marocaine de Sexologie, AMS), Abderrazak Moussaid,

M.D., 38, Boulevard Rahal El Meskini, 20 000 Casablanca, Morocco; +212-2-298-381 or +212-2-298-331; fax +212-2-221-114; psych@casanet.net.ma.

Les Orangers, E. Abdel Krim Hakam, Executive Director, Rabat RP, Morocco (or BP 1217, Rabat RP, Morocco); +212-7-721-224; fax: +212-7-720-362; cable: FAMPLAN RABAT.

## *Demographics and a Brief Historical Perspective*

ROBERT T. FRANCOEUR

### A. Demographics

The Kingdom of Nepal is the world's only official Hindu nation. The landlocked kingdom is bordered on the north by the Tibet autonomous region of China, and on the west, south, and east by India, countries with the world's highest population rates. Nepal measures approximately 54,360 square miles (140,800 km<sup>2</sup>). As a comparison, Nepal is about the size of the state of Arkansas in the United States. However, the state of Arkansas has a population of only 2.7 million people to Nepal's 25 million. Of the world's 10 highest mountains, eight stand between Nepal and Tibet, including Mount Everest. The country has three different regions with three different geological terrains: the mountains, the hills, and the *terai* or "plains." The climate varies

from cool summers and severe winters on the mountain slopes of the north to subtropical summers and mild winters in the southern plains.

In July 2002, Nepal had an estimated population of 25.3 million. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 40% with 1.07 male(s) per female (sex ratio); 15-64 years: 56.4% with 1.05 male(s) per female; 65 years and over: 3.6% with 0.97 male(s) per female; *Total population sex ratio:* 1.05 male(s) to 1 female. Nearly 30% of the country's population are adolescents or teenagers. Much of the available data about sexuality and relationships are, therefore, from adolescents.

**Life Expectancy at Birth:** *Total Population:* 58.22 years; *male:* 59.01 years; *female:* 58.2 years

**Urban/Rural Distribution:** 11% to 89%. Nepal's most densely populated areas, with nearly half of the country's entire population, are Kathmandu, the capitol, Chitwan, and Sunsari.

**Ethnic Distribution:** Burman: 68%; Shan: 9%; Karen: 7%; Rakhine: 4%. There are over 70 ethnic groups throughout the country speaking nearly 50 different languages. These different groups are classified loosely into two main categories: Indo-Aryan and Tibeto-Burman. The Tibeto-Burman groups are predominantly Buddhists, although many are still Hindu. Among these groups are Brahman, Chetri, Newar, Gurung, Magar, Tamang, Rai, Limbu, Sherpa, Tharu, and more. Caste and ethnicity are terms that are often used interchangeably to describe the population. The refugee issue of some 100,000 Bhutanese in Nepal remains unresolved; 90% of these displaced persons are housed in seven United Nations Offices of the High Commissioner for Refugees (UNHCR) camps.

**Religious Distribution:** Hinduism: 86.2%; Buddhism: 7.8%; Islam: 3.8%; other: 2.2%. As of 1995, Nepal was the only official Hindu state in the world.

**Birth Rate:** 32.94 births per 1,000 population

**Death Rate:** 10.22 per 1,000 population

**Infant Mortality Rate:** 72.36 deaths per 1,000 live births

**Net Migration Rate:** 0 migrant(s) per 1,000 population

**Total Fertility Rate:** 4.48 children born per woman

**Population Growth Rate:** 2.29%

\**Communications:* Elizabeth Schroeder, M.S.W., 45 Essex Ave., 2nd Floor, Montclair, NJ 07042, USA; ElizSchroe@aol.com.

**HIV/AIDS** (1999 est.): *Adult prevalence*: 0.29%; *Persons living with HIV/AIDS*: 34,000; *Deaths*: 2,500. (For additional details from www.UNAIDS.org, see end of Section 10B.)

**Literacy Rate** (*defined as those age 15 and over who can read and write*): 27.5% (*male*: 40.9%, *female*: 14%) (1995 est.); school education is free and compulsory from age 6 to 11

**Per Capita Gross Domestic Product** (*purchasing power parity*): US\$1,400 (2001 est.); *Inflation*: 2.1%; *Unemployment*: 47%; *Living below the poverty line*: 42% (2001 est.) Nepal is among the world's poorest countries, with the majority of sources estimating an annual per capita GDP between US\$200 and US\$250. However, the *World and Time Almanacs* and *World Factbook* estimate the per capita GDP between \$1,200 to \$1,300.

## B. A Brief Historical Perspective

The earliest recorded history of Nepal goes back to somewhere around the 7th or 8th century B.C.E. in the fertile Kathmandu Valley. The people of the time were known as the Kiratis, but there is little other information about them, beyond knowing that they were sheep farmers. Prince Siddhartha Gautama was born in this region around 563 B.C.E. After Gautama achieved enlightenment as Buddha, he and his disciple, Ananda, established the Buddhist religion. In the 12th century C.E., the Nepali rulers ended their long patronage of Buddhism in favor of Hinduism, reflecting the growing influence of India. Buddhism all but disappeared as the Licchavis invaded from northern India, overthrew the Kiratis, and introduced Hinduism. Hinduism included a social caste system, which continues today.

Four successive dynasties prepared the way for Nepal to assume its present boundaries and be united under King Prithvi Narayan Shah in 1768. Treaties in 1792 and 1816 brought contact with Britain, which recognized the absolute independence of Nepal in 1923. After 100 years, during which hereditary prime ministers of the Rana family maintained political power, the king assumed all power in 1951 and proclaimed a constitutional monarchy.

When the British withdrew from India in 1948, the Ranas lost their major source of support and power. The people took advantage of the weakened state of the Ranas, and rebels rose up in opposition. In 1951, King Tribhuvan was crowned, and the government became a combination of Ranas and the newly established Nepali Congress Party. In 1959, the first democratic elections for a national assembly were held. However, King Mahendra declared parliamentary democracy a failure 18 months later, and instead established a "partyless" or "*panchayat*" system. The monarch retained absolute power, with the King having sole authority over all governmental institutions, including the Cabinet and Parliament.

In 1990, King Birendra, a widely popular and adored king, dissolved the *panchayat* system, lifted the ban on political parties, and released all political prisoners. The new government, with a prime minister, was comprised of members of the Nepali Congress Party, the communist parties of Nepal, royal appointees, and independents. A new constitution was established later that year, focusing on protecting fundamental human rights and establishing Nepal as a parliamentary democracy with a constitutional monarch. The King technically rules over the Parliament, but is not involved generally with day-to-day activities. The King has the power to grant pardons or to suspend, commute, or remit any sentence handed down by any court.

In June 2001, the crown prince assassinated the beloved king and queen and a good portion of the royal family be-

fore killing himself. Soon after, the Maoist insurgency that had been growing since 1996 took advantage of the turmoil created by the assassinations and increased its efforts to overthrow the Nepalese government. Since then, the country has lived in political and social instability, with high-level party resignations, strife throughout Parliament, and violence. The King, with the approval of Parliament, declared a state of emergency, and the government called out the army to help fight the Maoists. The violence has resulted in more than 7,000 deaths on both the Nepali army side and the Maoist side, with some civilian deaths occurring as well, and with the numbers continuing to grow. Attempted peace talks have been unsuccessful to date. Ceasefires continue to be broken, and Maoist bombings and violence between the two sides continue.

## 1. Basic Sexological Premises

### A. Character of Gender Roles

Gender roles are very well defined in Nepal. Expectations of girls and boys and women and men are clearly outlined, from social interactions to family communication to examples in school textbooks. Generally speaking, boys are valued higher than girls. Stories remain of families seeking to abort female fetuses, although these tend to be related by word of mouth. Men are usually the patriarchs of their families—although women have power within a social context. In many areas, men are expected to work outside of the home, and women are expected to tend to the home and the children. These values differ, however, based on the location of an individual community. In some of the hill communities, women may travel, while men remain in the community to tend to the home or family. In these communities, tasks are not gendered in any evaluative way. Folk beliefs about witchcraft remain in some areas, especially in the Terai (the southern plains). These generally target women, particularly elderly and/or widowed women, who are sometimes beaten publicly as part of an exorcism ceremony.

Some people report that seclusion rituals for girls and women during menstruation still exist in the rural areas. The most common ritual reported is having a girl or woman gather a week's worth of food and water and enter a hut where she stays for the duration of her menses. Other people maintain that these rituals are no longer practiced. However, menstruation is still seen as dirty. A menstruating woman is not supposed to cook or come into contact with anyone's food or water except her own.

### B. Sociolegal Status of Males and Females

As children and adolescents, boys have much more access to just about everything than girls do, from recreational activities to education to job opportunities. The literacy rate is significantly lower for girls than for boys. As adults, women face systematic, society-wide discrimination in many facets of life. This is particularly true in rural areas, where religious and cultural tradition, lack of education, and ignorance of their legal rights keep women from accessing such basic rights as voting or holding property in their own names. Access to jobs is much more limited for women than for men, and salaries for women are significantly lower—even though the Constitution specifically requires equal pay for equal work.

Part of the impediment to equal pay and treatment is that the Government has not taken enough action to implement its own provisions, even in government industries. Of the 265 members of Parliament, 21 are women. These women are only members of Parliament because a quota was established guaranteeing this many female representatives. More and more nongovernmental organizations (NGOs) are press-

ing for increased women's rights. Aside from the teaching profession, women seem much less likely than men to progress in their jobs. An increase in female volunteers in the health sector has increased awareness among women, and has encouraged more women to seek out health services. At the same time, however, they are unpaid and untrained in medical or health service provision.

According to legal experts, there are over 20 laws that discriminate against women. For example, the law on property rights also favors men in its provisions for inheritance, land tenancy, and the division of family property. The Citizenship Law discriminates against foreign spouses of female citizens, and denies citizenship to any children they may have together, even if those children are born in Nepal. Many other discriminatory laws still remain.

This is an area in which NGOs in Kathmandu are currently working to change. Over the last decade, efforts at increasing women's rights and equality have redoubled. In 2001, the Nepalese government created a National Women's Commission, designed to promote women's "active participation in the development of the nation" and promote women's rights. In addition, a law passed in September 2002 allows women for the first time to inherit property from their parents.

### C. General Concepts and Constructs of Sexuality, Love, Marriage, and Family

Virtually all sexuality in Nepal is seen within a heterosexual context; therefore, all examples in this chapter will be about heterosexual relationships unless otherwise indicated.

The concept of love and sexuality are quite romanticized, fed in part by the images presented in the Indian media that is prominent in Nepal. Young people tend to meet at social functions, become interested in each other, and decide to meet in secret. Part of the appeal is the secretiveness, and their behaviors might involve kissing, intimate touching, or sometimes, sexual intercourse and other sexual behaviors. Clearly, this behavior is normalized for boys much more than for girls; while many boys in a focus group said they had or knew someone who had had sex with a girl already, none of the girls would acknowledge that they had. If they knew of a girl who had engaged in premarital sex, it was through gossip.

Girls are more likely to romanticize love and marriage than boys. It is expected that young people will not have sexual intercourse outside of marriage, resulting in one of three outcomes: either young people will sneak off and get married at young ages, they will get married with their parents' support or intervention at a young age, or they will go ahead and have sexual relationships outside of marriage. While incidences of boys and girls running off together is more common in the rural areas of the country, it also does occur in the city. Often, the discovery that a boy and girl are having a romantic relationship will cause the parents of both young people to arrange for the adolescents' marriage. In fact, among the reasons for early arranged marriage is to protect a girl's reputation, which can become tarnished by public association with a boy.

In sexual and romantic relationships, men are expected to be the initiators. Women are expected to remain faithful to their husbands. Husbands, however, may have extramarital sexual relationships. In particular, men who travel for their work may seek out sex workers during their travels. Infrequently using condoms, these men often contract sexually transmitted infections, return home, and continue to have unprotected intercourse with their wives. A wife usually does not have the social power, clout, or right to insist that her husband use condoms—particularly if they have never used them before in their relationship. To do so could

raise questions about her own fidelity, rather than reflect the reality of her husband's sexual activity.

Childbearing is also valued highly in Nepal, although strains on natural resources, threats to women's health, and a desire for a higher quality of life have caused individuals, the government, and NGO professionals to focus on family planning methods. In one study, the vast majority of adults believed that a couple should wait at least two years before trying to conceive a child, with others favoring a wait of at least three or even four years. The reason behind this is to enable the couple to raise enough money to ensure that they can provide for the infant. At the same time, however, they do not believe that a married couple should use contraception immediately after marriage. The reason for this is a mistrust in family planning methods, and a concern that using, in particular, hormonal methods, will affect a woman's fertility once she is ready to have children. Therefore, pregnancies do occur shortly after marriage. Adults who push for pregnancy as soon after marriage as possible do so because having a child creates a family. Adults living in the urban setting tend to support fewer children, one or two per couple. Rural parents tend to favor larger families of at least four or five children.

There are different views from adolescents on friendships between the genders. Girls are not to do things alone, nor is it a good idea for a girl to have male friends. Once a girl is noticed or seen with a boy, questions are raised immediately about the nature of their relationship. Some report having friends of different genders outside of the context of romantic connections, while others do not believe that boys and girls can be friends.

Finding the language for talking about sexuality and reproductive health in Nepal remains an enormous challenge for Nepalese professionals, as well as professionals from other countries working on programs in-country. One U.S.-based professional working in Nepal reflected on the language of sexuality. She found:

Nepalis discuss sexuality in terms of kinds of relationships and ways of being sexual. Terms for specific sexual acts and body parts are a subset of this vocabulary, but not its core. Instead, the Nepali vocabulary for sex includes terms for sanctioned and unsanctioned relationships (marriage, elopement, lovers) and roles (husband/wife; patron/mistress; boyfriend/girlfriend; seducer; virgin; "loose" woman, etc.) It also consists of terms for feelings of love, sexual desire, arousal and attraction and an array of verbs for seducing, wooing, flirting, and the like. All these words are powerful, value-laden terms that immediately bring to mind elements of the social context, such as power relations between men and women, that are relevant to AIDS prevention efforts. These words, in and of themselves also draw attention to the fact that to be involved in a socially sanctioned sexual relationship has very different implications from being involved in a hidden or illicit relationship. Words relating to love, flirtation, seduction, and sexual coercion make evident the various ways people might come to be drawn into sexual relationships. (Pigg, n.d.)

Other professionals have found that talking about sexuality in Nepali to be impolite, and substitute English words as necessary.

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A. Source and Character of Religious Values

Religion is important in Nepal. The Kathmandu Valley has more than 2,700 religious shrines, which appear to exist together with mutual respect and without conflict. While

Nepal is referred to as a Hindu nation, Hinduism is not the “state” religion. A recent breakdown of religious representation put the Hindu population at 89.5%, Buddhists at 5.3%, Muslims at 2.6%, and others, including Christians, at 2.6% of the population. Buddhist and Hindu shrines and festivals are respected and celebrated by most people, regardless of their religious affiliations or beliefs.

Hinduism’s role in the social status of women in Nepal depends on how liberally or conservatively one observes Hindu tradition. Women’s sexual roles, as being either “maiden, married woman, or widow” are defined within the context of their relationship to men. Some sects do not consider women to be human, responding to the birth of a female child by stating, “nothing was born.” Others vehemently assert equality between men and women, and support the role of women in maintaining Hindu tradition.

Hinduism’s greatest social effect on Nepal is that it is the source of the caste system. The caste system continues to have a strong influence in society, even though it is prohibited by the Constitution. At Hindu temples, for example, members of the lowest castes have not historically been permitted to enter. There has been a growing desire, however, to change this. In 2001, the Prime Minister spoke out emphatically against caste-based discrimination, including barring access to temples. Since then, members of the lower castes have successfully entered many temples, including Pashupatinath, the most sacred national site to Hindus.

Buddhism has a fundamentally egalitarian view of men and women. As a result, Buddhism has offered social liberation to some women, if they have felt free to adopt the religion. As mentioned earlier, the beliefs and celebrations of Buddhism and Hinduism are equally celebrated and respected in Nepal.

Both Hinduism and Buddhism have teachings on sexuality, and there is extensive writing on both—including Tantric sex, practiced by some Buddhist and Hindu individuals. However, there is not as much literature specific to the effects of these teachings on the sexuality values in Nepal. It seems clear that some Nepalese individuals will base their values around sexuality on Hindu and Buddhist teachings, and others will not. Resources for further reading on Hindu and Buddhist teachings on sexuality are included at the end of this chapter.

## B. Cultural Values and Sexuality

In Nepal, parents are seen as a vital source of cultural values, including those around reproductive health and sexual behavior. As in other countries, research in Nepal has shown that parents who are actively involved in their children’s upbringing, and communicate their values clearly and openly, end up with children whose values are congruent with theirs. When it comes to sexuality, this translates into young people who postpone sexual involvement until they are older or married, and who are able to avoid pregnancy and sexually transmitted infections if they do not remain abstinent.

Modern Nepal is a society, like others, that is faced with conflicting messages and values around sexuality. There is a generation gap in comfort and knowledge levels around sexuality, with adolescents speaking more openly about sexuality issues if not often knowing more themselves. There is also an increase of sexual images in the media, because in great part of television programming from India, which includes Western programming and MTV India. As cable television grows, individuals in Nepal who can afford television will be “treated” to such “American” television shows as *Baywatch* and *Beverly Hills 90210*. The irony is palpable in Nepal as it is in other cultures: As a society, individuals can

barely discuss sexuality issues, yet the culture ends up bombarded by explicitly sexual media images and messages that can throw a culture into social chaos around sexual values.

Another example of the cultural values relating to discussing sexuality came when I was conducting a meeting with adult women living in Kathmandu. My plan was to conduct a brief activity about the menstrual cycle. The professionals with whom I worked recommended that when I was done, I was to apologize to the group for discussing such a personal subject with them. When I apologized after my talk, the group of women forgave me, and then apologized themselves for not knowing some of the details I had discussed.

## B. Source and Character of Ethnic Values

The terms “ethnicity” and “caste” are often used interchangeably. There may be larger populations of members of certain castes in particular parts of the country, and the available sexuality research data have revealed differences in sexuality values based on geographic location. Therefore, it is a reasonable assumption to make that different castes and ethnic groups will often have different values and beliefs around sexuality. At the same time, it is difficult to gather accurate information about people of different castes and ethnic groups for a number of reasons. First, geographic location often makes it challenging to obtain data from certain groups of people. Second, it is often challenging to obtain data from members of the highest caste, because they do not feel they need to participate in community-based programs. These programs are, they believe, for people of lower castes.

### 3. Knowledge and Education about Sexuality

#### A. Government Policies and Programs

Changing times and changing values are causing Nepali professionals and parents alike to face the task of talking about sexual and reproductive health issues with their children and other young people in the community. Most Nepalese teens say they would like to receive additional information about these issues. While some say they would like to be able to talk with their parents about these topics, others say they would be too embarrassed to speak with their parents and would prefer to learn from television, radio, and social clubs. Community-based programs and studies have found that young people have more information than one might think—but at the same time, the information has been filtered through unreliable sources (such as peers) to create misinformation.

General education is a highly valued aspect of Nepalese society. However, it is not compulsory. Young people are expected to go to school, and parents will often sacrifice their needs in order to ensure that as much money is allocated to the children’s education as possible.

When it comes to sexuality, there is a curriculum titled, *Health, Population and Environmental Education*, that is used in the 9th and 10th grades. This curriculum includes reproductive health, family life education, and “safe motherhood.” Teachers are widely undertrained in sexuality issues, and often extremely uncomfortable about discussing the topic with young people in class. While some schools require teaching about reproductive health, teachers have been known to assign the chapters without allowing time for in-class discussion or questions. Teachers who do address the topic tend to stick to easier topics, including biology, without discussing emotions or more challenging topics. They are also more likely to lecture on this topic rather than taking a more interactive, participatory approach. Some teachers believe that sexuality information should only be accessible by adults—and still others believe it should only be available to married adults. Local and inter-

national NGOs have been increasing efforts to provide teacher training on sexuality and reproductive health topics.

Most parents say they support some kind of sexuality education for their children, although some opposition remains. Supporters believe that this kind of education will keep young people pregnancy- and disease-free; opponents believe that providing information about sexuality will encourage young people to have sexual relationships.

### B. Informal Sources of Sexual Knowledge

As mentioned earlier, Nepali parents support information for their children about sexuality issues. However, one survey found that only one in ten parents had actually discussed these issues with their children themselves. Discussions that did take place differed, based on the gender of the child. In the urban areas, parents were more likely to talk with both their sons and daughters. In the rural areas, parents were more likely to talk with their daughters than sons.

Many parents, particularly those living in the rural areas, are unaware of where they can access this information. According to one group of parents living in the urban areas, sources of sexuality and reproductive health information are government hospital (85%), private doctor/clinic (49%), and pharmacies (28%). Parents in the rural areas named health post (76%), health workers (17.9%), and pharmacies (13%) as sources for this type of information and support.

Local organizations, like the BP Memorial Health Foundation, have been working to establish language that can be used with individuals in the community that are both medically accurate and culturally respectful. In addition, international organizations, such as Family Health International and EngenderHealth, have been working in collaboration with local organizations to provide accurate, respectful sexuality information. Research conducted by EngenderHealth and the International Center for Research on Women revealed that young people want to receive information about sexuality and reproductive health, particularly from their mothers, older sisters and brothers, and sisters-in-law. However, they say they do not feel comfortable approaching these individuals with their questions, nor do they feel confident that these identified family members would be comfortable or well equipped to answer. Young people, in particular, have questions and concerns about the menstrual cycle, nocturnal emissions, and dealing with feelings of sexual arousal that are heightened during puberty. As a result, young people and adults alike are likely to ask questions of the local pharmacist—although concerns about confidentiality remain high.

Another effort came from the Family Planning Association of Nepal, when they introduced a confidential telephone hotline in Kathmandu to answer questions about sexuality and reproductive health. In the first two months, they received over 200 phone calls on this line, which was staffed by a trained counselor. FPAN has also published materials, including *Your Queries: Our Answers*.

### 4. Autoerotic Behaviors and Patterns

Masturbation is, like many other sexuality topics, generally not discussed. This is changing among younger people. In one focus group of teenagers throughout the country, professionals found that masturbation was discussed, but only by boys. These young men saw masturbation as a sign of a boy's maturity and approaching adulthood. If masturbation is discussed among girls or between girls and their mothers or older sisters, they do not share this publicly.

### 5. Interpersonal Heterosexual Behaviors

Having the word "heterosexual" before the word "behaviors" when discussing sexuality and Nepal is assumed.

Homosexuality is rarely discussed, and the assumption is that people are or should be heterosexual. When referring to relationships and/or sexual behaviors, heterosexuality is implied by default. This will be discussed more in Section 6, Homoerotic, Homosexual, and Bisexual Behaviors, below.

Sexual exploration by children is not discussed, if it exists. Conversations and concerns tend to arise when a young person reaches puberty. This is because of perceptible physical changes, and the understanding that pregnancy can happen.

According to one study, 40% of unmarried men who are 19 or older are sexually active. Most of these men report having their first sexual relationship during adolescence. A study in Kathmandu found the average age of first intercourse for males to be 21 and for females to be 20. (UNICEF Nepal & UNAIDS 2001). Adolescents and teens with less education and from more-marginalized ethnic groups are more likely to engage in early and premarital sex than those who are educated and have a high potential for achieving their life goals.

Not surprisingly, young men are much more likely than young women to report having multiple sex partners, of those acknowledging that they were sexually active. Of those males who report being sexually active before marriage, more than 50% report having multiple sex partners. Of adolescents reporting to be virgins, more than a third say they engage in some kind of non-intercourse behavior, such as mutual masturbation or oral sex.

Most teenagers say they know that parents frown upon premarital sexual relationships. However, nearly 20% of teens in a survey conducted by UNICEF Nepal and UNAIDS (2001) believed there to be nothing wrong with a premarital sexual relationship. There is a significantly higher acceptance of premarital sex among teen boys than among teen girls, and a higher rate of sexual behaviors among boys than among girls. This suggests any of three things: that teen boys are being sexual with older women, that teen boys are being sexual with commercial sex workers, and/or that teen girls are not truthful in reporting their sexual experiences because of social mores that frown much more upon girls' sexual activity than boys' engaging in sexual activities.

In Nepal, there is an expectation from childhood that a person will be married at some point. Marriage is seen as the greatest rite of passage in a person's life, the true sign that a person has gone from being a child to an adult. Marriage is highly valued, as is childbearing. One study of parental attitudes around marriage found a majority of parents favoring early marriage for girls and later marriage for boys (Moktan 2001). Attitudes toward this tend to differ in urban and rural areas. Most parents say they would prefer their children to be at least 18 before getting married, although younger marriages do take place. In the rural areas, marriage is common between young girls (ages 14 to 16) and much older men. Women who are unable to become pregnant are often ostracized or thought to be "improper." The assumption is widely held that if a woman cannot get pregnant, there is something wrong with her. Rarely does one explore the possibility that a man could be infertile. In some situations, men will take second wives in order to partner with a woman who can bear them children. A man may take on several wives, even if a pregnancy does not occur, rather than consider his own potential infertility. It is not known how widely this type of polygamy exists.

Arranged marriages are common in Nepal. The average age at marriage for girls is 16, with over half of these girls becoming pregnant by the time they are 20. The majority of parents surveyed say they favor arranged marriages, although 25% of parents living in the urban center expressed support for love marriages as well.

Divorce is possible, however, it is not socially sanctioned. While there are still reports of men having more than one wife—particularly in situations where one or more wives are unable to bear the man a son—the practice of polygamy seems to be less and less frequent. There are also reports of women having more than one husband, although if this were to occur, it tends to be in the more remote areas of the country.

### 6. Homoerotic, Homosexual, and Bisexual Behaviors

Information about same-sex behaviors and relationships is rare. According to both professionals and other individuals living in Kathmandu, homosexuality “does not exist” in Nepal. I was, therefore, not to include discussions on sexual orientation in any of my meetings or training manuals. To have done so would have been culturally irrelevant. The International Lesbian and Gay Association states that same-sex sexual behavior between two men is against the law in Nepal. As in many other countries, sexual activity between two women is not mentioned. People visiting the country who are caught engaging in same-sex behaviors can face expulsion.

The true prevalence, real or perceived, of same-sex relationships and sexual behaviors in Nepal depends on the person with whom you speak. Some will acknowledge that “these types of relationships exist,” but that there is no community for it. Others will say that there is an underground community in Kathmandu. Still others will insist that there are no lesbian, gay, or bisexual people in Nepal. Health professionals, however, are beginning to acknowledge same-sex behaviors, at least between men. This is happening primarily within the context of screening for HIV. Physical intimacy, however, appears to be common between people of the same sex. Adult men and women may walk arm-in-arm or hand-in-hand. A teen girl might sit with her head on a female friend’s shoulder; two male adolescents might sit with fingers interlaced, lovingly stroking one another’s fingers. However, there was no perceptible identity attached to these behaviors as being homoerotic or implying anything about a person’s sexual orientation. The extent to which intimacy translates into same-sex sexual behavior is unknown.

The first Nepalese gay rights group, the Nepal Queer Society, was created in 1993. However, there is no readily available information on whether the group is still in existence, or what their activities are or have been. The Internet has also begun to provide a source of information and support for lesbian, gay, and bisexual Nepalese individuals. Gay Cyber Nepal and Queer Nepal are two sites created for gay or bisexual men. Other websites have been created by South and Southeast Asian individuals not living in Nepal or India, which seem to provide more of a community for people living abroad than there would be in that region.

### 7. Gender Diversity and Transgender Issues

In my fieldwork in Nepal, I had no conversations with Nepali professionals about transgender individuals, and there is very little written information specifically for transgender people in Nepal. There are, however, a growing number of transgender websites and organizations covering South and Southeast Asia, which may serve as sources of support for transgender individuals throughout the region, including Nepal.

### 8. Significant Unconventional Sexual Behaviors

It is virtually impossible to document this aspect of Nepali society beyond the presence of commercial sex

work. Discussions of non-coercive fetishes or sexual behaviors are infrequent, so that admitting to, let alone discussing, any type of unconventional behavior would be virtually unheard of. Perhaps the most unconventional behavior would be a man who avails himself of a commercial sex worker—and even if the sex worker fulfills a non-traditional sexual fantasy, this type of work has not been reported on in the literature about Nepal.

It is estimated that there are 25,000 women engaged in commercial sex work in Nepal. UNICEF estimates that over 40% of the commercial sex workers in the Kathmandu Valley are between the ages of 15 and 19. Other studies indicate that nearly two thirds of commercial sex workers in Nepal are infected with some kind of sexually transmitted infection.

#### A. Rape, Sexual Abuse, and Human Trafficking

According to the United States State Department, Nepali laws against rape carry prison sentences of 6 to 10 years for the rape of a woman under 14 years of age and 3 to 5 years for the rape of a woman over 14. The law prescribes imprisonment for one year or a fine for the rape of a prostitute. The law does not forbid spousal rape. A 2001 survey found that 39% of rape victims who reported the crime to police were under the age of 19. Of the reported rapes, 25% resulted in convictions and jail sentences.

Statistics relating to domestic violence are as sketchy as the many other statistics relating to Nepal. However, in 2001, the *Kathmandu Post* reported that Nepalese non-governmental organizations believe 75% of the female population have been subjected to some kind of domestic violence. Included in these figures are physical assault, harassment, and incest. When an adolescent girl is married off to an older man, this age difference is often seen as a cause or contributing factor to the domestic violence. In addition, citizens, law enforcement officials, health professionals, and government authorities tend to minimize the severity of violence against women. Forty-two percent of respondents in one survey said that they experienced medical practitioners to be uncooperative or negligent in cases of violence against women and girls.

Sexual abuse and incest are not discussed as much. In fact, before September 2002, there were no laws against sexual abuse of a child. The new law carries penalties of up to 16 years in prison for pedophilic acts. Teenagers surveyed in Kathmandu overwhelmingly expressed disagreement with domestic violence. Some, however, both male and female, did say that they thought that a man had the right to beat his wife under certain circumstances. These include a woman who does not look after her children well, or who is disrespectful to her in-laws.

When working with teenagers in Kathmandu, there was much discussion of “teasing,” which translates in Western terms to “sexual harassment.” The term “sexual harassment” was not used, because it does not translate, both in terms of language and in terms of its significance. It is used in Western cultures as a legal concept—a term that describes behaviors and situations that can result in legal actions and remedies. Nepal, as other cultures, may use the phrase “sexual intimidation” or “teasing.” According to Nepali professionals, this is not to minimize the experience—it is culturally more accurate. Discussions have begun, however, in the media about sexual harassment of women in the workplace. These discussions, as the discussions of teen-to-teen harassment, tend to focus more on what the people being harassed should do to avoid giving mixed signals, and less on teaching men more appropriate, respectful behaviors.

Human trafficking is an issue that has gained wider attention over recent years, particularly in South and South-east Asia. Nepali law prohibits human trafficking, with penalties of up to 20 years' imprisonment for breaking this law. However, trafficking in women and girls remains a serious problem in several of the country's poorest areas. Girls are sold into sexual slavery by their parents, or leave for India thinking that they are going to get married or have a decent paying job. NGOs working on this topic in Nepal believe that parents do not understand the true consequences of trafficking until it is too late—and that if they did, there would be less done. Organizations like Maiti Nepal are working to provide alternatives to trafficking, such as viable job options, and to help bring trafficked girls and women home from India, to where the vast majority are sold. There are very little, if any, data on the prevalence of young boys who are sold into sexual slavery in Nepal.

A common statistic puts the number of girls and women currently trafficked from Nepal into India at 200,000, with approximately 3,000 girls being trafficked out of the country each year. A children's human rights group states that 20% of prostitutes in the country are younger than 16 years old. Many of the girls who are sold into the commercial sex trade in India return to Nepal, which creates a number of problems. Cultural attitudes toward returned victims of trafficking are often negative and the Government response often reflects that bias. In addition, girls who return to Nepal often have sexually transmitted infections (STDs). In fact, of the 218 girls rescued in February 1998, somewhere between 60 and 70% were HIV-positive. Testing for STDs, including HIV, is a rare occurrence, particularly for young, unmarried girls. The stigma associated with visiting a healthcare provider of any kind, let alone one relating to reproductive or sexual health, far outweigh a young person's concern about diseases. As a result, trafficking not only does extensive physical, psychological, and emotional damage to the young women being trafficked—it also puts a great segment of the population at risk for STDs.

While the vast majority of trafficking is for sexual exploitation, women and girls are also sold for domestic service, manual or semi-skilled bonded labor, or other purposes. In some cases, parents or relatives sell women and young girls, especially if they are destitute and do not see their daughters as marriageable. Unverified estimates say that approximately 50% of trafficking victims are lured to India with the promise of good jobs and marriage, 40% are sold by a family member, and 10% are kidnapped. If prevention programs are established in a particular district, traffickers simply move to other areas and continue their work.

The Human Trafficking Control Act of 1986 prohibits selling persons in the country or abroad, and provides for penalties of up to 20 years' imprisonment for traffickers. However, there are many social and legal obstacles to successful prosecution, and convictions are rare. Since border guards commonly accept bribes to allow contraband and trafficked girls in or out of the country, many professionals are pessimistic about significantly reducing the trade without true government and legal support.

There are more than 40 NGOs in Nepal combating trafficking, several of which have rehabilitation and skills-training programs for trafficking victims. These groups commonly use leaflets, comic books, films, speaker programs, and skits—short plays with a few actors—to convey anti-trafficking messages and education. Some organizations involved in the rehabilitation of trafficking survivors

state that they have been threatened and their offices have been vandalized because of their activities.

## 9. Contraception, Abortion, and Population Planning

### A. Contraception

The government of Nepal has a Ministry of Health, which oversees its national health policies. The most recent, 1997-2017 long-term National Health Policy, includes mention of access to reproductive health, as well as the benefits to having "small families" by accessing family planning information and services. The government also developed guidelines for national maternal health (the National Maternity Care Guidelines and the National Safe Motherhood Plan of Action). These guidelines provide a blueprint for how women should receive care during their pregnancies and postpartum, and how babies should receive care once they are born. The programs, as other health programs in Nepal, have been focusing much more on increasing training for healthcare professionals. There are still a low number of women who seek antenatal care and services, and home deliveries for infants, without a trained professional present, remain the norm.

The National Reproductive Health Strategy of Nepal (adopted in 1997) was designed to make integrated reproductive health services available to all people in Nepal by focusing on the following:

- Family planning;
- Safe motherhood, including newborn care;
- Child health;
- Prevention and management of complications of abortion;
- RTI (reproductive tract infections)/STD/HIV/AIDS;
- Prevention and management of infertility;
- Adolescent reproductive health; and
- Problems of elderly women, particularly cancer treatment at the tertiary level/private sector.

Contraception is available in Nepal, gaining in use and access dramatically since the 1970s, when approximately 3% of couples were estimated to use contraception. More current figures put this at approximately 33%. At the same time, however, access to contraception depends greatly on where a woman or couple lives.

According to the Center for Reproductive Law and Policy, the country's family planning policies tend to favor the use of the IUD and injectible hormonal methods.

Any reproductive health service that can be accessed in Nepal is most likely to happen in the urban areas, and the rural areas closest to the cities. As one moves farther and farther away, up through the hills and into the mountains, the quality and access to healthcare diminishes dramatically. Problems exist with staffing reproductive or any other health facility in remote areas, as well as with non-appearances of the staff who have been hired. As a result, inhabitants of the more-remote areas receive even less care than those in the urban areas.

Because of insufficient prenatal care, it is estimated that nearly one in ten pregnancies are terminated spontaneously. This translates to roughly 90,000 miscarriages in Nepal per year. Nepal also has one of the highest maternal mortality rates in the world. Most of this can be attributed to unsafe abortion practices, as well as to pregnancy-induced hypertension and/or other illness occurring during pregnancy. In addition, only half of pregnant women obtain any kind of prenatal care, only 14% have some kind of trained medical professional present during the birth, and only 9% of babies are born in some kind of healthcare setting.

## B. Abortion

Nepal's abortion laws were historically among the most restrictive and punitive in the world. Providers are neither trained nor skilled in performing abortions because of these laws. The result has been up to 12 women dying every day—or nearly 4,500 every year—because of unsafe abortions.

Nearly 5,000 women appear at Maternity Hospital in Kathmandu each year with an incomplete abortion, necessitating the completion of the procedure. Statistics on abortion-related deaths, as most statistics about Nepal, range depending on the source. According to JHPIEGO, 15% to 30% of all pregnancy-related deaths were attributed to abortions that were unsafe, incomplete, or spontaneous. Other sources of data do not mention spontaneous abortions specifically, but state that nearly half of all pregnancy-related deaths were caused by unsafe abortions. Even in situations where a woman obtains an illegal abortion, she runs the risk of being jailed afterward—possibly reported by the very family member or friend who brought her to the provider in the first place. In fact, the Center for Reproductive Law and Policy estimates that one out of five women in Nepal who are in jail are there for obtaining an abortion. Girls and women living near the border to India have historically crossed the border in order to obtain a legal abortion there.

In September 2002, King Gyanendra approved a law legalizing abortion up to 12 weeks on demand, and up to 18 weeks if the pregnancy is a result of rape or incest. Abortions will be allowed at any time if the woman's life or health is in danger, or if the woman learns that she is going to give birth to a disabled child. (The types of disabilities were not specified. This may raise a whole other range of concerns relating to people with disabilities in Nepal.)

Although this law is a significant victory for women's rights, two challenges remain. First, women already in jail for having obtained an abortion remain there, and the government has not mentioned anything about whether they plan to release them. Second, access to abortion services remains a challenge. In addition, the so-called global "gag rule" of the current Bush administration (USA) restricts any international organization receiving United States funds from discussing abortion. This, therefore, forces Nepalese reproductive health professionals to choose between directly needed U.S. funds and providing information and services to women seeking abortion.

According to the 1996 Nepal Health Survey, approximately half of all girls begin having babies by the time they are 19. While most teenage boys and girls report that they know what condoms are and where to get them, only about two thirds of teenage boys in one survey reported using condoms during premarital sexual relationships (UNICEF Nepal & UNAIDS 2001). When a pregnancy does occur out of wedlock, the father of the child is not usually seen as partially responsible, although this varies depending on where the couple lives. In some areas, the male is forced to marry his female sex partner, or, if he refuses, must either pay a fine or spend time in jail. As with the likelihood of sexual initiation, the likelihood of condom use was higher with boys living in Kathmandu and who were educated.

## 10. Sexually Transmitted Diseases and HIV/AIDS

### A. Sexually Transmitted Diseases

A major challenge in tracking STD incidence is obtaining local data. The World Health Organization estimated that in 1999, there were 340 million new cases of curable STDs throughout the world—specifically syphilis, gonor-

rhea, chlamydia, and trichomoniasis. Of these, nearly half, or 151 million, were said to have happened in South and Southeast Asia alone. Specifically, this breaks down to 43 million new cases of chlamydia in this region, 27 million with gonorrhea, 4 million with syphilis, and 76.5 million with trichomoniasis. Statistics specific to Nepal about STDs other than HIV are difficult to come by accurately.

There is much stigma surrounding STDs. People who think they might have an infection are unlikely to seek out medical treatment, often exacerbating an easily treatable or curable infection. In one survey, adolescent and teen boys who ended up with an STD say that they are more likely to go to a pharmacy and purchase medicine in an effort to treat themselves, than they are to go to a family planning clinic to be diagnosed and treated appropriately by a health professional.

The majority of information and data available around infections relates to HIV and AIDS, described in the next section. Of the limited information about infections, there is information about syphilis within one population. In 1997, 1,800 women who went in for prenatal screening tested positive for this infection.

Culturally, myths and misinformation about STDs abound. One is the concept that a man who urinates on the grounds of or against a temple will be stricken with an STD as punishment. There is also a strong sense of invulnerability among males if they do not engage in sexual behaviors with a commercial sex worker. Unprotected sexual behaviors with a girl or woman who is not a commercial sex worker is, therefore, not seen by men and boys as risky. Unprotected sexual behaviors may be seen by young girls and women to be risky; however, they usually do not have the option of insisting that their partners wear condoms.

### B. HIV/AIDS

As with other health issues, there are little updated, reliable data about the incidence and prevalence of HIV and AIDS in Nepal. However, professionals can say with certainty that the HIV epidemic is increasing, and has been since the first HIV/AIDS case was recorded in 1988.

As in many parts of the world, the AIDS epidemic has forced previously silent countries to start addressing sexuality issues more directly and explicitly—although nowhere nearly as explicit as is done in many Western countries. As in other parts of Southeast Asia, it is estimated that HIV and AIDS cases are much more prevalent and are spreading much more rapidly than the limited statistics currently report. According to one source, the government will confirm that there were only about 500 HIV or AIDS cases over an eight-year period, something that most professionals in Nepal will say is a gross underestimate. Family Health International (FHI) estimates that between 30,000 and 50,000 individuals are currently infected with HIV; the World Health Organization puts the number at around 33,500. The *CIA World Factbook* estimated in 1999 that there were approximately 34,000 people living with HIV or AIDS and 2,500 AIDS-related deaths, numbers that many professionals believe to be a gross underestimate. According to UNAIDS, 10,000 of these cases are among women ages 15 to 49, and 930 are among children ages 0 to 15. UNAIDS also estimated that there were 2,500 AIDS-related deaths in Nepal in 1999, with approximately 2,200 children living as orphans as a result of losing one or both parents to an AIDS-related death. Without appropriate interventions, FHI estimates that the number of people living with HIV could reach between 100,000 and 200,000 by the year 2010.

The source of many HIV cases in Nepal are from sexual encounters with sex workers, both in Nepal and in other

countries, such as India and Thailand, when men are traveling for business. Among the main locations for such encounters is the north-south highway that runs from Nepal to India. Rest stops, teahouses, restaurants, and other types of lodges along the highway and in border cities provide significant venues for prostitution, leading to significant transmission of HIV. At the same time, however, it is important to note that sex workers would be more likely to access health services. Other individuals at high risk for HIV and other STDs do not avail themselves of testing and other health and/or preventative services. There is a concern, therefore, that commercial sex workers will be held exclusively responsible for spreading HIV and other STDs, when they are not the exclusive conduits for the rise in HIV in Nepal. In fact, according to UNAIDS, the incidence of HIV among intravenous drug users in Kathmandu alone increased from nearly 0 in 1993-1994 to 50% in 1997.

According to a survey conducted by UNICEF of 1,400 Nepalese teens, the majority surveyed reported that they know what HIV is, but only about three quarters said they knew to use a condom during sex. A higher reported rate of sexual activity for boys rather than girls suggests that boys who are sexually active are doing so with commercial sex workers, putting them at higher risk for HIV and other STDs if they do not have knowledge of or insist upon using condoms.

Injection drug use is seen as being among the greatest causes for the increase in HIV in Nepal. According to UNICEF Nepal (2001), the incidence of HIV increased in intravenous drug users by 48% within a short four-year period. Since the majority of these drug users are in the 16- to 25-year age range, the implications for sexuality education and prevention services for adolescents and teens are significant.

HIV has overcome the conservative attitudes toward discussing sexuality issues. Media campaigns starting in the mid-1990s raised public awareness and touted the importance of condom use. Radio ads, public service announcements, and even a comic book discuss the dangers of HIV and the importance of using condoms. An annual observation of World AIDS Day on December 1st has also begun in Nepal. However, these campaigns are not consistent because of a number of factors, including the expenses involved in airing the ads, and the conflict between promoting the government-supplied free condoms and the concern from merchants selling condoms that they will lose money as a result. In addition, discomfort and modesty often keeps people from purchasing condoms and merchants from selling them. Yet, interestingly enough, Nepalese parents cite TV and radio as among the most important sources of sexual health information for young people.

[Update 2002: UNAIDS Epidemiological Assessment: As with virtually all other countries in Asia, the first cases of AIDS or HIV infection were detected during the late 1980s and early 1990s, either in a foreign visitor or in a citizen who returned from international travel. During the early 1990s, HIV seroprevalence surveys detected HIV infections among STD patients and female sex workers throughout most regions in Nepal. As a result, there has been great public health concern that extensive spread of HIV, similar to that in the neighboring countries of Cambodia, Myanmar, Thailand, and India might occur. Injecting drug users in Nepal were initially believed to share injection equipment in relatively small and isolated networks. However, since the mid-1990s, an explosive increase in HIV infection has occurred, infecting about half of all injecting drug users throughout the country.

[Large numbers of young Nepalese girls are recruited as female sex workers to Indian cities, and large numbers of

young Nepalese males working in India frequent female sex workers there and within Nepal. Thus, in addition to the increasing number of HIV infections occurring among persons with high HIV-risk behaviors in Nepal, there are also increasing numbers of Nepalese female sex workers and young male Nepalese workers who have been infected with HIV in India, and who have or will be returning to Nepal. The estimated HIV prevalence in Nepal in 2001 was 58,000 or close to 0.5% of the total 15- to 49-year-old population. Asian countries with the highest HIV prevalence (from 2% to 3% of their 15- to 49-year-old populations) in the region all have brothel-based female sex workers as a dominant factor. Because Nepal's pattern of female sex workers is primarily non-brothel based, it appears likely that its HIV prevalence may not reach such high levels. Effective public health programs capable of increasing consistent condom usage levels in female sex workers and their male clients to 80% to 90% may be capable of keeping HIV prevalence in Nepal to less than 1% (i.e., less than 100,000) of the 15- to 49-year-old population.

[Based on an estimated HIV prevalence of about 34,000 in 2000, the number of AIDS deaths that can be expected in the year 2000 is close to 3,000 and this figure is projected to more than double (about 6,000) in 2005. It is estimated that these AIDS deaths will increase total deaths in the 15- to 49-year-old age group by about 4% in 2000, and account for close to 20% of total deaths in this age group in 2005.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	56,000 (rate: 0.1%)
Women ages 15-49:	14,000
Children ages 0-15:	1,500

[An estimated 2,400 adults and children died of AIDS during 2001.

[At the end of 2001, an estimated 13,000 Nepalese children under age 15 were living without one or both parents who had died of AIDS. (*End of update by the Editors*)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

The scope of sexual dysfunctions is widely unknown, because of, in great part, the lack of information and education, and taboos about discussing sexuality, especially for women. If girls do not know what to expect when going into their marriage or sexual relationships, it is unlikely that they will know that something painful or pleasureless is not simply part of their duties as wives. And it is even less likely that a woman would request information about sexual behaviors or pleasure. Male sexual dysfunction is not discussed either, although men are less likely to be seen as "responsible" for their dysfunction or stigmatized for it.

## 12. Sex Research and Advanced Professional Education

Data are sorely lacking in Nepal. Organizations that conduct research are often able to survey only a small population at a time. As in the United States, data appear to be much more easily collected from individuals in urban settings and from individuals and families with a lower socioeconomic status.

As a result, Nepal's true diversity is often lost in research methodology. Census screening does not begin to show the true diversity of multicultural relationships and families. In Nepal, it is difficult to reach the many different ethnic groups who speak different languages and have different social norms. This means that presenting data on a typical Nepalese adult or teenager is virtually impossible. The research available about sexuality and sexual health in Nepal

is quite limited in scope. What is available is primarily collected about men and boys, with more information being found more recently on girls and women. Statistics are unreliable, but they provide a preliminary snapshot of some of the issues facing Nepal.

There are no university programs or scientific journals specifically focusing on sexuality issues. However, the following organizations either do work on sexuality-related issues in Nepal, or maintain statistics on sexual and reproductive health. Several of these groups are Nepalese, while others are based outside of the country and work collaboratively with NGOs in Nepal.

## *Demographics, a Brief Historical Perspective, and Dutch Sexology*

### A. Demographics

ROBERT T. FRANCOEUR

Located in northwest Europe on the North Sea, the Netherlands' 16,030 square miles (41,525 km<sup>2</sup>) are roughly the size of the states of Massachusetts, Connecticut, and Rhode Island combined. Belgium borders the Netherlands on the south, Germany on the east, and the English Channel and the United Kingdom on the west. The Kingdom of the Netherlands includes the Dutch Antilles, the autonomous Caribbean islands of the West Indies. Curacao, Aruba, and Bonaire are near the South American coast; St. Eustatius, Saba, and the southern part of St. Maarten are southeast of Puerto Rico. (The northern two thirds of St. Maarten island belong to French Guadeloupe). Combined, the six islands have an area of 385 square miles (995 km<sup>2</sup>).

\**Communications:* Koos Slob, Ph.D., Erasmus University, Faculty of Medicine, P.O. Box 1738, 3000 Dr. Rotterdam, Netherlands; slob@endov.fgg.eur.nl. Jelto J. Drenth, M.D., Visserstraat 39, 712 CS Groningen, Netherlands.

Much of the basic information in this chapter is based on the 1991 Special English Issue of the *Tijdschrift voor Seksuologie*, published on the occasion of the Tenth World Congress for Sexology, Amsterdam, June 18-22, 1991. We gratefully acknowledge the authors of this volume and the editors for their kind permission.

\*\**Editors' Note:* Because of time and space constraints, the Editors have converted most of the original bar and line graphs of the original chapter into tables. We have referenced the original figure or table number and page number in *IES2*, i.e., the original chapter on the Netherlands in volume 2 of the *International Encyclopedia of Sexuality*, in the new tables' footnotes. For those original graphs that did not contain actual numbers, we have approximated the percentages, which are noted where appropriate. The reader is referred to the original figures in the original volume or on the Web at <http://www.SexQuest.com/ccies/ies2-ref-figures.html>.

(CIA 2002)

In July 2002, the Netherlands had an estimated population of 16 million. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 18.3% with 1.05 male(s) per female (sex ratio); 15-64 years: 67.9% with 1.03 male(s) per female; 65 years and over: 13.8% with 0.7 male(s) per female; Total population sex ratio: 0.98 male(s) to 1 female

**Life Expectancy at Birth:** Total Population: 78.58 years; male: 75.7 years; female: 81.59 years

**Urban/Rural Distribution:** 88% to 12%

**Ethnic Distribution:** Dutch: 91%; Moroccan, Turks, and others: 9%

**Religious Distribution:** Roman Catholic: 31%; Protestant: 21%; Muslim: 4.4%; other: 3.6%; unaffiliated: 40% (1998 est.)

**Birth Rate:** 11.58 births per 1,000 population

**Death Rate:** 8.67 per 1,000 population

**Infant Mortality Rate:** 4.31 deaths per 1,000 live births

**Net Migration Rate:** 2.34 migrant(s) per 1,000 population

**Total Fertility Rate:** 1.65 children born per woman

**Population Growth Rate:** 0.55%

**HIV/AIDS** (1999 est.): Adult prevalence: 0.19%; Persons living with HIV/AIDS: 15,000; Deaths: 100. (For additional details from [www.UNAIDS.org](http://www.UNAIDS.org), see end of Section 10B.)

**Literacy Rate** (defined as those age 15 and over who can read and write): 99%; education is free and compulsory from age 5 to 18

**Per Capita Gross Domestic Product** (purchasing power parity): \$25,800 (2001 est.); Inflation: 4.5%; Unemployment: 2.4%; Living below the poverty line: NA

### B. A Brief Historical Perspective

ROBERT T. FRANCOEUR

In 55 B.C.E., Julius Caesar conquered the Celtic and Germanic tribes that inhabited the region that is now the Netherlands. After Charlemagne's empire fell apart in the mid-800s, the Netherlands—then what is today Holland, Belgium, and Flanders—was divided among dukes, counts, and bishops. Holland soon passed through the Duke of Burgundy to King Charles V of Spain. In the later 1500s, as the

area drifted toward political freedom and Protestantism, William the Silent, prince of Orange, led a confederation of the northern provinces that declared independence from Spain in 1581. The United Dutch Republic's rise to naval, economic, and artistic eminence came in the 17th century, only to end in 1795 when Napoleon made his brother Louis king of Holland. Napoleon annexed the country in 1810, but the French were expelled in 1813 and the kingdom of the Netherlands, including Belgium, established. The Belgians seceded and formed a separate kingdom in 1830.

The Netherlands remained neutral in World War I, but was invaded and brutally occupied by the Germans between 1940 and 1945. After several years of fighting, Indonesia gained its independence in 1949; West New Guinea was turned over to Indonesia in 1963. The independence of former Dutch colonies was followed by mass emigrations to the Netherlands.

### C. Dutch Sexology

JELTO J. DRENTH and A. KOOS SLOB

To understand Dutch sexology, one needs to keep in mind five general characteristics of our society that crystallized in the latter half of the 19th and first half of the 20th centuries:

1. The role of the family and the position of men and women is central in Dutch society. Excluded from the labor process, women were supposed to derive their task, fulfillment, and satisfaction from marriage and family. Together with Ireland and Sicily, the Netherlands has the lowest rate of working wives and economically independent women. Even today, many politicians support this inequality of social roles. In recent decades, however, the position of the housewife has gradually declined, a factor that may have an impact on sexual problems for women and men.
2. Since the origin of the Netherlands in the 17th century, there has been a strong segregation between Catholicism and Protestantism, with many subdivisions among the latter. In the 19th century, humanism, socialism, and liberalism were influential. As a result, the Netherlands now has a very strong compartmentalization or "denominational segregation." Some 40 different organizations and over 25 political parties have access to television broadcasting and the elections. Because of different, sometimes very powerful religious influences, extreme contrasts in social and sexual behavior exist between various groups. For instance, one fundamentalist Protestant political party still discriminates against women in membership and office eligibility, although over half of those voting for this party are women. On the positive side, this compartmentalization has resulted in a willingness to cope with differences in opinion and a rather liberal attitude towards varying social groups and lifestyles. The pedophile movement, for example, openly expresses its views on child-adult sexual relations. Our homosexual movement is widely respected, and our national organization for homosexuals even received royal assent. The Protestant University of Amsterdam houses the world's only chair of transsexology.
3. Holland in the west was rich and industrialized with extensive colonial ventures; the east was less prosperous and mainly agrarian. The west is the focus of political, economic, cultural, and social development, including a large group of sexologists. This geographic separation also influences differences between groups in Dutch society.
4. When the Dutch East Indies became independent, Indonesia in 1949, several hundred thousand people came from this culture to the Netherlands. A similar immigration occurred in 1975 when Dutch Guiana became independent Suriname. The Netherlands has also received its share of labor from the Mediterranean. A second and third generation of Turkish and Moroccan origins, most born in the Netherlands, still struggle with the problem of being rooted in two cultures. Political refugees are the latest contribution to our multiethnic society. Some 7% of our population was born in other countries. The result is a profoundly multiracial society in which sexual rules and values sometimes differ greatly, presenting a major challenge for sexological research and treatment.
5. Sociosexological research in the Netherlands has been quite extensive since the 1960s. Initial research focused on problems resulting from a restrictive sexual morality. During the 1970s, attention shifted to the rapid process of sexual liberalization and its practical consequences, such as the need for family planning education and services. The past decade has been dominated by research on sexual abuse and the spread of STDs and AIDS. Published mostly in the Dutch language, this research has not had a significant impact outside Holland, despite the fact that open and permissive sexual attitudes give Dutch sexology a unique position, not just in terms of attitudes and behavior, but also in terms of research possibilities. More international comparative and collaborative research would benefit all.

Research on sexual behavior, attitudes, and related subjects began in 1968, when the largest women's weekly, *Margriet*, commissioned a national *Seks in Nederland* (SIN) survey using a representative sample of 1,284 men and women ages 21 to 65, and 809 youngsters ages 16 to 20 (Noordhoff et al. 1969). This study was repeated in a modified and extended way in 1974 (with teenagers only) and in 1981 and 1989. These surveys present a fairly accurate description of major social and demographic correlates of sexual attitudes and behavior, and the changes in these variables over time.

While strongly inspired by the 1948/1953 Kinsey studies, the 1968 Dutch study reflected the main interests and concerns of Dutch society at that time, namely self-pleasuring, premarital and extramarital sexual contacts, sexual desires, prostitution, homosexuality, contraception, and (illegal) induced abortion.

Kooy (1975) analyzed the 1968 SIN survey, putting the data in a theoretical perspective of changing family relationships, declining moral influence of religion, and growing social equality between the sexes. The second SIN survey (in 1981) had the character of a trend report (Kooy et al. 1983). The main trends observed were growing tolerance towards different kinds of sexual behavior and more equality between partners in heterosexual relationships. Secularization seemed to be the most important background factor in these changes. The 1989 survey was strongly influenced by fear of AIDS and a need for knowledge to underpin prevention programs.

In part, the study of adolescent sexuality parallels the adult studies, including sexual development, relationship development, sexual education, prevention of unwanted pregnancy, and induced abortion, and recently STD and AIDS prevention. In 1974, the first SIN survey was repeated for adolescents only. De Haas (1975) interpreted and reported the data from an educational viewpoint; Kooy (1976) used a sociological perspective. The 1981 adolescent data were not analyzed before they were used in the

framework of the much larger 1989 study (Vogels & van der Vliet 1990). The 1974 and 1981 studies included 600 and 800 youngsters ages 15 to 19, while the 1989 study included 11,500 youngsters and 11- to 14-year-olds. Finally, both the 1989 adolescent and 1989 SIN adult surveys were motivated by the fear of the HIV epidemic.

## 1. Basic Sexological Premises

### A. Character of Gender Roles

It is difficult to generalize on gender roles in the Netherlands. Dutch society has become so diverse that, at any given moment, different groups will be influenced differently. Yet, in all but the most isolated groups, an awareness of the variation in social and sexual role responsibilities must have led to a rise in tolerance for less-conventional behaviors.

The classic Western role separation, men being providers and women housekeepers and caregivers, has been criticized intensively. Some feminist principles have found almost universal support. Holland is subject to Europe's legislation against sex discrimination, and today it is hard to find examples of sex discrimination in the workplace. Government policy includes a "positive action" plan: In some segments of paid labor, women will be favored in the job-application process to bring down the underrepresentation of women in these professions. The government has funded a mass-media campaign intended to raise girls' awareness of preparing for financial independence.

Countering these conscious efforts, mass-media influences, such as soap operas and commercials, are often extremely conservative in their depiction of role ideals. The impact of this on the general public's role awareness is hard to estimate.

### B. Sociological Status of Males and Females

In recent years, legislation reforms have tended to equalize legal rights for men and women, homosexuals and heterosexuals. For instance, a 1991 reform of rape laws encompassed male and female rape. Children under age 12 are protected against all sexual contacts; for 12- to 16-year-olds, sexual contacts are legal offenses only if the adolescent, his/her parents(s) or guardian, or the Child Welfare Court files a complaint. Existence of a dependency relation between the adult partner and the adolescent is an exception to this. The law's intention is that the child's own judgment outweighs the parent's.

In the Netherlands, bypasses are available for teenagers to obtain oral contraceptives and abortions without parental permission.

### C. General Concepts of Sexuality and Love

As oral contraception has uncoupled sexuality and procreation, so the possibility of uncoupling sexuality and love has also been recognized. Large groups of Dutch men and women sympathize with the need for sexual gratification of people who are not in steady relationships. Self-pleasuring and "recreational" sex are no longer taboo. Virginity is disappearing as an ideal. Self-pleasuring as a variation within a steady relationship is also no longer universally scorned.

Yet, love is still probably the most-valued principle in Holland. Almost all Dutch men and women believe that steady relations must be built on love, and that sexuality with love is more satisfying than without it.

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A. Source and Character of Religious Values

Denominational segregation, 34% Roman Catholic and 25% Dutch Reformed, has not played an important role in

Dutch sexuality. The Dutch Society for Sexual Reform (NVSH) found its Protestant counterpart in the Protestant Society for Responsible Family Planning (PSVG) and a Catholic Bureau for Sexuality and Relations. But these religiously inspired organizations are small and limited to providing written information and educational materials. NVSH has separated into a laypersons' organization for political action and education, and a professional organization, the Rutgers Foundation, for medical and psychological help. The Dutch government funds the foundation's counseling centers and participation of foundation administrators and staff in international organizations, such as the International Planned Parenthood Federation.

Religious motivations have played an important role in our legal reform. The Dutch abortion law adopted in 1985 permits abortion on request with the sole restriction of a five-day waiting period. Opposition from fundamentalist Catholics has little support. Moreover, the Pope's regulations on contraception is almost universally ignored by Dutch Catholics, as are restrictions on homosexual behavior and the sexuality of the handicapped. Catholic and Protestant groups have played important roles in the acceptance of gays and lesbians, with some churches celebrating ceremonies of gay and lesbian unions. (See "Update 2001" in Section 6, Homoerotic, Homosexual, and Bisexual Behaviors, on the legalization of marriage for homosexual couples in Holland.)

### B. Source and Character of Ethnic Values

Most Muslims in the Netherlands came from Turkey or Morocco as "guest laborers" in the booming economy, women and children following the men after they settled in. The Netherlands now has a second generation and a third on its way. Tension between Muslim traditions and the Western way of life is common. Islamic traditions emphasize family honor, with specific restrictions on sexual behavior and distinct social roles for men and women.

Arranged marriages are common and the confrontation of two cultures sometimes leads to conflicts between parents and children who, raised in the Western world, want to choose their own spouse. Muslim tradition includes the ultimate measure of kidnapping to force a marriage. Incidents of this, and of Muslim girls running away from home to avoid an arranged marriage, are common, leading to the establishment of a shelter home for Muslim girls only. Muslim honor sometimes conflicts with the Dutch legal system, leading to tragic misunderstandings in the law courts. Helping professionals are only slowly learning how to handle such problems without trespassing on Muslim taboos. Relevant for sexological practice are the following:

- A male doctor will not be allowed to perform a physical examination of a Muslima in the absence of her husband;
- A male patient will often be embarrassed if asked about his sexual problems by a female doctor;
- Self-pleasuring is an almost-absolute taboo and should not be advised as a therapeutic modality;
- Prostitution is much less forbidden for Muslim men; and
- Direct communications are uncommon—a metaphorical presentation of the most distressing problems, infertility and erectile failure, is the rule.

Comparative research data on the influence of religious background on sexual topics include:

- Muslim adolescent boys commonly initiate all types of sexual activity earlier than their Christian and nonreligious male and female peers; Muslim girls are considerably less experienced;

- Christian and nonreligious adolescents tend to prefer sex in steady relationships, Muslim adolescents tend to have more casual sexual experiences and less steady relationships;
- Attitudes toward premarital sex in steady relationships are more accepting in Christian and nonreligious adolescents (80%) and less so in Muslim adolescents (40%). Muslima are very restricted.
- Muslim adolescents tend to advocate abstinence as the best way to avoid HIV infection, and are less willing to use condoms for this purpose (Sandfort & van Zessen 1991).

While incidence figures for induced abortion are generally low in the Netherlands, some ethnic groups have a higher risk of unwanted pregnancy and abortion (see Section 9, Contraception, Abortion, and Population Planning). Among autochthonous\* women, unwanted pregnancy is mostly because of contraceptive method failure; among Caribbean, Mediterranean, and refugee women, nonuse or inconsistent use of contraceptives is the more likely cause. A 1990 study of unwanted pregnancy among Caribbean women (Lamur et al.) identifies three groups with distinguishing attitudes towards contraception:

- Among women born in the six Caribbean islands, the strongest influence on sexual attitudes and practices is the Roman Catholic Church. Information on sexuality is extremely scarce. Strong negative moral and practical feelings toward contraception are common. The pill and IUD are often seen as severe health hazards; when used, physical complaints are common.
- Creole women from Suriname (formerly Dutch Guiana) also have little access to sexual information, but this is changing for Creole women born after 1960. In this younger group, middle-class women from stable families are mostly highly career-oriented and very concerned about unwanted pregnancy. Lower-class women are often familiar with a pattern of single women having children with fathers who are more or less distant. Among middle-class Creole families in the Netherlands, sexual information is more adequate and attitudes towards sex and protection less taboo-burdened. Yet, these women are less constant in their choice of contraceptive methods and tend to have more physical complaints when using the pill. For all Creole women, abortion is not an easy solution for unwanted pregnancy. Despite a high abortion rate in this group, moral restraints are strong and abortion is definitely not seen as a normal contraceptive method.
- Hindustani women of Suriname descent have very strict family rules, and honor (*Izzat*) is a leading principle. Premarital sex is an absolute taboo. Education is highly valued and often considered part of a girl's dowry. In recent years, information on sexuality and contraception is provided to Hindustani girls, but effective premarital contraceptive use is rare. A sex taboo seems to prevent information from being absorbed adequately for practical use.

The problems of political refugees have not yet been researched. Dutch Amnesty International workers have some

experience with the atrocious problems of sexual torture and humiliation some refugees have experienced.

A particular problem causing some public discussion is clitorrectomy. A modified form of clitorrectomy, incision of clitoral prepuce, has been under consideration as a result of requests mainly from Somalian women. The Dutch government recently prohibited all forms of clitoral mutilation. Incidentally, Islamic and Hindustani women commonly consult Dutch gynecologists for hymen reconstruction, as part of preparation for marriage.

### 3. Knowledge and Education about Sexuality

#### A. Government Policies and Programs for Sex Education

The Netherlands has the lowest rate of unwanted teenage pregnancies of all the industrialized nations. Some attribute this to a relatively effective use of contraceptives, especially the pill, among teenagers. This effective use is explained, at least in part, by a pragmatic and liberal attitude towards sex education, the high quality of information and education on sex and contraception in secondary schools and the mass media, and the wide availability of confidential and low-cost contraceptive services.

These results, however, are no reason for self-satisfaction or complacency. For one thing, contraceptive behavior among ethnic minorities and young adolescents is still ineffective, and the abortion rate among adolescents is still about 45 per 100 pregnancies. In terms of AIDS, about half of the sexually active teenagers appear to engage in risky behavior.

The Dutch government finances a number of sexuality organizations, including the Netherlands Institute for Social Sexological Research (NISSO), the Rutgers Foundation for contraceptive information, sexological education, and STD prevention, and the Foundation for the Study of STD. Recently, the government policy has tried to integrate these special service organizations into the general health institutions. The Rutgers Foundation, which has for decades provided the easiest access for teenagers to contraceptive information, has been forced to concentrate its services in seven offices in large cities and start a training program to share the foundation's specific knowledge and skills with physicians, mental-health workers, and educators.

In recent years, the government has strongly encouraged and promoted prevention programs. Health promotion is now obligatory in secondary schools, even though, traditionally, Dutch schools have formed their own curricula. Numerous educational courses and an amalgam of materials on sex and AIDS have been developed by several local and national organizations. Special materials have been developed for Catholic, Protestant, and nonreligious schools. Despite underlying philosophical differences, most of these programs are very similar in terms of goals, methods, and materials.

On a national level, knowledge of the proportion of schools providing sex and AIDS education, what teachers teach, and what methods and materials they use is limited. A late 1980s survey suggests that some sex and AIDS education was provided by about 85% of the Dutch secondary schools, generally by hygiene or biology teachers. The major topics covered were biological-physiological aspects of puberty and unwanted pregnancy. Topics such as intercourse and sexual desire received lowest attention. As for AIDS education, practical guidelines for reducing risk were the main topics covered, along with attitudes towards homosexuality. The way teachers covered these topics, however, varied widely, depending on the teacher's area of expertise and teaching methods. Biology-hygiene teachers seemed to fo-

\*Note: In Dutch sociology, "autochthonous" means "of Dutch descent," including Dutch nationality, Caucasian, and raised in Western traditions. "Allochthonous" includes immigrants and their next generations from former Dutch colonies, immigrants from Mediterranean countries who came to Holland seeking work in the 1960s and 1970s, and political refugees from all over the world.

cus on transmission of knowledge of biological and physiological aspects. Sociology teachers and counselors seemed to emphasize relational aspects, such as gender-role patterns, cohabitation patterns, friendship, sexual orientations, and being in love.

Eighty percent of Dutch secondary schools offer a mean of four to five hours of AIDS education. Forty percent use one of four AIDS courses developed for national use on AIDS, though often not according to the specific methodological guidelines. More time is devoted to knowledge transfer than to training in social skills. Teachers were not sufficiently trained or supported to implement these courses, and the materials are not tailored to normal school practices.

Criticism of teachers' training in providing sex and AIDS education is widespread. Yet, there was for some years in the mid-1980s, a three-day in-service postgraduate course for secondary schoolteachers, during which about 500 participants were trained (Schraag 1989). A unique feature of this course was that teachers and pupils worked together to express their underlying convictions and wishes about sex education in school and to develop a program for sexual education. The course program and contribution of the trainers have been evaluated on many occasions, leading to continuous adjustments and corrections.

Although it is frequently argued that health education should be a systematic process, most sex-education courses and materials have not been developed in a systematic way. Very few consider behavioral determinants, and little is known about the effectiveness of the various courses and materials. Besides, only two of the evaluative surveys on sex- and AIDS-education classes have used an adequate experimental design. Both surveys concluded that the courses under scrutiny produced only an increase in knowledge and minor changes in some attitudes, results similar to evaluations of United States sex-education programs and the more general results of health education. Besides knowledge transfer, health education should offer students the opportunity to involve their social environment and develop skills necessary for an adequate performance of the desired behavior. In the 1990s, organizations responsible for implementing educational innovations in health and sex education were encouraged to cooperate with groups responsible for development of educational programs (Kok & Green 1990). Future research should clarify how interventions based on behavioral science theories can improve diffusion and adoption of health-education programs.

Government-financed mass-media campaigns are an important means of educating the public. In 1987, the first campaign to alter social norms of condom use focused on a number of Dutch celebrities who use condoms themselves. In 1988, a second campaign focused on "Safe Sex for Holidays," followed in 1989 by ironically confronting 18- to 24-year-olds with irrational beliefs and popular excuses for risky behavior. "Sleep well" was the final comment on each poster and the campaign's title. A pretest/posttest evaluation proved that the majority of respondents had noticed the poster campaign and understood its irony. Those who had noticed the campaign differed from the pretest group by better acknowledgment of the personal risks they took and a lower endorsement of three popular excuses. Condom use in this group rose slightly. Yet, only half of the group ever used condoms, and a quarter were inconsistent in their use.

A 1992 addition to government involvement in sex education and prevention is a mass-media campaign directed at child sexual abuse. This campaign, "There Are Secrets You Should Talk About," is designed to reach children in abusive situations and make the public aware of the reality of child sexual abuse. A second mass-media campaign, "Sex

Is Natural, But Never Self-Evident," addresses boys and men on the topic of coercion in sex. Evaluative data on these campaigns are not yet available.

## B. Informal Sources of Sexual Knowledge

Veronica, a Dutch broadcasting company, has had a Sunday-afternoon, three-hour phone-in radio program on sex and related subjects since 1985. Themes discussed on program "Radio Romantica" range from light-hearted to serious, including sexual fantasies, falling in love, rape, incest, sexual abuse, safe-sex techniques, coping with AIDS, unwanted pregnancies, homosexuality, bisexuality, and pedophilia. A professional sexologist hosts the program with a liaison officer and a team of students and graduates trained in psychology and social work. The program draws about 250,000 listeners.

In a less systematic way, almost all Dutch broadcasting companies have programs dealing with sex and AIDS. Since the sexual revolution of the 1960s and 1970s, sexuality has provided prime topics for radio, television, and magazines. Books on sex education, for adults and adolescents, are numerous, and vary widely in quality. Pornography is easily available, although the information and messages propagated in these magazines is a matter of concern for many educators. The impact of pornography as an educational source has not been evaluated. (Section 10B deals with numerous mass-media campaigns on AIDS and safe sex.)

## 4. Autoerotic Behaviors and Patterns

### A. Children and Adolescents

Research on child sexuality is relatively underdeveloped. In 1990, readers of the magazine *Ouders va Nu* [*Parents Today*] responded to a questionnaire about their children's sexual behavior and their own attitudes concerning sexual education (Cohen-Kettenis & Sanford 1991). The children's ages ranged from 0 to 7. The results of this survey on child autoeroticism are shown in Table 1.

In the 1989 adolescent study, 88% of 12- to 13-year-old boys and 77% of the girls reported at least one sexual fantasy. Frequency of sexual fantasy correlated strongly with self-pleasuring experience. Self-pleasuring according to age is shown in Table 2.

### B. Adults

In the 1989 research (Sandfort & Van Zessen 1991), questions on personal habits disclosed a distinct sex difference on several issues.

Table 1

#### Percentages of Childhood Self-Pleasuring Behavior

Behavior	Boys	Girls
Touches genitals with the hand	96%	94%
Self-pleasures by hand	58	39
Self-pleasures using an object	13	21

Table 2

#### Percentages of Boys and Girls Engaging in Self-Pleasuring

	Ages 14-15	Ages 16-17	Ages 18-19
Boys	81%	90%	91%
Girls	43	55	62

Source: Vogels & van Vliet (1990, 37, Fig. 3.2). *Editors' Note:* Percentages are approximations from the original line graph (*JES2* Fig. 1, p. 906).

- 55% of the women and 23% of the men had never read sexually explicit books or magazines;
- 71% of the women and 47% of men had never watched sexually explicit videos or movies;
- 30% of the women and 5% of the men never looked at an attractive man with sexual intent, 26% of the men reported this behavior "often";
- 77% of the women and 90% of the men were familiar with sexual fantasies. Men tend to fantasize more often and have a more positive view of fantasies. Fantasies featuring power balance and violence were uncommon.
- 92% of respondents reported a positive attitude toward self-pleasuring; only 16% opposed self-pleasuring in a steady relationship. Autoerotic behavior was related to sex, age, and current relationship status. (See Tables 3, 4, and 5.)

5. Interpersonal Heterosexual Behaviors

A. Children

In the *Parents Today* study (Section 4A, Autoerotic Behaviors and Patterns, Children and Adolescents), many questions referred to childhood sexual behavior. Table 6 gives a selection of the data. In this study, Dutch parents reported considerably more sexual behavior than United States parents in similar studies, so U.S. data are not useful as criteria in diagnosing child sexual abuse in Dutch children.

B. Adolescents

Puberty Rituals

There are no common puberty rituals among autochthonous Dutch groups, although as a result of the more open attitude towards sexual development in some progressive

families, young girls will have their menarche greeted by some festive, yet intimate, parental or family attention.

It has been argued that in modern Western society, parallel to individualization tendencies, rituals have disappeared, leading to loss of emotional anchors. In psychotherapy, the use of individually tailored rituals is quite often recommended.

Premarital Sexual Activities and Relationships

The 1989 survey of children ages 11 to 19 involved more aspects than previous studies, and the presentation of many subjects that were put into longitudinal perspective. Data suggested an expanding "sexual moratorium," a period in which the adolescent is sexually active, but not in a steady relationship open to procreation. In recent years, it has been increasingly common for young adults to go through a period in which they have a number of sexual partners in more or less steady relationships (see Table 7).

Survey responses revealed a common pattern of four years between the first French kiss and sexual intercourse. The sequence of steps in this personal development is remarkably uniform and showed no sex difference (see Table 8).

In earlier studies, the concept of a "stepwise interaction career" was developed by Straver and coworkers (1986), based on Glaser and Straus's (1980) elaboration of symbolic interactionist theory and Simon and Gagnon's (1980) approach to psychosexual development. This approach emphasizes the active role of youngsters in shaping their own sexual identity and their sexual relationships. Rademakers (1992) later used this theoretical framework in her study of the causes of ineffective contraceptive behavior at initial sexual contact among adolescents (see Section 9, Contraception, Abortion, and Population Planning).

Going out to bars or discotheques is a major factor affecting sexual experiences, increasing sexual experiences at all ages and in all aspects. Young people with lower educational levels showed less permissiveness and less experience in communication, but experienced sexual inter-

Table 3

Percentage Frequencies of Self-Pleasuring According to Sex

	Men	Women
Never	17.5%	44.2%
Less than once a month	19.0	29.2
About once a month	30.0	19.5
About once a week	28.0	7.2
Daily	4.0	1.9
More than once a day	1.4	0.4

Percentage Frequencies of Self-Pleasuring According to Relationship Status

	Never	Less than once/week	More than once/week
Casual Relationship	9%	41%	50%
No Sex	27	54	19
Steady Relationship	38	49	13

(n = 982; steady relationships, 75%; casual relationships, 13%; no sexual contact in past year, 12%). Source: Sandfort & van Zessen (1991, 129, Table 4.6). Editors' Note: Percentages are approximations from the original line graph (IES2 Fig. 4, p. 908).

Table 6

Percentages of Childhood Heterosexual Behavior

Behavior	Girls	Boys
Interested in the opposite sex	63%	63%
Plays doctor-and-nurses games	44	43
Tries to see nude people	44	43
Touches genitals of others	39	32
Tries to undress other people	30	22
Shows genitals to adults	15	25
Shows genitals to children	16	24
Kisses with tongue out of mouth	13	16

(IES2 Table 2, p. 908)

course at an earlier age than adolescents with more education.

Responses to the question “Do you ask your partner what he/she likes in love making?” suggest that boys take responsibility for their partners’ satisfaction more often, especially at an earlier age (see Table 9). Assessing personal limits is another competence aspect; girls more than boys seem to consider this to be their task at all ages (see Table 10).

Sexual contacts between children and adults have been examined in several Dutch studies. Unlike most such research data, these contacts were not considered abusive by definition. Sandfort (1982) studied the experience of 25

boys, ages 10 to 16, involved in sexual relationships with adult men. Almost all the respondents indicated the sexual contact was predominantly positive and did not have a negative influence on their general sense of well-being. The friendships also fulfilled several of the boys’ personal needs. Although these results do not have general applicability, they counterbalance the predominant notion that all adult-child sexual involvement is abusive. In a later study, Sandfort (1991) used a much broader design to study the possible influences of voluntary, as well as nonconsensual, sexual experiences before age 16 in a random sample of 283 male and female subjects aged 18 to 23 years, who had had sexual experiences with adults. Controlling for other factors, these sexual experiences seemed to have positively influenced sexual desire, arousal, and anxiety irrespective of the partner’s age. Nonconsensual experiences seemed to have caused sexual problems in later life, as well as more-general psychosomatic complaints. The more severe these experiences, the stronger were the negative effects. Nonconsensual contacts with peers seemed, on average, to be less severe than nonconsensual experiences with adults. Using the same data, Goddijn and Sandfort (1988) showed the importance of the opportunity to express one’s feelings about traumatic experiences in order to diminish the psychosocial complaints in later life. Studies on involuntary sexual contacts are dealt with in Section 8A, Significant Unconventional Sexual Behaviors, Coercive Sex.

**C. Adults**

*Some Demographic Outlines*

Remarkable changes in the popularity of marriage have occurred in the Netherlands in recent decades (Beets et al. 1991). Before the end of World War II, the Dutch tended to marry at a relatively late age. In the years of rapidly expanding economic possibilities in the 1970s, more men and women married at a younger age. In 1945, only 18.5% of 20- to 24-year-olds were or had ever been married; in 1974, the figure was 41.8%. Since 1974, marriage has again declined in popularity, especially for the young, as cohabitation became more popular. The mean age of first marriage was 22.8 in 1970; in 1990, it was 28.2 for men and 25.9 for women. Data on cohabitation are scarce, but what data are available provide some insights.

**Table 7**

**Trends in Women’s Median Age at First Menstruation, First Sexual Intercourse, and First Marriage or Cohabitation by Year of Birth**

Year of Birth	Median Age	
<b>First Menstrual Period</b>		
1922	14.3	
1952	13.5

- Around 1985, almost half of all 20- to 24-year-olds who were living together were not (yet) married, and in the 25-to-34 age group, 20% were not married;
- 70% of the unmarried said their living together would be long term; 40% of a cohort were still in the same relationship at a three-year follow-up;
- Cohabiting couples have fewer children than married couples; the wish for children is often the motive for marriage.
- Until 1975, only 2% of the children born annually were born out of wedlock. Since then, the figure has risen to 10.6%. "Extramarital birth" today can have several meanings: a child of cohabiting parents (about two thirds of all extramarital births); a child in a Living Apart Together (LAT) arrangement, a lesbian couple's child, or a homosexual or heterosexual unwed mother who intends to raise the child alone. By 1989, 10% of unwed mothers were single women and lesbian couples who were artificially inseminated with donor semen (AID). In the past decade, self-insemination has gained in popularity, probably equaling physician-managed AID today.
- The classic unwed mother who had an unwanted pregnancy is almost extinct in Holland, forcing the Dutch organization for the support of unwed mothers to reorganize with new goals to support one-parent households and the victims of sexual violence (and their mothers).

Combining cohabiting and married couples, there is a recent slight decrease in the number of Dutch men and women living in two-person households. Divorce rates have gone up fast since 1968, from 11% of marriages in 1970 to 28% in 1988. One out of six children in the 1970s marriage cohort will experience their parents' divorce before age 21. One-parent families are also increasing. Ten years ago, 19% of Dutch mothers were raising their child(ren) alone. Divorcees outnumbered widows and never-wed mothers in this group, with most single mothers holding full-time employment outside the home.

Divorced persons are increasingly postponing a second marriage. In 1990, the mean age for males entering a second marriage was 42.7, and for women, 38.8 years. In 1990, 77% of all marriages were first marriages for both partners. In 23%, one or both partners were divorced, and in 10%, one or both were widowers.

Fertility rates have been decreasing, from 3.2 in 1964 to stabilize at just over 1.5 since 1976. In 1988, 4% of all 20-year-olds had one or more children, 32% of the 25-year-olds, 67% by age 30, and 87% by age 40. Government policy aims at zero population growth, a goal that seems feasible even though it will bring a considerable increase in the proportion of senior citizens. In 1990, 13% of the total population was over 65, compared with only 8% in 1950.

### Single Adults

Prompted by a need for data and insights useful in AIDS prevention, the 1989 SIN adult study was the first to pay specific attention to the sexual behavior of singles.

In this survey, 13% of male respondents ( $n = 421$ ) and 11% of females ( $n = 580$ ) reported no sexual contacts in the year before the interview. Some 40% were sexually inexperienced. Part of this group could be adequately characterized as "late starters," but at age 30, 8% of males and 4% of females were inexperienced in heterosexual intercourse. The higher percentage of male homosexuals in the sample may only partly explain the high figure of inexperienced males, because half of the male respondents who labeled themselves as homosexuals had in fact had sexual intercourse. Men tended to be more dissatisfied than women with being single, 70% versus 57% preferring to have a re-

lationship. In the larger cities, the proportion of respondents with no sexual relationships is slightly lower. In their solo-sex experiences, this group differs only slightly from couples: 18% never fantasize sexually, and only 19% more than once a week; 28% never engage in self-pleasuring and 26% do so more than once a week.

In the 1989 study, "singles with sexual contacts" were defined as: no steady relationships of at least one year at the time of interview, and one or more casual or short sexual contacts. By definition, this group must include a certain number of persons with new relationships that will eventually turn out to be long term: 10% of women and 18% of the men fell into this category. Respondents under 25 contributed most to this group, with respondents 33 to 50 rarely in this group. Singles with sexual partnerships tended to live in larger cities. Like the group with no sexual experiences in the last year, they, too, tended not to be politically involved. One-night stands were uncommon: only 13% had casual sex (defined as once or twice); 50% of men and 25% of women had casual sex besides one or more longer partnerships (the latter with a mean of 25 sexual encounters). Males reported a higher number of partners in the past year (mean 2.4 versus 1.8 for women, with a maximum of ten for men and five for women). Vaginal intercourse was the most popular technique for men (96%), but women preferred manual stimulation to vaginal intercourse, 95% to 86%. Anal intercourse was quite unpopular. Men used condoms in only 31% of their coital acts; women scored even lower with 21%.

### Adults in Dyadic Relations

In 1989, mean coital frequency for men and women in stable relations was seven times a month, higher than in 1968 and 1981, but respondents in the earlier surveys were aged 20 to 65, while the 1989 sample was 18 to 50 years old (see Tables 11 and 12). Length of the relationship is more

26-33	8.8	73	20	7
34-41	14.1	86	5	9
42-50	22.4	97	1	2

(Men:  $n = 276$ ; Women:  $n = 452$ ). Source: Sandfort & van Zessen (1991, 65, Table 3.3). (IES2 Table 3, p. 915)

**Table 12**  
**Percentage Frequencies of Making Love in 751 Stable Relationships**

	Men	Women
Less than once in 2 months	3.5%	3.5%
Once a month	5.0	5.0
About 2-3 times a month	15.0	12.0
About once a week	19.0	23.0
About twice a week	40.0	40.0
Three or four times a week	15.0	16.0
Five or more times a week	2.0	2.0

Editors' Note: Percentages are approximations from the original line graph (IES2 Fig. 9, p. 915).

important than age for coital frequency (see Tables 13, 14, and 15). In all groups, women tended to be content with their current frequency and men more likely to want more. Men were more affirmative in thinking their sex could be better. Women were more likely to admit to making love without the desire to do so and engaging in sexual acts they did not really like. Other satisfaction-related statements on which men and women gave similar responses included: general satisfaction with sex, conflicts about sex, admitting gender differences in sexual desire, admitting being pressured to engage in sexual contact, and communications on sexual preferences. On a 1-to-10 scale, the mean rating of men for their satisfaction with their own sex life was 7.3; for women 7.5.

Abstinence in these stable relations is nonexistent, when defined as refraining from all sensual body contact (hugging, kissing, and cuddling). When sexual contact is defined as genital contact, 0.5% of these relationships were abstinent; when defined as vaginal intercourse, 4% were abstinent during the past year (see Table 16).

*“Extramarital” Sex*

Marriage was the only form of stable relationship studied in 1968 and 1981. In the 1989 study, questions regarding sex with more than one partner were edited differently to include

cohabitation and stable Living-Apart-Together (LAT) relations. Moreover, the 1968 and 1981 studies focused on 21- to 65-year-olds, whereas the 1989 study dealt with 18- to 50-year-olds. Longitudinal comparisons must therefore be done with some caution.

In 1968 and 1981, men were more tolerant than women on extramarital sex, with a shift for both genders toward more tolerance. In 1981, 13% of the men and 6% of the women had no objections at all, with 48% of the men and 39% of the women accepting extramarital sex in certain situations. In 1989, more questions were included on this topic. Seven percent of the men and 5% of the women agreed that partners in a stable relationship should allow each other to have sex with a third party; 82% of men and 88% of women firmly opposed this (see Table 17).

Since extramarital sex is taboo more than other behaviors, underreporting cannot be ignored. In 1989, the fear of AIDS seemed to be a more potent motive for denying extramarital sex than moral restraints in general. Marriage is the type of stable relationship that contributes most to monog-

Source: Sandfort & van Zessen (1991, 751, Table 3.10). (IES2 Table 6, p. 918)

amy: In the total group of respondents in a stable relationship for over one year, 14.6% of the men and 9.2% of women reported sexual contact with more than one partner. In the year preceding the interview, 6.4% of the men and 2.8% of the women had engaged in sex with a second partner; 2.1% of the men and 3.7% of the women were aware of their partner's extramarital relations. Three quarters of the men keep their extramarital sex a secret; three quarters of the women informed their partners of their affair. "Extramarital sex" was casual in 50% of the cases; longstanding affairs were limited to one out of six. Prostitution and sexual contacts abroad were only a small proportion of the reported extramarital-sex contacts.

### *Sexuality and the Disabled and Chronically Ill*

In the early 1970s, when Heslinga gained national and international notoriety with his plea for better information and sex education for the handicapped with his book, *Not Made of Stone: Sexuality of the Handicapped People*, these services were not routinely provided by doctors, and empirical research was also scarce. Today, close to 100 organizations provide support and written information on the sexual consequences of such conditions as adrenogenital syndrome, anorexia nervosa, breast cancer and mastopathy, depression, diabetes, gynecological cancer, incontinence, ostomy, multiple sclerosis, premenstrual syndrome, postmenopause, posthysterectomy, and schizophrenia patients and their families.

Direct sexual services for the handicapped are available through the National Foundation for Alternative Partnership Mediation. In one ongoing research project, the Rotterdam sexology department and the department for industrial design at Delft Technical University developed a water-driven self-pleasuring aid for manually disabled men and women to be used in the bath or under the shower.

Mental-health institutions have also gained some awareness of their residents' sexual problems and the tension between controlling and understanding patients' sexual needs. Professionals in homes for the mentally handicapped seem more eager to take additional courses in sexual education. Awareness of the high figures for past sexual abuse among patients is growing rapidly, and competence in addressing these problems is probably also expanding.

In the past decade, Dutch sexologists have carried out longitudinal research on sexual rehabilitation of 1. women with ovarian, cervical, endometrial, and vulvar cancers, 2. men with testicular cancer and Peyronie's disease, and 3. men and women with diabetes, various ostomies, chronic kidney disease, and skin diseases. Because of the uniqueness of these studies, a summary of their findings follows.

1. *Cancer of the Female Genitals* (Main sources: Leiden and Groningen universities gynecology departments). The Dutch Cancer Foundation has funded a steady series of research programs on treatment for female genital cancers. Bos-Branolte used a semistructured interview and questionnaire to evaluate psychosexual functioning of 69 women treated for ovarian (29), cervical (24), endometrial (12), and vulvar (4) cancers. Posttreatment follow-up ranged from six months to seven years. Results showed a decrease in sexual activity (59%) and intimacy (22%) with an increase in need for intimacy (19%), emotional support (30%), and open communication (23%). In addition, 33% reported a negative change in their partner's sexual activity. Many women had the impression that, although their partners needed emotional support during their illness, they did not receive this help. Intimacy, emotional support, and open communications seemed to contribute more to a positive relationship than sexual expressions.

In 1984, Weijmar Schultz and Van de Wiel started a series of research projects with a pilot study of ten women treated for vulvar cancer. A self-report questionnaire evaluated sexual functioning some two years after treatment. Despite many problems, eight of the ten couples resumed sexual contacts, with or without restrictions. Sufficient information, coping, and communications did not guarantee complete sexual rehabilitation. Motivation for sexual expression and mutual affection might be more important than any physical restriction imposed by surgery. A small-scale prospective longitudinal study of the sexual functioning of women treated for vulvar cancer tested this observation. Ten couples and an age-matched control group were interviewed and filled out questionnaires at admission and at six, 12, and 24 months posttreatment. Only at six months could an increase in sexual dissatisfaction be detected. Over the remaining period, in spite of persisting poor perception of genital symptoms of sexual arousal, the women's satisfaction did not differ from pretreatment satisfaction and control-group ratings. Satisfaction with sexual interaction under these circumstances appears to be more dependent on intimate aspects than on physiological arousal, suggesting information and counseling as the most promising focus for intervention.

A more detailed assessment of seven of these women at 12 months posttreatment confirmed that although, in the patients' own opinion, cancer and its treatment had caused rather dramatic changes in their sexual life, comparison with the age-matched group revealed only minor differences in sexual satisfaction, behavior, and motivation. The only significant differences were in experienced sexual arousal and orgasm. The authors hypothesized that sexual rehabilitation itself is guided on a higher level by a more general striving for balance in the relationship. Interventions to prevent or reduce sexual problems after treatment for cancer of the female genitalia should be directed toward both the patient and partner.

A similar design was used for 13 couples with wives treated by simple hysterectomy for benign gynecological disease and 13 age-matched control couples. At a one-year follow-up, all patients reported some disruption in the sexual response cycle, whereas current behavior and motivation for sexual interaction were within the normal range. The women clearly expressed general satisfaction with their sexual functioning and little relational dissatisfaction. Here too, arousal experience is found not to be the sole reason for sexual motivation and satisfaction. The authors stress that posttreatment counseling should not be limited to hysterectomy patients with a cancer diagnosis. A more-detailed examination of 11 cervical cancer patients at six months posttreatment revealed that sexual interaction was valued significantly less than control subjects, while no changes in overt behavior occurred. The most important psychosexual variables underlying this reduced sexual valuation were found to be a considerable decrease in the self-image of oneself as a sexual partner. Apparently, women try to cope by conforming to the sexual demands of their partner and to prevailing norms. Cervical carcinoma treatment appears to have a strong negative effect on the sexuality of the patients, and often amplifies an already existing ambivalence toward sexual interaction common in many women.

Sixteen partners of patients treated for female genital cancer were interviewed one year posttreatment on two general themes: involvement and support, and sexuality and relationship. Many men reported experiencing the process of providing support as stressful, and had serious doubts about the efficacy of their efforts. Furthermore, these men appeared to have extensive sexual problems,

which could not be adequately solved. It was hypothesized that the disease and its treatment also poses a crisis for the partner, which leads to a regression towards a more rigid, male-stereotypical way of coping. Consequently, while treating the patient, the partner and their communication patterns should be the focus of attention too.

Finally, data on seven vulvar cancer patients and 25 cervical cancer patients were analyzed for prognostic variables for future sexual adjustment. The small sample size allowed only a few cautious conclusions. Overt sexual behavior after treatment can be predicted quite accurately by past sexual experience. Satisfaction, motivation, and sexual response are less predictable. This outcome supports the conclusion from the comparative study on cervical cancer treatment and simple hysterectomy, that psychological variables are more decisive than physical ones in predicting future sexual rehabilitation.

2. *Testicular Cancer Treatment* (Source: Groningen University urology department). Nijman et al. studied sexual functioning of 101 patients following bilateral retroperitoneal lymph node dissection for stages I and II nonseminomatous testicular cancer. All patients were without evidence of disease after at least four years' follow-up. Twelve men experienced antegrade ejaculation, while 89 experienced retrograde ejaculation ("dry" orgasm). In 75 of the 101 men, urine analysis after intercourse or self-pleasuring showed retrograde ejaculation in 55 men, and lack of ejaculatory emission into the urethra in 20 patients.

Seventeen patients had diminished sexual desire (especially after radiotherapy), 12 experienced difficulty reaching orgasm, and six complained of erectile dysfunction. A second study of 56 men with nonseminomatous testicular cancer stages II and III, before and after treatment (surgery and chemotherapy), showed that two years after completing therapy, 54% experienced sexual dysfunctions. Greatly reduced or absent antegrade ejaculation was reported by 26 patients; 18 of them had undergone retroperitoneal lymph node dissection in varying degrees of extensiveness, whereas eight had not. Chemotherapy may have caused ejaculatory disorders in 30% of the patients. Only two reported a change in quality of erections; seven experienced a markedly reduced libido, and five reported their orgasms had changed in a negative way. The remaining testis showed signs of atrophy in 21 patients.

3. *Diabetes Mellitus* (Source: Rotterdam University sexology department). Slob et al. recorded subjective and objective psychophysiological responses to erotic visual stimulation for 24 women with diabetes mellitus type I and ten control women. No significant differences in subjective response (general sexual arousal and genital arousal) were reported. The objective response (thermistor readings from one minor labium) varied with the height of the initial temperature. Since the initial temperature was significantly higher in the patient group, the subsequent rise during erotic visual stimulation was less in diabetic women than in controls. When samples of the two groups were matched for initial temperature, the difference in increase of labial temperature was no longer significant. When women with high initial temperatures (37° C/98.6° F) were excluded, there was in both groups a significant correlation between the degree of subjective arousal and the rise in labial temperature. Patients with serious neuropathy and/or angiopathy did not participate in this study.

4. *Peyronie's Disease* (Source: Groningen University urology department). Van Driel studied surgical treatment, compared with the natural course, in 32 patients with Peyronie's

disease and 12 with a congenital penile curvature. Subjective symptoms were recorded by checklist, and objective symptoms by means of Polaroid photography during erection at home. Patients were seen at three-month intervals until a steady state was reached. In 23 patients, spontaneous recovery was sufficient. When pain persisted longer than one year, a Nesbitt operation (surgical shortening of the contralateral side) was performed; 21 patients were treated this way. All were satisfied with the functional and cosmetic outcome, although a completely straight penis was not accomplished in four. No complications were met. Conservative management in cases of bent penis seems preferable; however surgery is a good and safe alternative when complaints and dysfunctions persist.

5. *Ostomy* (Source: Groningen University sexology department). The first step in Dutch research on sexological sequelae of ostomy operations was a study in which readers of a stoma patients' monthly were asked to complete a questionnaire: 995 men and 512 women gave a retrospective account of changes in their sexual life following ostomy. Results confirmed that men are more hampered in their sexual functioning by ostomy than women, and that colostomy had a stronger negative effect than ileostomy. Results suggest the most serious impact on sexual functioning is found with urostomy, especially in men. Prospective confirmation is needed.

6. *Chronic Kidney Disease* (Source: NISSO). Van Son-Schoones used a semistructured interview and psychometric questionnaires to evaluate psychosexual functioning in 70 men and 47 women with chronic kidney disease; 34 male partners and 47 female partners were included. Evaluation included the effect of treatment method (hemodialysis, continued ambulatory peritoneal dialysis, or transplantation) on sexual functioning, personal well-being, and coping with the disease, as well as the quality of information and counseling. Few differences were found between the three treatment modalities. Organic sexual dysfunctions, psychosocial problems, and acceptance problems were most frequently found in the hemodialysis group. Partners, irrespective of treatment, did have more sexual problems and were less satisfied with the sexual relationship. The quality of information and counseling appeared to be insufficient.

7. *Skin Disease* (Source: Leiden University dermatology department). In 1990, a research study was initiated to quantify the well-known sexual problems of patients with psoriasis and constitutional eczematous rash: 52 psoriasis patients (28 men and 24 women, mean age 37) and 25 eczema patients (9 men and 16 women, mean age 28) completed extensive anonymous questionnaires: 10% had no partner, and 3% had only incidental partners. Men felt most ashamed in social situations of partial nudity, and women were more ashamed in sexual situations. Sexual motivation was lower than average, and women scored lower than men. On sexual satisfaction, only women scored below average. Facial skin symptoms were most embarrassing. One third had difficulties initiating contacts and entering a sexual relationship, and felt shame in an intimate relation. Psoriasis patients felt more inhibited than eczema patients. Many expressed the conviction that a good sexual relationship is beneficial for the skin disease.

The authors advocate more discussion of sexuality in the care for skin-disease patients, especially when young and inexperienced in sexual relations. Women, psoriasis patients, and patients with facial symptoms are most in need of counseling.

### *Incidence of Oral and Anal Sex*

Growing concern about HIV transmission and recognition that anal intercourse is high-risk behavior have attracted researchers' attention to anal sex. In 1989, 12% of women and 6% of men in steady heterosexual relationships reported being more or less experienced in anal intercourse. Anal sex seemed to be nonexistent in casual and extramarital heterosexual relations.

In the Amsterdam large-scale longitudinal cohort research project on homosexual behavior and seroconversion, the proportion of men who engaged in anal intercourse slowly declined from 88.6% in 1984-85 to 62.4% in 1987-88.

There are no legal restrictions on anal sex in Holland; social attitudes towards this form of eroticism probably show wide variation. The idea that anal sex is not an exclusively homosexual variation, but can be part of heterosexual lovemaking as well, is gradually being acknowledged in the general public.

In 1989, experience with fellatio and cunnilingus was the rule for both men and women (see Table 16 above).

### *6. Homoerotic, Homosexual, and Bisexual Behaviors*

In the United States, the Kinsey-scale differentiation between exclusive homosexuality and exclusive heterosexuality based on combined sexual behavior and erotic experiences dominates most orientations theory and research. Historical, sociological, and psychological studies of homosexuality in the Netherlands lean toward a different paradigm in which homosexuality is seen as a design for living in which erotic and sexual attraction is embedded in a wider context. Dutch study of homosexuality thus focuses on gender and gender development, family studies, and lifestyle and lifestyle management. Changing social attitudes to homosexuality made this paradigmatic change possible.

#### **A. Children and Adolescents**

The large-scale 1968 and 1974 studies of adolescent sexuality paid only limited attention to homosexual behavior and feelings. Tolerance towards homosexuals had grown considerably: In 1968, 55.3% believed that homosexuals should be free to lead their own lives; in 1974, 84.9% held this position. In 1968, 18.6% of male respondents said they had at least one self-pleasuring experience with peers; in 1974, this was 16.1%. In 1968, 5.5% reported being mostly or exclusively attracted to the same sex; in 1974, 1.8%. Some attraction was indicated by 10% in both surveys.

Information useful in AIDS prevention was a major objective of the 1989 study of 11,431 12- to 19-year-old boys and girls. On self-definition, 47% of the 12- to 13-year-olds reported not knowing the meaning of "homosexuality" and "bisexuality"; 6% of 18- to 19-year-olds were ignorant on this subject. Slightly less than 1% of boys and girls defined themselves as exclusively or predominantly homosexual; 1.3% of boys and 0.8% of girls defined themselves as bisexual; 8% of boys and 15% of girls reported fantasies of a homosexual nature. Such fantasies produced uncertainty on self-definition in only a minority; the youngest age group is most often uncertain on the subject of self-definition (60% of 12- to 13-year-olds did not know how to self-label).

Percentages of respondents experienced in homosexual behavior were low: boys 1.5% and girls 1%. Anal intercourse was practiced by half of these boys—among heterosexual 14- to 19-year-olds, 7% had at least one experience with anal intercourse. Bisexual experience was reported by 64% of the boys and 70% of the girls.

In the 1980s, several studies of homosexualities examined the process that homosexuals go through in self-defini-

tion. A large difference was found between males and females. More than 50% of men called themselves homosexual by age 17, 50% of women self-identified around age 23. Half of the boys experienced their first same-gender attraction by age 8; girls did so by age 14. In the process of sexual-identity formation, behavioral, psychic, erotic, and sexual responses appear more important for self-definition for boys. For girls, relational factors are characteristic, with identity formation and identity management centered on social, instead of sociosexual aspects. Defining oneself as a homosexual for boys means the coding of erotic and sexual responses, and for girls, the coding of feelings of intimacy, bonding, and togetherness. These are relative differences and one could predict that, as soon as gender differences in development become less important, the gap between a gay and lesbian development of the self will disappear. This accounts for intergenerational differences and the positive influence of a warm and permissive climate at home on identity development. In a theoretical perspective, in families without polarized sex roles, not only do male-female differences become less important, but also the distinction between homosexual and heterosexual differences. What counts is the capacity for management of social interactions.

Of special interest are Dutch studies on the construction of intergenerational male intimacy. Sandfort (1987) described how this developed in the gay movement and how concepts of male homosexuality and male homosexual pedophilia changed between 1946 and 1981. In a monumental two-volume work, *Loving Boys* (1988, 1990), Brongersma maintained that intergenerational male intimacy has a biological as well as a sociological foundation. At the beginning of puberty, boys tend not to interact sexually with girls. In this period, the sexual drive is high, so boys enter into sexual contact with peers and with older men. This view of man-boy relationships uses a theoretical framework that relies heavily on historical and anthropological material. These relations are seen as a *rite de passage*, emotionally loaded by images of becoming male, not homosexual. Another sociohistorical illustration was presented by Maassen, who described the work and life of Gustav Wyneken, an influential pedagogue of pre-Nazi Germany, accused of having had sexual relations with some of his pupils.

In a 1992 special women's issue of *Paidika*, the journal of pedophilia, some Dutch authors described woman-child intimate relations, of which the majority was homosexual and in some way pedagogic. While woman-girl relationships appear rare in Holland, Wekker describes a special kind of woman-girl relationship in Suriname Creole working-class women (*mati*) who are self-supporting and have children by men with whom they are in more or less steady relationships. They become familiar with homosexual contact in their teens and are mostly initiated by older women, and large age differences are common at all ages in this cultural group. One wonders whether the subject of adult-child sexuality is changing under the influence of coeducation, the development of youth cultures, and the acceptance of sexual relationships in early adolescence. Nowadays, adolescents can have sexual contacts with peers of both sexes, so the motivation for erotic commitments with adults may decline or disappear.

#### **B. Adults**

##### *Gender Roles and Relationship Patterns*

Tielman's *Homosexuality in the Netherlands* (1982) describes the Dutch Gay Emancipation Movement between 1911 and 1982. Warmerdam and Koenders (1987) described the homosexual organization COC between 1946 and 1966. Detailed oral histories of the discrimination against homo-

sexuals and their emancipation are available. There are numerous impressions, accounts, and photographs available, and a lot is analyzed in *Homologie*, a scientific and cultural bimonthly. Still missing, however, is a broad and thorough study of the homosexual and lesbian subcultures in these periods from a nonpolitical perspective.

Hekma (1987) analyzed how during the 19th century, Dutch physicians and psychiatrists, influenced mainly by German and French ideas, constructed a homosexual identity with specific bodily and mental characteristics. This widely accepted image of gay and lesbian identity was disputed by Muller (1990), who showed that most German physicians relied heavily on personal statements of their clients, who in their self-confessions constructed homosexuality themselves. The theoretical issue is, as in other psychiatric cases of alcoholism and anorexia, who has the power in the discourse: Who "invents" the images, the categories, the definitions of the self? It seems that in the 19th century, the "making of the homosexual" was mainly an interaction of physicians and their patients. In the 20th century, homosexuals discovered themselves as a community.

Dutch research on gay and lesbian relationships took root in our tradition of research on alternative relationships. Instead of focusing on differences between marriage and alternatives, Dutch researchers try to understand the dynamics of different forms of relationships. Straver (1981) found that among unmarried couples—heterosexual, homosexual, and lesbian—some couples structure their relationship in a traditional, strong role differentiation, while others accentuate complete togetherness with a tendency towards interdependence. Still others emphasize self-development. Living together is no longer an essential condition in forming a relationship. Straver does not present a correlation between these models and sexual orientation.

Schreurs (1990) compared lesbian, cohabiting women (above average in education, income, and professional activity, and mainly in their 20s and 40s) with a similar group of heterosexual couples. Analysis produced Stravers' types of relationships, except for the strong role-differentiation type. Relations characterized by togetherness led to the highest scores for relationship satisfaction; couples in autonomy relations expressed satisfaction with autonomy as well as with togetherness. A group characterized by distance scored identical on autonomy, but lower on togetherness. In comparison with heterosexual couples, only emotional and recreational bonding scored lower in heterosexual couples, and men scored lower on satisfaction with emotional bonding.

Schreurs criticizes current theories in which lesbian relations are considered a risk for symbiosis (i.e., high bonding with loss of autonomy). In lesbian relationships, a high degree of emotional bonding obviously is possible without loss of autonomy, an important consideration for therapists working with lesbian couples.

In a similar study, Deenen (1991) analyzed 320 men in steady homosexual relationships: 69% lived together; the mean relationship duration was 8.2 years (10-39 months:  $n = 88$  with mean age 30; 40-199 months:  $n = 138$  with mean age 36; 120-446 months:  $n = 93$  with mean age 45). He found no support for the phasic developmental model of McWhirter and Mattison (1984), who hold that sexual and emotional satisfaction depend on the time of a relationship between two men. Deenen found differences between short- and long-lasting relationships, and a difference between men younger than 30 years and older men. Both variables, relationship duration and partner's age, predicted relationship satisfaction and sexual satisfaction better than the phasic developmental model.

For women and men in homosexual relationships, emotional intimacy is the best predictor for relationship satisfaction. Sexual contact seems more important for men, but this difference may disappear if one relies on a less-strict definition of sexual contact and replaces it by affectionate bodily contact. One can go even further, seeing the whole erotic and sexual attraction embedded in the more general context of living, a line of reasoning also found in Dutch studies of sexual identity and identity development.

### *Social Status; Legal and Religious Restrictions*

In the late 1960s, Dutch research on homosexuality was characterized by a social-scientific perspective in which the changing of social attitudes towards homosexuality was a primary objective. In 1968, 36% of Dutch adults believed that homosexuals should be restricted in leading their own way of life. In 1980-1987, this figure stabilized around 6 to 7%.

Until 1971, the legal age of consent for homosexual acts was 21 years of age; for heterosexual acts, it was 16. This statute was abolished in 1971, mainly on the argument that scientific research showed that people did not become homosexual by seduction at puberty or in adolescence. The new law and general tolerance had a great impact on the counseling of people with problems of homosexuality. Gradually, the image of homosexuality as a psychiatric symptom disappeared completely. In the 1980s, newly established departments of gay and lesbian studies at the Universities of Utrecht and Amsterdam triggered a diversity of studies on homosexuality. Studies of genetic, hormonal, and neural factors are insignificant, the emphasis being placed instead on history, sociology, and social psychology.

While tolerance certainly has increased, this does not exclude all sorts of gross and subtle discrimination, including violence. For decades, youth gangs have beat up gay men in cruising areas. It took the homosexual movement a long time to persuade the gay victims (often men seeking anonymous sexual contacts while they were still "in the closet") to accuse their assaulters in court and to convince police officials that this form of violence should be taken seriously.

Two legal topics are currently under discussion, legislation against discrimination and legal recognition of gay unions. Legislation against discrimination on grounds of race, sex, sexual lifestyle, and so on, has taken more than a decade. During these years, religiously inspired parties have tried successfully to introduce exceptions based on conflicting interests. The central issue is always whether Christian schools will dismiss or refuse to hire homosexual teachers.

Although Dutch civil laws do not specify the heterosexual essence of marriage, no gay or lesbian couple has been able to enter a legally recognized marriage. Two recent efforts to gain this recognition have been turned down by the high court with the suggestion that the matter should be studied by the government and a law reform prepared. All political parties support this opinion. (See "Update 2001" below.)

Discrimination and homophobia are expected in macho cultures such as the military. Since 1971 and the abolition of the penalty for homosexual acts after age 16, homosexuality has been tolerated in the military. A 1992 NISSO study of homosexuality in the military concluded that:

- Drafted men did not differ from the general population in homosexual feelings and experience;
- Male professionals less often reported homosexual feelings and experience;
- Female professionals more often reported homosexual feelings and experiences—women are not drafted for military service in Holland.

- In all branches and at all levels, respondents were aware that discrimination was not tolerated; female soldiers were more tolerant than their male colleagues. Yet, distancing and isolation in some form was a common reaction, and unconditional support was often withheld from homosexuals. When open about their sexual orientation, homosexuals were excluded from the comrade culture. Homosexuals tend to be isolated much more than allochthonous soldiers.
- Excesses, from abusive language to physical attacks, are not uncommon in the army.
- Homosexuals tend to mask their orientation while in service. In their immediate environment, homosexuals have little support—the Foundation Homosexuality and the Armed Forces functions only on a national level.

This 1992 NISSO research marked a milestone in the development of attitudes towards homosexuality in the military. COC, the national organization of homosexuals, gave the Dutch Minister of Defense and the Foundation Homosexuality and the Armed Forces its annual award. In 1993, a national confidential counselor on homosexuality in the military was instituted.

There is not much information on homosexuality in other organizations, e.g., prisons. Coercive homosexual contacts in institutions, as is known from reports in the United States, are reported incidentally, but these acts are definitely not prison routine. Homosexual rape is seldom reported to the Dutch police. A few cases of male pedophilic or incestuous offenses are brought to trial each year, but cases involving adult victims are rare.

#### [Gay Marriages Approved

[Update 2001: In 1998, the Dutch enacted a law allowing same-sex couples to register as partners and to claim pensions, social security, and inheritance. In September 2000, the Dutch Parliament voted to convert the country's "registered same-sex partnerships" into marriages, complete with divorce guidelines and wider adoption rights for gays. The Dutch law allows same-sex couples even more rights than the Danish law, which also recognizes gay marriages. When effective early at midnight, March 31, 2001, Dutch couples were able to marry at city hall and adopt. They are also able to divorce through the court system. As of March 2001, Iceland, Finland, Norway, Sweden, France, and Germany allowed legal registration of gay partnerships. The only restriction is that one of the two must be Dutch and live in the Netherlands.

[The new Dutch law had unusual and overwhelming support from all three parliamentary factions in the governing coalition in the 150-seat Parliament. Only a few small Christian parties opposed the law. Both Protestant and Roman Catholic churches rejected the change. At midnight, March 31, 2001, three gay male couples and one lesbian couple had their marriages witnessed by the Mayor of Amsterdam. Because gay Dutch couples may run into trouble traveling in countries where homosexuality remains illegal, the Foreign Affairs Ministry planned to offer legal assistance in such cases. (End of update by R. T. Francoeur)]

#### Prevailing Patterns in Sexual Behaviors

The 1989 survey showed that homosexual and bisexual people tend to be the most permissive on the subject of sex in general (Table 18 gives results for 421 male and 580 female respondents).

Physical attraction for same-sex partners was felt at a mean age of 14 for male and 19 for female respondents. This difference was smaller in the younger age groups. Respondents reporting attraction to same-sex partners generally

were confused and worried by these feelings. After a mean duration of three years, these feelings subsided in about half of the men and two thirds of the women. Men who are attracted to men tend to have had some form of sexual contact at least once; in women, attraction led to sexual behavior in only a minority. The time from first sexual attraction to sexual contact was shorter for men than women (see Table 19).

Homosexual and bisexual men had a much larger number of sex partners; for women, total numbers were too small to form conclusions. For homosexual men, the mean number of partners in the past year was 9.1; in the past five years, 48.6, and in their whole life, 270.3. In comparison, heterosexual men reported means of 1.1, 1.4, and 3.9 for the same periods. Bisexuals reported numbers between these two extremes.

Long-term relationships (mean duration, six years) were reported by two thirds of the homosexual respondents. Of the men, half of this group had an open relationship with incidental contacts tolerated. The mean for such incidental contacts was 12, which is not different from the mean of homosexual men not engaged in a steady relationship. In steady re-

**Table 18**

#### Homosexual Experiences

Experience	Male		Female	
	Number	Percent	Number	Percent
Ever felt physical attraction	54	13	59	10
Ever been in love	25	5	18	3
Ever has thought to be homosexual	33	8	19	3
Ever had sex with a person of the same sex	50	12	25	4
More than incidentally had sex with a person of the same sex	24	6	13	2
Same-sex attraction is currently present	24	6	19	3
Feels to be (primarily) homosexual	17	4	2	0.4

**Table 19**

#### Current Sexual Orientation, by Self-Labeling and Behaviors, in Percentages

Criteria	Males	Females
<b>Self-labeling</b>		
Exclusively heterosexual	89.5	92.9
Almost exclusively heterosexual	4.5	4.1
Mainly heterosexual	1.9	2.1
Equally homosexual and heterosexual	0.0	0.5
Mainly homosexual	0.7	0.9
Almost exclusively homosexual	1.9	0.2
Exclusively homosexual	1.4	0.2
<b>Behavioral</b>		
Exclusively heterosexual	81.7	88.4
Bisexual	1.9	0.5
Exclusively homosexual	3.6	0.3
Never had sexual relations	12.8	10.7

(IES2 Table 8, p. 930)

lations, anal intercourse was common (82%) and condom use was extremely rare. In incidental homosexual encounters, anal intercourse is practiced by a quarter of the men, with condom use uncommon. Gay bars and cafes, saunas and Turkish baths, some well-known highway parking places, and parks were the main sites for incidental contacts. All sorts of subculture variations are available, especially in Amsterdam, including leather and S-M, piercing, and tattooing.

In Deenen's 1991 gay-couples research, high frequency of sexual contact correlates with short duration of the relationship (but not very strongly) and with younger age (especially in longer-standing relationships) (see Table 20). A positive evaluation of the sexual interaction correlates with higher frequency, but less so in beginning relations. Dominance as a self-reported trait correlates with high frequency of sexual contact. No correlations were concluded for emotional distance, intimacy in the family of origin, or positive self-image.

### *Bisexuality*

Bisexual respondents in the 1989 study are relatively young. They tend to self-label as heterosexual and their behavior pattern is similar to heterosexuals with short-term relations. Anal intercourse is rare and, when practiced, condoms will be used, contrary to vaginal intercourse in which condom use is rare.

It is remarkable that there has never been a research study on homo(bi)sexuality in marriage in Holland. The 1968 and 1981 studies showed that 2.3% and 3.3%, respectively, of male respondents with predominant or exclusive homosexual attraction were, or had been married. Married homosexuals sometimes will seek help from professionals, but the only organization for marriage and homosexuality is the self-help group, Orpheus.

## *7. Gender Diversity and Transgender Issues*

The first and most important clinic specializing in gender dysphoria is the Academic Hospital of the Free University of Amsterdam. The Dutch Gender Foundation was established in 1972. After several years of informal contact with the Free University Hospital, the ethics committee gave its approval to the medical treatment of transsexuals. The clinic started in 1976, mainly with hormonal treatment and a small number of surgical corrections. In 1982, a multidisciplinary team was formed, following the guidelines of the Harry Benjamin International Gender Dysphoria Association. Medical treatment is covered by health insurance. Support and peer-group contact are provided in some large cities by the Dutch Society for Sexual Reform (NVSH) and the Organization for Humanistic Help. Self-help groups often include transvestites. Special groups for parents and other family members have been organized recently. The most recent, and tragic, expan-

sion of self-help for transsexuals is a group of persons treated with sex-reassignment surgery who regret the operation.

There are few legal barriers to the sex change after a legal reform that took place in 1985. A transsexual's sex may be corrected on the birth certificate if a medical declaration states that the person is irreversibly bodily corrected to the other sex and is permanently infertile. Married transsexuals must divorce before the birth certificate can be changed. At the same time (or sometimes earlier), a person's given name may be changed.

Thus far, some 1,500 transsexuals have been assessed by the Amsterdam gender team; approximately 150 sex-reversal surgeries (SRS) have been performed. In 1988, the Free University founded a chair for transsexology, which was awarded to Louis Gooren. Utrecht professor Peggy Cohen-Kettenis, whose chair (installed in 1992) is dedicated to gender development and psychopathology, works in close collaboration with the Amsterdam team. In some adolescent cases, treatment began before the patient's pubertal maturation process was fully completed; some 20 patients completed their SRS before or shortly after age 18. These teams also carry out training and research activities. Two smaller gender teams are active in Groningen and Arnhem, but, unfortunately, they are not active in research.

The incidence of male-female transsexuality has been estimated at 1:12,900; and for female-male 1:30,400. Scientific attention to further diagnostic specification is expanding, especially for the concept of primary (aware since early childhood) versus secondary (awareness developing later in life) transsexuality.

Kuiper (1991) has provided the most extensive evaluation of the Amsterdam SRS treatment approach, reporting on 105 male-to-female and 36 female-to-male transsexuals, all at least in the phase of hormonal treatment. In a long-term follow-up, 50% of male-to-female and 75% of female-to-male transsexuals participated, with mean duration since the start of hormonal treatment being over ten years. The main conclusion is that there is no reason to doubt that SRS is effective in ameliorating the patient's gender-related distress. Other personal and social problems were much less influenced by SRS, and female-to-male transsexuals were found to be better adjusted socially (criteria: relations, work, sexual satisfaction, and loneliness). Psychic functioning was characterized by high scores on negativism, shyness, and psychopathology (delusional, paranoid, and bizarre thoughts), and this did not change after SRS. For male-to-female transsexuals, SRS proved to be a major health risk: In a group (mean age 37), 11 out of 105 had died at eight-year follow-up, with myocardial infarction as the most common cause. There is a great need for psychological help on nongender issues, such as loneliness and shyness.

Verschoor (1990), a founder of the Amsterdam gender team, reported on a comparison of biographic questionnaires from SRS clients, transvestite members of the NVSH self-help groups, members of the homosexual organization COC, and controls. The youth of the transvestites appeared less conflicted than those of the transsexuals and homosexuals. Two thirds of the transvestites are married, often with resulting major problems in the relationship. Cross-dressing is sexually arousing for most transvestites. Progression towards transsexual wishes is uncommon—the transvestites in this group are certainly a selected group. For some transvestites, there is a link with S-M.

In 1984, Slijper studied female Congenital Adrenal Hyperplasia (CAH) patients (aged 6 to 16), comparing them with type I diabetes patients and controls. Diminished sex dimorphism in behavior correlated with severity of health problems (e.g., more pronounced in the salt-losing variant

**Table 20**

### **Frequency of Sexual Contact in Steady Same-Sex Relationships**

Frequency	Percentage
None	4.1
Once in a while	6.9
1-3 times a month	17.3
1-2 times a week	43.1
2-5 times a week	25.2
6 or more times a week	2.2

Source: Deenen (1991). (*IES2* Table 9, p. 931)

of CAH) and with the degree of their parents concern with the illness, especially the gender-confusion aspect. Genital virilization itself does not correlate with degree of tomboyism. In 1992, ten patients aged 16 to 33, were reevaluated on sexual and relationship experience and sexual anatomy. Self-pleasuring was frequent in seven. While gender-role behavior had been masculine throughout primary and secondary school, self-expressed sexual orientation was heterosexual in all. Yet, falling in love and sexual experience with partners was very rare. Only three women menstruated regularly. In contrast with the patients' conviction that their genitalia were normal, adequate functional anatomy was found in only four.

## 8. Significant Unconventional Sexual Behaviors

### A. Coercive Sex

#### *Child Abuse, Incest, and Pedophilia*

Years of feminist activities directed at sexual violence resulted in 1982 in a large-scale government-organized conference to develop policies for future years. Since then, sexual violence has been high on the political agenda. Research flourished, volunteer movements were supported financially, the concept of expertise through personal experience was widely acknowledged, public attention was raised by mass-media campaigns, a network of confidential doctors for the anonymous reporting of child abuse was set up, and education for helping professionals was made available all over the country. In psychiatric hospitals, a more profound interest in the patient's sexual-abuse history is growing. Knowledge of the more complicated reaction patterns of childhood abuse, such as dissociative disorders, is expanding. More incest cases were brought to court, and perpetrators were sentenced to heavier penalties—the legal maximum being six years. A modest attempt with outpatient psychological help for perpetrators of sexual abuse was started, as an adjunct to the already existing residential compulsory programs for mentally disturbed violent sex offenders. A systems approach was introduced, in which all family members are supported by their own therapist, who work together to integrate the therapeutic process.

In the mid-1980s, Draijer (1990) carried out a nationwide representative study of female child sexual victimization by family members with in-depth interviews of 1,054 women, ages 20 to 40. This was 50% of all women approached. Intrafamily sexual abuse before age 16 was reported by 15.6%. For 25%, this study was their first discussion of these events. On a severity scale, 55.6% were found to be mild or not severe; 44.4% were classified as severe or very severe. (Step)fathers were the most inclined to commit more-intrusive forms of abuse. The level of education, level of professional occupation, religion, and geographical isolation were insignificant predictors. Family backgrounds that correlated significantly with incest included: conservatism in male-female roles, restricted sexual norms, child emotional neglect, lack of physical warmth in childrearing, discontinuity in family life, physical aggression, illness, depression, emotional instability of the parents, and the father's possessiveness and controlling tendency. Sexual victimization correlates with problems in later life in a much higher degree than all other negative family dynamics. Only 13% had no negative effects whatsoever.

Child sexual abuse outside the family has gained less attention (see Section 5B, Interpersonal Heterosexual Behaviors, Adolescents). In the 1970s, because of society's greater tolerance for all sexual expressions, pedophilia was for some years less tabooed. A public discussion about adult-child

sexual contact on a nonexploitative base was then possible. Since the legal reform of 1991, adult sexual contacts with boys aged 12 to 16 are felonies only if the boy or his legal representative wants prosecution: The maximum penalty is six years. Gender equalization of pubertal sexual rights was also part of this reform.

Following a low in child sexual abuse cases reported in 1983, there has been a steady increase in both reported cases and the percentage of cases prosecuted. In 1989, cases of child sexual abuse by nonfamily members or authority figures was 1.9 per 100,000 inhabitants.

Male victims of childhood sexual abuse come out of the closet much later than females. The double taboo on homosexuality and powerlessness results in massive shame and repression. Volunteer and professional help for male victims is more difficult to find. Some child-abuse cases attract a lot of the general public's attention, especially the difficulties in truth finding, e.g., the use of interviews with the so-called anatomically correct dolls.

### B. Sexual Harassment

Since the 1982 government conference on sexual abuse, sexual harassment has been recognized as a major problem in all sorts of organizations, including schools and business organizations. It has certainly become easier for workers to lodge complaints. Confidential counselors have been introduced in schools, and training of personnel managers and administrators on this issue is available all over the country. Verbal and physical misconduct on gender-related issues is extinct, but the general public's recognition of the intolerance of such behavior is widely acknowledged.

One special type of sexual abuse requires mention: the sexual contacts between (para)medical professionals and their patients or clients. It has been found that women abused in childhood were often revictimized during therapy. Recently, extra attention has also been given to the mentally and physically handicapped. In the 1980s, ethical codes on this particular type of misconduct were formulated. In the 1991 law reform, medical and social work professionals were included with civil servants, teachers, youth leaders, and prison wardens in those faced with a maximum penalty of six years for abuse of authority.

### C. Rape

Rape was an early target for the feminist movement in the 1970s. It took some years to convince police and the courts that rape cases deserved much more attention, and rape victims much more sensitivity during interrogation. Some rape characteristics shocked the general public, for instance, the almost universally denied fact that date/acquaintance rape is more common than stranger rape. A government-financed mass-media campaign in 1992 addressed young men on sexual coercion: "Sex is natural, but never self-evident." Until 1991, Dutch law did not allow prosecution for marital rape. Sexual assault, meaning all other forced sexual acts except vaginal intercourse, is a criminal offense between husband and wife. This law reform has been a major target for emancipation action. Rape victims have also profited from the victim movement's help initiatives and its achievements in training professional social and psychotherapeutic workers.

Maximum penalty in rape cases is eight years. The number of rape cases brought to the police is steadily rising. In 1991, 1,333 accusations (9 per 100,000 inhabitants) resulted in 858 rape cases (65%), 746 suspects being cleared, a rather stable percentage over the years. For sexual assault, 2,427 accusations (16 per 100,000) resulted in 1,060 cases (43.7%) and 632 suspects being brought to court by the police.

#### D. Prostitution

Studies on prostitution are numerous, but almost all data are nonrepresentative. In Holland, prostituting oneself is not illegal, but creating the opportunity for prostitution, e.g., profiting from a brothel, is. In 1993, a legal reform lowered the sanctions and allowed local governments to formulate their own policies. Prostitute activists are dissatisfied with this reform, arguing that the new situation will not improve the prostitute's legal position. In the last decade, a movement to abolish exploitation and improve working conditions (safety, hygiene, and privacy) was initiated. Prostitutes fear that the new legal situation will lead to registration and taxing (including a Value Added Tax [VAT]), which will again force the weaker group members into evading the law. Today's urgent problems include the trade in women from Third World nations, exploitation, illegal immigration, and fraudulent parental claims by Antilles men for South and Central American girls intended to legalize their working for Dutch brothels, and violence.

The total number of prostitutes in the Netherlands has been estimated at 15,000 to 20,000, the vast majority being women. Some 10% are supposed to be streetwalkers, 30% in window prostitution, 30% working in a sex club, 15% in an escort service, and 15% work in their private residence. Drug addicts, including drug tourists, are numerous in the streetwalker group. Window and club prostitution are dominated by Caribbean, South American, African, and Asian women. In recent years, condom use among these groups has been promoted by means of audiotaped messages. It is generally believed that today, most prostitution intercourse is protected, with drug-addicted streetwalkers as the most likely exception.

In 1968, more than half of all single men and 12% of husbands refused to answer questions about paid sexual encounters. In both groups, 12% admitted to having visited a prostitute at least once. In 1981, refusal was almost nil and 11% admitted to having visited a prostitute at least once. Moreover, 19% of the married group, especially the younger-age group, had visited a sex club at least once. In 1989, 13.5% of the male respondents reported having paid for sex at least once; 2.6% had had at least one paid sex experience in the past year.

In the 1989 study, visiting prostitutes seemed to be motivated more by the desire to maintain independence than by social inadequacy. For men in steady relationships, common motives are variation or a strong desire for special forms of sex their partner refuses them. Condom use seems almost to have doubled as a result of the safe-sex campaigns.

Male heterosexual prostitution is extremely rare in Holland, but one study of escort boys was published in 1989. In recent years, male strippers ("Chippendales") have made a remarkable appearance in the entertainment world.

Male homosexual prostitution is estimated to count some 1,300 men, of which a large group must be relatively young. Some consider themselves true professionals, with a professional pride in working according to their own standards. Others are motivated largely by drug addiction and homelessness. Sexual orientation is problematic: Most boys consider themselves to be heterosexual, which suggests limits on the behaviors they consider acceptable or not. Fortunately, these restrictions result in a rather low prevalence of unsafe sex; homosexual prostitution seems to be a minor risk factor in the AIDS epidemic. Unfortunately, this discrepancy between self-perceived sexual orientation and behavior can lead to resentment and violent outbursts. A boy who feels trapped, especially when a man wants to perform anal penetration, will sometimes commit violent acts against his customer, as this behavior is most threatening to his masculinity.

In ten years, 18 murder cases with this dynamic were reported in Amsterdam. Moroccan boys were overrepresented, and this may reflect high vulnerability for threats to their masculinity as a result of their Islamic culture.

#### E. Pornography

Pornography as a subject of public decency laws has almost completely disappeared from the legislative discourse since the 1960s sexual revolution movement. Feminist criticism of the misogyny obvious in a lot of pornography has been heard throughout the nation, but this did not influence legislation to any substantial degree. In the latest reform, the protection of children and women in the pornography-producing business has gained more impetus than the decency aspect. Penalties up to three months can still be given for public exposure of indecent materials, exposure to children under 16, and selling child pornography. Child-abuse laws are often applied in cases of the production of child pornography; the maximum penalty is six years.

Child pornography has been under scrutiny as a result of allegations from the U.S.A., implying that enormous amounts of these materials were being imported from the Netherlands. It cannot be denied that in the mid-1980s, Holland produced and exported child pornography, some of which, especially heterosexual material, clearly qualified as hardcore. Yet, the American interest in Dutch pornography has all the characteristics of a witch hunt, exaggerating the numbers of victims. In 1989, six child pornography cases led to convictions.

The use of pornography is quite common. In the 1989 study, only 23% of the men and 55% of the women had no experience at all with erotic magazines or books, while 54% of the men and 12% of the women had watched pornographic movies or videos. The "new kids on the block" are erotic pay-phone lines (06-numbers); 12% of the men and 4% of the women reported having phoned a sex line. This erotic option has become an addiction for some Dutchmen. Recently alcohol-and-drug services have begun treating some of their patients for 06-phoning problems.

#### F. Other Unconventional Behaviors

Some paraphilic behaviors are well embedded in society. Transvestites, for instance, have formed groups, often with transsexuals, for mutual support and opportunities to cross-dress without the risk of ridicule or violent reactions. People interested in sadomasochistic sexual contacts have formed two national organizations, and numerous sex clubs offer opportunities for expression. Gay and lesbian S-M groups are also active, and one occasionally sees some very aesthetic expressions of the S-M preference, especially in photography.

Indecent exposure is the most common sex crime; in 1990, 1.8% of all women were confronted with an act of exhibitionism. The number of reported cases shows a slow decline: 3,840 in 1991 (26 per 10,000). Only 30.5% were brought to court by the police. Exhibitionism complaints often result in a warning, and when brought to court, suggestions for some sort of therapy will often be the judge's sentence. Unfortunately, no studies of results of court-ordered outpatient treatment of exhibitionists are published.

### 9. Contraception, Abortion, and Population Planning

#### A. History

Contraceptive advice in Holland started in the 1880s. The inspiration for a Neo-Malthusian League was imported from the United Kingdom by Alette Jacobs (1854-1929). This remarkable woman, the first Dutch woman ever to en-

ter secondary school, the university, and become a medical doctor, was strongly influenced by feminist ideals and a heartfelt concern for the poor. The League, founded by Jacobs and two other doctors, found little support and more often violent opposition in medical circles.

After Mensinga invented the diaphragm in 1881, this became the main weapon in the struggle against large, poor families. Free clinics started in Amsterdam in 1882, and soon afterwards in Rotterdam and Groningen. The Neo-Malthusian League produced leaflets and books in enormous numbers. Some midwives joined the clinics, and from the 1890s on, laywomen were trained in instructing and prescribing the diaphragm. The clinic network expanded rapidly, as condom quality improved and more precise information on the Ogino-Knaus method of periodic abstinence became available.

In 1939, the Neo-Malthusian League performed Holland's first sociosexual research, distributing 26,010 questionnaires to its members; 7,788 were returned and analyzed (Nabrink 1978); see Table 21 for some results of this survey.

When the Germans occupied the Netherlands, the Neo-Malthusian League was abolished. After World War II, a new organization replaced it, the Dutch Society for Sexual Reform (NVSH). Again, a chain of consultation bureaus was established and education for the general public gradually became more accepted. The ideals of the NVSH became more political, and the sexual revolution further radicalized the movement.

Following the introduction of the oral contraceptive in 1962, general practitioners and gynecologists were initially reluctant to prescribe the pill, sometimes for reasons blatantly moralistic. The NVSH consultation bureaus soon became a well-known alternative for teenagers, unmarried couples, married couples who wanted to postpone procreation, widows, and divorcees. Professional expertise in the NVSH bureaus was also on a higher level in those pioneering years. In 1969, the society separated into a professional organization for the management of the consultation bureaus, the Rutgers Foundation, and a layman's organization for political action, education, and discussion and self-help.

Since the mid-1970s, contraceptive advice has become part of the regular physician's routine; gynecologists play a minor part in contraception in Holland. The Rutgers Foundation still was a useful alternative for girls and women who sought extreme discretion (e.g., young girls and women in extramarital relations whose spouses had vasectomies) and for more specialized questions on contraception and "second opinions." Since 1992, the Rutgers Foundation has concentrated its services in seven large cities, and guides its

efforts more to educating the regular providers of contraceptive and sexological services.

From the mid-1960s on, contraceptive use and attitudes have been major research issues. Unwanted pregnancy and induced abortion caused major social, medical, and political concern. Accordingly, in the past two decades, questions about contraceptive use and the prevalence of unwanted pregnancy were almost always included in surveys, particularly those for adolescents.

Several studies directly addressed the issue of family planning. Initially, research was mainly done by general practitioners and family-planning doctors. Social scientists entered the field a few years later. A 1974-75 representative study, involving 1,200 men and women, revealed that modern methods of family planning had been rapidly accepted, irrespective of social status or religion. NISSO did several studies in close collaboration with Stimezo-Nederland, the national abortion federation, which began its own research program in 1974. The role of induced abortion in society was studied as it related to changing patterns of family formation, sexual behavior after the "sexual revolution," and emerging modern contraceptive behavior. An international comparative investigation of the consequences of legal changes regarding abortion in Western Europe and the U.S.A. was followed by a study of contraceptive behavior throughout Western Europe (Ketting 1990).

In 1986, NISSO started a new research program on family planning, concentrating on specific groups. Studies published prior to 1993 include:

- Anthropologically inspired in-depth interviews on sexual and contraceptive behavior of Turkish immigrants;
- A similar study on Caribbean immigrants;
- An in-depth study of the social and psychological mechanisms underlying the effectiveness of contraceptive behavior of young girls at the start of their sexual careers;
- A study on the rather new phenomenon of women's ambivalence towards childbearing; and
- A representative study of the experiences of 1,200 women with, and attitudes towards, oral contraception.

## B. Some Data

Vogel and van der Vliet's 1990 study on adolescent sexuality gave a lot of information on contraceptive use and the various motives for the use of condoms. They concentrated on contraceptive motives, although this distinction is not always possible.

Mean age for first coitus in this survey was 17.5. In this first coital experience, 57% used a condom. The earlier first coitus occurred, the higher the proportion of condom users. Allochthonous youngsters scored lower, especially when not born in the Netherlands. In the older age groups, as relations become steady, oral-contraceptive use is the rule, and condom use for STD/AIDS prevention loses most of its impetus.

Many girls are using oral contraceptives before their first coitus. One in five girls are taking the pill by the time they start petting naked. (A prescription for medical reasons, e.g., menstrual discomfort, may account for a proportion of this number.) Two thirds of all girls with some coital experience have at some time used the pill; 60% were using oral contraception when interviewed. When first intercourse was experienced at an early age (11 to 13), the percentage was lower (just over 10%); in the oldest group, almost three quarters were current users.

In keeping with the Dutch slogan, "If you take care of the condoms, I'll take care of the pill," combined use of the pill and condom was practiced by 13% of respondents (boys: 18%, girls: 9%) in their last intercourse experience. The 14-to-15 age group is most conscientious in this regard,

**Table 21**

### Contraceptive Use and Failures in 1939 Neo-Malthusian League Survey ( $n = 7,788$ )

Method	Females			Males		
	<i>n</i>	Failures	%	<i>n</i>	Failures	%
Coitus interruptus	155	29	18.7	165	46	27.9
Diaphragm	1,484	75	5	1,409	44	3.2
Condom	1,105	67	6	1,036	79	6.7
Cervical cap	95	19	20	91	12	13.2
Patentex jelly	56	20	35.7	61	20	32.7
Periodic abstinence	56	12	21.4	53	17	32

(IES2 Table 10, p. 938)

22%. The use of no contraception at all is rare; only 11% of 16- to 19-year-olds used no contraception in their last sexual intercourse (see Table 22).

### Adults

Van Delft and Ketting (1992) have reported the most recent number data from 1988: Of the 18- to 37-year-old women, 43% used an oral or injectable contraceptive, 22% no contraceptive, 7% each for the condom or vasectomy, 5% each for vasectomy and IUD, and 3% tubal ligation. Only 13% of the married women, 5% of the cohabiting women, and 14% of the women in steady relationships used no contraceptive (see Tables 23 and 24).

No Dutch data are available on contraceptive failures for different methods. While a number of unplanned pregnancies are accepted after discovery, it is known from various sources that over 90% of all children born in the years 1981-88 were planned. A comparison of Dutch failure data with U.S.A. figures reveals that each method, except for periodic abstinence, is more reliable in Holland and the difference is enormous. Three sources of confusion are mentioned by van Delft and Ketting:

- American data often report method failure in the first year of use. Most methods gain in reliability in time.
- The "morning after pill" is easily available in Holland and is used by women who are aware something has gone wrong with their usual method.
- Some American data may be distorted by including users who deliberately stopped using the method.

**Table 22**

#### Pregnancies per 1,000 Unmarried Women, Grouped According to Consequences, 1980-1988

Year	"Forced" Marriage	Birth Out of Wedlock	Abortion	Total
1980	2.8	2.4	5.3	10.5
1981	2.9	1.9	5.3	10.1
1982	2.5	2.1	5.1	9.7
1983	2.3	2.2	5.3	10.0
1984	2.1	2.0	4.4	8.5
1985	1.9	2.0	4.4	8.4
1986	1.9	2.1	4.1	8.1
1987	1.6	2.3	3.8	7.7
1988	1.6	2.3	3.8	7.7

**Table 23**

#### Current Contraceptive Method, by Age, in Percentages (1988)

Contraceptive Method	Age of Women (in Years)					Total 18-37
	18-19	20-24	25-29	30-34	35-37	
Oral-injectable	45	59	48	31	22	43
IUD	1	2	5	9	6	5
Tubal ligation	0	0	1	6	11	3
Vasectomy	0	0	3	12	23	7
Condom	5	5	9	9	8	7
Other methods	4	6	4	5	3	5
No contraception	45	24	19	16	15	22
Pregnant	0	3	9	6	2	5
Infertile	0	1	2	6	9	3

Source: van Delft & Ketting (1992, 10, Table 1). (IES2 Table 12, p. 941)

It is generally acknowledged that U.S.A. data on method failure cannot be used for Dutch educational materials (see Table 25).

Estrogen dose-dependent side effects, especially cardiovascular ones, led to the introduction of the so-called sub-50s in 1975. In five years, they became the leading oral contraceptive. Today, most physicians prescribe sub-50s. This seems to work reasonably well: Abortion data show that women on 50s and sub-50s have comparable risks of unwanted pregnancy.

Concern over the pill's side effects around 1980 led to a short but sharp decline in pill use. Introduction of sub-50s largely removed this concern. Today, most women are aware of positive side effects. Nevertheless, total oral-contraceptive use once again showed a slight decrease in 1990. Condom use for STD and AIDS prevention may have led some women to stop or postpone oral contraception. The decline in popularity of hormonal contraception led to a short increase in IUD use (see Table 26).

Gynecologists and the Rutgers Foundation were the early providers for IUDs. From 1983 to 1987, the Dutch industry producing the most popular IUD ran educational workshops for physicians, increasing the use of IUDs. Early on, there was an awareness of negative side effects, menstrual discomfort, and a rising number of extrauterine pregnancies.

Because condom use has been so strongly motivated by disease prevention, it is discussed in Section 10 below.

**Table 24**

#### Current Contraceptive Use, by Relationship Status, in Percentages (1988; Ages 18-37)

Contraceptive Method	Married	Cohabiting	Steady Relationship	No Male Partner
Oral-injectable	35	68	67	28
IUD	7	7	3	1
Tubal ligation	5	2	2	1
Vasectomy	13	3	1	—
Condom	9	6	6	4
Other methods	4	5	6	4
No contraception	13	5	14	58
Pregnant	9	4	1	0
Infertile	5	1	1	3

(IES2 Table 13, p. 942)

**Table 25**

#### Distribution of Hormonal Contraceptive Use by Type of Method, 1980-1989, in Percentages

Year	Sub-50 Combination		50-(plus)	Injectable	Others
	Tri-phasic	Tri-phasic			
1980	41.9	0.1	46.7	4.3	7.0
1981	47.5	5.6	36.5	4.8	5.6
1982	55.6	10.1	25.3	4.7	4.3
1983	57.2	14.8	20.4	3.9	3.7
1984	58.7	18.8	16.6	2.8	3.1
1985	69.7	20.8	14.5	2.4	2.6
1986	61.0	22.1	12.5	2.2	2.2
1987	61.4	23.8	11.2	1.8	1.8
1988	61.7	25.2	8.2	1.6	2.0
1989	62.8	25.2	8.2	1.6	2.2

Source: van Delft & Ketting (1992, 26, Table 11). (IES2 Table 14, p. 943)

The diaphragm was never very popular after World War II, being used predominantly by women in steady relationships and dissatisfied with alternatives. It has its place in a lifestyle characterized by conscious living with health risks. In small circles, modified and perfected forms of periodic abstinence are also used. We have no reason to suppose that Roman Catholics are a large proportion of abstinence users. In 1992, the woman's condom (Femidom) was introduced. Among 300 women, ages 21 to 40, who were regular users of oral contraception, IUD, or sterilization during the trial period, 155 women reporting using Femidom on at least three occasions. Both men and women appear reasonably satisfied with the Femidom.

Surgical sterilization peaked in 1979, when 132,000 men and women had vasectomies or tubal ligations. The proportion of men is growing steadily, because it is well known that sterilization is much easier in men. The operation is most often performed between ages 35 and 44. Since 1985, the percentages of sterilized men and women in each age group has been rather constant. In the 35-to-39 age group, 18% of women and 20% of men are sterilized; in the 40-to-45 age group, about 25% of women and men are sterilized; about 30% of men and women 45 to 49 have been sterilized. Forty percent of all couples aged 30 to 49 have one spouse sterilized.

In recent years, sterilization has decreased in the younger age group, most probably because of an ongoing tendency to postpone having a first child. Also, some couples are debating for a number of years whether or not they want to have children at all. This has led to an expanding group of last-chance mothers with considerable fertility problems caused by a more-advanced age. This group of doubters, combined with a growing conviction that oral contraception is not a major health risk, will likely lead to a further decline in sterilizations.

Interception with the "morning after pill" (MAP) and the "morning after-IUD" (MA-IUD), along with abortion, is one of the adjuncts of planned contraception. The MAP is easily available for use after unprotected intercourse, as well as for backup for incidental failures with the regular method. The largest group using MAP is the 16- to 18-year-olds. Around 1980, when the negative attitude toward the pill peaked, use of MAP also peaked. The original MAP (5 x 5 mg ethinyl estradiol) has been replaced with the Yuzpe regime (100 mg ethinyl estradiol plus 500 mg norgestrel repeated after 12 hours) introduced in 1982. By 1986, the Yuzpe MAP accounted for 85% of MAP prescriptions. In 1986 and again in 1992, some doubt was cast

on the effectiveness of the Yuzpe regime, leaving the future of this method open to question.

### C. Abortion

Just over 30,000 abortions are performed yearly in Holland, a quite stable number in recent years. More than 90% are done in abortion clinics, almost all under local anesthesia; the rest are done in gynecology departments, 80% under total anesthesia. Among women living in Holland, 69% have their abortions within six weeks after conception; 2.2% were pregnant longer than 15 weeks in 1989-90. Large numbers of abortion patients (35 to 40%) visit our clinics from western Germany, Belgium, Spain (showing a sharp decline since 1988), and numerous other countries.

Separate data are available from women in Holland, Suriname, the Dutch Antilles, Turkey, and Morocco. Abortion rates in these groups show significant, but rather stable differences, with a slight increase for the Moroccan and a slight decrease for Suriname, Antilles, and Turkish women (see Table 27). Moroccan women tend to be relatively young, primigravidae, and unmarried; it is supposed that the rising number for Moroccan women indicates some alienation from their traditional culture. For Turkish women, data suggest that abortion is used mostly to put an end to the expansion of the family. Allochthonous women have used abortion more often than autochthonous women, and it must be assumed that this implies more user failures. Moreover, one third of these women had used no contraception at all, compared with 20% for Dutch women. For allochthonous women, some 25%, the abortion in 1989-90 was not their first. For Suriname and Antilles women, it is recognized that they show more fear for unhealthy side effects of oral contraceptives. This leads to an eagerness to stop taking the pill, for instance, when a relationship falls apart.

Teenagers as a group are constant in their risk of abortion in recent years, around 4 per 1,000 girls aged 15 to 19. Teenagers have shown a slight increase in live birthrates in recent years.

As Dutch couples conceive later in life, the number of prenatal diagnostic tests for fetal malformation and disease will rise, and so will the decision for an abortion to resolve an unfavorable outcome. Precise numbers of such abortions are not available.

### D. Government Policies on Contraception and Population

In 1970, the Dutch Parliament decided that medical contraception and the cost of medical contraceptive advice should be included under general health services. Condoms are the only contraceptives that are not covered. Even in AIDS-prevention campaigns, a recommendation to include condoms has been ignored. In the recent economic recession, with a growing need to reduce health expenses, hormonal contraception is quite often mentioned as one possibility to cut costs. Thus far, these suggestions have led to

**Table 26**

**Total Number of IUDs Sold in the Netherlands and Estimated Duration *in Situ*, 1980-1990**

Year	Number Sold	Mean Years <i>in Situ</i>
1980	100,000	2.00
1981	97,000	2.25
1982	79,000	2.50
1983	78,000	2.75
1984	77,000	3.00
1985	67,000	3.25
1986	48,000	3.50
1987	45,000	3.75
1988	40,000	3.75
1989	39,000	3.75
1990	38,000	3.75

(IES2 Table 15, p. 943)

**Table 27**

**Abortion Rates, per Ethnic Groups, Ages 15-44, per 1,000**

Ethnic Group	Rate
Autochthonous	3.4
Surinam	28.8
Antillies	31.1
Turkey	17.8
Morocco	12.4

(IES2 Table 16, p. 945)

strong reactions, especially because risk groups, such as minors and allochthonous women, will be the first to suffer the consequences of unwanted pregnancy and abortion.

In 1979, the Dutch government endorsed its State Committee on Population Questions recommendation that all Dutch couples were free to decide their number of children and the time they wanted to have them. Since then, the government has supported effective contraceptive behavior by stimulating and financing research, general education, and low-level professional help. The effectiveness of Dutch contraceptive practice is based on the opportunity for almost all young people to get the pill. Today, most general practitioners are able to handle the delicacy of prescribing the pill to young girls, even if their parents are not informed. In coming years, it will be learned whether or not unwanted pregnancy will increase as a consequence of the Rutgers Foundation's concentration in seven cities.

Abortion was a criminal offense in the Netherlands until a long-awaited legal reform took place in 1982—1953 was the last time a physician was prosecuted for performing an abortion. In 1969, Stimezo, a national organization for medically qualified induced abortion, was formed. Stimezo standards of good advice and care have found their way into today's practice. On the insistence of the religious parties, the 1982 law includes one aspect contrary to the practice of that time, e.g., a waiting-and-reconsideration time of five days after the initial consultation with a doctor. Since that law passed, abortion has been free for all Dutch citizens. Minors living with their parents need their parents' consent, but a legal alternative is available.

Population planning is not an active concern of the Dutch government. Zero growth is accepted, and a changing population stratification (young groups shrinking, elderly groups growing) causes only moderate concern. Will the future active group be able to support a large retired population? In gynecological circles, some concern is growing about the tendency of couples to postpone having children until an age when fertility definitely is lower. A popular slogan, "A smart girl plans her pregnancy in time," is a variation of an earlier advertisement by the Institute for Idealistic Propaganda: "A smart girl is prepared for a future for herself."

## 10. Sexually Transmitted Diseases and HIV/AIDS

### A. Sexually Transmitted Diseases

#### *Incidence, Patterns, and Trends*

According to Mooij's (1990) history of STD, gonorrhea and syphilis were rare in the Netherlands in comparison with the surrounding countries—until 1942. During World War II, a rapid increase was reported, with a peak in 1947. In 1952, numbers were again as low as they were in the 1930s. A steady decline was observed until 1960; but, since then, a second, and longer, epidemic has occurred, with rapid increases in the 1970s. Undoubtedly, these growing numbers were the result of a new enthusiasm for sexuality, the sexual revolution, supported by the general public's knowledge that STDs were now easily cured. Public education almost forgot primary prevention in these years.

The sexual revolution certainly changed the medical and health professionals' ideas on specific risk groups. Prostitutes were no longer the main source of concern; homosexuals, teenagers, foreigners, and Dutch tourists who had sex while vacationing abroad became new targets for information campaigns. It is remarkable that these predictions, based on information from abroad, were not confirmed by Dutch experience, except for homosexuals, and recently Turkish and Moroccan men.

The neglect of primary prevention gradually ended when hepatitis B and herpes, which are not curable by penicillin, appeared. Herpes caused considerable panic in heterosexual circles. Alarming data from the U.S.A. were uncritically transposed to Holland and connections with cervical cancer and neonatal disease exaggerated. The number of diagnoses peaked in 1985, perhaps biased by a more widespread availability of diagnostic services and an antiviral medication that might have prompted people in fear of herpes to be finally tested. In this peak year, the number of herpes cases at the Amsterdam free clinic was 25% of the number of gonorrhea cases. Today, herpes is infrequently diagnosed and the attention paid it by the general public and media is insignificant. However, it is reasonable that herpes promoted a growing concern for primary prevention in the 1980s, as the sharp decrease in STD diagnosis started some years before AIDS appeared.

Two STDs are among the infectious diseases for compulsory notification to the National Health Inspection: gonorrhea and syphilis. Unfortunately, only about 35% of all cases are reported. Free clinics have a more complete reporting, including data on location of the disease (urethral, rectal, and/or pharyngeal), ethnic background, sexual preference, prostitution, and earlier infections. Unfortunately, they have no information on the characteristics of groups using their services, and whether or not this group's composition is stable or changing.

National registration numbers for gonorrhea steadily decreased from 13,199 in 1983 to 3,024 in 1989. The peak year for men was 1981 (140 per 100,000 inhabitants), and for women, 1984 (65 per 100,000). An increase in 1990 was followed by the lowest number ever in 1992. In free clinics, similar trends were observed. The fastest decreases were among male homosexual and bisexual men, since 1984. Female prostitutes showed a little slower decrease, and later—since 1985. For homosexual and bisexual men, 1989 already showed some increase, including more anorectal infections, and, unfortunately, this trend has continued into 1990 and 1991. Moreover, these patients tend to be slightly younger in recent years.

For the Amsterdam free clinic, repeaters are a growing population in the total numbers. Percentagewise, homosexuals are declining and prostitutes are increasing. In all years, the peak age for male infections is 25; for women, it is age 20.

The percentage of Penicillinase-Producing *Neisseria Gonorrhoeae* (PPNG) in Dutch patients is steadily increasing. The first cases of PPNG were reported in the Netherlands in 1976; in 1990, 29% of all gonococcal infections was caused by PPNG. Since 1985, a rapid increase in Tetracycline-Resistant Gonorrhea (TRG) has been observed. In 1989, 40% of PPNG cases also involved TRG.

Syphilis was still decreasing in 1992, with only 190 new infections reported. In Amsterdam free clinic, in 1987, an increase in syphilis incidence was reported in heterosexual men, and some increase in female prostitutes. In that year, heterosexuals for the first time outnumbered homosexuals. In 1989, homosexual men in Amsterdam also showed an increase in new cases of syphilis, similar to tendencies in gonorrhea and seroconversions, perhaps because of a decrease in safer-sex practices.

In Holland, since the early 1950s, all pregnant women are screened for syphilis in the first trimester. In the Amsterdam area, 1985-89, only 55 out of 3,520 blood samples were positive for both TPHA- and VDRL-tests. Only four cases of congenital syphilis were reported in 1990. However, screening is still cost efficient in Amsterdam, and a second screening later in pregnancy should not be introduced as a routine restricted to women having many partners during pregnancy.

Chlamydia trachomatis probably is the most widespread STD today, but information is scanty on this subject since reporting it is not mandatory. The most thorough research took place in 1986-1988. In a 1986-1988 Amsterdam free clinic survey of 1,000 clients (65% male) at the free clinic, chlamydia was found more often than gonorrhea: 14.3% versus 11.5% in men, and 19.2% versus 6.3% in women. Combined infections were found in 2% of men and 2.6% of women. Combination infections were low in homosexual men. In men, signs for urethritis were found in all but one, with negative tests for gonorrhea and chlamydia in 41% of the cases. In the department of gynecology of a large Amsterdam hospital, 1985-1989, the incidence of gonorrhea dropped from 1.1% to 0.4%, and chlamydia from 8.6% to 4.1%.

While chlamydia definitely is the most common STD in Holland, there are good grounds for concluding that the epidemic has peaked. However, the serious consequences for fertility justify further efforts to control the disease. In 1986, in the Tilburg Infertility Clinic, of 77 women receiving their first treatment, tubal abnormality was thought to be the cause of infertility for 69; 54% had significant titers for chlamydia.

Data on condylomata acuminata are rarer, with indications that incidence is in the same range as herpes, increasing slightly up to 1985 and decreasing in recent years. Tropical STDs are rarely diagnosed in Holland, with occasional small epidemics of *haemophilus ducreii*.

Allochtonous men are a growing proportion of free clinic customers. Data suggest that Turkish and Moroccan men are six to ten times more at risk for contracting STDs. Turkish men have gonorrhea in a high proportion and a high proportion of PPNG. They also report prostitution as the source of their infection in a higher percentage. Suriname and Antillian men show a higher proportion of syphilis.

### Government Policies Concerning STD

The Dutch government has recognized STDs as a special group of diseases, with associated shame and stigma calling for special forms of illness management. Alternatives for discreet and anonymous help have been financed. Local health services provide free clinics in all large cities; the Rutgers Foundation is another alternative for STD diagnosis and treatment. For syphilis and gonorrhea, a service is offered to assist patients anonymously in contacting the sexual partners they think they have infected or been infected by.

A national organization for STD control, the SOA Foundation, produces a scientific bimonthly and contributes to the discussions in medical and political circles and to prevention programs. In the last decade, physicians' organizations have produced consensus for standard medical care. More intensive health and STD education programs have been incorporated in a framework of sexuality and relationship management in schools. STDs other than AIDS have never been the target for specific primary prevention programs until recently. The SOA Foundation has applied for funding for a Chlamydia Public Information campaign, but this has not been forthcoming. Target groups other than teenagers in schools also have never been defined for prevention programs on STDs other than AIDS. Special attention to allochtonous groups can be justified by these groups' higher infection rates, and their higher proportion of PPNG.

## B. HIV/AIDS

### Incidence, Patterns, and Trends

Unlike syphilis and gonorrhea, notification of AIDS cases to the National Health Inspection is voluntary. While syphilis and gonorrhea cases are underreported, AIDS reporting tends to be almost complete because of the serious

nature of the epidemic. Many intravenous drug users die of health risks inherent in their lifestyles before their HIV-positive status is detected. Starting with 5 new cases of AIDS in 1982, 437 cases were reported in 1991 and 419 in 1992. Only 10 cases of HIV-2 infection were reported. Homosexual men, followed by IV-drug users (male and female), and heterosexual men and women, account for most AIDS cases, with the incidence remarkably stable through the years. Men ages 30 to 45 and women 25 to 35 are most at risk. Survival time has increased from nine months in 1982-1985 to 22 months in 1989, because of earlier diagnosis and better treatment (see Tables 28 and 29).

The number of HIV-positive persons in Holland is unknown. Individuals may be tested anonymously, in which case their status is not reported. Some data is available on segments of the population from research groups studying pregnant women, drug users (30% of whom are IV users), clients at the Amsterdam free STD clinic, Amsterdam prostitutes and their customers, and voluntary applicants for blood donation.

In a national prospective research project on HIV-infection in pregnancy, testing is voluntary and the percentage of women choosing to be tested varies widely for different hospitals. Between September 1, 1985, and January 1, 1991, 55 women were found to be positive: 60% were not born in Holland. In 58%, intravenous drug abuse was the risk factor; in two of the 22 women supposed to be heterosexually infected, blood transfusion was also reported. Ten were born in an area where AIDS is endemic; seven had at-risk male partners. Of 36 women for whom test results were known before 20 weeks of gestation, two had spontaneous and ten had induced abortions.

Among the estimated 2,500-plus hard-drug users in Holland, only 30% are IV users. IV use varies from practically zero among allochtonous groups to 70% for "heroin tourists." Combining results of a cohort survey among injectors in Amsterdam started in 1985 with reported AIDS numbers,

**Table 28**

### Number of Newly Diagnosed AIDS Patients per Year

Year	New Patients	Year	New Patients
1982	5	1988	321
1983	19	1989	389
1984	31	1990	413
1985	66	1991	437
1986	136	1992	419
1987	242	Total	2,478

Source: National Health Inspection (1993). (IES2 Table 17, p. 950)

**Table 29**

### Number of AIDS Patients, According to Risk Group and Sex

Risk Group	Male	Female
Homosexual-bisexual	1,930	—
Intravenous drug user	145	67
Homosexual-bisexual + IVDU	26	—
Hemophilia	40	1
Blood transfusion	20	15
Heterosexual	108	74
Mother-to-child	2	9
Rest/unknown	33	8
Total	2,304	174

Source: National Health Inspection (1993). (IES2 Table 18, p. 951)

resulted in an estimation of 750 to 800 HIV-positive IV-drug users in Amsterdam as of July 1, 1991. Even more rough is an estimate of HIV-positive IV-drug users outside Amsterdam, ca. 500. Local differences are large and unexplained: Participants in a detox clinic in the Hague were all seronegative, while their injection behavior was no more risky than an Amsterdam group. Prevalence of seropositivity among all IV-drug users is estimated at 25 to 27%. Specific preventive measures include a syringe-exchange program and condom promotion, especially for those active in prostitution (some 80% of all female IV-drug addicts).

In an Amsterdam free STD clinic, during ten weeks in 1991, 90.5% of all the patients accepted testing: 22% of the homosexual men were positive, as were 12% of the male and 41% of the female IV-drug users. Prevalence in heterosexuals without other risk factors was 0.5% (5 of 997) for men and 0.1% (1 of 771) for women.

When prostitutes and their customers were tested in Amsterdam in 1991, three (from Ghana, Nigeria, and the Dominican Republic) of 199 prostitutes were HIV-positive. One customer who admitted to homosexual contacts was HIV-positive.

Blood-donor volunteers in any HIV risk group are asked not to donate. In 1985, 15 donors were found to be HIV-positive; in 1990, the new discouragement policy resulted in only five infected donors. This procedure does not totally exclude HIV transmission by blood transfusion, because of latency between infection and seropositivity. Blood products for hemophiliacs have been heat-treated since 1985, so this is no longer a risk group. Early in the epidemic, about 13% of hemophiliacs were infected.

#### *Effectiveness of Prevention Education Programs*

In a sample of 1,013 homosexual men in Amsterdam followed since 1984, an extensive change in behavior has been documented in two directions: a decrease in the number of sex partners and a lower prevalence of anogenital contact. These behavior changes resulted in a decline in seroconversions to almost zero in 1987. However, since the end of 1989, there is an increase in the incidence of HIV infection in the same cohort. Interviews with this group revealed that higher percentages of both seropositives and seronegatives had had anogenital sex without protection, especially in casual sexual relations.

In recent years, AIDS health promotion has changed its message from "avoid anal sex" to "avoid unprotected anal sex." The availability of special condoms for anal intercourse has been a major factor in this development. Recently, condom efficacy was studied among cohort members. Condom failures (torn, slipped) were seen more often when vaginal condoms were used or when no lubricants, or oil-based lubricants, were used. Personal efficacy prevents failure by slipping, but not by tearing the condom. In-depth interviews with men who seroconverted indicate the significant role of the use of alcohol and other drugs, as well as the divergent individual background of each seroconverter. Personality factors, like coping styles and health locus of control, seemed to be almost completely unrelated to behavioral change. Preceding sexual behavior seems to be the best predictor of actual behavior.

In a quasi-longitudinal telephone survey, changes in beliefs, attitudes, and behaviors related to AIDS were followed from early 1987 onwards. Knowledge regarding the use of condoms to prevent HIV transmission increased to a level that can be considered sufficient by the end of the 1980s. The general population seems to opt for monogamy and condom use as preventive measures. The use of condoms rose, especially among teenagers and persons in nonsteady relation-

ships. These observations were confirmed by condom sales figures and STD incidence. However, there seems to remain a discrepancy between the inclination to use condoms and the actual use.

In the 1989 study, sexual behavior of 1,000 respondents is described in the context of HIV transmission as it relates to potential risk, awareness, knowledge, and endorsement of misconceptions on transmission. Based on sexual behavior, 12% should be considered to have taken at least some risk in the year preceding the interview. Of these 124 subjects, 58% completely ruled out the chance that they might have been infected. In general, the level of knowledge is rather high. The knowledge of the subjects who have been at risk ironically is slightly greater than average. This might imply that more intensive prevention strategies should be directed at subgroups who are relatively more at risk.

In the 1989 teen study, sexual mores are found not to be changed by AIDS. To avoid HIV infection, teens prefer postponing sex until one has found the right partner or using condoms during intercourse. In general, however, in fact, youngsters do not postpone their first sexual contact. Only a few of those who advise the postponing of sex have had unsafe sexual contacts. Half of those recommending the use of condoms do not stick to their own advice. Condoms are used especially in the beginning of affairs; but later on, many couples switch to oral contraceptives to avoid pregnancy. Moreover, a questionnaire survey among schoolchildren revealed that intentions of consistent condom use for HIV prevention decreases with the amount of actual intercourse experience. They seem to ignore the fact that their relationship career will most likely be characterized by serial monogamy. This research suggests more attention to efficacy aspects of condom use: buying them, raising the topic with a new partner, and so on.

Based on a theory of sexual networks, 60% of the 18- to 19-year-olds seem to run no risk whatsoever of getting infected with HIV. This network analysis research is a promising new branch of sociosexual study. Other new approaches are studies on negotiations between male and female prostitutes and their customers to find out to what extent they could take health-promoting measures.

#### *Treatment, Prevention Programs, and Government Policies*

Since the onset of the AIDS epidemic, an elaborate system of care and prevention for homosexual men has been developed in the Netherlands. The gay community took the initiative for the first nationwide AIDS education campaign (1983) aimed mainly at homosexual and bisexual men. Also in 1983, an ambulatory venereal disease and AIDS clinic for homosexual men was started in Amsterdam, the Supplementary Services Foundation (StAD), supplementing regular services.

In 1984, as the AIDS epidemic spread among gay men, the StAD started a small-scale primary prevention course for gay men aimed at altering sexual habits. This was modeled after an American example and was successful throughout the country. The foundation still organizes numerous prevention activities aimed at gay men, such as safe-sex workshops, video workshops, shows in gay bars, and activities in gay cruising areas (parks, public toilets). Postgraduate education programs and material on AIDS have been produced by StAD and a number of Amsterdam physicians who have many AIDS patients. Doctors employed by the StAD support some of the doctors in Amsterdam with the heaviest burden of AIDS patients by taking over office hours and home visits.

Another important gay healthcare institute is the Schorer Foundation. In the AIDS field, the foundation has offered

psychosocial care for gay men and their friends and families since 1984. It also initiated, and now coordinates, the "buddy" homocare projects all over the country. This project offers AIDS patients free volunteer support at home. The foundation also produces education programs and training courses for workers in psychosocial healthcare.

Although these gay organizations are important care providers, most gay men with AIDS make use of general health institutions, such as general practitioners, district nurses, hospitals, psychiatrists, and social workers. Therefore, gay (and other) lifestyle elements need to be included in postgraduate education for all caregivers to prevent communication problems. After all, HIV has no precedent as an extremely serious health and culture problem in the gay community.

The total number of women infected is smaller, but the progression is faster in women. Attention to women and AIDS seems to be restricted to their role as infectors (prostitutes, IV users, and pregnant women). In December 1990, on World AIDS Day, which was dedicated to women, it was observed that women should be the target for more and better campaigns for the prevention of AIDS, and that care for women should be improved. For some years, the Rutgers Foundation has provided short-term support and education groups for HIV-infected women.

Care for HIV-positive IV-drug users is often complicated by aggravated addiction behavior, which often makes these patients difficult to deal and make appointments with. Municipal health centers and general practitioners in the big cities, and local clinics for the addicted, monitor a substantial percentage of IV-drug users. This includes health education, education on HIV prevention, assessment of physical condition, and often also the prescription of methadone, a heroin substitute. A needle/syringe exchange program is an important part of prevention. Education for hemophiliacs and support for those infected have been helped by the very active national hemophilia patient association.

Treatment for HIV is evaluated nationally. Recently, a national consensus on early Zidovudine (AZT) treatment was published. In the early years, testing was thought to be of limited value because no health gain was to be expected, and for preventive measures, the individual's serostatus was supposed to be of no importance: Safe sex should be practiced by seronegatives as well as seropositives. Today, early detection is expected to be effective, even if it does not change the patient's sexual habits. Testing is always on a voluntary basis, and if the patient wants to be tested anonymously, this is always possible.

A policy decision currently under discussion is the desirability of contact tracing and notification in heterosexually infected cases of HIV, as is common practice for gonorrhea and syphilis. Because of low heterosexual prevalence, this approach might be highly cost effective.

[Update 2002: UNAIDS Epidemiological Assessment: HIV testing is systematic for blood donors and for some specific insurance applicants. A screening program in pregnant women was first conducted in a few hospitals and then extended to all hospitals in Amsterdam and to 16 of the 21 midwifery practices in the area (estimated coverage of 70% to 75%). From 1992, screening was restricted to high-risk hospitals. Systematic screening of pregnant women has been under discussion. There is no national HIV case-reporting system.

["Unlinked anonymous testing-consent" surveys have been conducted among women seeking abortions in Amsterdam, among injection drug users from the street or treatment centers in several cities, and nationally among readers of the popular gay magazines. Since 1991, repeated surveys

have been done in STD patients in Amsterdam. Among pregnant women, several cases of HIV-2 have been found, especially in women attending abortion clinics (about 40% of all HIV infections). Overall, the HIV prevalence (HIV-1 or HIV-2) was around 0.1% and remained unchanged between 1989 and 1991. Prevalence varied between 0.2% to 0.4% in women attending hospitals considered at high risk, and about 10 times higher in women seeking abortions (except in 1993). The HIV prevalence in injection drug users was as high as 37% in Amsterdam, while much lower in other cities (11% in Rotterdam, 5% in Utrecht, 9% in the southern regions (Maastricht), and 2% in Arnhem (east region). It remained relatively constant over time. A cohort study on 675 initially seronegative injection drug users showed a decrease in incidence from 8.9 per 100 person-years in 1986 to 2 to 3.6 per 100 in 1991-1995. HIV prevalence among gay magazine readers was in 1991 13% in Amsterdam, 7% in the rest of urban areas, and 3% outside urban areas. In homosexuals attending HIV-testing sites in Arnhem (considered as outside major urban areas), prevalence was 8% and remained constant over time. In STD clinics of Amsterdam, prevalence in homosexuals reached 21% in 1991 and 17% in 1992. A cohort study on 770 initially seronegative homosexuals showed a decrease in incidence from 7.2 per 100 person-years in 1985 to 1 per 100 in 1995. HIV prevalence in non-injection-drug-using prostitutes was around 2% in 1991. Comparison of prevalence over time needs to be looked at according to the city or area referred to by the data. Indeed, prevalence varies considerably from one area or city to another. Among pregnant women, HIV prevalence refers to HIV-1 or HIV-2 infections, while it only refers to HIV-1 in other populations.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	17,000 (rate: 0.2%)
Women ages 15-49:	3,300
Children ages 0-15:	160

[An estimated 110 adults and children died of AIDS during 2001.

[No estimate is available for the number of Dutch children who had lost one or both parents to AIDS and were under age 15 at the end of 2001. (*End of update by the Editors*)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

### A. General Views

Dutch clinical sexological practice follows the international framework of diagnosis and the *DSM-III-R*, with some hesitance about the normative aspects of such procedures. Feminism and emancipatory trends have had an enormous impact on Dutch sexology. Health Care for Women projects have been substantially financed by the government with sexuality a major area of concern. In recent years, most of these projects have been integrated, sometimes unwillingly, into the general mental healthcare institutions. Health Care for Women is situated methodologically between self-help and professionalism. Group approaches are highly valued and the group-therapy approach is used more often than for men.

Another concern inherited from Health Care for Women is the power issue in heterosexuality. Since the early 1970s, there has been a passionate plea for better help for sexual-violence victims, stimulated by independent nonprofessional self-help organizations. Dutch sexologists have responded by initiating discussion on professional standards and ethical codes on therapist-client sexual contact. Current interests include: sexual abuse of the mentally and physi-

cally handicapped, and introduction of sexological diagnostic and treatment approaches as an adjunct to personality-oriented diagnosis.

*Desire problems:* There is a modest amount of literature on desire discrepancies. The interactional aspect, the incapacity for intimacy, has gained most attention, along with unrealistic expectations and the balance of power. There is no literature available comparing male higher-libido with female higher-libido.

*Arousal problems:* The medical-sexological approach used with many cases of male erectile dysfunction has resulted in numerous articles but no relevant quantitative data. While clinical criteria are set by the Dutch Society for Impotence Research, concern is growing about overuse of methods prompted by cost and patient acceptance. Psychophysiological methods and pharmacological scanning are the most widely used methods; neurophysiological, hormonal, and invasive methods are restricted to specific indications. It is widely recognized today that psychological inhibition can prevent the reaction on intracavernous vasoactive drugs, and that an erotic atmosphere enhances the reaction. Regarding treatment, a preliminary, cautious conclusion might be: Dutch men seem to be rather reluctant to accept prosthesis as a solution for erectile failure; intracavernous injections are acceptable for a larger group with a high discontinuation rate; vacuum devices are used, but here, too, discontinuation is high.

There is no specific literature on arousal dysfunction in women, except for a study on diabetes.

*Orgasm problems:* In 1977, the Utrecht psychology group enriched sexological theory by contrasting the "interaction phase" with the "solo phase" and emphasizing surrendering to one's own feelings as essential during orgasmic release. Lonnie Barbach's group treatment is widely used for primary female anorgasmia, but there are no outcome studies. For female secondary and/or situational orgasm difficulties, sex therapists tend to prefer couple therapy. After analyzing 1,112 respondent questionnaires, De Bruijn (1982) tried to describe backgrounds of female anorgasmia. Among her conclusions: To some women, orgasm is simply not important in lovemaking; those regularly having orgasms during partner interaction tend to use techniques similar to their self-pleasuring techniques; in interaction, some women simply do not get stimulation long enough to attain orgasm; and orgasm by following the male's movements in intercourse is the only stimulation technique in which orgasm is linked to feelings of love and intimacy. Her findings, published in a bestseller, have been widely acknowledged by both professionals and the general public. Ironically, the 1939 survey of NVSH members reported female respondents attributing differences in satisfaction found in men and women to the short duration of intercourse. *Plus ça change, plus c'est la même chose.*

Inhibited and premature male orgasms have received less attention. Premature ejaculation is common and treated by standard modalities, but no treatment results are published.

*Coitus problems and genital phobias:* Vaginismus, dyspareunia, unconsummated marriage, and phobic avoidance of vaginal penetration are subjects of intense interest, characterized by an increasing tolerance of the symptom's hidden meaning. As early as 1917, Treub concluded that fear is the main cause, and refrained from incision of the perivaginal muscles; in the 1960s, Musaph stressed the usefulness of psychoanalytical interpretations. During the 1979 World Congress of Sexology in Mexico City, Dutch women sexologists vented their annoyance with sexology's neglect of sex-role bias. Cohen-Kettenis criticized medical and be-

havioral sexologists for having only one goal in the treatment for vaginismus: consummation. Bezemer was the first to report on group treatment for women suffering for vaginismus, together with other primary dysfunctions in one group. Moch (1987) broke the taboo on reporting relapse after successful treatment for vaginismus. Drenth (1988) pointed out that for some couples, vaginismus is a fertility problem and can be treated as such by artificial insemination. In 1989, Drenth also identified genital fears, phobias, and obsessions as the male counterpart of vaginismus, pointing out that phobic avoidance of genital play can result in pseudo-phymosis. In 1989, the Dutch Society for Sexology organized a symposium on "Vaginismus and Dyspareunia: The Dutch View."

## B. Availability of Diagnosis and Treatment

Historically, treatment for sexual problems in the Netherlands began in the Neo-Malthusian League. In the League's counseling centers, psychoanalytic treatment of sexual problems was strongly influenced by Van Emde Boas and Musaph, pioneers in the Sexual Reform movement, until the 1970s. In 1969, when the Rutgers Foundation separated from the Dutch Society for Sexual Reform (the League's postwar successor), treatment of sexual problems was very much still part of its activities. As demand increased, the foundation reorganized its staff in multidisciplinary teams.

Dutch gynecologists also played a major role, led by the internationally renowned Theodor van der Velde. His book, *The Perfect Marriage* (1925), was the first such work to find a large general public. Fertility studies led to the formation of the Society for Psychosomatic Obstetrics and Gynecology in 1979. All academic hospitals now have a sexological outpatient department. Unfortunately, these clinics are much too small, except for Amsterdam and Leiden. Since psychiatry departments pay little attention to sexual problems, a Society for Impotence Research (NVIO) was founded in 1986.

The work of Masters and Johnson opened the sexological territory for social scientists. Between 1975 and 1986, Utrecht trained psychology students in the practical applications of group and couple sex therapy. Since then, some psychologists and social workers in private practice provide treatment for couples with sexual problems. The sexological knowledge of helping professionals has certainly expanded in recent years. However, specialized sexological help is sometimes hard to find for many patients. The total number of sexologists is small and concentrated in certain areas. Health insurance will pay for sexological help if a physician refers. Clients almost always have to pay their own sliding-scale bills for treatment by psychologists and social workers in private practice and by Rutgers Foundation sexologists.

## C. Therapist Training and Certification

Sexology is not a regulated profession in Holland, so full-time sexologists are rare, and reliable sexologists and therapists will always have other basic training in medicine, psychology, psychiatry, or social work, perhaps with some postdoctoral education in sexology. Sexological education in Holland lacks cohesion and formal recognition. A very small number of professionals has been educated in the Flemish University of Leuven Sexology Department, where one can earn a doctorate in sexology.

Recently, the Dutch Society for Sexology (NVVS) started to regulate sexological training. Since 1992, an introductory course in sexology is provided by the NVVS and Erasmus University Rotterdam. Specialized curricula for

medical-sexological workers, educators, prevention workers, and researchers will follow. An applications course for psychopathic rapists will be the next step in regulating sexological training. Recently, the Amsterdam Psychotherapy Training Institute included sexology in behavioral psychotherapy training. A register of trained members and establishment of set standards for the education of professional sexologists are short-term goals for NVVS.

## 12. Sex Research and Advanced Professional Education

### A. Sexological Research

The Dutch Institute for Socio-Sexual Research (NISSO) has been the center of surveys on sexual behavior, sometimes in collaboration with other organizations. Considerable research has been done on contraception, abortion, sex and disabilities/illness, homosexuality in the armed forces, and prostitution. Other areas being explored are: the (in)adequacy of sexual help by different groups of helping professionals; an interview study on respondents of earlier surveys who reported exceptionally positive sex lives; child sexual development; forensic sexology; and construction of sexologically relevant psychometric scales.

The multidisciplinary nature of Dutch sexology is illustrated by the diverse backgrounds of the professors holding the six chairs dedicated to sexology in Dutch universities: endocrinology (Gooren, Amsterdam), psychiatry (Hengeveld, Utrecht), medicine (Van Dijk, Amsterdam), psychology (Frenken, Leiden), psychology (Cohen-Kettenis, Utrecht) and physiology/biology (Slob, Rotterdam).

The Psychology Department at Utrecht University has examined the therapeutic effect of different behavioristic treatment methods for sexual dysfunctions in individuals with different sexual orientations. The Utrecht University Gay and Lesbian Studies group has ongoing studies in: historical research on lesbian lives; various subjects on discrimination and homosexuality-related violence; homosexuality and education; and homosexuality in healthcare. The Amsterdam Psychology Department initiated Dutch psychophysiological research, including the effects of sexual imagery on sexual arousal, women's reactions to male- and female-made pornography, the effect of mood induction on subsequent visual stimulation, and the effect of subliminal visual stimuli. In Rotterdam, psychophysiological research includes study of the effects and interaction of visual and vibrotactile penile stimulation; the effect of papaverin-induced tumescence on perceptual threshold of penile stimulation in sexually functional and dysfunctional men, and the effect of menstrual phase on sexual arousability in women. In Groningen, research has included vaginal sensitivity in nonerotic conditions. Almost all academic urology departments are in some way active in research on erectile failure.

Animal sexology, centered in the Utrecht Department of Comparative Physiology, is an important aspect of Dutch sexology. Research at Utrecht and Rotterdam has focused on mating strategies in natural and semi-natural conditions: wolves, plains zebras, chimpanzees, orangutans and long-tailed macaques, savanna baboons, and stump-tailed macaques. The Rotterdam and Amsterdam groups have studied female initiative and hormonal influences on proceptivity and receptivity in rats, reward and aversive components in female sexual experience (including homosexual versus heterosexual preference conditions), hormone-dependency of self-stimulation behavior in the medial preoptic area; brain and behavior gender differentiation, and

the determination of the different influences of various steroids. The sexually dimorphic nucleus of the preoptic area is also being researched.

### B. Postgraduate and Advanced Programs

Treatment of human sexuality in medical, psychological, and social work curricula is subject to considerable variation, with the personal interest of faculty determining the impetus sexuality will have in the programs. Precise requirements and interdisciplinary training are defined in psychiatry and gynecology. There are no university sexology programs in other areas such as education, prevention, or research. In 1992, the Dutch Society for Sexology (NVVS) started a postgraduate training program (see Section 12C, Therapist Training and Certification, above).

### *Demographics and a Brief Historical Perspective*

ROBERT T. FRANCOEUR\*\*

#### A. Demographics

Nigeria is located on the southern coast of the horn of northwest Africa. Its 356,669 square miles (923,768 km<sup>2</sup>) makes it about twice the size of the state of California. Benin lies to Nigeria's west, Niger to the north, Chad and Cameroon to the east, and the Gulf of Guinea to the south. Geographically, the country is divided into four east-to-west regions: In the south is a coastal mangrove swamp 10 to 60 miles (16 to 96 km) wide; in the north is a semi-desert. In between are a tropical rainforest 50 to 100 miles (80 to 160 km) wide and a plateau of savanna and open woodland. Nigeria is currently made up of 30 states plus the Federal Capital Territory of Abuja; 16 of the 30 states are situated in

(CIA 2002)

the northern Muslim-dominated part of the country and the other 14 in the predominantly Christian south. The climate varies from equatorial in the south to tropical in the center and north. The Niger River enters the country in the north-west and flows south through tropical rainforests and swamps to its delta in the Gulf of Guinea.

Like all African nations, Nigeria's boundaries are the capricious result of European and other colonial conquests and power struggles that ignored ancient tribal and ethnic distributions. To understand sexual attitudes, customs, and behavior in Nigeria, one must be aware of the diversity of tribal, ethnic, and religious traditions among its 130 million people.

In July 2002, Nigeria had an estimated population of 130 million. Demographers expect the population to double by the year 2025, to 238.5 million. These estimates explicitly take into account the effects of excess mortality because of AIDS. This can result in lower life expectancy, higher infant mortality and death rates, lower population and growth rates, and changes in the distribution of population by age and sex than would otherwise be expected. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 43.6% with 1.01 male(s) per female (sex ratio); 15-64 years: 53.6% with 1.04 male(s) per female; 65 years and over:

\**Communications:* Dr. Uwem Edimo Esiet, Action Health, Inc., P.O. Box 803, Yaba Post Office, Lagos, Nigeria; ahi@linkserve.com.ng. Beldina Opiyo-Omolu, B.Sc., Department of Health, East Stroudsburg University of Pennsylvania, East Stroudsburg, PA 18301 USA; bopiyo@yahoo.com.

\*\**Editor's Note:* This chapter presented an unusual editorial challenge, in that on most issues, two or more contributors chose to provide complementary insights and information. This is particularly valuable because the contributors approached the topic from different gender, professional, religious, and ethnic (tribal) backgrounds that clearly enrich the views and interpretations presented. In Section 8A, Significant Unconventional Sexual Behaviors, Coercive Sex, Christine Olunfinke Adebajo, Deputy General Secretary of the National Association of Nigerian Nurses and Midwives, and Imo I. Esiet, a member of the Nigerian Bar Association, present not only their own respective views as a Nigerian woman and man, but also the two complementary views of two women's rights advocates, one

a healthcare professional and the other a lawyer. To identify the contributors of these varied views, their name or names are given at the beginning of a section or in brackets [name] at the end of individual paragraphs.

This rich diversity of perspectives on one of Africa's major nations is also apparent in the unusual comparisons of tribal and regional differences on sexuality education, menstruation, sexual intercourse, conception and pregnancy, menopause, homosexuality, and male and female circumcision presented in this chapter. The information in these comparisons is based on the responses of local healthcare professionals who met in Lagos in January 1999 under the aegis of Action Health, Inc, headed by the main author of this chapter, Uwem Edimo Esiet, with Nigerian government leaders, nongovernmental organizations (NGOs), and international United Nations agencies. The comments are from many healthcare professionals and social workers based on their field observations and experiences with clients in their own regions (Francoeur, Esiet, & Esiet 2000).

2.8% with 1 male(s) per female; *Total population sex ratio:* 1.02 male(s) to 1 female

**Life Expectancy at Birth:** *Total Population:* 50.59 years; *male:* 50.58 years; *female:* 50.6 years. By 2010, experts expect that the HIV/AIDS epidemic will reduce life expectancy in Nigeria to age 47 compared with 61 before the arrival of AIDS (Garrett 2002).

**Urban/Rural Distribution:** 40% to 60%. By the year 2001, half of Nigeria's youth were expected to live in cities, searching for better living and job opportunities.

**Ethnic Distribution:** Nigeria has over 250 different and distinct ethnic groups: 20% Hausa; 20% are Yoruba; 17% Ibo; and 9% Fulani; while the remaining one third belong to other ethnic minorities.

**Religious Distribution:** 50% Muslim and living mostly in the north; 40% Christian and living mostly in the south; 10% follow indigenous beliefs.

**Birth Rate:** 39.22 births per 1,000 population

**Death Rate:** 14.1 per 1,000 population

**Infant Mortality Rate:** 72.49 deaths per 1,000 live births

**Net Migration Rate:** 0.27 migrant(s) per 1,000 population

**Total Fertility Rate:** 5.49 children born per woman

**Population Growth Rate:** 2.54%

**HIV/AIDS** (1999 est.): *Adult prevalence:* 5.06%; *Persons living with HIV/AIDS:* 2.7 million; *Deaths:* 250,000. (For additional details from [www.UNAIDS.org](http://www.UNAIDS.org), see end of Section 10B.)

**Literacy Rate** (*defined as those age 15 and over who can read and write*): 57.1% (*male:* 67.3%, *female:* 47.3%) (1995 est.); education is free and compulsory between ages 6 and 15, with about 42% of the youth attending elementary school

**Per Capita Gross Domestic Product** (*purchasing power parity*): \$840 (2001 est.); *Inflation:* 14.9%; *Unemployment:* 28% (1992 est.); *Living below the poverty line:* 45% (2000 est.)

## B. A Brief Historical Perspective

Between 500 and 200 B.C.E., the Nok culture, in what is today's Nigeria, was one of the richest and most advanced ancient civilizations in West Africa.

Around 1000 C.E., the Muslim Kanem civilization expanded into northern Nigeria. By the 14th century, the amalgamated kingdom of Kanem-Bornu took northern Nigeria as its political center, dominating the Sahel and developing trade routes that stretched throughout northern Africa and as far as Europe and the Middle East. During the 15th and 16th centuries, the Hausa Songhai empire rose to power. The Hausa Songhai were overthrown by the Fulani Muslim leader, Uthman Dan Fodio, who created the Sokoto caliphate.

At the same time that the Muslim Kanem civilization expanded into northern Nigeria, around 1000 C.E., southern Nigeria was dominated by the Yoruba, whose Oyo kingdom was centered at Ife. The Oyo kingdom gave rise to the Benin civilization, which flourished from the 15th to the 18th centuries. The Benin culture is famous for its brass, bronze, and ivory sculpture.

The Portuguese established trading stations on the Benin coast in the 15th century. Initially, the contact and trade relations were cordial, and Benin became well known in Europe as a powerful and advanced kingdom. However, with the rise of the slave trade, which began with the cooperation of the Benin kings who brought slaves from the interior, relations became hostile, and Benin declined under European pressure. The Dutch, British, and other Europeans competed

strenuously with Portugal for control of the slave trade. Britain seized the port of Lagos in 1861 during a campaign against the slave trade, and gradually extended its control inland with the exploration of the Niger River until about 1900. By the end of the 19th century, because Britain had suppressed the slave trade, they transported the slaves they captured aboard European ships to Freetown in Sierra Leone.

In 1861, Nigeria became a British colony. Despite native resistance, the colony was expanded in 1906 to include territory east of the Niger River, which was called the Protectorate of Southern Nigeria. The two areas were administratively joined in 1914.

During the 1920s, Britain began to respond to Nigerian demands for local self-rule. In 1946, the colony was divided into three regions, each with an advisory assembly. In 1954, the colony was reorganized as the Nigerian Federation, and the regional assemblies were given more authority. Nigeria became independent on October 1, 1960, and a republic on October 1, 1963. Attempts to partition the country along tribal lines for administrative purposes provoked controversy, and charges of corruption and fraud in elections held in 1964 and 1965 led to violence and rioting. In January 1966, civil war broke out when Ibo army officers overthrew the central government and several of the regional governments. Prime Minister Balewa was killed, along with many other political leaders in the northern and western parts of the country, and the Ibo forces took control of the government.

The new government abolished the country's federal structure and set up a strong central government dominated by the Ibo. Anti-Ibo riots broke out in the north, and many Ibos were massacred. In July 1966, the Ibo leader was assassinated by a group of northern Yoruban army officers, who formed a new military government. The people in the eastern region refused to acknowledge the new government. In 1967, they seceded, proclaiming the eastern region as the Republic of Biafra. This plunged the country into a devastating civil war that left over a million dead, including many Biafrans (Ibos), who died of starvation despite international relief efforts. The war ended in 1970, and within a few years, the Ibos were reintegrated into national life.

A civilian government returned to power in 1979 after 13 years of military rule. Four years later, a military coup ousted the democratically elected government, and has remained in power ever since under various leaders. Revenues from the export of crude oil have made possible a massive economic development program, but agriculture has lagged.

### 1. Basic Sexological Premises

#### A/B. Gender Roles and the Sociolegal Status of Nigerian Females with Implications for the Male

IMO I. ESIET

##### *Issues of Nigerian Constitutional Law*

The social and legal status of women has, over the ages, been a cause for grave concern in every culture and clime. In some areas, this concern has passed the stage of sympathy and has entered an era of aggressive feminism (Oputa 1989, 1). In Nigeria, as in other countries, the time has come to recognize that denial of rights solely because one is a woman is a human rights violation. Practices that expose women to degradation, indignity, and oppression on account of their sex need to be independently identified, condemned, compensated, and, preferably, prevented (Cook 1994, 228).

A wide range of evidence can be cited for a constructive trend in modern legislation on women's rights that are relevant to Africa and to Nigeria. Examples of this trend include

the Convention on the Elimination of All Forms of Discrimination Against Women, the International Covenant on Economic, Social, and Cultural Rights, the 1981 African Charter on Human and Peoples' Rights (which endorsed the United Nations Declaration on Human Rights and the Human Rights Covenant), and the 1979 Constitution of the Federal Republic of Nigeria. Although the clear trend is to establish women's equality with men before the law, the battle against sex-based discrimination and for equality of opportunity, equal pay for work, equal privileges, and equal access to political, social, and religious power is still raging with unabated fury in Nigeria (Oputa 1989, 4).

According to Rebecca J. Cook, the term

discrimination against women shall mean any distinction, exclusion or restriction made on the basis of sex which has the effect or purpose of impairing or nullifying the recognition, enjoyment or exercise by women, irrespective of their marital status, on a basis of equality of men and women, of human rights and fundamental freedom in the political, economic, social, cultural, civil or any other field. (Cook 1994, 235)

The constitutions of most African countries today affirm the right to nondiscrimination on the basis of sex. Other rules of law and legislation may, however, discriminate against women in certain instances. Even where provisions of law are not overtly discriminatory, their application to women may yield discriminatory results, because of women's economic and social positions in society (Ilumoka 1994, 341). In this section, we examine the constitutional provisions for and cultural rights of Nigerian women. (Legal provisions related to marriage, sexual coercion, and prostitution in Nigeria are dealt with in Sections 5C, Interpersonal Heterosexual Behaviors, Adults, and 8A and B, Significant Unconventional Sexual Behaviors, Coercive Sex and Prostitution.)

The Constitution of the Federal Republic of Nigeria (1999) succinctly highlights the fundamental human rights to which all persons are entitled. These are the usual civil and political rights contained in most modern constitutions (Ilumoka 1994, 314). Chapter 4, section 39, of the Nigerian Constitution provides that:

1. A citizen of Nigeria of a particular community, ethnic group, place of origin, sex, religion, or political opinion shall not, by reason only that he is such a person,
  - a. be subjected either expressly by, or in the practical application of, any law in force in Nigeria or any executive or administrative action of the government to disabilities or restrictions to which citizens of Nigeria of other communities, ethnic groups, places of origin, sex, religions, or political opinions are not made subject; or
  - b. be accorded either expressly by, or in the application of, any law in force in Nigeria or any such executive or administrative action, any privilege or advantage that is not accorded to citizens of Nigeria of other communities, ethnic groups, places of origin, sex, religions, or political opinions.
2. No citizen of Nigeria shall be subjected to any disability or deprivation merely by reason of the circumstance of his birth.
3. Nothing in subsection (1) of this section shall invalidate any law by reason only that the law imposes restrictions with respect to the appointment of any person to any office under the state or as a member of the armed forces of the Federation or a member of the Nigeria Police or to an office in the service of a body cor-

porate established directly by any law in force in Nigeria.

Section 39 renders all laws, including customary and religious laws, subsidiary legislation, regulations, and official government practices that permit discrimination against women unconstitutional, null, and void. The only exception, stipulated in subsection 3, relates to appointments in the public service, the armed forces, and the police force. In effect, Nigerian women, therefore, have all the human rights stipulated in the Constitution, including the right to nondiscrimination on the basis of sex. However, they enjoy no positive rights specifically addressed to their particular needs or vulnerabilities, nor is there any statutory recognition of the need for such rights (Ilumoka 1994, 316).

Chapter 2 of the Nigerian Constitution, "Fundamental Objectives and Directive Principles of State Policy," contains principles of economic, social, and cultural rights relating to equal access to resources, provisions of basic needs, an adequate means of livelihood, provision of adequate health facilities for all, and free education. The State has a duty to conform to, observe, and apply these principles and provisions, but cases of alleged nonobservance cannot be tried in court (Ilumoka 1994, 314). The distinction made between the internationally accepted economic, social, and cultural rights guaranteed by the "Fundamental Objectives and Directive Principles of State Policy" and the fundamental human rights in the Nigerian Constitution clearly indicates that there was no intention to enforce them. Accordingly, Jadesola Akande asserts that:

The Nigerian Constitution has entrenched fundamental rights and made them justiciable\* but economic and social rights have been reduced to a mere declaration of pious hopes because it is believed that they can only be achieved progressively according to available resources of the Nation and the policies pursued by the Government. (Akande 1989, 123)

In addition to the various constitutional provisions guaranteeing fundamental human rights, Nigeria subscribes to various international declarations and charters, which aim at eliminating discrimination against women (Oyajobi 1986, 16). Article 18(3) of the African Charter on Human and Peoples' Rights became national legislation with Nigeria's Ratification and Enforcement Act of 1983. This Act provides that "the State shall ensure the elimination of every discrimination against women and also ensure the protection of the rights of the woman and the child as stipulated in international declarations and conventions." To be able to ascertain how much real emancipation women have received in Nigeria, we need to examine the treatment of women in Nigeria by the laws of the land (see also Sections 5C, Interpersonal Heterosexual Behaviors, Adults, and 8A and B, Significant Unconventional Sexual Behaviors, Coercive Sex and Prostitution).

### *Specific Issues of Sex Discrimination*

*Women's Property Rights.* The unmarried woman has the same right to hold property as any Nigerian male under both customary and statutory law. Also, since the passage of the Married Woman's Property Act of 1982 (Otaluka 1989) as amended in 1993, a married woman has the right to contract as a *femme sole* [single woman] to the extent of her separate property. However, it has been a longstanding custom that women in some areas of Iboland cannot acquire immovable property like land. Iboland women are devoid of such con-

\*Any breach of such entrenched fundamental rights can be referred to the court for necessary redress.

tractual capacity (Otaluka 1989). This issue does not arise in Yoruba custom, where both married and unmarried women have the full capacity to contract, acquire, and dispose of all forms of property, including land.

*Women's Rights in Sureties.* Although there are no legal provisions that distinguish along sexual lines between the rights and/or capacity of any citizen to stand as surety for another in an application for bail, Nigerian police regularly deny women this right. This obviously contradicts every legal provision regulating bail practices; it also violates section 39(1)(b) of the Nigerian Constitution, which prohibits any executive or administrative practice that discriminates along sexual lines. The arguments for exempting women from the category of "fit and proper persons" are usually not based on any objective criteria.

*Women and Income Tax Law.* The Nigerian law on personal income tax discriminates largely against women. The tax system does not treat individuals within the marriage structure as persons in their own right. For instance, it is often generally assumed that the children of the marriage belong to the husband, and so it is to him that tax relief is granted. Married women who wish to claim tax relief for expenses related to rearing children are required to show documentary evidence of those expenses and evidence that the father of the children is not responsible for their upkeep. Men are not required to produce such documents. Although the Joint Tax Board justifies this practice by saying that these measures are designed to discourage duplication of claims, the present assumption in favor of the man is discriminatory and groundless.

*Women's Inheritance Rights.* Under the Yoruba customary law of intestacy, the succession rights of a male who dies without a will devolve not only on his children, but also on his brothers and sisters. The Ibo and Bini Customary Laws are governed by the primogeniture principle, so that on the death of a male without a will (intestate), the eldest son succeeds to his estate. The widow, however, has no customary right to inherit her intestate spouse's property. Although death does not necessarily terminate a common (customary) law marriage, the rights of a wife to retain membership in her husband's family, and possibly maintenance, remain only insofar as she remains in her matrimonial home. This holds whether or not she chooses to marry her husband's kin, except where the latter is not raised as an option, but is made mandatory.

Islamic law discriminates in the amount of entitlement granted the deceased intestate's children along sexual lines. The male children acquire in equal shares, whereas the daughters receive only a half share each. In a case where the deceased is survived by a single daughter, she would be entitled to only half the net estate, whereas an only son would take the whole estate. The widow is allowed a quarter of her husband's estate, whereas a widower takes half the net estate of the deceased wife (*Lewis v. Bankole* 1909; *Adedoyin v. Simeon* 1928).

*Women and Passports.* When a married woman applies for a passport, she is as a matter of practice required to submit a letter of consent from her husband. Similarly, a woman cannot apply to include the name(s) of her child(ren) on her passport without a letter of consent from her husband. There is, however, no such requirement for male applicants.

### Conclusion

It cannot be argued more that there is an urgent need for a reappraisal of the status of women in Nigeria. The need to make all the constitutional rights of women a practical real-

ity that would continually guarantee that they have their fair share of power, education, financial resources, positions, and so forth in our society cannot be overemphasized.

### C. General Concepts of Sexuality and Love

UWEM EDIMO ESIET

Whereas sexuality is not openly discussed in Nigerian life, it is an underlying activity that is commonly displayed at publicly celebrated festivals. In most tribal cultures, dance dramas convey sexual values and attitudes as well as other more-general messages. Similarly, folk tales and drama are used to depict specific tribal sexual values and expectations. This is particularly true of the tradition of early marriage, whether consented or forced, which is the most accepted means of containing adolescent sexuality. Issues of love of children, especially of males who will perpetuate the family name and heritage, also run deep within the family and society in most cultural settings.

In times past, the virginity of the female at her marriage called for a family celebration with appropriate gifts and visits from the in-laws. In some cultures, especially among the Yorubas, where "hawking" (street vending) and "night marketing" is common, young girls are learning to receive "passes" from men and acquire skills in dealing with these. Since the introduction of Western values and education in Nigeria, women have continued to acquire skills in dealing with males in a culture in transition. This has led to an increased tendency to delay marriage and an increased incidence of premarital sexual relationships. In some tribal cultures, in fact, it is more common today to demand pregnancy rather than virginity as a prerequisite for marriage. This is especially true among the educated young.

Also, most of the popular music and advertisements glamorize sexuality, even though there is still a strong disapproval of open discussion of sexuality.

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

BILKISU YUSUF and RAKIYA BOOTH

### A. An Overview and a Christian Perspective in Southern Nigeria

RAKIYA BOOTH

Religion and culture in Africa are closely interrelated. While religion has at times been used to oppress and exploit people, it has also been appropriated to enhance political liberation.

Maduro (1989) defines religion

as a structure of discourse and practices common to a social group referring to certain forces (personified or not, multiple or singular) that believers consider as anterior and superior to their natural and social surroundings in whose regard they express their sense of a certain dependency (through creation, control, protection, threat, or the like) and before which they consider themselves obligated to a particular pattern of conduct in society.

Every religion is situated in a specific human context in a concrete, determined geographical space, historical moment, and social milieu. Members of a religion share certain collective dimensions—social, economic, political, cultural, educational, military, and so on. Religion is, therefore, closely linked and interrelated with all the dimensions of the life of a community. Because religion is part of a society, it follows that anything that affects people's lives will affect their religion. Hence, religion affects sexuality.

Nigerian society is dominated by two religions: Islam and Christianity. They are the main source of our Nigerian religious value systems, which affect sexual attitudes and be-

havior. Christianity, for instance, expects men and women to hold in high esteem the religious value of sexual purity. Girls are expected to be virgins at the time of marriage. Islam allows female children to be given in marriage before the age of puberty. These practices ensure that the female child is a virgin at marriage. Similarly, Christianity and Islam emphasize that adultery is unacceptable. However, our culture expects men to do what women are not to do. Our culture allows and even encourages a man to contract polygynous marriages. While extramarital sex is publicly frowned on, a man who engages in extramarital sex is privately hailed for his behavior. The same culture deals severely and ruthlessly with married women caught in adultery. In both the Islamic and Christian religions, a man can ask for and be granted a divorce if his wife is confirmed to have committed adultery. This is not, however, the case if a wife discovers her husband's illicit affairs with other women.

Generally, Nigerian men believe that because woman was created out of a man, a woman must be subservient to man in all spheres of life at all times. Women are described as having a small brain in comparison to men's, being deficient in logic, analytical abilities, and critical thinking. In fact, this is the guiding principle that governs the behavior of Christian women who are the most submissive. While women constitute a larger portion of the church membership, women are not allowed to preach or take leadership positions in Nigerian Christian churches. As a result, women have been consistently kept passive and denied equal status with men in decision-making, both in the family and at the national level. Men believe that the only things women control are fertility and the sex of the child. Thus, quarrels and even divorce arise where a marriage does not produce a child or where only female children are born.

Similarly, it is a taboo in the Islamic religion for a woman to lead prayers or pray jointly with men. Besides, local interpretations of both the Islamic and Christian faiths forbid men to accept sexual advances from their women. That is to say that sexual advances should be made by men, and not women.

## B. The Muslim Hausa of Northern Nigeria

BILKISU YUSUF

The Hausa people constitute one of the most numerous and influential ethnic groups in West Africa. The majority of Hausa live in northern Nigeria, and in Nigeria's three neighbors, the Niger and Benin Republics and the Cameroon. There is also a large population of Hausa living as immigrants in the Sudan Republic. Their language, Hausa, is widely spoken by about 50 million people in West Africa (Coles & Mack 1999, 4).

Hausan history dates back to the 8th century when city-states and empires flourished in Western Africa (Crowther 1972). Tradition traces the establishment of the seven Hausa city-states to Abu Yazidu (Bayajidda), a prince from Arabia, who fled his homeland after a succession struggle. On reaching Daura, he killed the snake that had troubled the inhabitants of the city, and Daurama, the Queen of Daura, impressed by Abu Yazidu's bravery, married him. They had seven sons who established the seven Hausa states (*Hausa bakwai*), Daura, Kano, Biram, Zazzau, Gobir, Katsina, and Rano.

The single most important factor that influenced the development of Hausa culture was their interaction with the peoples of North Africa through the Trans-Sahara trade. After Islam was introduced to the land of the Hausa by Arab traders, it gradually became the religion of the ruling class, and later the religion of the majority of Hausans. However, pockets of non-Muslim Hausa (*maguzawa*) still survive today and have retained their traditional religion. Although

other ethnic groups, such as the Fulani and Kanuri, have mixed with the Hausa for centuries, the Hausa culture has retained some of its original features.

Hausa culture today is predominantly Islamic, making it difficult to distinguish tribal Hausa cultural norms from Islamic injunctions. Although Hausa culture has remnants of non-Islamic and distinctly indigenous practices that are part of their rites of passage, a marriage of convenience has evolved between Islamic injunctions and aspects of Hausa cultural norms that do not conflict with the religion.

Islam is a way of life for its adherents, with rules and regulations guiding all aspects of life. Its strong moral code emphasizes chastity, and prohibits loitering, soliciting, and unnecessary intermingling of the sexes. Islam permits women to go out of their houses only to pursue lawful needs, such as the acquisition of knowledge or to work and contribute to societal development. Marriage before age 18 was the norm among Muslim Hausa girls before the colonial era and the introduction of secular education. Most parents in those days preferred to marry off their daughters at age 12.

The Qur'an, the basic source of Islamic law, allows the marriage of girls who have not started menstruation (*Qur'an Suratul Talaq*, verse 4). It is common among the Hausa to marry off preadolescent girls and delay the consummation of the marriage. Although the marriage of minors is lawful, the various schools of Islamic jurisprudence have guidelines about how such a marriage must be performed for it to be valid. Hammudahah Abd al'Ati (1982, 70-84) clearly outlines the arguments for and against it. According to jurists and the schools of law, a minor cannot give herself away in marriage. Her marriage must be arranged by her father and her consent sought. Others argue that the father may give his daughter away in marriage with or without her consent if she is underage, i.e., 9 years or younger, a virgin, and is given in marriage to a suitable and socially equal husband. The father in such a case is also her guardian (*wakil*), and Islamic law stipulates that the *wakil* must be legally and religiously qualified. As a legal guardian, he has authority to do only what is beneficial to his daughter or ward.

Arranged marriages were and are still common among the Hausa. In the past, some were actually arranged through pledges made by the parents while their children were toddlers. It is also quite common for the educated elite and royalty to arrange their children's marriages. Cousin marriages are also widely practiced among both Flausa and Fulani commoners and royalty, particularly so among the latter.

Marriage age in Hausa society is now gradually changing, shifting away from child marriages contracted at 7, 8, or 9 years of age, which were quite common in royal households in the past, and away from teenage marriages contracted at 12 years of age among the other classes. With the increase in the number of females attending school, the average marriage age is now 16 or 17 for secondary school graduates and 13 for those who drop out of school. However, the marriage age may be lower in rural areas, where fewer females attend school. It is a common practice for the formal Islamic marriage (*dauphi aure*) to be performed early, after which the girl continues her schooling for several years and completes it before the Hausa cultural ceremony (*hiki*) takes place and the marriage is consummated.

## C. Character of Ethnic Values

Ethnicity develops and is expressed in multiethnic situations where a sense of "us" and "them" leads an individual or group to behave in exclusionary ways. This presupposes the existence of more than one ethnic group, an ethnic group being a group of people set apart from others by language, culture, political organization, territory, and myth of com-

mon descent. These shared group values constitute the basis for conscious identity and behavior by members when they relate with people from another group. However, it is important to point out that ethnic groups, such as those in Nigeria, are not necessarily homogeneous entities. Quite often, an ethnic group that contains several subgroups, languages, dialects, and cultural variations is classified as a homogeneous entity by bigots who emphasize selected specific traits as representing the whole group.

As with the Islamic, Christian, and indigenous religious traditions, the culture and norms of every ethnic group in Nigeria affect not only the sexual attitudes and behavior of its members, but all spheres of life. All ethnic groups in Nigeria believe strongly in sexual purity. Girls who are virgins at marriage are praised and showered with gifts. Married women are expected to avoid adultery. Although the same is expected of men, cultural norms give room for men to do otherwise. In a study of concubinage conducted among the Ngwa Igbo in southern Nigeria, such norms are viewed as cultural discrimination, especially in a polygynous society that deprives women of sufficient sexual satisfaction and emotional security.

However, the idea of eliminating this discrimination would definitely be considered offensive by decision-makers, both at the family and legislative levels. Such a move, if ever contemplated by a woman, would end the marriage in divorce. Cultural values clearly demand that, because they are family-oriented, women must be honest with their husbands and endeavor to prevent family disruption.

Studies have shown that women are more worried than men are by post-divorce problems. Furthermore, the wife's inability to initiate a divorce, the stigma of divorce, and a divorced woman's alienation from her natal descent group, along with early child betrothal and the payment of bride wealth, only increase women's subordination and resignation into acceptance of men's decision-making role in the family.

The subordination of women is most manifest in the family. It is in the family that one finds attitudes and behavior that give priority to education of males over females. Our culture believes that men have stronger sexual drives, need more sex than women do, and have greater control over sexuality. It is tradition and culture that socializes women to be sexually submissive to men. Moreover, it is the family and cultural attitudes that define the attributes of a good wife and, through sanctions, force females to fit into these qualities. To a girl, marriage is the ultimate goal. Hence, following cultural and family dictates, she has to appear less intelligent than men and behave with a certain amount of diffidence in dealing with men if she is to achieve that aspiration.

Economically, Nigerian women are expected to be dependent on men, in line with their traditionally assigned roles of wives, mothers, and homemakers. Whereas men are trained for remunerative employment outside the home, the process of socialization prevents, limits, or demobilizes women in their march to economic emancipation. Men are regarded as the breadwinners of the family. Because "he that pays the piper dictates the tune," men make all major decisions in the family. For instance, development efforts that provide men access to factors of production simultaneously deny women access to production inputs, such as credit, ownership of land, and skill training. As the family breadwinner, the husband's domain includes all major decisions, such as number of children the spouse should have, the spacing of births, the couple's sleeping arrangement, use of contraception, and even the type of contraceptive used. Although this is a general cultural value, it does vary with the couple's level of education.

Generally speaking, Nigerian women are sexually submissive to men because of the culturally determined masculine roles performed by men. Men pay the house rent and children's school fees, provide kerosene or firewood for cooking, and fulfill other chores that steer men towards leadership responsibilities and give them the legitimacy of decision-making in the family and in the larger society. Still, the internalization and perpetuation of sex roles are achieved through socialization processes. Although Nigerian role stratification is unequivocally male-oriented, as principal actors in child socialization, women unfortunately are used as instruments for its propagation, enforcement, and perpetuation. There is a thriving attitude in Nigeria that a male child should, among other things, exhibit decision-making skills, whereas a female child is expected to be passive, submissive, and portray the "nice girl" image, an image which attempts to control women socially through value construction.

The Ibo culture gives women more freedom of assertion than either the Yoruba or Hausa cultures. Ibo and other cultural groups agree that household activities, such as the pounding of yam (*fufus*), sweeping, and similar domestic chores, should be jointly done by male and female children. The Yoruba, on the other hand, see such tasks as female responsibilities, thus creating gender gaps in the division of labor in the family. The Ibo allow some women to seek divorce, whereas the Yoruba encourage them to engage in extramarital sex. In both ways, ethnic values affect the sexual attitudes and behavior of people.

Both religious and ethnic values are thus intimately interwoven and most profoundly affect the sexual attitudes and behavior of Nigerians in all spheres of our social existence.

### 3. Knowledge and Education about Sexuality

#### A. Sexuality Education

UWEM EDIMO ESIET and FOYIN OYEBOLA

Because of the culture of silence on sexuality, there has been little or no structured way of teaching Nigerians about sexuality. In the late 1950s and early 1960s, family planning education was introduced in some areas of Nigeria. However, this met with considerable opposition from cultural traditions and religious institutions. At the time, the only way a wife could have access to family planning services was with the prior consent of her spouse. This situation has changed in recent years and married women can now obtain family planning information and services without the husband's consent.

The government has been working to get POP/FLE (population and family life education) into the schools' curricula, and this effort is ongoing. However, adolescents continue to be denied access to sexual information and services on a national scale. There have been some efforts by nongovernmental organizations (NGOs) to assure that marginalized groups have access to sexuality education. This effort is increasing, as data from studies continue to show that five out of ten girls and seven out of ten boys have had sexual intercourse at least once by the time they leave secondary school.

In 1996, this effort culminated in the production of *Guidelines for Comprehensive Sexuality Education in Nigeria*. This effort by about 20 government and nongovernmental organizations was publicly released by the then-Minister of State for Education chief, Mrs. Iyabo Anisulowo. Despite this laudable effort, the government still did not take the bold step of ensuring access to this education of our youth out of deference to the interests of religious leaders. However, in

March 1999, at the Forty-Sixth Session of the National Council on Education, a resolution to integrate comprehensive sexuality education into Nigeria's school curricula, sponsored by the Federal Ministry of Education, was unanimously ratified. As a result, the federal Ministry of Education made a historic commitment to implementing sexuality education throughout Nigerian schools. (National Guidelines Task Force 1996; SIECUS 2000). [U. E. Esiet]

The majority of Nigerians have the misconception that sexuality is equivalent to coitus. This has been a major obstacle to the integration of sexuality education into school curricula and other youth-related activities. Because of this equation of sexuality education with intercourse, the focus tends to be on the biological components. [F. Oyebola]

### *Sexual Education and Discussion: A Regional/Ethnic Comparison*

The following summaries of the attitudes and practices regarding sexuality education and the discussion of sex of several ethnic groups in eight geographical regions of Nigeria were compiled by the authors during a meeting with healthcare professionals in January 1999 (Francoeur, Esiet, & Esiet 2000) (see Editor's Note at the beginning of this chapter).

1. Regions: Ipoti-Ekiti, Oyo, and Yorubaland. Ethnic Group: Yoruba

Sexual knowledge is acquired through storytelling myths, from peers, schools, apprenticeship centers, television, films, romantic novels, magazines, and overheard adult conversations. There is no positive attitude regarding sexuality education. Educated adults see nothing bad in sexual education, but the uneducated say it is an abomination and such things should not be heard of. Sex is freely discussed in the beer parlor, at home when husband and wife are quarreling, or during marriage preparation in the church or mosque. Otherwise, sexuality issues are never discussed and people are repulsed by sexual talk. When compelled to discuss sexuality issues, the uneducated are very shy and hardly give any correct information of participation. More-educated persons discuss sex mostly among peers and with persons of the same gender.

2. Regions: Kano, Katsina, and Kaduna. Ethnic Group: Muslim Hausa

Most children in these states learn about sexuality through their peer groups, media, and films. Parents do not discuss sex with their children. Parents are very negative about sexuality education in the schools because of the misconception that it will negatively affect the children. People will discuss sexual topics freely among friends and peers.

3. Region: Borno

Sexual information is acquired from peers as well as parents. The general attitude towards sexuality education in schools is negative. Talking openly about sexuality is clearly taboo.

4. Region: Benue. Ethnic Groups: Tiv, Idoma, and Isala

Children learn about sex from their peers, and through storytelling and the cultural practices of gender roles. Sexual intercourse is learned by experimentation. Mothers tell their daughters about the consequences of sexual intercourse when they start menstruating. They usually provide no knowledge on hygiene. People are generally not comfortable with sexuality education. Spouses rarely communicate about sexuality. They are, however, beginning to discuss family planning. Talking about sex is considered "wayward."

5. Regions: Akwa-Ibom and the Cross River: Ethnic Groups: Efik and Ibibio

Children acquire sexual knowledge by listening to stories told by their elders, by eavesdropping on adult talk, and from older sisters, cousins, house helpers, school peers, and electronic and print media. Young people also learn about sex during moonlight activities with their peers. In these activities, known as *Edibe Ekok* (hide and seek), children make a ring with a broomstick with a sand heap in the middle, around which they sit, mostly naked. They try to locate a ring in the sand heap. When found, they are joyous and exchange pleasant times, which sometimes results in sexual activity. Knowledge about sexuality is considered inappropriate for children but acceptable for the married. Sexuality education is seen as a way of corrupting the children. People do not discuss sexual topics, but this can be done in private and secretly.

6. Region: Delta State. Ethnic Groups: Uhobod, Ibos, Ijaws, Isaw, and Itsekirus

Children learn about sexuality from their peers and from the media in urban areas. Most people view sexuality education negatively because they believe it initiates the young ones to sexual relationships. Discussion of sexual topics is taboo. Males do, however, discuss sexuality—especially when they want to tell their peers how many girlfriends they have had intercourse with.

7. Region: Edo

Children in Edo learn about sex through their parents, but mostly through peers. The general attitude toward sexuality education is negative. Discussion of sexual topics is avoided because it is believed that discussing the subject will result in promiscuity and exposure of adolescents to bad influences. People do not easily discuss sexuality topics because it is considered a taboo.

8. Regions: Imo, Enugu, and Anambra States. Ethnic Group: Ibo

Knowledge about sexuality is picked up accidentally—mostly from peers. There is no formal sexuality education. Parents teach their children through their own attitudes and behavior. Knowledge comes mainly from peers. The Ibo believe talk about sexual matters is vulgar, sexual education should not exist, and sexuality should never be discussed.

## **B. Sexuality Education among the Hausa**

MAIRO V. BELLO, RAKIYA BOOTH,  
and BILKISU YUSUF

Sexuality education among the Hausa is imparted by parents and by the Qur'anic schools (*Islamiyyah*). Parents teach the rudiments emphasizing the gender roles expected of men and women, while the details of sexuality are left to the Qur'anic schoolteachers who instruct the children in *fiqh*, the law of Islamic jurisprudence. The *fiqh* curriculum for children and adults of both sexes includes lessons on the onset of puberty, menstruation (a sign of maturity for girls, when fasting becomes obligatory), and ritual purifications after menstruation, sexual intercourse, and childbirth. For the boys, instruction includes the discussion of wet dreams and voice changes as marks of the onset of puberty, when fasting becomes obligatory. Boys are also instructed in the requirement of a purification bath after sexual intercourse and wet dreams. All Muslim Hausa children routinely attend *fiqh* lessons, which prepare them for the prayers and fasting, the two fundamental requirements for Muslim men and women. *Fiqh* lessons also focus on what constitutes sexual intercourse, the virtue of abstinence for unmarried

people, and what the law stipulates about fornication and adultery. [B. Yusuf]

Although adolescents in the predominantly Muslim Hausa are expected to learn about sexuality in *fiqh*, many Hausa boys, and most of the Hausa girls, are withdrawn from school, both Qur'anic and public, before they get to the stage of learning about *fiqh*. Those girls and boys who stay in school to the stage when *fiqh* deals with sexuality, often find that the instruction does not include much, if anything, beyond the rituals, purification baths, marriage, and divorce, because of shyness that is part of the societal culture and the culture of silence that surrounds sexuality issues in the Hausa society. [M. V. Bello]

*Fiqh* teaches that married couples are entitled to sexual satisfaction from their partners, and the absence of sexual satisfaction is a valid reason for divorce. Likewise, *fiqh* enjoins Muslims to maintain their chastity and avoid high-risk sexual behaviors. Affliction with a communicable disease, such as leprosy, and perhaps by extension one could add HIV/AIDS, is also a valid reason for divorce. [B. Yusuf]

Among Hausa parents, sexuality education is constrained by the cultural practice of *kunya* or modesty, whereby parents are too embarrassed or shy to impart sexuality education to their children. The observance of *kunya* varies from parents who do not show affection in the presence of their children and do not talk to their first child, to those who only refrain from calling the child's name and/or feel too shy to discuss sexual and reproductive topics with their children. In the extreme cases, *kunya* ensures that the child grows up without knowing who his mother is, with the father, stepmother, or grandparents filling the communication and affection vacuum created by the *kunya*-observing mother. The practice of *kunya* is being gradually eroded by the interaction of the Hausa with other ethnic groups, and young Hausa mothers these days refrain from observing *kunya*, calling their first children by their names and openly showing them affection. [B. Yusuf]

However, an aspect of sexuality education solely entrusted to parents in Hausa society is the expression of sexuality during courtship and marriage. Both Islamic and Hausa culture do not permit dating, but the suitor is allowed to visit the girl in her parents' house, discuss with her gifts (*zance*), and give her token money or presents (*toshi*). During such visits, the young couple is not allowed to stay alone in a secluded place. Although Hausa sexuality education and socialization is replete with measures designed to prevent premarital sexual intercourse, such attempts are being steadily undermined by the prevalent Hausa practice of sending children and young girls to hawk (*talla*). These hawkers (street vendors) run the risk of early exposure to sexual overtures, sexual abuse, and harassment from unscrupulous men posing as buyers of their wares. [B. Yusuf]

### C. Sexuality Education among Christian Nigerians

FOYIN OYEBOLA

In Nigeria, the Catholic Church provides some limited sexuality education, emphasizing abstinence education for unmarried persons and the Natural Family Planning method for married couples, and condemning other forms of contraception. Other Christian groups, especially the indigenous Christian churches, emphasize menstrual hygiene and the separation of women during menstruation as described in the Old Testament. These churches tend to be more liberal on premarital sex and polygyny. The modern-day Pentecostal churches tend to be more receptive to contraceptive use within marriage, while emphasizing premarital abstinence. Overall, the Christian churches have yet to pay sexuality education its deserved attention. [U. E. Esiet]

It would be incorrect to say that sexuality education is not being provided in Nigeria. However, what is taught is not as comprehensive as it should be. Whatever is provided can be called moral education. Most adults are not comfortable with the concept of "sexuality education," because of the ambiguity of the term *sex*, and because of the low level of knowledge about sexuality among adults. [F. Oyebola]

However, in recent years, challenges to societal values and serious public health issues and problems have made sexuality education increasingly acceptable everywhere, including the Christian communities and informal sources. The Christian churches have been recognized as an agent of socialization for young persons in Nigeria. Consequently, most of the churches, especially in the urban centers, have been sensitized by the relevant NGOs through seminars and workshops, while some of the key religious leaders have been trained as counselors and educators. [F. Oyebola]

The integration of increasingly comprehensive sexuality education into church activities is a slow process for now, but it is expected to pick up with time. Most of the churches plan various activities and invite experts to make presentations on such topics as "Adolescent Sexuality: Making Responsible Decisions," "Bridging the Parent-Child Communication Gap on Sexuality Issues," "Teenage Pregnancy and Abortion: Consequences and Prevention," "Sexually Transmissible Infections," and "Developing Positive Self-Esteem with Others." [F. Oyebola]

[Update 2003: In August 2002, the Catholic Church in Nigeria developed a curriculum on sexuality education for use in homes and parishes. The adoption of the curriculum was the outcome of a workshop on sexuality education organized in Enugu by clerics in collaboration with Community Life Project, a nongovernmental organization. The curriculum gives guidelines on how to teach sex education to married couples, adults, youths, and couples preparing for marriage. The curriculum makes it obligatory for the priests to include sex education in their preachings. (End of update by B. Opiyo-Omolo)]

### D. Informal Sources of Sexual Knowledge

UWEM EDIMO ESIET and FOYIN OYEBOLA

There is a definite increase in the informal sources of sexual knowledge in Nigeria. Young people have access to a lot of information, including both foreign and local magazines, television shows (more foreign than native), books (mainly foreign), and peers. There is also what we refer to as "environmentally available sources of sexual knowledge" that accompany and are associated with the prevalence of poverty and unemployment, the increase in commercial sex work, and the international trafficking in commercial sex workers. Sexual knowledge is also picked up in the course of everyday living at neighborhood gatherings, affiliations, and at home as a consequence of the lack of privacy in many housing patterns. In general, the underground information network on sexuality has acquired greater prominence in the lives of Nigerians.

## 4. Autoerotic Behaviors and Patterns

UWEM EDIMO ESIET and FOYIN OYEBOLA

### A. Children and Adolescents

It is not unusual for the growing child to engage in thumb sucking and some self-body massage. Both behaviors are commonly frowned on by adults, and parents try to discourage both "bad" behaviors. Pacifiers are encouraged as a substitute for thumbsucking, but parents tend to punish masturbation. [U. E. Esiet]

Masturbation is a common sexual behavior in Nigeria among adolescents and adults alike. However, it is more

common in adolescents, who rely on masturbation to satisfy their sexual urges. This they do by fondling the clitoris, breast, nipple, or penis. Masturbation is common in girls-only schools where same-sex relations occur. [F. Oyebola]

## B. Adults

While adults may engage in masturbation, they do not openly admit to this practice, because the whole topic of sex is a taboo. However, some counselors and healthcare providers are beginning to encourage an open discussion of masturbation and recommending it as an alternative to risky sexual behavior. [U. E. Esiet]

## 5. Interpersonal Heterosexual Behaviors

### A/B. Children and Adolescents

MAIRO V. BELLO, NIKE ESIET, FOYIN OYEBOLA,  
UWEM EDIMO ESIET, BILKISU YUSUF,  
and RAKIYA BOOTH

#### *Puberty, Menstruation, First Sexual Intercourse, and Marriage*

The northern area of Nigeria has the lowest age for first marriage. Local studies conducted among Hausa communities in Kano State, in Zaria (Kaduna State), and in Dutse (Jigawa State) have confirmed the prevalence of early marriage. Clara Ejembi, a staff member at Ahmadu Bello University, Zaria, found that 83.4% of girls in the Zaria Local Government Area were married before 14 years of age and 98.5% before age 20. A study by Adolescent Health and Information Project (AHIP) in Kano and Jigawa States confirmed that 75.5% of girls who do not have formal education got married before the age of 13 years of age, while 99.5% were married before 16. Most Hausa adolescent girls are married before or as soon as they enter puberty, which occurs between ages 12 and 15 (Goddard 1995). [M. V. Bello]

In an AHIP study of adolescent socialization, most respondents confirmed that they had their first menstrual period in their husband's house, suggesting that they were taught nothing about puberty before their first experience with menstruation. Research by the International Reproductive Rights Research Action Group (IRRRAG) found that the few young women who learned anything about menstruation before their first experience got their information from friends, books, or schoolteachers. [M. V. Bello]

Recently, however, the increased rate of Western-style education, a downward turn in the country's economy that has made marriage very expensive, and the terrible rate of inflation are affecting the age of marriage for young people. Many girls now get to finish their secondary school, and learn a little about puberty, their bodies, and life in general from school, friends, and the media before they marry. The boys now think that they cannot take wives, because they do not have jobs, and families no longer live in communal settings, where feeding is centrally handled. Young Hausans are fast adopting the nuclear-type family setting because they think it is more convenient for them. [M. V. Bello]

According to the 1990 Nigerian Demographic and Health Survey, the median age at first intercourse for girls is just over 16 years. By age 18, 63% of women have experienced intercourse; by age 20, approximately 80% have experienced intercourse. Thirty-four percent of 15- to 19-year-old females are married and 27% of adolescent married women are in a polygynous union, with rural and northern women more likely to be in such a union. A 1992 study by Makinwa-Adelzuso also showed that among urban youth aged 12 to 24, over 20% of the females are married compared to 3% of the males. [B. Yusuf]

A common though not recent pattern of marriage among the Hausa is for girls to have many suitors (*samari*) from whom she selects her mate. Yet, it is not unusual to find forced marriages (*auru dola*) made out of monetary or other considerations in contemporary Hausa society. Victims of forced marriages may accept the union. However, there are instances when such brides leave the husband and return to their parents' home (*yaji*) or go to court to get a divorce. Forced marriages are now on the decline and are usually limited to girls who have not attained the age of puberty or do not attend school. Some girls are also withdrawn from school by their parents and given out in marriage. The prevailing economic hardship has made education too expensive for poor parents, who view marriage as a means of reducing the burden of maintaining their daughters in school (Goddard 1995; see also Section 2A, Religious and Ethnic Factors Affecting Sexuality, An Overview and a Christian Perspective in Southern Nigeria, for information about childhood and arranged marriages among the Hausa). [B. Yusuf]

#### *Menstruation: A Regional/Ethnic Comparison*

The following summaries of the attitudes and practices regarding menstruation of several ethnic groups in eight geographical regions of Nigeria were compiled by the authors during a meeting with healthcare professionals in January 1999 (Francoeur, Esiet, & Esiet 2000) (see Editor's Note at the beginning of this chapter).

1. Regions: Ipoti-Ekiti, Oyo, and Yorubaland. Ethnic Group: Yoruba

In Yorubaland, menarche is seen as coming of age, and a young girl is then advised not to be close to a man because she may get pregnant. There are quite a number of taboos associated with menstruation. Powerful people, such as warriors and traditional leaders, are not supposed to copulate with their wives during this period because it neutralizes the efficacy of any charms they are using. Albinos are believed to be the result of conception occurring during the menstrual period. In Ipoti-Ekiti, a menstruating woman is considered dirty and people will not associate with her during this time.

2. Regions: Kano, Katsina, and Kaduna. Ethnic Group: Muslim Hausa

The social and cultural beliefs of the Muslim Hausa treat menstruation with silence. It is simply not discussed. If a single girl starts menstruating in her father's house, she is quickly given off in marriage to any available man. This is referred to as *Sadaka*. Menstruation prior to marriage is considered a bad omen. When a young girl begins menstruating in her father's house, her mother-in-law is faced with the task of teaching her all she needs to know about menstruation. During menstruation, women do not sleep with their husbands, do not say their five daily prayers, and are also not allowed to fast.

3. Region: Borno

There are no special taboos or rites relating to menstruation in the Borno State.

4. Regions: Tiv-Benue. Ethnic Groups: Tiv, Idoma, and Isala

There are no rites or taboos related to menstruation in the Tiv-Benue State, except that a family must give a daughter in marriage when she begins menstruating. This early-marriage tradition, however, is weakening.

5. Regions: Akwa-Ibom and the Cross River. Ethnic Groups: Efik and Ibibio

Some people in this region see menstruation as an unclean process. They consider a woman dirty during

her period. Hence, she should not cook or serve food at this time. Some churches and cults refuse to let women attend services during their period. Young menstruating women must hygienically and properly dispose of used sanitary napkins; otherwise, the enemy may use them to charm the individual. Sexual intercourse during menstruation is taboo. Menstrual cramps are relieved by using hot water to massage the waist and lower abdomen, by drinking illicit gin, and by taking a hot pepperish sauce to flush out the bad blood.

6. Region: Delta State. Ethnic Groups: Uhobod, Ibos, Ijaws, Isaw, and Itsekirus

For people in these tribal groups, menstruation is a welcome development and a sign of attaining womanhood. In some parts of the Delta State, no special attention is paid to menarche, apart from the mother telling her daughter that she has become a woman and should not "go near men." In other regions, a girl who is already betrothed is visited by her prospective husband as a sign of homage to her family. In some areas, a menstruating woman is not restricted to any area within the compound; in other regions, she cannot stay in the main house with her husband and others. Instead, a mat is used to construct a hut for her, where she stays for about seven days. Some fathers may exempt their daughters from such restrictions. But if they do, the father must perform a ritual cleansing when the daughter's menses end.

7. Region: Edo

During menstruation, women are forbidden to prepare meals for their husbands. In fact, they must refrain from doing anything for their husbands during this period. A menstruating woman must not sleep in her husband's room, or even in their main house. People believe the husband may die if she doesn't comply.

8. Regions: Imo, Enugu, and Anambra. Ethnic Group: Ibo

In the past, a menstruating woman could not cook for her husband. This is no longer taboo. She cannot, however, have sexual intercourse during her period.

### Courtship

When courtship reaches an advanced stage, the Hausa suitor indicates his intention to marry the girl by sending money. He also sends cosmetics and items of clothing (*kayan zance*) and money to her parents (*Gaisuwan uwa da uba*). Before the bride is conveyed to her husband's house, the groom's family sends *kayan sa lalle*, a combination of food and cosmetic items, such as henna (*lalle*), sweets, perfumes, sugar, millet, and head ties. The millet and sugar are used to prepare *tukudi* for the bride. *Tukudi* is a porridge prepared from dates, millet flour, yogurt, cheese, spices, and herbs that contain aphrodisiac substances given to the bride a few days before she is conveyed to her husband's house. Because a lot of emphasis is placed on chastity, retaining one's virginity is a virtue. Hausa culture makes it desirable, if not compulsory, for the groom to send a gift to the bride's parents after the consummation of the marriage (*kama hannu*) in appreciation of the fact that she remained a virgin until her wedding night. The Islamisation of Hausa culture is steadily eroding the practice of the forceful consummation of marriage and the publicity given to a private marital affair between a couple. *Fiqh* teaches that the couple's sexual experiences are confidential matters to be disclosed only to a marriage counselor for counseling purposes. In contemporary times, especially among city dwellers, nobody asks questions about the wedding night and the status of the bride. [B. Yusuf]

### Premarital Sexual Activities and Relationships

MAIRO BELLO, BILKISU YUSUF, and FOYIN OYEBOLA

In urban Nigeria, premarital sexual intercourse can be defined as sexual relations prior to the time a woman is socially recognized to be married. Premarital sexual relations with the man a woman eventually marries, as well as with other men, are included in this definition, as long as the sexual activity takes place before the time societal norms confer on the woman the right to have a sexual relationship. Premarital relationships in the Nigerian setting are guided by normative principles and beliefs, whose baseline is premarital chastity. [F. Oyebola]

Anecdotes drawn from living Yoruba heritage and sexual networking in Ekiti District showed how the traditional Yoruba society attaches a high degree of importance to female virginity. Every new Yoruba bride is expected to be a virgin at the time of consummation of her marriage, that is, during the first night when the woman and the husband sleep together. A virgin bride has been a source of real pride to the family. [F. Oyebola]

In the Ibo tradition and the attitude towards virginity in urban Nigeria, it is said that "A woman never forsakes the man who breaks her virginity." Other informal studies of the Ekiti in Ondo State confirmed that virginity was so important that two women waited outside the couple's room on the wedding night to take the good news to her parents that the bride had been intact. In traditional Fulani and Yoruba societies, a white cloth was spread on the bed on the night of marriage consummation; in the morning, the cloth was examined for blood marks. The husband sent a gift of money and kola nuts to the bride's parents if the new bride was found to be a virgin. However, in order to forestall any departure from this norm, some girls were betrothed in childhood. [F. Oyebola]

With the advance of Western values, however, the situation has changed. Previous informal studies have indicated a gradual erosion of the traditional premarital sexual norms. This change in the norms may be a consequence of the transformation taking place in the institution of marriage itself and, in particular, the transition from family-arranged to individual-choice marriages. [F. Oyebola]

Informal networking among sexuality workers in the Ekiti District of Nigeria revealed that sexual activity begins at about 17 years of age for both males and females, and that while 33% of rural females were virgins at marriage, only 25% of the urban females were virgins at marriage. [F. Oyebola]

Other possible reasons identified for the erosion of the traditional premarital sexual norms are the education of young adults, the rural-to-urban drift, and, most recently, the poor socioeconomic situation in Nigeria, which has thrown many female young adults into prostitution or commercial sex work. [F. Oyebola]

With the breakdown in the traditional value system, the value placed on virginity is gradually decreasing. Among the Yorubas, the practice of spreading a white bed sheet on the couple's bed on the night of betrothal has almost stopped, especially in the urban centers. In the case of the Hausa-Fulani society, it has been reported anecdotally that the new bridegroom now sends money and nuts to the bride's parents whether or not the new bride is found to be a virgin. This observation suggests that attitudes towards premarital sexual relations are becoming more positive. [F. Oyebola]

Also, the longer period of schooling, the increasing divorce rate, and the fact that there is no longer insistence on the traditional virginity test indicate that the Ibo may not take a bride's virginity seriously anymore. Westernization

has therefore shifted the emphasis on virginity from a reality to an ideal. [F. Oyebola]

This picture of an increase in premarital relations is confirmed by the 1990 Nigerian Demographic and Health Survey, which revealed that by age 18, 63% of Nigerian women had had intercourse, while only 56% had married [F. Oyebola]. The 1988 Ondo State Demographic and Health Survey revealed greater exposure of young urban people to sexual activity. This was related partly to the influence of the mass media, as well as the availability of effective modern contraceptive methods that greatly reduce the risk of pregnancy in premarital relations. Other reasons why young people engage in premarital sex include:

- Ignorance about sexuality—it is still a taboo to educate young people about sexuality;
- The urge to experiment during adolescence without considering the consequences;
- For the fun of it and for sexual enjoyment;
- Peer pressure—doing it because others did it;
- Girls giving in to boys to show their love in the hope of marriage; and
- The influence of alcohol and drugs at parties, clubs, or drinking places. [F. Oyebola]

Traditionally, there were strict codes of sexual behavior and strict penalties were prescribed for transgressors. Indeed, the traditional custodians of society's values went to great lengths to ensure parallel but separate development of teenagers. Boys and girls were usually educated in separate institutions supervised by teachers of their own sex. In recent years, however, more and more schools are becoming coeducational. In addition, according to a 1992 study by Professor Makinwa-Adelzuso, Nigerian youth today are maturing at younger ages and are doing so in an urban milieu that permits them a great degree of freedom from adult supervision. Add to this new environmental mix longer time in school, later marriage, urban mobility and independence, and financial hard times, and it is clear why premarital sexual intercourse is increasing among teenagers. As a result, today's young Nigerians are exposed to a lot of dangers, especially from unsafe sex, sexually transmitted diseases (STDs), HIV/AIDS, unwanted pregnancies, and unsafe abortions. [M. V. Bello]

In addition, Hausan youth appear to possess little knowledge of and considerable misinformation about contraceptives and their use. Less than 30% of Hausan youths used a contraceptive for their first intercourse. This proportion only increased to about 40% for currently young, unmarried, sexually active Hausans. These percentages are, however, higher than national rates as revealed by the Nigeria Fertility Survey (1981/1982). [M. V. Bello]

Many older Nigerians and religious leaders express anxiety about the moral decline reflected in premarital sex among adolescents and the increasing number of teenage pregnancies among students. Islam enjoins Muslims to remain chaste. To satisfy their sexual needs, Muslims are enjoined to marry. Although marriage is not compulsory, it is highly recommended as a very strong *sunnah* or custom in the tradition of Mohammed, the prophet of Islam. Muslims who have reached marriageable age and can afford it are enjoined to marry. Indeed, child and teenage marriage is often urged as a precaution against premarital sex and teenage pregnancies. [B. Yusuf]

### Forced Marriages

In its proposal for a new social order for Kano State, the 1987 Committee for Women's Affairs identified forced marriages (*aren dola*), which are often contracted before

puberty, as one of the causes of high divorce rates and prostitution. Young girls forced into marriage not infrequently flee their marital homes and seek refuge in brothels (*gidan karuwai*) in urban centers. When this happens, these girls are believed to have "disappeared" into the world (*shiga duniya*) or to have become their own mistresses (*mata masu zaman kansu*). There have been cases of young girls threatening to *shiga duniya* (disappear) if and when they are forced to marry husbands they do not love. [B. Yusuf]

Early fertility and early childbearing are linked to teenage and child marriage in Hausa society. According to Makinwa-Adelzuso and Feyiset (1994, 99), the fertility rate for women ages 15 to 19 is much higher in the largely rural north than it is in the south: 196 births per 1,000 in the northwest, 212 per 1,000 in the northeast, and 71 per 1,000 in the southeast. The Nigerian Demographic and Health Survey of 1990 showed that one half of all women became mothers before age 20. Ten to 12% gave birth before age 15, and 21 to 28% gave birth between ages 15 and 17. [B. Yusuf]

### C. Adults

MARIO BELLO, IMO I. ESIET, UWEM EDIMO ESIET, FOYIN OYEBOLA, and BILKISU USUF

#### *Premarital Relations, Courtship, and Dating*

FOYIN OYEBOLA

Nigerian youths start dating at about age 16. Most of them date without knowing what dating entails, hence they do not know how to comport themselves during dates. There is a general belief that sexual intercourse must take place during dating. Most young people do not see dating as a first stage of courtship. Courtship in the real sense starts when young persons are in the tertiary institutions preparatory to marriage. Generally, the duration of most courtships is relatively short, and the courtship is kept secret from the parents, so there is no parental guidance. (See Section 5A/B, Interpersonal Heterosexual Behaviors, Children and Adolescents, above, for additional details on dating, courtship, and engagement.)

#### *Conception, Pregnancy, and Sexual Intercourse: A Regional/Ethnic Comparison*

The following summaries of the attitudes and practices regarding conception, pregnancy, and sexual intercourse of several ethnic groups in eight geographical regions of Nigeria were compiled by the authors during a meeting with health-care professionals in January 1999 (Francoeur, Esiet, & Esiet 2000) (see Editor's Note at the beginning of this chapter).

1. Regions: Ipoti-Ekiti, Oyo, and Yorubaland. Ethnic Groups: Oyo, Yoruba, and Ipoti-Ekiti

The Oyo do not allow premarital sexual relationships. They also view "modern" (non-male-above) techniques of coitus as abnormal and unmentionable. They think sexual intercourse is solely for procreation; pleasure comes second. They prefer male offspring because they will carry on the family name. The Yoruba culture also prefers male offspring. In fact, a Yoruba man will seek a new wife if his current wife produces only girls. Sexual relations are male-dominated, with the male initiating it and dictating the pace. Female response or satisfaction is not considered important. Coitus takes place at night and in the dark. Among the Ipoti-Ekiti, premarital sex is a taboo. The male-above position is standard, and coitus is for procreation and not really for pleasure. Male children are preferred.

2. Regions: Kano, Katsina, and Kaduna. Ethnic Group: Muslim Hausa

These cultures frown on premarital sexual relations. Sexual foreplay before coitus is also frowned on;

sexual intercourse usually occurs in the dark or semi-dark. The man indicates his readiness to penetrate by clearing his voice. This tells the wife to position herself. The woman always remains clothed or at least semi-nude. At the end of sexual intercourse, both partners have a ritual bath called *Ghusul Janabat*. Male children are preferred because they continue the family name, help with the farming, and assure inheritance.

3. Region: Borno

Premarital sex is a taboo. Contraception is not acceptable. Female children are appreciated more than males.

4. Region: Benue. Ethnic Groups: Tiv, Idoma, and Isala

Premarital sex is not encouraged. A divorced woman, however, is free to have sexual relations with any man. Sexual relations are for procreation; hence, polygamy is acceptable. Women abstain from sexual relations while breastfeeding. There is no foreplay before coitus and techniques for coitus are not even discussed. A wife must allow her husband to have a girlfriend, a "sister," from his own clan. The wife relinquishes the bed for "the sister" and must treat her nicely. A man is always unhappy when his wife has a female child. The wife is believed to be responsible for determining the sex of the child. Fathers are responsible when children are well-behaved and mothers are responsible when a child misbehaves. Aleku is a traditional god of the Idomas. When a man marries, his wife takes an oath to Aleku, who oversees women and checks on their fidelity. During the Aleku festival, the men are allowed to have sex with any girl or woman who has not taken an oath to Aleku.

5. Regions: Akwa-Ibom and the Cross River. Ethnic Groups: Efik and Ibibio

Premarital sexual relations are considered an abomination. The male-superior position is conventional and foreplay is highly valued. However, because intercourse is for the man's satisfaction and for procreation, a childless wife has no place in her own home. Because women are believed to determine the child's sex, a woman who has only daughters is often thrown out of the home. A badly behaved child is usually blamed on its mother. Among the Efiks and Ibibios, during the "fattening period" before marriage, an engaged girl is taught how to manage and keep a clean home, take care of her husband, help him to reach orgasm, treat in-laws respectfully, care for babies and children, cook delicious meals, maintain personal hygiene, and do a full body massage. In this culture, there is no preference for male or female offspring; inheritance is by seniority and is hereditary. In the river communities, a female is preferred for the first child, whereas the inland communities prefer the first child be a male. This has to do with the fishing and farming activities of the men. Wives visit their husbands in the fishing ports, like Bakasi, where the husbands also keep mistresses.

6. Region: Delta State. Ethnic Groups: Uhobod, Ibos, Ijaws, Isaw, and Itsekirus

In some regions of the Delta State, sexual intercourse is sacred; in others, it is not a big deal. Premarital sex is taboo and shameful in areas where virginity at marriage is cherished, but it is allowed in other areas. A girl is expected to become pregnant soon after marriage. There is a preference for male children, and a woman who has only daughters is in trouble. More often than not, her husband and his family will hate her. Such husbands may take another wife.

7. Region: Edo

Wives must respond to their husbands' sexual demands. Male children are preferred. Premarital sexual relationships are accepted depending on the girl's age. It is discouraged in the teen years. The male-above position is preferred and intercourse is for procreation and to feel good. Pregnancy should occur in the first year of marriage, and the first child should be male. Female children are not warmly welcomed, although children are considered God-given and many children are a blessing.

8. Regions: Imo, Enugu, and Anambra. Ethnic Group: Ibo

Even though premarital sexual relations were previously prohibited, in some areas of Anambra it is no longer a crime. Pregnant teenage girls are quickly married because it shows they are fertile. The male-above position is preferred. Intercourse is for procreation. Conception is a thing of joy, but male offspring are preferred. Any odd behavior is inherited from the mother; the father only passes on good traits. Pregnant women are forbidden to eat certain foods, like snails and grass-cutter meats (herbivores), because they are believed to cause excessive salivation and prolonged labor.

*Women and Marriage in Nigerian Law* IMO I. ESIET

Nigerian marital laws have helped to consolidate sex-role discrimination in the family. Traditional customs, known as the "customary law," is still accorded recognition in the area of family law, and in fact plays a very dynamic role in determining related issues.

*Women and Parental Consent in the Brideprice and Marriage.* According to Nwogugu, "For a girl, parental consent is mandatory under customary law even where she has attained majority, . . . on the other hand, an adult male may contract a valid marriage without the consent of his parent" (Nwogugu 1974, 20). The reason given for this inequality is that the brideprice, which is an essential characteristic of customary marriage law, cannot be properly paid, nor can the formal giving away of the bride be properly effected without parental consent. The brideprice has been described variously as a gift in kind or monetary payment to the parent/guardian of a female person on account of marriage to that female person (Nwogugu 1974, 50). Although brideprice is supposed to be a token of appreciation for the worth of the female chosen as a bride, the amount of the modern brideprice is less a token of appreciation than evidence that a daughter is regarded as an investment property whose total market value and capital outlay should be realized at the time of disposition. This situation has led to the intervention of the law in some jurisdictions, although the laws are hardly enforced. In 1956, for instance, the Eastern Region enacted a Limitation of Dowry law to regulate the amount that can be demanded as the brideprice. The reality of this transaction having an economic and investment nature is evident in the entitlement of the husband to a refund of the brideprice upon dissolution of the marriage.

*Women and the Right to Consortium.* By virtue of marriage, spouses acquire a right to associate in matrimonial circumstances (known as *consortium*) and enjoy certain incidental rights that flow from that marital/spousal relationship. Any interference with this right is actionable against a third party.

1. *Enticement and Harboring.* A spouse may bring an action against a third party for enticing, procuring, or inducing the other spouse to violate the duty to provide consortium to him or her. Whereas a husband can file a

tort against another man for “harboring” his wife, a wife cannot make an actionable claim against another woman for “harboring” her husband (*Adv v. Gillison* 1962, 390).

2. *Loss Due to Tort of a Third Party.* Whereas a husband can recover damages from a third party for loss of consortium and accompanying benefits or services of his wife as a result of that third party’s action, a Nigerian woman does not have this same right and may not recover for the actual loss of consortium. She may, however, receive damages awarded for matters which are somewhat incidental to the loss of consortium (Nwogugu 1974, 66).
3. *Adultery.* Under statutory law, the right of claims in cases of adultery is mutually enforceable, because it is tied up with divorce grants based on adultery and there can be no separate civil action for adultery. However, in most parts of Nigeria, customary law recognizes only the husband’s right to file claim against a third party who commits adultery with his wife. Hence, the husband can claim damages from the third party whether or not he uses the adultery to file for divorce from his wife. According to customary law, a wife can only apply for divorce if she claims adultery as the grounds for the breakdown of her marriage (Nwogugu 1974, chap. 7). In reality, Nigerian customary laws derive from the traditionally prevalent view that the wife is owned by her husband, whereas the husband is owned by no one but himself. Hence, adultery with the wife offends against the husband’s proprietary interest, and payment of some kind must be made to compensate. On the other hand, adultery by the husband does not offend the wife because he belongs to himself (Oyajobi 1986, 30).

*Women and Maintenance under Customary Law.* Although customary law recognizes the duty of the husband to maintain his wife, it does not provide any judicial machinery for enforcing this duty, except for the rules of the Maliki School of Islamic Law, which allows an Alkali court to issue an order to the husband. However, when a husband fails comply with this duty, even when ordered to comply, the Alkali Court, which is a customary Court, can do no more than grant dissolution of the marriage. The High Court, on the other hand, can enforce compliance to such duty.

*Mothers and Child Custody.* In the past, customary law gave the father absolute right to the custody of his legitimate children. This position, however, has been altered by recent statutes, particularly the Infants Law 1978 (Oyo State, Section 12, 1). Also, the Matrimonial Causes Act (Section 71) places the parents of a child on equal footing, and the decision of the court is to give paramount regard to the interests of the child.

However, the customary legal systems on custody still discriminate against the woman. The right to custody of children is vested in the father, although the child’s welfare is considered when the child is of tender years. In this particular case, although the mother may be given physical custody (when the parents are separated), Nwogugu notes that “the father’s right is merely in abeyance” (Nwogugu 1974, 260).

*Women and the Matrimonial Home.* Property disputes, especially regarding the matrimonial home, may arise between a couple anytime during the life of a marriage. Oftentimes, there are complaints from women that although they contributed to the acquisition of matrimonial property, their husbands disregarded their interest at later dates and dis-

posed of the property without their consent. The property is usually purchased in the husband’s name only. Efforts have been made in other countries to remedy this position; for instance, in 1967, England passed the Matrimonial Homes Act recognizing the rights of a spouse to occupy a matrimonial home whether or not that spouse is entitled by any legal right devolving on contract, by enactment, or estate (Section 1(1)). This was designed to protect a spouse who is not a legal owner against the power of the other spouse to dispose of the property and also against a third-party purchaser. The spouse’s right of occupation ceases on the termination of the marriage, except if an application is made to the court while the marriage subsists to direct otherwise by an order. Given the years of British colonial rule in Nigeria, legislation such as this protecting women’s rights in England is used by women’s rights advocates in their efforts to improve the legal status and protection of Nigerian women.

Since the right of occupation terminates with a divorce, the matter becomes one of property adjustment, and the court can be called upon by virtue of section 7(1) of the Matrimonial Causes Act to resolve distribution of the property in a way it considers just and equitable. Because of the special and domestic nature of the marriage relationship, transactions between couples are not evidenced in the same way as commercial transactions. But the position of the courts in Nigeria, as held in *Nwanya v. Nwanya* (NWLR 1987, 3, 697), is that a claimant for settlement must show evidence of her contributions.

#### *Marriage and Family* UWEM EDIMO ESJET

Individual married couples stipulate their sexual norms and values, protected by the male decision-making role and the custom of total silence regarding sexuality. Menopause may bring a major change, but the extent and nature of this effect has not been researched. Within the family, incest is not accepted.

#### *Menopause: A Regional/Ethnic Comparison*

The following summaries of the attitudes and practices regarding menopause of several ethnic groups in eight geographical regions of Nigeria were compiled by the authors during a meeting with healthcare professionals in January 1999 (Francoeur, Esiet, & Esiet 2000) (see Editor’s Note at the beginning of this chapter).

1. Regions: Ipoti-Ekiti, Oyo, and Yorubaland. Ethnic Group: Yoruba  
Menopause means a woman has finished her sexual activity. She can neither give birth nor give sexual pleasure to her husband. It is the end of her womanhood, and her husband hardly gives her any emotional attention. A menopausal woman “is old and should be preparing for the grave.” Women don’t talk about menopause because there are no issues attached to it and it is not celebrated. Menopause often results in the man taking another, younger wife. Menopausal women are looked at as old people and are recognized as mothers, but not as wives.
2. Regions: Kano, Katsina, and Kaduna. Ethnic Group: Muslim Hausa  
Special considerations regarding menopause are unknown.
3. Region: Borno  
“Menopause is like having a sleepy pregnancy.” (There is no indication of whether this is good or bad.)
4. Region: Benue. Ethnic Groups: Tiv, Idoma, and Isala  
Menopause is rarely recognized, as life goes on normally. It simply means that a woman is getting close to retirement.

5. Regions: Akwa-Ibom and the Cross River. Ethnic Groups: Efik and Ibibio

This culture does not accept or see menopause as a natural aging process. It is attributed to the attacks of witchcraft. When this happens, the man starts looking for a younger wife, while the woman starts seeking a traditional treatment or cure. During menopause, women become psychologically unstable, suspicious, erratic, irritable, and talkative. Menopause means the woman has outlived her reproductive role and her usefulness in the home. A menopausal woman is not expected to continue sexual relations with her husband, so she arranges for a younger girl to live with her husband.

6. Region: Delta State. Ethnic Groups: Uhobod, Ibos, Ijaws, Isaw, and Itsekirus

Menopause is seen as the end of a woman's reproductive and sexual life. Her husband may take another wife to satisfy his sexual urges. Menopausal women often become depressed when they feel they are no longer useful and therefore not cherished by their husbands.

7. Region: Edo

Men do not find a menopausal woman useful or productive. People feel that the "bad blood" lost during menstruation now collects in the body, causing problems.

8. Regions: Imo, Enugu, and Anambra. Ethnic Group: Ibo

Menopausal women gain more respect because they are now considered men. There are usually no acceptance problems for menopausal women. As for the men, they like running away from their menopausal wives, although our society frowns on this.

### *Cohabitation, Monogamy, and Polygyny*

UWEM EDIMO ESIET

In the past two decades, an increase in the incidence of cohabitation has been observed. However, this is far from being the norm as it has become in Euro-American countries. Because this is a new phenomenon in Nigerian culture, the partners are left to work out their own terms and conditions as appropriate, without benefit of or guidance from the legal structure.

Monogamy has been the hallmark of Christian marriages, even though a few indigenous Christian churches allow or endorse alternatives. Polygyny has been a traditionally accepted marriage pattern in Nigeria and it continues to have some support among Islamic adherents and members of some indigenous Christian churches.

### *Divorce, Remarriage, and Extramarital Sex*

UWEM EDIMO ESIET

"Til death do us part" has long been the Christian marital ethic. However, this is increasingly being flouted, as spouses are now insisting on their personal rights within marriage, including the right to love and be loved, and have mutual respect and care for each other. Despite the Christian ethic, there is an increased incidence of divorce in contemporary Nigeria. Remarriage after divorce is also becoming more acceptable, especially within traditional tribal norms and Islamic practices and tenets.

Extramarital sex is permissible for the man but not for the woman. However, with the downturn in the economy and women being more assertive, such occurrences are becoming more realistic even for women.

### *Sexuality and the Physically Disabled and Aged*

UWEM EDIMO ESIET

The physically disabled have not been overtly discriminated against, as most children and families wish that their

disabled family members could have children as a compensation for their efforts in contributing to the family.

The elderly enjoy their sexuality within their socio-cultural norms and values, and like all Nigerians, are left to deal with their sexual desires and needs within the code of silence regarding all sexual matters.

### *Attitudes on and Incidence of Oral and Anal Sex*

UWEM EDIMO ESIET

Anal penetrative sex is frowned on even now, particularly in view of the HIV/AIDS risk. Although oral sex is practiced, it is not glamorized as it is in other countries, primarily because of the general culture of silence on sexual topics.

### *Aphrodisiacs*

BILKISU YUSUF

Traditional aphrodisiacs are quite common in Hausa culture. They vary from those used as food to special chemical preparations. There are different types used by men and women to increase libido and vaginal lubrication, and to ensure that married couples derive maximum sexual satisfaction from their partners.

While a variety of male aphrodisiacs exists, the most widely used among Hausa men is *Gaggai*, a root which is either boiled, powdered, and mixed with spices and eaten with meat, or soaked with spices to make a drink. For women, *tukudi* is routinely prepared for brides; its content depends on the local aphrodisiac herbs available in a particular area. *Hakin maye*, very common among Hausa in the Sokoto and Kebbi States, is a combination of herbs used as food additives mixed with chicken broth, sprinkled on yogurt, or mixed with honey.

The herb *Gyadan mata*, which grows in the wild and looks like a nut, is chewed by women. Two groups of aphrodisiacs, known as *Ko gida* and *Ko mota*, are popularly hawked by women: One is taken orally, whereas the other, used as a topical application, is used to tighten the vaginal muscles. *Maganin mata* (women's medicine) is a more general term used in a variety of female aphrodisiacs that include local herbs, a white sweet substance imported from Arab countries, and a dark substance called *laximi* imported from the Indian subcontinent.

It is quite common to see local female herbalists (*yar mai ganye*) hawking these aphrodisiac herbs in the markets. Those who prepare aphrodisiacs for brides and other users buy their herbs from the local female herbalist or her male counterpart. After they prepare their special variety of ingredients, they sell their mixes wholesale to retail hawkers, *dillalai*, and it is not unusual to see these aphrodisiac hawkers making brisk business at social gatherings and sharing in hushed voice with friends their experiences on the efficacy of their own brand of tried and tested aphrodisiacs. There is no existing research on these traditional Hausa aphrodisiacs, but their usage is widespread. Dealers in Sokoto, Nigeria, and in Maradil in neighboring Niger Republic are known for their virtual monopoly on some of the most popular brands.

## *6. Homoerotic, Homosexual, and Bisexual Behaviors*

UWEM EDIMO ESIET

### **A. Children and Adolescents**

From what little is known, the incidence of same-sex sexual behavior among children and adolescents is very low. Incidents have been reported within same-sex institutions.

### **B. Adults**

More adult homosexual behavior is being recorded. One reason cited for this behavior is the myth that homosexual re-

relationships enhance one's personal wealth acquisition. Persons who engage in homosexual behavior tend to be bisexual, because exclusive homosexuality is greatly frowned on.

### *Homosexuality: A Regional/Ethnic Comparison*

The following summaries of the attitudes and practices regarding homosexuality of several ethnic groups in eight geographical regions of Nigeria were compiled by the authors during a meeting with healthcare professionals in January 1999 (Francoeur, Esiet, & Esiet 2000) (see Editor's Note at the beginning of this chapter).

1. Regions: Ipoti-Ekiti, Oyo, and Yorubaland. Ethnic Group: Yoruba  
The people believe that homosexuality does not exist, only heterosexuals. People who engage in same-sex acts are seen as outcasts.
2. Regions: Kano, Katsina, and Kaduna. Ethnic Group: Muslim Hausa  
Homosexuals exist. They are not accepted and keep their sexual activities hidden.
3. Region: Borno  
Both homosexuals and bisexuals exist, but such behavior is taboo.
4. Region: Benue. Ethnic Groups: Tiv, Idoma, and Isala  
The people may hear about homosexuality and bisexuality, and it may occur, but no one has ever seen it.
5. Regions: Akwa-Ibom and the Cross River: Ethnic Groups: Efik and Ibibio  
There are no forms of homosexuality or bisexuality in this culture: These acts are forbidden. Anyone known to be engaging in this activity is stigmatized and regarded as outcast.
6. Region: Delta State. Ethnic Groups: Uhobod, Ibos, Ijaws, Isaw, and Itsekirus  
Special considerations regarding homosexuality are unknown.
7. Region: Edo  
There are no forms of homosexuality or bisexuality allowed in this culture.
8. Regions: Imo, Enugu, and Anambra States. Ethnic Group: Ibo  
People say they know nothing about homosexuality in this culture.

## 7. Gender Diversity and Transgender Issues

Gender-conflicted persons are not recognized in our culture, which maintains a strict either/or belief regarding male and female gender. Transvestitism is neither acknowledged nor encouraged.

## 8. Significant Unconventional Sexual Behaviors

### A. Coercive Sex

CHRISTINE OLUFUNKE ADEBAJO and IMO I. ESIET  
*Coercive Sex and Nigerian Law: An Overview of the Current Status* CHRISTINE O. ADEBAJO

Sexual abuse, assaults, and harassment all involve violence against women or men. Any of these forms of coercive sex can occur in the home, workplace, or in public. And each, as an issue, remains complex, ambiguous, interwoven, and extremely dangerous in the traditional Nigerian society. They all entail subjugation of the victim and the stripping of her (or his) autonomy and self-esteem. The occurrences against women are more pronounced because such acts are encouraged by the societal perception of a

woman's low status. In Nigeria, as described above, women are subject to several dehumanizing and oppressive traditional values, which ultimately dictate how women are regarded, treated, and acknowledged.

As a traditional, tribal-based society, Nigeria has mechanisms that legitimize, cloud, and deny sexual abuse, assaults, and harassment as forms of violence against women in particular. In many instances, even when a particular act of violence is deplored, some conventional institutions, such as the family structure, as well as religious and traditional rulers, protect the status quo, making it more difficult to challenge. For example, most Nigerian communities, if not all, believe in male supremacy; hence, any of these acts is perceived as an acceptable exercise of the male's prerogative over women's sexuality.

Within the context of women's almost helpless social position, ridiculous scenarios and rhetorical questions are widely used in casual conversations to make light of the reality of oppression and subjugation that these acts inflict on women. For example, men and women alike ask, "Why should a man not chastise his wife for an offense?" Note that such "chastisement" can include physical assaults of varying degree. Another question usually asked involves female genital mutilation (female circumcision): "Why should a woman choose to be uncircumcised, or make her daughter an 'outcast' by not allowing her to be circumcised?" This act is not considered sexual abuse, when in reality it is indeed just that. In fact, one would like to ask who and what makes an uncircumcised woman an outcast? Obviously, it is the society. In this perspective, it could be concluded that sexual abuse, assaults, and harassment affecting women are in most cases not accidental; instead, they serve the sociopolitical function of keeping women subordinate. They are most often expressions of power that connote an unequal relationship between male and female sexuality.

The occurrences of sexual abuse, assaults, and harassment against men in Nigeria are very negligible. When such incidences do occur at all, they occur among children and adolescent males. Ironically, when any act of this nature is directed against a male, it is viewed with great seriousness. In some communities, the same powerful institutions that downplayed these acts perpetrated on women view them as an abomination when directed at a male.

Socially, sexual abuse, assaults, and harassment against women are subtly tied to sexism and women's oppressed status, particularly their sexuality. The law is seemingly insensitive to these acts, whether it is dealing with marital rape (see below) or with other more clear and documented cases. A typical case in which the courts evaded and ignored the need for redress is the outcome in the case of *Jos N. A. Police vs. Allah Nagari, Nigeria*, in which a 7-year-old girl gave evidence against the man she claimed raped her. Her bloodstained clothes were produced as evidence while a medical report confirmed injury to her genitalia. Despite this evidence, the man was not convicted because a clause in the law stipulates that any child less than 8 years of age needs her case corroborated, before the court can rule in her favor. Unfortunately, cases like this abound, even though requiring a witness to the rape makes a mockery of the law's professed lack of bias between the sexes.

Even though economic deprivation in Nigeria affects all groups, ages, and sexes, the worst hit are women and children. Women in particular suffer from unequal and inequitable access to vital development resources, such as education, employment, housing, and so on. Yet, women are mainly responsible for raising the children. This dependency exposes mothers and children to prostitution and other forms of sexual abuse. They are also prone to assaults and

harassment from frustrated husbands and fathers. With the father's situation highly precarious because of the prevalence of unemployment, male frustration is common in the Nigerian home. Nigerian wives can easily be sexually exploited by their husbands for the benefit of their family. Also, fathers at times encourage their daughters to prostitute themselves, either directly or while hawking goods in the marketplace, in order to help the family's economic stress.

#### *Ethnic Variations* CHRISTINE O. ADEBAJO

Although sexual abuse, assaults, and harassment occur among people of all ethnic, cultural, religious, and social classes, their pattern and causes can only be understood and remedied in specific social and cultural contexts. However, in all ethnic regions of Nigeria, almost all reported cases of sexual abuse, assaults, and harassment are perpetrated by men. For example, in a study conducted by Francisca Isi Omorodion between 1982 and 1988 in Benin City, Edo State, all cases of battering reported to the Social Welfare Department were perpetrated by men. The same study showed that the men who battered their wives were between the ages of 20 and 45 years, while their wives were between the reproductive ages of 18 and 36 years.

The study went further to ascertain that battering was not limited to level of education or class. It showed that 50% of the men and 30% of the women involved had attained at least a primary school certificate. More frustrating was the finding that 40% of the men and 30% of the women involved had an educational level ranging from secondary school to college. The findings portrayed a further worrisome fact that most of the cases reported to the Social Welfare Department were from the lower strata, while most of the upper-class cases went unreported and were kept secret by the victims.

Certain acts that qualify as sexual abuse, assault, and harassment are seen in some Nigerian communities as normal and hidden under the umbrella of traditional practice, culture, and beliefs. Examples include female genital mutilation, nutritional taboos in pregnancy and children, body scarification, seclusion in labor, hot baths during the six weeks after birth, and a host of others. Some of these acts are perpetrated as a societal norm. In the case of child battering, some communities believe that parents or guardians have a prerogative over their children and thus can scold and beat them to any degree without interference from a third party. In such a circumstance, a child can be ill-treated and badly injured without it being seen as battering. In certain communities where the wife is viewed as the man's property to be used as he desires or sees fit, beating one's wife is therefore nobody else's business. Worse still, in the same communities, a wife who expresses a need or seeks a favor from her husband can be seen as purposely aggravating the husband to beat her. This is because it is believed that such a domestic scuffle would be settled by the husband offering a gift.

#### *Current Data* CHRISTINE O. ADEBAJO

Statistical information on the extent of sexual abuse, assaults, and harassment in Nigeria is very scanty, as most data have been compiled in small studies. This data therefore provides only a small insight into the incidence, and the data cannot be used as concrete indicators on the extent of these acts in Nigeria as a whole. However, some of the available studies portray serious health, emotional, and physical consequences that cannot be ignored.

For example, after a 1985-1986 study of the national prevalence of female genital mutilation (FGM), Christine Adebajo reported that female genital mutilation was ac-

tively promoted and advocated in 21 out of the 30 states in Nigeria. The prevalence within the newly adjusted state boundaries and newly created states indicated that 35% to 90% of the women in 18 states are mutilated, while in nine other states the percentage of mutilated women was 90% or higher.

Other documented cases of sexual assaults, abuse, and harassment include the following:

- In 1987, 12-year-old Hauwa Abubakar from northern Nigeria died after having both legs amputated by her husband after the girl made several attempts to run away from her forced marriage.
- A case of rape of a 10-year-old girl by a police officer was reported in Benin City. The police officer grabbed the girl who was returning from an errand, locked the door, and threw her to the floor, tearing her underclothes. Before her cries could attract a passerby, she had been raped. The only redress was a fine of 2,500 Naira (roughly \$2,500 U.S.) which was never paid by the offender.
- In June 1995, some neighbors brought a 37-year old married woman to my husband's private hospital with a fractured collarbone. She had just been mercilessly beaten by her husband, because he suspected that their son told her about his infidelity. Despite the fact that she did not react, the husband's guilt could not hold him back from challenging his wife for knowing of his infidelity. The husband was, of course, reported to the police by the hospital, but the case was eventually thrown out of court as a mere family squabble that should be settled out of court.

These few cases typify the outcome of many reported cases of assault, sexual abuse, and harassment in Nigeria. Unfortunately, the majority of abuse/assault cases are not reported and do not get public notice. A culture of silence seems to be responsible for the inadequacy of documentation and population-based data. In addition, the socio-cultural and legal barriers on the issue of violence, particularly relating to sexuality, make it almost impossible to acquire accurate data on any of the acts. Nevertheless, the few available data and several deafening whispers of daily occurrence of violence are sufficient to justify increased attention to this issue.

#### *Sexual Abuse, Assault, and Harassment*

CHRISTINE O. ADEBAJO

In this discussion, we have tried to discuss the various forms of sexual abuse, assault, and harassment, respecting the ways in which these are perceived and categorized in Nigeria. However, sexual abuse, assault, and harassment are so interwoven that one can hardly talk of one without overlapping into the other. Clear operational definitions are difficult to come by, because the distinctions are often subtle and varied according to the interpretations of the victim, varying cultural perspectives, and differences in the way males and females view individual occurrences. The application of definitions, even when such are clearly delineated, is often difficult or impossible, because particular cases frequently involve a combination of various actions which cannot be separated out. Whatever form these actions take, they usually share a common motivation: to gain and sustain dominance and control over the victim. Sexual harassment, abuse, and assault in Nigeria constitute a major component of violence against women, since it is often associated with male dominance, although a variety of assaults are common among adolescents, peer groups, and adults of either gender.

**Sexual Abuse.** [Christine O. Adebajo] Sexual abuse is here defined as someone forcing another to engage in sexual activity, or interfering with someone's sexuality, against his or her will and without his or her consent. Such abuse, which may involve a male and a female or persons of the same gender, may result in, or is likely to result in, physical, sexual, or psychological harm or suffering to the victim. Abuse, in private or in a public place, can range from being kissed without one's consent to touching the sex organs to forced sexual intercourse. Sometimes, sexual abuse can occur between an adult and a child or teenager. Most commonly, however, sexual abuse occurs among people with a personal relationship or where they have had such a relationship in the past. While terms such as sexual assault, sexual coercion, and sexual aggression are sometimes used as synonyms for sexual abuse, in Nigeria sexual abuse includes the following acts: verbal aggression/assault, unwanted physical touch, rape, incest, child prostitution, female genital mutilation (FGM), and *Yankan Gishir* (salt cut)—these variations are discussed below individually.

**Unwanted Physical Touching.** [Christine O. Adebajo] It is not uncommon in public places such as work and school, especially colleges, for women to experience physical touch with a sexual connotation. This can involve patting the buttocks (bum-patting), open display of sexist images, rubbing of the body, and more-overt molestation. In Nigeria, it is difficult to take these particular types of abuse too far, because they are not viewed with any legal seriousness. Perhaps one of the reasons for this is the fact that Nigerians are known to be warm and close people, where touching is generally seen as an act of kindness and friendship. However, where it involves an adult male touching the genitalia of a child, particularly of the opposite sex, it is viewed with more seriousness.

**Verbal Assault.** [Christine O. Adebajo] Verbal assault or aggression occurs when words are used to control, dominate, and intimidate the victim by yelling, insulting, speaking unkindly, and name calling. Other forms of verbal assault involve judging and criticizing; discounting what the other says, feels, or thinks, and in repeatedly disagreeing with the victim. Verbal assaults can be very psychologically damaging, making the victim feel dehumanized and belittled. This can lead to serious emotional health problems. Verbal abuse also very often leads to physical assaults. Unlike other forms of violence, verbal assaults are not primarily limited to males against women; they are perpetrated by both sexes and in all age groups.

**Indecent Assaults.** [Imo I. Esiet] Section 360 of the Criminal Code provides that: "any person who unlawfully and indecently assaults a woman or girl is guilty of a misdemeanor, and is liable to imprisonment for two years." However, according to section 353 of the same Code, this felony is punishable with three years imprisonment when the victim is a male, rather than two years as in a case of female victims. A fundamental principle of criminal law is that all persons should be equally protected from harm of like degree. It is hard to see any justification for creating different offenses with different penalties to cover the same conduct for persons of different sexes.

**Sexual Harassment.** [Christine O. Adebajo] In Nigeria, harassment can be categorized under two headings as direct or indirect. Direct sexual harassment, including verbal assault and unwanted touches, such as bum-patting, sexist remarks, open display of sexist images, and more-overt molestation, is a major gender issue, particularly in the work setting and in colleges where it can manifest in the form of victimiza-

tion and/or molestation. Indirect sexual harassment/abuse occurs as a result of traditional practices or beliefs referred to as "harmful traditional practices" (HTP); see Section 8D, Female Genital Mutilation and Other Harmful Practices.

In Nigeria, as elsewhere around the world, sexual harassment is commonly perpetrated by men against women. However, a few cases have been reported of Nigerian female executives harassing their subordinates. Also on record are a few cases of sexual harassment by female college students against their male lecturers. Even though it is common knowledge that sexual harassment of females by males occurs in public spaces, such as the workplace, school, market, and street, it is often very difficult to prove such in a traditional society such as Nigeria, where the behavior correlates with the society's gender power differentials.

In the workplace, sexual harassment has been manifested in limiting the female to designated sex roles through blackmail or other means. For example, in labor unions, an assertive woman unionist is looked on as defiant. This also occurs when women try to move into professional jobs that are believed to be the exclusive preserve of men. In a research work very applicable to the Nigerian situation, Dr. Madeline Heilman of New York University showed that there is a general consensus that pretty career women have problems on the job. Heilman found that when an attractive woman is looking for lower-level jobs, her looks could earn her a plus. However, when she is in a managerial position, competing with a good-looking man puts her at a disadvantage. A good-looking man is seen as competent, tough, decisive, and hard-nosed, whereas an attractive woman with the same qualifications, background, experience, and recommendation is dismissed as gentle, soft, and indecisive.

Because of the nature of Nigerian social codes and values that stress male dominance of women, sexual harassment often goes unnoticed. This societal posture makes the victim unwilling to report cases of sexual harassment. It has also been observed that victims are not sure of what constitutes sexual harassment.

**Domestic Violence and Spousal Abuse.** [Christine O. Adebajo] These are aggressive acts, such as pushing, kicking, slapping, hitting, punching, grabbing, biting, throwing objects, burning, wounding, or in the extreme, killing. Even though physical assaults are perpetrated by both genders, the worst recorded cases are those perpetrated by males against females, particularly those associated with domestic violence. Domestic violence usually leads to severe injury and, in a few cases, to death. Unfortunately, this problem is not receiving adequate recognition from the society, which does not consider it a problem worth addressing. Physical assaults within the family are central to the violence in Nigerian culture at large. It is embedded within the traditional values that place men above women, and the concept that domestic violence is a private matter between husband and wife or man and woman. There is a quiet willingness to accept it.

Case studies of wife battering in some parts of Nigeria have documented that the injuries sustained by battered wives include: facial bruises, blackened eyes, cuts on the mouth, loss of teeth, fractures, and severing of hand(s). Another study, conducted by the Akwa-Ibom State branch of Women in Nigeria (WIN), listed the following major causes of violence in-home in terms of descending importance:

- arguments over money;
- jealousy and fear of the partner's infidelity;
- a partner's attempt to intervene in the punishment of children;
- arguments over drinking habits;

- being overburdened with family chores;
- in-law interference;
- a partner being blamed for the children's behavior;
- a spouse's desire to go for further studies or to advance her career;
- ignoring a spouse;
- frequent demands for sexual relations; and
- disputes over the number of children wanted.

The same survey went further to elucidate steps taken by spouses to protect themselves. Among the coping mechanisms used were:

- reporting the assault or abuse to parents, in-laws, the police, social welfare agencies, or a religious leader;
- doing nothing;
- leaving the home with the children;
- praying to God to change him; and
- keeping quiet until it is over.

The majority of the respondents considered domestic violence as natural and not to be questioned or challenged. Victims were optimistic that their partners who had shown a violent tendency would change with time, although all of them confirmed that their health was affected when violence occurred. The majority, who see acts of domestic violence as wrong, still feel that they should stick to their marriage, because:

- divorce and separation are considered shameful;
- there is no place to keep the children; and
- they do not want the children to have different fathers.

Thus, it appears that many marriages have seriously deteriorated, although things are patched up on the surface. Even when physical injury is not inflicted, many women live in perpetual emotional turmoil, obviously with impaired health.

*Domestic Violence and Spousal Abuse.* [Imo I. Esiet] Although much of spousal assault involves wife battering and is exploitative and abusive of the marriage relationship, keeping in mind the fact of female subordination in Nigerian society helps one understand the peculiar social setting that exposes the married woman to such an attack on her physical person.

One of the reasons often given to justify wife battering is the right of the husband to chastise his wife and an erring wife's need of discipline. This defense and claim to moral justification is based on the view that by consenting to marriage, a woman consents to revert to the status of a minor. The provisions of law which allow a defense to assault on grounds of reasonable chastisement gives the right only to parents or those who stand *in loco parentis*. In essence, then, this defense places the wife in the same position as her children in relation to the husband's supreme authority. In most cases, we may safely assume that the wife would have attained civil majority. So the question becomes one of whether an adult woman loses her maturity and capacity to be responsible simply because she has married, and her husband decides to discipline her like a child when she errs.

*Rape.* [Imo I. Esiet] Section 357 of the Nigerian Criminal Code defines rape as "unlawful carnal knowledge of a woman or girl, with or without her consent, or if the consent is obtained by force or by means of threats, intimidation of any kind, or by fear of harm or by means of false and fraudulent misrepresentation as to the nature of the act or in the case of a married woman, by impersonating her husband." The offense is punishable with life imprisonment with or without whipping. This definition in section 357, however,

needs to be read with section 6, which excludes forced sexual intercourse between spouses. Marital rape is not recognized in Nigerian law. The customary law reasoning for this exclusion was succinctly stated by Hale (in Smith & Hogan 1983), when he said, "The husband cannot be guilty of a rape committed by himself upon his lawful wife, for by their mutual matrimonial consent and contract the wife has given up herself in this kind unto her husband which she cannot retract."

It would appear from the above definition of rape that rape is deemed to differ qualitatively from the act of mutual and reciprocal lovemaking only on the issue of consent. According to Nigerian law, in consenting to contract marriage, a married woman gives up any right to refuse sexual intercourse with her husband, even when he forcibly imposes his will on her (Oyajobi 1986, 18). This legal position has prompted one commentator to ask: "If the law recognizes the need to protect the wife from other physical assaults from her husband, why should she not be entitled to protection simply because the assault this time is of a sexual nature" (Oyajobi 1986, 18; Criminal Code sections 335, 338, 351, 352, 362).

There are, however, some situations in which it has been ruled that a husband should be held liable for raping his wife (Oyajobi 1986, 19). These situations are where:

- a divorce decree has been given, even though the marriage is still in existence;
- the spouses are living apart under a court separation order;
- one spouse has filed papers to commence divorce proceedings;
- a husband has been given a court order not to return to his wife;
- there has been a separation by agreement; or
- there is a court order prohibiting molestation of the wife.

It is important to note that legally the sexual history of the victim is inextricably tied to the issue of whether or not the party gave consent to the alleged forced intercourse. Section 210 of the Evidence Act allows evidence of previous sexual dealings of the accuser with other persons as well as the accused. But the fact that the plaintiff gave consent to having sex with the accused on a previous occasion may not be conclusive evidence that consent was given on the alleged occasion.

Corroboration of evidence regarding the plaintiff's alleged previous behavior is not an express requirement of the law of rape in Nigeria. However, following the customary law trend, our courts have evolved the rule of practice of warning juries about the danger of convicting based on uncorroborated evidence. The difficulties inherent in providing corroboration in rape cases are obvious. This is not unconnected with the fact that these offenses take place in private, and it is unlikely that there will be any human witnesses apart from the parties themselves.

*Another View of Rape.* [Christine O. Adebajo] In addition to marital rape and stranger rape, Nigerian women have been subjected to brutal rape as part of war and violence against refugees. This experience was documented during the Nigerian Civil War with Biafra (1966-1970).

The Nigerian Criminal Code section 221 stipulates that it is a criminal offense if a man has sexual intercourse with a woman:

1. without her consent;
2. with her consent given under fear of pain or death threat; or

3. if the female is under 14 years of age or of unsound mind, whether with or without her consent.

Ironically, the age of consent for sexual intercourse varies from one part of the country to another. Specifically, the Nigerian Criminal Code puts the age of consent for boys at 14 and for girls at 16 (unless she is married). It will be seen that the law itself can be open to a lot of abuses. Law enforcement agencies are usually not sensitive to sexual rights violations, often making it difficult to establish a case of rape. The record shows that very few cases of rape offenders have been prosecuted. On the other hand, a child victim is often labeled as being sexually aggressive, even by the courts of law.

This unfavorable societal outlook on the issue of rape has not helped in the proper documentation of its incidence. Victims are reluctant to report rape cases because they feel ashamed that the society might insinuate that they made themselves a target of attack. They are also afraid of repeated occurrences by the perpetrator, because the victim is not sure of adequate redress by law enforcement agents. In some cases, victims have been driven to commit suicide because of the stigma and possible dishonor, particularly in cases of illegitimate pregnancy.

A common form of rape in Nigeria occurs with domestic help, usually a teenage girl, when she is molested by her master or by a teenage male child or relation of the master.

Nongovernmental organizations (NGOs) and other groups and individuals need to agitate for law reform that will provide adequate redress for victims. Such a law should also facilitate the prosecution of offenders, more so because the present provision under the criminal code makes a case of rape lapse if prosecution does not commence within two months of the offense. The other obstacle is the requirement of providing an eyewitness when the offense itself can hardly be committed in the presence of anyone.

*Incest.* [Christine O. Adebajo] It is difficult to provide a clear definition for incest in the Nigerian context, because its meaning varies from community to community. For example, certain ethnic groups permit marriage between cousins. Neither the criminal nor penal codes make provision for incest as a categorical form of crime. Sexual intercourse between father and daughter is illegal and regarded as an infringement on the daughter's sexual rights. Documentation of incest is almost totally lacking. Nevertheless, unreported cases do exist in almost every community. It is known that victims who were abused by their fathers or stepfathers, whose abuse involved genital contact, and whose molestation involved force, are at greater risk of long-lasting effects that can include: nightmares, flashbacks, disassociative responses, emotional numbing, and so on. It has also been established that the long-term psychological complications usually manifest as physical complaints, some of which may be linked with chronic pelvic pain, headaches, asthma, and gynecological problems (Koss 1987).

As with rape, a substantial number of cases of incest do occur among cousins, even in communities where cousin marriages are not allowed. The majority of these cases occur among teenagers. Most are never allowed to reach public notice, as the parents collude to "bury" such incidences within the family to avoid "dishonor." Other common cases involve sexual molestation of stepdaughters by their stepfathers, and of stepsisters by their stepbrothers. In recent times, it has been observed that teenage girls are increasingly more likely to initiate incestuous relationships. This development is perhaps linked with two facts: Girls mature biologically at a younger age than boys, and today's society

allows girls more freedom, which exposes them to opportunities of early sexual interaction.

## B. Prostitution

### *Adult Prostitution*

IMO I. ESIET

Adult prostitution is on the increase, especially with the downturn in the economy. The connection between increasing prostitution and increased incidence of HIV/AIDS in this group has created considerable interest among health-care providers. Several nongovernmental organizations are now working with prostitutes to get them to practice safer sex.

Section 1 of the Criminal Code defines prostitution as "the offering by a female of her body, commonly for acts of lewdness for payment . . ." whereas, by virtue of sections 222A, 223(2), and (4) of the Criminal Code, the male can only be liable for the offense of procuring a female to become a prostitute.

According to Ayo Oyajobi (1986, 23), there is hardly any moral justification or logical reasoning for the exemption of males from the definition of who can be a prostitute, while asserting that there is no reason why a man cannot offer his body for acts of lewdness for payment. The truth is that men in fact do so more often than we would like to admit. This assertion is based on the increased obviousness of homosexual activities by males, in which case male prostitution has become more common and evident. But in reality, only less economically fortunate women in Nigerian society find themselves policed and labeled for subsequent discriminatory treatment by the law (Oyajobi 1986, 24). Although, economic factors cannot adequately explain prostitution, they must not be treated as marginal considerations. Insofar as our male-dominated society offers relatively limited opportunities for women to earn a good living wage, win promotions, achieve a secure career, and generally attain economic independence from men, women will be only too willing to give their bodies to achieve these ends (Oyajobi 1986, 24).

### *Child Prostitution*

CHRISTINE ADEBAJO

Child prostitution, which used to be a taboo, is now a reality in Nigeria. Since the economic downturn that is hitting every family, child prostitution has increased steadily. The practice comes in different forms. In certain situations, parents actually encourage their teenage daughters to prostitute themselves.

In a survey carried out in some cities of Nigeria by a soft-pornography magazine, *Hints* (March 1996), most children interviewed confirmed that their mothers, the majority of whom are prostitutes themselves, introduced them to prostitution in an attempt to augment the family's earnings. The age range of these girls is from 8 to 13 years. The same survey revealed that secondary-school girls between the ages of 10 and 13 hang around hotels and streets soliciting male patronage. Others who appear physically mature take older men, referred to as "Sugar Daddies," for boyfriends. These men, in return for sexual gratification, assist the girls with their school fees. Another form of child prostitution occurs when young girls aged 8 to 15 are sent by their parents or guardians to hawk goods on the streets. Some of these children are easily seduced by older men and are paid for any contracted sexual act. More worrisome in recent times are a few reported cases of child-prostitute exporters and importers. This is most often perpetrated by foreigners.

In Nigeria, child prostitution and child pornography are illegal. Any such act that reaches the notice of law enforcement agents is handled with seriousness. Although one would have expected constant raids on perpetrators because

they usually have specific designated areas, such raids are very sporadic where they exist at all. Child prostitution is a gross sexual abuse because the act is illegal, and most of the time, the act is forced on the prostitutes either by some older person or by circumstances beyond their control.

### C. Pornography and Erotica

See Section 3D, Informal Sources of Sexual Knowledge.

### D. Female Genital Mutilation and Other

#### Harmful Practices CHRISTINE ADEBAJO

Female circumcision (FC), or female genital mutilation (FGM) is a traditional practice in Nigeria in which an unskilled person or a health worker cuts off parts or whole organs of the female external genitalia. This practice is tied to culture, religious belief, and myth. Beyond this, it is a gross sexual abuse, which infringes on a woman's rights with abundant negative consequences (Goddard 1995).

The type of FGM performed varies from community to community, mostly based on their beliefs. In a nationwide survey carried out between December 1985 and May 1986 by Christine Adebajo for the National Association of Nigerian Nurses and Midwives (NANNM), the following facts were established:

- In the 21 states in Nigeria (out of 30 states) where FGM is carried out, it is believed that an uncircumcised woman is usually promiscuous. In Anambra, Bendel, Imo, Ondo, and Oyo States, more than 90% of the women have had some form of female circumcision, compared with only 30% in Lagos, the capital.
- In states where type III FGM (infibulation or pharaonic circumcision) is practiced, it is done to preserve virginity. Type III FGM involves surgical removal of the whole of the clitoris, the labia minora, and part of labia majora, and the stitching together of the two sides of the vulva, leaving tiny openings for the flow of urine and menstrual products. In parts of Edo State, FGM is carried out on a woman when she is about seven months pregnant. In 1985-1986, over 30% of the women in Bendel and Imo States had infibulation.
- Type II FGM (called reduction or excision) involves removal of the prepuce and the glans of the clitoris, together with adjacent parts of the labia minora or the whole of it. People believe that if the head of a newborn baby touches the clitoris, the baby will die. In 1985-1986, Bendel and Imo States had, respectively, a 55% and a 60% prevalence of excision.
- Among the 1,300 individuals who reported performing female circumcision, only 5% were skilled health professionals.
- In some eastern parts of the country, FGM is carried out as part of a pubertal rite. In this case, the extent of mutilation varies, depending on the circumciser's "expertise" and associated beliefs.
- In the western parts of the country, FGM is performed for cosmetic reasons, the belief being that if the female genitalia, particularly the clitoris, is not trimmed, it will grow and elongate like a penis.
- In some areas, Type I FGM (*Sunna*), which involves the removal of the prepuce or foreskin of the clitoris, is performed. In 1985-1986, three quarters of reported female circumcisions were *sunna* circumcisions.

Some of the health consequences of FGM include: injury to surrounding body parts, severe bleeding, shock, fainting during the mutilation, infection, and the inability to pass urine. Other long-term health hazards include: tetanus, blood poisoning, infection to the urinary and reproductive

tracts, menstrual disorders, complications during childbirth, scar formation, painful sexual intercourse, and infertility because of fibrosis of the vagina. There is also a wide range of emotional and psychological effects, which may include embarrassment resulting from deformity of the vaginal area, anxiety and irritability, depression, marital problems of varying degrees, sometimes because of painful sexual intercourse, and psychosis as a result of frustration, particularly when one is unable to have intercourse.

Basically, FGM can be traced to a desire of the society to control female sexuality. Behind the various superstitions that perpetuate FGM, what seems to have sustained the practice is that men will not marry uncircumcised women, because they are believed to be unclean and promiscuous.

#### Male and Female Circumcision: A Regional/Ethnic Comparison

The following summaries of the attitudes and practices regarding male and female circumcision of several ethnic groups in eight geographical regions of Nigeria were compiled by the authors during a meeting with healthcare professionals in January 1999 (Francoeur, Esiet, & Esiet 2000) (see Editor's Note at the beginning of this chapter).

1. Regions: Ipoti-Ekiti, Oyo, Ile-oluji, and Yorubaland. Ethnic Group: Yoruba

Both male and female circumcision are traditional practices in Oyo State. Normally, circumcision is done in the first three months after birth. In the old days, one hardly heard of any complications, infections, or other harm to health. Now, because there are many incompetent people handling circumcision, we hear of complications, infections, and harmful effects. Some educated persons in the medical field now discourage female circumcision. In Yorubaland, male circumcision is generally practiced on the eighth day after birth. Male circumcision is accepted traditionally and is encouraged by the dominant religions in this region. In Ipoti-Ekiti, male and female circumcisions are usually carried out on the eighth day after birth. Female circumcision is practiced in some areas and not in others—in Ondo, Ilesha, and Ekiti towns, but not among the Ijebus. Female circumcision reduces a woman's sexual desire and the temptation to promiscuity. It also prevents the death of the child during delivery. It is believed that the child will die if its head touches the clitoris during birth. In Ile-oluji, female circumcision is an initiation into womanhood.

2. Regions: Kano, Katsina, and Kaduna. Ethnic Group: Muslim Hausa

Only male circumcision is practiced in these regions. Males are circumcised at age 6 to 7 years, when they realize that a male must endure pain. An elderly person, a *Wanzami*, carries out this procedure with locally made tools (*Aska*) and medicinal herbs. He begins with some incantations and digs a hole in the ground for the blood to flow into. He then holds the boy's legs apart with two sticks and circumcises him. Afterwards, the cloth the boy sat on, the soap used for washing hands by the *Wanzami*, as well as money and other gift items, are given to the *Wanzami* as presents. The circumcised boy is fed with special food and taken to a home different from his own to recover. The boy is showered with gifts from well-wishers and relatives. These days, the rate of infection from circumcisions has decreased, because the *Wanzami* now boil their instruments to disinfect them (although some infections still occur).

## 3. Region: Borno

Male circumcision is usually done sometime after age 7 years. Unsterilized instruments are used, leading to infections; excessive bleeding can result in death. Females are not circumcised but may participate in other traditional rituals.

## 4. Region: Tiv-Benue. Ethnic Groups: Tiv, Idoma, and Isala

Males are usually circumcised eight days after birth, but some are circumcised at age 4 or 5. Traditional leaders or ordinary people who have gained some skill in male circumcision perform this both in hospitals and in the villages. Males sometimes become infected as a result of poor hygiene.

## 5. Regions: Akwa-Ibom and the Cross River. Ethnic Groups: Efik and Ibibio

Among the Efiks and Ibibios, males are circumcised as babies. Female circumcision is done for aesthetic reasons, to avoid promiscuity, and to maintain virginity before marriage. People believe that if females enjoy intercourse, then they are likely to seek it from different men. Females may be circumcised during infancy or childhood, as a pubertal initiation, or just before marriage in "the fattening room," or not at all. Only the clitoral hood is removed. If done with unsterile instruments or by an inexperienced person, female circumcision can be harmful and life-threatening, or not at all. Some believe that female circumcision helps the fetal head descend smoothly during labor. In female circumcision, some practitioners drink illicit gin and spit it on the new wound; some use iodine on it, whereas others use a feather to spread fresh palm oil or engine oil to commence the healing process. Circumcision at birth has no rituals, but at other ages, feasting is usual for those who participate in the ritual as a sign of respect and acceptance or as initiation into the age group. Infections, tetanus, formation of keloids and fibrosis, extensive tears during labor, postpartum hemorrhage, social stigma, psychological trauma, and frigidity, are reported consequences of female circumcision.

## 6. Region: Delta State. Ethnic Groups: Uhobod, Ibos, Ijaws, Isaw, and Itsekirus

Males are usually circumcised within a few weeks of birth. Female circumcision is no longer common in some parts of the Delta. In other parts, however, it is still routinely practiced with a lot of importance attached. People see it as a sign of a girl's honor, a sign of maturity, a source of parental pride, and for the prevention of promiscuity. Usually the girl is between 13 and 21 years of age. In some areas, it occurs when the girl is expecting her first baby. In areas where female circumcision is common, the whole community celebrates and other young girls with their waists beautifully beaded come to stay with the circumcised girl for ten days. She does not do any work and is given tender, loving care by all. If she is engaged to a man, he comes to pay homage to the family, brings gifts, and helps the girl, including grinding her food. Depending on how it is done, both male and female circumcision can result in infection and other conditions that are harmful to health.

## 7. Region: Edo

Males and females are circumcised seven days after birth to reduce promiscuity. Even though new razor blades are used, males sometimes experience infections, wounds that do not heal, and excessive bleeding. Circumcision of females may interfere with normal

sexual desire. In some cases, female circumcision results in injury to the major and minor labia, or a vesico-vaginal fistula (VVF) that can lead to difficult delivery and other complications.

## 8. Regions: Imo, Enugu, and Anambra. Ethnic Group: Ibo

In Enugu and Anambra, males are circumcised eight days after birth. Previously, in certain areas, like Nsukka, female circumcision was practiced, but generally no longer. When performed for cosmetic purposes or to reduce promiscuity, female circumcision may be done with the low-risk orthodox method or a high-risk crude native method. Complications of the native crude method include infections, vesico-vaginal fistula, and the narrowing of the vaginal opening leading to painful intercourse. In Imo and Anambra States, a male child must be circumcised within eight days after birth. There are no rituals attached to male or female circumcision.

*[Mating Practices: Dry Sex and Wet Sex]*

*[Update 2001:* As noted earlier, in both Christian and Muslim cultures in Nigeria, sexual relations are male-dominated, with the male initiating and dictating the pace. Female response and satisfaction are not considered important. Coitus takes place with no foreplay. The male-above position is standard, and marital coitus is for procreation, not for pleasure. Women in many African cultures do not even know what female orgasm is, and have never experienced it. In describing mating customs in the chapter on Ghana, Augustine Ankoma reports that penile-vaginal penetrative sex with little foreplay is the normal sexual style. Although among the well-educated youth, some forms of foreplay are gaining a foothold, fellatio and cunnilingus are still abhorrent. Genital touches and caresses are hardly accepted, and, traditionally, women feel shy about touching the penis, and most men are not interested in having their genitals manipulated.

[Male-oriented cultural values, such as those in Ghana, Nigeria, and Kenya, are echoed throughout the traditional cultures of Africa. They underlie what is appropriately termed "dry sex," a common practice throughout sub-Saharan Africa. The "dry sex" mating behavior fits comfortably with the Nigerian/Ghanaian distaste for vaginal secretions, foreplay, and disinterest in female sexual arousal and orgasm. In this setting, males quickly reach orgasm and satisfaction. Women are left with painful intercourse, no arousal, and no orgasm.

[In many African cultures, women prepare themselves to pleasure their husbands with a dry vagina by mixing the powdered stem and leaf of the *Mugugudhu* tree with water, wrapped in a bit of nylon stocking, and inserted in the vagina for 10 to 15 minutes before intercourse. Other women use *Mutendo wegudo*, soil mixed with baboon urine, which they obtain from traditional healers. Still others use detergents, salt, cotton, or shredded newspaper. These swell the vaginal tissue, make it hot, and dry it out. The women admit that sexual intercourse is "very painful . . . , but our African husbands enjoy sex with a dry vagina" (Schoofs 2000).

[The inevitable results of "dry sex" include increased friction, vaginal lacerations, suppression of the vagina's natural bacteria, and torn condoms (when these are used). All these consequences increase a woman's risk of STD and HIV infections. Fortunately, the tradition of "dry sex" is waning among the educated urban young, but any change in this traditional mating behavior is also resisted, because of rejection of Western gender roles (Stellwaggon 2001). (*End of update by R. T. Francoeur*)]

[*Comment 2003*: In Africa, as in cultures elsewhere, there are certain sexual practices and topics that Africans simply do not discuss or acknowledge with non-Africans, because they are very sensitive, sometimes taboo, and many times very racially charged. Even within an individual tribal culture, some sexual topics and behaviors are not open for discussion between men and women, or between children and their parents. Unless one lives within a native community and becomes very, very close to the people, Africans balk at discussing these issues, and “dry sex” is one such practice.

[“Dry sex” is not something new. It is a well-established and more or less widespread practice in various subequatorial African cultures. It is very common in Southern Africa, particularly in Zimbabwe, Zambia, Malawi, some parts of Nigeria, some parts of Uganda, in Southern Sudan, and even in Kenya and Botswana. The only difference is in what the women use for drying up their vaginas. However, you will never hear about these practices unless you are a woman who lives within the community for some extended time and the women learn to trust you.

[Personally, as I was growing up in the rural town of Kisumu, Kenya, there were many practices and myths that we were taught by our peers and even older women that we were to do to attract men. Some of these practices were good, but some I do not feel comfortable talking about to this day. We were told that if you want your breasts to grow fast, you had to rub a certain poisonous leaf on your breasts or let boys touch them so that you could have them grow faster and more round. Many African men like women with large buttocks as well. As a result of this, many girls tried to do whatever they could to have big buttocks. One technique to accent the buttocks was to tie their belt so tight that the lower parts of their body stood out.

[Even today, many African men have three to five wives. These women compete among themselves to be the best cook for the man of the house, or the best in bed. Some women consult traditional healers and witchdoctors who sell them love portions so they can outdo their co-wives. Some of these love portions come in the form of soil mixed with baboon urine, or even salt, that women use before they have sexual intercourse with their husband. It is the traditional healers who teach these women about the importance of drying their vaginas as a way to please their husbands. These concoctions also make their vaginas swell and become very hot, making it tighter so that when a man inserts his penis, he feels “big” and, therefore, a “real man.”

[Until recently, very few people knew about these practices. Unless one grew up in the village or became very, very close to the people, you can never know what goes on. As the HIV/AIDS epidemic devastates subequatorial Africa and non-Africans have become aware of female genital mutilation, taboos about other sensitive sexual practices have weakened. Mark Schoofs (2002) discussed the implications of dry sex in the spread of AIDS in his eight-part Pulitzer Prize-winning report on “AIDS: The Agony of Africa. Death and the Second Sex”; see also Stillwaggon (2001). In the section below, the main authors of this chapter, Uwen Edimo Esiet, a public health physician, and his wife Nike Esiet, M.P.H, a former public relations officer for the Society for Women and AIDS, raise the issue of “salt cuts.” But these new insights into the complexity of the HIV/AIDS epidemic only came after considerable trust was achieved.

[In the northwest part of Tanzania and neighboring regions, “wet sex” is widely known and practiced. “Wet sex” consists of foreplay where there is intense stimulation by the male partner on the woman’s labia and clitoral regions.

This stimulation results in copious production of secretions (thought to come from the Bartholin’s glands). People talk about it openly, sometimes mixed with a sense of humor and intertribal jokes. Some researchers have blamed this practice for the high incidence and prevalence of HIV and STDs. The implications of this kind of information for action plans (resource inputs and sociocultural issues) are enormous. Now that these behaviors have been brought into public attention, a well thought-out survey that is representative of different segments of the populations becomes essential for an effective public health policy (Tanzania Personal communication 2003).

In March 2003, when Francoeur, coeditor of this *Encyclopedia*, inquired whether “dry sex” was observed in Botswana, Dr. Ian Taylor replied; “‘Dry sex’ is common in Botswana as well and leads to vaginal tears and lesions which help spread HIV/AIDS, it is true.” (*End of comment by B. Opiyo-Omolo*)

#### Yankan Gishiri or Salt Cut

This traditional “cure,” practiced mainly in the northern part of Nigeria by the Hausa in Kaduna, Kano, and parts of Borno, involves a different kind of mutilation of the female genitalia. It is a traditional surgical cut in the vaginal wall of a woman who has been diagnosed by a traditional healer or traditional birth attendant (TBA) to be suffering from *gishiri* disease. *Gishiri*, a Hausa term, refers to a wide range of conditions or symptoms, including: pruritis vulvae (itching vulva), amenorrhea (absence of menstruation), infertility, obstructed labor, anemia, malaria, and any condition that presents the symptoms of headache, edema, fainting attacks, or dyspareunia (painful intercourse). Unfortunately, health workers have found it difficult to associate *gishiri* with any clinical condition.

The “salt cut” is usually made on the anterior vaginal wall; repeated cutting over a period of time may extend the incision area to the posterior vaginal wall. The *gishiri* cut is also performed when certain changes occur during pregnancy, such as hypertrophy of the vaginal muscle and vaginal discharge. The cut is performed by a traditional birth attendant (TBA) or healer, few of whom are knowledgeable of the anatomical structure of the area they are cutting. There is no scientific basis for the *gishiri* cut, and despite the fact that it effects no cure, the practice goes on unabated. A *gishiri* cut leaves behind both immediate and long-term health complications, such as hemorrhage, infection, shock, and scar formation. Some of the most debilitating effects include a breakdown in the wound-healing process. This is caused by repeated cuttings, which can be done anytime any of the above-mentioned symptoms surface. Damage can also be done to the bladder, leading to vesico-vaginal fistula (VVF) or damage to the rectum causing recto-vaginal fistula (RVF).

This practice, which has no benefit whatsoever, illustrates the minimal value placed on female sexuality in Nigeria. No Nigerian male would suggest similar pelvic cuts to cure symptoms of *gishiri*, which occur as often in males as in women.

#### Other Traditional Practices Harmful to Women

There are widespread cultural practices in Nigeria that pose serious health concerns to female victims and can be classified under gender harassment. Some of these include: nutritional taboos associated with pregnancy, childbirth, lactation, and the six weeks following childbirth; forced feeding; rites associated with widowhood; preferences for a male child; inheritance rights; hot bath during the six weeks following childbirth; and discrimination against female

infertility, to name a few. In each of these, depending on the ethnic region, women are pressured to go through harmful practices in order to satisfy societal biases.

In the case of nutritional taboos, pregnant women are forbidden to eat specific foods that are rich in vitamins and protein because of the erroneous belief that such foods reduce contraction strength during labor. Other vital foods are prohibited during puerperium for other superstitious beliefs. For example, eating of salt and pepper or palm oil are forbidden for at least seven to nine days after birth, depending on the baby's sex. Some communities forbid breastfeeding, whereas others forbid eating of all kinds of nuts for fear of hemorrhoids. As expected, none of all these taboos has any scientific basis.

Forced feeding is a traditional practice whereby an adolescent is made to eat with the intention to fatten her up. This practice occurs during pubertal rites in preparation for marriage. This practice occurs also in areas where it is not acceptable for a man to marry a slim woman. The weight of the woman, not her personality or other characteristics, is the basis of choice. Unfortunately, the women who are subject to this practice live an obese life with all the health risks thereof.

Widows in some parts of Nigeria are forced to go through various dehumanizing rituals that can affect their physical and psychological health. These include sleeping on a concrete floor for upwards of 40 days to three months after their husbands' death, drinking the water used to bathe her husband's corpse, and the shaving of her hair, among others. Another form of gender-based cultural belief is the preference for a male child. A male child gets all the family attention, including educational opportunities. The female child, on the other hand, is forced to assist in all domestic chores while the male child is free to play.

The widely documented gender biases and discriminatory harm to Nigerian women resulting from the prevalence of violence and abuse against women, and the fact that few such cases are reported, and fewer still are addressed appropriately in the legal system, clearly indicate that there is a serious need for more research into the factors that favor these acts in order to be able to develop appropriate strategies and programs to combat the resultant problems. Health professionals also need to be exposed to specialized training that will enhance their knowledge when dealing with such cases. There is a need for special counseling units in health institutions where victims can be assisted. More non-governmental organizations (NGOs) in Nigeria need to focus on these unconventional behaviors, with the aim of helping victims to seek redress, as well as combating the problems. The underlying cultural beliefs and social structures that perpetuate these behaviors must be challenged. NGOs should also sponsor laws that criminalize these behaviors in a more direct manner than the present legislation does, which glosses over them.

### [Sexual Rights and Sharia Death Penalties

[Update 2003: Since 1999, more than a dozen states in predominantly Muslim northern Nigeria have adopted Islamic law or *Sharia*, with its penalty of death-by-stoning for those convicted of fornication, adultery, rape, and other crimes. Since 2000, local Muslim courts in northern Nigeria have sentenced several women, and men, to death-by-stoning after they were convicted of fornication, adultery, or rape. In Sokoto State, on March 22, 2002, a *Sharia* court of appeals dismissed, on technical grounds, a death-by-stoning sentence for Safiya Hussaini Tungar-Tudu, a 33-year-old mother of five convicted of adultery (Sengupta 2003).

[The most celebrated case, which captured international attention in 2002 and 2003, was that of Ms. Amina Lawal

Kurami, a 31-year-old divorced mother living in her father's house in Kurami. When someone reported she had borne a child out of wedlock, the man she identified as the father of her child denied the charge and swore to his innocence on the Holy Qur'an. The court accepted his oath as proof of his innocence and her guilt—under Qur'anic law, the only way Ms. Lawal could have proven her allegation would have been to produce four eyewitnesses of the fornication. The court postponed her execution until she weans her child in 2004.

[In an October 2, 2002, radio and television broadcast marking Nigeria's 42nd anniversary of independence, President Olusegun Obasanjo said that Ms. Lawal and others under sentence of death-by-stoning should appeal their Muslim court decision to Nigeria's Supreme Court, where they will be guaranteed justice. Nigeria's Constitution bans capital punishment. "We have never entertained doubts that whatever verdict a lower court may give, the appellate courts will ensure that justice is done. We fully understand the concerns of Nigerians and friends of Nigeria, but we cannot imagine or envision a Nigerian being stoned to death. It has never happened. And may it never happen" (*Agence France-Presse* 2002; Sengupta 2003).

[In late 2002, Muslim opposition to holding the Miss World contest in Abuja, the Nigerian capital, erupted across northern Nigeria. Ensuing riots in nearby Kaduna left an estimated 220 dead and 400 injured. To prevent further deaths, the contest was moved to London, where there was a pause in the show at the contestants' request in tribute to Ms. Lawal, then under sentence to death by stoning. Once before, in 1996, the Miss World contest provoked violence in Bangalore, India, when police fired teargas and rubber bullets at stone-throwing protestors (Hoge 2002).

[Nigeria's position as Africa's largest nation and a secular democracy guarantees that however these conflicts between religious freedom and secular democracy are resolved, such conflicts will continue in this age of transition in Nigeria and in other African nations. (*End of update by B. Opiyo-Omolo*)]

## 9. Contraception, Abortion, and Population Planning

### A. Contraception

#### *Contraception among the Hausa*

BILKISU YUSUF and RAKIYA BOOTH

Hausa society frowns on too-frequent and poorly spaced pregnancies (*Kwanika*), and nursing mothers who get pregnant before they wean their babies are sometimes derided. There are many traditional methods of contraception among the Hausa, such as *rubutu*, Qur'anic verses written on a wooden slate (*allo*) with black ink (*tawada*), which is washed off with water that is then administered orally. Others include *guru*, a string of leather, which the woman wears around her waist, and a Qur'anic verse written on a sheet of paper, bound with leather and worn as an amulet. No research has yet been conducted on the efficacy of these contraceptive methods. However, the Hausa practice one of the surest methods of contraception, voluntary abstinence from sexual intercourse. The pregnant Hausa wife leaves her husband's house to live with her parents when her pregnancy reaches an advanced stage, usually seven months; she remains there until she delivers. During this period, known as *goyon ciki*, the young mother is given lessons in pregnancy management, breastfeeding, and childcare. The length of the stay varies from 40 days to several months, while some remain in their parents' home until the child is weaned. Voluntary abstinence from sexual intercourse pro-

motes child spacing. *Goyon ciki* has no basis in Islamic jurisprudence.

Islam recommends contraception, not through voluntary abstinence from sexual intercourse as *goyon ciki* promotes, but by breastfeeding their babies for two years. The *Hadith* also recommends *azl* (coitus interruptus) as a method of preventing pregnancy by mutual consent of the couple.

According to scholars of the Federation of Muslim Women's Associations in Nigeria (FOMWAN), family planning, which is permissible in Islam, should be geared towards child spacing to promote the health of the mother, rather than limiting childbirth out of the fear of poverty. Family planning can only be practiced with the full agreement of both spouses, who are free to choose any suitable method. FOMWAN specifically prohibits all methods that are harmful to the body, such as oral contraceptives, sterilization, and the injectibles. Condoms are recommended in addition to coitus interruptus (the *azl* recommended by the *Shariah* (Muslim laws and governance).

According to the Nigerian Demographic and Health Survey of 1990, nationwide, 5.9% of 15- to 19-year-old females currently use contraception. Two thirds use traditional methods, including rhythm and withdrawal. One percent uses oral contraceptives, less than 1% uses condoms, foaming vaginal tablets, or IUDs.

## B. Teenage Pregnancies and Hausan Maternal Health Practices

BILKISU YUSUF and RAKIYA BOOTH

Teenage marriage poses some health problems for Hausa society. When the husband of a young girl marries a man who is not patient enough to wait before consummating the marriage until she has matured and her body has fully developed, she runs the risk of getting pregnant before she is old enough to take care of the child. These minors, especially in the rural areas, are susceptible to superstitions. Pregnant teenagers living in the rural areas cannot attend pre- and postnatal clinics, and, where poverty and ignorance are rampant and healthcare facilities either not available or affordable, these young girls are left solely in the hands of untrained, traditional birth attendants (*Ungorzoma*).

There is a sociocultural preference for home delivery among the Hausa, and most husbands are adverse to the idea of male healthcare personnel attending to their wives. With the onset of labor, these girls are supposed to observe *kunya*, exhibit bravery and silently endure pain. It is considered shameful among the Hausa for women to cry, shout, or express pain during labor (*Nakuda*) and childbirth (*Haituwa*). Yet, protracted labor lasting for days is quite common. The local preventive measure is to give the pregnant woman one of several bitter herbal mixtures that prevent development of *zaki* (amniotic fluid). Literally translated, *zaki* means "sweet." There is a widespread superstition among Hausa that *zaki* obstructs delivery. Hence, pregnant women drink bitter herbs or *tsamiya* (tamarind) soaked in water to reduce the amniotic fluid, and thereby ease labor pains and hasten childbirth. They are also advised to avoid eating sweet foods in order to control *zaki*. This web of cultural practices does not ease the protracted labor nor the trauma most pregnant girls undergo.

Local birth attendants cannot handle other complications of pregnancy, such as eclampsia, which requires monitoring of the blood pressure, and pelvic malformations, which require a cesarean operation. These complications go undetected and often lead to the death of the mother and child; the Nigerian infant mortality rate is 70 to 87 per 1,000

live births. Use of unsterilized instruments by the local birth attendants also leads to life-threatening infections. In some cases, the placenta is not expelled after childbirth, leading to hemorrhaging, infection of the uterus, and death. When a lot of blood is lost, local birth attendants are ill trained and unequipped to provide blood transfusions. Cases of retained placenta and hemorrhage are often referred to hospitals from the rural areas when the patient's situation is critical and hopeless. The 1995 statistics released by the National Council for Population and Environmental Activities (NCPEA) show that Nigeria's maternal mortality rate of 15 per 1,000 births is one of the highest in the world. Teenage girls also account for almost 25% of maternal deaths in Nigeria.

Certain Hausan practices also lead to maternal morbidity. During labor, particularly a prolonged one, the local birth attendant performs a local episiotomy to facilitate delivery of the baby. These *gishiri* cuts are incisions made by the local midwife to cut off membranes in the vaginal region during labor, oftentimes using unsterilized instruments. Subsequent infection and the extension of the cut to the anal and urethral areas may damage the muscles that control the passage of the urine, resulting in a vesico-vaginal fistula (VVF). VVF research by Lawanson (1993) has revealed that the Hausa also believe that, in addition to facilitating childbirth, *gishiri* cuts also alleviate amenorrhea, infertility, and painful intercourse. However, these VVF patients often experience involuntary seepage of urine, a defect that requires a costly and complicated operation to correct. (See additional discussion in Section 8D, Significant Unconventional Sexual Behaviors, Female Genital Mutilation and Other Harmful Practices, above.)

Many pregnancy complications go untreated because of inadequate medical facilities and sometimes ignorance on the part of the patients, who fail to seek hospital treatment. Those who do seek treatment at a hospital usually compete for treatment, waiting for years for their turn. The seepage of urine makes the VVF patients undesirable, and they are often abandoned in hospitals or treated as outcasts by their families, especially husbands who desert them. These women, most of them in their teens, are thus condemned to living a life of misery. There are currently 200,000 reported cases of VVF in the country, with a heavy concentration in the northern states of Kano, Jigawa, Katsina, Sokoto, and Borno. Several cases have also been reported in the southern Nigerian state of Akwa Ibom.

## D/E. Abortion and Population Planning

FOYIN OYEBOLA and UWEM EDIMO ESIET

Abortion is a criminal offense in Nigeria except when the life of the woman is endangered by the pregnancy. It is not, therefore, an approved method of population planning and family limitation. Nevertheless, the abortion rate is high in Nigeria. Unsafe illegal abortion is one of the leading causes of maternal death in women of reproductive age. Also, abortion affects adolescent women who lack basic information about reproduction and the prevention of pregnancy, as well as the information and resources necessary for obtaining safe abortions. [F. Oyebola]

The Campaign Against Unwanted Pregnancy (CAUP) conducted a study recently in collaboration with the Alan Guttmacher Institute of the United States of America, focusing on the incidence of induced abortion in Nigeria ("Incidence of Induced Abortion" 1998). In each year studied, Nigerian women obtained approximately 610,000 abortions. Most of these women resorted to abortion as an outcome of an unwanted pregnancy. Sixty percent of the abortion seekers were age 15 to 25 years old, with a third of them

being students, and 63% never being married. The study recommended better policies to improve access to contraceptive services to reduce unwanted pregnancy and abortion, as well as greater access to safe abortion to help preserve the health and lives of Nigerian women. [F. Oyebola]

Abortion has continued to generate controversy in Nigeria. Whereas Nigeria has one of the highest maternal mortality rates in the world, over 800 maternal deaths per 100,000 women, consensus as to how the issue of abortion should be addressed has not been agreed on. The 1998 report by the Campaign Against Unwanted Pregnancy mentioned above further corroborated this need. Thus far, the government has not taken appropriate steps to address this scourge, preferring the ostrich approach of burying its head in the sand and wishing the problem were over. There is no doubt that contraceptive usage is low, especially among adolescents, and that sexual ignorance is very high, with about 60% of Nigerian youth not knowing that pregnancy is possible at first intercourse. [U. E. Esiet]

In a 1994 countrywide report submitted by the Federal Ministry of Health and Social Services, Nigerian adolescents accounted for 80% of Nigeria's unsafe abortions. The government has responded to Nigeria's high fertility rate of six children in a woman's lifetime by formulating a National Policy on Population for Development, Unity, and Self-Reliance. Unfortunately, this 1988 document is not gender-sensitive. It recommends that each woman should have no more than four children, and that the minimum age for female marriage be 18 years. The document is silent on the age of marriage for men, and takes no notice of the well-known fact that many men have more than one wife and, therefore, father more than four children in their lifetime. Also, the issue of reducing early marriage is not supported by any appropriate legislation, education, or mass mobilization. It is obvious that the gender-interest perspective was not utilized in making this policy—not unexpected in a patrilineal society. Attempts have since been made to link population with Family Life Education in a POP/FLE effort (see Section 3A, Sexuality Knowledge and Education, Sexuality Education). In 1999, this resulted in a paradigm shift on the federal level, with a reproductive health strategy that addresses the people's needs primarily, and then hopes that this will empower the people to address the population issue. All of these strategies are going to be within the framework of a primary healthcare strategy. It must be acknowledged that government has done much within its new purview, without ignoring the fact that still more needs to, and can be done. Civil societal groups, especially the NGOs, have continued to make family planning services available, accessible, and directed at people's needs. [U. E. Esiet]

## 10. Sexually Transmitted Diseases and HIV/AIDS

### A. Sexually Transmitted Diseases

Data on sexually transmissible diseases (STDs) in Nigeria are limited. The prevalence of syphilis among antenatal clinic attendees in 1993 from sentinel surveillance was 3.8%.

STD clinics are underutilized because of stigmatization and the lack of appropriate facilities and specialists in STD management. Manuals for training health workers, and for syndrome management, have been produced with the support of donor agencies and specialists. Several health workers have been trained, and others are being trained to use these manuals. Appropriate drugs and condoms have been made available, and information and education about STDs is being incorporated into Primary Health Care facilities. It

is, however, important for Nigeria to have baseline data, so that adequate and appropriate planning and education can be carried out.

Government support has been far below expectations, and it is hoped that NGOs will participate more actively in the near future in Information, Education, and Communication (IEC) activities and training.

Recommendations from various workshops and meetings are that measures aimed at control and prevention should be integrated into other development projects, such as Family Planning and Maternal and Child Health Services. This will ensure that women and children with STDs are treated in the same clinic by the same service provider in one hospital visit. Nigeria needs intensive IEC advocacy and mobilization of specific groups. We also should promote the best practices as a concept and as a tool for effective and expanded responsiveness to STDs (Family Health International 1996; UNAIDS 1994).

### B. HIV/AIDS

UWEM EDIMO ESJET

#### *The Current Status*

Nigeria reported its first case of AIDS in 1986. However, based on the most recent published data by the National AIDS and STD Control Programme, Nigeria can now be identified as a major locus of HIV infection in sub-Saharan Africa, with a national seroprevalence rate of 4.5%. The progression has been 1% in 1990, 1.2% in 1991-1992, 3.8% in 1991-1992, and 3.8% in 1993-1994. It has been estimated that one new infection of HIV occurs every minute in Nigeria. Esiet cites data suggesting that 95% of all infections are by heterosexual intercourse, 4% are through blood transfusions, and 1% are through mother-to-child transmission. Nigerian population surveys from both urban and rural areas indicate a seroprevalence rate of 5 to 8% in the general population, with a preponderance of HIV infection in females age 15 to 19, whereas for males, the peak age is 20 to 29 years old (WHO 1997; National Symposium 1998; Lagos State Seminar 1999).

Data from population and hospital-based studies indicate that about 80% of HIV transmission occurs through heterosexual intercourse while 10% occurs through blood transfusions. Vertical transmission (mother-to-child) is also becoming a significant route with the increase of HIV prevalence among women of reproductive age.

Factors responsible for the rapid spread of HIV in Nigeria include:

- low-risk perception, especially among youths;
- cultural and religious attitudes, which make it difficult for women to make decisions about reproductive health issues;
- myths and misconceptions about HIV/AIDS;
- the worsening economic situation;
- low acceptability, availability, and use of condoms;
- lack of appropriate medical care for STDs, opportunistic infections, and AIDS;
- lack of data management for planning and decision making; and
- lack of voluntary testing and counseling services.

All these factors mitigate against the behavioral changes needed for a decrease in the incidence of HIV/AIDS in Nigeria. At the same time, government efforts at all levels to address the epidemic over the past ten years have been grossly inadequate, and certainly not commensurate with the magnitude of the problem (Akinsete et al. 1997, 1999; Akanmu & Akinsete 1999; Federal Ministry of Health 1999).

Many NGOs are involved in the fight against HIV/AIDS, especially in the areas of information, education, and

communication, and a few are involved in home-based care for people living with HIV/AIDS. However, their resources are limited, although several donor agencies support many of them. Sustainability of programs is a major problem.

The government response has included formulation of a National Policy on HIV/AIDS, the syndrome management of STDs, sentinel surveys, massive mobilization and AIDS awareness, and a national conference on HIV/AIDS, at which programmatically workable solutions were addressed. It must be acknowledged that despite all these efforts, HIV/AIDS programs continue to remain underfunded. However, NGOs have also been complementing government efforts in all areas that include IEC and service provision to people with HIV/AIDS. Despite all these efforts, a lot of Nigerians have yet to be reached with the appropriate information and support necessary to bring about altered behavior changes. Condom use is still low, and the abilities of women to negotiate safe sex also low. Even though it has been introduced, the female condom is quite expensive when viewed from the income level of the people.

#### *Gaps, Future Challenges, and the Way Forward*

Nigeria is still going through a phase characterized by denial, stigmatization, panic, and political instability. The financial and material resources committed by the government fall far below the level required to adequately and effectively deal with the magnitude of the HIV/AIDS epidemic in Nigeria. AIDS cuts across all aspects of life, and therefore, the responses must be multisectoral and multidisciplinary (National Conference 1998).

There is a need to intensify advocacy at all levels, private, public, and community, and to prioritize responses. The priorities for action are:

- Promoting rational responses and priority-setting by the government, NGOs, and donor communities based on knowledge and information (accurate data) rather than anecdotes and prejudice. This makes it imperative that accurate assessment of the magnitude of the problem be undertaken for planning and decision making.
- Assembling usable economic data and knowledge to facilitate decisions about where best to spend limited resources.
- Advocating for appropriate budget allocations for HIV/AIDS/STD activities by the government at all levels and by donor agencies.
- Ensuring that there is a fair spread of resources allocated for HIV/AIDS/STD, which includes both prevention, care, and support activities by all stakeholders.
- Promoting the care and support agenda by government, donors, the community, traditional healers, and the public and private health sectors.
- Linking care with prevention at all levels.
- Encouraging private-sector sensitization, advocacy, and mobilization in support of intervention programs in the workplace.
- Increasing acceptability, availability, and access to condoms through condom social marketing supported by government and donor agencies.
- Finding funds to support Health Care Systems in dealing with conditions that increase vulnerability to HIV/AIDS, e.g., sexually transmitted diseases (STD), tuberculosis (TB), and malnutrition, through capacity-building for medical personnel. The promotion and support of such services, and their integration into reproductive health services, are necessary.
- Identifying and supporting income-generating activities and credit plans to reduce vulnerability to the poverty that accompanies and abets the epidemic.

- Promoting activities aimed at addressing issues of gender inequality, e.g., developing negotiation skills for women, knowledge of human rights, and income-generating projects for women.
- Providing access and linkages to counseling services and other activities that address the emotional and spiritual needs of both adults and children.
- Supporting and catalyzing groups of people living with HIV and AIDS, and encouraging their involvement in HIV/AIDS programs.
- Supporting activities that advocate legal rights for HIV/AIDS-affected persons, particularly women and children. AIDS intervention must address issues that promote the marginalization of some sectors of the society, thus increasing their vulnerability.
- Recognizing the rights of all individuals to care, as well as legal, economic, and inheritance protection.
- Encouraging accessibility and affordability of drugs for treatment of opportunistic infections and antiretroviral drugs.
- Preventing vertical transmission through breastfeeding.
- Preventing the transmission of HIV through blood transfusions by educating and recruiting voluntary non-remunerated blood donors, screening of blood for HIV, and the training of personnel.
- Promoting programs that are integrated into other routine activities, e.g., schools, cultural and media reporting, agricultural extension programs, and so on, because these are more effective in internalizing the epidemic than programs specifically focused on AIDS.

#### *Conclusion*

As the HIV/AIDS epidemic continues to spread worldwide, we are learning more about how individuals, households, families, communities, organizations, government, and the nation are affected. Strategies to prevent the spread have been focused on the promotion of condoms, the reduction of multiple sexual partners, and the treatment of STDs.

Many of these interventions have failed to address the social, economic, and gender issues, as well as the care and support of persons living with HIV/AIDS, adolescent reproductive health, and the disabled. Future interventions need to take into consideration all these factors in all planning. There is a need to be forward-looking, if responses are to keep pace with the speed and impact of this epidemic.

Evidence from different countries, not just industrialized nations, has clearly shown that prevention works. In Nigeria, we need a multisectoral, multidisciplinary approach, as well as political commitment at all levels of our government.

[Update 2002: In late 2002, a special National Intelligence Council meeting, convened by the independent Center for Strategic and International Studies, identified Nigeria as one of five countries facing devastation by a second wave of HIV/AIDS infections, with famines, civil wars, and economic reversals predicted. The projection was for the collapse of social and political institutions in Nigeria, Russia, China, India, and Ethiopia by 2010 (see Table 1; Garrett 2002).

[Nigeria and Ethiopia are pivotal to the future of Africa, because of their large populations and strategic influence. Nigeria, the world's sixth-largest oil producer with a sizable well-educated elite, is second only to South Africa in military, cultural, economic, and intellectual influence over the continent. According to the director of Nigeria's AIDS control programs, about 6% of the population was infected in 2002, with an infection rate over 15% among 15- to 30-year-olds in some areas. Experts also predicted a growing orphan population. Nigeria and Ethiopia are home to 130

million and 64.5 million people, respectively, or about half of Africa's total population. Considered the most strategically important country in West Africa because of its large population and vast oil reserves, Nigeria is experiencing a rapidly growing heterosexually transmitted HIV epidemic. By 2010, experts predict that 11% of Nigerian children will be orphans, 40% of them because of AIDS. (*End of update by R. T. Francoeur*)

[*Update 2002: UNAIDS Epidemiological Assessment: Median HIV prevalence in Nigeria has steadily increased from 1.8% in 1991 to 5.8% in 2001. In 2001, the range of HIV prevalence from 85 sites across the 36 states and the Federal Capital Territory was from 0.8% to 16.4%. Twenty-one out of the 86 sites were rural, where HIV prevalence ranged from 2.2% to 16%; the sites with the highest prevalence in the 2001 sentinel survey were both rural. In 2001, HIV prevalence among the 15- to 19-year-old antenatal clinic attendees tested was 5.9%, among the 20- to 24-year-olds, the rate was 6.0%, and among the 25- to 29-year-olds, 6.3%. Of the antenatal clinic attendees who were HIV-positive in 2001, 97.5% had HIV-1, 0.4% had HIV-2, and 0.1% had both HIV-1 and HIV-2 infection. In the major urban areas, HIV prevalence among antenatal clinic attendees has increased from 1% in 1991 to nearly 5% in 1999; in 1999, HIV prevalence ranged from 3% to 8%. Median HIV prevalence among antenatal clinic attendees tested at sites outside the major urban areas increased from less than 1% in 1991-1992 to 5% in 1999; the range of HIV prevalence rates went from less than 1% to 21%. In 1999, peak infection occurred among those women less than 25 years, where 6% were HIV-positive. Categorization of HIV-prevalence data by major urban and outside major urban areas was not available for 2001. No antenatal clinic surveillance survey was conducted in 2000.*

[Two percent of sex workers tested in Lagos in 1988 to 1989 were HIV-positive, increasing to 12% in 1990-1991; by 1993-1994, 30% of female sex workers tested were HIV-positive. In 1991-1992, sex workers tested in seven sites outside of the major urban centers had a median HIV prevalence of 13% with a range of 0% to 44%. By 1995-1996, 15 sites were reporting a range of prevalence among sex workers of 7% to nearly 70% of sex workers tested. In 1994, 5% of STD clinic patients tested in the major urban areas were HIV-positive. HIV prevalence among STD clinic patients tested from 21 sites outside of the major urban areas increased from 7% in 1993-1994 to 12% in 1995-1996; in 1995-1996, HIV prevalence ranged from 1% to 70%. In 2000, median HIV prevalence among STD patients tested in a survey covering 10 states was 11.5%, with a range of 5.6% to 23%. In 1993-1994, 4% of long-distance truck drivers tested in Anambra State were HIV-1 infected. Among the TB patients tested in the 2000 survey, median HIV prev-

alence was 17%, ranging from 4.2% to 35.1%. In 2000, HIV prevalence among IV-drug users surveyed was 8.9%; among non-injection drug users, the rate was 10%.

[The seroprevalence of syphilis among antenatal clinic attendees tested at 72 sites in 1999 was 2.3%, while in 2001, the seroprevalence of syphilis from 86 sites ranged from 0.3% to 2.99%.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	3,200,000 (rate: 5.8%)
Women ages 15-49:	1,700,000
Children ages 0-15:	270,000

[An estimated 170,000 adults and children died of AIDS during 2001.

[At the end of 2001, an estimated one million Nigerian children under age 15 were living without one or both parents who had died of AIDS. (*End of update by the Editors*)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

UWEM EDIMO ESIET

The introduction of Viagra has opened up a public discourse on sexual dysfunction by providing a new, effective therapy for the primary sexual-dysfunction concern of Nigerian males, functional impotence. In Nigeria's traditional societies, many therapies have long been available to most Nigerians for dealing with functional impotence and other sexual dysfunctions. Some of these remedies have already been described by Bilikisu Yusuf in Section 5D, Interpersonal Heterosexual Behaviors, on aphrodisiacs. The efficacy of these traditional remedies has yet to be clinically ascertained. Sexual dysfunctions of women are hardly discussed, because, for the majority of Nigerians, the prime objective of sexual intercourse is not sexual pleasure but procreation. Therefore, the issue of counseling and therapy is not as profound as it should be in our society. Professionals need to educate the Nigerian public about sexual dysfunctions other than male erectile dysfunction, so that both men and women will seek appropriate counseling and therapies. Hopefully, as the study of human sexuality and sexology becomes more developed in Nigeria, challenges such as these will be addressed.

## 12. Sex Research and Advanced Professional Education

There is no sexological organization or publication in Nigeria. Nor is there any basic research unless it has practical health applications that address the major health issues facing our nation. The contributors to this chapter gained their expertise from training abroad, including the International Women's Health Coalition in New York (USA), and from their extensive fieldwork among the people.

Nigeria has three organizations that deal with sexuality issues. These are:

Action Health Incorporated, Youth Center, Plot 54 Somorin Street, Ifako, Gbagada, Lagos, Nigeria; Tel./Fax: 234-1-861-166; [AHI@linkserve.com.ng](mailto:AHI@linkserve.com.ng).

Association for Reproductive and Family Health (ARFH), 13 Ajayi Osungbekun Street, Ikolaba GRA, Ibadan, Nigeria; Tel.: 234-1-820-945.

Planned Parenthood Federation of Nigeria, 224 Ikorodu Road, Palmgrove, Somolu, PMB 12657, Lagos, Nigeria; Tel.: 234-1-820-526.

## Demographics and a Brief Historical Perspective

ROBERT T. FRANCOEUR

### A. Demographics

Norway occupies the western half of the Scandinavian peninsula, stretching about 1,100 miles (1,770 km) from the North Sea in the south along the Norwegian Sea to 300 miles (480 km) above the Arctic Circle, the farthest north of any European country. Slightly larger than the state of New Mexico, Norway's eastern neighbor is Sweden, with borders on Finland and Russia in the northeast. Nearly 70% of Norway's 125,180 square miles (324,220 km<sup>2</sup>) is uninhabitable, covered by mountains, glaciers, moors, rivers, and deep fiords cut into the coastline of 12,000 miles (19,300 km). Along the western coast, nearly 50,000 islands form a breakwater and safe coastal shipping channel. Norway also administers four largely uninhabited island clusters, Svalbard in the Arctic Ocean with a declining population of about 3,000, Bouvet Island south of the Cape of Good Hope, Jan Mayen Island between Norway and Greenland, and in Antarctica, the region of Queen Maud Land and Peter I Island.

In July 2002, Norway had an estimated population slightly over 4.5 million. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 20% with 1.06 male(s) per female (sex ratio); 15-64 years: 65% with 1.03 male(s) per female; 65 years and over: 15% with 0.71 male(s) per female; *Total population sex ratio:* 0.98 male(s) to 1 female

*Editors' Note:* Because of space constraints in volume 4 of the *International Encyclopedia of Sexuality* published in 2001, the original chapter on Norway, like Hong Kong, was not included. Instead, the Editors published them as "Supplemental Countries on the World Wide Web" at <http://www.SexQuest.com/IES4/>.

(CIA 2002)

**Life Expectancy at Birth:** *Total Population:* 78.94 years; *male:* 76.01 years; *female:* 82.07 years

**Urban/Rural Distribution:** 73% to 27%

**Ethnic Distribution:** Norwegian (Nordic, Alpine, and Baltic); Sami (Lapps): 20,000

**Religious Distribution:** Evangelical Lutheran: 86% (State Church); other Protestant and Roman Catholic: 3%; other: 1%; unaffiliated or unknown: 10% (1997 est.)

**Birth Rate:** 12.39 births per 1,000 population

**Death Rate:** 9.78 per 1,000 population

**Infant Mortality Rate:** 3.9 deaths per 1,000 live births

**Net Migration Rate:** 2.1 migrant(s) per 1,000 population

**Total Fertility Rate:** 1.8 children born per woman

**Population Growth Rate:** 0.49%

**HIV/AIDS** (1999 est.): *Adult prevalence:* 0.01%; *Persons living with HIV/AIDS:* 1,600; *Deaths:* 8. (For additional details from [www.UNAIDS.org](http://www.UNAIDS.org), see end of Section 10B.)

**Literacy Rate** (*defined as those age 15 and over who can read and write*): 100%; education is free and compulsory from age 6 to 16

**Per Capita Gross Domestic Product** (*purchasing power parity*): \$30,800 (2001 est.); *Inflation:* 3.1%; *Unemployment:* 3.6%; *Living below the poverty line:* NA

### B. A Brief Historical Perspective

The ancestry of Norwegians, like the Danes and Swedes, has been traced back to early Germanic or Teutonic tribes that settled in the Jut Land, the Danish peninsula, in the 4th century B.C.E., although there have been found traces of settlements in Norway that are at least 6,000 years old. The Norsemen, or Vikings, emerged as a power in Europe when Norway's first ruler, Harald the Fairhaired, led the sacking of Lindisfarne, Ireland, in 793. Between the 8th and 11th centuries, Norse Vikings raided all the coastal lands and navigable rivers of Europe from Germany to Spain, often occupying widely scattered territories. In the beginning of the 10th century, Harold I united the petty kingdoms of western Scandinavia and extended his rule as far as the Orkney and Shetland Islands. Viking nobles fleeing his conquests strengthened and expanded the Norse duchy of Normandy in France.

Christianity arrived under Olaf II (Saint Olaf) early in the 11th century. Medieval Norway reached its zenith of power and prosperity under Magnus VI (1263-1280), but lost its independence in 1319 when Magnus VII, king of Sweden, also assumed the Norwegian throne. Under the Kalmar Union of 1397, Norway and Sweden merged with Denmark under Danish rule. In 1814, Denmark, which had sided with France in the Napoleonic wars, was forced by the victors to cede Norway to Sweden. Within a year, Norway attempted to assert its own independence from Sweden, but failed. The Norwegians had nevertheless made their own constitution, which was declared on May 17, 1814. May 17 was later to become the Norwegian day of independence. A compromise was reached in 1815 when Sweden acknowledged Norway's independence "in perpetual union with the Swedish crown." The union of Norway's merchants, fishermen, sailors, and peasants with Sweden, dominated by an aristocracy with large estates and tenant farmers, was never a happy one. In 1905, Norway's legislature deposed Swedish King Oscar II and declared its independence, with Prince Charles of Denmark ruling as Haakon VII for 52 years.

Neutral during World War I, Norway declared neutrality at the start of World War II, but was occupied by German troops from 1940 to 1945. By 1948, Norway's economy had returned to prewar levels. A founding member of the United Nations, Norway joined the NATO alliance in 1949 and the European Union in 1994. The 1980s were marked by turmoil in the oil market and a temporary downturn in the economy that brought questions and challenges to Norway's strong welfare state and large wage increases. Long a world leader in social experimentation, Norway has recovered in recent years, as the country became the second-largest net oil exporter after Saudi Arabia in 1995. Norway has chosen by binding referendum not to become a member of the European Union. By the onset of 2003, discussions on a new application for the Union are emerging.

### 1. Basic Sexological Premises

Tracing the origin of Norwegian sexology through the written record is like trying to understand the lives of our ancestors by studying footprints preserved in Paleolithic clay. The Norse warrior culture that gave rise to the Vikings recorded its feats in the *Sagas*. It is in *Gunlaug's Saga* that we find the first instance of individual love and passion in northern European literature. In this tale, Gunlaug and Ravn fight a duel (*Holmgang*) for the love of a woman. After Gunlaug defeats Ravn, he fetches water to his dying opponent in a heroic act of mercy. As Gunlaug approaches, the treacherous Ravn dishonors all the laws of *Holmgang* by giving him a deadly wound to the head. Gunlaug sinks to his knees and asks, "Why?" Ravn answers, "I could not bear the thought of her being in your arms." It seems that the Nordic record of love begins with tragedy.

The Feudal Age that followed the breakup of the Roman Empire persisted for approximately a thousand years in Norway. Sigrid Undset, the daughter of one of Norway's foremost philologists, was a prescient observer of medieval life. Her two masterpieces, *Kristin Lavransdatter* and *Olav Audunsen I Hestviken*, depict a probable texture of life in Norway during the 13th and 14th centuries. The drama of life is played out against a backdrop of warfare and perilous voyages for men and the bearing of children and household management for women. Olav and Ingunn are betrothed as children. Later, Olav flees the land after slaying a man and joins the war band of a Viking chieftain. He returns to Norway, marries Ingunn, and takes her to his ancestral manor.

Childbearing and the hard work of running a household soon crush the fragile Ingunn, and Olav is left to raise the children alone. We are left to speculate what sexual interactions were really like in a world dominated by incessant war, the betrothal of children, marriages arranged to advance feudal interests, long separations of spouses, and the absence of birth control. While faith, love, and nature's beauty must have had an elevating effect, medieval life in Norway was lived out in a newly Christianized society, where sexuality came to be viewed as an unholy temptation. The highest value was placed on chastity and celibacy, and this earthly life was regarded as a pause between Heaven and Hell. Nonetheless, the population continued to grow, and Norwegian folk tales and songs with erotic themes were widely popular. They are preserved in a collection called *Erotic Folk Tales* (Asbjørnsen & Moe 1977).

The period between 1319 and 1814, when Norway was part of the Danish Empire, was called "The 400 Years' Night." In the literature of this period, very little can be found of an explicitly sexual nature. The first formal study of sexuality in Scandinavia was done in Norway by Eilert Sundt (1817-1875), a theologian from the staunchly religious southwest coast. Sundt (1976) embarked on a study of Norwegian morality by systematically recording the instances of extramarital births throughout the country. His primary purpose was to investigate the living conditions of the poor; the orderly methods by which he undertook these studies has caused Sundt to be honored as one of the pioneers of Norwegian sociology and sexology. The analysis of data from these studies, however, must have profoundly shocked 19th-century Norway, which was influenced by the repressive morality of Victorian England. Sundt found lively and widespread sexual activity throughout the country, especially around Tromsø, Trondhjem, and Oslo.

Although the 18th-century Swedish biologist Carl von Linnée (Linneus) (1969) described women's desire and pleasure in the sex act in a most sensuous way, Victorian morality denying the sexual nature of women was widespread. As in many other countries, however, just below the surface, a widely different and more primordial form of sexual behavior was thriving. In his book *Love and Lovesickness*, John Money writes about the Nordic legacy:

Today's adolescents who establish their sex lives by breaching the doctrine of the virgin bride and the double standard are, whether they know it or not, adopting a modern counterpart of another very ancient tradition, one which undoubtedly covered an area much wider than the term Nordic or Scandinavian would imply. This is the tradition of betrothal and sexual egalitarianism. It is called Nordic because it survived longest in Scandinavia. There it resisted the incursion of the Mediterranean system, which spread into Northern Europe as an adjunct to Christianity. . . . There, especially in rural areas, it still can be traced. As its name implies, the betrothal system is one in which not the marriage, but the betrothal of a young couple is the ceremony that marks the high point of their beginning as a breeding partnership. . . . The season for the betrothal began with the advent of spring, for in the winter a typical farm family and its hired hands survived the sub-zero nights by sleeping in the big kitchen around a fireplace or heating stove. In spring, the loft became sleeping quarters for the young, unmarried women. To admit visitors, they either unlatched the inside trap door or hung a rope from their upstairs window. When it happened that a boy and girl became romantically interested in each other, it was proper for their friends to allow them to meet alone. Thereafter they followed a pre-

scribed routine where the boy would spend the night with his girlfriend, but sleeping with his clothes on and above the covers. Step by step, visit by visit, he got under the covers, and then under the covers with his clothes off, at which point the couple announced to their families their intention to be betrothed. The betrothal would lead eventually to marriage, but only if pregnancy had ensued. Marriage itself was a confirmation of parenthood rather than coition. (Money 1981, 57-58)

In 1841, Lord Acton published *The Functions and Disorders of the Reproductive Organs in Youth* in England. This book became influential in learned circles in Norway. Lord Acton was a specialist in diseases of the urinary tract who advocated a program of sexual abstinence before marriage, suppression of onanism (masturbation), and rigid control of sexual activity in marriage as the means of preventing inevitable mental and physical deterioration caused by excessive semen loss. This pseudoscientific doctrine reinforced the prevalent belief that sexuality was harmful to manly virtues and could lead to the degeneration of society.

The Norwegian Dr. August Koren was a dedicated follower of Lord Acton's philosophy. He became an active member of Sedelighetsforeningen (Moral Guardians) and fought energetically against public prostitution in Norway. He had his work cut out for him; during the second half of the 1800s, a virtually uncontrollable epidemic of venereal disease was spread by prostitutes in Norway, particularly in Christiania (later to be named Oslo). In 1880, 1,200 cases of gonorrhea were reported, which indicates that 4% of the male population between the ages of 15 and 60 years old caught the disease in one year. At the same time, 1% of the adult male population was infected by syphilis. It was at this time (1881) that Henrik Ibsen wrote his play *Ghosts*, which deals exactly with the effects of inherited syphilis. Peculiarly enough, the play was poorly received and not really performed until long after that.

The population of Christiania had grown enormously during the 18th century, and prostitution grew right along with it. The debate over prostitution grew heated by the end of the century, and many authors and members of the arts participated in it. Christian Krogh, a well-known author and painter (1852-1925), wrote a novel that denounced the hypocrisy of society and the control of prostitution by the police. *Albertine* is the story of an innocent young girl who comes to grief when she is seduced by a police officer, then is forced to become a prostitute. The novel was confiscated by the order of the minister of justice the day after it was published, but it sparked a heated debate that resulted in the renewed prohibition of public prostitution. Although the ban on this novel has never been removed, it was included in a collection of Krogh's works and subsequently published in 1921. The works of Hans Jæger (1854-1910), another popular author during this period, were confiscated in the 1890s because of their frank descriptions of sexuality. They were not published again until 1969.

The debate about prostitution ceased abruptly around the turn of the 19th century. This about-face was most likely a result of the more liberal attitude concerning sexuality that can be traced to three basic causes: the revolutionary theories of Sigmund Freud, the entry of women into the world of work during the Industrial Revolution, and the availability of birth-control devices.

Prior to the work of Freud, the origin of mental illness—"hysterical" behavior and "phobias"—was attributed to neurological impairment of unknown origin, or simply to possessions of demons. It was not until Sigmund Freud began to publish his findings in the late 19th century

that subconscious disturbances were identified as the underlying cause of many behavioral disturbances or "psychopathologies." What was truly revolutionary about Freud's theories was his belief that libidinal energy (the Id) manifested itself from earliest infancy; that the Id's goal was to obtain satisfaction (the Pleasure Principle), which, if thwarted by external or internalized repressions from the Superego, resulted in a psychological disturbance or neurosis, which in turn destabilized the self (the Ego). These disturbances, which were often traceable to trauma experienced in some early stage of psychosexual development, tended to manifest themselves in hysteria, physical paralysis, anxiety, dream imagery, inadvertent speech, and ego defenses. By expanding the parameters of the libido to include the subconscious and unconscious, Freud put the realm of sexology on the scientific map.

The working class may not have been privy to the wonders of Freud's discoveries, but they were exposed to a number of technological and social innovations that transformed their existence. The first was the mechanization of production that accompanied the Industrial Revolution in Norway in the middle of the 18th century. Rural populations were drawn to the new industrial sites, and women and children were encouraged to join the workforce. It is worth noting that women and children were actually preferred to men wherever possible, because they were weaker, more docile, and could be paid less. For the first time, the manly virtues of strength and aggression were bested by the female virtues of timidity and subordination. In fact, it was in the impersonal new order of the industrial environment that no basic distinction was made between the sexes. In the new industrial environment, women were subjected to the authority of men other than consanguine males, found themselves in close proximity to men who were strangers, and gained a measure of financial independence. As a result, traditional family bonds changed, as did traditional standards of modesty. The demands of regulated work hours took priority over spontaneous sexual expression and procreation. Workers had to rush sex in the morning before work, or have sex at night, when they were tired. Even childbearing conflicted with the demands of productivity.

The historical record shows that methods to terminate unwanted pregnancies were frequently employed, often with tragic results. Infanticide was a second desperate measure resorted to by impoverished parents. The means to improve this situation, fortunately, were soon available. The technological process of vulcanizing rubber made the production of condoms possible. By the 1860s, "rubbers" were being sold in England and Germany. In 1890, Dr. von Gelsen published *Nødvendige Lægeråd til Nygifte*, which provided advice to those who wished to avoid pregnancy, but the book was banned by the Fredrikshald Chief of Police. Lars Oftedal, a well-known clergyman from Stavanger, appealed this decision in the Norwegian parliament (*Stortinget*), but the ban was upheld by a small majority, and it remained illegal to advertise or promote the use of contraception until the 1920s.

In reaction to the emerging trend of sexual liberation, a wave of pietism swept through many rural areas of Norway. Music and dancing were condemned as sins, and women were branded as temptresses whose carnal wiles, unless curtailed, would lead the spirit of men astray. Although the radical negativity of these views seems absurd, they have survived in many religious subcultures until today, underwriting the suppression of sexuality and propagating the myth of male superiority. There was also widespread anxiety about masturbation and the supposed ill effects that resulted from its practice. In a widely circulated paper pre-

sented in 1895 by Dr. Klaus Hansen, this “unnatural” way to satisfy sexual urges was condemned; it was claimed that “self-contamination” resulting from this practice led to a host of diseases that impaired the central nervous system.

A notable proponent of sexual freedom was Karl Evang (1902-1981), who became the most active advocate of public sexuality education in the 1930s. Evang became the Director of Public Health in Norway, and published the popular and informative *Magazine for Sexual Information*, which for many years provided the public with a source of information concerning sexuality. Evang took umbrage with the notion that the loss of human semen caused deleterious physical effects. He once stated that this belief was as ridiculous as claiming that the loss of spit led to physical and spiritual degeneration. Evang was one of the cofounders of the World Health Organization (WHO), and presided over its Second General Assembly in 1949. During his career, he made major contributions to the contemporary understanding of drug abuse, work-related illnesses, and contraception.

Psychoanalytic theories gained momentum when Wilhelm Reich fled to Norway in 1934 to escape persecution by the Nazi regime in Germany. Reich was a substantial influence in Norwegian psychology and sexology. At the Nordic Association of Clinical Sexology (NACS) meeting in Oslo in 1983, Rolf Groensteth presented a summary of the Reichian view: Sex is a natural and health-promoting human drive. In *The Function of the Orgasm* (1927), one of his major works, Reich postulated that sexual fulfillment was key to emotional stability and physical health. Reich believed that every human being had a “healthy core” that served as a natural defense against cultural repression. Although Reich’s sexual theories met with acceptance, his research on Orgone and the effect of cosmic fields was considered eccentric. He gradually lost support and had to leave Norway in 1939. Ola Raknes, one of Reich’s most prominent Norwegian proponents, did extensive research on the results of the socialization of sexuality in childhood. Raknes was able to identify many adult sexual problems that were related to the repression of the natural sexual urge in childhood.

Because of the severe disruptions caused by World War II, not much was written on the topic of sexology in the 1940s. The German invasion of Norway, and the atrocities that took place throughout Europe, dealt deathblows to the legitimacy of war as an extension of foreign policy. The anachronistic myths of the proud warrior and the nobility of combat were cast upon the trash heap of history. Women around the world, who faced up to the rigors of war and the challenge of taking over tasks previously considered “men’s work,” found true freedom in self-sufficiency. When the war ended, this habit of self-sufficiency persisted, and women demanded equality in sexual, as well as domestic matters. This new woman, a full-fledged personality with the capacity to make choices, became one of the central characters in Agnar Mykle’s controversial 1956 book, *Sangen om den Roede Rubin* [*The Song of the Red Ruby*]. In Mykle’s novel, a young man is torn between his love for his mistress and the devotion he feels for his father. It is finally the admirable personal qualities he perceives in the woman that empowers him to leave his father, become an adult, and find a fulfilling new life with her. At the time of publication, the radical theme and explicit sexual descriptions were considered obscene, and both Mykle and his editor were forced to stand trial for foisting pornography on the public. Upon appeal, the Supreme Court decided that the book was not immoral, and Mykle was exonerated.

In 1964, *Profil*, a literary magazine, began to publish the work of a number of talented young radical authors. The un-

derlying purpose of their innovative and sexually explicit material was to permeate the watertight neurotic system of bourgeois morality. A number of sexuality education books were also published by PAX, a Norwegian publisher specializing in political and controversial books, in addition to a collection of erotic short stories.

Jens Bjørneboe was a controversial author whose well-crafted, revelatory books about the school system (*Jonas*), the postwar legal settlements, and the penal system were popular in Norway. When his book, *Uten en Traad* [*Without a Fiber*] was published in 1966, it sent a reactionary convulsion through conservative circles. Authorities confiscated the book and Bjørneboe was brought to trial for attempting to circulate pornography. The trial ushered in an intense debate to determine which descriptions of sexuality were to be considered illegal. The debate continues to this day.

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

For several decades, conceptual influences on Norwegian sexology have come from a growing number of sources. A primary influence was the Sexual Revolution of the 1960s and 1970s, which served as a means of correcting societal norms for human sexuality that were too narrow and exclusive. One example would be the refusal of gay men and women to allow society to condemn their behavior or to label it abnormal. Unmarried heterosexuals, freed for the first time in history from the threat of unwanted pregnancy by “the Pill,” began to view the opportunity to interact sexually as a form of liberation guided by choice and freed from the stigma of sin. This new freedom from biological and moral constraints shook the prevailing norms imposed by church and academia, which had formally labeled all sexual activity not in the service of procreation and marriage as either lewd or abnormal. Prototypes of appropriate behavior founded upon married couples tending their offspring, the economic dependency of women upon men, and the conceptualization of masculinity and femininity as monodimensional opposites, have all been challenged by the dissemination of this transformative concept of sexual freedom. The voices of previously ignored “unfit” sexual minorities, physically and mentally challenged individuals, the aged, children, and people in hospitals and institutions, were heard for the first time as they gave their own bold testimonies. However, the state-supported Lutheran Church still refuses to allow practicing lesbians and homosexuals to hold consecrated positions. At the turn of the millennium, this is one of the most heated religious debates in Norway. Likewise, religiously influenced views of erotica and pornography are being challenged by new insights into the possible harms and benefits of these phenomena. There is a growing awareness in many religious circles of sexuality as a force of good rather than one of evil.

There has been a significant shift in focus among feminists since women began to populate the universities in the 1960s. At first, there was a tendency to adopt male ideas and values in pursuit of the goal of entering previously male-dominated professions and fields of study. Subsequently, a gynocentric phase has ensued in which feminist theories have focused upon the substitution of masculine ideals with woman’s values. It seems that success in “a man’s world” has inspired women to find their own center of gravity. Women’s self-help groups, women’s issues, such as single motherhood and affirmative action in hiring practices, women’s literature, and even women’s rock bands are all examples of this trend.

### 3. Knowledge and Education about Sexuality

The first person to become known as a "sexologist" in Norway was the psychiatrist Berthold Grünfeld. He has long been considered a pioneer in sex information, and has held a central position on the team that enacts and performs gender-reassignment procedures. Grünfeld must also be honored for his effort on behalf of women's rights in the question of abortion. He has questioned the wisdom of those who assume that their opinions on sexual issues are infallible, and has warned against the indiscriminate use of male labels in gender-related terminology.

Although general knowledge about sexuality in Norway is high, the problem is that this knowledge is based on traditional masculine values, pornography, and the absence of women as spokespersons for sexuality. The authorities have played a rather passive and hesitating role in the spread of sex education after World War II (1945), and sex education has been a cause for politically radical people and pioneer groups. The Norwegian Society of Clinical Sexology was founded in 1982, and even if it has not been able to influence the authorities, it has been an important forum for those who have been interested in sexological education and sex information. In 1998 and 1999, the Nordic Sexological Societies received government support from the Nordic Minister Council to develop guidelines for the authorization of clinical sexologists in the Nordic countries, and to make an outline for sexological education. Norwegian politicians have begun to show an interest in sexological education, which gives rise to optimism about sexological education and the integration of sexology into clinical practices.

With the spread of HIV/AIDS, the National Organization Against AIDS was founded with government support. This organization has played an important role in spreading information about homosexuality and in the rapid change in attitudes towards homosexuals. Even as the most heated debate about homosexuality in Norway today is whether homosexuals should be allowed to perform holy services in the State Church, it is encouraging that one by one, the bishops have expressed positive attitudes towards homosexuals in church.

According to government plans for education, there is not much sex education during the first ten years in school. In the 9th grade, under the subject of science of nature, the pupil should be taught about how hormones work in the body. In the 10th grade, there is a topic called sex and cohabitation, which is taught as a subject under education in religion and philosophy of life. Tenth-grade pupils are also taught about contraceptives, sexually transmitted diseases, procreation, love, sexuality, sexual identity, and other topics concerning sexuality. This is far from the ideal that sexuality should be taught as an integrated part of many aspects of life throughout school. Young people are left to learn about sexuality from the media and their peer groups. Many parents still find it difficult to talk to their children about sexuality; they hope that the school will take care of this. Even if the school system does not take very good care of sex education, young people seem to be quite knowledgeable about the basic principles of sexuality and the use of contraceptives and sexually transmitted diseases. We believe, however, that this knowledge is poorly integrated in young people's emotional life and behavior. There are still too many negative effects of sexual activity among young people, like unwanted pregnancies, abortions, and sexually transmitted diseases. Studies show that such statistics vary with the level of sex education. Very good statistics from the Netherlands clearly support this conclusion, as well as the

benefits of extensive sex education at all levels of education. The Netherlands has become a model for many other countries that want to reduce the negative consequences of sexual activity, teenage abortions, and sexually transmitted diseases.

### 4. Autoerotic Behaviors and Patterns

In two surveys with identical questions, one carried out in 1987 and the other in 1997, a representative group of the Norwegian population was asked about the importance of masturbation. In 1987, an average of 24% (men 32%; women 17%) found this kind of sexual stimulation "very important" or "rather important." The corresponding number from the 1997 survey was 35% (men 44%; women 28%). In both surveys, self-pleasuring is more important for men than for women (Norwegian Society for Sexology 1987ab).

A mailbox sexual information service in a Norwegian men's magazine (*Vi Menn*) regularly receives questions from men concerning the normality of self-pleasuring activities. The notions of self-stimulation as unhealthy and even perverse still exist, but on the whole, the attitudes within Norwegian society are increasingly permissive. A recent newspaper discussion concerning the Norwegian armed forces disclosed attitudes to the effect that Norwegian soldiers should not masturbate during their 12 months of compulsory service. In the discussion, these attitudes were gently refuted by general insights and multiple personal experiences.

The psychologist Thore Langfeldt, one of Norway's sexological pioneers, has engaged himself in the teaching of masturbatory techniques through the erotic magazine *Cupido* (Personal communication 1984, 1985). Several textbooks on female masturbation are on the shelves of Norwegian bookstores. Norwegian textbooks of sexology offer instructions for female and male sexual self-pleasuring.

### 5. Interpersonal Heterosexual Behaviors

Heterosexual life in Norway is still influenced by heterosexist views and belief systems. At the same time, sexual life as such is constricted by notions of sin and deeds of darkness. Progress has, however, been remarkable. Magazines for women and men have open, professional, and permission-giving columns for questions on sexuality and sexual matters. There is a growing awareness of the beneficial effect of a satisfactory sexual life for most of human sexual diversity. For instance, there is a group working for the removal of the psychiatric diagnosis of paraphilias like fetishism, sadomasochism, and transvestic fetishism. While conservative views about sexuality still exist, the public debate is increasingly marked by liberal views. The general interest in sexuality as such is increasing; the debate focuses on the social construction of sexuality, pair bonding, and sexual relationships. One of the new topics is discrimination against singles in the debate around the organization of sexuality in relationships.

#### A. Single Persons

##### *Age of First Intercourse*

According to studies, Norwegians seem increasingly to have their first sexual intercourse at younger and younger ages. The median age of first intercourse is between 17 and 18 years for people below the age of 30. For older groups, the median age of first intercourse gradually increases up to age 21. There seems to be a tendency for those who had their first intercourse when they were very young to have more sex partners thereafter. They also report more extramarital sex

than those with a higher age for first intercourse (Seksjon for Epidemiologi 1993). Træen, Lewin, and Sundet (1992) reported that boys had more coital partners than girls, but girls had had intercourse more often than boys.

### Premarital Sex

Premarital sex has gradually come to be regarded as a normal part of sexual development. Even if more-conservative Christian societies still regard sex after marriage as the preferred option, more and more Christians have come to question this as a sound moral guideline, as marriages are more and more based on love and partnership, and less on economic and social dependence. As people are free to divorce, people also seem to be more cautious getting married. It now seems to be a general attitude that people want to get to know each other before they get married. Also, the old Norwegian tradition, where people marry after they get pregnant or have had children, seems to be having a revival. The new moral seems to be that people put more effort into marrying the right partner, than they do in following any tradition that demands that at least the woman be a virgin before marriage.

### What Turns Norwegians On?

In the surveys by the Norwegian Society of Clinical Sexology (NSCS) and Markeds of Media Instituttet (MMI) in 1987 and 1997, the respondents were asked who and what turned them on sexually. In 1987, 91% of the population reported that they were turned on to some degree by individuals of the other sex (men 95%; women 87%). The corresponding number from 1997 is 94% (men 95%; women 92%). The general increase in sexual interest that seems to have developed during the ten-year span is even more apparent when we look at those who turn on to the opposite sex "to a very large degree." In 1987, 34% of the women and 49% of men reported that they were turned on by the opposite sex "to a very large degree." The corresponding numbers from 1997 were 47% for women and 62% for men. There has been a tendency over the ten-year time span towards an increase in sexual and erotic interest, especially among women.

The most important sexual activity among all couples, homosexual couples included, was bodily closeness. In 1987, an average of 64% (men 59%; women 68%), and in 1997, an average of 66% (men 60%; women 70%) selected the option "very important" to describe this form of sexual activity or intimacy. Mutual genital contact was the second most-important sexual activity. In 1987, an average of 54% (men and women both 54%), and in 1997, an average of 54% (men 57%; women 53%) scored this activity as being "very important." Foreplay and petting was the third most-important sexual activity, with an average score on "very important" in 1987 of 48% (men 39%; women 57%), and in 1997, an average of 48% (men 45%; women 50%). Kissing was also rated rather high as a "very important" sexual contact or stimulation. In 1987, an average of 34% (men 29%; women 38%) chose this option. The proportion increased during the ten years that followed. In 1997, the number was 45% (men 35%; women 44%). Oral sex also had a high score of 15% in 1987 (men 17%; women 13%), and in 1997, an average of 22% (men 23%; women 21%).

### Number of Sex Partners

To no one's surprise, the number of sex partners increases with chronological age, but it is also possible to see the effect of the so-called "sexual revolution" in the fact that men between 30 and 49 years have had more partners than men who are older than 50. Whereas in the group of men between 18 and 29 years old (who have had at least one sex

partner), 31% report having had more than ten partners, in the group of men between 50 and 60 years, 51% report having had more than ten partners. Among men between 20 and 39 years, 64% report having had more than ten partners, and in the group of men age 40 to 49, 62% have had more than ten partners. In all age groups, it is more common to have had between two and five sex partners in a lifetime.

Women, in general, have had fewer partners than men. Among women aged 18 to 29, 24% report having had more than ten partners in their lifetime. Among women age 30 to 39 years, 51% report having had more than ten partners, whereas in the older groups, among women age 40 to 49 and age 50 to 59, 41% and 26%, respectively, report having had more than ten partners (Seksjon for Epidemiologi 1993).

## B. Couples

### Marriage

Norwegians are increasingly marrying at a later age. The mean age for men and women at first marriage in 1961 was 26.4 and 23.4, respectively. In 1997, this had increased to 30.6 and 28.3. The number of Norwegians who are not married, divorced, or single is also increasing. In 1961, 7.6% of all men and 3.6% of all women at age 50 were unmarried. In 1997, the corresponding numbers were 37.2 and 32.1, respectively (*Statistisk Årbok* 1999).

### Frequency of Intercourse

There seems to be a continuous interest in the question: "How often do people do it?" Table 1 shows the results of a study from 1992 (Seksjon for Epidemiologi 1993) for men and women who had sex with another person, but who did not live with a partner. This study also reported that the number of intercourses per year for people who did not live with a partner declined in 1992 compared to 1987 (see Table 2). When we look at the frequency of intercourse for all people, with and without a partner, there is no difference in 1992 compared to 1987. Table 3 shows the combined distribution for men and women. Couples who have cohabited longer seem to have a lower frequency of intercourse than couples who have lived together for a shorter length of time.

In the survey done by NSCS/MMI in 1997, 28% (homosexuals not excluded) had had sexual contact/intercourse between two and four times in the past four weeks, 22%

**Table 1**

**Frequency of Intercourse for Men and Women Who Lived with a Partner, 1992**

Number of Intercourses Last Month	Men	Women
0	58%	57%
1-2	10	13
3-4	10	12
5-10	11	10
> 11	10	9

**Table 2**

**Comparison of Frequency of Intercourse for Years 1987 and 1992**

Number of Intercourses Per Year	1987	1992
0	17.9%	20.2%
1-9	27.2	37.0
10-49	29.8	22.5
50+	25.1	20.3

stated five to ten times, and 13% eleven times or more. There were more women in the group of five to ten times. Otherwise, the numbers were equal for men and women.

Norwegian men and women both like variety in the locations where they have sex. Close to 50% often or sometimes had sex outside the bedroom in 1997. Correspondingly, about 40% wanted the same variety in 1987. In spite of a climate that often offers temperatures below comfortable, Norwegians are not adverse to outdoor sexual activities. As many as 24% of the men and 18% of the women are in favor of "sex outdoors in nature" either often or sometimes. The higher proportion of men may indicate outdoor activities are more popular among homosexual men than among heterosexuals and lesbians (Dalen 1987, 1997)

**Divorce and Remarriage**

Twice as many individuals lose their partner by death than by divorce in Norway. While the number of widowers has stayed relatively constant, the number of divorces increased steadily until 1991. In the years since 1991, the divorce rate has oscillated between 11.2 and 11.7 per 1,000 married couples. The percent of men and women who have been widowed or divorced and remarried is rather constant. In 1961, 43.7% of men and 38.3% of women remarried. In 1997, 44.9% of men and 41.1% of women remarried (Statistisk Årbok 1999).

**Extramarital Sex**

Official statistics show that there is a weak tendency towards fewer extramarital sexual affairs among Norwegian couples. This is a marked tendency in the younger groups, whereas there is a tendency towards more extramarital sexual affairs in the older groups (see Table 4). In two studies by the Nordic Association for Clinical Sexology (Dalen 1987, 1997), a representative group was asked whether they

had ever had sex with others while they lived in a steady relationship. The tendency seems to be that people have more extramarital sexual affairs (see Table 5). When we look at the different age groups, we see that people between ages 40 and 59 have the most extramarital affairs (see Table 6). While more people seem to have extramarital affairs, more people seemed to be unfaithful only once in 1997 compared to 1987.

**C. Sexuality and the Elderly**

While an Egyptian philosopher allegedly said, "Old age is the worst of all diseases that can happen to a person," in northern European countries old age is not regarded as an age of wisdom to be honored, as in some African countries. An older man expressing sexual desire is looked upon as a "bold pig" rather than as a remarkably strong and potent man in his old age. This situation is slowly changing, as most people learn that sexuality is not limited to procreation. As we learn that sexuality is to be enjoyed from childhood throughout old age, our attitudes and practices are challenged, and new practices in institutions for older people are changed to allow older people more privacy and opportunities to enjoy love and sexuality with their life partner or with a new partner. Elderly people who are asked what love and sexuality means to them say that coitus is no longer so important. Instead they appreciate tenderness, satisfaction, and mutual trust. Instead of orgasm, they appreciate intimacy and sensuality.

**D. Challenged People**

Many people with chronic diseases and people with physical and mental handicaps encounter extra difficulties in their love relationships and sexual lives. Not many studies have been done to get more knowledge about these groups, but we experience an increasing demand from people who work with these groups to have more education in sexual matters, and people with chronic diseases and handicaps themselves ask for help in their sex life. In all communities in Norway, there are supposed to be places where people who need it can go for special devices that are necessary to be able to have sexual activity alone or together with a partner. Ethical discussions arise as to what extent or in what way people who work with these groups are obliged to assist their clients in obtaining sexual satisfaction.

**Table 3**

**Frequency of Intercourse by Age Group**

Frequency	Age 18-29	Age 30-39	Age 40-49	Age 50-60
Less than once a day	1.1%	0.5%	0.6%	0.7%

## 6. Homoerotic, Homosexual, and Bisexual Behaviors

It is estimated that approximately 5% of the Norwegian population is exclusively homosexual. Table 7 shows the results of a study from 1992 (Seksjon for Epidemiologi 1993) concerning people who have had at least one sexual contact, and who reported to have had sex with a person of the same sex.

Of men who lived with a partner, 1.3% lived with another man, and 1% of women who lived with a partner, lived with another woman. However, only 36% of these men and 52% of these women reported that they had had sex with a person of the same sex. This should be interpreted to mean that single people live together with people of the same sex without being sexual partners. Of women who lived with a man, 2.7% reported having had sex with another woman, while 2.4% of men who lived with a woman reported having had sex with another man. Of those who lived alone, 6.4% of men and 4.6% of women reported having had a homosexual experience.

The first center for sexual counseling in Norway for people who find themselves attracted to people of the same sex was opened at the Counseling for Homosexuals at the Public Health Council in Oslo in 1983. This vital service was greatly expanded in response to the AIDS epidemic. Nils Johan Ringdal, a historian, writer, and himself a homosexual, has pointed to the tremendous impact of the AIDS campaign to augment the general public's awareness of homosexuality. Ringdal feels that it has not been unduly difficult to be homosexual in the last half of the 20th century (personal communication, December 2, 1993). In his history of the police in Norway during the German occupation in World War II, Ringdal (1994) notes that although homosexuality was officially forbidden, homosexuals were seldom punished unless they were engaged in sexual liaisons with Germans, or were found guilty of sexual offenses involving minors.

The Organization of 1948 was founded by Norwegian homosexuals inspired by a Danish organization for gay activists. Throughout the 1950s and 1960s, homosexuals courageously expanded their subculture. According to Ringdal, many homosexuals today become extremely nostalgic when they recall those exciting years. Section 213 of the Penal Code, which considered homosexual relations between men to be a criminal offense, was repealed in 1972. In 1979, Norway followed the example of the American Psychiatric Association by removing homosexuality from its list of mental diseases. In 1981, the Ministry of Justice passed a proposal that provided legal protection to homosexuals.

During the 1960s, Norwegian homosexuals were influenced by the sexual revolution that led to the "Golden Age of the Seventies." In the 1980s, HIV and AIDS caused the "Great Backlash" of increased caution and discretion. A recent publication from the Ministry of Children and Family

Affairs (1999) states that, although homosexuality is now considered a variety of normal sexual behavior, most homosexuals remain reluctant to "come out" to their families, tend to live alone, and are likely to seek places of residence in the anonymity of the big cities. When interviewed, most respondents stated that they wished to live as a partner and want to bond with another. The findings indicate that a strong degree of alienation results from a homosexual orientation. This alienation may be ameliorated by the Law of Partnership, which gives Norwegian homosexuals equal rights to form legal partnerships. This law was passed in April 1993 and was effective August 1, 1993. The law allows people of the same sex the right to form formal partnerships with the same legal rights as married heterosexuals. They were, however, not given the right to a church blessing. Some priests have on their own given Christian blessing to homosexual couples. Although these partnerships may not be blessed by the church and do not confer the right to adopt children, the legal rights conferred upon homosexual unions represent a tremendous victory in the struggle for social acceptance. Mette Sorensen, information secretary of the Organization of 1948, was asked to comment upon the likely outcomes of the new law. She said that since the law was passed (April 1993), it was too soon to tell. However, there is every indication that Norwegian partnerships will prove to be at least as stable as heterosexual marriages. Sorensen believes that homosexuals and heterosexuals have essentially the same needs, to love and to bond. She adds that the purpose of marriage is not only to make and safeguard babies, but to make a life choice and have it recognized by one's society. Official statistics show that in 1995, 98 couples entered into partnership. In 1996 and 1997, the numbers were 127 and 118. So far, twice as many male as female couples have entered partnership.

## 7. Gender Diversity and Transgender Issues

[Update 2003: Norway has two organizations for transpeople. The older is FPE-NE. It was founded in 1968 to meet the needs of "heterosexual transvestites." Today, members of the FPE-NE include a continuum from classical part-time cross-dressers through self-defined bi-gendered and transgendered persons to transsexuals. By 2002, FPE-NE organized 142 individuals.

[LFTS, the younger organization, was founded in January 2000 with three purposes, the most urgent being to seize offers of the government to pay for gender-confirming surgery for transsexuals seeking this. The second was the willingness of some transsexuals to display themselves as transsexual women and men, thus generating the power to influence on most levels in society, including the arenas of politics and media. The third reason was the need for transsexuals to come in contact with other transsexuals and/or with other transpeople, to generate a context where each could find friendships, insights, and addresses of approved therapists in the field. LFTS was by 2002 organizing 120 individuals. There is an option of a supportive membership with cheaper dues for parents, siblings of transpeople, and for any other that may find such a membership meaningful. LFTS is receiving economic support from the Norwegian state, but is not yet securely financed. A bill to enforce the rights for transsexuals to receive optimal medical treatment is proposed, but was not ratified by the beginning of 2003. (End of update by E. Almås and E. E. Pirelli Benestad)]

Norwegian transsexuals over age 18 are offered professional assistance by a centralized team in Oslo. The team generally follows the standards of care recommended by

**Table 7**

**Number of Men and Women by Age Group Who Reported Having Sex with a Same-Sex Partner, 1992**

Age	Men	Women
18-29	5.1%	3.9%
30-39	6.3	5.1
40-49	4.0	2.0
50-60	3.4	0.9

the Harry Benjamin International Gender Dysphoria Association. The degree of pre- and postsurgical support is lower than wanted and needed by many transsexuals. Very little is done concerning children and adolescents who display transgendered feelings and behaviors. A Norwegian child psychiatrist, Trond Diseth, recently presented a thesis on the problems of addressing children with ambiguous external genitalia (Diseth 1998). One of the authors of this chapter, who is both a professional and a transgendered person, Esben Benestad/Esther Pirelli, has been a frequent oral and written presenter on transgender issues both nationally and internationally. He/she is presently working on a clinical project on how to address children and adolescents with unusual gendered feelings and/or expressions. Benestad/Pirelli also points out that most of the transgendered adults do not suffer from gender dysphoria, but are dysphoric about a body that does not affirm their ego syntonic experience of gender identity. Working with gender issues and problems concerning gender, we have found it most useful to apply the term "gender belonging" (gender identity) to the process by which a person develops a sense of belonging that is both generally appropriate and self-confirming within the parameters of cultural roles, erotic preferences, body status, and the subjective synthesis of sexual experiences. Work with male transvestites has provided ample material to discuss alternative gender belongings, including male, female, male and female, and others still not named. Dr. Benestad/Pirelli has found the individual experience of gender belonging to be a dynamic state of interaction between internal "beliefs" and external affirmations, decisively influenced and confirmed by subjective gender reference, body consciousness, body picture, gender-role behavior, and erotic preference.

Professor Per Schioldborg at the University of Oslo has done significant research on gender roles. He has based much of his research on Sandra Bem's scales, and his proposal, presented at the NACS meeting in 1983, represents an important development in the way we perceive masculinity and femininity. Schioldborg (1983) proposed that we regard masculinity-femininity as two orthogonal dimensions, rather than one. This concept is projected as a model with four groups: androgynous (high on both variables), masculine, feminine, and undifferentiated (low on both variables). Although the term "identity" is virtually ineluctable, we believe that it is too inflexibly linked to traditional thinking that defines sexual roles as being *either* male or female. Quite a few cultures give other possibilities of belonging to individuals that are "somewhere in between." We could call them "both-and" solutions. Even though deviation from the two approved gender stereotypes has been categorized in the psychiatric literature as "gender identity disturbances," "gender dysphoria," "perversions," or by John Money's term "paraphilias," we are inclined to ask whether the individuals in question really are disturbed, or whether they have a gender that disturbs their surroundings.

Since Freud introduced his trauma theories, psychiatric professionals have attempted to explain gender differences as the result of traumas suffered in childhood. In the last few years, clinicians have developed reservations about this. We believe this is because of the fact that transsexuals and transvestites themselves are increasingly active in scientific sexology as professionals. It is painfully obvious that much of the pathology that transsexuals and transvestites bring to the therapist's office is caused by culture-induced pain and rejection, rather than childhood traumas. There is reason to be optimistic about the future because of a widening acceptance of gender differentiation, a trend already manifesting itself in the growing acceptance of homosexuality.

## 8. Significant Unconventional Sexual Behaviors

### A. Coercive Sex

#### *Incest and Child Sexual Abuse*

In Norway, as in many other countries, only a small proportion of reported cases of incest and sexual abuse leads to conviction. It is, therefore, difficult to get exact statistics about how frequent these phenomena are. While some studies report that 20 to 25% of all children have been victims of sexual abuse of some kind, researchers in this field suggest that 5% is a more likely estimate. The public discussion now is whether the molester should have treatment or punishment or both. Today, not even the victim is granted relevant treatment, because of a shortage of therapists.

[Update 2003: In 2002, the Norwegian police, in collaboration with police forces in several other countries, unraveled a league of child pornography users and distributors. The number of individuals involved lies between 100 and 200. Still, the case is under investigation and more individuals may be involved. (End of update by E. Almås and E. E. Pirelli Benestad)]

#### *Rape*

The numbers of reported rapes were relatively stable during the early 1990s, but since 1996, there has been a steady increase. In 1994, 366 rapes were reported, according to official statistics (Ukenst Statistikk, Statistisk Sentralbyrå); 57 of these resulted in convictions. Estimates suggest that 90% of all rapes are not even reported. In 1998, 456 rapes were reported. In the period between 1989 to 1994, the severest penalties were between five and ten years in prison. The mean penalty was 2.4 years. The maximum penalty is now ten years in prison. If the victim dies as a result of the rape assault, the highest penalty is 21 years in prison.

#### *Sexual Harassment*

The Danish sociologist, Henning Bech describes the characteristics of sexual relationships in different cultures as follows:

In most English-speaking countries, it is a question about power. In the Nordic countries, except Denmark, it is a question of prohibition. In Denmark, it is a question of ability to play the game. This may be one of the reasons why the question of sexual harassment has been such a big issue in the United States, but not in the Nordic countries. (From an interview in the Danish newspaper, *Politiken*, April 11, 1999)

However, some studies have been done concerning unwanted sexual attention in Norway. In 1992, a group of female researchers conducted a study based on a questionnaire printed in *Kvinner og Klær*, a women's magazine. The results showed that 20% of the women between 18 and 50 years reported that they had experienced unwanted sexual attention that had resulted in psychological, physical, or work-related problems (Brantsæther & Widerberg 1992). Another study showed that 8% of women had experienced unwanted sexual attention during the last six months. Table 8 shows the results of the NACS/MMI studies from 1987 and 1997. It is difficult to explain why these numbers are so low, compared, for instance, with American studies. One explanation may be that general attitudes toward sexual attention are more positive and not so thin-skinned in Norway.

### B. Prostitution

In 1993, a Scandinavian Conference on Prostitution was held at Lillehammer with a number of prostitutes actively participating in the dialogue. On the agenda were legal issues

involving sexual legislation, contemporary morality, the organization of brothels, and the need for a societal consensus regarding sex workers. The politicians were encouraged to adopt a “harm reduction” approach, which accepts prostitution as a time-honored societal phenomenon, rather than to persist in the more harmful and costly punitive approach, which criminalizes prostitution. Liv Jessen, leader of the PRO-Center, a prostitutes group in Oslo, emphasizes the importance of addressing the problems associated with prostitution on a structural meta-level, rather than belligerently attacking the prostitutes and condemning the existence of brothels. In response to the feminist activist Women’s Front raid upon brothels, Jessen asks whether it is more immoral to prostitute oneself under a roof rather than on the street. Jessen stresses the need for more reflection and awareness, rather than for slogans and headlines, which merely stigmatize prostitutes. From her work with men who seek prostitutes, Liv Jessen concludes that sexuality is in difficult straits in our society. The typical “john” Jessen interviewed confided that, although he desires to experience an adventurous and loving sex life with his wife or girlfriend, he feels rejected and attempts to experience fulfillment by acting out fantasies with prostitutes (1993-1994).

Jessen reports that many men lose respect for themselves when they buy sex and usually experience a bad conscience. By neglecting to frankly express their sexual needs to their partners, these men are asking too little. In Jessen’s opinion, the entire therapeutic community remains victimized by repression, and the reluctance to take sexual issues more seriously is because of the ubiquitous inhibition still hampering many clinicians.

### C. Pornography and Erotica

When standards regarding the appropriate depiction of sex-related subjects are discussed, the first question that comes to mind is whether the subject is pornographic or erotic. Although these terms have been used interchangeably, there is a significant difference between them. Pornographic is defined as the depiction of obscene or unchaste subjects in literature or art, while erotic pertains to the depiction of love.

Terje Gammelsrud, editor of a popular erotic magazine, *Cupido*, for many years the only legal magazine devoted to sex in Norway, informs us that the term “erotic” is preferable to most people, because it has a less lewd connotation. Also, it is easier to discuss sexual subjects when they are presented as erotica, rather than as pornography. Gammelsrud notes that, in his view, the difference between good and bad pornography is obvious once we determine whether the subject is expressing passion in an authentic state of sexual arousal, or whether the subject is acting out some form of sexual behavior that conforms to a predetermined stereotype of what

sexual arousal would look like if it were actually taking place. Gammelsrud expresses surprise at the absence of reaction from feminist activists when new magazines depicting the overtly sexual involvement of women are published. He wonders whether this lack of protest is because of a sense of resignation or to a more open and positive acceptance of sexuality (1993-1994).

Gammelsrud raises the important question: What is the price our society pays for not having a sexual politic? It surely amounts to billions if we factor in the costs spent in healthcare, the judicial system, the social system, and reduced work productivity. There is also the commonly invisible cost in human suffering and exploitation. As of January 2001, there were two bills that might change the present Norwegian law, which prohibits any depiction of sex organs in motion. One is a bill from the Sex Crime Committee that suggests that pornography should be prohibited, but defined as an unacceptable depiction of sexuality, using children, animals, or coercive sex. The other bill is from the Freedom of Speech Committee, which will move the responsibility from the state authorities to the editors. Both of these reforms are heavily debated.

### D. Paraphilias

Since 1997, a committee has been working to remove sexual turn-on patterns from the lists that classify mental diseases. The most influential such lists in Norway are the *DSM (Diagnostic and Statistical Manual)* and *ICD (International Classification of Diseases)* systems. There are several diagnostic categories related to gender identity and role that can and are being questioned. In terms of orientations, homosexuality was taken out of the classification of mental disorders in Norway in 1979, but it can still be found as subcategories in the description of “Gender Identity Disorders in Adolescents and Adults” in *DSM-IV*.

Sexual turn-on patterns are still considered mental diseases, if we look at *DSM-IV* and *ICD-10*. It is interesting to see how ideas about sexual behavior have developed, but are still defined on the basis of fulfillment of procreation. Sexual deviation has been specified on the basis that it does not serve the act of fertilizing the egg. As a consequence, we have long lists of sexual deviations regarded as mental diseases in both *DSM-IV* and *ICD-10*, including:

*DSM-IV*: 302.4 Exhibitionism; 302.81 Fetishism; 302.89 Frotteurism; 302.2 Pedophilia; 302.83 Sexual masochism; 302.84 Sexual sadism; 302.3 Transvestic fetishism; 302.82 Voyeurism; 302.9 Paraphilia not otherwise specified. *ICD-10*: F65 Disorders of sexual preference, including paraphilias: F65.0 Fetishism; F65.1 Fetishistic transvestism; F65.2 Exhibitionism; F65.3 Voyeurism; F65.4 Pedophilia; F65.5 Sadomasochism; F65.6 Multiple disorders of sexual preference; F65.8 Other disorders of sexual preference; F65.9 Disorders of sexual preference, unspecified.

Instead of being classified as mentally ill persons, people who regard themselves as fetishists or having a different gender identity now claim themselves to be normal healthy people, as far as these matters are concerned. In addition to having a specific sexual turn-on pattern, some might have developed mental problems because they think of themselves as “wrong” in the eyes of society, or because it is difficult to find a partner that matches one’s sexual needs.

### *Exhibitionists: Male Artists vs. Female Entertainers*

[Update 2002: Under Norway’s strict gender-equality laws, men and women can demand equal treatment for doing the same job, even if it involves disrobing on stage. In November 2002, Norway’s Gender Equality Ombudsman, Kristin Mile, investigated a complaint that tax authorities

**Table 8**

**Percentage of Men and Women Who Reported Having Experienced Unwanted Sexual Attention During the Previous Six Months in Two Studies**

	Percentage Experiencing Disagreeable Sexual Attention at Work

Never	59	66	74	71
Irrelevant	30	18	21	15

define female strippers as entertainers while male strippers pay a lower tax rate because they are considered artists. Mile told *The Associated Press* (2002) she had received a complaint from Norwegian booking agent, Magnus Morland, complaining that the all-male American Chippendales only had to pay a 15% artists tax for their November tour of Norwegian concert houses, while his female strippers, also foreigners, had to pay a 24% tax on their tickets. "It seems like they are doing the same job," Mile suggested to the press. "This is pure discrimination," Morland told the Oslo newspaper *Dagbladet*. (End of update by R. T. Francoeur)]

### 9. Contraception, Abortion, and Population Planning

Positive attitudes toward sexuality and positive information about sexuality documented throughout all levels in public schools are related to a lower frequency of undesirable consequences of sexuality, like unwanted pregnancies and abortions. In this respect, Norway still has a long way to go, in spite of the positive ways we ordinarily present ourselves internationally. The government proudly announces full support of family planning and that services are provided in maternal and child clinics and other health outlets free of charge. All contraceptives are widely available, and contraceptive use is high. Nevertheless, Norway is one of the countries in Europe with the most abortions among teenage girls. Compared to the Netherlands, one of the "winners" on these statistics, Norway has three times as many births among teenage girls and five times as many abortions.

The most heated part of the family planning debate of Norway concerns the issue of self-determined abortion. The decision is now left with the pregnant woman herself, which has been regarded as a victory in the struggle for women's independence. First-trimester abortion on request has been legal since 1975, and three years later, the woman was given the right to make the decision herself. The government holds that family policy is based on and strengthens gender equality. The importance of governmental and nongovernmental collaboration in this field is also emphasized as essential. Men's participation in childcare, both in the family and at work, is encouraged by paid maternity leave for the father. In practice, few men use this opportunity because of the decrease in income. Another factor is the amount of time needed to change attitudes. Whereas some men take this opportunity, the majority still holds traditional attitudes and prefers to leave childcare to the mother.

### 10. Sexually Transmitted Diseases and HIV/AIDS

#### A. Sexually Transmitted Diseases

A study done by the National Institute of Public Health in Norway in 1992 shows that 18% of men and 16% of women, among those who have had sexual relations, reported to having had a sexually transmitted disease at least one time in their life. The current incidence of STDs is shown in Table 9. In the group that has had homosexual experience, 36% have had an STD during their lifetime, 42% of the women and 32% of the men. The incidence pattern is shown in Table 10.

[Update 2002: The state of STDs is as follows:

- [Chlamydia: In the year 2001, more cases of chlamydia were diagnosed than in any year since 1991. The reason may be linked to more spread, better diagnostic tools, more test-focused professionals, or combinations of these factors.

- [Gonorrhea: 358 cases of gonorrhea were reported in 2001 compared to 252 in 2000; 82% of these patients were born in Norway. Of the total, 258 were men and 70 were women. (End of update by E. Almås and E. E. Pirelli Benestad)]

*Chlamydia trachomatis* was registered the first time in Norway in 1959, but was not recognized as a distinct disease until the 1970s. Today, this disease is the most common STD and is probably the most common cause of infertility. The infection is most common among sexually active people under the age of 25. The 1997 incidence in Norway was 9,889 (women 5931; men 3958). The incidence of gonorrhea has fallen drastically during the last few years. The highest incidence of gonorrhea in Norway was reported in 1975 and 1976, with approximately 15,000 cases yearly; the incidence in 1997 was 193. Presently, there seems to be an increase in primary and secondary stages of syphilis, mainly among homosexual men in Oslo. Medical authorities are following closely this trend. In 1998, the incidence of gonorrhea was the lowest ever registered in Norway. There is, however, reason to be worried about the increase in the number of cases of gonorrhea among men who have sex with men and in people who travel to Thailand, because this is an indication of unsafe sex, which also can give an increase in HIV infections.

#### B. HIV/AIDS

There has been a steady increase in voluntary HIV testing in Norway. In the 1993 study (Folkehelsa 1993), 16% of the men and 13% of the women had been tested. More people with higher education (17%) than lower education (14%) had done so, and more people in urban districts (21%) than rural districts (10%) had been tested. Thirty-eight percent of the men and 28% of the women who had had sex with a person of the same sex had been tested. During the first six months of 1999, 70 new cases of HIV were detected, compared with 49 new cases in 1998. The increase is mainly attributed to people coming as refugees from pandemic African countries. In other risk groups, there have been few changes from year to year. As of June 30, 1999, a total of 1,932 HIV-positive persons (1,427 men and 505 women) were registered in Norway.

Since 1998, there has been a major decrease in the incidence of AIDS, which is explained by new treatment methods that has been available since 1996. Even with the present reports of increasing problems concerning therapy failure and the development of resistance and serious side effects, this positive development in the AIDS situation has continued throughout 1998. During the first six months of 2000, 85 new cases of HIV were detected; in the same period in 1999, 70 new cases were detected. The increase is mainly attributed to people coming as refugees from pan-

**Table 9**

#### Incidence of Sexually Transmitted Diseases, 1992

Chlamydia:	7%	Gonorrhea:	6%	Genital warts:	4%

Herpes:	7%	Other STD:	5%	Unknown STD:	3%

(Seksjon for Epidemiologi, 1993)

demographic African countries. In other risk groups, there have been few changes from year to year. As of June 30, 2000, a total of 2,095 HIV-positive persons (1,528 men and 567 women) were registered in Norway. Up to June 30, 2000, Norway had a total of 672 diagnosed AIDS cases (558 men and 114 women). Of this total, 672 cases registered since 1983, and 519 have died (Meldingssystem for Smittsomme Sykdommer 1998, 2000). [Update 2002: The recent increase continues to be mainly attributed to people coming as refugees from pandemic African countries. In other risk groups, there have been few changes from year to year. (End of update by E. Almås and E. E. Pirelli Benestad)]

[Update 2002: UNAIDS Epidemiological Assessment: HIV testing and case reporting: HIV testing is systematic for blood donors, pregnant women (including women having abortions), and STD patients. Diagnosed HIV cases are reported in a national HIV database using an identifying code. By the end of 2001, 2,323 HIV cases were reported. Among the cases reported in 1997 to 2000, 61% are heterosexuals, 27% are homosexual men, and 8% are intravenous drug users. Prevalence data come mostly from ongoing testing programs.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	1,800 (rate: 0.1%)
Women ages 15-49:	400
Children ages 0-15:	< 100

[An estimated less than 100 adults and children died of AIDS during 2001.

[No estimate is available for the number of Norwegian children who had lost one or both parents to AIDS and were under age 15 at the end of 2001. (End of update by the Editors)]

### 11. Sexual Dysfunctions, Counseling, and Therapies

Many psychotherapists have persisted in the hopeful notion that sexual problems tend to become resolved automatically along with other personal problems as the client progresses in therapy. Clinical experience has indicated that this view is overly optimistic. We know that people without any psychopathology may develop sexual problems. Many such individuals resist seeking traditional psychotherapy where sex therapy is not available. In the late 1970s and early 1980s, a number of Norwegian therapists began to utilize the techniques developed by Masters and Johnson and Helen Singer Kaplan in treating sexual dysfunctions. In the beginning, there was a high level of enthusiasm for these innovative methods. However, many therapists found that they were handicapped by a daunting level of inhibition when it came to openly discussing sexual matters with clients. Working through these taboos together with colleagues was one step in facilitating communication.

Another step in guiding the helping professions to improve their sexological efforts has been in the application of the PLISSIT model as an effective paradigm developed by the psychologist Jack Annon in Hawaii. The aforementioned acronym is composed of the four levels of therapeutic intervention: Permission, Limited Information, Specific Suggestions, and Intensive Therapy (Annon & Robinson 1978). The model is originally illustrated as a funnel, but this has been turned upside down, and the PLISSIT model is in Norway shaped like a pyramid: The foundation is composed of the most frequently utilized intervention. *P* indicates permission to be in touch with one's sexuality and to discuss sexual matters, while *LI* focuses on providing limited information about these matters in question. It is impor-

tant for any therapist or professional to become comfortable enough to give his or her clients permission to talk freely about sexual problems. The levels of specific suggestions (*SS*) and intensive therapy (*IT*) involve the actual working through of the specific sexual problem. The counselor or therapist operating on the highest level, intensive therapy, requires highly specialized training and skills to be effective, whether this be in counseling, psychotherapy, psychiatry, or medicine and endocrinology.

### 12. Sex Research and Advanced Professional Education

Thore Langfeldt, a pioneer in the field of sexology in Norway, began his scientific career in research on sex and aggression in cats. He went on to investigate the neurophysiological function of the temporal lobes, then began his groundbreaking research with children. During the 1970s, he supervised several students, Jens Skaar, Bjørn Helge Gundersen, and Per Steinar Melås, in their task of collecting information from parents and nursery staff about the sexual behavior observed among children. The findings, published in *Hverdag*, caused a public protest against the invasion of the pristine world of children by lewd professionals. The debate initiated by this research showed the necessity to work with adult attitudes as well as with the lack of educational practices and guidance of childhood sexuality. Langfeldt (1993-1994) has criticized the trend of contemporary psychotherapy to focus on pathologies rather than sexual health. In a paper published in *Nordisk Sexologi* in 1983, Langfeldt drew attention to the work of Earl Barnes, an American psychologist who, as early as 1892, questioned the emphasis upon sexual abnormality. Barnes, cited by Langfeldt from Kern, 1973), stated: "None make any attempt to trace the normal development of sexual feelings and ideation in children, nor to examine the condition of sexuality actually existing in children's lives." Langfeldt's contribution to the increased awareness of the nature of sexual behavior in children has been considerable. Today, he lectures in numerous seminars and courses in childhood sexuality for professionals all over the world. His studies on unresolved sexual problems arising in childhood, and their consequent manifestation in adolescence, have made his work the focus of international attention since he began to publish his theories around 1980. Subsequently, Langfeldt has devoted his energies to the rehabilitation of juvenile sexual offenders and has founded the first sexological institute in Norway concentrating on this work.

The Norwegian Society for Clinical Sexology has been working for many years to integrate sexology into professional education for health professionals, without overwhelming success. (The current president is Elsa Almås, Storgaten 42, N-4890 Grimstad, Norway.) The problem seems to be that there is no room for new fields in the already existing curricula. As a consequence, the Nordic Association for Clinical Sexology (NACS), which represents Denmark, Finland, Iceland, Norway, and Sweden, has applied for and been granted money to develop guidelines for sexological certification/licensing and education. With these guidelines, it will be possible to develop inter-Nordic courses on different levels of sexological education. The programs, presented at the NACS meeting in 1999, build on three different levels of sexological education: The first level is a one-year, half-time university course in basic sexology. The second level is a one-year, half-time course for health professionals in sexological consultation. The third level is a two-year, half-time course in sexological therapy. These guidelines must be implemented in different

ways in different countries. In Norway, politicians have recently become much more interested in sexological education, prevention, and treatment, and there are reasons for moderate optimism regarding the possibilities of developing sexology as a new field adding to the existing health professions in Norway in the future.

Today, research in sexologically related fields is scattered and dependent on money that follows time-limited projects that are politically motivated. It seems that a lot of this research has too few resources to secure the quality essential for publication internationally and even nationally. As in many other countries, the Norwegian government has granted money for some years to describe risk behavior for the spread of HIV/AIDS. When the situation seemed to be under control, much official funding disappeared. There also seems to be some money in projects that aim to prevent unwanted pregnancies and abortions, but reports on such research are difficult to find. Easily found, however, are national statistics with their options and limitations.

### Conclusion

Sexuality is a powerful human force within the context of human culture. In compiling information for this overview of Norwegian sexology, it has become obvious that the most important body of knowledge, that which teaches us how to be comfortable with our sexuality, remains incomplete. We have observed that the male-dominance complex was an inevitable outcome of the institution of warfare. Now that Norway is committed to peaceful coexistence with its neighbors, indeed has evolved into a catalyst for international accord, the barbaric anachronism of sexual inequality has lost its *raison d'être*. The liberation of sexual minorities, homosexuals, transgendered people, and fetishists, has kept pace with the nascent equality of women; we view these developments with grateful optimism.

There are several volatile foci that require all of our professional acumen and personal courage if we are to accurately deal with them. One such area is the sexual molestation of children; a second area is a scrupulous inquiry into the differences between male and female sexuality. If our goal involves defusing repressive taboos, child molesters, who stand in the shadow of a long tradition of dark deeds, shall benefit the most. If we can combine open-mindedness and willingness to address this highly interactive malady with a more professional approach, we shall be more able to bring this fearful issue into balance. The women's liberation movement has immensely improved the status of women in our society, and has made it unacceptable to discriminate against women on basis of gender. In the justifiable efforts toward equality, the unique aspects of women's sexuality have frequently been overlooked. In our opinion, the full equality of women awaits the full awareness of women's uniqueness.

As a result of the enormous changes brought about by the sexual revolution, sex education, and the advances made in sex therapy, we may occasionally feel like acceding to the temptation to relax our efforts. An antidote to this kind of thinking is to remind ourselves that centuries of repression and limited access to educational resources have caused many people to fear and conceal their sexual feelings. Only yesterday, the notion of social equality for women, acceptance of homosexual behavior as a form of normal sexual expression, ecological activism, and systems

theory were unthinkable. They became realities as a result of the unremitting efforts of many dedicated individuals. There is still a great deal of work to do, and many people in grave need of help. In reality, the history of sexology in Norway has only just begun.

### *An Introduction to Life in Extreme Environments*

Antarctica and outer space are considered two of the most extreme environments with which human beings have to contend. Because of certain similarities, these two are well-suited to being addressed in one chapter because of their common elements, which allow one—Antarctica—to be a research environment studied to find solutions to potential problems in the other—space habitats. In fact, numerous authors continue to consider them together in the human factors realm (e.g., Harrison, Clearwater, & McKay 1991; Stuster 1996; Palinkas, Gunderson, Holland, Miller, & John-

son 2000; Dudley-Rowley, Whitney, Bishop, Caldwell, & Nolan 2001). Sexuality in extreme environments is often a second thought—or later, if it is even thought about at all—for good reason: These environments are such that they require meeting the most basic of human needs in terms of immediate survival. In Maslow's (1970) motivational hierarchy of needs, this would include the lowest levels of survival and safety. Sexuality is at a higher level on the scale, and entails needs that, of necessity, would come later once the others have been adequately met. For additional analysis of this thesis, see Noonan (1998a). In addition to this are the corporate or state-sponsored interests in these endeavors (because of the costs and the technologies involved), which typically ignore or discourage sex-related behaviors because they are conceptualized as potentially (or likely to be) disruptive.

Extreme environments are not limited to space and the polar regions of Earth. Studies—particularly those in the psychosocial realm—focus on those factors that push the envelope of human survival and performance, because of environmental-system extremes in the physical, psychological, and social spheres. They have high barriers and sharp boundaries that limit both life and effective performance under normal circumstances, many of which require technological advances and intensive training for adaptation success. In addition to Antarctica and the space environment, extreme environments include arctic and other isolated environments, undersea operations and deep-ocean submarining, high-performance and general aviation, the armed services and special forces, caving, mountaineering, and vulcanology, and mining and hazardous-substance work, as well as medical, emergency, police, and firefighting scenarios in natural and man-made disasters. Essentially, extreme environments are those in which humans, either individually or in groups, have to perform under highly stressed, complex, and challenging conditions. The difference between space and Antarctic environments, however, is much less than the difference between those two and most of the other earthly pursuits listed above, and will be detailed more fully later in this chapter. Of particular importance to the success or failure of a particular space mission or polar expedition that makes the consideration of sexuality factors necessary, is the fact that these environments entail day-to-day living and working, and thus increase the likelihood that sexuality factors could have a determinative impact.

Suffice it to say that the physical environment of space has several important characteristics that Antarctica does not have: microgravity, high electromagnetic and particle radiation levels, high vacuum conditions, lack of oxygen, and extremes in temperature and pressure. Although it has extended periods of extreme cold and lack of humidity, Antarctica is protected by the Earth's mass, which provides a magnetic

\**Communications:* Raymond J. Noonan, Ph.D., Health and Physical Education Department, Fashion Institute of Technology of the State University of New York, 27th Street and 7th Avenue, New York, NY 10001 USA; 212-217-7460; rjnoonan@SexQuest.com.

In addition to updates, this chapter now includes a new section on life in extreme environments and a new section on Antarctica.

field, called the magnetosphere, that deflects most of the charged particles that are carried by the solar wind, which give rise to the Van Allen radiation belts surrounding the globe as well as the polar auroras. In both environments, it is necessary to construct ecologically more-or-less closed, self-sustaining habitats for protection, and it is difficult if not impossible to effect a quick rescue in the case of an emergency.

Psychosocial factors are the key items of interest, however, in terms of scientific research relating the two environments. These include: isolation, remoteness, hazardousness, and extremely confining quarters—and the resulting high levels of emotional and physical stress that accompany them, including decreased motor function, fatigue, and unpredictable and potentially life-threatening occurrences. It is here that sexuality factors could have an impact, potentially both positive and negative, that need to be considered.

The Society for Human Performance in Extreme Environments (<http://www.hpee.org/>) is the organization for professionals involved in these fields. The Society publishes *Human Performance in Extreme Environments*, a journal devoted to fostering knowledge of and improving the levels of human performance in these environments.

## OUTER SPACE

---

### *Demographics and a Brief Historical Perspective*

#### **A. Demographics**

At this point in history, only a few hundred men and women from more than 25 countries have traveled and lived for some period of time in space.\* With the advent of the new millennium, and despite the catastrophic loss of the Space Shuttle Columbia on February 1, 2003, the permanent human presence in space has become firmly entrenched, with the sixth crew of three beginning its stay on the new International Space Station (ISS) in November 2002. The largest cooperative scientific program in history, the ISS was developed jointly by the United States, Russia, Canada, Japan, and Brazil, and the participating nations of the European Space Agency (ESA): Belgium, Denmark, France, Germany, Italy, Netherlands, Norway, Spain, Sweden, Switzerland, and the United Kingdom (NASA 2003). Because of this virtually unprecedented mixing of cultures in a peacetime endeavor, we must expect that participants' cultural backgrounds will have an impact on gender interactions and any sexual relationships that will inevitably develop in space environments. Certainly, our common biological nature will have a different set of challenges in the sexological realm that will have to be met as well. Evidence for this comes from recent studies by Italian researchers that found that levels of the sex hormone testosterone are temporarily decreased in male astronauts by exposure to space, along with a concurrent decrease in sexual drive or libido (Strollo et al. 1998).

The "territory" of outer space, the study of which broadly comprises the domain of cosmology and astronomy, is open to interpretation. As Fazio (1997) has noted, where space begins depends on the physical properties of the area in question, specifically the problems that need to be resolved to allow humans to travel and live there. For example, extreme cold occurs, and sufficient air to breathe is lost, at considerably lower altitudes rising from Earth than the oxygen

needed to power a jet engine. Thus, humans would require physical protection much sooner than they would need a rocket engine, which does not require atmospheric oxygen to fly. In addition, at various points in space, we would be faced with the potential effects of microgravity, several types of radiation, extremes in temperature and pressure, a near-complete vacuum, and the impact of meteorites. Therefore, for men and women to live and work effectively and safely in various space environments, engineers either have or will design vehicles and habitats, including spacesuits, with countermeasures to protect spacefarers from some of these extreme conditions. Others are pervasive, however, like radiation, which could have serious consequences outside of the protection of the Earth's magnetosphere, in which lie the Van Allen radiation belts, and microgravity, which will likely have an impact on sexuality factors.

Perhaps the most critical aspect of space with which we have to contend, however, is a psychosocial environment that is "characterized by isolation (a separation from the normal or daily physical and social environment), confinement (restriction within a highly limited and sharply demarcated physical and social environment), deprivation, and risk" (Connors, Harrison, & Akins 1985, 7). In fact, they said that in space, "... the physical environment, when not terrifying, is likely to be bland" (p. 9). Pesavento (2000), in a very recent study of the psychological and social effects of isolation in space and during space-simulation analog studies on Earth, said that these may be the ultimate barriers to extended human spaceflight. He noted those factors that have yet to be resolved, including: "depression-like symptoms on orbit [(which Russian space physicians have named "neuresthenia")]; less-than-encouraging social interactions with mixed-gender and mixed-foreign-national groupings; sensory deprivation; as well as the emotional and sexual affects of close confinement on crew members" (p. 1; see also Cabbage 2001).

Yet, many astronauts have also described the profound sense of spiritual and philosophical awareness they gained being in space and viewing the awe-inspiring panoramas, especially looking back at the Earth (White 1987). Some have noted the absence of geographical boundaries, other than land and sea, and the meaning they ascribe to it in terms of the absence of political boundaries and the unity of humanity. Almost certainly, our collective sense of the fragility of Earth's environment has come from some of the widely published photographs taken in space.

For the foreseeable future, however, the laboratory for this grand human experiment will be the International Space Station (ISS), the largest and most complex scientific endeavor ever attempted on an international scale, which began assembly in orbit in late 1998 and had its first sustained trio of inhabitants in November 2000. When finished, the ISS will have a mass of over 1 million pounds (454,000 kg), measuring about 360 feet (110 m) across and 290 feet (88.5 m) long, with almost an acre (4,000 m<sup>2</sup>) of solar panels for electrical power. Flying at an altitude of 250 statute miles (400 km) with an inclination of 51.6°, at which it can be reached by all of the international partners, the ISS will be able to observe 85% of the globe, covering 95% of the Earth's population. It will be the site of a wide range of scientific endeavors and research (NASA 1999).

#### **B. A Brief Historical Perspective**

The realization of the fantasy of space travel is a distinctly 20th-century phenomenon, having its antecedents in the age-old fantasy of human flight dating at least from the ancient Greek story of Daedalus and Icarus. Combining the human need for exploration and discovery with the political

---

\*Citizens from the following countries have flown in space: Afghanistan, Austria, Belgium, Bulgaria, Canada, Cuba, Czechoslovakia, France, Germany, Great Britain, Hungary, India, Israel, Italy, Japan, Mexico, Mongolia, Netherlands, Poland, Romania, Russia, Saudi Arabia, Syria, Ukraine, USA, and Vietnam.

realities of striving for nationalistic prestige and military advantage, and now, with the possibility of vast economic returns, the spaceflight revolution began during World War II with the development of the first V-2 ballistic rockets used by Germany against Great Britain. One of the fascinating stories surrounding the end of the war involves the race, won by the Americans, with the then-Soviet military to capture these rockets after the fall of Nazi Germany, which, in 1946 and 1947, were used by the U.S. to carry its first biological payloads into space (Bushnell 1958). It was the V-2 rocket that made human spaceflight a theoretical possibility, and this, in turn, both stimulated an interest in suborbital test flights and spurred the development of space biology, as well as space medicine, which was first discussed by leaders at the U.S. Air Force School of Aviation Medicine in 1948 (Nicogossian, Pool, & Uri 1994). Thus began the pervasiveness of a military culture, with its similarities yet distinct dissimilarities with the wider culture of which it is a part, which once dominated but still persists in national space programs.

Test flights by the U.S. continued, including two primates in V-2 rockets prior to 1950, various animals in rockets until 1952 and high-altitude balloons from 1950 through 1954, and two men in balloons in the summer of 1957. Similar ballistic rocket flights by the Soviet Union from 1949 through 1957 used dogs as subjects. The Space Age proper is said to have begun with the launching by the Soviet Union in October 1957 of Sputnik-1, the first artificial satellite to orbit the Earth. This was followed a month later by Sputnik-2 carrying a dog named Laika, the first animal in orbit. The U.S. responded with the February 1958 launch of Explorer 1, which detected what would be named the Van Allen radiation belts. Subsequently, both the U.S. and the Soviet Union launched a number of animal flights, using mice, rats, monkeys, dogs, or other small animals, sometimes to test systems that would later contain humans. In April 1961, the Soviet cosmonaut Yuri Gagarin became the first man to orbit the Earth, with Gherman Titov being the second in August 1961. Following two manned suborbital flights by the U.S., John Glenn was the first American to reach orbital flight in Mercury's *Friendship 7* in February 1962. In June 1963, Soviet cosmonaut Valentina Tereshkova became the first woman in space.

It would be almost two decades later, August 1982, before the second woman, cosmonaut Svetlana Savitskaya, would fly; she would later be the first woman to conduct an EVA (extravehicular activity) in July 1984. Although it is widely accepted today that women will always be a part of the American space program, it was over 20 years, almost to the day from Tereshkova's historic flight, before the first American woman, Sally Ride, would fly on the space shuttle in June 1983, and October 1984 for the first EVA by an American woman, Kathryn Sullivan (Cassutt 1993; Nicogossian et al. 1994). Although it is interesting to note that Tereshkova's flight was considered by many at the time to be a Cold War public-relations ploy by the Soviet Union (Santy 1994), the United States had tested women as potential astronauts as early as 1960 (Atkinson & Shafritz 1985; McCullough 1973), although this fact is not widely recalled today. When news of it reached the press, it was treated with skepticism and flippancy. In fact, these women had been systematically barred from the space program, even though it was thought by some in the scientific community that women might be better suited, both physically and psychologically, for the severe requirements of those pioneering spaceflights (Levin 1989). These events illustrate an example of the collision of prejudice (sexism) with scientific knowledge that occurs all too often with sex-related issues (see Noonan 1998a).

Santy (1994) expressed her belief that a contributing factor to women's finally being selected as astronauts, although less obvious, was the fact that the first private toilet had recently been designed for use on the space shuttle:

The issue of privacy, linked as it was to sexuality and personal hygiene, had been a big factor in NASA's reluctance to include women as astronauts, and the development of the private toilet—probably more than any other reason—encouraged NASA to believe that females could finally (and without embarrassment to the agency) be integrated into Shuttle missions in a way impossible during the earlier missions. In *Gemini* and *Apollo* missions, the spacecraft required that crew members live side by side without even the most minimal capability of providing privacy for personal activities. (p. 51)

In 1978, the first group of astronauts to include women and male minorities was chosen. It was considered a watershed event, signaling a change in the way in which future astronauts would be recruited and selected (Atkinson & Shafritz 1985). In fact, it was probably our first experience with what would later be called the "development of space cultures" (cf. Harris 1996), given that racial and ethnic minorities have distinct cultural attitudes and behaviors, and many regard males and females as having different cultures as well (Francoeur 1997, 1998). Cultural factors later became important in the Space Shuttle Program, which first flew in April 1981, and in the Shuttle-*Mir* Program, including Shannon Lucid's current-American-record 188-day stay on *Mir*, which resulted in unprecedented cooperation and trust between the U.S. and Russian space programs. The Shuttle-*Mir* Program, in which several Americans flew on *Mir* between 1995 and 1998, was designed in part to elicit some of the possible psychological, psychosocial, and human performance aspects of multicultural crews in preparation for the International Space Station (Morphew & MacLaren 1997). All of these experiences led to the present ISS, first known as *Alpha*, with its historical antecedents in the early space stations of the U.S. (*Skylab*) and USSR (*Salyut*) in the 1970s.

At the present time, international treaties govern the use of space, including the Outer Space Treaty of 1967, the Liability Convention of 1973, the Moon Agreement of 1979 (which was never signed by the U.S. or Russia), and others, under the auspices of the United Nations Committee on the Peaceful Use of Outer Space. Also, other agreements have been entered into in the telecommunications realm (Harris 1996). In addition, in the United States, Congress and the President determine space policy. Federal agencies also affect space activities, including NASA (the National Aeronautics and Space Administration), the Federal Communications Commission, and the Departments of State, Defense, Transportation, Commerce, and Energy, as well as the military, as noted earlier. Similar national organizations function in other countries. The Space-World Bar Association (Smith 1997) is working further to develop a prototype Lunar Economic Development Authority that would coordinate the planning of more extensive uses of space resources, not the least of which are the mineral resources expected to be mined and the microgravity environment expected to make possible new manufacturing opportunities.

Space tourism, in fact, is expected to be a very important, although initially expensive venue in which ordinary citizens will be able to visit space habitats for their vacations. Just as air travel has become common today with its mass-market availability and the concurrent affordability resulting from it, a few entrepreneurs are already creating private companies to offer the service. One expected attraction is

what a former U.S. congressman called widespread public attention to: the honeymoon in space (Gingrich 1995). Such ideas, of course, echoed similar predictions by science fiction writers, such as the space visionary, Arthur C. Clarke (1986), but this was the first time that such an inherently sex-bound human activity was included in a political vision for future Americans (if not for the bulk of humanity).

### 1. Basic Sexological Premises

#### A/B. Character of Gender Roles, and Sociological Status of Males and Females

Early in the space programs of both the United States and Russia, men were virtually the only ones recruited for space missions. Although this has been attributed to the fact that the Eisenhower Administration in the U.S. directed that military test pilots be the first to attempt these early missions because of their skills in testing new aircraft designs, and the inherent danger they entailed, women had been considered as early as 1960 (see Section B, A Brief Historical Perspective, above). At present, women have been an integral part of the various space programs, including commanding the space shuttle, although there is still not a gender-balance in the ranks of astronauts. In addition, some authors have noted that sexist attitudes have been a part of the experience of some women, as well as attitudes that some women still have to prove themselves because they are women (Casper & Moore 1995; Connors et al. 1985). The issue with regard to the development of the toilet, noted above, serves as an example of the constraints surrounding the biological aspects of our differing anatomies, and psychological differences have been cited as well (see Noonan 1998a).

#### C. General Concepts of Sexuality and Love

##### *Conjecture on the Influence of Spaceflight on Sexological Issues*

Levin (1989), a British consultant on reproductive and sexual physiology, has written the most extensive review of the possible effects of space travel on these human systems. In surveying the research literature, he wrote:

Despite th[e] large number of people who have been exposed to space flight with all its attendant hazards, our knowledge about the effects of space travel on the human reproductive system, and human sexuality, is sparse, bordering on the non-existent. Some of the most elementary questions seem not to have been investigated, indeed in some respects not even to have been asked. For example, it appears that no programme to evaluate the effect of space travel on human spermatozoa was ever initiated despite the obvious hazard of exposure of astronauts to radiation, stress and G forces. Even if asked, answers have not yet appeared in the open literature. (p. 378)

With regard to the lack of research on the behavioral aspects of human sexuality, Levin provided additional insight:

In some respects this near-complete avoidance of what is a sensitive area of human behaviour represents a significant failure to investigate fully the possible reasons for the known stresses of living in isolated, confined environments. It is remarkable that there is no study as to whether human sexual activity, *or its loss* [italics added], can influence the adverse effects of such environments e.g. boredom, listlessness, sleep disturbances, fatigue, impaired cognition, irritability, hostility, depression and deterioration of personality. (p. 382)

Despite these concerns expressed within the space science literature—and readily available in their headquarters

library in Washington, D.C.—little research has been done by NASA, whose typical response has been that sex is not yet an issue (Date 1992; Vaughan 1992). It is my contention that much of this official response to sexual expression and to sexual research by the U.S. space establishment has been guided by attitudes distorted by a conceptualization of human sexuality as a capacity to be feared, avoided, sensationalized, problematized, or trivialized unless considered within the traditional boundaries of American sexual propriety. Similar negative views of human sexuality have failed to alleviate many of the perceived problems of people on Earth—and, in fact, have created many more problems because of ignorance and irrational fear (see Francoeur & Perper 1997; Weis 1997). Americans, after all, whether educated scientists or the generally scientifically ignorant general public, are Americans first. As such, we have been profoundly influenced by cultural values publicly accepted and promulgated by those who define society's norms, even if those norms have often been privately ignored by significant numbers of people, including, often enough, the very leaders who promote them.

In 1998, the first comprehensive analysis of human sexuality factors in relation to extended spaceflight, *A Philosophical Inquiry into the Role of Sexology in Space Life Sciences Research and Human Factors Considerations for Extended Spaceflight* (Noonan 1998a), was published, in which the author explored the issues and constraints surrounding the study of sex in space and conjectured about the potential impact of our sexual nature on mission success or failure. It suggested new terminology, the *human sexuality complex*, as a useful construct in which to consider the various sexuality factors in which human beings interact in and with their various environments.

The complexity of human sexuality, human sexual relationships, and sexual responses suggests the advantages of adopting a complex systems approach, one that draws on chaos and complexity theories, in future research on sexual phenomena and the interactions of its various components conceived as systems (Noonan 1998ab). Research on human sexuality in space, it would seem, could definitely benefit from the systems perspective, much as it was essential in developing our space programs. It also seems worthwhile and reasonable to consider the space environment to be a culture in itself, a “microsociety in a miniworld,” as Connors et al. (1985, 2) described it, although it is also influenced by the outside cultures that sponsor it, much as any organization or workplace develops an indigenous culture, and the cultures of birth and subsequent origin of the individual crewmembers. In time, of course, any group will develop its own culture and norms that may be independent and/or an intricate mix of the others.

[Update 2003: Stuster (1996, 180-181) discussed the reluctance of NASA to deal with sexual behavior mainly because of concerns about media reactions, and noted historical parallels with some earlier explorers (restricted to commanding officers and expedition leaders when it occurred) who took wives or mistresses with them on long voyages. He cited Kanas and Federson (1971), who “tongue in cheek” discussed “Tension Reduction” associated with a multiyear mission to Mars:

The question of direct sexual release on a long-duration space mission must be considered. Practical considerations (such as weight and expense) preclude men taking their wives on the first space flights. It is possible that a woman, qualified from a scientific viewpoint, might be persuaded to donate her time and energies for the sake of improving crew morale; however, such a situation might

create interpersonal tensions far more dynamic than the sexual tensions it would release. Other means of sexual release (masturbation, homosexuality) would be discouraged because of the confined quarters and the lack of privacy on such a mission. Thus, it appears that methods involving sublimation are more practical than these more direct alternatives. (p. 38)

[Stuster (1996) also noted how women contributed a stabilizing influence to the isolated Antarctic research stations when they were first introduced to the continent and became a regular part of expeditions. In contrast to the men's previous boisterous and disruptive behavior, he wrote:

Winter-over crews now tend to be less disruptive and more concerned about their behavior or, more accurately, how women in their groups perceive their behavior. More important, the groups are believed to be more productive now than they were in the male-only days of Antarctica. Several experienced Antarctic managers confirm this observation. (p. 178)

[Thus, it appears that this behavior is similar to ordinary American life. (*End of update by R. J. Noonan*)]

On the International Space Station or future space habitats, it is likely that conflicts will occur when the status of women and men are inherently unequal, or if there is a perception of sexual deprivation among some members of a crew when others are in a sexual relationship there, as has occurred in Antarctica analogs (see Noonan 1998a). An anecdotal story tells of a Muslim passenger on an international spaceflight who had to take directions from a woman. Whenever she addressed him, he ignored her, because his cultural heritage, influenced by his religious beliefs, prohibited such contact between men and women. As a result, directions needed to be given by the woman to a male colleague who then repeated them to the man who then carried them out.

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A/B. Source and Character of Religious Values, and Character of Ethnic Values

The experiences of U.S. astronauts on *Mir* are well-known examples of some of the problems encountered by international crews of different ethnicities. Pesavento (2000) and Harris (1996) highlight the potential impact that cultural differences have had or might have on future missions. Of particular importance with respect to cultural and religious factors would likely be the compatibility of crewmembers' worldviews, as Francoeur and Perper (1997) have elucidated. The example previously noted of the Muslim crewmember's inability to interact with women as a partial result of his religious beliefs about innate differences between the sexes would also be relevant here. Of equal or greater importance might be the organizational (i.e., NASA's) stance and corporate-cultural beliefs about sexual issues that are transmitted to crewmembers (probably reinforcing similar beliefs in the astronauts), although such beliefs may have the same questionable effectiveness long-term as similar ones do generally in the U.S. and in other societies today.

## 3. Knowledge and Education about Sexuality

### A/B. Government Policies and Programs, and Informal Sources of Sexual Knowledge

The impact on extended spaceflight is likely to occur as a result of policies that resist the study of both the potential positive aspects inherent in the human sexuality complex

as well as the potential negative ones. There may also be problems in failing to communicate the findings—and their importance—to the space community, Congress, and the American public as a whole, once they have been studied. The sexual myths of individuals at all levels of the scientific, administrative, and other parts of space organizations and their contractors or subcontractors are also likely to have a negative impact, as the myths become the guiding principles that are incorporated in the organizational philosophy. Perhaps another benefit of the space program (the so-called spinoff effect) could be the furthering of sexual knowledge by combining sexuality education and space education. Young people are very interested in both, and each subject could be used to impart knowledge about the other, particularly in the realm of science.

## 4. Autoerotic Behaviors and Patterns

### A/B. Children and Adolescents, and Adults

Today, masturbation is believed to be a generally healthy and normal part of the experiences of human beings throughout their lifecycle. Nevertheless, we are still influenced by some of the beliefs of the 19th century, that masturbation (and ejaculation in general) depletes certain personal mental and energy reserves, such as when coaches sometimes suggest that neither be engaged in prior to competing. Money (1985a) has shown that this now-discredited degeneracy theory of masturbation, which some people thought could be counteracted by proper fitness and nutrition, prompted prominent health proponents, such as John Harvey Kellogg and Sylvester Graham, to develop foods they believed would extinguish sexual appetite and masturbation. Today, two of these foods remain associated with their creators, Kellogg's corn flakes and graham crackers, respectively, although their original purpose is long forgotten. Nevertheless, some religious traditions continue to oppose masturbation as moral degeneracy. Both of these traditions—the medical and the religious—are likely to be important in the context of space, because they have and will prevent the study of masturbation as a sexual activity that will likely be practiced in space, in the unlikely event that it has not been already. Among other things, it can help to counteract boredom and stress, and the environment is amenable to it, in that sufficient privacy can be found in which to practice it. Pesavento's (2000) recent study noted that in the early 1970s, a physician suggested that masturbation would be an effective countermeasure to maintain prostate health and avoid urinary tract infections for astronauts on *Skylab*, the longest mission of which lasted 84 days. Children and adolescents will, of course, practice masturbation when they become a part of settlements in space in the distant future, just as they will have hetero- and homosexual experiences, as they do on Earth in various societies today.

## 5. Interpersonal Heterosexual Behaviors

### A/B/C. Children, Adolescents, and Adults

Heterosexual behavior encompasses a wide variety of possibilities: in specific activities, such as kissing, oral and anal intercourse, and vaginal-penile intercourse, for example, and in the variety of ways in which they can be done. A device has been patented, the "Belt to Paradise," to enable sexual intercourse in microgravity (McCullough 1992). In addition, there are numerous fantasy behaviors that can be acted out with a partner or imagined alone. Any of these heterosexual activities are very likely to occur in space at some point in the future, if some have not occurred already. Pesavento (2000) has discussed some of the rumored pairings that have occurred, although everyone officially denies

that anything happened. However, it seems likely that sexual intercourse and oral sex have already occurred in space. It is likely because, in our culture, sex is pervasive, gender awareness is ubiquitous, and the astronauts are mostly young, healthy people. However, given the current political climate, it is not possible nor expedient to prove that sexual behavior has occurred because of the potential harm to the astronauts involved, as well as to the space program as a whole. Speculation at this time may be the best approach until the next sex-positive cultural phase, which, if Reiss (1990) is correct in his characterization of sexual revolutions as being cyclical, will probably occur early in this century, that allows and emphasizes healthy sexual experience as the predominant social norm (see also Noonan 1996, 1998b).

Given our experience on Earth, it is also very likely that at least a few astronauts have entertained the notion of being the first to “do it” in space—unknown to the world, but still a shared, cherished, intimate secret. In addition, there has long been evidence that higher levels of intelligence and overall education—characteristics selected-for in astronauts—increase the likelihood that certain sexual behaviors will be experienced (Hunt 1974). At this point in the space program, the astronauts are a large-enough population so that individuals would likely be able to find appropriate partners. Privacy and space in which any sexual activity can occur, albeit scarce, can be made available with appropriate planning. Sexual intercourse can also be done rather quickly, if need be, with very satisfactory results.

Our experience on Earth with some of the heterosexual subcultures, such as multiple sexual partnerships, also would imply that, although they have been sometimes problematic when flaunted in an atmosphere of sexual deprivation for other crewmembers in the analogous Antarctic settings (see also Stuster 1996), in the more-normal conditions of typical urban, suburban, and sometimes rural settings, extramarital affairs, multiple relationships, and even group sex, have the potential to coexist with the more traditional expressed norms of heterosexual monogamous marriage (Libby & Whitehurst 1977). When these alternative relationship patterns are successful (i.e., functional), it is usually because the couple and the subcultural network in which it functions have adopted it, and group norms have evolved that define their expression, often in contrast to how they perceive the outside world's views of their subculture's behavior. In space, because there will be limited populations for the foreseeable future, both with and without a balanced gender mix, the various diverse alternative sexual lifestyle patterns might be an avenue of inquiry to minimize potential problems. Again, given the current political and social climate in the country, it may be necessary to keep it an internal group secret. Nevertheless, a television news magazine reported the possibility that group sex had occurred in space (Anderson 1992).

[Update 2003: The first wedding took place in space on August 10 between International Space Station commander, Yuri Malenchenko, a Russian cosmonaut, and Russian-born Ekaterina Dmitriev, an American citizen, in Texas. A quirk in Texas law allows a person to get a marriage license and to get married by proxy if one of the parties is not in the state. Malenchenko was present via a video downlink, with a lifesize cutout of him also used in the ceremony in a Johnson Space Center meeting room. Neither the Russian space agency nor NASA was enthusiastic about the marriage, however—Russia because, as a colonel in the air force, he needs prior clearance for changing his family status, and NASA because of the use of ISS resources. They will need to remarry when they return to Moscow, because the marriage is not recognized as valid by the Russians. (Boyle 2003; Stewart 2003). (End of update by R. J. Noonan)]

## 6. Homoerotic, Homosexual, and Bisexual Behaviors

### A/B. Children and Adolescents, and Adults

Connors et al. (1985) considered the possibility of homosexual relationships in space, although they considered heterosexual relationships to be the more realistic problem. At this time, it appears that homosexual activities in their varied forms are significantly less likely to have occurred in space, even if there are gay astronauts, simply because the majority of their colleagues are likely to be heterosexual; in addition, the process of coming out (making their homosexuality known to others) would very likely be the end of their career. However, homosexual sex may have occurred, because individuals are often able to find each other by conscious and unconscious subcultural cues. Then, allowing for the accidents of time and scheduling, potential homosexual partners may have been assigned to the same flight, guaranteeing training together for the mission and allowing them to be together in space for sex to occur. Again, it would not be politically expedient to prove that homosexual activities have occurred for the same reasons noted above for heterosexuals, but in this instance, there would also be the potentially greater harm that might come to a gay astronaut if his (or her) sexual orientation were unintentionally made public (although losing one's career would likely hold true for heterosexuals as well, if the activity occurred outside the accepted bounds of marriage).

The number of women who are astronauts would make lesbians even less likely to be represented in the astronaut corps than gay men, and thus would make it less likely that lesbian sexual activity has occurred. Nevertheless, both lesbians and gay men are represented in other aspects of the space program. The likelihood of bisexuals who might be astronauts is more difficult to assess, because many bisexuals typically do not identify themselves as a distinct subculture, but tend to shift between heterosexual or homosexual affiliations. Bisexuals, female and male, who are attracted equally to females and males are less common than those who tend to focus on one sex or the other. With regard to multiple pairings, my comments with reference to heterosexual astronauts would also likely apply, although in the case of gay astronauts, more or less their whole sexual persona would need to be kept secret in the present social climate.

## 7. Gender Diversity and Transgender Issues

At present, this issue probably has no relevance in the space programs.

## 8. Significant Unconventional Sexual Behaviors

### A. Coercive Sex

#### *Sexual Harassment and Rape*

Sexual harassment has been cited as a significant problem in the military, and, although it is often used now as a means of extortion or harassment itself, trivializing its actual victims as well as obscuring its real meanings and incidence in general, there is little information as to whether it has been a problem in the training or other professional or social settings involving the astronauts; it could be a problem in a space setting where significant levels of stress might precipitate that or other antisocial behavior. The same might be said for rape, although it is less common than sexual harassment. Clearly, we have not yet found the solutions to these problems in many of Earth's cultures.

Casper and Moore (1995), noting the instances of friction in the analog and space environments that have occurred as a result of the psychosocial stresses covered earlier, at one point highlighted the possible sexual violence that might occur because of these stresses. Apparently rejecting the evidence that shows that mixed-sex groups function more effectively in many ways than single-sex groups (Bishop 1996a; Pierce 1991; Stuster 1996), they wrote:

These accounts raise compelling questions about the limits of the "complementary sexes" model proposed by NASA as leading to more harmonious and productive work. Psychological disturbances raise the specter of sexual violence, racial violence, and other serious interpersonal conflicts resulting from stress induced by long missions. It is somewhat disturbing to us that sexual behavior in space is assumed to be "total consenting adult free-choice sex." Given contemporary gendered power dynamics, this seems naively idealistic. Yet, an interesting research question is presented by the possible effects of weightlessness on expressions of sexual and other types of violence. For example, how would physical/bodily deterioration affect an individual's capability to overpower, force, and/or injure another astronaut? What does force look like in a 0-gravity context? Despite these concerns, issues of sexual violence are rarely raised with respect to long-term travel, and when we mentioned this possibility to informants they seemed vaguely puzzled. (p. 325)

Coercive sexual behaviors and blatant sexual harassment are not likely to be a problem in space, except in the event of a complete breakdown of the microcommunity within the space culture. As Pierce (1991) noted, such microaggressions are usually more verbal and do not result in explosive violence. Rather, Casper and Moore frame outcomes of sexual expression as likely to be negative, reflecting the prevailing antisexualism of our culture, and is a clear example of the concerns noted by Money (1995b) regarding the effects of the pseudoscience of victimology today.

Nevertheless, Pesavento (2000) noted that an attempted sexual assault did occur in a more-than-six-month-long simulated *Mir* mission module at the Institute for Biomedical Problems in Moscow. Alcohol was involved, as it occurred during a New Year's celebration. Still, it is important to emphasize that possibility does not equal likelihood. [Update 2003: Dudley-Rowley and her colleagues (2001/2002) continue to look at crew and mission characteristics that might affect deviance, conflict, and dysfunction in extreme environments. (End of update by R. J. Noonan)]

### B. Prostitution

Prostitution will likely find its way to space settlements once commercial exchange becomes established there, but it will not likely be an issue in any scenario until some time later in this century. It may well be a part of the expected sex-tourism industry that is expected to occur in the not-too-distant future.

### C. Pornography and Erotica

It seems reasonable to expect that there would be a place for pornographic and erotic materials during a long flight. Bluth (1985) has noted that at some Antarctic research stations, "the men liked to watch pornographic films and it's best if a woman is not offended by pornography" (p. 143). This brings up questions of a sexological nature that may have relevance to extended spaceflight. If sexually oriented materials have the ability to relieve stress under extremely trying conditions, then they should be studied to determine if, in fact, they do. They also may serve as a morale booster.

In addition, they may have value in places where there is currently a disproportionate ratio of women to men. The issue of sexual harassment would also be a factor when women are also members of the crew, because many courts have adopted the standard that such material sexualizes a workplace because some women (and some men) are offended by it. Although it is unlikely that it in fact does typically sexualize an environment, this position fails to take into account the sexually oriented materials marketed to gay males or lesbians, nor the feminist-produced corpus of literature and films for women. As a result, the ban on such materials as an expression of sexual harassment is typically applied only to materials oriented to heterosexual males.

Recently, Pesavento (2000) revealed that pornographic films were available to cosmonauts on the space station *Mir*, which Russian space psychologists recommended viewing only in the later stages of an individual cosmonaut's flight. He also described the surprise that American astronaut Norman Thagard had when he found that these soft-core French and Italian erotic videos were there. Pesavento also described plans for a movie to be made on *Mir*, in which sexual activity would be filmed, for which the Russian Space Agency had already been paid millions of dollars for training the actors for their time in space. However, the filmmakers were not able to raise the additional millions needed to save the *Mir* from its planned deorbiting, which occurred at the end of March 2001.

### D. Paraphilias

The paraphilias are those behaviors that are dependent on atypical or socially unacceptable things for sexual arousal, such as inanimate objects or parts of the body or events that are linked erotosexually to a person's childhood. They are thought to arise out of a traumatic or similar event that affects psychosexual development at critical periods during a child's life. Nevertheless, one may speculate that a generally sexually repressive environment would, at the same time, facilitate the expression of paraphilias. In relation to spaceflight, therefore, it would be incumbent upon space officials to create and maintain a sexually positive environment to avoid the problems associated with paraphilic behaviors.

## 9. Contraception, Abortion, and Population Planning

### A/B. Contraception and Abortion

Effective contraception is essential for long-term space travel for heterosexual couples, and efforts need to be undertaken to develop safe and effective contraceptive techniques, both for use on Earth and in space. Pregnancy is currently a contraindication for spaceflight because we do not know what effect the space environment would have on a fetus conceived on Earth. Abortion would probably be required in the event of failed contraception while in space, because of mixed results found with the development of fertilized eggs of various animals, although the morning-after pill could be available as an alternative of first choice. Because abortion at the earliest stages is relatively simple to perform, the necessary equipment for a menstrual extraction or for a later suction curettage should be available in the medical station, as well as appropriate pregnancy-testing kits. Returning to Earth would simply not be an option, at least for the foreseeable future, given that we do not know whether human development *in utero* is possible, nor what would occur later in life if a birth did occur after conception in space.

In an series of articles dealing with the effects of space on humans posted at one time on NASA's website, Jenks (1996) noted that "NASA has not studied the subject of hu-

man reproduction in space.” It was the first sentence of an article mistitled “Sex in Space,” which went on to briefly discuss developmental biology and plant and animal reproduction. However, it did, perhaps, unintentionally serve to highlight the pronatalist bias that persists in many societies’ conception of the primary purpose of sexuality, that is, its procreational aspects. The more-common (and probably more important at the individual level) recreational and relational aspects of sexual behavior, on the other hand, were simply ignored, likely because of the erotic components that tend to fuel them (Noonan, 1998a).

### C. Population Programs

Population planning will become an issue when settlements are needed to be designed for lunar, Martian, or other outposts, and in that case, it is likely to be at the level of engineering the social environment around the professional expertise needed for the various parts of the mission (Harris 1996).

## 10. Sexually Transmitted Diseases and HIV/AIDS

The typical Earth-bound STDs with which we have to contend may present additional problems in space. This is because there is evidence that the immune system is compromised by spaceflight, although Sherr and Sonnenfeld (1997) wrote that some results are difficult to interpret. However, if this is found to be true, they thought it could severely limit long-term human spaceflight. Certainly, additional studies are needed to clarify this possibility, as well as to continue to learn more about our immune systems to be able to meet these challenges. There might also be the possibility that other disease organisms could mutate and become new STDs. The same is true for HIV/AIDS as well. In addition, there is the possibility that studies that gain a better understanding of the human immune system in space may have direct application for dealing with HIV/AIDS. It is also possible, given that drugs are expected to be manufactured in space because crystals form more purely in microgravity, that space science could assist in eradicating AIDS, as well as the STDs and other diseases and conditions.

## 11. Sexual Dysfunctions, Counseling, and Therapies

Sexual response can be viewed physiologically as essentially a series of cardiovascular and muscular events resulting in a buildup of vasocongestion and myotonia to a psychophysiological peak and release known as climax or orgasm—coupled with a buildup and release of muscular tension. In the human sexual response cycle, as sexual stimulation progresses, blood engorges the vascular tissues of the clitoris, penis, and other parts of the body in the process called vasocongestion, while the buildup of muscle tension (myotonia) occurs. This is usually accompanied by an increase in respiration and metabolic activity. Orgasm releases and is typically considered the climax of this vasocongestion and myotonic buildup of sexual tension, in a paroxysmal, rhythmic, reflexive discharge of energy, typically resulting in a feeling of relaxation throughout much of the body.

Among the most visible physiological effects of spaceflight are the shifts in body fluids, most importantly the blood, which rises from the lower extremities to settle into the chest cavity and head. In time, the cardiovascular system acclimates itself to the new environment. At the same time, with less blood volume and no longer the need to pump blood against gravity, the heart muscles begin to relax

somewhat, and the process of deconditioning begins (unless exercise is used to compensate for the loss by forcing the heart to pump harder). A similar condition occurs with overall body muscle tone, especially the large, weight-bearing, anti-gravity muscles that allow us to walk erect and maintain an upright posture. Therefore, we can probably expect a change in our perception of the various physiological phases of the sexual response cycle.

Anecdotal stories confirm that erections can and do take place in space, although a characterization of the quality of these erections has not been done. Information about whether women have experienced clitoral erections and vaginal lubrication has not been forthcoming, although the homologous nature of this aspect of the sexual response cycle would support the conclusion that they have. NASA could be easily monitoring this while the astronauts slept. One may conjecture that both female and male astronauts, when they are not asleep, would perceive a difference in their genital responses from their normal preflight experiences. Using Masters and Johnson’s (1966) four-phase model of the human sexual response cycle, each phase might be affected in the following ways. During the excitement or arousal phase, penile erections in men may not feel as physically strong, particularly as the time in space gets longer and the body continues to adapt to weightlessness by deconditioning. The increase in respiration—the heavy breathing or hyperventilation, along with the increase in blood pressure and heart rate experienced during arousal through the plateau phase to orgasm—may also take more effort and feel more tiring as time progresses for the same reason. In women, clitoral erections and vaginal lubrication are likely to be similarly perceived.

Both vaginal lubrication in women and the erection of the clitoris and its homologue in men, the penis, are essentially vasocongestive in character. Vasocongestion forces the lubricating fluids through the pores of the walls of the vagina. This response varies with age, decreasing as women get older. This is likely to have an impact on astronauts who eventually travel to Mars, because older individuals are now thought to be among the prime candidates for such a trip because of the higher exposure risk to radiation in interplanetary flights. The main idea is that because the radiation effects are usually manifested many years later, it would be more likely that the astronauts would approach the natural end of their lives before the radiation effects would become evident. In addition, it is likely that the older astronauts would be well past the stage of starting families than younger ones would, given the impact of the possible and probable effects of radiation on gamete production.

The myotonia, the increase in muscle tension also characteristic of the sexual excitement and plateau phases, is likely to be experienced by the astronauts as being less intense during spaceflight than they normally experience on Earth, particularly in the voluntary muscle groups over which we have conscious control. This effect may increase as the time in space increases because of the progressive deconditioning of the muscles. Sexual activity, thus, might be an ideal part of an exercise program that people would very likely want to do regularly to maintain overall body and sexual fitness.

All of the effects on the human sexual response cycle just described provide possible mechanisms for a breakdown at some point in the cycle. Thus, there is the distinct possibility that any of the sexual dysfunctions experienced by men and women on Earth may increase or be aggravated in the space environment. But, just as Masters and Johnson (1966) indicated with respect to human sexual functioning on Earth, the range of normal functioning in space will need

to be clarified before mechanisms and ameliorative actions for sexual dysfunctions can be described. Counseling practices will also need to take into account the unique psychosocial environment and the total space experience to be effective. In addition, countermeasures found to treat space-related sexual dysfunction should have application to the same problems on Earth.

Recently published data support the speculation that there would likely be some effect on sexual functioning, although deconditioning was not the focus of the study. Strollo et al. (1998) measured hormone secretion in four male astronauts pre-, in-, and postflight to test their hypothesis that stress-induced hormone changes might impair gonadal function by reducing testicular androgen (especially testosterone) secretion. In addition to its many roles in the differentiation of the fetus and the development of the secondary sex characteristics at puberty in males, testosterone stimulates the sex drive (libido) in both sexes. Strollo et al. found that "[s]exual drive was reduced inflight and postflight as compared with preflight ( $p < 0.05$ )" (p. 135), which correlated with a decrease in testosterone levels in the men. In addition, they noted that there were no endocrine signs of acute stress, in that the levels of adrenocorticotropin (ACTH) and cortisol (CS), although high from the preflight anticipation that astronauts typically feel, did not change inflight, although interstitial-cell-stimulating (i.e., luteinizing) hormone (LH) levels unexpectedly increased. LH stimulates the secretion of testosterone in the testes. The researchers also found that testosterone levels recovered dramatically one day following the astronauts' reentry from space. Thus, they noted, "For the first time, space life sciences research has shown reversible primary hypoandrogenism in man during exposure to microgravity" (p. 136). Nevertheless, although testosterone levels recovered quickly (as measured in the saliva), they noted that 15 days after reentry, other measurements suggested that more than two weeks were required for complete recovery at the cellular level. The timeframe for libido recovery, however, was not revealed in the article, or even whether it did recover. The authors stated that further research was needed to clarify whether fluid shifts or altered androgen distribution in the body because of microgravity was responsible for the results.

## 12. Sex Research and Advanced Professional Education

In the space arena, the time will eventually come when sexological concerns are recognized as legitimate topics for research in support of extended spaceflight missions. Administrators at the top levels of management and those with influence within the space life sciences of national and international space agencies, such as NASA, the Russian Space Agency, and the European Space Agency, need to encourage and support relevant biomedical, psychosocial, and human factors professionals within their organizations to receive advanced sexological training. These professionals should be urged to make contact with colleagues in sexology to find out the advances and concerns within this discipline that might have relevance to their spaceflight responsibilities, as well as to offer their knowledge from the space program that might be relevant to the work of sexologists. The Society for the Scientific Study of Sexuality (SSSS), with its international membership, would be the professional organization of sexologists whose expertise in sex research, counseling and therapy, and education would provide the best interdisciplinary support that would benefit the work of space life scientists. In addition, training pro-

grams for space life scientists should incorporate sexological information into their curricula, and sexologists have the expertise necessary to provide knowledgeable input at all levels of the educational spectrum, including advanced medical training for physicians.

## Conclusion

It should be clear that the integration of various human and mission components work synergistically to provide the context in which space missions will function and how they might be affected by the human sexuality complex. At the same time, it is not yet as clear that humans on Earth will soon come to terms with their own sexualities, as Perry (1990) has noted, and this should be a cause for concern. Despite this truism and the demonstrated evidence that various space life scientists and others have projected that sexuality factors are likely to have an impact on future long-term space missions, the intersection between the two scientific specialties whose domains encompass either the space life sciences or sexuality and gender has scarcely begun to be investigated. This should serve as a call to action to prepare adequately for meeting the challenges expressed here. One focus of intervention will need to be directed toward the managers and mission planners; the other focus will need to be on the individual crewmembers, as well as their families and intimate partners. My earlier work (Noonan 1998a) might well serve as a rationale and an outline for action for the managers and planners in the space endeavor. Certainly, wherever humanity goes, our sexuality will surely follow.

To me, possibly the most important conclusion to come out of my study was embodied in the new terminology I coined, the human sexuality complex, that conceptualized the various factors of human sexuality to be components of a unified system, one that has characteristics ascribed to chaotic, complex systems. Such a conceptualization, I believe, will allow scientists in both the sexual and space life sciences, as well as policymakers in the public domain, to better understand and address both the potential problems of sex and the role that healthy sexual expression has in society and in space. Once we are effectively able to do that, the consideration of the human sexuality complex in the closed ecological environments of space will appear more justified, and so a space sexology might well be established.

## ANTARCTICA

### *Demographics and a Brief Historical Perspective*

The continent of Antarctica at the southern pole of the globe encompasses 10% of the world's landmass, about the size of the United States and Mexico combined. Covering 5.4 million square miles (14 million km<sup>2</sup>), it is the fifth-largest continent, with only 108,000 square miles (280,000 km<sup>2</sup>) ice-free. It is the coldest place on Earth with temperatures ranging from about -25° C to -80° C (-13° F to -112° F), with the lowest recorded temperature of -89° C (-129° F). It holds 90% of the world's ice and 70% of its fresh water. It is a landmass with an average ice thickness of 1.24 miles (2 km) and can be as thick as 2.97 miles (4.776 km). For about six months of the year, there is no sunlight at the pole. Most activity there occurs during the brief Antarctic summer from November to early February, although summer storms with temperatures as low as -60° C (-76° F) and blizzard conditions can occur. Chile, Argentina, Australia, and South Africa are the countries closest to the continent, which is surrounded by the Southern Ocean, which meets the South Atlantic, the South Pacific, and the Indian Oceans (Cornelius 1991; Taylor 1991; John Spletstoesser, polar consultant, personal communication, April 25, 2003).

In July 2002, Antarctica had an estimated winter population of 964, about one quarter of the summer population of 3,687. No other demographic data are available, other than the number of individuals representing each country that is a party to the Antarctic Treaty; these data are available in *The World Factbook 2002* (CIA 2002).

### **B. A Brief Psychohistorical Perspective**

There is no indigenous human presence. However, both men and a few women have been part of the pioneering exploratory efforts over the years since interest in Antarctica began in 1892. Since the 1957 International Geophysical Year (IGY), there has been a continuous human presence on the continent, which no country owns and which has been set aside for scientific and peaceful uses by treaty. As such, approximately 27 nations\* have research programs in Antarctica, either in the summer or year-round, of which those of the United States, Chile, Argentina, Russia, and Australia

\*The nations with research teams in Antarctica at various times include: Argentina, Australia, Belgium, Brazil, Bulgaria, Chile, China, Finland, France, Germany, India, Italy, Japan, Netherlands, New Zealand, Norway, Peru, Poland, Russia, South Africa, South Korea, Spain, Sweden, Ukraine, United Kingdom, USA, and Uruguay.

(CIA 2002)

lia were the largest in terms of number of people in 2002 (according to the CIA data). Although a novelty in the beginning, women are now an integral part of life there.

Once the arduous task of reaching the continent was accomplished for the first time, scientific discovery became the major focus. Often-introspective accounts written in diaries by the early explorers provide valuable knowledge about their psychological experiences and social interactions. These introspective reports gave way after World War II to formal behavioral studies. During the winter season between February and November, the stations are closed to outside travel. Cornelius (1991) described the isolation, which can vary, depending on the station and its distance from the pole, from about seven to nine months:

The isolation is almost complete: no mail, no visitors, no leaving, and no fresh supplies. Outside contact is primarily by the high-frequency radio and sometimes by a satellite link. The first-ever midwinter airdrop at [Amundsen-Scott] South Pole [Station] was accomplished with a C-141B (refuelable version) in June of 1981 and has been done almost every year since. (p. 10)

The airdrop brings mail, fresh fruit and vegetables, movies, and other items. Cornelius expressed his view that this somewhat diminished the totalness of the isolation. He also noted that the radios and other transmissions were sometimes unavailable because of solar storms. Today, the Internet and email provide better communications capabilities than ever existed before, although they too can be sporadic. In 1999, the first midwinter rescue from the United States' Amundsen-Scott South Pole Station was attempted that succeeded in the emergency evacuation of Dr. Jerri Nielsen (2001), who diagnosed and treated her own breast cancer before being airlifted out, which made headlines around the world.

Antarctica is often described as an extreme environment, and human performance in extreme environments is just one major focus of research being explored there today. Pierce (1991) wrote that Antarctica was an environment (like space) in which people would experience the stressful effects of prolonged isolation, confinement, uncertainty, and hazard. In addition, he described other sources of stress and the potential results:

Inhabitants in both places are subject to important psychosocial stresses that affect the success of the expedition. These include lack of privacy, boredom, inability to escape, forced socialization, anxiety, and nostalgia. While operating under these burdens, each individual must comply with a welter of regulations, formal and informal. Some of these are imposed by outside authorities, some by the person's culture, and others by developing traditions within the group. Sensitivity to obligations and regulations is compounded in stressful environments because of the heightened importance of vigilance and leader-follower relations. Constantly, the individual must assess and evaluate each crewmember's entitlements.

Under these conditions, orders from the outside world, differences in lifestyle, differing preferences for such things as music, and conflicts over the use of an exercise facility can develop compliance frictions. This psychosocial travail can yield offending slights, or microaggressions, rather than full-blown explosions or social turbulence. (p. 126)

Pierce (1991) also listed a number of other possible physiological and psychosocial disturbances that could result in some people at some point during their stay. These included: sleep disturbances, anxiety, increased territoriality, decreased performance, reduced motivation, impaired mental efficiency, withdrawal, and occasionally, augmented suggestibility and biological dysrhythmia. However, he noted, unlike the space environment in which space motion sickness has been a recurring problem, no polar-peculiar illnesses or derangements have yet been found. The reader is referred to Harrison, Clearwater, and McKay (1991abc) for a comprehensive review of other Antarctica research that is being applied to space habitability issues (see also the Outer Space section of this chapter).

In terms of possible ramifications for the human sexuality complex (Noonan 1998ab) in extreme environments, it is interesting to compare the occurrence of these microaggressions with similar minor problems that many couples living in more-normal situations experience after living together or being primarily focused on each other over extended periods of time. These microaggressions are usually expressed as verbal, often subtle comments, which can be perceived as insults that sometimes build up to what often appear to be major arguments over minor issues. The apparently almost-universal occurrence of this friction on some level in almost every group in the close quarters of the Antarctic stations (in the apparent absence, at least presumably in most cases, of any sexual interaction) might provide us with some insight into the phenomenon, both on Earth as it so commonly occurs with intimate couples and small workgroups, and its potential occurrence in space. In addition, it might be worth looking to the results of research that seeks to discern the mechanisms for its occurrence and the efforts that are being sought to prevent it, and apply them to everyday life on Earth. In those groups that had both men and women, certain frictions surrounding the actual or presumed heterosexual activity of others have been highlighted by a few reports, which I will review shortly.

Nevertheless, as with any frontier, national prestige factors entered into some of the very early attempts to be the first to reach the "white continent," similar in many respects to that which motivated the explorations that found the New World centuries earlier. Pierce (1991) noted that commerce, science, defense, and politics are the factors that are of strategic importance today for both Antarctica and space exploration, of which Antarctica is considered an analog for scientific research purposes, because both environments are

characterized by isolation, confinement, deprivation, and risk, as noted earlier. In addition to space-based experience (Boeing Aerospace Company/National Behavior Systems 1983a; Bluth & Helppie 1986/1987), space scientists rely on information learned about human behavior in so-called analog environments found here on Earth. Analog environments are those that scientists believe closely approximate some of the key conditions found in space, such as the research stations in Antarctica, which are also remote and hazardous. Studies include those in Antarctica (Bluth 1985; Harrison, Clearwater, & McKay 1991a) and underwater habitats such as long-range nuclear submarines (Boeing Aerospace Company/National Behavior Systems 1983b). The descriptions of Antarctica by Cornelius (1991) and Taylor (1991) highlight why it is considered the best Earth analog for studies of the psychosocial processes that will occur during long-term space missions. Based on such analog studies, extended space missions, like Antarctic expeditions, are expected to follow what might seem to be a quite-obvious pattern, i.e., they have a beginning, a middle, and an end, each with varying durations. Yet, each has specific characteristics with distinct psychological ramifications for the participants, regardless of the full length of the entire mission. Of primary importance are the coping mechanisms that the individuals use to deal with the stresses at hand (Palinkas 1989, 1991, 1992; Palinkas & Browner 1995).

## 1. Basic Sexological Premises

### A. Character of Gender Roles

For most of the 20th century, the primary organization that supported exploratory and scientific expeditions to Antarctica for the United States was the U.S. Navy, although civilians conducted virtually all of the exploration and science after the 1957 IGY (John Spletstoesser, polar consultant, personal communication, April 25, 2003). As such, the old military's attitudes toward women were decidedly exclusionary—and all-male cultures were the norm. As women began to intrude in this all-male world, attitudes slowly changed, although then-current biases were tenacious. Today, private contractors conduct most of the American research in Antarctica, under the auspices of the National Science Foundation (NSF), and women are a regular part of the programs. Kanas (1992) has noted that during long-term Antarctic expeditions, status leveling occurs, in which leadership diverges into domains of expertise, such as emotional support functions, out of which conflicts may arise (of which some may be gender-based).

Similarly, other nations' expeditions originally consisted exclusively of men. Conditions were considered so severe that only men were thought to be able to withstand the rigors of Antarctic life. Finally, after a number of women—always vastly outnumbered by men—joined expeditions over many years, in 1984, an expedition consisting solely of women was sponsored by Germany. Since then, women have begun to approach, but have not yet fully achieved, parity with men in terms of their number and job functions. Today, it appears that women make up about 25% to 40% of most expeditions, with a higher percentage of women in the summer than who winter over, although some still consist of all men.

Robin Burns (2001) provides important insights into this history through the lives of women, mostly Australian, who have lived and worked in Antarctica, providing at the same time important insights into various aspects of the character of gender roles there. A summer expeditioner herself, she interviewed 130 women who spent some time there. Although the timeframes of the expeditions of most of the women were the 1980s and 1990s, some traveled there in the 1960s and

1970s, with a few going there even in 1959. Thus, Burns gives us a sense of the changes that have occurred as reported by these women, as she highlights the history of women on the continent. She also provides a look at the hardships faced by women and the impact of the extended separation from their families, which probably apply to others as well. She writes:

Even with modern communications between Antarctica and Australia, twelve to fifteen months is a long time for couples to be separated. New relationships can form that are difficult to explain, and each may find it hard to understand the experiences of the other; for example, the intensity of life in Antarctica, or the new-found independence of the partner left at home. (p. 18)

She also discussed the difficulties in keeping up with younger children's development, although the use of the Internet now enables closer contact and the exchange of photos.

Burns's subjects tend to say that, although things have changed for women, in many ways the traditional roles of men and women are still in effect, with some men still viewing Antarctica as the "last frontier . . . where men go to prove they're men" (p. 25). Yet Burns also sees Antarctica as beneficial in breaking down some women's stereotypes of men. In some ways, there seems to be some hope of moving toward an interdependence between men and women.

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

Although Antarctica has a multinational appearance, it is really largely a collection of national "neighborhoods," each station being staffed and run by its sponsoring country. As such, religious, ethnic, and other cultural factors tend to reflect, in varying degrees, the composition of the respective countries. One could anticipate, then, that these cultural factors operate in a similar manner to the way they do on their native soil, and, thus, their impact on sexuality factors might be assumed to operate in large measure the same way. Research has yet to be carried out to determine whether the physical and psychosocial environments peculiar to Antarctica mitigate their impact on people's sexuality in any significant way. As noted earlier in the Outer Space section of this chapter, idiosyncratic local cultures at the various stations are likely to develop as well, which will likely have an important impact as well. A good example follows:

Cornelius (1991) described the use of a ritualized nudity activity that was conducted every year at one Antarctic station, usually just past the midpoint of winter. The 300 Degree Club is a South Pole Station custom, whose name came from the fact that the temperature in midwinter (in September) drops below  $-100^{\circ}\text{F}$  ( $-73^{\circ}\text{C}$ ) and there is a sauna that is set to  $200^{\circ}\text{F}$  ( $93^{\circ}\text{C}$ ) for the event. The crew would sit in the sauna wearing nothing but footwear and build up a profuse sweat. They would then dash out into the cold to the marked site of the geographic South Pole (about 325 feet, or 100 meters), pose for a quick picture, then dash back. The trick is not to fall, as the ice would burn like dry ice; the quick freezing of the sweat actually protects the body. Cornelius did not detail whether or how this was done when women were part of the crew. However, a 1996 Discovery Channel documentary reported a similar custom at another Antarctic station in which the members, male and female, after leaving the sauna took a quick dip in the water in a hole that was cut in the ice, before running back inside. This was described as a rite of passage that signified a major turning point of the expedition. This is also relevant to this discussion because of the common idea that many people have of

confusing nudity with inviting sexual activity. However, in both of these cases, there is apparently no overtly sexual significance involved.

Given the realities of sexuality today and the widespread perception that being associated with it somehow compromises one's professional standing and credibility, it is necessary to look at ways in which researchers can release the results of any sex-related research that might be done. Gender-related research does not carry the additional burden that specifically sex-related research does, and is thus being released and results presented at conferences often today (e.g., *Gender on Ice: Proceedings of a Conference on Women in Antarctica*, Edwards & Graham 1994; "Gender-Based Differences in the Cardiovascular Response to Standing," Gotshall, Tsai, & Frey 1991). This may be partly because gender has become neutered, in effect allowing it to be "uncontaminated" by sex, (i.e., the "clean" part above the belt vs. the "dirty" part below), as hypothesized by John Money (1995). In fact, today, it is common to use *sex* and *gender* as if they were synonymous, when sex is actually the biological (genetic, hormonal, and morphological) basis of gender, and gender is the cultural manifestation of sex.

With respect to gender factors, it is clear that, generally, women tend to change the environment in positive ways, because men appear to behave differently than they do in all-male groups (Bishop 1996; Stuster 1996). Nevertheless, Pesavento (2000) has noted that less-than-encouraging social interactions can occur in mixed-gender groupings. (See Section 5, Interpersonal Heterosexual Behaviors, below.)

## 3. Knowledge and Education about Sexuality

Antarctica is by and large an all-adult world, and children and adolescents are not part of most expeditions. Thus, sex education is not and probably will not be relevant in American or most other stations in Antarctica for the foreseeable future. Chile and Argentina, however, do have families, including children, living there year-round, with schools and other small-town facilities (John Spletstoesser, polar consultant, personal communication, April 25, 2003). The children are taught by teachers who come from their respective countries, although it is not known what kind of sex education might be taught. It is thought that the settlements were established to support territorial claims by these two countries should the Antarctic Treaty be dissolved, although none of the claims of the seven countries who make such claims are currently recognized by any others.

## 4. Autoerotic Behaviors and Patterns

No studies have been found that discuss masturbatory behavior in Antarctica. It can be presumed, however, that it is and has been practiced there, not only because of our human nature, but because, in the past, it would have been expected if no (heterosexual) partners were available in all-male crews (although it is normal behavior in individuals in couples in ordinary environments as well). It can also be expected in high-risk environments, in which it can function as a stress-reducer.

There is some anecdotal evidence, however: In all-male groups, masturbation was often the subject of a lot of jokes. At some Australian stations, stories were told of Wednesday nights being "wank night," although they may have been made in jest (Desmond Lugg, former head of polar medicine, Australian Antarctic Division, personal communication May 9, 2003). Dr. Lugg also related the story of how, when he gave the same preparatory lecture to new expeditioners prior to going to Antarctica (after having

been admonished by some women that they get the same information as the men), one woman said, "We wank too."

### 5. *Interpersonal Heterosexual Behaviors*

Intimate relationships do develop, some quite open and some quite secret. I might expect that the open or secret nature might parallel the experience of people in ordinary workplaces or small towns, where group norms establish its acceptability and the positive, negative, or neutral impact on the individuals involved in and around them. There are no data available on the incidence or prevalence.

In an American Antarctic analog study commissioned by NASA for the Space Station Program (Bluth 1985), several aspects of heterosexual interaction were noted under a subheading called "Sex Roles." Among the issues discussed were the benefits and drawbacks of having married couples in the crew and the effects of fraternization, as well as of men's attitudes toward women. Some findings were that fraternization did occur at stations and that it "did not seem to be a problem as much when a woman remained with one person and did not flaunt or change relationships" (p. 141). The comments of one man indicated that those men who did not have a partner felt upset and resented those crewmembers who were indiscreet about sexual relations. Many of the women who wintered-over said they became the victims of gossip. The men also had a variety of other attitudes toward the women, some positive and some negative. One finding recommended that women need to be able to deal with male sexual attention.

Stuster (1996) echoed these observations and provided additional information about mixed-sex pairings:

Promiscuity has had a rare but occasionally disruptive effect at Antarctic stations. Winter-over personnel have reported that if a woman chooses to have a relationship during her stay in Antarctica, it is usually with one man. Senior personnel are typically selected over junior staff, and clean-cut Navy men tend to be favored over the civilian construction workers, which can contribute to friction between military and civilian members of a remote-duty crew. In most cases, the other men tend to respect the decision once a woman makes a choice or makes clear her unavailability. Persistent, unwanted attention has occurred, however, with negative consequences to individual adjustment and group solidarity. Particularly disruptive problems develop when a woman and the station leader are involved in a relationship. In these circumstances, others in the group tend to claim that the leader has an unfair advantage. (pp. 178-179)

Stuster went on to suggest that leaders of space missions should avoid such involvements, but added that "it might be unwise for mission managers to dictate how crew personnel conduct this aspect of their personal lives" (p. 179).

Bluth (1985) also identified the "Antarctic Queen Syndrome," in which "every woman is beautiful," which "[s]ome women take advantage of . . . and play man against man" (p. 142). The Antarctic Queen "flirts with all the males, . . . always asks for favors [and] attention, . . . [and], "[i]f they need help . . . honey up to one of the guys, [which] causes problems between people and groups" (p. 142). Clearly, many of the situations noted can occur in non-isolated environments as well; however, in the latter situations, there are alternatives outside the group that can mitigate the frustration and problems that can occur.

Nevertheless, the benefits of both men and women working together appear to outweigh the disadvantages, as noted by Bishop (1996) and Stuster (1996). Bishop noted that in

Earth-based studies, mixed-sex groups appeared to perform workgroup tasks better than all-male groups. She also reported that in military mixed-sex interactions, aggressive behavior appeared to be lessened, disciplinary cases were fewer, and the problems with sexual liaisons and pregnancies anticipated by critics failed to materialize. She also said that the addition of women tended to normalize group functioning, in that the presence of women seemed to enable or encourage the men to engage in a greater range of expression and cooperative behavior than in all-male crews. Women and men on extended spaceflights are likely to experience similar pressures and benefits, even though the crew sizes for the foreseeable future will remain smaller than on most Antarctic stations today. Law (1994) anticipated that many of the problems would not be solved until a more even balance of women and men is achieved. Lugg noted that women's entry into Antarctica after the transition from all-male to mixed-sex expeditions caused disruptions at times, but that it depended on the leadership and other factors (personal communication May 9, 2003). All this suggests that sexuality factors will still likely be stresses that will need to be addressed in both Antarctic and space environments.

Careful planning of living quarters with the assumption that sex is likely to take place is just one aspect that needs to be considered. In describing the differing characteristics of the Palmer Station, which is located near the coastline and so enjoys slightly less harsh conditions than the South Pole Station, which is located deeper in the interior on the high ice plateau, Cornelius (1991) noted in passing that the design of that station was poorer than that of the South Pole Station. In describing the crew's private quarters at Palmer, he wrote that, as a result of the station's poor design, which caused additional problems and stress, the acoustic privacy left much to be desired: "One can hear the crewmember in the next room breathing, making love, or listening to *his* music" (p. 14). In a follow-up article by ABCNews.com (2001) discussing Dr. Jerri Neilsen's outcome of her breast cancer and her planned return to Antarctica to work as a doctor on a cruise ship, she was quoted as saying that there were little of either sex or romance for similar reasons. Thus, some acceptance that sexual activity will take place, and a little foresight and planning, can help to alleviate some future problems with respect to sexuality factors.

Nevertheless, Burns (2001) has written that sexual relationships do happen in Antarctica. She noted that one third of the women she interviewed had been in Antarctica at the same time as their current partner, although fewer than half of these had started the relationship there. She noted that women entered sexual relationships for two reasons: One was to share the special experience of being in Antarctica with an intimate partner; the other reason was to handle the various pressures that had to be addressed.

In addition, Burns (2001) described the psychosocial aspects of relationships, such as dealing with male competition and the sexual activities of women who are known to be married, and the impact these can have on the men who might resent the fact that women have a choice of partners, whereas they do not. With respect to the married woman, it may arouse fears about what their wives at home may be doing. It appears that many of these dynamics, which are not uncommon outside of Antarctica, may be heightened in the extreme environment there. These dynamics might be useful for space mission planners in their Mars mission planning, for example, as the trip is expected to take maybe three years with far fewer people, which could exacerbate these effects further. It will be important to ascertain the differences between the two environments, however, as well as the psychosocial relationship variables that are different to more accu-

rately gauge what can be done to minimize any potentially negative impact and to maximize the positive potential.

## 6. Homoerotic, Homosexual, and Bisexual Behaviors

### A. Adults

It is unlikely that there have been no gay Antarctic participants, and Burns (2001) has noted that “differences in ethnicity, class and sexual preference, as well as gender, are all reasons for not belonging” for women “to the male hierarchy” (p. 87). Thus, we might assume that this might apply to gay men as well. In my early research on this topic (Noonan 1998a), I came across Lugg (1991), who, writing of Australian expeditions, wrote that descriptions of “groups who lisped or used ‘quaint’ language” (p. 32) are part of the folklore of the Australian experience. I took this as a possible reference to the use of stereotypical American gay-male behaviors, which are often used for either ridicule or self-parody, although they are not typically used in everyday life by gay men. In a subsequent conversation, Dr. Lugg noted that it really was not related to gay caricatures, but rather that the language in the group mimicked the lisping of jokes that circulated one year at one Australian station, as well as the quaint language (i.e., old British-style accents and such) of old movies, which they would watch without the sound and the men would provide the dialogue imitating the actors. Thus, this is a good example of how different cultural behaviors and their meanings can lead to misunderstandings. He noted further, with respect to the lisping, that the language of the men had changed—they had developed their own language (inflections, meanings, and vocabulary) because of the isolation and their response to the environment. For the same reason, dogs at the station would sometimes be personified and become quiet partners in conversations. A parallel can be seen in less-isolated workgroups, and especially in intimate couples, where private languages often develop because of their insular nature.

Law (1994), a leader of 28 all-male Antarctic expeditions for Australia from 1947 to 1966 that established that country’s three Antarctic stations, speaking at an Australian international conference on women in Antarctica, said:

So far as I know there was no overt homosexuality at our stations. We of course, went to some pains to avoid homosexuals in the selection process. I heard that one man, a bisexual ex-naval rating, did some soliciting early on, but there were no takers, so that sort of fizzled out. Whether there was any covert homosexuality I would not know, but it would have been very difficult at a station to have kept secret such a liaison, and I was never informed by any of our men that anyone knew of anything of that sort happening. (p. 72)

Despite these comments, he appeared not to be necessarily opposed to homosexual behavior, however, as he qualified his statement:

In that regard, however, I must point out that if we are to advance arguments justifying heterosexual behaviour at ANARE [Australian National Antarctic Research Expeditions] Stations now that women are admitted as expeditioners, then for the same reasons we shall have to accept possible homosexual behaviour and modify our selection processes accordingly. (p. 72)

He added, “It is important to stress the need for discretion in both heterosexual and homosexual behaviour at stations. Overt behaviour is objectionable for a number of reasons.” He went on to say that the role of the leader in the event of

sexual behavior was important and could have a “considerable effect in moderating undesirable behaviour” (p. 72). Puskeppeleit (1994), the leader of the first-ever all-female expedition to Antarctica that was sent by the German Polar Institute, also speaking at the women-in-Antarctica conference, did not address the possibility that homosexual behavior was an issue at all for the women. She did note, however, that all of the women “would have preferred a mixed over-wintering team” (p. 80), which the Institute would not allow.

Even today, potential problems could emerge with crewmembers who discovered that one of their team was homosexual or bisexual—just as they have when certain behaviors have been perceived as inappropriately heterosexual.

## 7. Gender Diversity and Transgender Issues

Although intersexual issues may become an issue in Antarctica in the future, it appears not to be so now, although it is known that men, as in some other all-male analog environments, sometimes dress up and act as women for parody and entertainment. The explanation seems to be that it occurred when there were no women who were part of the expeditions, and the men missed the company of women and sought to “normalize” the social environment. Burns (2001, 83-84, 91) noted, however, that “cross-dressing, ‘girlie’ posters and magazines, regular blue movie nights and ‘page three girls’ in the daily station news bulletins have been part of the tradition” at Australian stations, “and all have become contentious in recent years.”

## 8. Significant Unconventional Sexual Behaviors

### A. Sexual Harassment, Rape, and Prostitution

Personal accounts of those who were in Antarctica when women first arrived suggest that mild forms of what has come to be known as sexual harassment, i.e., constant attention and cajoling for dates and such, appear to have taken place. As noted by Stuster (1996) in Section 5, *Interpersonal Heterosexual Behaviors*, apparently more-recent persistent, unwanted sexual attention has occurred, with negative consequences to individual adjustment and group solidarity. No reports of real (quid-pro-quo) sexual harassment, as opposed to the current social construction of “sexual harassment,” or rape were found. Prostitution does not seem to occur.

### B. Pornography and Erotica

Cornelius (1991) noted that the ways in which the crew decorated common areas, such as with a large mural of a forest, probably helped to relieve stress during the period of isolation. This is likely to be true for the individual crewmember’s small private quarters as well, in which he noted the “[m]any nature scenes and posters of the opposite sex” (p. 13). Law (1994) further noted that the Australians were always astonished at the number of nude photos on the walls of the American stations. The role of the use of sexually oriented materials in the leisure activities of the crew is, however, an issue that was not addressed in any of the analog studies, except that of Bluth (1985), who noted that at some of the stations, “the men liked to watch pornographic films and it’s best if a woman is not offended by pornography” (p. 143).

Also, stories are told of how, along with Russian fur hats, American *Playboy* magazines, when they were banned in many countries, would become a valuable local currency in trade. In fact, *Playboy* centerfolds became part of the history of one station in the 1950s, where they were used to cover a ceiling, nicknamed the “Sistine Ceiling.”

Anecdotal reports say that when women first became part of the expeditions, they tended to ignore the pornographic pictures or pinups (typically less sexually explicit), although they were eventually taken down from common areas. Private areas were considered private, and so these images usually stayed. In the late 1980s and early 1990s, when anti-pornography feminists came in and sexual harassment laws became common, they caused much acrimony and angst at the stations, as pinups and other materials had to be removed. For example, an uproar in the Australian press occurred over one explosive episode when a female leader banned the private posting of this type of material in one's personal area.

## 9. Contraception, Abortion, and Population Planning

### A. Contraception and Abortion

In a report prepared by George Washington University and Analytic Services Inc. (GWU/ANSER 1994a) on potentially difficult and sensitive events, including pregnancy, that might occur in space prepared for the National Aeronautics and Space Administration (NASA), the GWU/ANSER (1994b) team reviewed the Australian and U.S. Antarctic analog environments, and found the following related information. Both countries' stations have reported that pregnancies have occurred during expeditions. The policy they followed was that the woman be evacuated at the earliest possible time. "It is interesting to note," according to these authors, "that the father is not also sent home. The implication of this policy is not that sexual relations resulting in pregnancy are condemned but that the pregnant woman represents a medical liability unsuited for an extreme, isolated environment" (p. 30). They noted that an incubator was available at the Australian station in case the baby was born before evacuation was possible, and that abortions will not be performed there because of legal liability concerns, even though abortion is legal in Australia. However, they noted, pregnancies do not often occur in Antarctica, "[p]erhaps because birth control is readily available at all of the stations studied" (p. 30). The possibility that heterosexual relationships did not occur was discounted with the statement: "As one [Australian] female crew member reported, 'Just about every woman ends up in a relationship'" (p. 40).

CNN.com (2001) reported that New Zealand's Scott Base, located on the Ross Ice Shelf, installed their first two condom machines in anticipation of the influx of visitors in August 2001 in preparation for the warmer spring season in October. The supplier was quoted as saying, "It's pretty much a little village down there where everyone knows everyone, so if they can walk into a loo and buy a condom, it's a lot easier than going to the local shop and buying them, when everyone knows what's going on." It was expected to serve about 400 people, as well as about 1,200 Americans at their nearby McMurdo Base.

## 10. Sexually Transmitted Diseases and HIV/AIDS

It appears that most if not all countries do some screening for various diseases and conditions, and, if one is found with a condition, he or she is not allowed to go to Antarctica, so many diseases apparently do not appear there. Nevertheless, as noted above, condoms are now being sold in vending machines at New Zealand's Scott Base, which are also expected to serve the needs of the U.S.'s McMurdo Base nearby. UNAIDS.org (2002) does not list Antarctica among its list of countries for which it offers an epidemiological assessment, so HIV/AIDS does not appear to have reached that continent.

Various epidemiological data on STDs in Antarctica also suggest that STDs may not be an issue, although STDs have been taken to Antarctica in a number of national expeditions, but were not passed on to others within the group (Desmond Lugg, personal communication May 9, 2003). This suggests that those who had them got them earlier, perhaps in one of the South American entry points or their homelands. Screening specifically for STDs is not done. HIV screening is done through walk-in blood banks, and is provided as an ancillary finding. Because of the possibility of an HIV-infected person converting to full-blown AIDS, that person would probably not be allowed to go to Antarctica, because of the lack of medical support to treat it. It is unknown what would happen with someone who got an HIV-positive test result once there.

Some studies suggest, further, that the polar environment does depress the human immune response in otherwise healthy individuals, although specific environmental factors have not been identified that contribute. I would conjecture that stress is a likely candidate, and it would be interesting to compare the results of any studies on stress-hormone levels with Strollo, et al.'s (1998) study of male astronauts, which showed decreases in libido and testosterone levels while in space, which returned to normal postflight. No similar effects—or reports of sexual dysfunction specific to the polar region—have been reported in Antarctic settings.

Dr. Nancy Chin, a medical anthropologist from the University of Rochester School of Medicine who is studying social interactions in Antarctica, has noted that many summer participants clearly have an away-from-home attitude about being in Antarctica, and being there for sexual exploration is part of the Antarctic experience. However, she noted that sexual diseases are not screened out at the U.S. stations prior to arrival, and so, contrary to some myths, Antarctica is not the safest place in the world to have sex. For the most part, the same risks they faced at home were possible in Antarctica as well (personal communication August 12, 2003).

## 11. Sexual Dysfunctions, Counseling, and Therapies

Cornelius (1991) highlighted some of the major psychosocial factors that contribute to stress in Antarctica:

For example, absent are windows, privacy, living green things and animals, the sun, thick moist air to breathe, freedom to travel, or freedom to leave a rumor-infested, isolated human outpost. The "rumor mill" can be quite potent. Cliques can develop and be quite cruel and stressful to an individual with a different background than the rest of the crew. Cliques can also be quite insensitive to their own kind. Lack of acoustic privacy in the small "private" rooms can also lead to stress. Privacy becomes a cherished commodity. Time away from the group alone is very important for "charging one's batteries." Lack of a partner of the opposite sex can also lead to stress. Married couples who have wintered tend to handle the isolation much better. Constant low light levels can cause stress, too. It was observed that much higher light levels inside the dome at South Pole Station during the isolation period seemed to increase the morale of the crew. The higher light levels tend to decrease stress. (p. 10)

Thus, we can see that the level of stress, which is a major factor in disrupting interpersonal couple relationships and small-group interactions, can be quite high. In addition, stress is a major factor in many sexual dysfunctions. Therefore, we can expect that although stress can affect overall sexual performance and relationships, at the same time some undelineated aspect of the marital relationship (perhaps sex)

tends to mitigate against the effects of stress for some married couples. It has been noted that most of the American work being done in Antarctica is being conducted by private contractors, who often send married couples to Antarctica.

In Antarctica, the value of off-duty leisure activities has been documented (Kelly & Kanas 1994). Such activities can provide the crew with a welcome respite from the monotony and stress of the long winter. Cornelius (1991) noted that, although they depend on the individual, they can include: conversation, watching movies and videos, listening to music, short excursions outside, looking out the windows if there are any, or doing group projects (e.g., building a jacuzzi at South Pole Station). He noted that they also try to find an excuse for a party, not only the standard birthdays and holidays, but also to celebrate midwinter (which signifies roughly the halfway point of the expedition) and the sunset and sunrise (there is only one sunset, corresponding roughly with our vernal equinox, and one sunrise, at about our autumnal equinox, in the interior parts of the continent each year).

Still, anecdotal stories have been told that suggest that some marriages have failed as a result of the Antarctic experience. Stuster (1996) confirmed this when he wrote:

It is true that extremely disruptive and even dangerous relationships have developed among mixed-gender crews at both large and small Antarctic stations. Many relationships, including long-standing marriages, have dissolved while one or both parties were on the ice; other situations have been so bizarre that it is remarkable that the individuals were capable of coping with the experience. (p. 179)

He suggested that careful crew selection (as opposed to screening) was important, as well as special training about the many potential problems associated with life in isolation and confinement, which would allow most of the concerns about mixed-sex crews to dissipate.

Lugg has noted that marriages have been performed in Antarctica, and he also noted that some married couples have separated during their stay in Antarctica (personal communication May 9, 2003). He noted anecdotal stories that reveal that occasionally expeditioners may become involved with a new partner from the group, which can add additional stress to an already-stressful situation affecting established relationships. Today, people have psychological support services available by satellite phone, and doctors and many section leaders can also counsel those who winter over. Often, as well, the participants themselves can give useful support to those within the group who might need it.

## 12. Sex Research and Advanced Professional Education

It appears that no specifically focused sex research has been done in Antarctica. However, as can be noted from the previous sections, research has been done for NASA that has looked at the interpersonal relationships that occur in research stations there to help suggest what impact the psychosocial environment, in terms of isolation, confinement, deprivation, and risk, might have on extended space-flights. In addition, personal accounts of expeditioners have drawn some attention to sexuality factors. Together, both can begin to suggest avenues of sex research that might be done in both environments, which, as I have argued elsewhere (Noonan 1998a), can be used to improve the sexual lives of everyone.

## *Demographics and a Brief Historical Perspective*

ROBERT T. FRANCOEUR

### A. Demographics

Papua New Guinea (PNG) occupies the eastern half of the island of New Guinea, the world's second-largest island, in the southwest Pacific Ocean, north of eastern Australia's Captain Cook Peninsula. The Indonesian province of Irian Jaya occupies the island's western half. To the east are the Melanesian and Solomon Islands and the Coral Sea. North and east of New Guinea are about 600 islands in the Bismarck Archipelago, including Manus, New Britain, New Ireland, Bougainville, and the northern part of the Solomon Islands, which are also part of Papua New Guinea. The total territory of Papua New Guinea is 178,700 square miles (462,840 km<sup>2</sup>), making it about a tenth larger than California in the United States. Most of the main island, especially the interior, remains isolated from outside contact by rugged mountains, deep gorges, and swamps. The mainland's high plateau climate is temperate, contrasting with the tropical climate of the coastal plains. Two major rivers, the Sepik and the Fly, are navigable to shallow-draft vessels.

In the past, the very rugged topography of Papua New Guinea made communication and movement from one place to the next very difficult. This resulted in extraordinary variations in attitudes, behavior, ethnic groups, culture, traditions, customs, religion, and linguistics throughout the country. There are more than 850 spoken languages in Papua New Guinea. Only 1% to 2% of the people speak English, the official language, but Tok Pisin English is widely spoken. Only 15% of Papuans live in the few cities, about a quarter of a million in the administrative center of

(CIA 2002)

Port Moresby. The majority of the people make their living in small-scale agriculture, although only 1% of the land is devoted to permanent crops and a negligible percent of the land is arable. The large majority of Papuans live in villages with settlements averaging about 800 persons. Many live in scattered homesteads with residents numbering no more than five to ten. The average-size village is about 200 to 300 people, located within a half-hour's walk to other neighboring villages.

In July 2002, Papua New Guinea had an estimated population of 5.17 million. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 38.6% with 1.03 male(s) per female (sex ratio); 15-64 years: 57.7% with 1.07 male(s) per female; 65 years and over: 3.7% with 0.9 male(s) per female; Total population sex ratio: 1.05 male(s) to 1 female

**Life Expectancy at Birth:** Total Population: 63.46 years; male: 61.39 years; female: 65.64 years

**Urban/Rural Distribution:** 15% to 85%

**Ethnic Distribution:** Predominantly Melanesian in the northeast, and Papuan mainly in the south and the interior, with some Negrito, Micronesian, and Polynesian.\*\*

**Religious Distribution:** indigenous religions: 33%; Roman Catholic: 22%; Lutheran: 18%; other Christian: 28%

**Birth Rate:** 31.61 births per 1,000 population. Experts project that if the high rates of fertility persist, the population will double by the year 2020.

**Death Rate:** 7.75 per 1,000 population

**Infant Mortality Rate:** 56.53 deaths per 1,000 live births

**Net Migration Rate:** 0 migrant(s) per 1,000 population

**Total Fertility Rate:** 4.21 children born per woman

**Population Growth Rate:** 2.39%

\*Communications: Shirley Oliver-Miller, 6 Calumet Court, Dix Hill, New York 11746 USA; somatppnyc@aol.com. Comments: Edgar Gregerson, Ph.D., 302 West 12th Street, NYC 10014, USA; eagqc@qc.vaxa.acc.qc.edu.

This overview of some attitudes and practices of the people of Papua New Guinea as they relate to sexuality is based on the author's own work experience in PNG over three years, her interviews with Papua New Guineans, studies done in Papua New Guinea, and current anthropological literature.

\*\*Melanesians, Micronesians, and Polynesians constitute the three main ethnic groups in Oceania in the central and south Pacific. The brown-skinned Polynesians occupy the most-eastern islands of Oceania, from Hawaii to New Zealand, including Tahiti, Samoa, and Hawaii. The Micronesians inhabit the islands north of the equator and east of the Philippines, including the Mariana, Caroline, and Marshall Islands. The dark-skinned, frizzy-haired Melanesians occupy the islands in the south Pacific northeast of Australia.

**HIV/AIDS** (1999 est.): *Adult prevalence*: 0.22%; *Persons living with HIV/AIDS*: 5,400; *Deaths*: 450. (For additional details from www.UNAIDS.org, see end of Section 10B.)

**Literacy Rate** (*defined as those age 15 and over who can read and write*): 52%, with 65% of the children attending primary school and 13% in secondary school. Illiteracy is disproportionately high among females.

**Per Capita Gross Domestic Product** (*purchasing power parity*): \$2,200 (2000 est.); *Inflation*: 10.3%; *Unemployment*: NA; *Living below the poverty line*: 37%

The country's health indices remain an abiding source of concern. Less well documented quantifiably, but widely acknowledged by healthcare providers and researchers, is the rapid proliferation of sexually transmitted infections (STIs/STDs) and AIDS, as random sexual contacts both within and outside marriage increase.

Like other developing nations, internal migration from rural communities has resulted in rapidly expanding urban populations. Although 85% of Papua New Guinea's population lives in isolated rural areas, urban values exert very strong influences in the village communities. People seeking a better life in the city find few employment opportunities. Many have resorted to crime as one way to survive. Today, violence in Papua New Guinea has become a dominant and critical reality in the country.

## B. A Brief Historical Perspective

New Guinea, the world's second-largest island, was settled many thousands of years ago by waves of Papuans and Melanesian migrants. These many waves of immigration developed into hundreds of diverse, mutually hostile tribes of hunters and small cultivators, each with their own language. The eastern half of the island of New Guinea was first visited by Portuguese and Spanish explorers in the 16th century, but the Europeans did not become established there until the 19th century, when the island was divided between the Dutch in the west (the current Indonesian Irian Jaya), and the Germans and the British to the east. In 1884, Germany declared the northern coast a German protectorate. Britain followed suit in the south. Both nations then formally annexed their protectorates. In 1901, Britain transferred its territory to the newly independent Australia. During World War I, Australian troops invaded German New Guinea and maintained control under a League of Nations mandate that eventually became a United Nations trusteeship that incorporated a territorial government in the southern region known as Papua.

Australia granted the territory limited home rule in 1951, and autonomy for internal affairs in 1960. The country attained independence September 16, 1975, when the United Nations' trusteeship under Australia ended. In February 1990, guerrillas of the Bougainville Revolutionary Army (BRA) attacked plantations, forcing the evacuation of numerous workers. In May, the BRA declared Bougainville's independence, triggering a government blockade of the island until a peace treaty was signed in January 1991. However, the independence rebels still threaten and limit foreign investment on Bougainville.

### 1. Basic Sexological Premises

#### A. Character of Gender Roles

The societies of Papua New Guinea are male-dominated and the attitudes of men toward women, on the whole, are poor. Women are valued as objects to be owned by men along with pigs and gardens; hence, few women exercise any real sort of power or control over their lives. Men are hunters and warriors; women are laborers, gardeners, and mothers who bring food to the men's house. The penis

makes a man incapable of doing onerous gardening and tending the crops of edible sweet potatoes. Cultural tradition makes women subservient and responsive to male needs.

Whereas women's roles are clearly defined, men suffer from the loss of their traditional roles in defending their clan and land. The government of Papua New Guinea has now usurped these powers. Many young men find themselves unemployed and alienated from the society at large. Their capacity to produce income, the single most important prerequisite to securing a lasting relationship, remains the most difficult objective to achieve. These factors combine to make a very negative climate for gender equity both within and outside sexual relationships.

There are many examples of the low status of women in Papua New Guinea, not the least being the extent of violence used against them by males who exert authority and control, batter, and rape them. These social dynamics also contribute to the high risk for STD, including HIV infection, as well as adolescent pregnancy. While babies born out of wedlock are generally absorbed into the extended family without rancor, many girls drop out of school and otherwise foreclose their life options in terms of education and employment. Despite increasing educational opportunities, women continue to take a back seat to men in many aspects of development. Most men view women's development as breaking a longstanding taboo tantamount to entering "a man's house" in a rural culture where men and women, including married couples, often live segregated lives.

Although government officials and community members alike express private concern over adolescent sexual behavior and teen violence in general, a larger programmatic response has yet to be forthcoming.

#### B. Sociolegal Status of Males and Females

Whereas the vast majority of cultures around the world and in Papua New Guinea adhere to a gender- and sex-dimorphic paradigm in which only males and females are recognized, the Sambians of Papua New Guinea's eastern highlands are among the interesting minority of societies that accept three sex categories: male, female, and a "third sex" or hermaphrodite. Classic examples of "third-sex persons" include the *hijra* of India, the *berdache* of American Indian and Eskimo societies, the *acaaults* of Myanmar, the *kathoe* of Thailand, the *vehine* of Polynesia, and the *fa'afafine* of Samoa.

The Sambian third-sexed persons, known as *kwolu-aatmwol* ("male thing-transforming-into-female thing") or *tarnim man* ("expected to become a man"), are the result of a rare genetic variation known as delta-4-steroid-5-alpha-reductase deficiency, or DHT (dihydrotestosterone) deficiency, first reported in the Dominican Republic as *guevedoces* by Imperato-McGinley (1974) (Francoeur et al. 1995; Herdt 1981, 1984a, 1987, 1990; Money & Ehrhardt 1972). Individuals with DHT deficiency lack the gene necessary to produce the 5-alpha reductase enzyme that converts testosterone into dihydrotestosterone (DHT), the hormone that causes the undifferentiated external genitals of a fetus in its third month to differentiate as a penis and scrotum. As a result, during pregnancy, the external structures differentiate more or less as a female clitoris and labia. Given this pseudo-female appearance at birth, Sambian parents of such a child may identify and raise the newborn as female or male. However, the pubertal surge of testosterone causes the pseudo-female external genitals to more or less convert to male structures, along with the deepening of the voice, male facial, pubic, and axillary hair, penile enlargement, and labioscrotal fusion (Gregersen 1996, 84).

Unlike the Dominican society, which celebrates the pubertal conversion of a *guedoces* “daughter” into a son, the patriarchal Sambians are much less comfortable with their third-sexed offspring, even though their ability to function as a male would seem to be considerably more attractive in terms of personal power and prestige. Sambians, however, regard a newborn with ambiguous genitals as a boy with a defect, who is rejected by both parents, teased, and humiliated. After transformation at puberty, the male becomes the fellator (giver) in the sequential bisexual life of a male. When raised as males from birth and later married, they were rejected by their wives as unsatisfying. When raised as girls and married, they were soon rejected by their outraged husbands who found testes and a small penis within the labia when they attempted to have vaginal intercourse (see Section 6, Homoerotic, Homosexual, and Bisexual Behaviors).

### C. General Concepts of Sexuality and Love

In several highland Papuan societies, incest restrictions dictate that wives must be taken from other clans. But, because relationships between different clans are often so hostile as to verge on warfare, men who abduct women from hostile clans trigger armed retaliation and counter-abductions, which result in an endless cycle. “Marriage in these societies, and the sexual relationships within marriage,” according to Davenport (1997, 126), “are always fraught with fear, hostility and anger.”

The Dobo, who live on a small island off the coast of the main island, live in constant fear of sorcery from their wives. Because they believe that they are particularly vulnerable during intercourse, Dobo men have to continually weigh their need for sexual gratification against the possibility of sorcery when they try to satisfy their sexual need (Davenport 1997, 126)

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A. Source and Character of Religious Values

After a century of Christian missionary influence, most of the indigenous ethnic-based rituals and customs described in the next section no longer exist. Today, Christianity dominates in Papua New Guinea, although a third of the people still practice traditional indigenous religions, especially in the remote mountainous areas.

### B. Character of Ethnic Values

Before the 1900s, no Papuan traveled too far from home for fear of being killed or even eaten by more distant neighbors, suggesting that marriage patterns were likely to have been locally endogamous. As most villages are composed of multi-clan hamlets, one might marry a spouse from another hamlet within the same village. The most common marriage pattern was based on the requirement that one must marry outside of one’s clan, most of which were patrilineal. For the most part, marriage patterns still show couples come from the same contiguous villages. In the past, unmarried people from neighboring villages gathered together in courting rituals that included dance, song, and pair bonding. Married men looking for a second or third wife also participated in this ritual.

The following examples illustrate the wide range of traditional ethnic factors influencing the sexual attitudes and behavior of the diverse groups in Papua New Guinea. Contact with Western and other outside cultures are altering many of these patterns classic in the anthropology literature of the area, but to what extent in individual tribal cultures is not evident from the anthropological record pieced together over the last century.

- In the Eastern and Central Highlands, elders chaperoned festivities, which allowed young people from neighboring villages to sit opposite each other in pairs and rub legs, cheeks, or noses while they engaged in singing.
- In the Simbai areas of the Highlands, men adorned with heavy shiny beetle-decorated headdresses came together to dance in a ritual that lasted all night. A woman could take her pick of men during the night and the couple would then disappear into the nearby bushes. In the morning, women carrying men’s headdresses were clearly visible. Each couple then went to the man’s house, and word was sent to the woman’s parents to come to discuss a brideprice. She may have never seen the man before that evening, but, as they were all from nearby villages, the sexual pool was still quite localized.
- In the Trobriand Islands of Papua New Guinea, courting parties were openly explicit sexual events. Boys were called out from villages A and B to have sex with the girls from village C; the host and guest roles were reversed on the next occasion. Public events of sexual mixing among adults were also permissible in some areas. These open sexual events took place only on special occasions, as rituals of reversal, fertility, or renewal, allowing people to have sex with those with whom they ordinarily had no sexual rights, e.g., the spouses of other men and persons within proscribed kinship relationships.
- Plural copulation or group sex was also a traditional pattern in some areas, and took the form of a single woman having sexual intercourse with a series of men in tandem. Among the Ok of the Highlands and the Sepik on the North Coast, this was done as a punitive measure (e.g., Ok, Highlands, and Sepik, North Coast) and in others, it was an honor (e.g., Papuan Coast).
- In the Eastern Highlands, Papuan Plateau, and Papuan Coast, there were also male initiations, which required insemination, either anally or orally, by elder males initiating younger males.
- Every Banaro man has a “ritual brother” as a sort of alter ego with whom he shares mutual access to each other’s wives. The Banaro also require that a bride’s first intercourse be performed by her husband’s father’s ritual brother (Davenport 1977, 144).
- Among the Fasu of the Southern Highlands, older males had sex with younger males with less ceremony, but still within the context of traditional relationships and ideology.
- The Enga of the Highlands firmly believed that men and women differed in many fundamental ways. Because of these fundamental differences, contact with menstrual discharge could contaminate a man and cause illness, weakness, and even death. But reality told them they could not avoid all contamination, so males and females were highly segregated. The Enga men needed some sexual outlet, for their own release and to produce offspring, so single men almost never engaged in heterosexual intercourse, and married men only reluctantly did so with their wives. Purification rituals were important (Davenport 1997, 136).
- The Wógeo added to the Enga menstrual taboo the belief that men in a trance or sacred state were dangerous to women. The sacred state was in fact an imitative menstruation, induced by hacking the penis until it bled freely and was thus purified. This periodic male bleeding rid the body of contaminations received from women. Unlike the Enga, the Wógeo did not avoid heterosexual intercourse to avoid contamination (Davenport 1977, 136).
- The Manus treated all aspects of sex as ugly and shameful. Even marital intercourse was sinful, degrading, and

to be engaged in only in strict privacy. Women considered intercourse an abomination they endured, however painfully, until they produced a child. The sexuality of men was considered brutish. Sex outside marriage offended the sensibilities of watchful spirits and triggered supernaturally ordained punishments. Sexual talk was not heard, and women were so secretive about their menses that Manus men denied women ever experienced such a thing as a monthly period (Davenport 1977, 115, 123-124).

In the exuberance of mid-20th-century anthropological research, considerable cultural data, much of it related to sexual beliefs, attitudes, and behavior, were gathered by cultural anthropologists, led by Bronislaw Malinowski (1927) and Margaret Mead (1930, 1935).

One of their favorite subjects was the Melanesian matriarchal Trobriand Islanders, off the eastern end of New Guinea. Trobriand Islanders not only view the expression of sexuality with great favor, they are also quite comfortable with pre- and extramarital affairs, provided these respect certain incest and age taboos. Trobriand Islanders make frequent and open use of love magic to make themselves irresistibly attractive to desired partners. With a few slight alterations in the love magic formulae, they have an equally irresistible aid for their famous overseas exchange system known as *kula* (Davenport 1977, 131, 245; Gregersen 1996, 268).

Most of these tribal patterns of sexual activity were rationalized as mechanisms to gather the spiritual force residing in sexual fluids, i.e., sexual power, and redirect it to social and material aims, such as improving the growth of boys or strengthening the clan's reproductive powers, both human and agricultural. These belief systems nearly always had within them a strong component of female pollution and associated behavioral taboos. Colonial contacts in the 19th century and expanded contact with outsiders in recent decades have changed many of the tribal customs so carefully documented by anthropologists. Whatever the extent of enculturation, and regardless of how unchanged these customs remain in the remote and inaccessible regions of Papua New Guinea, their record is important in understanding how sexual diversity plays out within the social fabric of individual functioning societies.

### 3. Knowledge and Education about Sexuality

#### A. Government Policies and Programs

Recently, the Papua New Guinea government implemented a pilot Adolescent Sexuality and Reproductive Health Project, which targets adolescents, church groups, and teachers/lecturers. The program addresses a myriad of issues around sexuality, morality, reproductive health, STDs/AIDS, prevention of rape/child molestation/domestic violence/drug abuse, value clarification, decision making, and how to talk about sex (traditionally a taboo topic) with others. The project is the first of its kind in Papua New Guinea. Although it is too early to tell what impact the project will have, thus far, students, teachers, parents, and the church community (interdenominational) have welcomed the opportunity to learn more facts about sexuality, reproductive health issues, and the skills to communicate with others about sensitive topics.

#### B. Informal Sources of Sexual Knowledge

It is important to acknowledge that sexuality education to a greater or lesser degree has always existed in cultures around the world. Culture and traditions are vehicles by which sexuality information and knowledge are transmit-

ted. We tend to forget that there have always been systems that controlled sexual behaviors. The erosion of cultural norms, coupled with today's health concerns about teen pregnancy, maternal and child spacing, sexually transmitted infections, AIDS, rape, child molestation, and domestic violence, have made talking about sex very controversial. It is clear that former systems no longer provide effective approaches to addressing social problems.

Parents make an effort to teach their children what is socially acceptable and what is not in all areas of life, including the sexual. When young people go away to school, it is very difficult for parents to maintain constant input over the years when their children are becoming sexually mature. Instead, their peers have the most influence. Even when children remain at home, peer pressure is often stronger than the influence of parents.

This is true in most societies today. Some parents attempt to strengthen their teachings about proper morality by insisting their children attend church. When parents themselves are sincere followers and doers of the teachings of the church, this has the most effect. But where the church is simply used as another means of control by parents who themselves practice behaviors considered improper by the church, children will not listen. Although sex is a biological drive, all sexual behavior must be learned.

In some communities, young people have few examples of responsible sexual behavior to follow. From childhood, they repeatedly hear tales about who slept with whose wife, who was raped, and who got pregnant out of wedlock. These events are often the subject of public discussions at court hearings and in community gossip. The usual outcome is that someone must pay someone else a fine. Single or married men who make a young girl pregnant are rarely publicly criticized, even though people may talk about them behind their backs.

Knowledge about sexuality and reproductive health is generally low throughout Papua New Guinea at all ages. Younger people have slightly better access to information than did most of their parents. Information levels are higher in cities and towns than in villages. Some parents, especially in the villages, persist in telling their teenagers as little as possible about sex and reproduction. They continue to say that babies come from the garden or from stones, or offer other fanciful explanations. Unfortunately, parents' notions that keeping their children ignorant about sex will keep them from trying sex is completely without foundation. In all areas, the average age at first sexual intercourse is about 15 or 16 for both sexes. This means that many try their first sexual intercourse quite a bit younger than 15, as well as some at ages 17 to 19. [*Comment 2000*: The age of first intercourse is likely earlier than just stated. (*End of comment by E. Gregerson*)] Few enter a sexual relationship with any knowledge of contraception or STDs.

After a girl has her first menstruation, throughout the country, she is warned to stay away from boys or it will lead to pregnancy. But little else is revealed. Sometimes a grandmother or other relative decides to give a traditional contraceptive spell or herb to a young woman. This is reported to be more common if the girl is in school. Occasionally, a schoolteacher or a kinswoman who is a nurse explains more to a young woman and even helps her obtain modern contraception. But, for the vast majority, the early years of sexual activity are the most dangerous, because the elders have not considered sex one of life's most powerful drives, as a topic to be discussed with young people. With few exceptions, neither the schools nor the churches carry out adequate sex education early enough to be of any value. By the time sexual reproduction is discussed in high school, nearly half of

the young people have already begun having sexual intercourse. The health services do not make contraceptives accessible to young people. The result is many unwanted teenage pregnancies and STDs, including HIV. The known age distribution of HIV and AIDS cases up to 1995 in Papua New Guinea, compared to other islands in the Pacific with numerous cases, demonstrates this clearly.

Arguments against sex education, whether in the home or within an institution such as a school or church, focus on the fear that information will increase the desire for sexual experimentation. Evidence from studies conducted in several different countries point in the opposite direction. If young people are given adequate sex education, those who have not yet begun often delay starting, and those who have started do not increase their sexual activities. In either case, both groups are better informed about the pleasures and risks of sex. If sex education is carried out properly, they will then know how to have safer sex.

In *Sexual Networks and Sexual Cultures in Contemporary Papua New Guinea*, Carol Jenkins (1996), principal research fellow with the Papua New Guinea Institute of Medical Research (in Goroka), noted that:

only a minority of young people reported learning about sex through the school system or from their parents. Most girls and boys first learn from older female or male relatives or friends. Sitting around and telling stories about sex is a favorite pastime of teenagers of both sexes. More than any other factor, this activity spurs the imagination. Many times older young people deliberately try to persuade younger ones to try sex. Cousins, in particular, often help set up the first sexual encounters for their younger relatives. Sometimes cousins are the first sexual partners. On a world scale, this pattern is not unusual. It is unlikely, however, that older relatives and friends raised under similar conditions represent a good source of information.

Until recently, Papua New Guinea has remained isolated from the rest of the world. Today, Papua New Guinea struggles with all the influences and trappings of modern-day society, including radio, television, drugs, computers, videos, MTV, written literature, pornography, rape, child molestation, domestic violence, commercial sex workers, and so on. As more and more people are exposed to modernization, there is an emerging culture whose sexual practices are becoming fairly homogenized.

Agricultural and mining industries require travel to and from rural areas, and this greatly contributes to the diffusion of new ideas. Media, especially video and pornographic magazines, also play a large part in changing sex practices and attitudes. Some copy what they see and learn in urban centers, whereas others condemn what they see. In either case, the eroticism of more complex and commercial societies, both Asian and Western, presents issues of contention in sexuality to Papua New Guinea.

#### 4. Autoerotic Behaviors and Patterns

Although it is seldom discussed, masturbation is widespread and generally considered harmless but wasteful, particularly for boys. Therefore, the overwhelming pressure, when sexually aroused, is to find a partner of the opposite sex immediately. In some cases, this may lead to rape. Rape is very common in Papua New Guinea and can occur without the aid of pornography, simply because violence against women in Papua New Guinea is widespread and unopposed by strong cultural or legal norms (see Section 8A, Significant Unconventional Sexual Behaviors, Coercive Sex, below).

### 5. Interpersonal Heterosexual Behaviors

#### A. Children

Trobrianders, and likely other Papua New Guinea societies, approve of imitative copulation or sex rehearsal play about age 10 or 11 (Davenport 1977, 150).

#### B. Adolescents

##### *First Intercourse and Premarital Sex*

The initiation of first sexual intercourse among young people today takes place around the age of 15 for both girls and boys in both urban and rural areas. In general, virginity is not highly valued, but rather society denounces premenarcheal sexual intercourse for girls and getting pregnant before proper marriage arrangements, i.e., a brideprice, are made. In rural areas where traditional menarcheal seclusion ceremonies are still maintained, young men, often accompanied by their parents, begin to seek a young woman's interests as soon as she is allowed out of seclusion. Unless she is in school, a young woman is considered ready for sex and marriage immediately after menarche. And, as the age of menarche declines, so has the age of first sexual experience. Most rural girls experience their first sexual encounter willingly with young men slightly older than themselves from nearby villages. Others are forced into sex or raped. According to one study, 17% in a sample of 116 women said their first sex was with a boy they had just met, while only 8% had their first sex with an older man.

Studies conducted by the Papua New Guinea Institute of Medical Research indicate that nearly half of all adolescents in the country are sexually active by the age of 16, and by the age of 20, nearly a third studied reported having had at least one STD. Evidence suggests that sexual activity occurs among girls as young as 14, whose physiological immaturity and poor coping skills place them at particular risk for STDs and HIV.

Following the first experience of sexual intercourse, options for new and different sex partners increase. Young women fantasize that they will be rescued from the labor of rural subsistence farming, and hope for a man with a job, a permanent house, and car in town. Poor rural parents also want their daughters to "marry up," which usually means marrying a man from town. Approximately 25% of young women take married men as partners. Half of the women between the ages of 15 and 24 in our recent study of youth stated that they accepted cash, gifts, or both in exchange for sex. In the national study conducted in 1991, 66% of the women under 25 ( $n = 33$ ) and 43% of those over that age ( $n = 37$ ) had exchanged sex for goods. These young women do not see themselves as sex workers, although they say they earn some of their income through sex (see also Section 8B, Significant Unconventional Sexual Behaviors, Prostitution).

Young men are equally subject to earlier biological maturation, and the adolescent male is no longer subject to the dominating control of elder males as expressed through male initiation rituals. Few societies have maintained these rites of passage, and where they do exist, they are very much altered. Consequently, boys are free to experiment with sex more or less as they choose. Older siblings frequently teach a younger boy about sex in explicit ways, sometimes setting up a woman with whom he can "try his luck," often in a group situation. Two studies suggest some boys first have anal intercourse with each other several years before having intercourse with a female.

Whereas parents are concerned about the health of the mother and infant, they are more concerned about ensuring economic commitment from the purported father of the child.

Young people receive subliminal messages that say, a little sex is all right, but not too much with the same person. Long-term sexual involvement with a single partner implies the likelihood of pregnancy and is definitely to be avoided unless one is ready for commitment. Many people believe that pregnancy cannot take place unless a man has sexual intercourse with a woman at least six or more times. Hence, many girls and boys are taught to change partners frequently.

The sexuality of young, unmarried women is placed under fewer constraints than married women. Young women recognize this and seek to enjoy as many partners as possible while they remain unmarried. Whereas most Papua New Guinea societies do not allow a young girl to have sex before the onset of menstruation, Trobriand Islanders allow sex before menarche. First cousins may have temporary premarital affairs but can never marry (Davenport 1977, 145). [*Comment 2000*: However, certain kinds of first-cousin marriages may be permitted, such as a marriage with a child of one's mother's brother or one's father's sister (*End of comment by E. Gregerson*)]

### Courtship

Although Papua New Guineans still have widespread traditional sexual beliefs, practices, and unique customs, which differ by region and language areas, traditional courting customs have often been replaced with disco dances, CDs, cassette players, loudspeakers, alcohol, marijuana, and other recreational drugs. Anyone can enter a disco. This marks a major shift from the controlled courting practices in the past.

### A Puberty Ritual: Obligatory Universalized Transitional Homosexuality

Gilbert Herdt (1981, 1984a, 1987, 1990) and other anthropologists have reported on a pederastic puberty ritual shared by 30 to 50 Melanesian and New Guinea cultures that may be historically related to similar practices that developed among aboriginal Australians some 10,000 years ago. The focus of intense speculation by anthropologists and fierce opposition from Western governments and missionaries, these ritualized homosexual relationships are a necessary part of the coming-of-age training for boys. Their basis is the belief that boys do not produce their own semen and must get it from older men by "drinking semen," i.e., playing the recipient role in oral-genital sex or anal sex before puberty and during adolescence. This is the opposite of the traditional Western view in which the recipient (insertee) of anal or oral sex is robbed of his manhood.

Societies with this ritual practice characteristically maintain:

1. extreme social differences between men and women, with women clearly in an inferior status;
2. the blood of men and women are not ritually differentiated, but their semen and milk are; and
3. marriage often involves men exchanging sisters with no special marriage payment.

Other societies in the same area that do not share these beliefs or ritual pederasty are more likely to view menstrual blood as extremely dangerous and/or require a "bride price" to legitimize a marriage (Gregersen 1996, 274-276).

According to the Sambian people of the Eastern Highlands of Papua New Guinea, a young boy must be fed women's milk in order to grow until he approaches puberty, when the men of the village must rescue him from the society of women and feed him men's milk (semen). To trigger puberty and enable a youth to become a mature macho headhunter, he needs the semen of mature youths and unmarried

men provided by young bachelors. After eight to ten years of exclusive homosexual relationships, the 19-year-old youth has completed his defining rite of passage and is ready to marry (McWhirter et al. 1990, 42-43) (see Section 6, Homoerotic, Homosexual, and Bisexual Behaviors).

## C. Adults

### Marital Relationships and Sexuality

See Sections 1C, Basic Sexological Premises, General Concepts of Sexuality and Love, and 2A, Religious and Ethnic Factors Affecting Sexuality, Source and Character of Religious Values.

### Marriage and "Ritual Brothers"

Among the Banaro of Papua New Guinea, every male has a "ritual brother," a kind of alter ego, as a companion and support throughout life. Every ritual brother is allowed sexual access to his "brother's" wife. This is not, in our Western sense, "extramarital" sex, because the ritual brother is in some ritually real way the other man, the husband, and so is entitled to have sex with his alter ego's wife. The ritual brother also plays a role in Banaro marriages. The bride's first intercourse after marriage must be performed by the ritual brother of her husband's father, i.e., the father-in-law's ritual brother). In the Banaro society, it is the social father, not the procreative or biological father, who is important (Davenport 1977, 144).

### Coital Positions

Christian missionaries are commonly credited (or blamed) for trying to impose the male-superior coital position on the natives they evangelized, because they considered it "the natural and normal coital position." However, they do not deserve credit for its origins, which historians have traced back to the Stoics of ancient Rome and the early Egyptians, [*Comment 2000*: despite some modern assertions to the contrary. (*End of comment by E. Gregerson*)] Although popular in Western cultures, the male-superior position has not been adopted by the people of Oceania, despite Western advocates. In fact, the people of Oceania commonly view the male-above position as impractical and improper, placing too much weight on the woman, and are uncompromising in recognizing only two natural copulatory positions. The Dobuana and the Wógeo of Papua New Guinea prefer the rear-entry position, with the man standing behind the woman while she bends over and rests her hands on her knees. Also popular is the "Oceanic position," in which the man squats or kneels between the spread legs of his partner who lies on her back. He then pulls her towards himself and completes the intercourse. In a variation of this position, the woman lies on her back and keeps her knees up (Davenport 1977, 150).

One benefit of this position is that it can be carried out with minimal body contact, "which encourages young people to have sex with ugly and older partners. On the other hand, as Malinowski has expressed it: '... where love exists, the man can bend over the woman or the woman can raise herself to meet him and contact can be as full and intimate as is desired'" (Davenport 1977, 148; Gregersen 1996, 5, 67). The Tallensi point out another possible advantage (or disadvantage), in that this position enables the woman to push the man over with a kick.

### Premarital Pregnancy, Ritual Multiple Intercourse, and Extramarital Sex

A single mother often gives her child to her parents or another relative to rear and she continues with her single lifestyle. When a married man sleeps with a woman other than his wife, it is hardly noticed. If a woman is caught having sex with a man other than her husband, she is beaten. On

the whole, sexual infidelity does not cause marital breakups and life continues. In some communities, other sexual issues are more disturbing than sexual infidelity.

Colonial influences have changed the lives of the Marind-anim, a former headhunting people of southern Papua New Guinea, but some of their customs likely continue in remote areas. One tradition involved an unusual ritual of extramarital sex. Traditionally, Marind-anim men and women live in separate housing in their small villages, even after marriage, and always engage in marital sex outside in the bush. Immediately after a wedding ceremony, a few older women take the bride to a place they have prepared outside the village, where the bride has sexual intercourse with the male members of her husband's clan before the groom is allowed to copulate with his wife. These ritual multiple intercourses, *otiv-bombari*, may extend over several nights. Although not particularly satisfying for the wife, this sequential group sex is repeated at various specified occasions, when a woman returns from her seclusion after delivering a baby, when her husband's friends come to visit, or when another man gives the husband a gift of tools or food.

Apart from this custom, most [Marind-anim] marriages are monogamous and break up rarely. The rule is apparently that affection and love exist between the spouses, and the husband may get violently jealous if his wife should have secret sexual relations with a man without prearrangements and the husband's consent.

Extramarital relations are not supposed to become love affairs. They have the character of a ritual. The birth rate is low. *Otiv-bombari* are supposed to make women fertile. They are also used to collect semen, for semen is considered the essence of life, health and prosperity. Semen discharged from the vagina is ritually prized. After an *otiv bombari* it is collected in a coconut bowl to be used in food or medicine, and for body creams. . . .

Contemporaneously with marriage and heterosexual relations, men have also homosexual relations with young and adolescent boys while the younger ones are passing through an institutionalized phase of homosexuality. Here then one has a society in which the men but not the women are bisexual in experience, with some overlap from the homosexual to the heterosexual phase. (Money & Ehrhardt 1972, 132-135)

## 6. Homoerotic, Homosexual, and Bisexual Behaviors

### A. Children and Adolescents

Same-sex activities, boys with boys or girls with girls, are common in many Papuan societies, but they are generally viewed as play and meaningless, though somehow wrong. However, the ritualized pederasty for Sambian adolescents and their postmarital exclusive heterosexuality (see Section 5B, Interpersonal Heterosexual Behaviors, Adolescents) does raise a major question about the development of sexual orientation, or at least a question about the nature of erotic arousal.

On the one hand, Herdt (1984, 1987) suggests that among the Sambia only about 5% of the male population become exclusively homosexual—virtually the same percentage Kinsey found for the United States where all homosexual acts are tabu. On the other hand, to discount homosexual arousal altogether in these institutionalized semen transfers seems unrealistic; slavish performance of a ritual does not produce erection and ejaculation unless an erotic component exists as well. (Gregersen 1996, 276)

[Update 2002: In the 1980s, classic anthropological reports of the Sambians of Papua New Guinea described a society in which young men fellated their elders in order to receive the masculinizing force of semen and thereby become men. When the boys grew up, they married, but now became the recipients of fellation by younger boys who ingested their semen. General terms like “ritualized homosexuality” and “semen drinking” were widely used by cultural anthropologists, even though attempts to describe this phenomenon with Western terms as a cultural lifecycle passing from “homosexuality” to “bisexuality” and “heterosexuality” suggested the inaccuracy of such terms/concepts. At the time, this “ritualized homosexuality” was conceptualized as a cultural rather than a sexual phenomenon. In his early studies of the Sambians, Gilbert Herdt (1981, 1987) viewed this sexual lifestyle as a classic social constructionist phenomenon that emphasized the *dissimilarity* of “gay types” across cultures. Herdt's follow-up studies in the late 1990s appear to support a modified essentialist view that emphasizes a *similarity* of “gay types” across cultures. In this more recent view, the ingestion of semen is not a variety of “homosexuality,” but rather a variety of cultural masculinity.

[During fieldtrips back to Papua New Guinea in the 1990s, Herdt and his colleagues conducted interviews, gathered more data, and discovered that, in fact, there were some boys who had a real fondness for ingesting semen and who later had a real fondness for having their semen ingested, and did not marry. In other words, in the Sambian culture, all males were the recipients of “ritualized masculinization” in their adolescent years. As adults, they were expected to marry although they were now the ritual givers of semen. In this more nuanced description, most Sambian men can best be described as heterosexual males despite their teen years of “drinking masculine milk,” their adult role as providers of masculinity, and their cultural distaste for marital relations. At the same time, there are also some Sambian males who can be described as homosexual in the Western use of that term, males who really enjoy giving and receiving fellatio with other males in a sexuoerotic way. (Herdt 1981, 1984ab, 1987, 1993, 49, 432-441, 444, R. Norton 2002 Personal communiqué via SexNet listserv). (End of update by R. T. Francoeur)]

[Comment 2003: Linguists and anthropologists have suggested that several thousand years ago, several different tribal groups arrived in New Guinea. Because they shared a similar language, they also shared some sexual practices in common, such as the belief that drinking semen is essential for a boy to become a man. The Sambians are not the only tribal group that practices semen drinking.

[Sometimes extensive taboos on heterosexual coitus exist, but none on homosexual contacts. This is true of the Étoro (Étolo) of New Guinea who taboo heterosexual contacts for between 205 and 260 days a year (an earlier account suggested as many as 295 days). Although hard and fast statistics are lacking about the degree to which these taboos are observed, the seasonal clustering of births suggests general compliance with the rules.

[None of these taboos holds for homosexual acts among the Étoro. In fact, they are positively encouraged because semen is seen as a life force, of which men have only a finite amount. Boys are believed to have no semen at all at birth. It is through oral insemination by older men that they acquire the necessary semen to become men and to provide life for their offspring. Consequently, boys between the ages of 10 and the mid-20s are continually inseminated by older men. Among the neighboring Marind-anim, the cultural preference for homosexuality has allegedly helped produce so

low a birthrate that to sustain the tribe, large numbers of children must be kidnapped from other groups and raised to become Marind-anim.

[It is sometimes suggested that such homosexual rituals function as a kind of birth control. But more plausibly, they seem to provide a sexual outlet for males in an area with an unbalanced sex ratio (too many males) and the practice by older men of having many wives—very much like the situation among the Zande in Africa, who formerly had institutionalized pederastic marriages (Gregerson 1996, 276). (End of comment by E. Gregerson)]

An additional insight, offered by John Money suggests that:

Institutionalized homosexuality, in serial sequence with institutionalized heterosexuality and marriage, as among the Sambia and other tribal peoples, must be taken into account in any theory that proposes to explain homosexuality. The theory will be deficient unless it also takes heterosexuality into account. Culturally institutionalized bisexuality signifies either that bisexuality is a universal potential to which any member of the human species could be acculturated or that bisexuality is a unique potential of those cultures whose members have become selectively inbred for it. There are no data that give conclusive and absolute support to either alternative. However, genetically pure inbred strains are an ideal of animal husbandry, not of human social and sexual interaction. Therefore, it is likely that acculturation to bisexuality is less a concomitant of inbreeding than it is of the bisexual plasticity of all members of the human species. It is possible that bisexual plasticity may vary over the life span. Later in life it may give way to exclusive monosexuality—or it may not. (Money 1990, 43)

Another aspect of this complex-orientations picture is the fact that in many South Pacific societies, for example, the Marind-anim of southern Papua New Guinea and the (fictionally named) East Bay Melanesians, pubescent and adolescent boys are free to engage in homosexual relations with their peers and/or older married men. Unlike with the Sambia, these relationships are seldom exclusive or obligatory. In such societies, most men are more or less bisexual, and the women assumedly heterosexual (Beach 1976/1977; Marshall & Suggs 1971; Gregersen 1996, 276).

## B. Adults

The Trobriand Islanders admitted to Malinowski that homosexuality is contemptible, but also that it was formerly practiced (Gregersen 1996, 274). In general, the people of Papua New Guinea view homosexuality in a negative and unacceptable light. They cannot understand how a man might enjoy having sex with another man.

### 7. Gender Diversity and Transgender Issues

See the discussion of Sambian hermaphrodites, 5-alpha-reductase boy-girls, in Section 1B, Basic Sexological Premises, Sociolegal Status of Males and Females.

### 8. Significant Unconventional Sexual Behaviors

#### A. Coercive Sex

##### Rape

To most young women today, a man with money, a car, or even a schoolboy with promise, is a far more attractive prospect than a poor boy with no obvious future. For many young men, having no money with which to buy sex

directly, or simply with which to make a girlfriend happy, is a frustrating state of affairs. Some such men state that there is no opportunity for them to have sex at all, unless they rape a woman. Group rape is less likely to lead to trouble than individual rape, although most men who state they rape women do both. Gregersen (1996, 149, 358) includes the Trobriand Islanders among the societies that simply prefer to ignore rape altogether.

Rape of any sort is disturbingly common in all areas of the country, rural, town, and city. In addition to commercial sex, there is the issue of “line-ups” or pack rapes. Often associated with “six-to-sixes” (clubs that remain open from 6 p.m. to 6 a.m.) or video showings that run from evening to dawn in both rural and urban areas, a group of men/boys take turns in forcing a woman to have sexual intercourse with them. As they watch each other, the sexual dynamics of rape and homosexuality mix to produce, for some, a highly erotic event. In some communities, line-ups are reported to take place every weekend. Older men, many of whom are married, are also frequently involved. Younger men and even boys of 11 or 12 are able to join with their elders in sexually abusing a woman. One young fellow of 17 years told me about his village:

In here rape and forced sex exists just like in other parts of the province. It happens especially during disco nights and video shows. When we brought our village girls to the disco or video show, the boys from other places came and took our girls for dance and sometimes take them home to sleep with and have sex with. We thought they slept only with their friends, but somehow the boys arranged it with their village boys and made single file on them [line-up]. When the girls come back they never tell us about it because they are afraid and ashamed. Then we do the same to their sister in return. (Author's field notes)

This type of sexual behavior is extremely dangerous because the men involved are exposed to the semen of many of men, thus raising their risk of acquiring STDs and AIDS, not from the woman, but from the other men involved. The woman is placed at extremely high risk of acquiring STDs and HIV as well.

Many Papua New Guineans do not like to admit that such things are going on, but there is now a great deal of evidence from studies conducted in selected urban areas (i.e., Daru, Port Moresby, Lae, and Goroka) and many rural villages, indicating that such sexual activities are widespread. These sexual activities are highly dangerous from a public health point of view because they spread diseases very quickly, not just among the people who participate in them, but among all those other persons, wives and husbands, new and old boyfriends and girlfriends, with whom these people have sex. These activities are also responsible for many STDs, including HIV, among newborn babies.

#### B. Prostitution

Across the country, people are complaining that more and more young women are having sex earlier, and often with older, married men. The lure of social status, drinking beer, going to dances or parties, the institution of the “six-to-six” clubs, and, increasingly, payment in cash and/or gifts, are drawing women into commercial sex. Papua New Guinea does not yet have a major brothel-based commercial sex industry, but it does have a large, highly dispersed population of women who are willing to sell sex and men willing to buy it.

Much of the activity among women is driven by poverty, some of which is severe. Single mothers, widows of all ages, urban married women whose husbands do not bring

home enough money, and teenage girls everywhere are often poor in cash. There is little shame attached to selling sex in some communities, especially where the woman brings home the cash and food. Brothers, husbands, and other men in the family are often very willing to help a woman find a man who will pay for sex, especially if they can share the rewards. Young women are more saleable, and sometimes very young girls are offered to adult men for sex.

From their earliest contacts, outsiders and missionaries misinterpreted as promiscuity and/or prostitution the "casual" sexual relations and small gifts Trobrianders, and Papuans in general, offer their female partners. This is not the view of the Papua New Guinea people themselves, for whom sexual relations and small gifts do not carry the cultural messages of Western standards and norms. [*Comment 2000*: The contrast here is between the meanings and values insiders attach to some behavior and the way outsiders interpret this behavior from their "objective" perspective. The "objective" views of the outsiders represent what anthropologists label an etic view. In many, perhaps the majority, of customs, the "objective" etic view is quite different from the emic (insider) view of persons within the culture (Reiss 1997). (*End of comment by E. Gregerson*)]

### C. Pornography and Erotica

In most areas of Papua New Guinea today, pornographic magazines, picture books, and videos are available, despite laws to the contrary. Many adults and young people seem to enjoy looking at pictures of people having sex. They consider it educational, and given the dearth of printed or other media on sex, this is hardly surprising. To some young people, however, the experience is frightening, because they find themselves sexually aroused with little understanding of how to manage their desires.

### D. Paraphilias

In spite of fairly extensive reporting of sexual behavior in general, the paraphilia level for Oceania seems to be fairly low. Sexual contacts with animals has been reported in a few cultures, including the Marquesans, but such contacts are denied, condemned, or apparently unknown among the Wógeo and Trobrianders (Gregersen 1996, 278).

## 9. Contraception, Abortion, and Population Planning

### A. Contraception

Although male control over women is a significant factor in extramarital pregnancies and teen pregnancies, alcohol use by women and their inability to plan for protected intercourse are also factors. Condoms are readily available, but are deemed inappropriate for women to carry. Other contraceptive methods are unavailable and prohibitively expensive.

### B. Abortion

Abortion is illegal in Papua New Guinea and is considered to be morally wrong by the majority of the people. However, illegal abortions are increasing. It is not unusual to hear about young girls and older women inducing abortions. Many of these self-induced abortions result in serious infections and, on occasion, death. The methods of inducing abortions are done by ingesting certain mixtures or herbs, or inserting things into the vagina.

### C. Population Programs

Papua New Guinea health indices remain an abiding source of concern, with maternal mortality projected as high as 800 per 100,000 births and infant mortality at an underestimated 80 per 1,000 live births. Within the Action

Plan of the 1994 Cairo Conference on Population and Development, adolescent reproductive health is identified as a priority area. Hence, the government of Papua New Guinea, in collaboration with donor organizations, are launching programs to combat the spread of STDs, HIV/AIDS, and unplanned pregnancy, especially among young people.

## 10. Sexually Transmitted Diseases and HIV/AIDS

There is a National AIDS Committee in Papua New Guinea responsible for increasing public awareness and advocating prevention of HIV/AIDS and other sexually transmissible infections. Advocacy is done through media campaigns, advertisements, radio spots, local television, school curricula and classrooms, peer-education programs on university campuses, and community-outreach efforts, including training religious leaders about sexual and reproductive health issues.

Condoms are free but not always available. Efforts are presently underway to break through the walls of silence around issues related to sexuality and reproductive health. Although cultural taboos make this a challenging task, educators and service providers are making inroads by using culturally relevant videos and dramas on STDs and HIV/AIDS, and other related topic areas, to educate people about the facts.

[*Update 2002*: UNAIDS Epidemiological Assessment: The first HIV infections in Papua New Guinea were reported in 1987, with HIV prevalence increasing annually throughout the early 1990s. Reported cases are equally distributed among men and women, and infection appears to be concentrated in the capital city of Port Moresby. Prevalence remains low among blood donors (0.015% in 1997) and pregnant women (0.37% in 1998). The trend in the annually reported number of AIDS cases has continued to rise more sharply each year since the mid-1990s. Much higher levels of infection were found in female sex workers (17% in Port Moresby and 3% in Lae in 1998) and among patients attending STD clinics (7% in 1999, increasing from 3% in 1998 in Port Moresby, and from 0.7% to 1.2% in four other locations in 1997 to 1999). The estimated HIV prevalence in Papua New Guinea is, as of the end of 2001, about 16,000, or 0.5% of the total 15- to 49-year-old population, and continues to increase slowly, primarily because of heterosexual transmission.

[A wide range of social, economic, and cultural factors in Papua New Guinea have led to an environment in which sexual risk behaviors, including low levels of condom use in casual partnerships, are widespread. There have been a few behavioral surveys carried out recently. Among sex workers, the proportion reporting consistent use of condoms was around 15% in Port Moresby and Lae in 1999. The mean number of clients per sex worker was from three to five per week.

[STD prevalence surveys in Papua New Guinea show a high STD prevalence among both high-risk and low-risk groups. A 15% prevalence of gonorrhea among Highland's populations and 36% among sex workers were found. Chlamydia prevalence was up to 26% in Highland's populations, and 31% in sex workers. Prevalence of syphilis was 4% in Highland populations and 32% in sex workers.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	16,000	(rate: 0.7%)
Women ages 15-49:	4,100	
Children ages 0-15:	500	

[An estimated 880 adults and children died of AIDS during 2001.

[At the end of 2001, an estimated 4,200 Papuan children under age 15 were living without one or both parents who had died of AIDS. (*End of update by the Editors*)]

### 11. Sexual Dysfunctions, Counseling, and Therapies

Over the last few years, the author has conducted several training seminars on sexuality and reproductive health, including issues related to sexual dysfunctions. Common concerns among men were premature ejaculation, small penises, and erectile difficulty. Women complained of vaginal discharges, unpleasant odors, pain during intercourse, and dissatisfaction with their sex lives. Women reported that their husbands or partners use them for their own pleasure.

As in most developing countries, sexual diagnostic counseling is a luxury that most people cannot afford. However, through reproductive health interventions, information is being shared about the various types of sexual dysfunctions and treatment. In many instances, people need basic information about how the body responds sexually. Educators talk about some of the physical and psychosocial factors which can have an impact on sexual performance, including the negative effect that alcohol and other drugs can have on sexual performance. Other important issues that get discussed are gender roles, gender inequities, poor hygiene, and violence.

### 12. Sex Research and Advanced Professional Education

Despite the obstacles of geographic isolation and linguistic diversity until recent times, anthropologists, like Margaret Mead, Bronislaw Malinowski, Clelland S. Ford, and William Davenport, psychologists, such as Frank A. Beach, and others managed to gather considerable ethnographic data on the peoples of Papua New Guinea. Only recently, as modern transportation and electronic communication have broken down some of the obstacles, the HIV/AIDS and population/family planning crises have brought some limited and focused sex research. Sexological research, however, is just beginning to appear in very limited ways in Papua New Guinea, as it is in most other developing countries.

The main organization promoting sexological research is the Papua New Guinea Institute for Medical Research, P.O. Box 60, Goroka, Papua New Guinea.

### Conclusion

Although most societies and cultures around the world are experiencing major social change and tension, few are experiencing the transformation more intensely and radically than the people of Papua New Guinea. However, as Papua New Guinea moves into the new millennium, there is a great deal to be optimistic about. First, people are hungry for information and are open to learning new things about sexuality, as well as other aspects of life. Second, the government is working with agencies to prevent the spread of HIV/AIDS, and to educate the masses about population health issues. Third, the Ministry of Education, the Ministry of Health, and the faith-based communities in Papua New Guinea have developed curricula that address the issues of sexuality and reproductive health. Educators are being trained in sex and sexuality, family life education, reproductive anatomy and physiology, sexual and personal health, family planning and contraception, prevention of STDs and HIV/AIDS, prevention of sexual abuse and violence, and gender equity.

As Papua New Guinea continues to embrace the values and ways of the Western world, there will be many gains and losses. Culturally speaking, Papua New Guinea stands to gain information that will help to save lives. But, Papua New Guinea will no doubt experience all the problems and contradictions associated with Western society. Papua New Guinea's challenge is to maintain its cultural integrity as it struggles to become part of the modern world.

## Demographics and a Brief Historical Perspective

ROBERT T. FRANCOEUR

### A. Demographics

The Philippines is an archipelago of about 7,107 islands that stretch 1,100 miles (1,770 km) north and south in the Pacific Ocean off the southeast coast of Asia. With 115,830 square miles (300,000 km<sup>2</sup>) of total land area, the landmass of the archipelago is about the same size as the state of West Virginia, but slightly smaller than the British Isles. The Philippines is located northeast of Malaysia and Borneo, east of mainland China and Vietnam, south of Taiwan, and a distant west of the Hawaiian Islands in the Pacific Ocean. Ninety-five percent of the 1999 estimated 79.345 million Filipinos (Pilipinos) lived on the 11 largest islands, which are mountainous, except for the heavily indented coastlines and the central plains of Luzon. Slightly over half the nation's population live in the cities—in Manila, the former capital, with a 1990 estimated population of 1.6 million, in Quezon City, the new capital, with 1.7 million, and in Cebu City with 612,000. The Philippines is divided into three major regions: Luzon in the north, Visayas in the center, and Mindanao in the south.

In July 2002, the Philippines had an estimated population of 84.53 million. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** *0-14 years:* 36.6% with 1.04 male(s) per female (sex ratio); *15-64 years:* 59.7% with 0.98 male(s) per female; *65 years and over:* 3.7% with 0.8 male(s) per female; *Total population sex ratio:* 0.99 male(s) to 1 female

**Life Expectancy at Birth:** *Total Population:* 68.12 years; *male:* 65.26 years; *female:* 71.12 years

**Urban/Rural Distribution:** 55% to 45%

**Ethnic Distribution:** The large majority of Filipinos are Malays, either Christian- (91.5%) or Muslim- (4%) affili-

(CIA 2002)

ated, with small minorities of Chinese, American, Spanish, and Indian. Twelve percent constitute the ethnic and cultural minorities that include Aetas, Negritos (north), Ifugaos, Igorots, the "hill people" (north central), and the Muslims in the south.

**Religious Distribution:** Roman Catholic: 83%; Protestant: 9%; Muslim: 5%; Buddhist and other: 3%

**Birth Rate:** 26.88 births per 1,000 population

**Death Rate:** 5.95 per 1,000 population

**Infant Mortality Rate:** 27.87 deaths per 1,000 live births

**Net Migration Rate:** -1 migrant(s) per 1,000 population

**Total Fertility Rate:** 3.35 children born per woman

**Population Growth Rate:** 1.99%

**HIV/AIDS** (1999 est.): *Adult prevalence:* 0.07%; *Persons living with HIV/AIDS:* 28,000; *Deaths:* 1,200. (For additional details from www.UNAIDS.org, see end of Section 10B.)

**Literacy Rate** (defined as those age 15 and over who can read and write): 94.6%, with 97% attending primary

\**Communications:* Jose Florantes Leyson, M.D., 6 Ranney Road, Long Valley, NJ 07853 USA; Phone: +908-876-5482.

(elementary) school and 55% attending secondary school. Education is free and compulsory from age 6 to 15. The Philippines also has the distinction of having one of the oldest universities in the modern world, Santo Tomas University, founded in 1645, 25 years before Harvard University, the oldest university in the United States. Although ten major languages (Cebuano, Bicolano, Ilocano, Pampangino, Spanish, English, etc.) are widely spoken, and there are 80 different dialects, Tagalog (Filipino) became the national official language in 1937. English is still widely used today throughout the country, and it is the medium of instruction beyond the 6th grade.

**Per Capita Gross Domestic Product** (*purchasing power parity*): \$4,000 (2001 est.); *Inflation*: 6%; *Unemployment*: 10%; *Living below the poverty line*: 41% (2001 est.)

In 1997, *Time/World News* reported a 7% economic growth for the Philippines, with a per capita gross domestic product of \$2,600, and considered the Philippines as one of the 10 leading major Asian countries in a business boom. However, in 1999, because of global economic crises, the country was trying to recover and survive in agriculture, aquaculture, and industry.

## B. A Brief Historical Perspective

Several waves of Malay peoples arrived in the Philippine archipelago from Southeast Asia long before the arrival of Europeans. These tribal societies and petty principalities coexisted with links to China, the East Indies, and countries in the Indian Ocean. Discovered by Magellan, who was killed there in 1521, the islands were named Las Filipinas (the Philippines) in 1559 by the Spanish explorer Ruy L. de Villalobos in honor of Prince Philip of Asturias, who later became King Philip II of Spain. The first Spanish settlements came in 1564, and a colonial capital, established at Manila in 1571, quickly became the key transit point for trade between Mexico and the Far East. Under Spanish rule, a majority of Filipinos became Catholics, except in the southwest islands where the people remained Muslim. In the shadow of a tepid colonial administration, the Catholic Church grew in power and wealth.

A nationalist movement gained strength in the late 19th century, leading to an armed uprising in 1896, the Spanish-American War, and defeat for Spain. In 1898, Spain ceded the Philippines to the United States for \$20 million. When the nationalist movement declared the islands an independent republic, the United States refused to accept the declaration. A six-year war followed between 1899 and 1905, in which American troops brutally repressed the guerrilla uprising. In 1916, the Filipinos elected a Senate and House of Representatives, but the President was an American governor general. In 1935, a Philippine Commonwealth, modeled on the U.S. constitution, was established.

Japan brought the United States into World War II by attacking and then occupying the Philippines in December 1941. On July 4, 1946, the Philippines became the first Asian colony of the United States to gain independence, in accordance with an act passed by the United States Congress in 1934. In the 1970s, Muslim (Moro) secessionists fought repeatedly for their autonomy from the Christian majority on the island of Mindanao. In 1972, President Ferdinand Marcos declared martial law to combat riots by radical youth groups and terrorism by leftist guerrillas and outlaws. Despite some land reform and control of inflation, opposition continued, as a high population growth rate was aggravated by both poverty and unemployment. Opposition to Ferdinand Marcos continued despite his lifting of martial law and his election in 1981 to a second six-year term as president. The 1983 assassination of Benigno Aquino, the

prominent opposition leader, sparked demonstrations calling for the resignation of the president. When Marcos declared himself victor in the bitterly contested elections of 1986 despite widespread charges of fraud, Corazon Aquino, the widow of Benigno Aquino, proclaimed herself president and announced a nonviolent "active resistance" to overthrow the Marcos government. The 20-year rule of Marcos ended in February 1986, with the recognition of Aquino as the new president by the United States and other nations. A weak economy, widespread poverty, and communist insurgents kept the political scene unstable between 1987 and 1990. Government forces were able to put down an attempted coup in 1989 with help from the United States military stationed in the Philippines. In 1994, the government signed a ceasefire agreement with Muslim separatist guerrillas, although some rebels have refused to abide by the agreement.

## 1. Basic Sexological Premises

### A/B. Character of Gender Roles and Sociolegal Status of Males and Females

The traditional gender roles in Filipino society are strongly influenced by centuries of Islamic culture, Chinese mores, and 425 years of deep-rooted Spanish Catholic traditions. However, since the 1960s, traditional Filipino gender culture has been transformed by tremendous Western—European and American—influences, except in the Muslim-dominated southern islands, which have been much less influenced by Western contacts. Polygamy, the wife as the husband's chattel, and deferential behavior of women in the presence of men are still strong values in the Muslim-dominated areas. The Muslim ideals of feminine behavior still produce a dependent, inferior, passive, and obedient woman.

In traditional Chinese society, women were to be obedient to the father and elder brothers when young (single), to the husband when married, and to their sons when widowed. For Filipinas of Chinese ethnic origin, marriage was the only means to economic survival. Arranged marriages are still common, with the clear expectation of male offspring who will maintain the "family business" interests and continuity. A wife's position and security within her husband's family remains ambiguous until she produces a male heir. These women have no right to divorce or to remarry if widowed. Those who try to defy these traditions have been ostracized and sometimes driven to depression or even to suicide.

The traditional colonial Filipina was supposed to reach marriage in a virginal state. She was expected to take care of the domestic tasks, go to church, bear and educate children, and support her man in his political, professional, and economic endeavors. The oppressive attitude of colonial Spain toward the Filipinas was first challenged by Mechlora Aquino (Tandang Sora), a nonviolent intellectual woman. In the mid-1800s, she was considered as the equal of the French "political" heroine, Joan of Arc, for leading both a political and cultural revolt against the suppression of women's rights. However, the colonial government quickly extinguished the local revolt, and the treatment of Filipinas as second-class citizens remained in force until Spain ceded the Philippines to the United States in 1898.

In the early years of the American occupation, 1900 to 1930, both females and males were provided with free elementary education. However, only the children of the rich had access to a high school and college education. Although women's social standing was improved, it was not until the late 1950s that the majority of women achieved equal

rights; but this also happened mainly in the urban areas. For a long time, this double standard of colonial mentality was accepted without open criticism. That has changed since the Philippines gained its independence from the United States, with the democratic government taking steps towards recognizing the social and political rights of women. The Western influences on women have resulted in sociocultural independence from parents, spouses, and/or lovers. Women with a college education and businesswomen have started painstakingly to open spaces in the country's political, economic, legal, and administrative positions. On February 21, 1986, Mrs. Corazon Aquino became the first woman president of the democratic Philippines.

Today, Filipinas occupy key positions in university and medical schools, hospitals, both local and national government, large corporations, research-pharmaceutical companies, journalism, and all fields of the arts. However, discrimination against women and special privileges granted to men continue to exist simply because the males benefit from a deeply rooted and longstanding "male buddy" (*comparé*) network.

### C. General Concepts of Sexuality and Love

Virginity is no longer a universally expected prerequisite for the marriage covenant. The 1994 *Young Adult Fertility and Sexuality Survey (YAFSS)* of 11,000 young people, ages 15 to 24 years, conducted by Dr. Z. C. Zablan, professor of demography at the Population Institute of the University of the Philippines, revealed that 18% of Filipino youths approved of premarital sex, 80% disapproved, and 2% were neutral. Today, sexual attitudes are more liberal and accepting of radical changes in sexuality and love because of the influences of the media and global communications. The same *YAFSS* survey showed that a large number of female college graduates residing in urban areas (35%) were exercising their liberal roles, both in their personal and professional lives with flexible sexual attitudes, while 40% were more likely to employ contraception. Filipinas in all classes are trying to balance their responsibility as mothers and lovers with some real class distinctions. The mothering role of the middle- and upper-class Filipinas is often supported by housemaids, professional babysitters, and grandmothers. In general, sophisticated, well-educated Filipinas are more comfortable than older women in taking the initiative in foreplay and learning new erotic techniques to introduce a variety of sexual techniques in their sexual lives. Also, these younger middle- and upper-class wives try to increase both the depth and scope in the emotional and intellectual communications within the couple. On the other hand, the 65% of Filipinas who live in the rural areas are less educated, more conservative in their sexual lifestyles, less likely to use contraception, and less independent in their personal lives.

The Philippines is a third-world country that enjoys the benefits of a young population, with 37.6% under age 15 and 47% between the ages of 15 and 49 years. There are also more women than men, with the surplus women finding support as maids or "nannies." The Latino tradition of single women serving as surrogate mothers for infertile wives is morally and legally unacceptable in the Philippines. For some males, especially in the rural areas and in minority groups, it is often difficult to internalize the impact of the women's liberation movement both in their sexual and professional lifestyles. In my observation, most well-educated males, especially urban dwellers, are starting to perceive that they enrich the relationship by participating in the rearing and education of their children, and the sharing of two incomes are beneficial to the family. The sophisticated pro-

fessional men are also learning to relax during lovemaking, enjoying alternating passive and active roles, and accepting the fact that they can also be seduced and excited.

The majority of the Filipino urban population today is clearly Westernized, but still very conservative in its public and legal sexual values. Because of the dominant and pervasive influence of the Catholic Church, the only sexual behavior considered legal and moral is heterosexual intercourse within a monogamous marriage. Every other imaginable sexual variation is explicitly condemned. Thus, prostitution, pornography (nudity), polygamy (except in some minority groups and the Muslim south), premarital and extramarital sex, cohabitation, homosexuality, and other variant sexual behavior are all illegal. However, quiet homosexuality and heterosexual cohabitation seem to be more socially acceptable today, especially when they involve celebrities and politicians.

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A. Source and Character of Religious Values

Although 83% of the Philippine population are Roman Catholic, 8% are members of the Mormons (Church of the Latter-Day Saints of Jesus Christ), Seventh Day Adventists, Four Square Church, Philippine Independent Church (Aglipan), Church of Christ, Jehovah's Witnesses, and Iglesia ni Kristo. Five percent are Muslim, and 4% follow Hinduism, Buddhism, Taoism, or the traditional nature worship of the aborigines or hill people. Taoism was introduced to the Filipinos by Chinese merchants during the 10th century. Taoism has both a philosophical and a religious tradition. Before the Spaniards came to the Philippines in the 16th century, in 1521, Taoism had some definite ideas about sex. For example, the wife's purpose is to please the husband and conceive more children. If the wife is barren, the husband can have a concubine or mistress to bear children, especially sons, for him. As the traditional Chinese population has aged, Taoist temples are increasingly seen only in a few major cities where they serve as tourist attractions, not religious symbols and sites. As octogenarian males are dying and their religion is fading away, modern Chinese males are being Westernized or practice a more popular religious persuasion.

Buddhism was probably first introduced to the Philippines during the 18th century from India through the Malaysian peninsula and China. Chinese Buddhism, based on the Mahayana (Great Vehicle, Wide Path) school of India, was handed down from generation to generation by both Chinese traders and immigrants. This form of Buddhism is very similar to Taoism. More recently, Buddhism has become more of a social ceremonial practice rather than a religion, and its temples have become a tourist curiosity. The "fat-bellied" Buddha statue is a symbol of the family's wealth and fertility that bedecked a Chinese house's foyer or living room.

Nature worship, the traditional indigenous religion of the Philippines, has been practiced from prehistoric times by the aboriginal Aetas, Negritos, Ifugaos, Igorots, and the hill people. Their constant struggle with the forces of nature for their survival has led to a closer relationship with their ancestors and the elements of nature. This form of religion has little if any systematic doctrine. However, there is one basic characteristic: the belief in the spirits of their ancestors who influence the living in every conceivable sphere of life and apply rewards and sanctions where appropriate. These religions also have lesser gods and deities with different powers related to physical health and fertility. The majority of tribal peoples believe that the first woman came from the "split" of

the bamboo node, a kind of a tropical, tall, and slender palm with sequenced “nodes” in the trunk. Some tribal customs allow sexual activity as early as puberty, comparing this early exploration with sweet and tender young bamboo shoots. On the other hand, the expectation of virginity—the absence of penile/vaginal intercourse—with the assumed “tight vaginal entrance”—as “tight” like the nodes of an adult bamboo stalk—is favored for marriage.

Islam is practiced by 5% of the population, with the majority residing on Mindanao at the southwestern tip of the archipelago. Islam reached the Jolo and Zulu Islands in the Philippines, a century before the Spanish colonialists arrived, through Arab and Persian merchants arriving from the Malayan peninsula. Despite the fact that the Philippine government legally approves only monogamy, local Muslims, known as “Moros,” are allowed to have several wives provided they can afford them.

American settlers brought Protestantism to the Philippines after 1898. The sexuality attitudes of both old and new Protestant tenets are based on the basic Judeo-Christian doctrines. However, two offshoots of the Protestant tradition are homegrown: one established in 1902 by the Aglipay family, the Filipino Independent Church, and the other in 1914 by the Manalo family, Iglesia ni Kristo (Church of Christ). These two Filipino Protestant churches have sexuality restrictions similar to the basic Judeo-Christian principles, but each has added rules imposed by personal preferences from their Filipino religious founders.

The influence of the Roman Catholic Church was and still is hegemonic over 90% of the Filipino population. Throughout Filipino history, the political powers have been submissive to the Catholic Church. The Church is determined to maintain its hold on important aspects of civil life, such as education, the availability of contraception and abortion, and even the registration of major events in the lives of the people, like births, marriages, child adoptions, and deaths. A very conservative interpretation of Catholic decrees about sexuality and marriage have been inscribed in the minds of the Filipino people, in a way that has proven difficult to alter or delete. Outstanding among these are the Church’s views on the social roles of males and females, its insistence that any form of masturbation or premarital intercourse is sinful, and condemnation of homosexuality as unnatural behavior. The Church also places great emphasis on virginity as a prerequisite for matrimony, citing the example of the Virgin Mary, the Blessed Mother of Jesus Christ, who conceived her son without the need of sexual intercourse or a biological father. This sexual innocence and purity is clearly symbolized in the white clothing worn at baptisms, first communions, confirmations, and weddings. Catholicism also offers young men and women a celibate life that is supposedly more spiritual and rewarding in the priesthood and religious life.

## B. Character of Ethnic Values

Before the arrival of the Spaniards in 1521, the Philippine islands were inhabited by fierce, indomitable tribes that valued their freedom and had learned to survive by adapting to the climate and resources of the different islands (regions) of the archipelago. It is believed that the chain of islands was a geological product resulting from volcanic eruptions from coastal/mainland China. However, the aborigines came by land and/or ice bridges from the Malayan peninsula. The indigenous people were mostly nomads who fished and hunted wild game. But the “hill people,” the Ifugaos, who settled mainly in the north central part of the country about 1,000 years ago, developed and retain to this day unique sexual and marital ethnic values along with ad-

vanced engineering land cultivation. For instance, some tribal customs consider breast size and prominence of the hips to be financial assets that equate to the value or size of the dowry; large breasts and wide hips in the prospective bride would make a dowry of a few pigs or chickens unacceptable. The Rice Terraces of the “hill people” are considered one of the wonders of the world still existing today.

When the Portuguese explorer, Ferdinand Magellan, funded by Spain, discovered the Philippines in April 1521, he accidentally landed in the central part of the island country called Limasawa. Literally, “Lima” means five and “asawa” means wife. Limasawa, then, translates into “five wives.” Magellan noticed that the natives were practicing polygamy. Most of the men have five or more wives. He did not realize that polygamy was a common marital ethnic norm in most of the indigenous tribes throughout the whole archipelago.

During the 10th century, China was trading regularly with different Philippine tribal clans led by a merchant known as Limajong, who introduced monogamy. The arrival of Chinese traders resulted in about 10% of intermarriages with the indigenous peoples. There was also a great variety in the way religious values and sexual customs developed in different ethnic groups and tribal traditions. For example, Islam takes on a slightly different expression among its many followers in the southern part of the country where ethnic plural marriages occur. Most of the ethnic minorities—Negritos, Aetas, Ifugaos, and Igorots of the north—practiced monogamy. The sexual values of these ethnic minorities often allow marriage by the age of puberty, about age 13 or 14 years for girls and age 15 and 16 for boys.

On the other hand, Catholicism, introduced to the islands by colonial Spain in 1521, considers males not mature or ready for marriage until age 20 or 21 years, and girls only at age 18 or 19. Masturbation is prohibited by the Church as sinful, “dirty,” immature, narcissistic, and unnatural. In recent years, the traditional awareness of and opportunities for sexual initiation among adolescents have been relaxed, with male sexual exploits provided by an abundance of social opportunities, including birthday and college fraternity parties, community celebrations (*fiestas*), and public dances, which generally encourage sensual and erotic relationships.

The socioreligious education of women in traditional Catholic Filipino society encourages them to play the “cat and mouse” game. Young women are expected to develop social strategies that produce maximum enticement and individual satisfaction. This continual erotic stimulation and the hyper value of masculinity drives young men into the “courting game,” leading hopefully to marriages. A young woman’s ability to employ her virginity as a “bargaining tool” makes males inevitably impatient. The young male is then caught in an expensive web of socially productive and profitable engagements associated with courtship that resolves itself in betrothal to the young woman and “marrying” her, coupled with the expense of building his masculine image and sexual experience with prostitutes.

## 3. Knowledge and Education about Sexuality

### A. Early Sex Education Programs

For some 425 years, Spanish colonial rule afforded the Filipinos little political freedom and individual dignity. This began to change in the 1880s, when a multi-talented physician, Dr. Jose P. Rizal, broke through political, racial, and sociocultural barriers by studying medicine in Spain and Germany. Returning to the Philippines, Rizal estab-

lished architectural and ecological parks, and local health education. He also advocated interracial marriages and later married an Irish woman before his political execution in 1896. At that time, only the most sophisticated elite and rich Filipino students were admitted to the oldest university of the Philippines, the University of Santo Tomas. At the time, only a few colleges offered limited science and social courses, and absolutely no sexuality or health education. All university and college courses placed a heavy emphasis on religious subjects. Between 1600 and 1824, the colonial Catholic Church had a total monopoly over education that kept the people ignorant of the advances in science, technology, and political organization that were taking shape in the Western world.

In 1898, when Americans colonists replaced the Spanish, public education was drastically altered and some individual freedoms were granted. In 1916, the Filipinos elected a Senate and House of Representatives, with its president an American governor general. He was interested in economic growth and political participation. Gradually, in the 1910s and 1920s, free secondary education was introduced in the big cities. In the 1930s, college education was free only in national colleges. With political modernization and the advent of the Philippine Commonwealth of 1935, Filipino society became increasingly Westernized, specifically Americanized. However, there was still no formal sex education or published material on the subject. Sex education was completely limited to information about pregnancy and childcare passed on by word of mouth among the women in families.

When Japan invaded the Philippines on December 8, 1941, at the start of World War II, the political and educational climates changed hands. Between December 1941 to October 1944, the Japanese occupation was characterized by political oppression and indoctrination. The Japanese military government was interested in total sociopolitical suppression, not in education.

The “re-Americanization” of the Philippines began when U.S. Army General Douglas MacArthur liberated the islands on October 20, 1944. Two years later, the Philippines was granted its independence on July 4, 1946. Prior to independence, the educational system was reorganized and further modernized. United States soldiers who held educational degrees acted as model teachers and a catalyst for future Filipino teachers. From 1946 to 1968, there was rapid population growth, but still no formal sex education. What was not taught in the classrooms, the students would learn from their families at home and in the streets, although this information was often distorted, incomplete, or outright erroneous.

In 1969, in an effort to reduce the world population, the United Nations, through the World Health Organization in cooperation with the Filipino government, instituted a family planning and birth (conception) control program. In 1970 to 1971, this author was one of the principal instructors and trainers in the family planning program in the suburban and rural areas. The program consisted of teaching basic biology, conception/pregnancy, and the different options for contraception, but mainly the “pill.” Although the Catholic Church was overtly opposed to contraception, particularly the “pill,” the Church covertly supported this education in order to reduce the family’s burden of childrearing because of poverty. In 1970, the educational (college) system was rocked by a widespread explosion of “student unrest” demanding more student rights and an expanded curriculum. The author was again one of the medical student leaders who demanded students’ rights in a peaceful protest rather than a confrontational or violent demonstration. The college administrations finally settled and included in their curriculum

science courses, such as expanded public health, that included information on sexually transmitted diseases and limited information on human sexuality.

During this era, sex education was left to the biology teachers, both in high school and college, who gave very limited information as part of the classes in the biological sciences. In a few cases, when the teacher decided to do so, this instruction was more or less a description of the reproductive organs in plants and animals, with perhaps some references to the role of the ovaries and testes in human reproduction. Explicit mention or pictures of the male and female genitalia were unacceptable and forbidden by custom.

## B. The Present Situation

In 1972, President Ferdinand Marcos declared martial law and proclaimed a new sociocultural reform, the “New Society,” which purported to reduce crime, enhance land reform, and augment economic stability. During this period, the government also approved a program, and directed that formal sex education be taught in all levels of education. Sex education courses were offered, starting at the elementary level in science and biology (human development and population). The high school equivalent to the 10th grade in the American system and college courses included elementary basic-level biological information, plus discussion of family planning and separation—divorce being illegal. The information on legal separation (*de facto* separation) was more in-depth in the public schools because of its high incidence in the lower class as compared to the middle and upper classes (professionals), who sent their children to private schools. In the 1980s, the medical schools supplemented the courses on human sexuality with seminars and an international conference in which the author was one of the main speakers. In the 1990s, the government sponsored kindergarten classes. Research on population control, sexually transmitted disease (STD), premarital sex, sexual harassment, and AIDS are ongoing. (See Section 5B, Interpersonal Heterosexual Behaviors, Adolescents, for additional insights into sexuality education for adolescents and medical school students.)

Despite the government’s crackdown on illegal sex publications, which was supported by Catholic Church authorities, it is obvious to any careful observer that informal sources of sexual information—television talk shows, soap operas, radio phone-in programs, and different kinds of adult journals and magazines commonly found in metropolitan and other urban areas—are widespread in the Philippines and cannot be controlled by either the government or religious authorities.

## 4. Autoerotic Behaviors and Patterns

The Catholic Church still maintains its condemnation of self-pleasuring (masturbation), teaching that any sex outside marriage is sinful. At present, a majority of Filipinos still believe that frequent masturbation can cause neuroses, premature ejaculation, and even blindness. In 1969 and 1970, the author conducted an informal sex survey in Central Region colleges and universities, which revealed that only 22% of the students, mainly males, engaged in masturbation. Another survey done in 1995, limited to medical school students, showed that 32% of the males and 8% of the females practiced masturbation (total  $N = 280$ ).

## 5. Interpersonal Heterosexual Behaviors

### A. Children

In Filipino society today, it is not unusual for preteenage boys to engage in exploratory “sex” games with other boys and girls. Such exploratory play allows the child to reassure

him- or herself of the normality of his or her body. This kind of childhood sexual rehearsal games was more common in the past and in rural areas, when violence and drugs were not as devastating as they are now in the urban areas. In some cases, boys would observe couples kissing and hugging in the park. Occasionally, they sit in the balconies of movie theaters where couples are engaging in heavy petting. In the rural areas and *barrios*, boys commonly compare their bodies with a friend, relative, or schoolmates. Generally speaking, parents and other adults have a mildly negative response when they discover child sexual play, ranging from warnings to spankings.

## B. Adolescents

Our knowledge of the sexual attitudes and behaviors of the Filipino youth is limited to a very few anecdotal reports, most of which deal with middle- and upper-class urban teenagers rather than the rural poor and urban street children. In this very limited context, my personal experience was the basis of my premedical school thesis on "First Night Sexual Experience of Young Boys—1968." This study consisted of personal interviews with 80 adolescents in the rural areas of Cebu during social dances and summer festivals. The majority of these teenagers were interested in obtaining information regarding nocturnal emissions, love, sexual intercourse, and, for women, contraception and pregnancy. Most of the males' ideas on sexuality were derived from older boys, brothers, and their uncles. On the other hand, the girls were too timid or shy to answer the sexuality questions.

During the author's return visit to the Philippines in July 1995 as an invited speaker at a college sociocultural conference, he arranged an impromptu meeting with middle and high school students, grades 7 through 10. They informed me that most of their teachers believed that they were too young to hear about sex education. The teachers did not allow questions from their students during the lecture on "family education." Most instructors were too insecure and embarrassed, and so were unable to facilitate any in-depth dialogue. In Catholic Filipino society, the Christian dogma still has a strong influence on the teachers' moral and religious values, so that, despite the presence of a government-mandated educational climate, sexuality remains taboo in public discussion. Unfortunately, these teenagers were afraid to elaborate further, confessing only that it is attitudes like this, repeated in their conservative homes, that make them view society and family cynically.

In Christian colleges and universities, being pregnant out of wedlock can result in expulsion. In most public nonsectarian universities, sex education is still mostly nonexistent except for those basic biological courses and family planning programs mandated by the government in 1972. However, in the largest government-run university, the University of the Philippines, sex education courses are more in-depth and liberal, because of the sophistication of the instructors and department heads who are Westernized and comfortable with controversial and sensitive ideas.

Although still limited—some might say elementary—sexuality courses in most urban medical schools are generally open to updating because of the infusion of new ideas from visiting professors and experts in periodic international forums and conferences. The best medical school students can graduate as doctors at the young age of 23, a factor that makes their communications with patients about sexual issues difficult at best.

### *Pubertal Rites for Boys*

The anatomical and physiological changes that herald puberty are universal to the human race. However, in Fili-

pino society, the sociocultural pubertal rites are expressed in a variety of customs and traditions depending on the particular subculture and its religious orientation. In the Christian tradition, the custom is to circumcise all males. Male circumcision is performed either by a medical doctor trained in this surgery or by a traditional medicine man. Filipino boys may be circumcised as newborn infants or somewhere around age 8 to 10 years, when they are in the 3rd or 4th grade. City dwellers and the sophisticated elite have their newborn males circumcised before they are discharged from the hospital. Working-class and poor families seldom have their newborns circumcised, but usually wait until the boys are 9 or 10 years of age. The medicine man is not a medical doctor, but a man of ordinary skills who has learned the art of circumcision handed down from his father or grandfather.

Circumcision is done in two ways. In superincision, a dorsal-mesal cut is made along the length of the upper surface of the penis, from the base to the foreskin, or only on the top of the foreskin. In the coronal technique, the excess foreskin is removed with a circular incision, as is the practice in Europe and North America. When a medical doctor performs either of these types of circumcision, the incision is closed by sutures and oral antibiotics are prescribed to avoid postoperative infection. The medicine man, on the other hand, only performs the dorsal slit circumcision, using a specially "cleaned" (not sterilized) sharp knife or a modified slender "machete" as scalpel. The medicine man uses neither antibiotics nor anesthesia.

This pubertal initiation traditionally occurs in the spring or when the schools begin summer recess, somewhere in May or June. The ceremony commences when boys, aged 8 to 12 years old, march in procession, usually in groups of 10 to 12, to the medicine man's house. The medicine man, with the parents' knowledge and consent, will then lead the boys to a secluded place, a clearing in a thicket or on a farm to insure privacy. The boy, with pants removed, is seated on the edge of a rock or stump of a tree, while the medicine man sharpens and cleans the knife. Despite this tension-producing buildup, the boy must remain calm and composed to show that he is brave and ready to enter the new realm of adulthood and can handle the rigors of manhood. The medicine man places the knife's sharpest side underneath the tip of the excess prepuce (avoiding the glans penis). He instructs the boy to look up, saying "look for a bird or a plane," diverting his attention. In a split second, a piece of wood or a branch is struck down against the knife, resulting in a midline cut or dorsal slit of the prepuce. Bleeding may be profuse or minimal. The juice of a certain tropical palm plant (*nipa palm*) is squeezed over the wound as a post-surgical anesthetic and caustic agent to stop the bleeding. No wound dressing is applied to cover the fresh and rugged incision. A clamp of cobwebs or a mesh scraped from the underside of a coconut palm branch over the incision serves as a bandage and additional clotting agent (to stop further bleeding). In some parts of the Philippines, the medicine man spits on the wound pre-chewed tobacco or a concoction of guava (a tropical peach-like fruit) leaves to act as a clotting agent. Both the cobwebs and coconut palm scrapings act as mechanical meshes to trap blood platelets in order to stop bleeding. The guava leaves mixed with saliva has papase, a chemical agent that medically can minimize post-operation swelling and sometimes arrest bleeding.

After circumcision, the boys walk home without a sound of complaint or grimace of pain. It is interesting to note that a particular gait can be discerned before and after the circumcision. The boys naturally walk normally on their way to the medicine man's house. When they walk back to their homes, their gait is characterized by a "frog-like" walk, in

which the knees are spread away from each other in order to avoid the thighs touching the newly circumcised genitalia. For three to five days, the circumcised boys stay home. Some wear skirts borrowed from their sisters or mothers, not pants, so that clothes do not touch or accidentally hit the sensitive, partially exposed glans (head) penis. Despite daily wound washing in the ocean, a river, or stream, about 90 to 95% of these cases of nonsterile circumcision become infected. It takes about six to eight weeks for the wound to heal, usually without ugly scars or deforming penile skin adhesions.

In the 1970s, Muslim boys were not usually circumcised unless their parents were well-educated and health-aware of Westernized attitudes of that time. In the early 1950s, boys of minority families in the north were not circumcised. However, with the arrival of foreign Christian missionaries and their conversion to Christianity, most of the boys are now circumcised either by a medicine man or a physician.

### *Puberty Rites for Young Females*

Christian girls undergo two phases of social transition to womanhood: ritual ear piercing and a *cotillion* or debutante's ball. Ear piercing is neither a religious nor a pubertal rite. It is just a custom, a traditional "tribal" rite of socially announcing that the person is a girl. The piercing of the ear is usually done between one month after birth and 2 or 3 years of age. In some parts of the country, the girl is much older. Ear piercing is usually done by a hairstylist, a "medicine woman," or medical person. Outpatient procedures by medical personnel use properly sterilized needles. Oftentimes, however, no anesthesia or antibiotic is given when the piercing is done by a hairstylist or a medicine woman. In general, however, infections from ear piercing are not as common as in male circumcisions done by a medicine man with an unsterilized knife. Phase two, the debutante's ball or *cotillion*, is a social introduction of young females ages 16 to 18 years in the form of an elaborate party or dinner dance. The hostess of this social event is an 18-year-old female usually from the rich families. *Cotillion* is an old Spanish tradition, dating back to colonial days, when the daughters of foreign dignitaries or tenured Spanish government officials were introduced to the eligible bachelors of the equally rich in order to secure the daughter's future financial and sociopolitical status as eligible and eminently suitable future wives.

In the Muslim or Moros community, about 10% of the Filipino population, the ear-piercing ritual is the same as among Christians. In the early 1950s, the older girls would wear a veil. At present, young females seldom use veils or cover their faces. Some Muslims include the *cotillion* in their rite of passage, but for others, dancing or any form of partying is absolutely prohibited and considered sacrilegious.

The minorities, Ifugaos, Kalingas, Igorots, and others, account for 3 to 5% of the population. These females, like most Filipinas, have their ears pierced at any early age. However, in some tribes, family wealth and status are demonstrated by the number of earrings or the layers of necklaces worn. No form of female circumcision or genital mutilation has been recorded. Anecdotal reports suggest that during the pre-Hispanic colonial days, some tribal females wore multi-appendage rings, nose, and lip rings. These tribal cultures do not observe the *cotillion*.

### *Premarital Sexual Activities*

Sexual attitudes and behavior differ from one group of Filipino youth to another, depending on their social class, educational level, and place of residence. In metropolitan

and large cities, Manila, Quezon, Cebu, Iloilo, Davao, Dumaquete, and Zamboanga, adolescents and young adults are exposed to the cosmopolitan life and consequently receive more information on sex and sexuality. They are also freer to experience numerous options than are less-educated youths. Youth in small towns have narrower and more restricted ideas on sexuality, because of the family's and Church's strong control and influence. Furthermore, youngsters in big cities have easy access to adult magazines and entertainment, in which sexuality is openly discussed or shown, even though their parents and the Church try to hide such information from them. The majority of urban youth knows about contraceptives and can acquire these from pharmacies or from friends without problems. Despite the guilt and shame associated with sex, middle- and upper-class urban youth often engage in sexual contacts with girlfriends, household maids, and even prostitutes. For the youths of the poverty belts around the big cities, the situation is compounded by the lack of money and self-control. Even if they would prefer to use a contraceptive, they cannot afford them and there are no places where they can get them free. Oral contraceptives are only given free to married women for family planning purposes by government-run city and municipal health clinics. Although condoms were distributed freely in public high schools in the early 1990s on a mandate from the Secretary of Health as part of an STD and HIV prevention program, this practice was later discontinued because of a public outcry that it was ineffective and because of the Church's persistent objections.

The situation for rural (*barrios*) youth is quite different. They learn and receive information about sex and sexual behavior from observing farm animals, from magazines, from clandestine "boys only" meetings, and from the relations between parents and other family members in homes where there is little privacy. The prevailing Catholic dogma on sexual morality is written deep in the unconsciousness of every boy and girl. Only a few years ago, 98% of the youth associated premarital sex with guilt and sin. Only recently has this begun to change. In 1994, the *Youth Adult Sexuality Survey* (Zablan 1994) revealed that about 18% accepted premarital sex, although a majority of 80% still believed it was a sin and morally unacceptable.

Only a few general surveys about the sexual life of younger Filipinos exist; most of what is known is based on anecdotal reports. The author's experiences are with interviews of preselected groups of the youth population conducted during periodic sojourns back to the Philippines. The samples mainly consist of middle-class youth, ages 17 to 22, who were encouraged to bring to the meeting problems related to their sexual lives and development. Repeatedly, they expressed regret that these aspects of their lives that engender so much anguish and fears could not be explicitly discussed in the intimacy of their household.

It is becoming increasingly clear that first premarital sexual activities are initiated at an earlier age, especially for those in metropolitan areas, where the basic family structure often disintegrates because of a lack of parental supervision, with both parents working or the father absent and perhaps working overseas. Young males pursuing college and graduate studies in the city are often detached from parental supervision and frequently succumb to the lure of metropolitan temptations, go-go bars, and adult-entertainment houses. Twenty to 25% have their first sexual experiences with prostitutes, either out of peer pressure or curiosity. In a few cases, youths in smaller communities who impregnate their girlfriends may be forced to marry them or make an amicable financial arrangement with parental ap-

proval. The woman usually keeps the child in her parents' home instead of giving it up for adoption.

In the Muslim communities, premarital sex is absolutely prohibited. But young girls, ages 14 to 16, can be betrothed through the usual (parental) marriage arrangement, mainly to affluent and much older bridegrooms.

Among girls, the memories of being deflowered were somewhat different from those of the boys. Because of guilt and shame, the majority of young females did not bother to get prior information about sexual intercourse and the possible consequences of their first sexual encounters. They perceived their first intercourse as the fulfillment of young love, motivated by peer pressure to keep their boyfriends, and at the same time as a "challenge" to parental authority or a gross transgression of a religious or social taboo. For the well-educated and sophisticated city dwellers, it was a calculated act to get rid of the old-fashioned social taboo (virginity), which they perceived as an obstacle to entering into a more mature and fulfilling sexual life, or plainly to catch the men of their dreams. It is interesting to note that, compared with the United States and other industrialized nations, Filipino teenagers are probably less sexually active; thus, teenage pregnancy is less of a problem than elsewhere.

Most of the children born to single mothers are kept in the teenager's mother's home, instead of being given up for adoption. In the 1970s, a pregnant teenager was a social outcast and was subjected to severe parental scorn. However, in the 1990s, because of Western influence and financial difficulties, a pregnant teenager is somewhat more tolerated, and her parents are less condemning and more accepting of any financial help the teenage father might offer.

### C. Adults

#### *Courtship, Dating, and Relationships*

As mentioned previously, Chinese influence runs deep and the majority of Filipinas adhere to its simple social dictum, "Get married at a marriageable age." Marriage is considered the natural conclusion of a stable heterosexual relationship. Recently, however, Filipinos have started to replace their old-fashioned social concepts with ones that recognize that the right to remain single is as much a personal right as the right to marry. Because of the Western influence on women's liberation, to be a single older woman is no longer considered a social disgrace or the result of any personal inadequacy.

#### *Cohabitation*

The colonial view of the sacredness of marriage includes a strong social condemnation of cohabitation for unmarried couples. Thus, cohabitation was relatively rare during the 1940s. The social and legal implications of "common-law marriage" (cohabitation) are not significant in a society of less affluence and resources. Furthermore, the definition of unmarried used in compiling official statistics makes it difficult to estimate the popularity of this behavior in the sense it is understood in the Western Hemisphere. Beginning in the late 1980s, the increased tolerance of non-marital cohabitation in the West began to influence the middle-aged and younger generations. During the author's 1996 visit in the provinces of Cebu, Leyte, and metropolitan Manila, there was an estimated increase of half a percent and an estimated 340,000 couples in unmarried cohabitation. The majority of cohabiting couples in the provinces are separated from their legal spouses because divorce is illegal and they cannot be civilly or religiously married. The rest are college students, youth, artists, and intellectuals who are attracted to this lifestyle.

[*Update 2003:* In a recent survey conducted by a polling agency, the Social Weather Station (SWS), in late November 2002, 35% of the respondents considered cohabitation a "good idea" prior to marriage. This was virtually unchanged from 1998. However, an estimated twofold increase in cohabitation is expected by the year 2005, especially in the entertainment industry and among college students in metropolitan areas. The main reasons are financial and novelty. (*End of update by J. F. J. Leyson*)]

Courtship is a cherished Filipino tradition with certain specific rules based on religious, sociocultural, and family values. There are five widely shared rules or "commandments" associated with courtship:

1. Say "yes" to the first invitation.
2. It is a prerequisite to have an escort, either a friend or next of kin, on the first date (no escort is necessary for a woman 28 years or older).
3. It is all right to publicly demonstrate decent affection, such as kissing, touching, and caressing.
4. A young Filipina should reserve criticism after the first date, be discreet about her feelings, and the man must cover (pay for) all expenses.
5. If dating leads to marriage, one must remember that marrying entails marrying into the spouse's whole family as a clan.

The majority of young men and women believe that love, physical attraction, similar religious beliefs, and trust are the basic essentials in creating and maintaining a stable relationship.

#### *Adults, Marriage, and the Family*

The marriage ceremony is usually preceded by an engagement. For the rich and middle class, betrothal is marked with elaborate parties. On the other hand, the low-income class concludes the occasion with a firm handshake and/or a sip of a local wine or homemade ferment. The engagement and wedding are usually a happy, festive occasion. However, if questions of family honor and shame arise, the outcome may be violent and deadly, as happened at the time of this writing, when a male's family massacred the bride-to-be's family because she slept with another man two days before the wedding. The community accepted the outcome as a proper punishment for the betrayal and unbearable shame caused to the bridegroom's family.

Whereas the legal age for voting is 21 years for both males and females, the legal age for marriage is 21 for males and 18 for females. In the Muslim community, the parents of a girl between ages 14 and 16 may betroth her to an older man. Generally, in the Christian community, the courts do not consider pregnancy a valid motive to grant permission for the marriage of a minor. Legislation has also abolished the possibility of reparatory marriage; in the past a person accused of rape or forceful abduction could avoid punishment by marrying the victim. In the southern end of the archipelago, where the majority of the Muslims live, a dowry is agreed on before a formal marriage arrangement is signed. The dowry, given by the bride's parents to the groom, may be a large sum of money, property, or a sizable wedding present.

Muslim marriages are conducted by a judge or an *imam* (a religious cleric), Christian marriages by a priest or pastor. Civil marriages are recognized and accepted in both the Christian and Muslim communities when conducted by judges and commercial chiefs, such as pilots and ship captains.

Although polygyny had a long history in pre-colonial Filipino civilization and was common in the Muslim com-

munity prior to the 1970s, polygynous marriages are the exception today. The majority of sophisticated, highly educated males, whether Muslim or Christian, choose to be monogamous for financial reasons. Middle- and upper-class Filipino families also elect to have fewer children, two on average, as compared to three or more for the less educated and low-income families.

With the advance of information technology, foreigners seeking brides with traditional values can now surf the Internet for a modest fee. Companies also advertise "mail order brides" in different magazines and specialty journals. There are currently about 100 companies competing to lure mail-order bride customers, such as "Cherry Blossoms," "Asian Rose," and "Exotic Girls." The service charge can range from a basic \$150 to upwards of \$2,500. For \$150, the bridegroom-to-be will receive a brief biographical sketch and a photo or video of the woman. He can correspond with her in letters or even phone calls. He can arrange to go to the Philippines and see her at his own expense. For \$2,500, the services include airfare, hotel accommodations, and a two- or three-day tour to personally interact with the candidate bride(s). The client is introduced to different women during a party and the couples can interact socially.

A major shortcoming of this venue for finding a mate is that the interested males are not screened properly. These men can be psychopaths, criminals, or worse. In some cases, a syndicate of "Internet bride-merchants" sells young women aged 14 to 18, oftentimes with fake birth certificates, for a mere \$3,000. These women are admitted to the United States on a fiancée's visa. Parents with severe income hardship frequently sign the contract believing that their daughters will either be given a job opportunity or be future brides of these unscrupulous foreigners. Recently, a congressman from the state of New Jersey sponsored a bill in the United States Congress to severely restrict the issuing of these "fiancée's visas" and to stop the practice of "bride-to-be/sex slave" businesses. Newspaper reports and embassy communiqués have documented that many young Filipino mail-order and Internet brides are held captive, raped, divorced, and then pressed into prostitution.

There are no credible published data on marital sexual satisfaction or on the status of Filipino marital life. According to the author's informal survey and radio-talk-show interviews in 1995, 15 to 20% of Filipinos are unhappily married. Women, more often than men, reported having sexual intercourse not because they desired it, but to please their spouses. Whereas 35% of males would like to increase the frequency of sexual intercourse, especially those in their 20s and 30s, most of the women were satisfied with the frequency of sex; only 5% of the females were interested in more frequent sex. These gender differences may be explained as the result of a greater pressure on males for sexual performance to maintain their macho image and maintain total control over women.

A majority of women complained of the brief duration of foreplay and premature ejaculation. Sexual intercourse is limited almost exclusively to penetration, which is more common among the less educated, more devotedly religious couples, and the older age groups. The average duration of foreplay is about five minutes, that of coitus about five to six minutes. On the other hand, the more educated, sophisticated, younger age group, and the "unchurched" have a longer duration of sexual foreplay and coitus, about 22 minutes. Although premature ejaculation is not uncommon among males, very few men seek medical help. Husbands generally do not consider premature (early) ejaculation a problem.

In the Christian community, sexual activity is not prohibited during any religious event or celebration. In some

cases, Christian women make the personal choice of not having sex during their menstrual period. On the other hand, Muslim custom does not allow any sexual activity during the menstrual period, between sundown Friday and sundown Saturday, and during *Ramadan*, the month-long period of daytime fasting.

It is difficult to gather data on female orgasm because of religious repression and personal shyness. It is believed that Filipinas' sexual satisfaction is based on cultural and religious grounds. The husband's satisfaction is primary and the wife's orgasm clearly secondary. Young, educated, and less religious or unchurched women have a higher orgasmic rate as compared to their older, less-educated, (oftentimes) more religious, and shy counterparts. It is believed that for a majority of women who experienced orgasms, it was more a result of psychological and religious expectation and not so much because of oral or manual genital stimulation. However, the barrage of media and Western influences has increased the proportion of Filipinas who prefer both psychic and physical stimulation. Filipinas are bombarded by the mass media and performing arts with messages about more openness in sexual matters, greater gender equality, information about new techniques for lovemaking, new roles within the couple, and new opportunities for extramarital relationships. These issues are also conversation matter among friends and families, at business meetings, and at almost any social-civic gatherings.

### *Divorce and Remarriage*

The Catholic Church does not allow divorce of any kind, but it will grant annulments, which most Filipinos find socially distasteful. However, generally, we find civil decrees of legal separation, divorce, and annulment are becoming more socially acceptable for Christian and Muslim Filipinos. A civil divorce requires that the ex-husband support the children and provide some assistance to the ex-wife along with household maintenance.

[Update 2003: A recent survey by *Filipino 2.0* (2003) magazine revealed that most Filipinos are satisfied with their family life, but the survey also found a "significant" minority who agree with divorce despite a ban on the practice by Philippine law and the dominant Roman Catholic Church. According to the Social Weather Station (SWS) survey of 1,200 Filipinos nationwide, 36% agreed that "divorce is usually the best solution when a couple can't seem to work out their marriage problems." On the same question in SWS's survey the year before, 29% agreed that divorce might be the best solution. In the 2002 poll, 50% of the respondents disagreed with divorce, down from 61% in the 2001 survey.

[Asked about satisfaction with family life, 27% said they were satisfied, 29% said they were completely satisfied, and 31% claimed they were very satisfied. Only 6% said they were fairly, very, or completely dissatisfied, while another 2% said they were neither satisfied nor dissatisfied; the remaining 5% had no opinion. On the question whether married people are generally happier than unmarried people, an overwhelming 61% agreed while 19% disagreed.

[In January 2003, the Philippines Solicitor General (the equivalent of the U.S. Attorney General), A. Benipayo, said that judicial officials are considering reforms that will make it easier for estranged couples to have their church marriage annulled. The Philippine Constitution states that "marriage is an inviolable social institution and the foundation of the family, and shall be protected by the state." Under the proposed reform, special family courts handling annulment cases would no longer be required to gain the consent of the Solicitor General's office before voiding a marital union.

Benipayo remarked that he favored the new proposal, which came from a judicial reform committee created by the Supreme Court, that his office should stop representing the state in annulment cases. The reform would also be empowered to invalidate marriages on specified grounds, including psychological incapacity. The office of the Solicitor General received on average 410 annulment cases every week. Benipayo added that the special court judges are “already properly guided by the law and pronouncements and interpretations of the Supreme Court” to handle the reform (Bascug 2003). (*End of update by J. F. J. Leyson*)

Slightly more acceptable are consensual separations. What is popular today is having a court declare a marriage null and void under the Family Code (Executive Order 209, Article 36). The Family Code has adopted the grounds of “psychological incompatibility” as a basis for civil annulments. This was the criterion for annulment articulated by the Catholic Church 40 years ago after the Vatican II Council, when annulments became much more common. A civil annulment dissolves the marriage and leaves both parties free to remarry. With the incidence of annulments clearly increasing in the mid-1990s, Filipino Senator A. D. (Nikki) Coseteng introduced in the legislature a pro-marriage anti-divorce bill (No. 179), which now legally defines marriage as an inviolable social institution and the foundation of the family.

The incidence of remarriage is not presently known. However, both in the rural and metropolitan areas, cohabitation is on the upswing because of Western influences and financial problems. In major cities, younger, more sophisticated, and affluent women have more chances for remarriage, but priests will not officiate at a second marriage ceremony unless the Catholic Church has annulled the previous marriage. Despite liberalization in the dissolution or annulment of marriages, the main reason why the divorce rate is still relatively low, when compared to the industrialized countries, is most likely the pervasive influence of the Catholic Church and parental moral values. The importance of extended family norms derives, not only as a source of emotional support and the context for the development of profound personal relations, but also for many other aspects of social life, from financial support to finding a job. Legal separation, divorce, and annulment are still frequently perceived as evidence of personal failure and as a “social anomaly.” The end of the relationship is not viewed as freedom and independence, but as the beginning of a different period in one’s personal life.

### *Extramarital Sexual Activities*

Most of the causes of legal separation involve extramarital affairs. Adultery or extramarital sex is vehemently condemned by the Catholic Church and is socially detested. However, there is an issue of legal terminology and social definition. Under Filipino penal laws, a man does not commit adultery unless he violates the law against concubinage. To be guilty of concubinage, a man must:

1. keep a mistress within the conjugal dwelling;
2. have sexual intercourse with another woman under scandalous circumstances; or
3. cohabit with another woman outside the conjugal dwelling.

Having sexual intercourse with a woman who is not one’s wife does not in itself violate the law of concubinage. Nor is the ban on concubinage violated if a man fathers a child with a woman who is not his wife. A wife commits adultery simply by having sexual relations with a man who is not her husband, regardless of the circumstances.

The provisions of the Penal Code on female adultery and male concubinage are glaring examples, not only of the inequality between the sexes, but also of the inequity between erring spouses. The law provides a maximum penalty of four years imprisonment for the erring husband. The concubine shall be meted a penalty of *destierro*, wherein she is prohibited from setting foot within the man’s residence. A wife found guilty of adultery, on the other hand, may be imprisoned for a maximum period of six years. Some lawmakers have pointed out that it is easier to send a female to jail and that this violates the constitutional provision on equality of the sexes. In simple terms, the law does not criminalize the sexual infidelity of a married man except under certain circumstances. This, some lawmakers point out, seems to imply that the extramarital affairs of men are acceptable as long as they are discreet in handling them—a clear reflection of the double-standard mentality of society with regard to sexual infidelity.

A 1996 survey conducted by an advertising and research group revealed that out of 485 married men in metropolitan Manila, 51% admitted having had extramarital affairs. The survey results reflect the machismo culture in the Philippines, wherein a man’s worth, among other things, is also equated with his ability to lure other women. In an attempt to correct this inequality in 1997, Senator M. Santiago filed a bill simplifying marital infidelity. In her measure, she proposed that the extramarital sex by either the husband or wife be called *adultery*, whether the extramarital partner is of the other or same sex. The House committee made amendments to her bill and put the marital offense under a single crime called “marital infidelity,” eliminating the separate provisions on concubinage and adultery, and the consideration of whether the infidelity occurs within the couple’s home or elsewhere. Congress proposed a maximum penalty of six years for all parties concerned. Speaking for the Women’s Legal Bureau, a nongovernmental organization (NGO), E. Ursua claimed that imposing criminal liability on the offenders is not the answer. “We do not think criminalizing is the proper solution. We can’t force someone to be faithful.”

The new law penalizes the guilty party with imprisonment, regardless of the reasons behind the infidelity. A woman escaping from an abusive or violent relationship, or one who simply falls out of love and finds growth and fulfillment with another person, is treated no differently than a man who keeps several mistresses. In effect, the law also punishes individuals who get out of marriages that are bereft of love, respect, and trust. Some legal organizations propose a modified “divorce” law and/or a new bill to decriminalize sexual infidelity. But Senator Santiago countered that this might send a “subliminal message” to the youth that the state is encouraging “free love.”

In the Muslim world, adultery is severely punished, with the perpetrators either made social outcasts or, in rural villages, stoned to death in public. This “fatal justice” is carried out clandestinely as an expression of community justice that government magistrates (*datu*) can do nothing to either prevent or punish. The whole village maintains a “code of silence,” because this punishment is written in the Muslim moral marital law. There is no witness to interrogate or testify.

During the Spanish colonial days, 1775 to 1899, rich Filipinos who owned *haciendas* (estates or a large parcel of land) and employed several female domestic helpers could easily have extramarital relations with their female employees, with or without the knowledge of their wives. Today, we still find married men in all walks of life who maintain a longstanding relationship with a second woman, oftentimes with the knowledge and approval of their spouses,

and even of their grown children. In some cases, an extramarital affair can end a politician's career; in other cases, an affair, even when it makes headlines, may have no political consequences. Some couples find extramarital affairs a solution that keeps their marriage alive. The man may be freed to satisfy sexual needs he does not dare, because of religious restrictions, reveal to his wife, while the wife is relieved of any pressure to change her sexual behavior. Most wives who adopt this compromise have limited horizons in their lives and a very low sexual appetite. Less common is a marriage in which both the husband and wife have extramarital relationships by mutual knowledge and agreement. In such cases, usually the husband has a job that keeps him abroad for long periods of time, with periodic visits to wife and family. Occasionally, Filipinos who married, found employment abroad, immigrated for a few years, and married a second woman while abroad, bring their second wives back when they return and set up a second household in a different dwelling. Discovery of this bigamous affair can be costly if the courts become involved. Legal penalties for bigamy can bring up to four years in prison and fines for moral and psychological damages between US\$500 and \$1,300.

These relationships pose a serious problem in Philippine society because many of these men resist the use of condoms, do not practice safe sex, and pay no attention to the possibility that their regular or occasional partner(s) may be HIV-positive.

#### *Incidence of Oral and Anal Sex*

Both the Christian and Islamic sects abhor oral and anal sex acts. The Muslim tradition specifically requires the husband to enter the wife by natural means in penile-vaginal intercourse. Oral sex, which in the past was condemned as "unnatural," is practiced more or less by educated Christians who live in the metropolitan areas. From the 1950s to the 1970s, when there was no constant supply of electricity in many towns and areas of the country, professional couples enhanced their sexual lives by using pornographic and specialty magazines. In the 1970s and 1980s, with electricity more widely available, middle-class and upper-class couples used film projectors, and later videocassette players, to enhance their sexual repertoire and learn about alternatives to penile-vaginal intercourse that could bring renewed vigor to their routine sex lives.

Anecdotal reports suggest that oral sex is practiced by 10 to 15%, and tried by 20% of the professional couples (i.e., doctors, lawyers, and businesspersons who travel a lot). The majority of Filipinos, however, still consider oral sex as dirty and unnatural. For the few who engage in oral sex, cunnilingus is acceptable, but Filipinas will only very rarely engage in fellatio. In general, older and lower-class Filipinos have a more negative view of oral and anal sex.

Modern Filipino youth, however, seem to be taking a new look at Westernized sexual expressions, according to what they said at the author's impromptu meetings. Although no general survey data are available, a segmental study of metropolitan youths revealed two groups of young women based on their responses. One group accepts and practices oral sex as a way of avoiding the risk of pregnancy, maintaining their technical virginity until marriage, and/or as a form of safer sex. For the second group, oral sex was a more intimate form of sexual relationship, somehow more "romantic" than genital intercourse. Youths holding the latter view believed that oral sex should be only engaged in with a stable (engaged to be married) partner and not in the first few exploratory encounters or dates. Some other older girls joined some boys in rejecting this way of ex-

pressing love, and thought that only prostitutes could practice fellatio on boys.

Whereas anal intercourse is not part of the fantasies for the majority of devout Christian women, anecdotal reports revealed that 30 to 40% of males fantasized about having anal sex with women other than their wives. Prejudices against anal sex are even stronger in less educated youths. Most of the youths I spoke with do not accept anal sex even after marriage, perhaps influenced by the increasing incidence of AIDS in the Orient. Older boys agreed that a woman will never ask for it.

### *6. Homoerotic, Homosexual, and Bisexual Behaviors*

Early Christian and Muslim colonists brought their religious views of homosexuality as either sinful or at least unnatural and immoral. Today, the Philippines is still, to a large extent, a macho society, and macho men detest gays, whom they see as effeminate and "strange." For a majority of the population, including locally trained physicians, psychologists, and social workers, homosexuality is viewed as a perversion and a disease. Teenagers who feel a strong attraction to persons of their own gender at first experience confusion about their feelings and sexuality. Gradually, as their orientation becomes clearer in their minds, they awake to the unpleasant reality of belonging to a group that Filipino society marginalizes.

Homosexuality in the Philippines, however, is increasingly being tolerated, and a gay movement is gaining strength and demanding their rights. Twenty years ago, this would have been unthinkable. The scorn for gays is stronger among low- and middle-class men than in the upper class. There always were artists, beauticians, fashion designers, writers, and medical and dental professionals whose homosexuality was known among the elite, but which was carefully kept out of scrutiny from the media and the masses. Lesbians are still not too visible in Filipino society, in keeping with the Christian and Victorian tradition, which never wanted to think about sexual activities in a relationship between two females. To be gay or lesbian in a repressive environment whose stereotypes are the macho man and the submissive reproductive woman is not an easy task. Anyone who deviates from strict heterosexual behavior is ridiculed: A gay is not a man and a lesbian is a degenerate woman. The Filipino Armed Forces does not allow gays to join the military and expels them when they are discovered.

To be bisexual, however, is not so annoying, as long as one's same-gender behavior is kept very private. In the early 1970s, it was common for Filipinos to identify or classify two types of gays: those who engage in homosexual sex activities and those who act effeminate but do not engage in homosexual acts. However, in the early 1990s, the former group has been active in promoting gay rights for the whole gay community. Although the "Gay Organization for Liberty and Dignity" is not yet a formal organization, they speak for both the visible and the invisible, helping the latter to openly assume their identities. Part of the emergence of gay and lesbian subcultures are masseurs who advertise their services in the most important papers and magazines and in metropolitan "gay" bars, discos, and hair salons. Some vocal gay groups lobby to influence politicians for future legal status and/or political clout.

Most Filipino gays prefer to mix with the heterosexual mainstream in their own social class and not form exclusively or predominantly homosexual neighborhoods. Those who have a well-defined and highly visible economic or political role are still in the closet. The same is true for members

of the Armed Forces and the clergy. To admit their homosexuality would be unthinkable or suicidal. On the other hand, among artists, writers, movie producers, TV personalities-actors, dancers, some doctors and dentists, and university professors, to openly admit they are gay may bring rejection from the most conservative members of society, but they may end up being accepted and sometimes even see their popularity increase. In the medical community, homosexuality is still generally viewed in Freudian terms as a condition originating in conflicts and childhood sexual conflicts, which can be cured by psychotherapy. Whereas members of the locally trained medical community, with limited experience abroad, view homosexuality as a violation of the laws of nature, the general public continues to believe that homosexuality is a result of growing up effeminate in a family without a masculine image or male role model.

[Update 2003: In December 2002, the continual suppression of gay activity by the Catholic Church was further reinforced by the Philippine government's refusal to issue a special non-immigrant visa to a "female spouse" of a female bank executive, even though the two women were legally recognized as "domestic partners" in the U.S.A. Then Justice Secretary H. Perez said that the Philippine Constitution and Family Code were "very categorical" in stating that marriages are only between a man and a woman. However, the Justice Secretary also said that "their (gay couple) marriage cannot be countenanced under Philippine laws for reason of public policy." In his view, "determinations or conventions agreed upon in foreign countries" do not override local laws.

[As recently as 2002, the public's reaction to lesbian activities was mixed, ranging from the firing of a medical school dean and professor for having a "romantic" involvement with a medical student, to the acceptance of a movie star's son as a macho gay topless dancer. In spite of the public's "conditional" acceptance of Filipino gays in early 2003, Oscar Atadero, a spokesperson for ProGay Philippines, again accused the Catholic Church of family anti-gay hatred. He referred to the exclusion of Filipino homosexuals from the Fourth World Meeting of Families, which was held in Manila in 2003. At the time, Manila's Archbishop Cardinal Sin warned that Christian family values were being eroded by advocates of same-sex marriages, divorce, the modern media, and technology. In response, Atadero declared that homosexuals are "not calling into question the existence of the family or staging a rebellion," but are merely asserting that they should be given "the same love and legal rights that other children of God have" (*Filipino Express* 2003). (End of update by J. F. J. Leyson)]

## 7. Gender Diversity and Transgender Issues

Despite the prevailing Spanish machismo mentality, the advent of democracy and Westernized media messages are slowly changing traditional attitudes. Thus, the "eccentric" minorities have had a chance to come out of their closets and express themselves. For the moment, the public reacts with curiosity rather than violence or acceptance. In the world of beauticians, dressmakers/designers, and performing artists, there are well-known transvestites. Because these persons are celebrities in Filipino culture, the public, especially the women, accepts them with smiles and gentle jokes. There is an annual summer parade of transvestites in Manila, where some men are indistinguishable from real women in physique and even "beauty." This event is similar to gay, lesbian, and transgender pride parades in San Francisco and New York City's Greenwich Village. In his younger days, this author would cross-dress with other

young professionals to entertain hometown guests during *fiestas* and Christmas celebrations. On the superstitious side, folklore in the North Central and Central parts of the archipelago holds that, when someone is confronted by a witch or travels through a haunted region, it is advisable to cross-dress so that the witch or the devil does not recognize you. In some rare cases, transvestites have acceptance from their mates, and sometimes from their children, when they live in metropolitan cities, cross-dress in the privacy of their homes, and maintain the macho stereotype in their work and social environment.

If life is not easy for non-effeminate gays or non-masculine lesbians, it is more difficult for those who identify themselves as the opposite sex in manners and clothing, and even more so for those who want to see their bodies change towards the features of the other sex. Persons who want to change their physical sex and be socially recognized as being of the other sex have not been seriously considered in the Philippines. The Philippine Medical Association and the Philippine College of Surgeons have not officially reported any case of transsexualism. Transsexuals are provided with psychiatric treatment, not transsexual surgery. The courts have not addressed this situation, and any person who desires to undergo medical (pre-surgical) and transsexual surgery treatments has to seek such services abroad.

## 8. Significant Unconventional Sexual Behaviors

### A. Coercive Sex

#### *Sexual Abuse of Children and Incest*

There are no statistics on the incidence of incest in the Philippines. However, it is quietly known that adolescent girls are often raped by older male family members, and fathers often use them as sexual objects after the death of the mother, or when the wife's work takes her outside the home for long periods. Abusive males are usually unemployed people with a past history of family violence, high consumption of alcohol, social inadequacy, and impulsive behavior. Although less frequent, cases of incest are also known in which the male is the head of an upper-class household and respected by his community. Cases of incest in middle- and upper-class families seldom surface while the victim is a minor. The trauma may emerge during private sexual therapy with an older woman, but there is a strong reluctance on the part of most victims to make formal charges. Generally, indictment for incest by judicial authorities does not take effect unless a formal complaint has been filed or in cases of public scandal.

Reacting to the increase in cases of child sexual abuse reported in the media, law enforcement agencies and the courts have started taking this situation seriously. Sexual exploitation of minors is more frequent in the cities, in the form of child prostitution, child pornography, and sex tourism. The clients and supporters of child prostitutes and those who produce, sell, or transmit pornography involving minors risk heavy fines and imprisonment. Crimes of sex tourism are difficult to prosecute because they originate or transpire outside the geographic borders and legal jurisdiction of the Philippines. There is, however, an organization, Hand Extending Love to the Philippines (H.E.L.P.), based in Phoenix, Arizona, USA, whose primary mission is to help sexually abused Filipino children, provide counseling for pedophiliacs, and prevent teenage pregnancy.

#### *Sexual Harassment*

The Euro-American concept of sexual harassment has no place in the tradition of Filipina subservience to males

that is part of *marianismo*, the symbiotic culture to *machismo*. However, the experience of sexual harassment is emerging in the social consciousness, as Filipinas respond to Western influences and begin to assert their personal and political rights. Women from the *barrios* and small towns are easily intimidated, but it is the sophisticated and well-educated women who challenge the “old-boy buddy” system and file complaints. Sexual harassment is punished through an administrative indictment that may end with a dismissal from public service. The administrative procedure, however, does not preclude legal action by the alleged perpetrator. The strength of the current law shows that Filipinas are expanding their political presence/clout, and winning the support of men, who know the problem well from inside the system.

[*Update 2003*: In December 2002, Rodolfo Stavenhagen of the United Nations Human Rights Council issued a complaint to the Philippine government on the sexual harassment perpetrated on indigenous Filipinos by the Philippine Army. The report claimed that native Filipinos were physically abused and sexually harassed if they were suspected of being terrorists or communist guerillas. The report cited destruction of houses, herding the people into hamlets, torture, and sexual abuses. The sexual harassment consisted of sexual innuendos, poking guns into female vulvas, and frottage by intoxicated government soldiers.

[In order to put more legal teeth into preventing or reducing sexual harassment, the 12th Philippine Congress (2002) passed a more comprehensive anti-sexual harassment law. It provides more protection for victims and severe punishments for perpetrators. The law is gender neutral, applying to male-to-female and female-to-male cases. But, it does not clearly define or include same-gender sexual harassment. Despite the passage of this new law, the incidence of sexual harassment cases has not changed. A January 2003 incident is unfortunately still typical: A female vice-governor (American lieutenant governor equivalent) was groped by a businessman during a public works bidding. At the same time, groping (frottage) of female passengers on the MetroManila Light Railway train was so serious that the LRT assigned coaches exclusively for female passengers in order to protect women from physical sexual harassment. The all-female coaches are installed behind a special section reserved for the elderly, pregnant, and disabled passengers, and adults with infants or young children. To avoid confusion, security guards are assigned at the platforms to guide female passengers who want to use the all-female coaches. Women are not required to use the all-female coaches and can ride alone or with a male companion in the mixed-gender coaches. Sixty percent of the estimated 320,000 daily passengers are female. (*End of update by J. F. J. Leyson*)]

### *Rape and Family Violence*

Despite a long colonial period during which wealthy *hacenderos* controlled and regularly exploited their indigenous female employees without fear that the victims might find some recourse in the justice system, recent educational reforms and the transition to a democratic government are producing a more humane society. However, there is still considerable violence within Filipino households perpetrated by the male head of the household. Abuse of this kind is seldom reported to police, because women know that the male police usually behave in the same way in their homes.

In the poorest households, girls are conditioned from infancy to accept the violent behavior of their fathers, particularly when they return home intoxicated. The initial physical abuse may lead to sexual intercourse that amounts to marital

rape. Faced with a society that until recently did not recognize the possibility of marital rape or a woman's basic rights, abused women capitulate, repress their feelings, retreat into their taciturn dreams, and continue laboring for the survival of their families, especially their offspring. Even then, if she does not manage to hide at least some of her earnings, the husband may spend them with another woman or drinking with friends. Local newspapers occasionally report domestic incidents when a wife inflicts serious genital damage on her husband while resisting his violent carnal advances. Philippine Department of Social Work and Development (DSWD) statistics reported that in the first three quarters of 1998, there were at least 1,152 cases of rape and attempted rape, 656 cases of incest, and 400 cases of lasciviousness.

The seriousness of rape against an individual female was brought to the public eye by the media when a famous actress was “gang raped” in the mid-1960s. The public demanded the severest punishment, the death penalty, and they got it. Execution by hanging, electrocution, or lethal injection as a penalty for rape has been on the books since 1924. The death penalty was abolished in 1987 but reinstated in 1994. There are currently about 900 persons on death row, including a former member of Congress convicted in 1998 and awaiting execution for rape. Even though no actual executions for rape have taken place, the law has been instrumental in helping reduce such incidents.

After nine years of debate, the House of Representatives finally, in 1997, approved the bicameral conference report on a new law that heavily penalizes rape and makes it easier for government prosecutors to prosecute rape cases. This anti-rape law reclassifies rape from “a crime against chastity” to “a crime against a person.” Thus, if the victim is a minor and refuses to accuse the perpetrator, only the minor's legal guardian or the court can file a suit. This new law also penalizes marital rape, but opens the door for the spouse to forgive her husband, in which case the charge is voided. The new law also redefines the nature of rape, expanding the traditional definition of forced penile insertion in the vagina to include unwanted insertion of the penis, or any object or instrument, in any bodily orifice of another person. These “other acts” are now part of “sexual assault.” The law in the Revised Penal Code also eliminates the gender bias, so that a woman can now be charged with raping a man. Finally, the law makes it possible to present evidence in court, in which presumption is created in favor of a rape victim, so that any overt physical act manifesting resistance in any degree can now be accepted as evidence of rape. Similarly, evidence that the victim was in a situation where she or he was incapable of giving valid consent can now be accepted as evidence of rape.

### **B. Prostitution**

Tribal wars between the aborigines in the Philippine islands turned the vanquished into slaves for labor or cannibalism, but not sexual slaves. When Chinese merchants started trading with the inhabitants of the archipelago in 960 C.E., they intermarried with native women, but did not sexually exploit the women. With the advent of Spanish colonists in the late 1500s, a flourishing slave trade was established between the Philippines, the Caribbean, and Spain. Anecdotal reports revealed that some Filipina slaves were sold as “exotic sex objects” or prostitutes to European brothels. When Pope Gregory XIV abolished slavery in the Philippines in 1591, middle-class Europeans started to immigrate to the archipelago, but the sexual exploitation of Filipinas by the Spanish colonists continued.

During World War II (1941-1944), the Japanese Imperial Army forced Philippine women from Manila and sur-

rounding towns to serve as “comfort girls” (military prostitutes) to provide sexual favors to all Japanese soldiers serving in the Philippines and in the Pacific region. In the 1990s, with international (legal) backing, these comfort girls were partially compensated for their humiliation and moral sufferings. When the American troops liberated the Philippines from Japanese imperialism in October 1945, many American soldiers left illegitimate Amerasian children behind. The mothers of these children and their Amerasian children were social outcasts. In order for these mothers to survive, they became part-time prostitutes in the rural areas for single laborers and traveling salesmen and in the cities with all kinds of customers. In 1947, President Roxas signed a military agreement granting 22 military bases to the United States. In the following year, the two largest U.S. military bases in the Far East, the Naval Subic Bay and Clark Air Force Base, were established north of Manila. Angeles City, located near Clark Air Force Base, later became the “Mecca of Sex Trade,” the military adult-entertainment capital of the Philippines, with every variety of prostitution, exotic bars, pornography, and sex tourism conceivable.

With the advent of information technology and global travel, the old part-time prostitutes have moved to the big cities. Prostitution survives because of poverty, the commercialization of human relations, and the sustained carnal demand. Although for different reasons, all social classes made their contributions to the trade in sexual services. The rich are looking for entertainment and diversity of sexual practices that they would never dare to ask from their wives. These respectable matrons are assigned by society only to bear and raise children, manage households (sometimes businesses), and organize social activities. The out-of-town students, immigrant workers, and wayward youths may be looking for their first sexual experiences and to combat the loneliness of being separated from their family for the first time. The poor frequent the brothels to affirm their masculinity by using many women or to relieve their loneliness.

As in most other countries, there are three types of prostitutes or sex working girls in the Philippines: streetwalkers, entertainment girls (*hostitutes*), and call girls or high-class prostitutes. Streetwalkers are not common, are usually self-employed, and many have pimps. Their safety is at jeopardy on the streets. The majority of the prostitutes fall under the category of entertainment girls. These *hostitutes* include bar girls, nightclub hostesses (waitresses), masseuses, exotic dancers, and those that work in brothels. They are usually business employees and have contact managers (sophisticated pimps). Their safety is secure because they work inside an establishment. However, they cannot refuse clients who are produced by agencies and their managers. They cannot set the prices for their services. Some massage parlors are commercial fronts for prostitutes who offer their services from oral sex to regular intercourse (US\$25 to \$65). Call girls comprise approximately a third of the female sex-worker population. Self-employed or autonomous, they usually do not have managers. They advertise their services in specialized magazines disguised as escort services for sophisticated gentlemen and sometimes ladies. *Hostitutes* and call girls advertise their services through word of mouth, by taxi drivers, bar bouncers, club managers/owners, and hotel bell captains. These agents receive part of the price in exchange for referring clients. In the large sophisticated hotels, the bell captain may have an album with pictures of different prostitutes from which guests may choose. In 1997, a new phenomenon emerged, the *Japosakis*, Filipina *hostitutes* who return home from sex work in Japan and continue serving their Japanese special

clientele or sugar daddies on their periodic “business” trips to the archipelago. Recently, there are also reports of an increasing number of *gigallos* or *toy boys* who provide escort services and pleasures for lonely matrons and wealthy widows.

Although prostitution is still illegal, Filipino society believes that some regulation is always needed, based on the premise that prostitution is regulated in order to minimize the damage to society. Local city councils may require filing an application with the city to establish a brothel, indicating the location for legal reasons and/or tax purposes. Local authorities may also restrict brothels to certain areas and regulate any signs that would identify it as a brothel. Prostitutes cannot reside anywhere other than at the brothel itself, which is her official domicile. Brothels also have to have a bedroom for each working woman. The women cannot show themselves at the balconies or in a window, nor can they solicit in the streets. In order to work in a brothel, a woman has to register with the sanitary-health authorities (Bureau of Health). The authorities will check whether she is a victim of deceit or coercion and advise her that help and assistance is available from legal authorities.

Each prostitute is given a “sanitary notebook” with her picture, personal data, registration number (if any), and the main articles of the decree that concern her rights as a provider of a service. Her rights include being free to stay or quit the brothel in which she lives and works, debts cannot be used to compel her to stay in a given brothel, and no one can subject her to any abuse. Each prostitute has to undergo mandatory monthly medical examinations for sexually transmitted diseases (STDs). If an STD is diagnosed, the brothel pays for medical treatment. The sex worker must show her sanitary notebook to any customer that asks to see it. The manager of the brothel cannot accept any “prostitute-candidate” or applicant who has not first registered and passed a medical examination. The manager also has to report immediately to the sanitary authorities whenever a prostitute is ill, be this an STD or nonsexual disease.

It is easy to imagine the rampant corruption that this naive attempt to protect customers and suppliers of contractual sex alike has produced. Police protection is bought, violations are ignored, and politicians and judges are bribed, often on the pretext of protecting the free practice of a fully consensual sex by the client and sex worker. In reality, this law and its application or lack thereof does little to protect the health of the women and their clients. The women have no protection from customers already infected. The prostitutes can request that their clients wear condoms, but cannot demand the performance of safe sex practices. The clients are not subject to compulsory medical “control,” and many may be infected but not show any symptoms, while others suffer in silence and continue practicing unsafe sex with other prostitutes, lovers, and even wives.

Transvestites also participate in prostitution, especially with unwary foreigners. Male homosexuals and child prostitutes who created Asia’s reputation for sex tourism are concentrated in major metropolitan cities.

### Sex Tourism

The Philippines has always been known as the “Pearl of the Orient Seas,” the Land of the Three Ss—Sun, Sand, and Sea. A fourth “S,” Sex, sold in “coolly” wrapped packages, has emerged to the point where it has already warranted the United Nations’ attention: sex tourism involving child prostitutes as young as 6 years old.

Angeles City in Pampanga, north of Manila, once home of the mighty Clark U.S. Air Base, is now being developed as an international airport. But the new airport has also be-

come the center of sex tours to the Philippines, openly promoted abroad, arranged by Filipino tour operators and their foreign counterparts, with attractive come-ons for men seeking sexual activities with “virginal” or child prostitutes who they hope are free of STD and HIV infections.

While the government is making major arrests in this trade, and sex establishments are regularly closed down, the front page of major dailies show bikini-clad young girls being led away by operatives, but never the brothel owners, the tour operators, their cohorts, and pimps. The Philippine Congress is still struggling to pass a law making a customer of a child prostitute criminally liable, even if he does not engage the services of a pimp. An increase of the maximum punishment for child labor and exploitation to 20 years was sought. The 1995 law set the punishment for child prostitution at 20 years in prison; the punishment for pornography and pedophilia, however, remained unchanged.

Sex tourism is the third-highest money-making industry in the Philippines. But the current penalties and enforcement policies do nothing to have an impact on the business. As in many other countries, the prostitutes are arrested, but not the clients, managers, and others whose enormous profits make this business so attractive. The punishment for committing prostitution is a US\$500 fine or 12 years in jail. While this law, in effect for three decades, applies to women dancing in the nude or in scanty bikini tongs, a major element in the prostitution trade, arrests are seldom made because of corruption and bribery.

In order to reduce the negative moral and economic effects of prostitution, government and some nongovernment agencies are working together to rehabilitate former prostitutes or entertainment girls who retire or change their “profession.” The government’s Department of Social Welfare and Development has programs to teach these ex-prostitutes other work alternatives and technical skills as a means to a decent living. A civic action and rehabilitation group, Marriage Encounter, is also training married former prostitutes to help them move back into mainstream society and divert single women from the sex trade by improving their personal skills for future relationships and family life. But funds and enthusiasm for such social programs are too limited.

### C. Pornography and Erotica

Under Spanish colonial rule, the Dutch (in 1600), and the British (in 1762), Filipinos were concerned about their personal freedom rather than freedom of the press. In 1820, the Spanish Cortes (government) granted the Filipino freedom of the press, but it was not until 1887, 67 years later, that Dr. Jose P. Rizal, a Philippine national hero, published in Germany the first Filipino novel, *Noli Me Tangere* [*Touch Me Not*]. This literary masterpiece exposed the Spanish political, economic, and sexual abuses in the Philippines. However, it was not until the early 1900s that Filipino romantic novelist Francisco Balagtas published *Florente at Laura*, his Filipino variation on the Romeo and Juliet theme.

In 1946, when the Philippines became a republic after 48 years of American colonialism, American and foreign magazines started to pour into the country. Pornographic magazines were illegal, but the rich and some devoted collectors managed to import literary exotic pieces (erotica). By the 1960s, changes were visible in the social attitudes and private interests of Filipinos. Women’s magazines are now found everywhere, in homes, hair salons, physician’s offices, and in businesses. And in almost every issue, there are articles about sexuality and eroticism. These articles also cover a variety of subjects, such as contraception, the influ-

ence of a healthy sexual life on physical and mental well-being, and how to improve a marital relationship.

Although there are no precise data on the production and commerce of pornography in the Philippines, there is no doubt about its widespread distribution and availability. The gradual blurring of the distinction between pornography and other forms of erotica has led to some level of social acceptance of pornography and opened new markets. In public debates, the anti-pornography position is weak, and pornography is often presented as a form of sexual liberation. Even some Catholic moralists have recognized that pornography can help couples to improve their sexual lives, as long as it does not replace the “natural” (romantic) sexuality.

Three types of Filipino magazines deal with sexuality and eroticism:

1. Magazines dealing with sexual issues, but avoiding pornographic images and full nudity, (e.g., *Superstuds*, *Gossips*, *Intrigue*, *Expose*, *Teen Stars*, and *Soap Opera Stars*). They are moderately to expensively priced, have quality printing, and are directed at informing a public that accepts a scientific (although popular rather than academic) language. *Sex Forum* magazine, published by a lawyer in the mid-1980s, provided sexual information reviewed and approved by the author of this chapter. Among the topics discussed in *Sex Forum* were techniques to enjoy an intense sexuality, to make your bedroom a more erotic place, to renew sexual passion without changing partners, safer sex practices, and ways of taking care of yourself without handicapping your pleasure.
2. Magazines of literary and sexual humor, with pornographic texts, advice columns, letters, and partial or total nudity (e.g., *Tik-Tik*, *Playboy*, and *Penthouse*).
3. Magazines and packages of playing or picture cards, clearly pornographic and devoid of artistic quality, some with scatological content.

In reality, a wide range of pornography and erotica is readily available, with distribution handled by regular newsstands, video shops, porno shops (major cities only), and mail-order services.

From the economic point of view, the most important sector of the Filipino pornography market is the sale of videocassettes, fueled by the wide distribution of videocassette players-recorders. In the 1960s, before video players, rich couples viewed adult films with an eight- or super-eight-millimeter portable film projector in the privacy of their own homes, or at some occasional college students’ “stag parties.” Videocassettes offer the possibility of greater privacy, and cater to the needs of middle-class and even poor men, women, and couples. Most of the pornography is produced abroad and imported for rental through video shops and typical newsstands. The legal situation seems to favor the newsstand as the primary channel for the rental/sale of these cassettes. Video shops, however, offer the advantage of greater anonymity and the higher technical quality of the cassettes. The sale and distribution of these pornographic materials are illegal. Although enforcement of the anti-pornography law is weak, sometimes it will produce a dramatic example. In April 1999, a 61-year-old Filipina grandmother was arrested for selling pornographic tapes on the streets of a metropolitan city.

Filipino pornography also comes in the form of “Live Sex Shows” arranged through special parties held in motels or hotels. The movie *UHAW* (*Sexual Hunger*), a soft-core film in the early 1970s, was the first erotica produc-

tion with the lead female role played by a former national Philippine beauty queen. Hardcore videos, although poor in quality, are also homemade, but lack the better quality of American and foreign imports. The advent of the Internet has brought a wide variety of sexual information and visuals, including local Web sites, like *sex maniacs* (*manyakis*, www.mayakis.com), with a modest monthly access fee.

The author's informal survey of consumers of pornography indicates that about 85% of the males and 15% of females are sexually excited by such films. Females prefer erotic films where sexual acts are embedded in a narrative context, whereas males are more easily aroused by simply viewing mere nudity and sexual organs. Female consumption of pornography seems to take place in the context of the couple, whereas for men it is more linked with solitary sex. Generally speaking, there are indications of an increasing trend toward increasing consumption of softcore (clean) pornography by educated, sophisticated, and professional couples.

### [Body Painting and Piercing

[Update 2003: The aboriginal civilization of the Philippine natives has flourished simultaneously with other native populations of Eastern Asia, Africa, and Mexico. While the Incas, Mayans, and Aztecs were erecting their temples, the aboriginal Filipinos were sculpturing rice terraces along the mountainsides that are considered one of the engineering wonders of ancient civilizations. At the same time, these ancient people perfected body painting (tattoos) for religious reasons and sexual attraction as an art form using primitive tools and different plant dyes. The tattoo artists, sometimes a medicine man, etched exquisite patterns mainly on the faces of females and on the extremities of the males as "spiritual armour" to scare evil spirits or their enemies.

[In the late 1970s, when "liberal nudity" was appearing in the cinema, body tattooing underwent a revival. With Americanization in the 1980s, young Filipino urbanites followed the trend set by young actors and entertainers, applying tattoos in some strategic sexual parts, buttocks, inner thighs, umbilicus, and breasts. On the other hand, young females in the *barrios* have modified their simple makeup into elaborate "facial painting." Body tattooing is limited to male college students and only on the body parts covered by clothing.

[Body piercing is as primitive as body painting for the Filipino aborigines. Both sexes subject themselves to ear piercing solely for sexual attraction. However, anecdotal reports indicate that cannibalistic natives also pierced their noses with animal or human bones for decoration or as a trophy of their conquest.

[In the late 1980s, when the majority of young Filipinos were concerned with finding a date or romantic interlude, eroticism was still considered a sexual taboo until they entered college. With the advent of global communications, the use of body piercing as a form of eroticism was popularized by young artists and Filipinos living in the metropolitan areas. The traditional ear piercing expanded to eyebrows and the umbilicus. In 2001, this author (a surgeon) had to surgically remove an infected "umbiliring" from a female patient to avoid the spread of an infection. Young Filipinos, and others, who decide to have body piercing and umbilical rings need to be clean the umbilicus and ring regularly to avoid infections. Also rings are more dangerous in the inverted ("inny") umbilicus than they are in the everted ("outty") umbilicus.

[At present, the art of body piercing as a form of eroticism has intensified and expanded to other parts of the torso, the

tongue and lips, and the genitals, labia, clitoral hood, and penile glans. The presence of erotic rings and balls in strategic sensual body parts will continue to pose a health hazard in the future. (End of update by J. F. J. Leyson)]

## 9. Contraception, Abortion, and Population Planning

### A/B. Population Planning and Contraception

[Update 2003: In the 1970s, Thailand and the Philippines each had populations of about 50 million and economies of similar sizes. Three decades later, Thailand has grown by 10 million to 60 million, while the Philippines has exploded exponentially to 85 million. Experts expect the Philippine population to double again to 130 million by 2025. Meanwhile, Thailand, Indonesia, South Korea, and Taiwan have brought their population growth under control. The Total Fertility Rate in the Philippines is 3.6 children per fertile woman, among the highest in the world outside Africa. Most of the larger families reside in the villages and *barrios*, especially among poor families. Families of 10, 12, or more children are the greatest source of pride. "If you have many children you are a great man," is a common belief. A few years back, when Cardinal Jaime Sin was asked about the country's population, his response was simple: "The more the merrier." The topography of the Philippines has made agriculture the main source of livelihood. This agrarian living needs workers. In order to provide "cheap" labor, it is advantageous for a Filipino family to sire more children, mainly boys, as workers and helpers in the agribusiness and aquaculture.

[The only contraceptive method accepted by the Catholic Church, the rhythm/cervical mucus or Natural Family Planning method, has a very low effectiveness rate because of menstrual irregularities. But in March 2003, President Gloria Macapagal Arroyo affirmed her backing for the "rhythm method." Mrs. Arroyo suggested that the rhythm method would promote family values by bringing spouses together, with the wife observing her body temperature, vaginal secretions, and menstrual cycle, and her husband writing them down on a chart. She also stated her belief that this natural contraceptive method would help teach patience, responsibility, and self-control. In the real world, critics say that the rhythm method is unreliable, complicated to follow (especially for the uneducated), and requires unusual restraint on the part of husbands. Another major barrier to the effectiveness of the rhythm method is the reluctance of Filipinas to check their cervical mucus, and their limited understanding of the physiology of fertility among those with limited school education.

[In 2003, Church officials announced they would be more vigorous in opposing all contraceptive programs, and would campaign in future elections against any politicians who support family planning, calling them "adulterers, fornicators and terrorists." Meanwhile, the Church has begun intimidating retail stores that offer condoms for sale. The Seven-Eleven grocery chain, for instance, stopped selling condoms following a Church-instigated boycott and picketing. Despite the fact that the government cannot educate, provide health services, and feed its present population of 85 million, let alone a population of 130 million 20 years from now, the Church continues its campaign in favor of large families and its ban on all artificial contraception. Family planning has become increasingly popular since World War II.

[Thirty years ago, between 1968 and 1970, the United Nations, through the World Health Organization and Planned Parenthood, initiated a massive population-control program,

distributing contraceptive pills to Filipino families. As one of the trainer/instructors, this author gave public lectures and provided training to all municipal healthcare personnel. The pills were given free to all married women. Fortunately, there was no strong opposition from the Catholic Church. However, after two years of implementation, because of government mismanagement of funding and pill distribution, there was no significant reduction in the pregnancy rate. With the increasing number of couples living together out of wedlock, the number of illegitimate children will double by the year 2005. Before the government started the "aggressive and formal" family planning in the late 1960s, middle-class couples learned the use of contraception through specialized pamphlets, magazines, and private channels (family doctors and pharmacists). Today, with the government restricting public education about contraception, the most effective teaching tools are the American television programs *Sex and the City* and *Friends*.

[Nowadays, in the large cities, contraceptives of all kinds—pills, condoms, diaphragms, IUDs, and vaginal spermicides—are available. These contraceptives can be freely bought in pharmacies without prescriptions. Women who can afford to pay can use the services of private physicians to help them acquire the correct kind of diaphragm or to insert an IUD. But two out of five Filipinos, 41% of the people, live below the poverty level, on less than a dollar a day. Jobs, food, and farmland are increasingly scarce. Urban slums are teeming with poor families with a dozen children (Mydans 2003). (End of update by J. F. J. Leyson)]

The situation is more difficult for women who live in scarcely populated distant rural areas. There, both the birth-rate and infant mortality rate are still high when compared to the urban figures. In these less-developed areas, the government has been trying to organize family planning services as part of its program of mother-child care including kindergarten classes. The number of abandoned children in metropolitan cities has increased. The Catholic Relief Services and other nongovernmental organizations are trying to house these children and provide contraceptive-control classes, including newspapers and television advertisements regarding practical birth controls for women and families who live in the city's slums and newly arrived urban immigrants. In 1997, faced with declining official development assistance from developed countries, the government requested increased funding for population programs. Former President F. Ramos suggested that developed countries must meet the United Nations target of committing 0.7% of their gross national product (GNP) to population control, and that this aid must follow the 20-20 formula on environment and development endorsed by the 1995 Copenhagen World Summit on Social Development.

[Update 2003: It is the Filipino women who bear the burden of raising large families and often seek to control their pregnancies. But the United States Agency for International Development reports that one fifth of women who want contraceptives do not have access to them. One reason, the agency reported, is that two thirds of the Philippine population cannot afford to buy condoms. The problem is immense: The use of modern contraceptive methods would have to rise by 40% for women to achieve the family size they want (Mydans 2003). (End of update by J. F. J. Leyson)]

According to recent studies, the Philippines has nearly 1.5 million street youth. At the same time, 74% of all unintended pregnancies in the Philippines occur in women 15 to 24 years old and 18% of Filipino youths engage in premarital sex. In late 1999, the Family Planning International Assistance office in Bangkok, Thailand, and the Reach Out

Reproductive Health Foundation announced the start of Barkadahan, a new project designed to curb the spread of sexually transmitted diseases and unintended pregnancies among Philippine's street youth, and have launched a program to address their reproductive health needs with sexuality education, treatment for HIV and STDs, and family planning options (World Reporter Asia Intelligence Wire 11/1/1999).

## B. Abortion

From 1581 on, the Spanish colonists suppressed women's rights, including the right to an abortion. Filipinas were considered second-class citizens until 1937, when a plebiscite on women's suffrage gave them the right to vote. For the first time, Filipinas could have some impact on decisions regarding their health. In the 1930s, abortion was controversial and performed in rural areas by quack doctors with improvised instruments and herbal concoctions. These crude gynecological procedures often led to serious complications including death. After World War II, the American influence resulted in most abortions being performed by physicians. However, abortion today is illegal in the Philippines and is severely condemned by the Catholic Church. This condemnation was reiterated in a recent Papal Encyclical on ethical questions, *Evangelium Vitae*. The current criminal code penalizes with prison sentences women who have an abortion and the professional who performs this service. Abortions are allowed in only two situations, when the pregnant woman is mentally deranged and the pregnancy is a result of rape or incest, and when the pregnancy endangers the woman's life. The Catholic anti-choice movement tries actively, but with limited success, to convince the political leadership to tighten the existing legislation and its enforcement. Muslim law supports the national law on abortion.

Abortion is a last resort everybody knows about, but nobody talks about. Instead of fighting against the powerful forces that arrogate to themselves control over women's bodies, Filipino society prefers to tolerate the officially condemned practices with a mischievous twinkle of tacit agreement among professionals and citizens. Criminal prosecution and denunciation of abortion practices are rare, and only occur when a woman dies as a consequence of an abortion performed by a non-professional. Given these conditions, the Ministry of Health has no exact statistics for abortion, but it is believed that its practice is not as widespread as previously thought. In the major cities, women who typically seek medical help for abortion are unmarried, mature women who already have several children or single high school and college students. These women resort to abortion mainly to put a stop to an unwanted pregnancy or to reduce the family size.

Although morally wrong, pregnant teenagers are now being gradually accepted by their parents. They do not resort to abortion, but agree to keep the child in their parents' house despite embarrassment and peer ridicule. Studies on the relationship between abortion and socioeconomic position suggest that middle-class professional women resort to abortion more frequently than high- or lower-class women. Studies in Manila and Cebu City during the 1980s and 1990s revealed that the highest rate of abortion was among women with a college education or college students who temporarily reside in college dormitories on city-owned housing. There are no written records of abortion among the lower classes because they are usually not performed by healthcare professionals, and the women deny having them to avoid problems for themselves and for those who help them in the procedures.

The morbidity rate associated with illegal abortions, especially those performed by non-professionals, could be reduced if the Church and the government would provide appropriate sexual education and promote the proper use of contraceptives, and expand the socioeconomic criteria/indications for legal abortion. In addition, the government and nongovernmental organizations should appropriate extra funding to provide better accessibility to well-equipped provincial or regional hospitals to treat the complications of abortion.

## 10. Sexually Transmitted Diseases and HIV/AIDS

### A. Sexually Transmitted Diseases

The estimated one million foreign women sold into prostitution in Japan, Singapore, Europe, the Middle East, and Southeast Asian countries and sex tourism are a major source of STD. In metropolitan Filipino cities, the most frequently reported STDs are gonorrhea, genital chlamydia, chancroid, genital herpes, papillomas, and AIDS. There is an alarming increase in the number of cases with the traditional STDs, particularly gonorrhea, herpes, and syphilis. Because of global travel, resistant strains of gonorrhea and trichomoniasis have been reported in some pockets around large Filipino cities with international connections. The lack of appropriate sexual education among mostly the lower social class, an attitude of indifference to prophylactic measures, and a poorly funded medical care system combine to increase the rate at which STDs are growing in the Philippines. The nationalistic policies of the government have meant that doctors are trained and medical services organized to take special care of pregnant women and newborns, not for the prevention of STDs.

Management of STDs is organized on three levels. The first and most advanced environment is provided by private medical practitioners in their offices. In this privileged setting, only prejudice or ignorance can prevent doctors from providing timely prophylactic advice, early diagnosis, and appropriate treatment of STDs. The second environment is industrialized medicine, clinics established by big corporations and specialized businesses. While the quality of care in this setting depends on the training and qualifications of the medical staff, the availability of consulting specialists, dermatologists, urologists, and gynecologists has helped a large number of workers and their families by educating patients about the risks of STDs and encouraging them to seek early detection and treatment. The third environment is provided by municipal health clinics and provincial and/or regional hospitals. These hospitals are entrusted with two missions: to provide medical services to the poorest sectors of the population and to serve as training grounds for medical students from both private and public medical schools and universities. Initially, these services were totally free, but because of escalating labor-management medical costs, these facilities now charge a small fee or donation to defray the recurrent and management costs. This small donation and transportation difficulties may further discourage Filipinos from the shantytowns in the poverty belts around the large cities from seeking early diagnosis and treatment of STDs.

Prostitutes form another subpopulation in the larger cities that requires special focus in terms of being a reservoir of the diseases and implementing measures for prevention. Children and young adults, especially women from the *barrios*/rural areas, pour into the city and become prey to drug traffickers and pimps. Through shared needles and sexual activities, they are infected with all kinds of STDs, further

contributing to the spread in their original milieus and city at large. Because of poor record keeping, there are no precise data or information regarding the incidence of STDs from city health offices. But anecdotal reports from the last ten years revealed that a small percentage of women who came to a medical office or made hospital appointments for gynecological problems, contraception, or family planning are infected with STDs. However, with the increasing population growth and the advent of sexual liberation, young Filipinos are vulnerable to STDs. The government and nongovernmental organizations (NGOs), including the Church, must marshal all their informational-educational resources to counteract the spread of STDs. Schools should incorporate STD-prevention information, with intense mandatory sex education starting in the 6th grade or earlier. Information provided by schools, social workers, health clinics, and NGOs should go well beyond this to help the youth develop a positive attitude towards the body, without shame and guilt about one's sexual nature, and to recognize their instinctive drives and develop an ability to establish tradeoffs between instinctual urges and the social moral constraints. Poor peasants and sophisticated urbanities can both understand a well-delivered message that these tradeoffs do not mean a repression of one's erotic life, but rather its enhancement by seeking to make it free of disease.

### B. HIV/AIDS

The current epidemiological explanation of the origins of HIV traces it to a mutant strain of SIV (simian immunovirus) found in "green monkeys" of the sub-Saharan regions of Africa. Two thousand years ago, the ancient Filipinos supplemented their rice and vegetarian diet with meat from a variety of game animals, including native Philippine monkeys. These simian creatures are the main prey of another world-famous carnivore, the Philippine monkey-eating eagle. In spite of their carnivorous appetite, the Filipino aborigines did not contract the HIV virus. Even today, there are Filipinos who still savor exotic menus of Philippine monkeys. Nevertheless, the HIV virus has reached the Philippines by other routes.

Acquired immune deficiency syndrome (AIDS) was first described in the U.S.A. in 1978. In 1988, an anecdotal report indicates that one infected Filipina prostitute from New York City came home to die in the Philippines. Twenty years after AIDS was diagnosed in California, the first 20 cases of AIDS were diagnosed in the Philippines (1990). Epidemiologists believe a major factor in the spread of HIV is the U.S. military personnel who frequented the sex bars and bordellos in the towns surrounding Clark Air Force Base and the Naval Base in Subic Bay. In 1992, it was estimated that 234 people were infected; by 1994, there were 834 cases. According to L. B. Duchene (1997) of Doctors Without Borders (*Médecins Sans Frontières*, MSF), 1,234 Filipinos were infected with the AIDS virus in 1997. But the World Health Organization (WHO) estimated that the true figures of Filipinos with AIDS in 1998 was approximately 23,350 persons. The dramatic increase in AIDS cases is attributed by MSF to exposure and infection of the virus through prostitution (heterosexual activities), the prohibitive cost of medicines, malnutrition, economic depression, untreated STDs, and limited access to modern medical care. Contrary to the experience in the industrialized nations, mortality is almost 82% in the first year of infectivity and 98% in two years. WHO and MSF estimated the Philippines would have 30,112 cases by the end of 1999, and about 39,780 cases by the year 2000. That is a 70% increase in the incidence of AIDS in just two years in a population of 79 million people.

The Department of Health AIDS Registry showed that 53% of the victims are men, 38% are women and 9% are children. Among persons diagnosed as being infected with AIDS, 55% are drug addicts, 40% were infected by heterosexual activities (mainly with prostitutes), and 5% by homosexual activity. Approximately 1.8 million Filipinos, 50,000 in Cebu City alone, are involved in the illegal drug trade, a US\$6.6 billion business. According to Duchene (1997), the drugs and AIDS situation in the Philippines is, for unknown reasons, less serious than it is in India and Cambodia. As of 1999, 90% of the world's 33 million HIV/AIDS cases were found in Africa, Latin America, and Asia. Furthermore, the WHO figures estimated that there would be 38 to 40 million people living in the world with the HIV virus by the year 2000.

[Update 2003: One puzzle in the Philippines, where condoms are not widespread, is the nation's extremely low rate of HIV infection. According to government figures, just 1,810 cases have been reported. The United Nations estimate is higher, but still minuscule at 9,400 cases. Experts warn of an explosion to come. According to local studies, only 23% of sexually active young men reported using a condom, and only 4% said they use condoms regularly (Mydans 2003). (End of update by J. F. J. Leyson)]

While the gay community initially interpreted the alarm about AIDS as an attempt by the medical profession to regain control and use the discourse about health risks to moralize against "disorderly sexual conduct," the real purpose of this crusade was to reduce the risks and mortality for gays who are sexually active. Government and NGOs are more actively engaged in the education and prevention of HIV/AIDS.

It is now clear that any plan to decrease the social and economic impact of AIDS in the Philippines, as in any society, requires an emotional engagement that facilitates an important paradigmatic change of beliefs and behavior. This paradigmatic change is essential to practicing abstinence, to increasing the use of condoms, decreasing promiscuity, promoting the use of disposable needles among drug addicts, understanding and respecting those who suffer, and helping individuals everywhere to enjoy sexuality while minimizing the risks for one's self and society.

In addition to emotional engagement, changes in individual attitudes require the active and creative support of social groups to which the individual belongs; namely families, schools, private businesses, and churches. In 1995, a private civic organization hired Magic Johnson, a famous American basketball superstar, to give talks to Filipino youth about HIV prevention and living a responsible and healthy sex (safe) life.

[Update 2002: UNAIDS Epidemiological Assessment: The Philippines remains a low HIV-prevalence country. Since the first cases of HIV/AIDS were reported in 1984, 1,515 HIV infections, including 508 AIDS cases and 196 HIV/AIDS-related deaths, had been reported as of June 2001. An estimated 9,400 people were believed to be living with HIV at the end of 2001 (prevalence less than 0.1% in people aged 15 to 49 years). The estimated rate of reporting of HIV infection is low (5%). HIV in the Philippines is predominantly sexually transmitted (90%). The number of HIV/AIDS cases is not expected to increase substantially over the next few years.

[There is a high prevalence of STD among sex workers, with the prevalence rate of selected STDs—predominantly chlamydial infections—reaching more than 40%. The prevalence rate of STDs among women attending antenatal clinics was less than 1% for STDs other than chlamydia (5.6%). Gonococcal resistance to penicillin, tetracycline, and cipro-

floxacin is high. Most of gonorrhea isolates (89.3%) were resistant to penicillin and 38% were resistant to quinolones in 2000.

[Behavioral surveillance data in 1997 and 1998 indicated high prevalence of HIV/STD risk behavior. Sharing of needles was reported by 52% of injection drug users in 2000, and unprotected sex (non-condom use during the last sex with a non-regular sex partner) was reported by 75% of men who had sex with men and 34% of female sex workers.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	9,400 (rate: 0.1%)
Women ages 15-49:	2,500
Children ages 0-15:	< 10

[An estimated 720 adults and children died of AIDS during 2001.

[At the end of 2001, an estimated 4,100 Filipino children under age 15 were living without one or both parents who had died of AIDS. (End of update by the Editors)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

### A. Concepts of Sexual Dysfunction and Treatment

The Philippines is a conservative society in which definitions of sexual dysfunctions often mirror the changing attitudes towards male and female sexuality. Thus, in the 1970s, inhibited or absent female orgasm (anorgasmia) was not considered a problem in a context where female sexuality was linked almost exclusively with procreation. Premature ejaculation became more of a problem in the 1980s with the emergence of the myth of simultaneous orgasms, promoted by the Western media, and the idea of heterosexual sex as spontaneously pleasant, which taken together created a new set of pressures, expectations, and tensions. Finally, the growing public rejection of the conservative attitude of the Church linking emotionally stable sexuality with orgasm might reduce the tendency to treat alternative expressions of eroticism as sexual dysfunctions.

Prior to the mid-1950s, Filipino physicians had no better knowledge or understanding of human sexuality than the sophisticated Filipino citizen. Both could, but seldom did, read Kinsey's works and Masters and Johnson's book *Human Sexuality*. Even after some sexuality education was introduced into medical training, the information they received was prejudiced and biased. The departments of obstetrics and gynecology in the public health and urology section taught the pathologic aspects of genitourinary (sexual) organs and reproductive mechanisms, but refused to consider with the same vigor or objective the sexual behavior of healthy males and females. In my interviews with medical students and young doctors during my periodic visits to the Philippines in 1984, this author perceived that two years later, the physicians still did not feel comfortable discussing healthy sexuality issues. Some of these doctors even felt personally offended, especially in being asked to deal with the "sexually oppressed" minority social groups, such as the aging, homosexuals, and the mentally and physically disabled (handicapped).

Gynecologists, psychiatrists, urologists, and general practitioners often have limited knowledge when people come for advice on sexual problems, such as frigidity, impotence, ejaculatory dysfunction, painful sex, sex during pregnancy and after delivery, consequences on sex life from drug/alcohol abuse, sex among the aged and physically handicapped, and sexual surgical procedures. Although their scientific information about sexuality is lim-

ited and incomplete, they perceive that science and common sense conflict with their ideologies and cultural-religious beliefs. The internal battles between these two opposing patterns of thinking and behavior only add confusion and distress to ignorance.

In 1990, this author initiated the creation of sexuality programs in major Filipino universities and medical schools. *Sexual Rehabilitation of the Spinal Cord Injury Patients* (Leyson 1991), by this author, was introduced, along with other resources, and quickly became popular among medical and paramedical personnel along with judges, lawyers, and teachers who are increasingly more aware of their need for advanced education on sexual topics/issues.

## B. Sexual Counseling and Therapies

Prior to the 1960s, the management of sexual dysfunctions was based mostly on folklore and "witchcraft." In the 1970s, management was a mixture of traditional folklore and medical science. In the rural areas, marital dysfunctions (sexual and reproductive) were treated with exotic concoctions and herbal remedies. In the urban areas, impotence was mainly treated with psychotherapy, occasional antidepressants, and hormones. Premature ejaculation was managed by psychotherapy. In 1998, the most common male sexual problem was impotence, followed by premature ejaculation, decreased libido, and infertility. Premature ejaculation was managed by antidepressants and psychotherapy, with perhaps some behavioral sex therapy. Impotence was treated with nonspecific vasodilators, sex therapy, and, for those who could afford it, penile prostheses. Libido disorder and infertility were treated with psychotherapy and pharmacological remedies. Among women, the most common sexual problems were painful intercourse (dyspareunia), vaginal spasms, and inhibited orgasm (dysorgasmia). Occasionally, older women complained of a decrease of sexual desire. Dyspareunia was treated with psychotherapy and sex therapy. The other sexual dysfunctions were grouped into one disease and managed with sex therapy and pharmacological remedies.

From 1995 to the present, sexual dysfunction management is almost the same as in the United States and Europe for those able to afford it. Most urologists and gynecologists have taken additional training in sex education and therapy. A few American- and European-trained sexologists have opened offices in major cities. With the infusion of new ideas and discoveries in sexology, management of sexual dysfunctions consists of behavioral therapy, sensory amplifications, advanced psychotherapy, and sex therapy. Modern impotence treatment includes erection vacuum devices, oral and intraurethral medications, intrapenile injection medicines, and solid and inflatable penile prostheses, as well as sexual performance medications like Viagra. However, some herbal remedies for impotence, infertility, and libido disorders have also been revived. The Church and NGOs with social services offer premarital and marital counseling, although the official Catholic position still maintains the traditional female role of motherhood, and perpetuates a generally more passive attitude towards sexuality and pleasuring even in marriage.

## C. Sexual Counseling for Emigrant Filipinos

Sexual counseling and therapy for Filipinos who immigrate to other countries presents some unique problems. The "Filipino Blend," which represents the majority of Filipinos, is the result of racial diversity and genetic pooling involving over 1,300 years of infusions from China, Indonesia, Malaysia, Indochina, India, Borneo, Java, Spain, and

the United States. The profound psychological and cultural result is a Filipino self-concept of being powerless and inferior. This perceived sense of dependency on the benevolence of envied Western masters detracted from the development of a strong national identity and solidarity, perpetuating a subservient mendicant role and passive resistance. A different generation of Filipinos immigrating to the United States and Canada are subjected to a variety of traditional and Westernized cultural and ethnical (values-communication styles) conflicts. This clash of values and behaviors may result in a cultural psychodynamic conflict, a kind of cultural baggage, which may include any or all of the following:

1. The primacy of family and small-group affiliation over the individual, a strongly held value that inhibits free expression of dissent and tends to detract from the creativity and autonomy that are highly prized by Americans.
2. A strict adherence to gender-role stereotypes and patriarchal family structure that goes against the egalitarian norms in the American family.
3. A primacy given to smooth interpersonal relationships that conflicts with the American ideal of openness and frankness.
4. An attitude of "optimistic fatalism" or *bahala na*, that is opposed to American beliefs in future orientation, careful planning, and the drive for excellence and economic development through determined effort.
5. A sensitivity to slight and criticism, which springs from an exaggerated need for self-importance, *amor propio*, and often leads to withdrawal and/or vengeance, in direct opposite to the American style of directness and sportsmanship.
6. A fear of *hiya* (devastating shame) that often inhibits competitiveness. This concern over face-saving is fostered by the use of ridicule and ostracism in child training.
7. The practice of *delicadeza*, or nonconfrontational communication, most evident among females, that is ineffectual in Western societies, where directness is appreciated and competitiveness is encouraged.
8. *Utang nang loob*, or reciprocity of favors, that derives from a sense of gratitude and belongingness, is incongruous in societies that give primacy to individualism and the "bottom line."
9. A strict adherence to Catholic belief on virginity, abortion, contraception, and homosexuality, which can nourish a self-righteous judgmental stance that is out of place in a pluralistic society with emerging alternative lifestyles.

The stress of immigration and acculturation have extracted a heavy toll on Filipinos, which can result in psychological and/or sexual dysfunctions and symptoms of depression, schizophrenia, and paranoia. These adjustment disorders may show up in family and marital conflicts, extramarital affairs, embarrassment from inadequacies in work situations, estrangement from the Filipino family, and even divorce. Unemployment and underemployment weigh heavily on the Filipino male's sense of his own masculinity, and he frequently takes his frustration out on his spouse and children. Filipino women may internalize their frustration against male dominance by developing symptoms of depression and/or arousal or orgasmic dysfunctions.

Santa Rita (1996) emphasized the need of professionals providing sexual and relationship therapy for native and emigré Filipinos to understand the psychodynamics and cultural and ethnic background of the Filipino personality

and their families. The therapist should try to discard the “cultural baggage” of the Filipino colonial mentality by utilizing alternative Filipino cultural norms and practices in the therapeutic role. Such role playing can be used to suggest alternative, more functional ways of interacting as individuals within a family and as a family in a changing Filipino culture or in a different culture. These stage scenarios might include:

1. A scenario for role playing *Lakas ng loob* (assertiveness) may be used to contrast *mahinhin* (self-effacing) and long-suffering, passive behaviors of Filipinos with assertive behavior. Assertiveness is an alternative to playing the martyr, which exacts such a high psychological price in the form of depression and other medical symptoms.
2. *Tinikling* (a bird in a bamboo trap) is the traditional Filipino dance simulating how a bird skips and jumps its way through clashing bamboo poles. This dance can be used to remind the family that, like the bird, Filipinos can be resilient and resourceful, and thereby escape whatever traps the colonial masters might concoct. This resourceful dancing-bird image suggests an alternative to maintaining *amor propio* (need for self-importance) and *hiya* (shame) at all cost. These traits are so often exaggerated in both Filipino men and women, that failures and disappointments often lead to depression and adjustment disorders, including arousal and erectile dysfunctions.
3. “God helps those who help themselves” is a study theme that can utilize the religious theme of “actively working with God” through one’s labor and accomplishments to “glorify” Him. This biblical view suggests an alternative to *Bahala Na* (fatalism) that may result in lack of initiative and impedes economic and social mobility.
4. “In my father’s house, there are many mansions” is another basic religious theme common among Filipinos that can be used as an exercise in “hospitality”—welcoming one’s fellow human beings. This thesis of “Christian welcome” may help Filipinos become more accepting of other people’s beliefs and lifestyles, especially on very emotion-laden issues like contraception, abortion, premarital sex, homosexuality, and bisexuality.

The marital and psychogenic sexual dysfunctions of immigrant Filipinos stem from their sense of vulnerability over their perceived, often acutely subordinate status as a minority in a pluralistic society that reminds them of their colonial history. Culturally sensitive therapeutic approaches are important in order to neutralize the Filipino family’s low image of self and provide the family and the individual an opportunity to discover its inner strengths and resources including the gaining of self-respect (Santa Rita 1996).

## 12. Sex Research and Advanced Professional Education

### A. Advanced Education

In August 1887, while on a trip to America, Dr. J. P. Rizal, a foreign-trained eye surgeon and “the Liberator of the Philippines,” deplored the American prejudice against Asians and African-Americans and was especially appalled by the laws against interracial marriages in some states. At the time, over 100 years ago, the Spanish religious teachings were solely limited to family life, and sexual issues were totally suppressed. Despite the declaration of independence

from Spain by Filipino nationalists on January 12, 1898, sex education was not formally taught in colleges until the American colonial rule. In the late 1940s, sexuality was introduced to the Filipino educated elite in the form of family planning and topics on reproduction and birth through pamphlets and specialized magazines.

Since the 1980s, despite the proliferation of medical schools, human sexuality courses have been limited to sexuality-related professional degree programs in nursing, psychology, and medicine. In 1996, through the author’s encouragement, three medical schools in Manila, Cebu City, and Quezon City established some form of sexuality courses in the gynecology, urology, and public health sections. Today, there is only one so-called accredited postgraduate program in sexuality and humanities, offered by the Population Institute of the University of the Philippines in Quezon City. The Ministry of Health regularly trains nurses and midwives in family planning and contraception through the municipal health clinics. The Philippine Psychiatric Association and the Philippine Urological Association are updating their diagnostic codes for the diagnosis and management of sexual dysfunctions.

### B. Research

Most of the government research dollars and interest have been earmarked for the prevention and treatment of childhood diseases, population control, and combating the spread of HIV/AIDS. The limited research resources from private and civic organizations are directed to traditional medical illnesses, such as heart diseases, hypertension and stroke, and tuberculosis. Some international, foreign medical associations and the Association of Philippines Physicians in America (APPA), and medical alumni associations sponsor research projects that relate to social and practical sexual issues, including:

1. Sexually transmitted diseases and HIV/AIDS;
2. Birth control—the effectiveness of new contraceptives and their side effects;
3. Management of sexual dysfunctions—old treatment and new alternatives; and
4. Sexual attitudes and behavior: child prostitution, sexual violence (rape, incest, and spousal abuse), extramarital sex, homosexuality, and the sexuality of minority groups (blind people and the handicapped).

## Conclusion

The peoples of the Philippine archipelago, both indigenous and immigrant, Muslim, Christian, and other, reflect the cultural attitudes and behavior of their mixed Malaysian and Chinese ancestries. There are also wide variations because of the sociocultural and linguistic mix. However, the dominant Catholic Church, the legislative body, and the educational system are essentially an amalgam of the old Hispanic dogma and the modern Western flavor with the present public sexual morality reflecting the values of these enduring institutions.

## *Demographics and a Brief Historical Perspective*

ROBERT T. FRANCOEUR

### A. Demographics

Poland borders on the Baltic Sea, Lithuania, Byelorussia, Russia, Ukraine, the Czech Republic, Slovakia, Kaliningrad Oblast (Russia), and Germany. The national frontiers contain an area of 120,725 square miles (312,685 km<sup>2</sup>), making it slightly smaller than the state of New Mexico in the U.S. The terrain is mostly flat plain, with mountains along the southern border.

In July 2002, Poland had an estimated population of 38.63 million. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 17.9% with 1.05 male(s) per female (sex ratio); 15-64 years: 69.5% with 0.99 male(s) per female; 65 years and over: 12.6% with 0.62 male(s) per female; *Total population sex ratio:* 0.94 male(s) to 1 female

**Life Expectancy at Birth:** *Total Population:* 73.66 years; *male:* 69.52 years; *female:* 78.05 years

**Urban/Rural Distribution:** 62% to 38%

**Ethnic Distribution:** Polish: 97.6%; German: 1.3%; Ukrainian: 0.6%; Byelorussian: 0.5% (1990 estimates)

**Religious Distribution:** Roman Catholic 95%, about 75% practicing; Eastern Orthodox, Protestant, and other: 5%

**Birth Rate:** 10.29 births per 1,000 population

**Death Rate:** 9.97 per 1,000 population

**Infant Mortality Rate:** 9.17 deaths per 1,000 live births

**Net Migration Rate:** -0.49 migrant(s) per 1,000 population

**Total Fertility Rate:** 1.37 children born per woman

**Population Growth Rate:** -0.02%

**HIV/AIDS** (1999 est.): *Adult prevalence:* 0.07%; *Persons living with HIV/AIDS:* NA; *Deaths:* < 100. (For addi-

(CIA 2002)

tional details from [www.UNAIDS.org](http://www.UNAIDS.org), see end of Section 10B.)

**Literacy Rate** (*defined as those age 15 and over who can read and write*): 99%, with 97% attendance during eight years of compulsory education

**Per Capita Gross Domestic Product** (*purchasing power parity*): \$8,800 (2001 est.); *Inflation:* 5.3%; *Unemployment:* 16.7% (2001 est.); *Living below the poverty line:* 18.4% (2001 est.)

### B. A Brief Historical Perspective

Local Slavic tribes converted to Christianity in the 10th century and Poland became a great power from the 14th to the 17th centuries. The country was partitioned among Prussia, Russia, and Austria in 1772, 1783, and 1795. After World War I, in which it was overrun by the Austro-German armies, it declared its independence in 1918. Large territories in the east were annexed after a 1921 war with Russia. In 1939, at the start of World War II, the country was invaded and divided by Germany and Russia. Some 6 million Polish citizens were killed by the Nazis, half of them Jews—practically all the Jewish population of the country. After Germany's defeat, Poland declared its independence and was recognized by the United States, while the Soviet Union pressed its claims. Following a 1947 election dominated by the Communists, Poland ceded 70,000 square miles (181,300 km<sup>2</sup>) to the Soviet Union and received, in turn, 40,000 square miles (103,600 km<sup>2</sup>) of German territory east of the Oder-Neisse, Silesia, Pomerania, West Prussia, and part of East Prussia.

After 12 years of rule by Stalinist Communists, workers in Poznan rioted to protest rising prices, nationalization of industries, collectivization of the farms, secularization of the schools, and imprisonment of Church leaders. A new, more independent Polish Communist government, which came to power in 1956, reversed some of these conditions. In 1970, new riots broke out in several cities, protesting new incentive wage rules and price rises. In 1980, after two months of labor turmoil crippled the country, the government met the demands of striking workers at the Lenin Shipyard in Gdansk. Following a nationwide referendum that favored establishing a non-Communist government, the government declared martial law and arrested the lead-

\**Communications:* Polish Sexological Society, Sex Research Department, ul. Marymoncka 34, 01-813 Warsaw, Poland. (Correspondence: ul. Londynska 12m 31, 03-921 Warsaw, Poland.)

ers of the opposition. An accord was reached in 1989, and a non-Communist government elected in 1990. A radical economic program, designed to introduce a free-market system, led to protests from the unions, farmers, and miners over inflation and unemployment. In 1993, former Communists and other leftists returned to power.

## 1. Basic Sexological Premises

### A. The Character of Gender Roles

The pervasive presence of gender-role stereotypes, consensual expectations about the fashion in which males and females behave, is likely to have a strong and continuing impact on male/female behaviors and on feelings about that behavior in Polish society. Gender roles in Poland were evolving away from the traditional stereotypes after World War II because of the very common situation when women had to look for work outside their homes.

Women now comprise 45% of total number of employees and 52.6% of the unemployed. However, their part in the workforce creates a semblance of equality between the rights of men and women. The average pay for women is 30% lower than that of men. In Poland, one can observe a visible feminization of certain professions, mainly education and social welfare, because they are so poorly paid. Although the paychecks for men in these professions are the same as women's, men usually try to find better-paying jobs because of their traditional role as providers. During the Communist regime, women had a number of privileges that protected their professional situations. For example, they could retire five years earlier than men and could obtain a leave of absence to take care of a sick child. In the present transition to a market economy, these apparent privileges significantly reduce women's chances in the work market.

Women's efforts to find employment were clearly connected with economic pressures and did not reflect the real situation of women in Poland. The part played by women in the political and social life of the country is rather marginal. Women, for instance, comprise only 10% of the members of Parliament. Feminist organizations are small and not particularly popular, playing an unimportant role in society.

### B. Sociological Status of Males and Females

From the legal viewpoint, as children, adolescents, and adults, Polish men and women enjoy the same rights. Men and women have the same right to vote and equal rights for education and employment. Children and adolescents attend coed schools.

Current political changes in Poland have created a danger in favor of conservative understanding of social roles, especially for women. The recently propagated family model has a patriarchal character, with the woman professionally inactive and playing only the role of mother. Very restrictive antiabortion legislation has produced a particularly heated discussion of women's rights that is assuming the form of a political campaign. [*Comment 1997*: Election results in late 1995 shifted political power away from the Church-supported government and back to former Communist politicians, in part as a rejection of the Church's antiabortion and anticontraceptive stance. (*End of comment by R. T. Francoeur*)]

### C. General Concepts of Sexuality and Love

In Poland, one can find two models of sexuality and love: both restrictive Catholic and permissive European models. While the sexual attitudes of Poles vary depending on gender, age, region of residence, and religious attitude, these two models have existed separately for several decades and have collided occasionally. At present, with the

increasing influence of religion and the Church on political and social life, they are the subject of acute confrontations.

The rural population and city dwellers of rural origin characteristically have strong links with Catholic religious ceremonies and the deep influence of the Catholic Church. This group is also characterized by a low level of education. This group is very numerous, because of the extermination of highly educated Poles during World War II and intensive migration from rural areas to the towns after the war. This group is the main standard bearer for the traditional model of sexuality in which sex and love can be fulfilled only in marriage. In this model, all premarital and extramarital sexual contacts are condemned, only the rhythm or so-called natural methods of family planning are accepted, and the use of other contraceptive methods, such as the hormonal pill and condom, are prohibited.

Among Poles with a higher level of education, one finds sex education based on publications, an acceptance of varied forms of petting and premarital sexual contacts, extramarital sex, liberal attitudes towards different sexual orientations and behaviors, the use of varied forms of contraception, and greater criticism of traditional sexual standards.

In comparing attitudes towards sexuality and love among Poles of different educational levels from different regions of the country, one seems to be dealing with two different societies, the first being attached to traditional attitudes and the second expressing permissive values and attitudes that are more and more popular in the West.

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A. Religious and Political Factors

Since the end of World War II, the people of Poland have generally shared a single ethic, and one religion, Roman Catholicism. According to 1990 research data, 94% of Poles are Roman Catholics and 79% of adult Poles considered themselves religious or deeply religious.

The Catholic faith has been predominant among Poles since the recorded beginnings of the state in the 11th century. The period of the Reformation did not change this situation, despite the proximity of German Lutheranism. The multiethnic Jagiellonian Poland of the 15th and 16th centuries, and the Commonwealth of the Two Nations, as the union of Poland and Lithuania was called until the 17th century, were comprised of at least one-third ethnic minorities who, to a great degree, represented religions other than Roman Catholic. In the first half of the 20th century and during World War II when eastern territories were lost and western lands added, one third of the country's population comprised Jews, Ukrainians, Germans, Byelorussians, and others. These ethnic minorities professed mainly the Jewish, Greek Catholic, Protestant, and Eastern Orthodox religions.

Catholicism has become one of the main elements of the national self-determination and self-image of Poles, possibly as a result of the historical destiny of Poland in the last few centuries, and especially since the 19th-century partitions. Religious ceremonies thus became the occasion for expressing national and political views, which were often of greater social and psychological importance than the pure religious feelings. Also in the 1980s, the Solidarity period, subversion of the totalitarian Communist regime and appointment of a Pole as Supreme Pontiff of the Church in Rome strengthened the political authority of the Church in Poland.

It should be stressed here that Poland is currently undergoing significant changes associated with the democratic processes common in countries of the late Communist re-

gime. At this turning point in our history, the situation of sexology in Poland is determined by two opposing tendencies: the increasing influence of religion and the Church on Polish political and social life, and European tendencies, which are coupled with the reality-based social attitudes to sex and sexual behavior. These opposing influences mark the main line of controversy on moral and legal policy in Poland today. Although there is a visible divergence between sexual behaviors and the formal religious views of society, the restrictive attitude of the Catholic Church is more and more evident, affecting most legal and medical problems as well as sex education.

## B. Ethnic Factors

According to unofficial data, ethnic minorities comprise about 5% of the population. Most of them are Byelorussians and Ukrainians. As a result of the invader's policy during World War II, and the change of borders after the war causing the loss of one fourth of the country's eastern territory, most ethnic minorities have disappeared. The remaining minorities, at present, do not demonstrate any particularly characteristic sexual attitudes or behaviors.

### 3. Knowledge and Education about Sexuality

It needs to be emphasized that sexual education has always been a kind of taboo in Poland. This was clearly reflected in the language used by the state in the past, referring to sexual education as "preparation for the life in a socialistic family." After 1989, sexual education was halted in the schools without any national debate about the relationship between the state and the Church, and the only textbook specially prepared by sexologists for school use was definitely forbidden. This was subsequently followed by introduction of religious instruction in all Polish schools.

Research in 1992 with a nationally representative sample revealed that friends were reported as the principle source of sex information with half of the men and one third of the women surveyed. The second source, reported most frequently by young people in large cities, was publications. Parents hardly ever wanted to provide input into sexual education, preferring to have their children obtain this information in school or from publications. Still, less than 10% of the respondents approved of school as a source of sex information.

### 4. Autoerotic Behaviors and Patterns

#### A. Children and Adolescents

Retrospective research on the autoerotic behaviors of Polish children and adolescents has been carried out on a few select groups. M. Beisert (1990) found that about 15% of the girls and 29% of the boys remembered touching and manipulating their genitals in a repeated manner during childhood to evoke some pleasant feelings. In most children, an intensification of autoerotic behaviors is observed at ages 5 to 6, during nursery school education. The main purpose of autoerotic behaviors is to awake some positive emotions in oneself. Up to 80% of all children who engage in self-pleasuring consider the pleasure obtained as an autonomous value, while about 12% treat that pleasure as a side effect of fulfilling the need connected with what is termed a stimulation deficit, the deprivation of the need of receiving new and attractive stimuli from the surroundings.

Research demonstrates that there are two types of autoerotic behaviors: one open, observed in children who are unaware of the common negative valuation of that behav-

ior, and the other hidden and characteristic of children who are aware of the forbidden character of that behavior. An important source of information about the need to hide autoeroticism from parents is the child's peers. According to investigations, 80% of parents have never learned about the autoeroticism of children.

Polish literature dealing with sexual education presents two opposite views: an opinion that self-pleasuring is a normal stage of psychosexual development in human beings, and the contrary view that self-pleasuring is a sin reflecting in a negative way on human development. These opinions lead to two contrary educational recommendations. Adolescents appear to be aware of these contradictory views and their implications. Survey data indicate that 90% of adolescent boys and 45 to 75% of girls engage in self-pleasuring. At the same time, 20% of girls and 32% of boys reported fears accompanying their self-pleasuring. Half of those investigated were afraid of parents, siblings, or other people learning about their self-pleasuring practices. The correlation of self-pleasuring and religiousness was not statistically significant in adolescents.

#### B. Adults

In a 1991 nationally representative survey, 28% of the women and 64% of the men reported engaging in autoerotic behaviors. In other research with university students, 99.1% of the men and 42% of the women reported autoerotic behavior.

### 5. Interpersonal Heterosexual Behaviors

#### A. Children

M. Beisert's 1990 investigation reveals an undulatory character in the child's interest in sex. The first inflow is observed before the end of 5 years of age with the next during the prepubertal period, about the age of 10 and 11.

Contacts with other children in nursery school are conducive to some exploratory activities. Up to 56% of investigated adults place their first discoveries connected with gender at that period. The most important source of knowledge are other children, particularly peers. The first discoveries are connected with playing together, bathing, and other hygienic activities. However, the awareness of a strict injunction not to stare at the naked bodies of others, and particularly their genitals, is passed down at a comparatively early age and is widely popularized. The division between erotic play and cognitive activities is a difficult one, especially since sexual curiosity is at the bottom of much of children's play. However, when children want to study their own bodies, they often do it openly and clearly state their interest. In approximately 2.8% of childhood sexual exploration, coercion is a factor.

The cognitive methods are a bit different in families with many children of both genders. When the children in a family are close in age, or when the age interval is larger but older children participate in taking care of the younger, sex differences are not particularly exciting nor do they offer any special discoveries. The situation is similar when a child has no siblings but is brought up in a family with liberal attitudes towards sex.

Many different children's games include an erotic element or produce specific pleasure connected with stimulation of the genitals. Nearly 70% of students surveyed remembered not only the fact of such games, but also all the details accompanying them. Gender was not a factor in such games. Considering all the functions fulfilled by erotic games, such as pleasure, learning, and stimulation, they were grouped separately from other forms of childhood activities. The essence of most games is to imitate a

fragment of adult life. The most popular games imitate adult roles that create an opportunity of mutual touching, undressing, and body manipulation, playing doctor, hospital, nurse, mother and father, king and queen, convalescent home, masseur, or the theater, ballet, and striptease. Among other inspirations for childhood games, direct observation of adult life takes place first, then movies, fairytales, and stories told by others. Imitations of such adult activities that provide excuses for body contact are the most important children's games.

A particular, qualitatively different variety of games is among those designed for only two children. In such games, watching and touching meet the needs of demonstrating a mutual bond. Children embrace each other, kiss, and touch. Such pairs are accepted by their peers, and their range of behavior does not differ from the behavioral patterns of groups. Solitary play also provides an outlet for sexual curiosity and rehearsal, as when a child enacts erotic scenes using dolls, draws pictures of naked girls and boys, or plays scenes that evoke pleasurable excitement.

The second period of interest occurs during the prepubertal age. Up to 35% of children report gaining knowledge about gender differences at the age of 10 or 11 years. The interest is focused on details and confirmation of earlier knowledge and intuition. Watching and touching is limited mainly to the genitals, and the aim is to gain pleasure along with a clear understanding of gender differences. These games occur in pairs, and sometimes in groups of peers of the same and other gender. Boys, for instance, may compare penis length or compete in urination contests. Girls concentrate on bust observations or dressing as adult women. Often pair games are clearly directed at pleasure, and consist of genital exploration and touching without the pretext of playing doctor or hospital.

According to survey data, most Polish children are well aware of the forbidden nature of these erotic games. The punishing attitude of parents towards erotic games reaffirms the fear of childhood eroticism and the unfavorable attitude towards self-pleasuring. Parental dissuasion and limiting the child's time with peers are more-mild forms of unfavorable reaction. However, two thirds of parents who catch their children in such games threaten them, punishing them verbally and/or physically for engaging in them. About 1% of parents do not adopt a punishing attitude, but quietly maintain their differing opinion of such games. Only 10% of parents treat these games as a normal stage in childhood development.

## B. Adolescents

### *Puberty*

The period of puberty involves three phases dominated by changes connected with biological, mental, and finally social maturity. In girls, signs of physical maturation generally appear at the age of 10 or 11. About a year earlier, mothers usually take some steps to prepare their daughters for their physical maturation and menarche. Research shows that nearly all unprepared girls react in a negative way to their maturation. Girls in this group usually start menstruating at an early age, around 10 years, and are easily distinguished from their peers by their physical maturity. Not knowing the purpose and course of the pubescence process, they exaggerate the significance of the physical changes, interpreting them as pathological symptoms.

The reactions of boys to the signs of maturation follow a different pattern. Only a small percentage of boys react negatively to the changes. Their negative reaction is usually conditioned by a lack of proper preparation. The male response to puberty shows greater uniformity, with a greater

acceptance of manhood often compensating for some neglect in their sex education.

Research shows that the first menstruation in girls and the first nocturnal emission or conscious ejaculation in boys cause a strong emotional reaction. In these specific experiences, the reaction is unfortunately negative, irrespective of gender. Most often, the girls inform their mothers about their first menstruation. However, about 20% try to hide the fact. On the other hand, few boys inform their parents, preferring to boast about it among their peers.

The appearance of a new sexual behavior, namely petting, also marks the pubertal period. Up to 50% of Polish girls admit that an emotional bond with a boyfriend prompted them to start petting. Only an emotional involvement would make them agree to physical contact, although that agreement does not indicate a real need for relieving their sexual tension or taking the initiative to do so. Only a small percentage of girls admit their strong sexual tension and the need to relieve it. Among the reasons reported by girls, curiosity played only a small part in their decision. Much more important was the pressure exerted by the partner, although they did not consider the decision to start petting as being imposed on them. In their opinion, it was the natural consequence of their feelings towards their partners and not the consequence of sexual pressure. Boys more often explained the decision to start petting by their sexual tension. The need to relieve this tension resulted in less sensitivity in choosing their partner. Even a girl they scarcely knew would be acceptable. Polish boys try to start petting at the age of 16 and girls a year later.

Petting sets the stage for first sexual intercourse. According to data from a nationwide representative sample, 12.5% of the men and 6.6% of the women have sexual intercourse before age 16. By age 19, 54% of the men and 43% of the women have had coitus. Every fifth man and every third woman has first sexual intercourse after age 20. For 73% of the women, emotional involvement is the prime reason for initiation. Men most frequently cite emotion and love (41%), curiosity (35%), and the need to become an adult (16%). Only 40% of the women and 46% of the men rate their first sexual intercourse as a positive experience.

## C. Adults

The first statistical investigations of sexual behavior were carried out in Poland at the end of the 19th century when Z. Kowalski examined the attitudes of Warsaw University students. More-recent sexological studies were carried out in the 1960s and 1980s with selected groups of students, soldiers, and workers. In 1963, H. Malewska studied the sex life and its determinants in Polish women. The first research of sexual behavior using a nationally representative sample of 1,188 adults was carried out in 1991.

### *Premarital Relationships*

According to 1991 data, 72% of unmarried adults admit to premarital relations. Among married people, premarital relations were acknowledged by 80% of the men but only 50% of the women. This reflects the attitude of women towards virginity. Contrary to men, women paradoxically more often reveal their belief in the need to preserve virginity until marriage.

### *Single Adults*

Data on sexual behavior of single adults in Poland are limited, mainly because of the strong pressure on sex for reproduction within marriage. In 1988, 85% of Polish women aged 37 to 49 were married, 6% were singles who had never married, about 6% were divorced, and 3% were widows.

### *Marriage and Family*

In the 1970 research of Trawinska on values in marriage, adolescent and adult respondents gave priority to fulfillment of emotional needs, love, sex, the chance for self-realization, and achievement of economic success. People who had been married for several years placed the relative lack of conflicts and stability of the union on a par with emotional ties, respect, love, and sex.

The courtship period is short, and up to 60% of marriages are contracted between ages 20 and 24. Despite early marriage, the time of reaching social and economic independence with a separate apartment is delayed. Since the prewar period of the 1930s, the stage of marital childlessness has become shorter. One fourth of all women are pregnant when they marry. As in most European countries, the model of a small family is becoming a standard. A family with two children is usual, less often three children. In a family of two children, procreation is over in three years; with three children, it usually ends in five or six years.

### *Monogamy*

In Poland, marriage is monogamic in character. In the 1991 survey, nearly half of the women and one fourth of the men had had only one sex partner. Monogamic behavior is more common among people from small towns with a primary or secondary school education and a strong religious affiliation. Eighty-five percent of wives and 56% of husbands reported no extramarital sexual experiences. Sporadic extramarital sex was acknowledged by 10% of men and women. Less than 1% of respondents had more than ten sexual partners during their marriage. Extramarital sexual relations are more frequent in respondents over age 40, living in large cities, with a higher education, and better economic status.

Data on attitudes to sex show that for over 85% of respondents, sex is an expression of love and bonding. Sex without any emotional ties is accepted by 14% of women and 35% of men. The frequency of marital intercourse for most respondents ranged from a few times a week to a few times a month.

### *Divorce*

In 1991, Polish courts granted 34,000 divorces. A peak of 53,000 was reached in 1984. The most frequent reported causes for divorce are infidelity (30%), excessive drinking, and incompatibility of character. Usually it takes four to six months to obtain a divorce. Most often, couples seek a divorce after five to ten years of marriage. Usually the divorcing couple has no children or only one child. In three out of four cases, the mother retains custody. About 1% of children in divorces are placed in children's homes or with foster families.

### *Incidence of Oral and Anal Sex*

According to 1991 data, oral-genital sex, usually cunnilingus, is practiced by 30% of Polish men and women. Anal sex is acknowledged by 2.4% of respondents. There are no legal restrictions on fellatio, cunnilingus, or anal sex in Polish law.

## *6. Homoerotic, Homosexual, and Bisexual Behaviors*

The Polish legal code of 1932, as well as the current code of 1969, are among the most progressive in respect to sexuality. Homosexuality was always legal in Poland. The current criminal legislation does not mention homosexuality or homosexual relations at all. As with heterosexual contacts, only the homosexual intercourse of an adult with a

partner under 15 years of age, or forcing a person to have intercourse against his or her will are against the law and liable to penalty.

There is a divergence between liberal legislation and the degree to which homosexual persons openly take part in the social life. The first homosexual movement and organizations started in 1985. At that time, representatives from Warsaw and Wrocław joined the International Lesbian and Gay Association. Programs and discussions with homosexuals appeared on television and the radio. The press published articles about the problems encountered by homosexual persons. The following years marked the appearance of official organizations and clubs for homosexuals in big cities in Poland. Also a homosexual section was organized to fight the spread of AIDS. Until this time, the public had little knowledge of homosexual issues.

In surveys, 4.4% of the women and 6% of the men acknowledged being homosexually active. So far, there has been no research in Poland investigating the character of homosexual relations, behaviors, and sexual patterns. A few publications on this subject have been based on West European and American research. Thus, the main source of information about homosexual issues and lifestyles is the gay press, which provides several local and national publications.

The Catholic Church in Poland maintains a restrictive attitude towards homosexuality. It is described as a "moral disorder," and homosexual activities are condemned as contradictory to the procreative purpose of sex. In the Church's opinion, sexual relations are morally right only in marriage. The Church also maintains that there are many ways to restrain a person from fulfilling his or her unnatural sexual desire.

## *7. Gender Diversity and Transgender Issues*

An estimated 1,000 Poles are transgenderists or transsexuals. The research of J. Godlewski indicates there is one male-to-female transsexual for every seven female-to-male transsexuals. Five hundred persons have had hormone treatment and 400 surgery. The development of therapy for transsexuals started in the 1980s. In Poland, there are about 100 unions or cohabiting couples in which one partner is a transsexual and five where both partners are transsexuals. Two marriages were contracted legally.

Polish legislation, in principle, allows the change of gender, but no law regulates the surgical treatment of a transsexual. According to the Polish Criminal Code, it is comparatively easy to have one's sex/gender and name corrected in a birth certificate. A correction in the birth certificate is a necessary condition for further surgical treatment.

There are no legal restrictions on transvestites. However, transvestism is a marginal phenomenon in Poland.

## *8. Significant Unconventional Sexual Behaviors*

### **A. Coercive Sex**

#### *Sexual Abuse, Incest, and Pedophilia*

Child sexual abuse has only recently forced its way into the social consciousness and scientific research. Investigations in 1991 revealed that 5% of the girls and 2.5% of the boys under the age of 15 years had had sexual contacts with family members, and 7.5% of underage girls and 17% of boys with virtual strangers.

In Poland, sexual contacts (coitus and coital equivalents) between children and their siblings (including adopted sibs), parents, and grandparents are subject to

legal punishment. The penalty for incest ranges from six months to five years imprisonment.

Polish criminal law forbids sexual contacts with minors under 15 years old. The term "sexual contacts" includes coitus and coital equivalents, fellatio, cunnilingus, anal sex, and digital-vaginal/anal penetration. The penalty for such contact can be up to ten years imprisonment. However, sentences of six to 24 months are not uncommon.

In cases of sexual abuse of a minor, it is impossible to ascertain the incidence of pedophilia because this sexological category is not included in the diagnosis. In these cases, some perpetrators exhibited a pedophilic character. In other instances, the victim would not be considered a child, being a postpubertal adolescent.

#### [*Clergy Sexual Abuse*

[*Update 2002*: In early 2000, the Vatican received several complaints that Archbishop Juliusz Paetz, of Poznan, Poland, had been sexually molesting seminarians in the Poznan seminary. The Archbishop was a longtime friend of Pope John Paul II and had spent more than a decade in the Vatican, including four years working in the Papal household. In November 2001, after the initial complaints from seminarians to newspaper editors brought no action and the Vatican ignored written complaints, Wanda Poltawska, an 81-year-old Polish psychiatrist and longtime friend of Pope John Paul II, brought the matter to the Pope's attention. However, the Vatican did not act until local priests issued a call for the archbishop's resignation, and the seminary rector forbade the archbishop to visit the seminary unless he was accompanied by one of the seminary priests. When a subsequent Vatican investigation found the claims were credible, the Pope accepted the archbishop's resignation on March 31, 2002 (Allen 2002; Tagliabue 2002abc). (*End of update by R. T. Francoeur*)

#### [*Domestic Violence*

[*Update 2002*: In 2000 and 2001, the Open Society Institute (OSI, Budapest) sponsored a series of media campaigns to combat violence against women. Although a third of women in Poland acknowledged that they had been victims of domestic violence, OSI claimed that Polish authorities had failed to recognize it as a grave social problem. On the contrary, after a new government entered into power in the fall of 1997, the situation deteriorated. Violence against women was neglected and presented, even in the international arena, as an issue of marginal importance. The result was a failure to implement comprehensive legal and policy changes aimed at preventing and combating violence against women more effectively.

[Despite some positive changes, the criminal justice system remains, in general, unresponsive to women's needs. The police continue to treat domestic violence as a family matter and either refuse to intervene or provide only ineffective intervention. Although domestic violence was sometimes publicly prosecuted, the police frequently collected evidence improperly and left the burden on the woman's effort. Victims filing complaints usually have to wait several years before their case is tried in court. In the meantime, the perpetrator usually continues to live under the same roof with the victim, even if they are divorced, which leaves the women vulnerable to further violence and other forms of pressure from the perpetrator. Convicted perpetrators usually receive the lowest possible sentence, which in 90% of the cases is then suspended. Legal actions taken against perpetrators of domestic violence often perpetuate further violence, and the rate of recidivism in these cases is very high.

[There is no doubt that the existing legal and institutional framework does not provide adequate protection to women and children victims of domestic violence. On the other hand, however, OSI argues that the existing laws need to be applied and enforced. Existing gender-based stereotypes and prejudices against women have a negative impact on the performance of the criminal justice system in domestic violence and rape cases. Too often, men's violence against women is justified, while women are perceived as provocateurs and, in fact, responsible for the violence they experience.

[While OSI and other civil rights groups work to increase awareness of domestic violence and its prosecution, social awareness that domestic violence constitutes a major threat to women's health, and even lives, remains very low in Poland (Open Society Institute 2001). (*End of update by R. T. Francoeur*)

#### [*Paraphilias*

There are no statistics on cases or the incidence of paraphilias in Poland.

#### [*Sexual Harassment*

As of 1995, Polish legislation did not distinguish this category of behavior. [*Update 2002*: By late 1996, however, the situation had changed somewhat as central European countries and corporations began to be influenced by publicity in the news media and by the policies of Western European and American companies conducting business in Eastern Europe. In 1996, Poland's main government television channel ran a prime-time docudrama about sexual harassment, followed by a discussion with a studio audience and telephone calls from viewers. Despite the message to women workers that if they took their case to court, they could win, Poland has weak labor and civil-rights laws that have been largely untested in court because so few sexual harassment cases have been filed. Only 5% of those responding to a 1996 Polish newspaper poll said they had encountered cases of sexual harassment at work. Adding to the reluctance of Polish women to report cases of sexual harassment is a heritage of 40 years of Communist rule in which they accepted and endured sexual harassment as the norm. Today's harsh economic circumstances also encourage women not to complain. "We have a long way to go in raising the consciousness of women and men and making them realize what is not appropriate," Ursuzula Nowakowska, director of Warsaw's Women's Rights Center, a pro-bono group of lawyers, has reported. In the summer of 1996, Ms. Nowakowska appealed to the visiting lawyer-wife of U.S. President Clinton, Hilary Rodham Clinton, to help by urging large Western corporations to drop what she called their "double standard." She was referring to the tokenism of many Western and American corporations which issue policies against sexual harassment for all their offices worldwide, but then seldom let the employees in Western European branches hear of these policies and fail to enforce their policies when charges are brought (Perlez 1996). (*End of update by R. T. Francoeur*)

#### [*Rape*

In Polish law, rape refers to coitus or coital equivalents (fellatio, cunnilingus, anal sex, and digital-vaginal/anal penetration) using force, violence, threat, or taking advantage of someone's vulnerable situation. The penalty for rape is between one and ten years imprisonment. A person under the age of 15 years cannot give legal consent to sexual intercourse. The concept of statutory rape does not exist. Within the legal category of rape, two types of rape are singled out: rape involving qualified cruelty involving brutal injuries to

the body or mind; and collective or gang rape. Application of the law prohibiting marital rape requires real evidence of the use of force or coercion.

The minimum penalty for convicted rapists is three years imprisonment. However, depending on the type of rape, the prison sentence can range from six months to over five years. According to the data collected by Polish sexological expert witnesses, the majority of convicted rapists were drunk when they committed the crime.

## B. Prostitution

In Poland, neither heterosexual nor homosexual prostitution is subject to criminal penalty. However, in 1952, Poland signed the United Nations Convention, undertaking an obligation to abolish prostitution. Inducing or soliciting another person to prostitution or profiting from another person's prostituting him- or herself are subject to legal penalties of one to ten years.

There has been a steady decline in the demand for prostitutes since 1987 because of the growing concern about AIDS. Statistics on the total number of prostitutes in Poland are not available. The police estimate that there are about 12,000 prostitutes working in Poland. There are no houses of prostitution, but there are call-girl agencies, massage parlors, and other avenues of contact.

## C. Pornography and Erotica

The development of democratic liberties in Poland since 1989 has been accompanied by a growing access to pornography and an increasing number of pornographic publications on the market, even though the law prohibiting production and distribution of pornography is still in force. Despite legislation, both hard- and softcore pornography are easily accessible in Poland today.

In recent discussions, there has been some pressure to extend the meaning of pornography to include erotica and introduce more-rigid restrictions. The controversy is complicated by the lack of a clear definition of pornography. Some forensic experts, referring to the criterion of social harm, want to limit the meaning of pornography only to materials dealing with sexual relations with animals and children, and cruel or violent material. The dispute over pornography is part of the more general discussion about sexual liberalism or rigorism.

## 9. Contraception, Abortion, and Population Planning

### A. Contraception

The lack of sexual education in recent decades has affected negatively contraceptive behavior. Data from a 1988 POLL survey with a nationally representative sample, from the Polish Family Planning Association and other sources, revealed that the number of women who used oral contraceptives and intrauterine devices (IUDs) was not higher than 10%. About a third of those polled reported using coitus interruptus as their contraceptive method. Another third used a method based on the menstrual cycle, sometimes only the calendar method. A lack of information about contraceptive methods and prejudice against contraception has created favorable circumstances for acceptance of the so-called natural methods promoted by the Church. In a 1988 study by W. Wróblewska of a nationally representative sample of 1,266 teenage mothers, about 90% had no knowledge whatsoever about contraceptive methods.

### B. Teenage Unmarried Pregnancies

In the 1988 study of 1,266 teenage mothers published by the Family Planning Association in 1992, W. Wróblewska

reported that the youngest mother was 13 years old and nearly 50% were age 19. At the time of childbirth, one fourth of the teenage mothers were unmarried. Polish law makes it difficult for girls to contract marriage at the age of 16 or 17. Girls who wish to marry at that age must obtain a special license. Girls who are not yet 16 cannot marry.

Prior to getting pregnant, a large group of these mothers, 41.2%, were professionally active. One third, 37.6%, were attending school. The research did not confirm the hypothesis that these mothers had poor relations with their parents and were using pregnancy as an excuse to leave home. Only 9% of the teen mothers described the atmosphere in their homes and family relations as not too good or even conflictive. Over 80% of the teenage mothers came from two-parent families and 80% of the parents of teenage mothers had at least an elementary education. Generally, the girls were brought up in large families and had many siblings. The mothers of most respondents had started their own procreation earlier than other women of their generation.

Nearly 40% of the teenage mothers did not anticipate the possibility of becoming pregnant, or even realize such a possibility, when they became sexually active between the ages of 11 and 19. Only 15% of the respondents knew anything about contraceptive methods. Only 10% mentioned the contraceptive pill, IUD, condom, and calendar method. They were totally unfamiliar with other contraceptive methods. Only a third of these teenage mothers had even the minimum knowledge of how to protect themselves against pregnancy when they first engaged in sexual intercourse. Books, publications, and magazines were the basic sources of information for 61% of the mothers. Friends and acquaintances provided information for a third of the respondents. Slightly under a third, 28.2%, learned about contraception in school. Sexual partners were the source of information more often than parents. Only one in ten teenagers reported parents as a source of knowledge. More rarely cited was a doctor or nurse.

### C. Abortion

Under Communist rule, from the end of World War II to 1989-1990, abortion was legal and widely used by Polish women despite the opposition of the Catholic Church. A restrictive law, enacted in March 1993, was overturned in October 1996. The situation, however, remains volatile and unpredictable.

Between 1956 and March 1993, abortion was legal for medical indications, when the pregnancy resulted from a crime, mainly rape, and for social reasons, such as the difficult circumstances of the woman. This law allowed for abortion in the first 12 weeks of pregnancy.

According to official statistics, the incidence of abortion remained stable for 15 years prior to 1993, with about 133,000 abortions per year, or 19 abortions per 100 live births. This statistic does not include abortions done in private clinics. Some sources estimated that an additional one million abortions were performed each year in private clinics, with about 30,000 of these being for women under the age of 18 years.

In 1992, pressure from the Catholic Church supporting a repeal of the liberal abortion law was evident in a new Ethical Code adopted for physicians. This code allowed abortion only when the mother's health or life was in danger, or when the pregnancy resulted from rape or incest. In practice, this code eliminated all prenatal fetal examinations and abortion of malformed fetuses. In addition, contraceptive information was to be given by the physician only when required by the patient or in special cases. The new Ethical Code was a real paradox, because it was much stricter than the then-existing liberal law.

Also in 1992, the Parliament rejected by majority vote a liberal proposal prepared by the Women's Parliamentary Group and instead accepted the antiabortion proposal of the Catholic Nationalist Party (ZChN), which forbade abortion. The sole exception was that of a danger to the pregnant woman's life. The proposal for a national referendum was not accepted by the Parliament. Meanwhile, research revealed that 56% of Poles were definitely in favor of abortion rights for women, 24% approved of some such rights, and only 13% were definitely against abortion rights.

In March 1993, the increasing influence of the Roman Catholic Church on Polish social life was a major factor in parliamentary enactment of a new law that replaced the 1956 liberal abortion-rights law with the most restrictive abortion law of any Eastern European country. A year after enactment of the 1993 restrictive law on abortion, critics pointed out that the number of clandestine abortions had increased, with unscrupulous physicians offering to provide an abortion for any women able to pay the equivalent of US\$350 to \$1,000. The average monthly income was only about \$200, with half of the population earning below the poverty line, defined as \$80 a month. Some travel agents offered "abortion trips" to the Ukraine at 8 million zloty, or about \$400.

The 1993 law permitted abortion only when the pregnancy threatened the life or "seriously threatened" the health of the mother, when there was "serious and irreversible malformation of the fetus," or when the pregnancy resulted from "criminal action" (i.e., rape or incest). These provisions were further limited by many restrictions. For example, in the case of danger to the mother's health, supporting statements were required from two physicians independent of the acting doctor. And while prenatal tests were required to prove that the fetus was malformed, another section of the law appeared to allow for extensive prenatal tests, such as amniocentesis, only when there was reason to suspect a serious problem, as when a pregnancy occurred in a family with a history of genetic illnesses.

In March 1995, Poland's strict antiabortion law faced a painful test in court when a 37-year-old divorced woman, who was already supporting a 10-year-old child, persuaded a doctor in private practice to terminate her pregnancy. The physician was brought into court to face charges of violating the 1993 abortion law. If convicted, he could have spent two years in prison and had his medical license suspended for up to ten years. The woman's lover, who could only contribute about \$10 to the child's support but gave her the equivalent of \$125 for the abortion, faced up to two years in prison. Like other incidents of illegal abortion, this case became a legal issue when the child's father reported the woman's abortion because she refused to have his child (Perlez 1995).

In August 1996, the lower house of Parliament moved to liberalize Poland's restrictive abortion law, despite strong opposition from the Roman Catholic Church and its political allies. The bill, backed by the former Communists who dominated the Parliament after the November 1995 elections and a leftist opposition party, would allow women to end pregnancies before the 12th week if they could not afford to raise the child or had other personal problems. Early amendments, however, required counseling and a three-day waiting period for women seeking an abortion, and penalties of up to ten years in jail for aborting a woman against her will, or after the fetus can survive outside the womb. Opinion polls suggested that most people favored this liberalization, although 90% of those polled were nominally Catholic. (In 1993, President Lech Walesa, a devout Catholic, had vetoed a similar bill.)

In October 1996, despite a huge campaign against the bill including a silent march on Parliament by 30,000 Poles, the lower house overturned a veto of the new law by the Senate with a 228-to-195 vote and 16 abstentions; Aleksandr Kwasniewski, the president, had already promised to sign the new bill.

Under this legislation, women would again be able to end pregnancies before the 12th week if they face financial or personal problems. However, abortion is available only after counseling and a three-day waiting period. The law also provides for sex education in the schools and less-expensive birth control. Despite enactment of the new law, polls suggested that antiabortion sentiment has been rising, and that Poles, about 90% of whom are at least nominally Roman Catholic, are almost equally divided on the question. The future of abortion legislation in Poland, thus, remains uncertain.

[*Update 2002:* According to government figures, the number of legal abortions in Poland plunged from 11,700 in 1992 to 1,240 in 1993, when the restrictive law went into effect. In 1999, the latest year for which figures were available at press time, there were only 151 legal abortions in Poland. Women's rights groups have estimated that as many as 200,000 women have illegal abortions each year in Poland, often paying exorbitant fees and subjecting themselves to dangerous procedures. Efforts to revise the 1993 law and remove some of the restrictions failed in the legislature in 2001 (CRLP 2001). (*End of update by R. T. Francoeur*)]

## D. Population Control Efforts

The model of a small family is at present predominant in Poland. There are certain premises for the advisability of a pronatal population policy with a model of families with two, or to a lesser degree, three children. The opposite model of uncontrolled fertility is promoted by the Catholic Church and is related to the Church's campaign to limit contraception and sexual education and prohibit all abortions.

## 10. Sexually Transmitted Diseases and HIV/AIDS

### A. Sexually Transmitted Diseases

The epidemiological situation of STDs was investigated by H. Zielinski and A. Stapinski in 1992. In the first years after World War II, there was a significant increase in venereal diseases, especially syphilis, which was epidemic. At the time, there were an estimated 100,000 to 150,000 cases of syphilis a year in a population of 23 million. The therapeutic program, the so-called Action W, which included education, prevention, and outpatient clinics in every city, produced positive results and the epidemic was controlled. By 1954, early symptomatic syphilis had decreased to about 2,200 cases annually, about 8 cases per 1,000 people.

Between 1963 and 1969, there was another rapid increase in syphilis to 52 per 1,000 people, and the incidence of early syphilis (symptomatic and asymptomatic syphilis stages 1 and 2) to 66.6 cases per 1,000 people. The incidence of gonorrhea, which reached a low level of 80 per 1,000, also increased, although not so rapidly, to exceed 153 cases per 1,000 in 1970.

A new program of syphilis and gonorrhea control produced positive results. In the 1980s, the incidence of syphilis decreased steadily until 1989. In 1989, the number of new cases diagnosed was 4.6 per 1,000; in 1990, it was 4.8. In 1990, new cases rose to 4.9 per 1,000, a 5% increase. The 1991 incidence of early symptomatic syphilis remained stable from 1990, 2.8 per 1,000. However, the 1991 incidence of early asymptomatic syphilis was 9% higher than in 1990, while the incidence of late syphilis decreased by 16%. Simi-

larly, the 1991 incidence of diagnosed gonorrhea decreased by 34% from 1990, less than 10% of what it was in 1970. In 1991, nongonococcal infections of the urogenital tract was 14% less than it was in 1990.

Information about the incidence of condyloma and genital herpes are fragmentary and have been included in the statistics only since 1990.

## B. HIV/AIDS

Serological examination for HIV status for people at risk was inaugurated in Poland in 1985. Of the 2,426 cases of HIV infection detected by November 1992, 1,776 were drug addicts. The real number of carriers is at least three times larger. Between 1985 and November 1992, 118 cases of AIDS were diagnosed. In this group, 58% were homosexual or bisexual, 30% heterosexual drug addicts, 10% heterosexual, and 2% unknown. Over half the 118 had died as of November 1992.

In 1989, A. Stapinski et al. published the data of the Institute of Venereology in Warsaw on the prevention of HIV infection in drug addicts. Noting "that the infection spreads rapidly in this population," the authors predicted "a further rapid spreading of this infection in this risk group," and recommended providing addicts with free syringes, needles, and condoms. They also recommended systematic intensive training of personnel in drug treatment and rehabilitation centers, as well as extensive informational education of all adults.

Also in 1989, D. Weyman-Rzucidlo et al. reported on the prevalence of HIV infection in a group of 1,297 homosexuals. In Poland, as in Western Europe and the United States, "homosexual and bisexual males are the group of high risk for HIV infection."

Dermatovenereological outpatient clinics provide HIV testing for anyone who wants to be tested and medical care for those needing it. Provincial clinics are also engaged in training health-service workers and providing health education in their own districts.

A program for AIDS prevention and control prepared by A. Stapinski in 1988 includes multidimensional activities: staff training, diagnostic facilities, research units, and prevention of infection by sexual contact, blood, needles, and syringes. Much attention was given to protecting health-service workers against infection, and to health education for at-risk groups and the general population, especially adolescents. Voluntary testing for HIV antibodies is encouraged, and stress is placed on preventing discrimination against persons who are HIV-positive and have AIDS.

[Update 2002: UNAIDS Epidemiological Assessment: By the end of 2001, 7,303 HIV infections have been reported. Most of the infections are seen in Warsaw, Gdansk region, and Katowice (south). Injecting drug users are systematically screened in treatment centers, outpatient clinics, and residential homes. All other groups are tested on a voluntary basis. Diagnosed HIV-infected cases are registered in a national HIV database using the name for identification, excluding those testing anonymously. A switch to anonymous reporting is being planned. From 1995 to 1999, annual numbers of newly diagnosed HIV infections were relatively stable, ranging from 539 to 638. Among HIV cases reported in 1997 to 1999, 53% were injecting drug users, 6% homosexuals, 3% heterosexuals, and 37% not determined. Underreporting is estimated to be 25% and has been increasing in Gdansk region; estimates for the number of cumulative HIV infections at the end of 1996 have been put at 10,000 to 12,000.

[Prevalence data comes mostly from ongoing testing programs. Prevalence among injecting drug users is esti-

mated between 15% and 50% in Warsaw, and is probably lower elsewhere. Since known positive injecting drug users are not retested, data presented cannot be used as an estimate of prevalence, nor can they be used as incidence estimates, because seronegative persons can be tested several times and seropositive persons may have been infected for several years. The numbers of drug users have reportedly been increasing in recent years. However, there is a shift from injection drug use to oral and inhaling practices; nevertheless, since 1993, there is an increasing number of HIV infections among injecting drug users in some parts of the country.

[No data on pregnant women were provided. Nationwide, levels of reported STDs have been stable and relatively low in the recent years. However, in some western regions of Poland, there is an observed increase in STD levels. Prostitution has substantially increased at the borders of Poland and Czech and German borders; levels of STDs in those areas have increased as well. In a survey of homosexual men, very few reported having had an HIV test. In addition, there is still stigma associated with homosexuality, reflected in the low number of those voluntarily identifying themselves as homo-/bisexual; the number of infections in this subpopulation may, therefore, be underestimated.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	14,000 (rate: 0.1%)
Women ages 15-49:	NA
Children ages 0-15:	NA

[No estimate is available for the number of adults and children who died of AIDS during 2001.

[No estimate is available for the number of Polish children who had lost one or both parents to AIDS and were under age 15 at the end of 2001. (End of update by the Editors)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

The diagnostic criteria developed by Masters and Johnson are accepted by some Polish sexologists, while others follow the *DSM-III-R*. Clinicians specializing in sexology require personality evaluation before sexological diagnosis. Sexual dysfunctions are viewed in the psychodynamic categories and diagnosis connected with the evaluation of neurotic mechanisms and personality disturbances.

There are two departments of sexology associated with the medical schools in Warsaw and Krakow. Outpatient clinics in all the larger cities and towns provide diagnosis and treatment for sexological patients. These clinics employ some 70 medical doctors with clinical specialization in sexology, and also some psychologists.

## 12. Sex Research and Advanced Professional Education

### A. Institutes and Programs for Sexological Research

The following are organizations for sexological research in Poland:

The Polish Medical Association, Medical Center of Postgraduate Education, Department of Sexology and Pathology of Human Relations, Director: Kazimierz Imielinski, M.D., Ph.D. Address: ul. Fieldorfa 40, 004-158 Warsaw, Poland.

The Medical School of N. Copernicus, Department of Sexology, Director: Julian Godlewski, M.D., Ph.D. Address: ul. Sarego 16, 31-047 Kracow, Poland.

The Academy of Physical Education, Sexual Division of Rehabilitation Faculty, Director: Zbigniew Lew-

Starowicz, M.D., Ph.D. Address: ul. Marymoncka 34, 01-813 Warsaw, Poland.

Polish Sexological Society, Sex Research Department, Director: Anna Sierzpowska-Ketner, M.D., Ph.D. Address: ul. Marymoncka 34. 01-813 Warsaw, Poland. Correspondence: ul. Londynska [n'] 12/13, 03-921 Warsaw, Poland. Programs are offered on sex offenders, sexual dysfunctions, transsexuals, and the handicapped and sexuality.

Postcollege, graduate programs and courses are provided for psychologists and medical doctors by the Medical Center of Postgraduate Education, Department of Sexology and Pathology of Human Relations. A medical specialization in sexology has been available since 1985 for psychiatrists and gynecologists. Training is also provided by the Polish Sexological Society, with certification of Clinical Sexologists since 1991.

### B. Publications

The Polish Sexological Society publishes the quarterly *Sexology*. Correspondence: Londynska 12/13, 03-921 Warsaw, Poland.

## *Demographics and a Brief Historical Perspective*

ROBERT T. FRANCOEUR

### A. Demographics

Portugal occupies the western part of the Iberian Peninsula in southwestern Europe. With the Atlantic Ocean on its western border and Spain to the north and east, Portugal has a land area about the size of the state of Indiana, 35,670 square miles (92,390 km<sup>2</sup>). It is crossed by many small rivers, and by three large rivers that originate in Spain and flow through Portugal to the Atlantic, dividing the country into three geographic areas. Between the Minho River, which forms part of Portugal's northern border, and the Douro River is a mountainous region with the city of Porto in the southwest corner. Between the Douro and the Tejo Rivers, the mountains yield to plains. South of the capital, Lisbon (Lisboa), and the Tejo River are the rolling hills of the drier Alentejo region. Culturally, the northern region is more traditional and religious and the southern region is more secular and less restrictive in gender and sexual matters.

The nine islands of the Azores stretch over 340 miles (550 km) in the Atlantic, about 900 miles (1,450 km) east of Cape da Roca in mainland Portugal. The Azores is a strategic station on the cross-Atlantic air routes. Madeira, Porto Santo, and two groups of uninhabited islands lie in the Atlantic about 535 miles (860 km) southwest of Lisbon.

In July 2002, Portugal had an estimated population of a little over 10 million. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** *0-14 years:* 16.9% with 1.06 male(s) per female (sex ratio); *15-64 years:* 67.3% with 0.96 male(s) per female; *65 years and over:* 15.8% with 0.68 male(s) per female; *Total population sex ratio:* 0.93 male(s) to 1 female

\**Communications:* Nuno Nodin, M.A., Av. Fontes Pereira de Melo, 35, 11-B Edifício Imaviz, 1050-118 Lisbon, Portugal; nunonodin@mail.teleweb.pt.

(CIA 2002)

**Life Expectancy at Birth:** *Total Population:* 76.14 years; *male:* 72.65 years; *female:* 79.87 years

**Urban/Rural Distribution:** 36% to 64%

**Ethnic Distribution:** Homogeneous Mediterranean stock with less than 100,000 citizens of black African descent who immigrated to the mainland during the independence movements in the colonies after World War II

**Religious Distribution:** Roman Catholic: 94%; Protestant 6%

**Birth Rate:** 11.5 births per 1,000 population

**Death Rate:** 10.21 per 1,000 population

**Infant Mortality Rate:** 5.84 deaths per 1,000 live births

**Net Migration Rate:** 0.5 migrant(s) per 1,000 population

**Total Fertility Rate:** 1.48 children born per woman

**Population Growth Rate:** 0.18%

**HIV/AIDS** (1999 est.): *Adult prevalence:* 0.74%; *Persons living with HIV/AIDS:* 36,000; *Deaths:* 280. (For additional details from www.UNAIDS.org, see end of Section 10B.)

**Literacy Rate** (defined as those age 15 and over who can read and write): 87.4%; education is free and compulsory between ages 6 and 15

**Per Capita Gross Domestic Product** (purchasing power parity): \$17,300 (2001 est.); **Inflation**: 4.4%; **Unemployment**: 4.4%; **Living below the poverty line**: NA

## B. A Brief Historical Perspective

Portugal's roots reach back to the warlike Lusitanian tribes of Roman times. Having gained independence in the 12th century by the hand of King Afonso Henriques (1128-1185) from a rebellion against his own Castilian mother, Teresa, Portugal was created at the expense of the conquest of territory from the Moors of Morocco who occupied part of the Iberian Peninsula until the 16th century. The country gained its final form after the conquest of the Algarve (Portugal's southernmost region) in the 13th century, and its frontiers have been kept almost untouched up to today. Prince Henry the Navigator (1394-1460) brilliantly coordinated Portugal's expansion that led to a period of great prosperity for the country. In 1488, Bartholomew Diaz reached Africa's Cape of Good Hope. Vasco da Gama followed by reaching India in 1498. By the middle of the 16th century, Portugal had colonies in West and East Africa, Brazil, Persia, Indochina, and Malaya.

In 1581, Philip II of Spain invaded Portugal, precipitating 60 years of occupation and a catastrophic decline in Portuguese commerce. By 1640, when the Portuguese dynasty was restored, the Dutch, English, and French had taken the lead in colonizing the world, although Brazil remained under Portuguese rule until 1822 and the African colonies until the 1970s. After years of weak governments, a 1926 revolution brought a strong, but repressive government into power under the rule of Antonio Salazar. The colonial wars of the 1960s placed a terrible strain on Portugal's economy, adding to the country's standing as Western Europe's poorest country. A successful military revolution in 1974 brought a socialist government into power. Fifteen years later, a "democratic economy" was introduced and industries were denationalized. In 1985, Portugal joined the European Community and, between that date and 1992, the per-capita income tripled so that Portugal was no longer the poorest country in Europe.

### 1. Basic Sexological Premises

#### A. Character of Gender Roles

In Portugal, there is an influence of traditional Latin perspectives on male and female roles in society, so that social status is still, in part, related to biological sex. Nevertheless, some significant changes have been occurring in recent years. Traditionally, women were expected to have a passive role in society, although generally assuming a leading position at home, taking care of children, and, in many cases, being responsible for the management of the domestic economy. The male was the decision maker in what concerned major issues at the community level and the main provider of financial maintenance for the household. Women were "naturally" supposed to be good housewives, mothers, and wives.

This situation, a reality for the majority of cases at all socioeconomic levels of society, was maintained and reinforced by the fascist government that ruled in Portugal until 1974. The political and ideological principles of this period, which lasted for 48 years, was strongly influenced by the Catholic Church and also determined social and sexual roles of the male and female. The worship of the Virgin Mary, the *Marianismo*, symbolically reflected the feminine ideal of maternity without sexual involvement to which every woman should aspire (Rodrigues 1995).

The Catholic and traditional ideals of the politics and social structure of this era are still a reference for the older generations, but the modernization of Portugal and of the Portuguese society in recent years has brought new values and realities. Women are more and more actively taking part in the social life, and they are also currently the vast majority of the university student population—about 80% of all university students are female. The *machismo*, once a value strongly associated with the male, is now considered a fault more than something positive.

Although it has been commonly accepted for several decades that women should also be gainfully employed outside the home to help support the family, gender differences exist here despite Portugal having one of the highest percentages of working women in Europe. The distribution of males and females according to professional categories, as well as to hierarchical levels, is unequal. Females mostly assume unskilled and lower-level positions and have the lowest salaries (Amâncio 1994). This fact is quite obvious in the Portuguese Parliament, in which after the 1999 elections only 19% of the commissioners were women. However, given the significant increase of college-graduate females, a shift should be expected in the near future.

The professional situation of men and women is not the only area in which gender differences can be found. It is easier for a parent to let a teenage son out at night than it is for a girl to have the same kind of liberty. The so-called sexual double standard also prevails and expresses itself through a more permissive attitude towards men's sexual behavior and a more conservative and repressive posture towards women's sexuality (Machado & Almeida 1996). This way, it is expected and somewhat valued that a male has several sexual partners, whereas the same is disapproved of in a female. However, this double standard has in recent times lessened, with a growing acceptance of female sexuality and the changing in the character of gender roles.

Among a new generation of couples and families, it is possible to find evidence of this change, as young men are more willing to share domestic tasks and are happy to take care of their children. These fathers are proud of their paternity and are assuming the traditional functions of the mother, which is reflected in publicity that uses images of young fathers changing diapers and playing with their infant sons and daughters.

#### B. Sociolegal Status of Males and Females

According to the Portuguese Constitution, all men and women are equal before the law. Legal majority is achieved at 18 years of age or with marriage after 16. Marriage is allowed at age 16 with parental consent. Nevertheless, as previously mentioned, despite legal gender equality, several differences still exist at various levels of society. To reduce this gap, in 1991, a commission, Comissão para a Igualdade e para os Direitos da Mulher (CIDM, Commission for the Equality and for the Rights of Women) was formed, succeeding a previous organization that had a key role in changing the legal status of women and in achieving gender equality before the law. The main objectives of CIDM are:

- to allow the same opportunities for men and women;
- to reach the same level of responsibility for women and men in what concerns family, professional, social, cultural, economic, and political life; and
- to contribute to the recognition of maternity and paternity as social functions.

Although this commission is mainly concerned with feminine problems and rights, it contemplates the work with men as a way of achieving equality, which is most obvious in the attention given to the questions of paternity.

In October 1999, a new ministry, the Ministério da Igualdade (Ministry of Equality) was created. As in similar ministries in other European countries, the goal is to achieve equality at different levels of society. Gender equality will obviously be one of its main areas of action. [*Update 2003*: In 2001, critics of the Ministry of Equality managed to have this agency eliminated, despite praise from some who originally considered it a useless organization.

[No other relevant event has occurred since 2000 concerning the sociolegal status of males and females except, even if ever so slightly, the fact that it is increasingly obvious that women are taking a more visible role in public and political life, adding strength to the trend previously suggested. Nevertheless, after the March 17, 2002, elections for the Parliament, only 17% of deputies and two Ministers (of Justice and Finances) are women. (The Finances Minister is at the same time the State Minister and has, therefore, the role of supporting the Prime Minister's activities. These two women account for 12% of the 16 ministers in the Portuguese government. (*End of update by N. Nodin*)]

### C. General Concepts of Sexuality and Love

As in many other parts of the world, sex and sexuality are uncomfortable topics for most people. Sex and sexuality are mostly discussed between friends, using jokes as a way to lighten the tension involved in these issues. However, in sexual education programs or when asked about sexuality for research purposes, most people will participate and show an interest in the topic. Sex-related issues, such as homosexuality, abortion, and AIDS, are also regular subjects of talk shows and programs on television as well as of reports in the press. Nowadays, a wide range of information and services are available and this has, in turn, influenced and reshaped the general Portuguese conceptions of sexuality in recent years. This fact does not necessarily mean that the Portuguese are very open-minded about these issues. A certain resistance exists towards minority forms of sexual expression, which are more likely to be tolerated than truly accepted.

Love and the existence of steady relationships are considered previous conditions for sexual intimacy with a partner, especially for women. Men, as well as individuals from the younger generations regardless of gender, value the hedonistic and pleasurable aspects of sex the most (Pais 1998). One has to assume that there are significant gender and generational differences over what is or is not considered a steady relationship, and also over other general conceptions of love and sex. In any case, the general picture shows us clearly that sexuality is no longer associated with procreation and that relationships are based on affection towards the partner, rather than in formal structures, such as engagements and weddings.

The two tendencies in love and sex in the Portuguese mainstream society, i.e., the importance of romantic love and the sexual pleasure ideals, are somewhat in conflict: The first implies monogamous relationships and the second reinforces the search for different and multiple sexual partners. However, it is known that a gap exists between what is said and what is done and, when confronted with a choice, most frequently, the romantic ideals lose in favor of a greater sexual freedom.

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A. Source and Character of Religious Values

Portuguese society has in the past been greatly influenced by the Catholic Church. In the 15th century, the clergy was one of the supporters of the colonial "discover-

ies" that led to a period of great prosperity for the country. One of the reasons for this support was the opening of new possibilities of evangelism and the spread of the influence of the Church throughout the world. This eventually happened in many parts of the world, in Brazil, India, Macao (China), and Japan, where the Portuguese were the first Westerners to arrive and to introduce the Catholic religion.

The Portuguese Church grew, enriched and hegemonic, especially after the expulsion of the Jews from the country in 1496, which came by royal order, but with a strong Catholic influence. The Holy Inquisition (Tribunal do Santo Ofício), established in the 16th century, was for a long time a powerful means of political and ideological repression that was also used to persecute people with sexual behaviors that were considered deviant, like prostitutes and homosexual men. Women who lived their sexuality freely were often considered witches, especially in the interior of the country. Many of the charges of witchcraft against women were, in fact, the consequence of revenge related to cases of adultery.

The Marquis de Pombal (1699-1782), the prime minister during the reign of King Joseph, ruled the country despotically, but introduced many reforms and turned the big earthquake of 1755 that destroyed part of Lisbon into a chance to rebuild the capital according to modern principles. He reduced much of the power and importance of the Church and of the Inquisition that was finally extinguished in 1821. This was also the beginning of the end of much of the religious influence in civil society, which was only again regained during the government of Salazar, in the period called the Estado Novo (1926-1974). The three mottoes of this time were *Pátria, Deus, Família* (Fatherland, God, Family) that, like the Holy Trinity, were the moral references of the Estado Novo. This period left several marks in Portuguese society that still has an influential Catholic community.

Of the majority Catholics, 26% go to church regularly and have some degree of religious influence in their lives, whereas 65% are nonpractitioners (Pires & Antunes 1998). Nonpracticing Catholics are believers that do not attend religious rituals, such as the Mass, or go to confession very often.

There is an important difference between the practicing and the nonpracticing Catholics that can help us understand different positions in Portuguese society, and not just those related to sexuality. In general, practicing Catholics have more-conservative positions on such different things as marriage, social intervention, drug addiction, nudism, and tax evasion (Pires & Antunes 1998). Usually in Catholic families, behavioral norms are stricter than in non-Catholic families, and there is a greater concern over the upbringing of children according to religious principles. Most practicing Catholic children go to religious schools that are generally considered among the best private education institutions. The Catholic University is also one of the most prestigious universities in Portugal.

This conservative perspective of the practicing Catholics obviously influences their views on sexuality. In general, they are more repressive over the expression of sexuality, less tolerant towards sexual minorities, and have more-traditional ideas on contraception and abortion. Religious practice is also negatively associated with sexual experience and permissiveness among university students, while the simple fact of being or not being a believer is not a condition to explain these kinds of differences (Alferes 1997). What does influence the beliefs about these issues is, again, the assumption of a practicing or nonpracticing Catholic position.

Lately, some criticisms have emerged among the Catholic community towards the stagnant position of the Church on different subjects related to sexuality. One such criticism is that the Church still associates several different subjects with sin, this way repelling Catholic couples and individuals who do not find in the Church the answers they are looking for in what concerns their private lives (Ferreira 1993). In 1993, an organization of Catholic students, Movimento Católico de Estudantes (MCE), published a document that considered the ideas of the Church on sexuality inadequate and detached from the scientific speech. It also condemned the use of power in ways that affect the individual experience of one's sexuality in areas such as homosexuality, premarital sexual activity, and masturbation (MCE 1993). Despite these critical movements, the Catholic Church still has considerable influence in Portuguese society, and is economically powerful. This became quite obvious in the recent referendum over the legalization of abortion.

As for other religious beliefs and practices, they also have a strong effect on the permissiveness towards sexual behavior. Little is known about these minorities, but one researcher tells us that people that follow these beliefs have attitudes towards sexuality even stricter than the Catholic majority, especially in what concerns prostitution and adultery (Pais 1998). However, more research is needed in this area in order to study the effect of these attitudes on the behavior of people belonging to these groups.

### B. Character of Ethnic Values

Portugal is one of the oldest nations in Europe and its actual frontiers are almost the same since the 13th century. There has also been a considerable stability in the constitution of the population in its majority Caucasian character over the centuries. Although having been influenced by several races and cultures throughout history, the Portuguese are essentially a Latin people, with concepts of gender roles and sexuality similar to those existing in other south European Latin countries like Spain and Italy.

After the revolution of 1974 and the independence of the colonies of Guinea-Bissau, Angola, Mozambique, Cape Verde, S. Tomas, and Principe, about half a million Portuguese who lived there returned to the mainland (in fact, many had been born and always lived in Africa). This mass return of people with a different experience and kind of living was socially quite problematic, and a certain xenophobic climate appeared against the newcomers who were pejoratively called the *Retornados* (the ones that returned). The *Retornados* must have had an influence on the concepts and practices related to sexuality of the rest of the Portuguese, for in Africa, there were not as many restraints as the ones that existed on the more conservative mainland. However, to our knowledge, there are no studies about this subject.

[Update 2003: Portugal has historically had a tradition of emigration, most significantly during the Age of Exploration/Discovery in the 1500s, when the aim was to conquer new lands and to explore their richness, and in the 20th century, between the 1950s and 1970s, when many Portuguese left the country in search of better living conditions not possible under the then-current political regime. With the recent economical revival and development of the country, this process has practically disappeared, replaced by a mass influx of immigrants from Eastern European countries. However, to our knowledge, no investigation has been conducted on the sexual attitudes and lifestyles of these immigrants from poorer countries, the influence they are having on the Portuguese, or on how these new people are affected and influenced by the culture of their new home. (End of update by N. Nodin)]

## 3. Knowledge and Education about Sexuality

### A. Government Policies and Programs

The history of sex education in Portugal begins in the 1960s. Before that, the Catholic Church was responsible for the moral orientation of education, separating boys and girls in public schools, and repressing the study or teaching of sexuality. It was only with the Vatican II Council, which brought new ideas and a different approach to several areas within the Church, that sex education began to be discussed. It was also at this time that new values and attitudes emerged, together with democratic ideals and expectations of liberty.

A new course, "Sexuality, Love, Marriage and Family," started being taught at a seminary in Lisbon, and several articles about sexuality appeared in Christian magazines and newspapers. In public schools, in the existing class "Religion and Morality," mainly taught by priests, the discussion of sexuality was included as a way to guarantee long-lasting and happy marriages for future adults. However, this approach was non-systematic, had no scientific basis, and was frequently inadequate.

In 1967, the Associação para o Planeamento da Família (Portuguese Family Planning Association, or APF) was created, supported by the International Planned Parenthood Federation, which was interested in reaching southern European countries. This organization is not very well accepted by the government, by the Church, or by the most conservative sectors of society, but it has initiated several actions aimed at the training of professionals, as well as implementing a service of family planning for the population.

In the early 1970s, the Ministry of National Education created the Commission for the Study of Sexuality and Education. This commission advocated the abolition of separate education of boys and girls and focused on the need for a different approach, integrated and not fragmented, to the human body in schoolbooks (Roque 1999). This commission became extinct one year after its creation.

The revolution of 1974 that ended the dictatorship in Portugal brought a rapid change to society. But although sex education could be and was, in fact, publicly discussed and defended at this time, the disturbed post-revolutionary atmosphere was not favorable to its introduction in the educational system. Other issues, such as abortion and the equality between men and women, were the main concerns over which new legal and practical measures were brought together. The APF became the main organization responsible for sex education in the school context, with actions carried out by professionals. However, these efforts were very limited and could not respond to the real needs of young people. Teachers were trained as a way to enlarge the reach of its intervention, and later, at the beginning of the 1980s, new programs aimed at young people and supported by the United Nations Fund for Population Activities (UNFPA) were put into action outside the school context. There was an urgent need to legally regulate sex education, and this came with the 3/84 Law, 24 of March 1984. According to this law:

- The state guarantees access to sex education as a basic educational right;
- The state is the responsible entity for the promotion, diffusion, and organization of the juridical and technical means necessary for a responsible maternity and paternity;
- The school curricula should include scientific knowledge about the anatomy, physiology, and genetics of human sexuality, and should also allow the overcoming of the social discrimination based on biological sex and of

the traditional division of duties between the male and the female;

- Teachers should be trained in sex education as a way to be able to respond to the needs of young people; and
- Parents should also be supported concerning the sex education of their children.

Although approved and authorized, the means to apply it in the school context were never standardized. Children and adolescents only had access to sex education because of the initiative of some teachers and other organizations. These initiatives were never truly systematic. In the meantime, new activities and classes, like “Personal and Social Development,” were created to facilitate the discussion of subjects directly related to the reality and practical needs of young people (Vaz 1996). This allowed a more regular introduction of sex and sexuality in the school system, frequently as a response to the requests of the students themselves. Programs for the prevention of HIV also started, because sex education is considered as a way to fight the growing spread of AIDS. Proposals for including sex education in different branches of education have been made and pilot projects have been introduced in some schools.

In 1998, a commission formed by representatives of several ministries presented a report proposing a plan of action for sex education and family planning, in which practical measures are proposed in several areas. Its goal is to provide students with access to sex education and to insure the availability of family planning services. New laws and initiatives are emerging, but a lot of work still needs to be done concerning the regular and effective availability of sex education for the young and also for the general population.

[Update 2003: A year later, in 1999, this commission issued a special report (*Relatório Interministerial para a Elaboração de um Plano de Acção em Educação Sexual e Planeamento Familiar—Interministerial Report for the Elaboration of an Action Plan on Sex Education and Family Planning*) that was then approved by the government. In this report, sex education is considered as a part of education and a vital part of health promotion in general. The *Report* also established new goals for sex education in the school context.

[In August 1999, a new law was published (Law 120/99) whose main objective is to affirm the right that every citizen, especially children and adolescents, have to sexual and reproductive health. This law contains the topics that should be addressed in any sex education program in a school setting. These are:

- Human sexuality,
- Reproductive anatomy and physiology,
- AIDS and other STDs,
- Contraception and family planning,
- Interpersonal relations, and
- Gender equality and sharing of responsibilities

[The legal framework existing in Portugal with regard to sex education now contains a number of norms for its application:

1. That sex education should be treated in an interdisciplinary way, i.e., included within all the previously existing disciplines,
2. That all sex education programs should include an articulation between the school and the community (including health services and parents), and
3. That teachers should have specific training for teaching such matters.

However, these norms have not been applied in any systematic way, which means that empirical work and subsequent

results are still very scarce, and effective actions are often dependent upon teachers’ initiatives.

[Following a political turn to the right after the 2002 Parliament elections, the government is valorizing a conservative approach to the questions of sex education in schools and has signed a protocol with the Movimento de Defesa da Vida (Movement for the Defense of Life), an NGO, that has a known and active social position against abortion. According to this protocol, this organization will be responsible for the training of teachers in matters of sex education. This protocol substitutes a previous one that the Ministry of Education had with the Portuguese FPA (Associação para o Planeamento da Família), whose positions are much more liberal. (*End of update by N. Nodin*)]

## B. Informal Sources of Sexual Knowledge

Sex and sexuality have become common subjects of television programs and are frequently presented in the media. There is a concerted effort to invite experts to talk about these issues in the media, so that the information that reaches the public is usually of a fairly good quality. A popular and light-reading magazine, called *Maria*, is famous for having a section of responses about the sexual problems of the readers. In the past, this was a major source of informal knowledge on sexuality when very little, if any, information was available from other sources.

Several books about sexuality by both national and foreign authors have been published in Portugal and are easily available. Different institutions working in the field frequently publish and distribute brochures and leaflets on subjects such as contraception, special care during pregnancy, and sexually transmitted diseases. Since the appearance of AIDS, many of these leaflets have also appeared aimed at specific groups of the population, such as women and gay men.

When asked about the sources of sexual information accessed or preferred, most young people will refer to the media, with television at the top of the list. Other significant sources mentioned are friends and the partner or consort (Pais 1996). In fact, sexuality is in great part played and learned in a relational context, both with peers in informal situations and with the sexual partner. In adolescence and even in young adulthood, the information obtained from friends is not always the most correct and is frequently filled with popular false beliefs. However, given the known importance of peer influence, some of the most recent health-promotion and HIV-prevention programs developed in Portugal integrate this new approach through the training of young people. It is expected that these programs will produce a positive influence from peers, instead of a negative one.

Intervention in the influence of the sexual partner is more difficult because it occurs in emotional and intimate situations that are hard to change. A person who has information on how to prevent HIV infection or an unwanted pregnancy might, in any case, engage in risky sexual behavior with a partner because of feelings of inadequacy, low self-esteem, or simply because of forgetfulness in the heat of the moment. It should also be mentioned that a high percentage of young people (about 80%) think they do not need to be enlightened or to have technical support on sexual issues (Pais 1996). Although this percentage is higher among younger adolescents who are not sexually active and tends to get lower as the age increases, these numbers are still very disturbing. They show a great feeling of self-sufficiency in these youngsters that can be the first step to high-risk behaviors because of a lack of correct knowledge.

A significant percentage of young people get information on sexuality (60.6%), contraceptives (49.7%), and HIV

(30.4%) from their parents, with the mother being the most frequently mentioned source of information. A great part also report they would like to have more information from either one of their parents.

In June 1998, a free and confidential telephone helpline, *Sexualidade em Linha (Sexuality on Line)*, opened to serve the information needs of young people. In its first year, 50,000 phone calls were answered and many more went unanswered because the amount of phone calls far exceeded the service's capability of response. The great majority of callers were between 13 and 18 years of age, and over half were girls (55.9%). The questions that led to the calls were varied. In most cases, the objective was to get information about sex (oral and anal sex, masturbation, virginity, etc.), contraceptives, and counseling for relational problems with the partner (GAEP 1999).

[Update 2003: Since pornography is currently easily accessible both by cable television and through the Internet, it is common that teachers in the classroom discover that children as young as 3 or 4, even if more commonly later, view such material. However, because many of the teachers and parents are ill at ease with the subject of sexuality, important opportunities for sex education using the viewing of such material by children are wasted. One consequence is that these children are often left with incorrect sexual information (and sometimes with anxiety) driven by the pornographic material they have viewed. (End of update by N. Nodin)]

#### 4. Autoerotic Behaviors and Patterns

##### A. Children and Adolescents

Autoerotic behavior is common in children and adolescents, but is usually repressed by parents and society, and condemned by religion. This induces some anxiety, especially for the adolescent who masturbates just the same, but often with guilty feelings about it. Adolescents sometimes request counseling over masturbation to know whether it causes illness, impotence, infertility, or pimples, or if it is bad for the health. All these questions reflect popular beliefs about this behavior.

##### B. Adults

Although also slightly influenced by repressive religious-based ideas about masturbation, Portuguese adults are more and more open to this behavior. A recent survey shows that it is accepted by approximately 40% of the population, although another 40% feels it should not be accepted (Pais 1998). However, these figures do not coincide with the percentage of individuals who admit masturbating. In a different survey, 69% of adults reported having practiced masturbation (Markttest 1995). This percentage was surprisingly steady in all age groups studied, 18 to 45, but significantly different between men and women, the former reporting a much higher practice of masturbation than the latter.

In a study conducted by Valentim Alferes (1997) with college students, 74% of the males and 27% of the females reported having masturbated in the month previous to the inquiry. It was also possible to determine that men who had had intercourse masturbated just as much as men who had not. As for women, the number of the ones who had not had intercourse and masturbated, more than doubled the ones who had had intercourse and masturbated. Apparently this means that for men, sexual activity is no impediment to masturbation, whereas for women, genital self-stimulation is more frequent in the absence of sexual intercourse, and rarer in its presence.

Men have a more open attitude about masturbation, but individuals of both sexes have a similar level of acceptance over the performance of masturbation by men and women.

Differences exist over the acceptance of masturbation according to religious position, age, and social status: The more religious, the higher the age, and the lower the social and economic status, the less accepting will the individual be towards masturbation (Pais 1998).

#### 5. Interpersonal Heterosexual Behaviors

##### A. Children

###### *Sexual Exploration and Sex Rehearsal Play*

Childhood exploration of the body of one's self and others is common, although usually repressed by parents and caregivers. Most Portuguese adults still have some difficulty admitting that children are sexual persons and are thus curious about sex, especially when the adult is not at ease with his or her own sexuality. This is important because sex education directed at children is basically nonexistent in the school system and is not done at home. However, from a very early age, children try to get information about sex as they can, usually through their peers.

In some cases, sexual experiences start in childhood or early adolescence. In a survey conducted in an urban sample, 15% of the males reported having had their first sexual intercourse before 13 years of age (Markttest 1995). This, however, happens only in the case of the male population, probably caused by early curiosity and partner availability; in most cases the female partner is older.

Among younger adolescents, from age 9 or 10 on, a game called *Bate Pé* (Foot Stomping) is played in small- to medium-sized groups. In this game, each girl and boy alternatively proposes a number to an element of the opposite sex. Each number is related to a given behavior, e.g., number one is a handshake, number two is a kiss on the face, number three is a kiss on the mouth, number four is a French kiss, number five is touching the breasts, and so on. The higher the number, the more daring is the behavior, with sexual intercourse being the upper limit. When the recipient of the proposal refuses, he or she will stomp the foot—hence the name of the game. This game is a common starting ground for the discovery of the opposite sex and of rehearsal without compromise. Needless to say that boys rarely stomp their feet and the numbers rarely pass beyond four or five at age 9 or 10.

##### B. Adolescents

The fast progress and improvement of life in recent years have affected the lifestyle of Portuguese youth. Major international fashion trends and influences reach Portugal within a few months from the rest of the world. The influence on youth is strongest for music. However, a gap exists between the urban and the rural youth. In the cities, access to leisure and information resources is much easier than in the interior and less-developed rural areas of the country. This makes it difficult to discuss Portuguese youth as a single group, because this cohort contains, in fact, a great range of different people. This should alert the reader to the fact that general information, like most of what we present here, can sometimes be misleading in terms of adolescents who live in different contexts. This fact should also be considered when interpreting information about adults and other groups of the Portuguese population.

###### *Dating*

Affective relationships in adolescence are frequent, and dating is common, usually starting at 14 or 15 years of age, at least in Lisbon (Silva, Dantas, Mourão, & Ramalho 1996). Dating is not seen as a first step towards marriage, but as a period of experimentation and discovery of the relationship. This pattern is accepted by the majority of young

people and is slowly replacing the more traditional ideas about how relationships should be, i.e., a phase leading to marriage. Nevertheless, the large majority of young people (92% between 18 and 20 years of age) have marriage in their plans, even if this is an idea that diminishes as age increases (87% at 21 to 24, and 81% at 25 to 29) (Vasconcelos 1998). This probably happens because of social and economic difficulties perceived as obstacles to marriage or simply because marriage is no longer considered a necessary condition for being with a consort.

### *First Sexual Intercourse and Premarital Sex*

Some decades ago, boys usually had their first sexual experience with prostitutes, whereas, for girls, marriage was a condition for starting their sexual experiences (Miguel 1987). The severe social laws that ruled peer and couple relationships at that time strongly disapproved of sex before marriage, but tolerated the sexual behavior of men who used professionals or "easy women" for their first sexual contacts. These easy women were not necessarily prostitutes, but also girls and women who, without great pressure from men, agreed to have sex without being married. These women were, of course, not seen by men as the traditional "marrying type" and were severely socially reproved.

By the end of the 1980s, sex outside marriage was still seen as reprehensible or even as a dangerous behavior, especially for girls (Figueiredo 1988). Ten years later, only 6% of young people considered marriage as a condition for starting their sex life (Pais 1998). Today, affection is the main reason for the sexual initiation of the young, and in fact, most of those who have already had sexual relationships were in love at that time (Alferes 1997). Nevertheless gender differences can still be found in these conceptions, although not as much in behavior. The importance of an emotional involvement with a partner is not considered a prerequisite for sex in the case of boys, as much as it is in the case of girls. This will also influence the psychological situation in which the "first time" takes place. In many cases, there is a strong pressure from the boy to have sex, and the girl will allow it to happen as a proof of her love, even though she might not feel ready for it. For boys, the erotic and hedonistic aspects of love are more important, whereas for girls, romance and love between the partners are the most valuable things.

In any case, sexual foreplay is frequently used as a way to discover sexuality and the body of the partner. There is a sense of inevitability connected with sexual activity in adolescents, for whom their sex life is something that can happen at any time, and often does. However, AIDS is considered one of the main general concerns for these young people, and 96.9% are moderately or very concerned with it (Sampaio 1996).

Despite the fact that sexual activity can, in some cases, be found at ages as early as 12, virginity is still considered something precious for many girls, who are sometimes anxious about the possibility of having lost it because of masturbation, sexual rehearsal, or sexual abuse during childhood. Also, the concept of virginity is not always very clear, and the absence of bleeding during the first intercourse can be interpreted as one still being a virgin.

## **C. Adults**

### *Premarital Relations, Courtship, and Dating*

The pattern of love and sexual relations of younger adults is much like the one of teenagers. People usually get together and date with people they like, even if it is against their parents' wishes. There is a growing acceptance of premarital sexual activity, so that the absence of marriage is not

considered a reason for not having sex with a loved one. Most people think that sex without love has no meaning, and this reason is often the determinant of sexual activity among young adults (Vasconcelos 1998).

This also explains the fact that the average age for the start of sexual activity has slightly decreased, at least for women. Thirty years ago, the average age for women starting sexual activity was 21.5 years; presently it is 19.8 years. For men, the average age for the start of sexual activity has been quite stable at around 17.5 years (Instituto Nacional de Estatística 1997). However, this gender gap tends to weaken as age advances. By 25 years of age, the great majority of people have already started their sexual activity, and the difference between the males and the females who have had sex is practically nonexistent.

As for young adults who still have not started their sexual activity, it is mainly because they have not yet found the right person, because they feel they are too young, or simply because they have not yet had the opportunity (Vasconcelos 1998). The start of sexual activity does not happen until certain conditions are met, foremost being a certain perceived level of self-development and the presence of the "right" situation or person.

Nevertheless, the so-called "one-night stands" do happen, 3.3 times more frequently for males than for females (Alferes 1997). Consistently, men are found to have much more positive attitudes towards casual sex and greater expectations regarding the number of future sexual partners. Real or imagined infidelity is also more common in males.

### *Marriage and Family: Structures and Patterns*

The family is the stage where life and social relations play out, and where the major influences of the society become more acute. This means that the characteristics of gender roles discussed earlier achieve their clearest expression. Traditionally, women are responsible for taking care of the house and children, but their growing participation in the workforce has also granted them an important role in the economic sustenance of the family. Their husbands are increasingly involved in domestic tasks. Relationships between the couple, as well as between parents and children, have become more equilateral and democratic (Vicente 1998).

There is a strong consensus among the Portuguese of different generations on considering the family the most important social organization in everyday life, couple life, procreation, relationships between parents and children, as well as the role of the female inside and outside the house. These findings are counter to the idea, sometimes defended, that there is a crisis in the institution of the family.

Crisis or not, demography shows us that changes are occurring in the Portuguese family. The median number of family members has decreased substantially, in great part as the result of a smaller number of children being born, from four in the traditional family to a current average of two (Instituto Nacional de Estatística 1997). Divorce rates have increased to 11% in younger generations, and new forms of family are emerging, such as single-parent families, reconstituted families (families formed by partners previously divorced and most times bringing together children from the previous marriages), and cohabitation. The number of families in which the female is the sole adult responsible for the family has grown to about 5%, greater than the number of single-parent families headed by a male, currently less than 1%.

All of these new realities exist peacefully and are generally unquestioned. The notion of family itself has changed and has integrated these alternative organizations of the household. An example of this is the acceptance of cohabitation as a valid alternative to marriage or, at least, as a first

step prior to marriage (Vasconcelos 1998). Actually, cohabitation is more easily accepted than it is practiced.

Family has truly become a place of relational and emotional belonging, and is no longer a rigid and institutional structure that has its own right to existence. This is true mostly for the younger generations, in which there is a rejection of the traditional institution of weddings associated with a clear gender difference, the functional division of the house tasks, and the idea of the irreversibility of the relationship. For many younger Portuguese, the main principles are freedom of association between the couple and the right to end the relationship when it no longer has any meaning for the persons involved.

Arranged marriages were never popular in Portugal, although they sometimes took place in the past, mainly in rural and interior areas. Frequently, however, marriage was a guarantee of economic sustenance, and it was also maintained for the same reason, mostly for women who depended on their husband to survive. Nowadays, the economic importance of the wedding has not disappeared, but it now has a different meaning since women have established their place in the workplace. Most Portuguese men and women consider economic stability a prior condition for getting married. Usually, couples do not get married before having a stable job or economic situation, although some will still rely on the parents for help and financial support.

Nevertheless, love is the main reason why two people get married. Marriage is thus seen as a public institutionalization of an affective relationship between two individuals, but it is sometimes also a way to legalize a situation of cohabitation when children are born (Vasconcelos 1998). One should not forget that the figure of the *bastardo*, a child born out of wedlock that previously was socially stigmatized, only disappeared from the Portuguese law in 1981, and still plays an important role at a more unconscious level, even among more progressive people.

Marriage is considered as a life project planned by both members of the couple, even if some concessions are involved. It is also considered as an engagement for life, which, curiously, is opposite to the idea of the reversibility of the relationship that most individuals defend. While romantic love is the basis for the marital relationship, its loss is also reason for ending a marriage. Separation or divorce is generally accepted and considered a way to reach the happiness that can no longer be obtained in the marriage. This fact might explain the growth of divorce rates in recent years.

### [Cohabitation

[Update 2003: In 2000, after heated debates in the media and the public sphere as well, a law recognizing cohabitation was approved by the National Assembly. According to this law, two people who can prove that they are living together for a period of at least two years can have access to some of the privileges that are traditionally granted by marriage, such as tax benefits and the possibility of not going to work to support a consort who is ill. One of the main issues in this discussion was the fact that this law considered equally the cohabitation of heterosexual and of gay couples. This led to discussion of several other proposals, some more conservative. In the end, the more progressive law was approved.

[Also worthy of note are new laws designed to protect maternity and paternity (Law 17/95 of June 9, 1995, later modified by Law 18/98). According to these laws, workingwomen have the right to a maternity leave of 120 days. In case the mother has twins, this leave may be extended an additional 30 days for each twin. This leave is mandatory for at least 14 days. The father has the right not to work for two days after the birth of a son or daughter, or to the same

amount of days as the mother in cases in which she is physically or mentally unable to take care of the child, in the case of maternal death, or by joint decision of both the parents. (End of update by N. Nodin)]

### Sexuality and the Physically Challenged

In its Rule Number 9 dedicated to the Family Organization and Personal Dignity Dimension, the United Nations calls our attention to the fact that disabled people should not be denied the possibility to enjoy their sexuality, to engage in sexual intercourse, and to have children. It notes that, because of the fact that disabled people may have difficulties in getting married and in having a family, governments should encourage the existence of the appropriate counseling services for this matter. Therefore, disabled people should have access, as other citizens should, to family planning methods and to reliable information regarding the sexual functioning of their body (Secretariado Nacional de Reabilitação 1998). This concern is also present in the lines of the "Rehabilitation Coherent Policy for Disabled People," a European Council Recommendation signed by the Portuguese Council of Ministries in April 1992 (Secretariado Nacional de Reabilitação 1994).

As in other European countries, the United Nations 45/96 Resolution, that establishes the rules regarding Equalization of Opportunities for Disabled People, led to the constitution of Law 9 (of May 9, 1989), called "Prevention, Rehabilitation and Integration for Disabled People," which emphasizes the Basic Principles of the Portuguese Constitution (Secretariado Nacional de Reabilitação 1999). As a result of this law, a permanent national organization included in the Social Security and Solidarity Ministry was created in Portugal. This organization, the National Commission for the Rehabilitation and Integration of Disabled People, is responsible for the planning and general coordination of the National Rehabilitation Policy in cooperation with nongovernmental organizations and the sectarian systems of the Portuguese Public Organization.

As an Information Supplier, this commission organized a national Disability Inquiry, and its last results were published in 1996 (Secretariado Nacional de Reabilitação 1996). They included the situations of 142,112 persons and 47,020 families in the Portuguese continental territory. This *National Inquiry of the Incapacities, Disabilities, and Disadvantages* was very important for understanding the Portuguese reality in this area and made it possible to identify particular priorities and strategies.

Its conclusions, elaborated with the support of the National Statistical Institute and the Instituto Nacional de Servicios Sociales of Spain, showed a national disability rate of 9.16%, similar to that of other countries in Europe. It draws attention to the considerable disability rates in children under the age of 9, and also to its major incidence in the periods of the end of the productive life, earlier retirement and retirement (45 to 54 years of age). Also, the disability incidence, especially regarding locomotion, was directly proportional to age.

The *Inquiry* also stated that, in Portugal, the rehabilitation and integration actions are insufficient and centered in the medical-functional dimension, despite the increased number of organizations dedicated to intervention in disability. Furthermore, there is no structured national program associated with the managing of sexuality in the disabled, in particular for those physically disabled, despite the partial actions associated with the intervention of the organizations dedicated to disability, sexology, and family planning (see Section 13D, Research and Advanced Education, Important National and Regional Sexological Organizations).

### *Incidence of Anal Sex, Fellatio, and Cunnilingus*

There is no legal restriction on the performance of oral or anal sex between consenting adults. Both are practices that can take place between couples, married or not, and apparently their incidence is growing. This might be because of the liberalization of sexual practices and the consequent curiosity over alternative forms of sexual experience.

Most people are pleased with the idea or practice of oral sex, either fellatio or cunnilingus, and over 60% report having practiced one or the other (Marktest 1995). Other studies have found values for the practice of oral sex as high as 67%, with no significant differences between males and females (Alferes 1997). In research conducted by one of the authors in a sample of young adults, 46.2% reported having practiced oral sex at least once with a regular partner, while 11.3% had practiced it with an occasional partner and about 1% with a prostitute (Nodin 2000).

The practice of simultaneous oral sex, also known as "69," is also documented, with 58.2% of respondents expressing enthusiasm or pleasure in anticipation of this activity, and a smaller proportion, 51.5%, reporting having practiced it (Marktest 1995). In this case, there is a slight difference between the attitude towards the behavior and the engagement in the behavior, which may happen because the ones who would like to practice it do not have the chance to do it, perhaps for lack of a willing partner.

Opinions are split on anal sex between the male and the female. The proportion of persons who anticipate it with enthusiasm or pleasure, 35.1%, is just about the same as the proportion of those who consider it unpleasant or disgusting, 35.0%, with 22.8% being indifferent about the subject (Marktest 1995). However, 43.3% have tried this sexual practice, especially men.

In the same sample of young adults mentioned before (Nodin 2000), 15.8% report having practiced anal sex at least once with a regular partner, 5% have tried it with a casual partner, and 1.2% with a prostitute.

## 6. Homoerotic, Homosexual, and Bisexual Behaviors

### A. Children and Adolescents

Studies of homosexuality in children and adolescents have not been done, and thus, little is known about its incidence or character.

### B. Adults

#### *Incidence and Relational Patterns*

There is no consensus regarding the percentage of homosexual individuals in the population. Different studies have arrived at different proportions: 0.7% (Nodin 2000), 1% (Lucas 1993), and 7.8% (Marktest 1995). Others only have specific data related to the incidence of same-sex experience, 2.9% in women and 5.2% in men (Alferes 1997). The marked differences found in these surveys are probably more because of the methodology used to assess the sexual orientation than to a real oscillation of its occurrence in the population. The highest results are obtained in studies made of urban samples, where it is possible to report that individuals who have had a sexual experience with someone of the same gender are mostly in their 30s, have lower educational backgrounds, and are married, cohabiting with a partner, or are divorced or widowed (Marktest 1995).

The prevailing patterns in relationships between homosexual individuals have not been studied, but it seems that it is very close to the heterosexual one, i.e., based on romantic feelings, affection, and sexual attraction towards the partner. This pattern is probably related to the devastating effects of

AIDS in the gay community that led to a slow but obvious change in the relational behaviors of this population.

Bisexuality is admitted as a behavior or tendency by a larger proportion of individuals, although sometimes it is a way to dissimulate a homosexual preference. Many bisexuals marry as a way to have a socially acceptable facade, but maintain a secret double life. The existence of this group was highlighted by the advent of AIDS and its spread to women by sexual contact with boyfriends and husbands previously infected in homosexual contacts. These men usually have problems dealing with their sexual orientation and are thus difficult targets for HIV-prevention programs.

#### *Social Status*

For over 70 years, homosexuality in Portugal was considered by the law as a behavior against nature and was considered equivalent to the crime of vagrancy. Individuals accused of this crime were kept, sometimes for years, in the *Mitras*, institutions for prostitutes, homeless, and other excluded persons. Others were blackmailed with the threat of being "outed." Prior to 1974, no form of organization or group consciousness existed for gays and lesbians, although some meeting points existed, like bars, mainly for individuals from the upper social classes. It was only during the national revolutionary process, in 1975, that the first organization of gays and lesbians, called CHOR (Revolutionary Homosexuals Collective), appeared, claiming dignity, freedom, and political rights for this minority (Vitorino & Dinis 1999). This collective had some impact in the community, but also had difficulties in gaining associates within a group that had but a vague consciousness of what the gay identity really was. Two years later, CHOR had disappeared.

The 1980s were a decade in which several things changed in the Portuguese society, among them, the questioning of the restricted sexual morality the country lived with for several decades. Echoes of the gay movements in other countries started to appear and the propagation of gay bars influenced a growing awareness of a national gay community.

A new lifestyle appeared, but unlike in other countries, there were no community organizations to support the minority in its needs and rights. In 1991, a homosexual work group (Grupo de Trabalho Homossexual) appeared inside a small left-wing party (Partido Socialista Revolucionário) that became the face of the gay movement in Portugal. However, because of its political association, it could only work as a group of reflection and public intervention.

It was only with the upcoming of AIDS and its impact in the gay community, together with the nonexistence of an active and effective government policy to control this disease, that a slow but growing alert to a need for action appeared. Several nongovernmental organizations appeared in the fight against AIDS, many of them integrating gay individuals. It was within these organizations that a group of people, with support from international organizations, created the ILGA-Portugal (International Lesbian and Gay Association), which quickly gathered a considerable amount of members. Its growth was also largely a consequence of the pioneer use of the Internet, which made it possible to reach gay individuals all over the country. ILGA is responsible for the organization of several successful events, such as the Gay Pride Festival and the Gay and Lesbian Lisbon Film Festival, with consistent support from the Mayor of Lisbon. ILGA, which launched an unprecedented awakening of the gay and lesbian community in Portugal, was followed in late 1997 by another institution, Opus Gay.

These institutions have played an active part in trying to change the several existing discriminatory laws against homosexual individuals. Although Portugal has signed in-

ternational conventions, such as the Amsterdam Treaty, and is a member of organizations that recommend the elimination of legal discrimination based on sexual orientation, it still exists. Most of the time, this discrimination in the Portuguese law is not explicit, excluding homosexual people by omission. Marriage, for instance, is not possible between two people of the same gender, which also makes it impossible for a gay or lesbian couple to adopt children, because, according to the Civil Code, only married couples can adopt children. A gay couple who live together is excluded from the recently proposed laws regarding the creation of cohabitation rights similar to those of married couples. Other legal differences can be found, for instance, the consenting age for same-sex sexual relations is 16 years compared with 14 for heterosexual persons. Individuals who admit to being homosexual are considered unable to enter a military career or the police force, and are also not allowed to donate blood (ILGA–Portugal 1999).

Socially, there is also a lot to be done. All forms of sexual behaviors and lifestyles considered different from the mainstream are usually not very well accepted by the common Portuguese. In a recent survey, a large majority of the population (86.1%) reported negative feelings towards homosexuality (Marktest 1995), although, in general, women were more open than men about the subject. Almost half the people, 48.5%, also think sexual relations should only be allowed between men and women (Pais 1998). Gender identity and sexual orientation are frequently confounded, even among professionals from the social and medical areas, and homosexuality is often associated with effeminate behavior.

Generally, Portuguese people have negative attitudes towards sexual minorities, but demonstrate some degree of acceptance when it comes to people they are familiar with. Perhaps the best word to describe this is not acceptance, but tolerance, which is a general attitude of the Portuguese also in other issues. In this particular case, the tolerance is usually related to the affection that one holds towards the homosexual individual, and that sometimes becomes incongruent with the ideas and positions otherwise held. This, however, is not seen as an internal conflict and is thus not resolved either way. Some degree of tolerance also exists towards public displays of affection between two people of the same sex, even though these are not very common. Gay bashing is almost unheard of in Portugal.

In the specific case of lesbians, they face the double discrimination of being women in a Latin country and of having a homosexual orientation. The lesbian community has much less visibility than the gay community. It is in any case easier for a couple of women to have a relationship or to live together and go unnoticed.

It is only recently that the lesbian community has started to get organized, with the publication of its first lesbian magazine, *Organa*, in 1990, and three years later of *Lilás* (Vitorino & Dinis 1999). The publication of these magazines, and the debate they launched in the lesbian community, allowed the organization of meetings and of small groups that stood for the rights of lesbian women in Portugal. Today, ILGA includes a group of women that integrates many of the members of those previous organizations and that is actively involved in working towards a greater acceptance and demanding of specific rights for lesbians.

## 7. Gender Diversity and Transgender Issues

### A. Sociolegal Status, Behaviors, and Treatment

There are no specific laws in the country regarding transgenderism or transsexualism, only a few court deci-

sions that serve as references about the latter, and these are sometimes contradictory (ILGA–Portugal 1999). According to one of these court decisions, someone that goes through the process of sex change cannot truly become someone of the other gender. The explanations are, in the case of a male-to-female transformation, that the individual cannot get pregnant or maintain sexual intercourse in the same conditions as a woman. Sex change is seen as an error and transsexuals are considered mentally unhealthy people. These ideas are a step back regarding a previous sentence (in 1984), according to which the moral personality of the individual should be respected, the sex change recognized, and the name change accepted by the civil registration.
