The first work found on the sexuality of male homosexuals in Cuba is a thesis presented at the Sociology Faculty in September 1999, which showed homosexual sexual initiation at adolescence in most adult interviewees. The subjects stated that they had satisfactory sexual relations, but to a certain extent, at certain stages of their lives, because of family pressure based on social stereotypes, had to assume an unsatisfactory heterosexual sexual role.

Generally, since the early 1970s, Cuban researchers in many specialties have continued to study the inexhaustible, diverse, and magical field of the human sexuality in a socio-cultural context, where fantasy, eroticism, sensuality, and affectivity mix to produce a their own local, as well as universal result.

In terms of continuous graduate education, it must be highlighted that in Cuba, there are many centers of higher learning that, in coordination with CENESEX, develop a system of studies for graduate degrees in the fields of sexology and sexuality education. In this sense, it must be emphasized that CENESEX offers free courses, two diploma courses on sexuality education and sexual counseling and sexual therapy, as well as a master's course in sexuality. At the Medical Sciences University of Havana, two diploma

courses on sexuality and the medical sciences, and sexuality are offered.

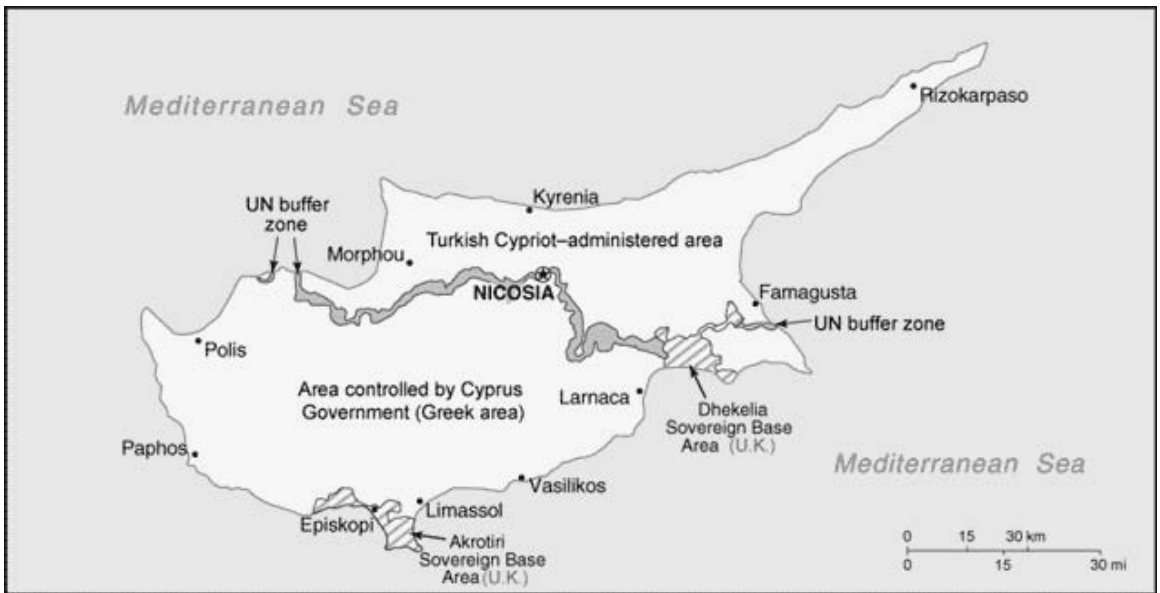

On the other hand, the "Enrique José Varona" Teachers' Training University offers free courses and another master's degree course in sexual education. Both master's degree courses deal with education, counseling, and sexual therapy from an education and health perspective.

The health sector, which includes the medical sciences universities, has been implementing for more than 10 years a set of sexual health prevention and education programs. Worthy of mention, because of their social impact, are the following programs: Mother-Child, Care for Pregnant Women, Responsible Motherhood and Fatherhood, and Comprehensive Adolescent Medical Care.

### *Demographics and a Brief Historical Perspective*

ROBERT T. FRANCOEUR

#### A. Demographics

Cyprus, the third-largest island in the Mediterranean Sea, lies in the Middle East off the eastern shore of the Greek Islands, the southern coast of Turkey, and the western shore of Syria, with Lebanon, Syria, and Israel to the southeast. Mea-

\*\*\**Note:* The Greek authors welcomed the opportunity to prepare this chapter on Cyprus because very little has been published on Cypriot sexuality in the international literature. This has been because of the lack of adequate funding and professionals to conduct methodologically sound research on the island, a lack of a coordinating body, the difficulties involved in collecting data given a conservative and sexually inhibited society, the suppressive influence of the Orthodox Church on human sexuality, and other factors. We have collected, analyzed, and integrated whatever information we could find, including statistical data, the results of professional experience and clinical work, and anecdotal reflections from professionals in fields related to sexology.

suring 141 miles by 60 miles (227 km by 97 km) wide, the island's total land area is 3,570 square miles (9,250 km<sup>2</sup>), a little more than half the size of the state of Connecticut. The island is divided between Greek and Turkish regions, with 2,275 square miles (5,895 km<sup>2</sup>) comprising the Republic of Cyprus and 1,295 square miles (3,355 km<sup>2</sup>) in the Turkish Republic of Northern Cyprus. Two mountain ranges cross the island from east to west, separated by a wide, fertile plain.

In July 2002, Cyprus had an estimated population of 767,314, of which Turkish Cyprus had about 200,000. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 22.4% with 1.05 male(s) per female (sex ratio); 15-64 years: 66.6% with 1.02 male(s) per female; 65 years and over: 11% with 0.77 male(s) per female; Total population sex ratio: 1 male(s) to 1 female

**Life Expectancy at Birth:** Total Population: 77.08 years; male: 74.77 years; female: 79.5 years

**Urban/Rural Distribution:** 70% to 30%

**Ethnic Distribution:** 99.5% of the Greek Cypriots live in the southern Republic and only 0.5% (about 500) Greek Cypriots in the Turkish-occupied territory; similarly, 98.7% of Turkish Cypriots live in the northern Turkish Republic and only 1.3% of Turkish Cypriots live in the south. The remaining 4.1% include: Maronites: 4,500 (0.6%); Armenians: 2,500 (0.3%); Latinos: 700 (0.1%); and other nationals, mainly British, Greek, European, Lebanese, and Arab: 23,000 (3.1%).

**Religious Distribution:** Greek Orthodox: 78%; Muslim: 18%; Maronite, Armenian Apostolic, and others: 4%

**Birth Rate:** 12.91 births per 1,000 population (18 per 1,000 for Turkish and 15 per 1,000 in the Greek Republic, according to G. J. Georgiou)

**Death Rate:** 7.63 per 1,000 population

**Infant Mortality Rate:** 7.71 deaths per 1,000 live births (12 per 1,000 for Turkish and 8.2 for Greek Cyprus)

**Net Migration Rate:** 0.43 migrant(s) per 1,000 population

**Total Fertility Rate:** 1.9 children born per woman

**Population Growth Rate:** 0.57%

**HIV/AIDS** (1999 est.): *Adult prevalence:* 0.1%; *Persons living with HIV/AIDS:* 400; *Deaths:* NA. (For additional details from www.UNAIDS.org, see end of Section 10B.)

**Literacy Rate** (*defined as those age 15 and over who can read and write*): 97% with nine years of compulsory schooling (1992 est.)

**Per Capita Gross Domestic Product** (*purchasing power parity*): Greek \$15,000 (2001 est.), Turkish \$7,000 (2000 est.); *Inflation:* Greek 1.9%, Turkish 53.2% (2000 est.); *Unemployment:* Greek 3% (2001 est.), Turkish 5.6% (1999 est.); *Living below the poverty line:* NA

## B. A Brief Historical Perspective

Recent excavations on the island of Cyprus have yielded evidence of human society at least 10,000 years old. The Mycenaean (Greek) culture flourished in the second millennium B.C.E. After Phoenicians colonized the island in the 10th century B.C.E., Cyprus remained a major *entre-pôt* for trade in the eastern Mediterranean. Annexed by Rome in 58 B.C.E., Cyprus later became part of the Byzantine Empire until the English King Richard I (Lion-Heart) established a crusader state there in 1191 C.E. The Lusignan dynasty ruled until 1489, when Venice annexed the island. In 1571, Cyprus became part of the Ottoman Empire.

In 1878, the Congress of Berlin placed Cyprus under British administration. After annexing the island in 1914, Great Britain made it a British colony in 1925. Between 1945

and 1948, the British used the island as a detention area for "illegal" Jewish immigrants trying to reach Palestine.

After 1947, the Greek Cypriot community expanded its longstanding agitation for union (*enosis*) with Greece, a policy strongly opposed by the Turkish Cypriot community. After violence in 1954 and 1955, Cyprus gained full independence under a 1960 agreement that forbade either *enosis* or partition and included guarantees of the rights of both Greeks and Turks. Efforts by the president, Archbishop Makarios, to alter the Constitution in favor of the Greek majority led to more violence in 1964.

A Greek Junta-inspired military coup against Makarios in 1974 led to Turkey's invasion of Cyprus and the *de facto* partition of the island and declaration of the northern 40% of the island as the Turkish Federated State of Cyprus. Some 200,000 Greek Cypriots were expelled from the Turkish area to the Republic, while many Turks fled the Republic for safety in the north. The Republic has experienced a return of political stability and economic prosperity, with agriculture, light manufacturing, and tourism leading the way. The economy in the Turkish sector has been generally stagnant, as the international community refused to recognize the 1983 declaration of independence by the Turkish Republic of Northern Cyprus. Tensions have eased since the United Nations-sponsored Greek-Turkish talks on Cypriot unity, even though little progress has been achieved thus far.

## 1. Basic Sexological Premises, and 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

NICOS PERISTIANIS\*

### A. Character of Gender Roles

Ethnographic and anthropological accounts of Cyprus (Peristiany 1974, Markides et al. 1978) stress the importance of the nuclear family as the paramount institution of Cypriot society, so much so that "an individual exists only as a member of a family," and the self cannot be conceived independently from its familial roles. This is in marked contrast to Western "solitary" conceptions of the self (Mavratsas 1992). The family has acquired such significance, because it was, and still is to a large degree, the primary social, economic, and moral unit of Cypriot society.

### *The Traditional Cypriot Family and Gender Roles*

The economy of Cyprus maintained its predominantly agrarian character well into the 20th century (Christodoulou 1992). The perennially heavy financial demands of conquerors and the especially hostile ecological factors—the strategic resources of water and land were always in limited supply, and diseases frequently destroyed crops—led to competition being a keystone aspect of life, and reliance on the family group being vital for survival. Economic activities were conducted by the entire household for the improvement of their common position, thus enhancing family solidarity and the strong distinctions between "insiders" and "outsiders."

In his survey of rural life in the late 1920s, SurrIDGE, a British colonial officer, noted an internal division of labor within the family, with men being responsible for heavy agricultural work and women (aided by the older children) for the lighter work in the fields, as well as housework. Usually one of the girls would stay behind to look after younger children and help with some housework (SurrIDGE 1930). At the same time, much as in Greece and elsewhere in the Med-

\*Note: This combined section on gender roles, marriage, family, and ethnic and religious factors was written by Nicos Peristianis, president of the Association of Cypriot Sociologists, based upon his research and that of his colleagues.

iterranean, there was a “moral division of labor inside the family,” revolving around the cultural codes, or values, of “honor and shame” (Campbell 1983, Schneider 1971).

Honor (*timi*) refers to the value or worth of an individual—but since the individual exists as a “member of a family,” whatever worth one earns for oneself automatically “spills over” to the family. Correspondingly, shame (*ntropi*) refers to a loss of honor, esteem, or worth, which brings humiliation, “staining” the individual and family.

It is important to appreciate the salience of these codes on the lives of individuals in traditional Cypriot society. Peter Berger has argued convincingly that contrary to modern societies’ emphasis on “dignity,” which implies a notion of the self devoid of institutional attachments and roles, more traditional societies put an emphasis on “honor,” which “implies that identity is essentially, or at least importantly, linked to an individual’s institutional roles.” In fact, an individual in a “world of honor” “discovers his true identity in his roles.” “To turn away from the roles is to turn away from himself” (Berger et al. 1973). What, then, were the roles through which individual Cypriot men and women discovered their true identities or selves?

The traditional role of the man in Cyprus was that of representing the family to the outside world. As head of the family, he engaged in all tasks necessary to protect and sustain the family. He was the main income earner who made decisions regarding production by obtaining knowledge about environmental conditions, resources, and markets. After work, he would spend time in the coffeehouse (*kafeneion*), where information was exchanged and contacts made, as well as views shared on political and village affairs. The highest value for man was “love of honor” (*philotimo*), that is, self-respect and self-assertive courage, which amounted to assertive masculinity, in all areas of social life, to protect the honor of the family.

The traditional role of the woman was to be responsible for the family inside the home. Her tasks revolved around three sets of duties: first, the duty of being a good mother, hence the tasks of nurturing and caring for the children; second, the duty of being a good housekeeper, responsible for cleaning the house, cooking, shopping, and looking after domestic animals; and finally, the duty of being a good wife, by being obedient, respectful, and submissive to her husband.

The separation of the sexes in traditional society, especially rural areas, was quite strict, even though it has lessened with modernization. A woman would keep away from public areas, which were the domain of men. Women would never enter coffeehouses or athletic clubs; similarly, they would rarely be seen passing through the central square of the village, where most male-dominated coffeehouses were concentrated. In churches, women would occupy the rear and upstairs sections, the front part being reserved for men only. Women could attain more freedom to circulate among men only when they were not considered sexually risk-bearing, i.e., young girls before puberty and elderly, no-longer-sexually attractive women (well past menopause). In these cases, women could walk in the streets more freely, pass through the central square, and converse with men. But in no case could women enter and contaminate in church the holy of holies where the altar is housed.

Women’s avoidance of public spaces related to their need to avoid sexual shame. In fact, shame-avoidance was the principal value governing all female behavior in traditional society. In his classic study of a Cypriot highland village in the 1950s, Peristiany (1965) noted that a “woman’s foremost duty to self and family is to safeguard herself against all critical allusions to her sexual modesty. In dress,

looks, attitudes, and speech, a woman in the presence of men should be virginal as a maiden and matronly as a wife.” A woman who behaves in conformity to the “code” regulating the behavior of her sex (femininity and passive modesty), is said to be an honorable woman (*timia gynaika*), whereas the one who doesn’t is without honor (*atime*), or, what amounts to the same thing, without shame—shameless (*adiantrope*). Again, honor and shame, respectively, are not restricted to the woman, but “spill over” to her family. Thus, for instance, in the case of an unmarried woman, shame taints directly the father and brothers, “who did not protect or avenge her honor.” After marriage, these responsibilities pass to the woman’s husband.

Whether father, brother, or husband, men bear the responsibility of caring for the women of the family. Indeed, this will be their conformity hallmark that regulates the behavior of their sex (“manliness and assertion of masculinity”). In both cases of non-conformity to the code of honor (“an unmanly man” or “an immodest woman”), the perpetrators are guilty not of breaking an externally given rule, but of betraying their very nature, their *physis*—because it is considered in the nature of men and women to act in those ways (Peristiany 1974).

Gender roles are taught throughout the socialization process. A study of the lowland village of Lysi in the early 1970s provides an account of the different patterns of socialization for the two sexes (Markides et al. 1978). From a very early age, in their games, boys try to imitate their father’s behavior and girls their mother’s. Until the age of 6, children are free to play in the streets and visit neighbors’ and relatives’ homes. But after this age, girls begin to spend most of their time at home, playing with their sisters or other friends, but also learning how to clean, cook, sew, and so on. As they grow older, they may be allowed to visit relatives or friends, once they have secured their mother’s consent. No such limitations apply for boys, who continue to be free to wander around and play in the streets, and to visit the *kafeneion* or other clubs and public places. Boys are encouraged to develop their masculinity as expressed through “physical courage, toughness, competitiveness, aggressiveness, and defending one’s honor,” whereas girls are taught to cultivate their femininity as expressed through “gentleness, expressiveness, responsiveness, tenderness and modesty” (Balswick 1973). The most important virtues that girls must learn are, again, those related to modesty and shame-avoidance. A girl must demonstrate that she is a virgin not only in the flesh, but also in spirit. She should avoid not only physical, but also social contact with men, because this could be associated with sexual desire. This entails accepting a number of social prohibitions, such as never to talk to a man in the street, unless he is a close relative; not to fraternize with men, and “when a man looks at her she should avert her eyes and blush; she should not laugh in front of men and if she does so, she must bring her hand in front of her mouth” (Markides et al. 1978).

If this behavior is maintained, her good name and family honor are preserved, which adds to her value as a future bride. Throughout socialization in the family and community, a girl learns to set marriage as the paramount goal of her life, since it allows her to become a wife and a mother. A woman who remains unmarried is destined to remain at the social and cultural periphery of the village, for she is not offered any role to play within the mainstream of society. Her destiny will, in fact, be to care for the elderly parents and the children of married sisters and brothers, and to engage in church-related activities.

Marriage and the creation of a family are also very important for young men, for it is only through them that they

will be considered full and mature members of society with equal rights and responsibilities. A man reaches manhood only when he marries. Until then, he is still a *kopellin*, a “lad,” which means he cannot hold any responsible position within the power hierarchy of the village.

### *Social Change, Modernization, and Gender Roles*

The roots of Cyprus’s modernization can be traced back to the beginnings of British colonialism. Prior to British control, Cyprus had been subject to Ottoman rule for approximately 300 years, during which time the land was owned by the State; the peasants had the right to use the land in exchange for the appropriate taxes. British colonialism introduced a connection between individual production and the right to private property. Peasants could now own the land they cultivated; but they could also lose it! Indeed, for various reasons, such as bad agricultural years and overspending on their children’s dowry, many peasants found themselves in heavy debt to insurers, to whom they had resorted for borrowing money, and to whom many eventually lost their land because they could not repay their mortgage.

Such destitute peasants sought employment in other sectors of the economy, namely the mines and small industries that started developing in the urban centers early on in the 20th century. After World War II, when Britain was forced to abandon her bases in the Middle East and to grant independence to India, Cyprus acquired enhanced strategic value. In response, the British constructed two large military bases on the island, at Episkopi and Dhekelia, with the resulting construction industry providing new employment opportunities. Furthermore, the increased needs of the British military and administrative personnel provided further jobs and new commercial possibilities.

During the 1950s, the final decade of British rule in Cyprus, the average annual rate of growth of the economy reached 12%, an indicator of the progress that was being achieved. Urbanization had also grown dramatically: Whereas at the beginning of British rule, the urban population was only 17%, by the time they left, it amounted to 36%. As Attalides (1981) showed in his study of social change and urbanization in Cyprus, the majority of the people who migrated to the towns were those who had no land of their own and no work, mostly unmarried men and women. Another major reason for migration was the decision to attend high school. This was because of the recognition that education provided a way out of the villages and hard toil in the fields, into “a better life” in the towns and employment possibilities in the newly created white-collar jobs.

Gradually, the urban centers became the foci of the economy as well as of social and cultural life. This, along with the emergence of a sizable urban middle class, led to a restructuring of power relations—a shift of power from the village to the city. As a result of these modernizing processes, the family underwent considerable change. Functions earlier performed by the family were gradually taken over by other institutions, even though not to the extent and with the consequences this had in the West. Thus, even though in many cases the family stopped being a production unit (as in the case of destitute peasants joining the working force in the mines or industry), in many other cases, money earned from work in the towns found its way back to the villages to help the family pay off debts and maintain its land and unity. In yet other cases, family businesses were set up in towns, so the family kept its production role in a new context (Argyrou 1996).

It is also interesting to note that, whereas in many other developing societies, urbanization led to a break-up of extended family systems into the nuclear system, in Cyprus

there was somewhat of a reversal in the process. We have noted how rural Cypriot society was characterized by a nuclear family system; urbanization, in its early stages at least, had an expanding effect, since kin members were added to the nuclear core (usually younger relatives looking for a job in town). Thus, it does not seem that modernization and urbanization negatively affected family cohesiveness and strength (Attalides 1981).

There were, however, gradual changes in gender roles within the family. Two of the most important factors leading to these changes have been education and employment. Education became an important mechanism of social mobility, advancing both the status of peasants to that of white-collar workers and improving the status of women (Persianis 1998). The first primary schools were established by the Orthodox Church toward the end of Ottoman rule. Very few girls attended these schools because women’s destiny was to marry and have a family at an early age. Besides, because there were only male teachers at the time, parents were unwilling to allow their daughters to stay in school beyond the age of 8 or 9. For the same reasons, this absence was even more pronounced in the case of the few secondary schools, which were concentrated in the towns. The first girls to attend schools came from the wealthier (bourgeois) class, which valued the cultural benefits of education, expecting their girls to be taught how to be “refined ladies,” but also to remain “modest and quiet.” It is from the 1920s onwards, the period in which we start having increasing rates of urbanization and industrialization, that we have sizable increases in student numbers, including girls. Most of these new students were children of the wealthier rural and, primarily, urban classes. The motives, henceforth, became mainly economic, because education was now considered instrumental in securing a job in the towns, in commercial shops, trading firms, banks, and similar work. Such motives were further strengthened in subsequent periods, when the economy grew at a faster pace, providing more and more opportunities for work. This was true after World War II, but especially after independence in 1960, when the service sector opened up. Cypriots thought service jobs to be more appropriate for women, since they more closely resembled their traditional roles.

The 1974 Turkish invasion brought destruction of biblical proportions to the Greek Cypriots. Almost 40% of the land came under Turkish control; a full third of the population became refugees and had to flee to the south for survival. Most of these ended up in refugee camps at the outskirts of the larger towns, creating a large new wave of “forced” urbanization. Women from such refugee families, especially of rural and working-class background, provided cheap labor for light manufacturing industries, mostly in shoes and clothing, which found unexpected opportunities for growth during this period. Furthermore, the expanded welfare and other state services, which tried to cater to the new needs, provided new opportunities for middle-class women, both refugee and non-refugee alike. The final pull was provided with the economic recovery and unprecedented boost, the “economic miracle,” in the early 1980s, which created numerous new jobs in tourism and the wider service sector.

Throughout this period, women’s employment increased by leaps and bounds, as did schooling for girls. By 1995, women’s employment was 38.6% of the total, as compared to 35.17% in 1985. In both primary and secondary education, the ratio of girls was equal to that of boys, with some marginal differences at the tertiary level, where more boys than girls study outside Cyprus, whereas more girls than boys study at tertiary institutions in Cyprus.

All these changes have obviously transformed the Cypriot family and gender roles within it, although continuity with past patterns remains strong. Mothers, especially of the younger generations, are not only "allowed," but "expected" to work. Recent research by Papapetrou and Pendekka in 1998 shows that family members believe the mother to be sensitive, permissive, and flexible toward children's demands. She is over-protective and worries a lot about her children, spending time in discussion with them, certainly more so than the father, which may explain why she demonstrates more empathy and understanding toward the children. This is seen to be related to the fact that she carries the care of the household and family, spends many hours at home, and thus has more opportunities to see each family member separately. This, it is speculated, may also provide her with the opportunity to "administer" or "rule," to know "what" and "when" something must take place. Such powers, however, are not tantamount to the role of "leader," which is reserved for the father. She is expected to work, but she is also expected to ungrudgingly interrupt her career to raise children. After all, woman's working role is seen as a secondary one, important for supplementing the family's income and not as the main breadwinner.

The father is the one considered to be really responsible for the economic well-being of the family. He is still considered to be the leader of the team and his opinions are "determinative" when it comes to "serious" matters, or matters which have an impact upon the whole family. He does very little in the house, his activity being mostly limited to heavy jobs (such as construction or repair-work) upon mother's requests. Usually, he does not spend much time at home, but prefers the coffee shop, a hobby, or a second job; when he stays at home, he usually watches television, especially news reports. He is thus seen as austere, strongly opinionated, and distant. Often he is "unexpressive," since man's socialization into masculinity (competitiveness, toughness, aggressiveness, physical courage, and defending one's honor) teaches him that expressiveness toward his wife and children is a "feminine" characteristic.

#### *Sociolegal Status of Males and Females, Children and Adults*

The traditional social and moral order has been sanctioned by the Cypriot Orthodox Church. The family is considered to be a divine institution, relations between its members being comparable to the relations between God, Mary, and the Christ Child. Icons were traditionally kept in a specific holder (*ikonostasi*) of every home, with an oil-lamp constantly burning, symbolizing the divine protection of the institutions of marriage and family.

During the marital ceremony, considered to be one of the seven "Divine Mysteries" or Sacraments through which God's grace is bestowed to humans, St. Paul's Epistle to the Ephesians is read to the newlyweds, reminding them that, in their relationship, the wife must fear her husband and be submissive to him at all times, whereas the husband must love the woman, as Christ loved the Church. Obedience, respect, and submission to husband are moral imperatives that highlight the patriarchal nature of traditional Cypriot society.

Modernization of all spheres of Cypriot life and secularization of the religious sphere have certainly brought about important changes. The 1960 Constitution of the Republic of Cyprus enshrines modern democratic ideals, including equality of men and women before the law. It also specifically prohibits any "direct or indirect discrimination against any person on the ground of his [*sic*] community, race, religion, language, sex, political or other convictions, national

or social descent, birth, color, wealth, social class or any ground whatsoever . . ." (Article 28).

Nevertheless, as has been pointed out by Stavrou (1998), the patriarchal "logic" lurks behind some of the provisions of the supreme legal document of the country. For instance, in determining the ethnic community to which a citizen should "belong," after marrying someone from the opposite community (i.e., a Greek Cypriot marrying a Turkish Cypriot or vice-versa), the Constitution clarifies that: "A married woman shall belong to the community to which her husband belongs." Similarly, in the case of children under the age of 21 who are not married, a child "shall belong to the community to which his or her father belongs . . ." (Article 2: Par. 7).

This patriarchal logic pervades other sociolegal institutions and respective provisions or regulations. Thus, if an alien man marries a Cypriot woman, he does not automatically acquire Cypriot citizenship, unless he fulfills almost all the conditions that any other alien must fulfill in order to acquire citizenship. If, however, an alien woman is married to a Cypriot man, she thereby acquires his residence as well as his domicile.

While there are often no specific laws determining discriminatory social practices, traditional norms and values may produce such outcomes. For instance, there is no legal provision that regulates the name the parties in a marriage should assume. "The practice, however, as has been customary throughout much of the European Christian world, is that upon marriage a woman takes her husband's family name. Also, the children take their father's family name except in the case of illegitimate children, who take the name of the father of their mother" (Stavrou 1998).

In many other instances, the laws may provide for equality and prohibit discrimination, but traditional institutions and practices may still prevail. A most glaring case is that of divorce, traditionally governed by Church law, which entails different divorce provisions for husband and wife. Two reasons that may be invoked only by the husband as against his wife are: First, that the wife was found not to be a virgin on the night of the wedding, which has to be reported to the local Bishop the next day; second, that the wife spent the night with persons unrelated to her (unless she could not find a relative's house to stay for the night, after being ousted from the home by her husband).

The Constitution perpetuated these unequal provisions by declaring marriage and divorce matters as the domain of the Church. It was much later, when Civil Marriage Law 95/89 amended the relevant article of the Constitution, to allow free choice of civil weddings for Greek Cypriots, and to place matters such as divorce, judicial separation, and family relations under the governance of special family courts. The Church of Cyprus reacted strongly against these legal changes and exerts all kinds of pressure in order to retain control of the institution of marriage. Until today, the Church insists that civil weddings are illegitimate and refuses to offer perpetrators the services of baptism and other holy sacraments. These pressures by the Church, but also (and perhaps most importantly), the weight of long-adhered-to traditions, explain why the vast majority of Cypriots (more than 70%) still choose religious, instead of civil weddings. Indeed, civil marriages between Cypriots account for only 3.6% of total marriages.

A similar situation prevails with divorce. The procedures for securing divorce through the Church are not only long and laborious, but they are also much more exacting and discriminatory against women. Nevertheless, because of the Church's pressures and the special weight of adhered-to traditions, most Greek Cypriots prefer to put up with the difficulties of Church divorce instead of resorting to civil

divorce. They are afraid of getting themselves entangled into a web of socially difficult or embarrassing situations. For instance, should one wish to remarry in church after a civil divorce, one may find oneself accused of attempting bigamy!

Interestingly, on the issue of abortion, women's span of control or available choices seems to be much greater than in many other countries, even of the developed West. This seems to have to do as much with historical circumstance as with current social realities. Up to the early 1970s, the Criminal Code completely prohibited the practice and provided severe penalties for perpetrators. Developments related to the 1974 Turkish invasion drastically changed the situation when many Greek Cypriot women became pregnant after being raped by Turkish soldiers during the hostilities. Obviously, Greek Cypriot society was not ready to accept the offspring of the "barbarians" into its midst. Many Greek Cypriot men found it difficult enough to accept the raped women themselves, who were violated or "shamed" publicly. Even though the women resisted this violation of their bodies, the public consequences of the rape indirectly brought shame on their families, and especially on their men. As a consequence, the relevant law was radically amended to allow medical intervention for the termination of unwanted pregnancy in such cases. In addition, a provision was made for pregnancy to be terminated if two doctors advised that the life of an expectant mother would be in danger should pregnancy be allowed to continue, or in cases in which a newborn baby would face the risk of serious physical or mental disability.

These loopholes in the law effectively opened wide the doors for abortions under almost any pretext. Although hard data are not available, there are many indications that a large number of abortions are carried out in modern-day Cyprus. This may appear strange for a society that is still quite conservative on a number of other counts. Even stranger is the fact that there hardly appears to be much anti-abortion talk from any quarters, let alone an anti-abortion movement. Finally, the Church, though in theory opposed to all forms of abortion, seems in practice to be only paying lip service to a cause it does not really care to fight for. One suspects that the main reason for this is that the Church cares mostly to control not the private decisions, but the public behavior and choices of Greek Cypriots, since it is the latter which serves as an index of its power.

Obviously, the historical circumstances, outlined earlier on, explain to some extent why abortions were initially "legalized," and why, consequently, once the legal prohibition was removed, the door was opened for abortions for all kinds of reasons. But why did the phenomenon grow to much larger proportions? It seems that social change and new realities in contemporary Cyprus account for the remaining part of the answer. Indeed, in recent decades there have been fast-paced and drastic socioeconomic changes, which seem to have eroded traditional values and norms without allowing the time for new norms to develop—the phenomenon of "cultural lag." This is evident in the area of sexual relationships. Many young people are experimenting with sex in their relationships, something that contemporary "open" or "liberated" Cypriot society seems to "allow." Yet the relationships of these young people with their parents (and teachers) do not seem to be so liberated as to allow for straight talk about sex and contraception—thus the many unwanted pregnancies and the use of abortion as an alternative to contraception!

Besides the young, many older people have problems with their marriage; hence the increasing rates of divorce. Both young and older couples also seem to be resorting to

relationships outside marriage, which may again lead to unwanted pregnancies and abortions.

To the above must be added the fact that Cypriot males, and sometimes their women partners, seem to think that male contraceptives will somehow render lovemaking "less natural" and enjoyable. Thus, contraception ends up being the sole responsibility of women. And if she has not taken the necessary precautions, they end up with unwanted pregnancies and abortions.

The ease of abortions may be an important explanatory factor for the fact that children born out of wedlock are rarely found in Cyprus. To this, of course, we must add the prevailing conservative traditional values, which view unmarried mothers as immoral, since they are seen to be flagrantly violating the sexual code and carrying the "shame of dishonor." Because stigma is a certain outcome for child-bearing outside wedlock, and because abortions are so easy to arrange, it is no wonder that illegitimate births are almost nonexistent.

Cyprus has, in fact, introduced legislation (Law 243/90) to bring itself in line with the provisions of the relevant European Convention. An interesting example, which highlights all the above issues, concerned a case in the mid 1990s of an unmarried woman working in the Church-run broadcasting station (Logos). When she decided to go against convention and not hide the fact that she was pregnant, she was soon fired, as she was seen to be a case of embarrassment for her employer and a bad moral example for all. The fired woman sued the station and managed to win the case and be awarded compensation (*Fileleftheros*, 9 May 1995).

Another recent law, which aims to protect women from the abuse of traditional norms, relates to the Prevention of Violence in the Family and the Protection of Victims of Violence (47(I)/94). Such a law was of absolute necessity in Cyprus, where many men consider it their legitimate right to uphold their power as husbands and/or fathers in the family through any means possible, including violence, whether it be physical or psychological violence against the wife and children, or sexual violence against the wife.

### *The Sociolegal Status of Men and Women in Work/Employment*

For many years, women in the labor force suffered various forms of discrimination as regards inequality in pay for similar work done, conditions of work, type of employment, and opportunities for advancement. Gradually, as a result of a number of factors, such as pressures from women's organizations and the trade unions, and political pressures emanating from the signing by the Cypriot government of various international treaties, the situation has substantially improved, at least as far as legal provisions are concerned. This has not, however, substantially improved the situation for all women, nor has such legal improvements dramatically improved the life of women.

A good example is that of social insurance legislation, enacted since independence, which provides for a marriage grant payable to working women when they marry, as well as a maternity grant and allowance, the former paid to a woman giving birth, the latter paid during a maternity leave of up to 12 weeks. Unfortunately, the plan does not cover self-employed women or unpaid family workers in agriculture, who comprise approximately a third of the total number of economically active women. Furthermore, it does not cover thousands of women involved with unpaid housework, as this is not considered "proper" work. This means that a great number of Cypriot women, particularly older women, have to remain in a state of complete dependence on their husbands. Social insurance legislation has been

modified appropriately, after ratification of the International Labor Organization Convention 100, and the Equal Remuneration Law (158/89), to provide for equal pay for men and women for work of equal value. This has decreased the gap between male and female wages, although it has certainly not closed it, since equal remuneration is practiced only by the government and a few large corporations, mainly banks, but certainly not by the private sector at large. Among the laws that seek to improve the legal position of women in employment is the "termination of employment" law (24/87), under which sex, pregnancy, or maternity can never constitute reasons for the termination of employment. Again, however, evidence shows that many employers tend to ignore the law, and that in such cases few women proceed to take legal measures against the perpetrators (Varnavidon & Roussou 1995).

Another interesting example, which illustrates how small an effect changes in laws can have on actual social practices, is the abolition of the pre-independence law (180), which prohibited the employment of women during the night. For many years following abolition of this law, social resistance to the idea of women working outside their homes during the night has been such that few women still dare to do so. The result has been an intense shortage of women working in jobs for which night duties are essential, such as nursing and paramedical occupations. For this reason, private clinics have been given permission to employ women from foreign countries. Also, Cypriot women employed in the Cypriot Police Force and the National Guard, as well as those working in the thriving tourist industry, are exempt from night duties.

Lastly, we should underline the fact that in 1985 the Cyprus government ratified the United Nations Convention (34/180) on the Elimination of All Forms of Discrimination Against Women (Law 78/85). This symbolized Cyprus's commitment to eliminate all forms of discrimination against women in all spheres of life, be it education, politics, employment, family, or public life.

In summary, two major comments could be made about legislative change and its impact on Cypriot society. To begin with, most ratifications of international conventions and relevant laws were passed in the recent decades, after independence in 1960, but mostly after 1974. This suggests that, until recent times, concerns about equality and the protection of the rights of various underprivileged groups in society, including women and children, were not a primary issue, because traditional Cypriot society was based on conservative norms, values, and morals. Cypriot life revolves around the central social institution of the patriarchal family, with the father enjoying controlling power over the behavior of the other members of the family, especially women, as the preordained "order of things," legitimated by religion.

Modernization and socioeconomic change have contributed to an "opening-up" of society and the gradual espousal of more liberal values and norms. Thus, the introduction of the various laws outlined above. Yet, it seems that Cyprus is going through a period of transition, in which new values coexist with traditional ones. This, as well as the efforts of traditional male and clerical power holders to cling to their powers, seems to explain the persistence of inequality between the sexes and generations.

Women themselves have been slow to organize and push for their rights. Traditionally, the main domain of women's participation in public life has been that of voluntary institutions, especially charitable organizations. This is true especially for upper- and middle-class women, the roots of the phenomenon dating back to the formative stages of the bourgeois class in Cyprus and its ideals of keeping women away from the world of production, as "queens" in the private

realm of the family, into which men would retreat after work. Women's involvement with charitable institutions was accepted and encouraged, because, in dealing with these, they could expend similar "feminine" services as the ones expended within the families themselves, namely care, love, and affection (Peristianis 1998). Voluntary organizations, and especially charitable ones, seem to have increased in numbers after the Turkish invasion of 1974, with the appearance of new social groups in need of support (Antoniou 1992). Interestingly enough, the leadership of most of these organizations is composed of men, with the exception of a handful of organizations, such as the Cyprus Red Cross and the Association for the Prevention of Violence in the Family.

Women from the working classes had a more prominent role in the trade unions, which started organizing early on in the 20th century. The oldest such union, PEO (Pancyprian Federation of Labor), is controlled by AKEL, the communist party of Cyprus. SEK (Federation of Cypriot Workers) is controlled by DISI, the right-wing party, and DEOK (Democratic Workers Federation of Cyprus), is controlled by the socialist party, EDEK. There are also strong autonomous unions representing government employees (PASIDI) and bank employees (ETIK).

In the labor history of Cyprus, women have fought alongside men for basic labor rights, such as social insurance, improvements in wages, and shorter working hours (Pyrgou 1993). However, trade unions do not appear to have actively pursued women's rights for equality in the labor market. In fact, trade unions have accepted pay discrimination against women in labor agreements with respective employers (House 1987). It is interesting that the first law (in 1961), which provided for equal pay for women in the public sector, was enacted, not after trade union pressure, but as a result of a private prosecution by a woman employee who sued the Republic of Cyprus for not upholding the Constitutional Law's provision for equal treatment of the sexes.

Cypriot women have never gone on strike in pursuit of their specific rights as women. One possible reason for this may be the fact that, whereas all unions have departments dealing with women's matters, policymaking of these departments is directed by men (Antoniou 1992). Overall, although women constitute more than a third of the total trade-union membership, they seem to exert little influence of their own.

A contributing factor is obviously the control of all general unions by the political parties, who are, once again, male-dominated, and whose primary objectives have to do with furthering their political ambitions. Even more surprising is the fact that women's organizations themselves seem to be controlled or strongly affiliated with political parties. Thus POGO (Pancyprian Organization of Women) is controlled by the communist party; Equal Rights and Equal Responsibilities is controlled by the right-wing party. The Socialist Feminist Movement and the Women's Organization of the Democratic Party are even more forthright in declaring their affiliation in their own names.

For decades now, the primary focus of concern for the political parties has been the ethnic conflict between Greek and Turkish Cypriots, "the Cyprus Problem." This has overshadowed all other issues, including those concerning women, equality of the sexes, and gender relations. Even though the higher officers of these women's organizations have the opportunity to participate in the decision-making processes of the political parties, their voices are seldom strong enough to make a real impact, as the leading teams are always male-dominated. This becomes even more obvious in times of elections, as women candidates seldom, if ever, make it on parties' lists. Because of prejudices and

stereotypes, hardly any women who do make it onto ballots manage to attract enough votes to enter the House. In 1999, there were only three women members out of a total of 53 members. Women seem to do somewhat better in local government, where they appear to be increasing their numbers yearly. Of course, these posts hold negligible political power, so women's gains in this area do not amount to a serious improvement in their status or impact.

### *General Concepts and Constructs of Sexuality and Love*

In traditional Cypriot society, marriages were arranged by parents and had nothing or little to do with the personal preferences of the young people involved. Often a young man coming of wedding age would suggest to his parents a particular girl of his fancy (usually a girl he found attractive in external appearance but had little knowledge of—since girls were expected to practice “male-avoidance,” in order to protect their reputation and honor). If the parents approved of their son's choice, they would proceed to sound out the parents of the girl, usually through the services of a mediator/matchmaker. If the parents disapproved of the choice, their objections usually prevailed, as they were supposed to “know best” because they were “older and more experienced.” Obviously, the girl's opinion was rarely asked for and her freedom of choice was much more restricted than the young man's.

The paramount criteria for parents' preferences had to do with considerations of their family's best social and economic interests—thus, they had to be satisfied with the economic well-being of the girl's family, the status of her family in the social hierarchy of the village, as well as the moral reputation/standing of the girl and her family in the village. Obviously, a good choice for marriage would enhance both the material resources as well as the status of their family in the village community. Parents would give a “dowry” to the young couple as a material aid to help the newlyweds make a good start in their married life. The bride's family would usually contribute the house plus furniture, kitchen utensils, household linen, and similar items. The bridegroom's side would provide some land and animals. Attalides (1981) notes that marriage settlements imply a bargaining process of matching the assets brought to the new household by the respective partners. Moreover, the practice of giving equal inheritance to all children means that parents must be aware so that what they give to one child at the time of marriage does not jeopardize the share of any remaining children. “In this situation, it is understandable that control of premarital sexuality should be extremely strict for girls.” Thus, if a girl acquires a “bad reputation,” the bargaining power of a potential husband is enormously increased, allowing him the chance to make “virtually extortionate demands for a property settlement, thus incapacitating the domestic group from provision for further children” (Attalides 1981). Of course, property considerations were only one set of reasons for the adherence to a strict moral code of behavior for women, but they were surely an important set.

The above constitutes one more set of reasons why families had to always be vigilant of the reputation of their women. Young women had to maintain their chastity until their wedding day. If a woman's sexual purity was questioned, she risked her chance of ever marrying. Virginity was a necessary condition of a woman's moral integrity and the principal prerequisite for marriage. It should be remembered that virginity did not entail only the “physical purity of a girl,” i.e., an “intact hymen,” but implied that “the girl should avoid any social contact with men that is automatically associated with sexual desire” (Markides et al. 1978).

So important was the value of female purity that during wedding celebrations, the visual display of the bloodstained sheets, proving the bride's virginity, had central importance. It has been noted (Argyrou 1996) that the virginity rite “expressed female subjugation but also the wider subjugation of younger people of both sexes to their elders and in particular their parents,” for the rite symbolized in a “tangible and indisputable way” that the parents had been managing and controlling the family well. Argyrou (1996) demonstrates how changes to the rite, leading to its disappearance, reflect changes in the power relations between the older and younger generations, as well as between the sexes. The first set of changes became visible in the 1940s, when new employment opportunities were created, giving young men the opportunity to move to the towns for jobs. The sons of wealthier parents moved to towns in order to obtain secondary education. Eventually, with mass education, this became true for all classes and for both sexes. Youngsters were now exposed to new ideas and values through books, magazines, and newspapers. Overall, opportunities for economic independence and education decreased the dependence of the young on their parents and eroded the latter's authority and powers of control, as children could be more knowledgeable or competent than their parents in some areas.

Other developments also contributed to the changing nature of power relationships between generations. For instance, a young man moving to a town often found it practical to stay with his in-laws, so that his fiancée and mother-in-law could look after him and he could also save money to contribute to the costs of building a house. This practicality made vigilant observation of the engaged youngsters difficult for the parents. It also meant that parents themselves chose to avoid the embarrassment of asking for evidence of a bride's virginity, whereas the couple itself increasingly considered the matter their private affair rather than a public spectacle. By the late 1960s and 1970s, “the practice of having fiancées move in with their in-laws became generalized” and “engaged youngsters were sleeping together with the parents knowledge and implicit consent.” Loizos (1975) notes that, in fact, by the 1960s, “youngsters had acquired power to veto their parents' choice of marriage partner.” Balswick (1973) points out that by this time, young people considered “romantic love” to be of primary importance, and this development was responsible for the challenging of parentally arranged marriages. The concept of romantic love was related to changing sexual standards. For if love was felt to be a prerequisite for marriage, then only the young people themselves could determine the existence of love, and this entailed a certain amount of familiarity with members of the opposite sex. Thus “dating” started becoming common.

Such developments cannot be taken to imply that youngsters have now been liberated from traditional values and that virginity and female chastity are no longer important to men. In fact, as Argyrou (1996) reminds us, what has changed has mostly to do with the “timing of sexual access to the bride.” Furthermore, the traditional “double standards,” requiring a woman to be a virgin until she marries but not so the man, are still prevalent in Cypriot society. Similarly, although some expected that modernization and romantic love would lead to the demise of the dowry system (Balswick 1973), the practice seems to be going strong with some minor changes. Nowadays, the bride's parents are still the ones who contribute to the house and most other items needed for setting up the new household. The groom's parents are expected to have invested considerably in their son's education, which will have led, or hopefully will lead in the future, to very good employment.

After 1974, with the displacement and impoverishment of a third of the population, who lost all their wealth and became refugees so they could not give any dowry to their children, the tradition suffered a setback. However, traditional values and expectations were so strong that the state was pushed to donate land or money to all unmarried daughters of refugee families as a form of dowry for establishing their own households in the free south. Besides, the economic recovery and boom after the 1980s has enabled Cypriots to continue with the practice (Stavrou 1992). Some analysts point out that the willingness of Cypriot parents "for deferred gratification" in order to invest in their children's dowry, may actually itself be one of the main reasons for the continued success of Cyprus's economy (Balswick 1973, Mavratsas 1992). The above realities may account for an interesting paradox, revealed by social surveys. On the one hand, young Cypriots claim that love is what is important in marriage and that the giving of a dowry is an outdated practice that they do not believe in. On the other hand, they say that parents should "help" with a house and in other ways so the young couple can make a start in life (Intercollege 1996). This seems to vindicate Argyrou's (1996) position that we are looking at developments in sexual mores and related practices, which are the result of "a struggle in which children won a dominated freedom and parents retained partial control through compromise."

## B. Religious Beliefs Affecting Sexuality

In Cypriot society, the religious attitudes and beliefs of the Greek Orthodox Church exercise a strong influence on the sexual attitudes and behavior of the people. Some insight into this factor can be gained from the responses of Greek Orthodox priests to a semi-structured questionnaire regarding seven sexual topics: a) adultery, b) premarital sex, c) masturbation, d) abortion, e) contraception, f) homosexuality, and g) coital abstinence. There were 130 (23.2%) responses from the total of 560 questionnaires distributed to all priests on the island, followed up with face-to-face interviews of 27 of the priests (Georgiou 1990).

On the issue of premarital sex, the priests were asked for their pastoral response to the following "situation":

A young, engaged Christian couple who has been cohabiting for three years is very much in love, but they cannot marry immediately as they have a number of difficulties. As they do not want to have sexual intercourse before the marriage ceremony, but are involved in heavy petting, they approach a priest for advice. (Georgiou 1990)

For their pastoral advice, the priests chose the following:

- to separate immediately (0.8%)
- to stop all caring gestures (5.3%)
- to stop all passionate caressing that lead to sexual excitement (22.3%)
- to continue as they are now until they get married (21.5%)
- not to the cohabit together, and (8.5%)
- something else (32.3%)

A thematic analysis was performed using subjective responses based on 14 mutually exclusive general categories. The responses were: The couple:

- should get married immediately, no matter what (32.6%)
- should refrain from sexual intercourse until they get married as soon as possible (19.7%)
- should refrain from heavy petting (19.7%)
- should live in separate houses or sleep in separate beds (18.2%)
- should be reminded that sex outside marriage is considered a sin of fornication (15.9%)

- should continue as they are until they get married (14.4%)
- should get married after a very brief engagement, otherwise problems are inevitable (6.1%)
- should use the engagement as a time to know each other, allowing their relationship to mature until marriage, before having sexual intercourse (5.3%)
- could proceed with their committed relationship and have sexual intercourse (2.3%)
- should read religious literature to help them overcome their passions (1.5%)
- should not consider their sexual relationship sinful, since their goal is to get married (0.8%)
- should realize that there is a danger that they will have an abortion if they have sexual intercourse (0.8%)
- should separate immediately (0.8%)
- it is not the job of a priest to advise how an engaged couple should behave sexually (0.8%)

Face-to-face interviews with the 27 priests revealed what appeared to be a confused attitude toward premarital sex. They offered a variety of legalistic definitions of premarital sex, which dichotomized sexual acts into "acceptable" or "not acceptable." Some, for example, drew the line of "acceptability" at light kissing between a couple engaged to be married. Others drew the line at a light caress, rejecting all other sexual expressions as either unacceptable or sinful, and so on and so forth. There was also no consensus as to why premarital sex was a sin. The majority said that it was a sin because the Orthodox Church said so. None of the priests, however, could refer to any specific writings of the Orthodox Church to validate their claim. (See other responses from this survey of priests on homosexuality in Section 6B, on contraception in Section 9A, and on abortion in Section 9B.)

## 3. Knowledge and Education about Sexuality

### A. Government Policies and Programs

There are no specific government policies and programs for sex education. There are no formal sex education programs taught in schools beyond the biology lessons, which cover subjects such as the anatomy and physiology of the reproductive organs, fertilization, twins and genetics, sexually transmitted diseases, changes during puberty, and birthing. These lessons are normally taught by biology teachers, and it is left to their discretion to answer specific questions that may be raised in class. These lessons are taught from the age of 15 upwards.

### B. Informal Sources of Sexual Knowledge

There is an element of informal sex education from organizations such as the Family Planning Organization, but this only covers specific groups of people, such as married women seeking gynecological or family planning assistance, soldiers doing their National Guard service, and other minority groups. There is also some teaching in hospitals and schools, but limited staff does not allow for further expansion.

When the main author arrived on Cyprus from the United Kingdom in 1983, there were no explicit sexual articles published in the Cypriot media for fear of reprisals. I wrote my first article on Cypriot male sexuality during this period, but found it impossible to find an editor willing to publish it in their newspaper, as it contained words such as "penis" and "vagina." There seemed to be an inherent fear of publishing sexual articles of any nature, as the editors believed that there would be a volcanic eruption from the Church and the conservative people of Cyprus. They could not have been further from the truth! When a brave editor of a relatively small, radical right-wing newspaper decided to

publish the article, there was applause from many sectors of society; one of the long-lasting, but superfluous taboos had been broken! Cypriots were thirsting to learn more about sexuality. After the newspaper editor's initial enthusiasm, I proposed a weekly column, which would allow people to write in their problems anonymously and receive replies in the newspaper. He agreed, and the first sexual column in the history of Cyprus was launched in 1984 in the newspaper *Alitheia (The Truth)*. The sales of this particular small newspaper increased dramatically in just over a year!

The degree of sexual ignorance from the questions being received was apparent: "Can I get pregnant by swallowing sperm?" "What is the clitoris?" and many, many other questions touching on topics such as anal sex, transvestitism, telephone sex, and sexual problems. At least a dozen letters were received every day. The columns gave people from all age groups and all walks of life an opportunity to write their questions or problems about sexuality, and get a response published in the media for all to read. The weekly column in the popular magazine *To Periodiko*, which ran from 1984 to 1994, reached a peak audience in excess of 30,000 people weekly. More than 1,000 articles covering all aspects of sexuality were published during this period. This, along with a weekly radio program titled *Human Sexuality*, broadcast live every Saturday at lunch time by the author, covered a wide variety of sexual topics and provided a large part of the informal sex education of the population. After a few years, other newspapers began to publish articles, usually translated from foreign magazines. Beginning in September 1999, this editor completed a series of six television programs on human sexuality for EF-EM, a local TV station in Larnaca. (See Section 10, Sexually Transmitted Diseases, for survey data on the knowledge of adolescents regarding STDs.)

In the Knowledge, Attitudes, Beliefs, and Practices (KABP) Survey on AIDS (Georgiou & Veresies 1990, 1991; see also Sections 5B, Interpersonal Heterosexual Behaviors, Adolescents, 6A, Homoerotic, Homosexual, and Bisexual Behaviors, Children and Adolescents, and 10A, Sexually Transmitted Diseases and HIV/AIDS), 3,176 15- to 18-year-old schoolchildren gave us additional insights into their sources of sexuality information. The respondents reported receiving their first sexual information from five main sources: books and periodicals (24.1%), newspapers and magazines (15.4%), friends (12.0%), videos (12.3%), and television (12.2%). It is not clear from the questionnaire, however, who is actually providing this information in the sources mentioned. Sex differences showed that the boys were more likely to obtain their information from videos (9% vs. 3.3%), probably commercial pornography, while the girls were more likely to obtain their information from books and periodicals (14.7% vs. 9.4%) and mother (4.4% vs. 0.6%). It appears that newspapers and magazines are read equally by both. Subsequent sources of additional sexual information included: television (13.2%), schoolteachers (12.3%), and medical personnel (11.7%). The same-sex differences as those noted above emerged, with the exception of books and periodicals, which are again read equally by both sexes.

When asked, "Where would you prefer to get information about human sexual behavior? (Circle only your first choice)," the great majority of respondents preferred to obtain their information from books and periodicals (24.1%), followed by newspapers and magazines (15.4%), friends (12.6%), videos (12.3%), and television (12.2%). All the other responses were below the 5% level.

It should be noted here that there are no known sex education videos circulating in Cyprus, apart from the commercial pornographic videos that are freely available for rental in most video shops, certainly before the clamp-down on piracy

came about. It therefore appears that 12.3% of the respondents are obtaining their information from pornographic videos. When asked to name their second preferred source of sexual information, students listed books and periodicals (16.1%), newspapers and magazines (14.2%), television (13.7%), videos (12.7%), and friends (11.4%). The remaining responses were below the 5% level. Sex differences showed that more males than females would prefer the radio as an important second source of sexual information (108 males vs. 46 females), newspapers and magazines (105 males vs. 70 females), television (224 males vs. 194 females), and videos (111 males vs. 38 females). More females than males would prefer sources such as books and journals (153 females vs. 137 males), mother (191 females vs. 56 males), and doctors and nurses (226 females vs. 143 males).

The survey gave no information regarding the specific books, videos, and magazines that students used, or how accurate the sex information was. Moreover, it is not clear how the students interpreted the question, "From where do you get information about human sexuality?" in a country where human sexuality courses have never been taught formally at school. Under the circumstances, the concept of "human sexuality" may be a difficult one for teenagers to interpret.

#### 4. Autoerotic Behaviors and Patterns

##### A. Children and Adolescents

The only data available on child and adolescent autoerotic behavior comes from retrospective histories taken with a clinical sample of 840 patients whom the main author saw in clinical practice between 1993 and 1996. While male masturbation in this sample is far more prevalent than female masturbation (85% vs. 15%), approximately 50% of masturbating females felt guilty about this behavior compared with 48% of males.

It appears that parents also have fears of the female losing her virginity if she is allowed to "play about down there!" Virginity is related to the "honor" (*timi*) of the family, and this is very carefully guarded. Males, on the other hand, are often encouraged and "cajoled" to continue, if they are caught fondling their genitals in infancy, as this is seen as a normal part of growing up. Given that the females get rather negative messages when caught masturbating, and indeed may be chastised for this behavior, then it is perhaps not a surprise to find that only 15% of the females in this sample masturbated.

Still, it may be a little surprising that such a large number of Cypriot girls begin masturbating at such a young age, before age 10. One of the factors is certainly the early growth spurt that females have in relation to boys, but there are probably other explanations also. Most males learn how to masturbate from their friends (77%) compared to only 26.5% of females. The majority of girls, however, learn to masturbate by themselves, through experimentation or accident (54%), compared to fewer boys (21%) that learn in this way. Again, more girls (19%) learn to masturbate from the media, books, magazines, and the like, compared to about 2% of boys. It appears that girls tend not to talk as openly as boys do with their peers about masturbating, and therefore, this is not the source of their information. Girls, it appears, prefer to find their sexual information from books and magazines, and self-experiment in the privacy of their own home.

The main author's clinical experience has shown that there is a widely reported incidence of childhood masturbation from infancy to nursery-school age. These cases are often reported by parents and are accepted by parents and caretakers if the child is male, and it is often joked about: "He's as potent as his father. Look, he's started young." If

the child is female, such behavior is often frowned upon, with punishment as a consequence if it continues. Over the last decade, I have had a number of parents coming to the clinic to discuss the “normality” of their young infant daughter’s masturbatory behavior, sometimes in horror that their little “innocent” should be capable of such “disgusting” actions! I have yet to see a parent come to discuss their son’s masturbatory behavior!

## B. Adults

There are no data available for adult masturbation, but from anecdotal evidence in clinical practice I would say that adult masturbation in a stable relationship is quite rare for both sexes. There are the few occasions when masturbation is reported by a married man who has problems approaching his wife sexually because of marital discord, but this occurred in less than 1% of the clinical population. I believe that the Cypriot male views masturbation more as a “child’s thing,” and not the sort of thing that a “man” does, unless compelled to do so by circumstances.

Women, on the other hand, will often refuse to masturbate even when the husband is in therapy, believing that coitus is the “proper thing.” They prefer not to become part of the therapy until it reaches a stage where coitus is allowed. It follows from this that the treatment of anorgasmia using the traditional European or American treatment protocols is doomed to failure in Cyprus, as masturbating to orgasm is the essence of this therapy. (In Cyprus, one has to be a very creative sex therapist to succeed!)

## 5. Interpersonal Heterosexual Behaviors

### A. Children

No data have been gathered to date regarding children’s sexuality or sexual rehearsal play in Cyprus.

### B. Adolescents

The only systematic survey that has been conducted to date in Cyprus regarding adolescent sexuality involves a sample of 3,176 (1,528 male and 1,643 female) Cypriot lyceum students conducted by Georgiou and Veresies in 1990 and 1991. The Knowledge, Attitudes, Beliefs, and Practices (KABP) Survey was organized and completed along the lines of work carried out by the World Health Organization (WHO), the Global Programme on AIDS, the Social and Behavioral Research Unit (SBR), the Cyprus National AIDS Committee, the Ministry of Health, and the Ministry of Education in Cyprus. The whole project was headed by the main author of this chapter as the WHO Principal Investigator.

Even though the premise of the research was to look at the knowledge, attitudes, beliefs, and practices of Cypriot adolescents toward HIV infection and AIDS, many of the 177 questions in the survey touched on other aspects of human sexuality. There were two questionnaires, one for high school adolescents and another for head teachers. A multistage random-cluster sampling strategy was used to obtain data for the survey, using 27 schools—20 (79.2% of the sample) in urban areas and 7 (20.8%) in rural ones. The 177-question survey was answered anonymously, and covered the following areas: sociodemographics, sources of information on AIDS, knowledge of AIDS, attitudes and beliefs about AIDS, attitudes toward people with AIDS, knowledge of sexually transmitted diseases (STDs), leisure-time activities, perceived norms in certain health-related behavior, drinking and drug abuse, attitudes about condom use, and sexual behavior.

### *Adolescent Attitudes and Behavior*

*Previous Heterosexual Experiences.* Students were asked to respond to a series of questions about individual behaviors

ranging from hugging to anal sex. Even though hugging, deep kissing, and petting are not considered sexual activities through which HIV is transmitted, they are often enough preliminary steps toward sexual intercourse. Therefore, the percentage of young people engaging in them indicates when these steps toward more-advanced sexual activity are first taken (see Table 1).

Three quarters of the adolescents (76.7%) surveyed have experienced hugging at least once. Of these, the majority were boys (1,340 boys vs. 1,075 girls). One in six (15%) of the boys and one third (32%) of the girls were “sexually inexperienced,” not having engaged even in petting. About half of the students have experienced deep open-mouth kissing and some sort of petting above the waist. Again, the majority of these were boys (963 boys vs. 439 girls). About one third have petted below the waist (850 boys vs. 289 girls) and a further one third have slept together without sexual intercourse (628 boys vs. 242 girls). Sexual intercourse was attempted by approximately one quarter (18.6%) of the students (550 boys vs. 97 girls), which means that about 94% of the girls and two thirds (66%) of the boys were technically still virgins, even though they may have had other sexual experiences.

Judging from the figures for sex differences, it appears that the boys are not having sexual intercourse with the indigenous females. This raises the question of who their sexual partners are. Is it mostly with prostitutes, either local girls or imported “artists,” or is it with tourist girls? This data does not answer these questions, but they are definitely worth further investigation because of the implications for HIV transmission.

A further 25% of the respondents reported experiencing oral sex at least once (563 boys vs. 103 girls).

There is no doubt that the most dangerous sexual activity in terms of contracting HIV is receptive anal sexual intercourse. Masters, Johnson, and Kolodny (1988) point out that the risk from a single episode of anal intercourse with an infected partner is considerably higher than with other sexual activities—probably on the order of one in 50 to 100. Just over 15% of the respondents reported experiencing anal or rectal sex. Of these, the majority were boys (424 boys vs. 41 girls). It would certainly be worth investigating further whether the boys had homosexual or heterosexual anal intercourse, whether they had used a condom, and whether they were the receptors or the penetrators. It is also not clear why there should be so many boys participating in anal intercourse. If a large majority of girls were involved, this would be understandable, given the patriarchal attitudes that prevail in Cyprus regarding the preservation of a girl’s (“technical”) virginity. Perhaps the males are using anal sex as a means of birth control.

**Table 1**

**Sexual Behaviors with the Other Sex  
for 14 to 18-Plus-Year-Olds**

	Never	1-2 times	3-6 times	7 or more
Hugging	23.3	26.7	13.2	36.2
Deep (open mouth) kissing	47.5	20.4	8.9	22.7
Petting above the waist	54.5	19.0	8.2	17.2
Petting below the waist	63.1	12.8	6.3	16.9
Sleeping together (without sexual intercourse)	71.9	13.3	5.0	9.1
Sexual intercourse	78.5	7.2	3.9	7.5
Oral sex	75.2	8.2	4.2	8.5
Anal (rectal) sex	84.4	8.0	2.3	4.4

Among the 19.4% of respondents reporting having had vaginal intercourse, 11.7% (296 males and 75 females) reported having had one or two sexual partners, 4% (123 boys and 5 girls) between three and six partners, and 3.7% (115 boys and 4 girls) admitted to seven or more partners.

**Table 2****Age at First Sexual Intercourse Experience**

Age	Percentage	Number of Males Versus Females		
Under age 11	4.2%	123 boys	v.	11 girls
Age 12	1.3	37 boys	v.	4 girls
Age 13	2.1	63 boys	v.	3 girls
Age 14	4.7	145 girls	v.	3 girls
Age 15	5.5	154 boys	v.	22 girls
Age 16	4.2	96 boys	v.	38 girls
Age 17	0.7	8 boys	v.	15 girls
Age 18-19	0.6	14 boys	v.	4 girls

**Table 3****Reasons Cited for First Sexual Intercourse**

	Number Citing	Boys	Girls	Percentage
I have not yet had intercourse	2,275			71.6%
Love for the person	232	160.0	72	7.3%
Physical attraction	162	152.0	10	5.1
Curiosity	106	100.0	6	3.3
To maintain a relationship	99	88.0	11	3.1
Got carried away by passion	72	64.0	8	2.3
It was expected by friends	23	0.7		
I was physically forced	13	11.0	2	0.4
Under the influence of alcohol or drugs	9	0.3		
Loneliness	4	0.1		
Other	99	55.0	26	3.1

**Table 4****Frequencies of Coitus with Different Partners**

	Freq.	Percent
Cypriot your age whom you have recently met	146	4.6%
Tourist your age whom you have recently met	249	7.8
Cypriot your age whom you have known a long time	434	13.7
Tourist your age whom you have known a long time	195	6.1
Cypriot you had recently met who was much older than you	111	3.5
Tourist you had recently met who was much older than you	132	4.2
Cypriot you had known a long time who was much older than you	118	3.7
Tourist you had known a long time who was much older than you	92	2.9
Cypriot prostitute, man or woman, who has sex in return for money	216	6.8
Foreign prostitute, man or woman, who has sex in return for money	140	4.4

Of those who reported vaginal intercourse, the most frequent age of first intercourse was 14 to 16 years old, 14.4% (see Table 2). Girls showed a marked increase in sexual intercourse starting at age 15, whereas for boys, a marked increase was noted after age 13. The figures for the 11- and 12-year-olds appear to be rather high on first impression and need to be examined further (see also Table 6.)

Table 3 shows the most common reasons given for having a first coital experience. Eleven males and only two females reported being raped; from anecdotal clinical evidence, male adolescent rape is uncommon in Cyprus.

*Contraceptive and Prophylactic Condom Use.* Knowledge and use of condoms is another important area of adolescent sexual behavior, with 2,298 (72.4%; 1,378 boys vs. 915 girls) admitting they had seen a condom, and 65.6% (1,312 boys vs. 771 girls) saying they knew how to use them. Of the roughly one-in-four teens who had had sex, 6.7% (168 boys and 45 girls) had never used a condom, 7.0% (193 boys and 7 girls) had used a condom sometimes, 3.6% (108 boys and 7 girls) most times, and 3.9% (110 boys and 15 girls) always.

These findings have dire implications for HIV and other STD transmission. Only one in five students who had had sexual intercourse at least once had always used condoms. Three out of four were unprotected sometimes or all of the time. Moreover, it is not clear from the question whether the condom was used correctly or not, whether it was placed on the penis before any type of intromission, or whether it was placed on the penis just before ejaculation for purely contraceptive purposes. It is also not clear whether the condom was used for other sexual practices, such as anal and oral sex, which are also high-risk behaviors. These issues can be incorporated into any safe-sex and health education program.

*Kinds and Duration of Relationships.* The disparity between a much higher incidence of sexual intercourse for Cypriot males and a much lower incidence for females raises the question about who the females are that these young men are having sex with. Questions were asked regarding the age of the sexual partner, the duration of the relationship, and the demographic identity of sexual partners. Given the very high influx of tourists every year—for the past six or seven years, tourists have outnumbered the indigenous Cypriots—questions were asked that differentiated between the kinds of sexual partners Cypriot men and women have. Table 4 analyses the responses to these questions.

It appears that there are a large number of longstanding relationships with indigenous Cypriots. A total of 434 students (13.7%) said that they had a longstanding relationship with someone their own age. Of these, there were many more boys than girls (346 boys vs. 88 girls). A further 146 (4.6%) admitted to having sexual intercourse with a Cypriot partner their own age whom they had recently met. Again, the majority of these were males (126 males vs. 20 females).

Another category of partner preference that has implications for HIV transmission are the large number of students who had sexual intercourse with tourists their own age whom they had recently met. The overwhelming majority of these were boys (236 boys vs. 13 girls). Another equally potentially high-risk behavior was with tourists their own age whom they had known a while, even though it is not clear how long a term is indicated by "a while." Of these, again the majority were males (181 males vs. 14 females). To the list of potentially high-risk partners could be added the students who had coitus with older tourists whom they had just met (120 males vs. 12 females), and the older tourists whom they had known for some time (77 males vs. 15 females). Further, potentially high-risk partners would include Cypriot prostitutes (212 males vs. 4 females) and foreign prostitutes (133

males vs. 7 females). It is not clear why there are a small number of females in the prostitute categories, as it is unlikely that they frequented a male prostitute. Perhaps they misinterpreted the question to mean that they themselves were paid for having sexual intercourse—there have been such known cases in Cyprus among the student population.

**Cohabitation.** In response to the question, “Have you ever lived with a man or a woman as a regular sexual partner without being married?” 148 (4.7%; 134 boys and 14 girls) said that they had cohabited with a sexual partner before marriage.

**Teen Pregnancy.** A total of 73 boys said that they had made their partners pregnant, and a further 11 girls admitted to being made pregnant by their boyfriends.

**Age of Marriage.** Table 5 summarizes the results of the question, “At what age would you like to marry?”

**C. Adults**

The following data were obtained from a clinical population of 840 clients of varying ages and educational backgrounds (see Section 12, Sexual Dysfunctions, Counseling, and Therapies, for details on sample and methodology).

**Virginity**

It is clear that far fewer males (9.4%) than females (69%) are virgins when they become engaged or marry. “Family honor” is at stake because of the prevailing belief that a nonvirgin or “soiled” bride should be considered a second-rate citizen in no way equal in social and ethical standing to a virgin bride. Indeed, many brides-to-be have been accused of not being a virgin by their fiancés on the first night. This often results in both families getting involved, taking the female by force to be examined by a gynecologist, and deciding whether the couple should stay together based upon the doctor’s diagnosis. Needless to say, such affairs are extremely degrading for the female involved. Even if the couple decides to stay together, there is no guarantee their relationship will stabilize and survive. In my clinical practice, I have encountered many cases of males who believe that virgin females should bleed like a chicken with it’s head chopped off! The males expect to see much blood on the sheets, and if this does not happen—which inevitably it does not—then the accusations will begin, and the horrid saga begins. (See also comments on premarital sex under Sociolegal Status of Males and Females, Children and Adults, in Section 1A.)

Nonvirgins before marriage who have slept with a partner before making a firm commitment to marriage will often visit a gynecologist and ask for a hymenorrhaphy or hymen-repair operation. This is one way of “fooling” the potential husband and avoid being ridiculed and belittled by the “expert” spouse who thinks that he has the ability to differentiate between a virgin and nonvirgin with his penis on the first night. My national live radio program at Radio Proto (1991 to 1992) and my advice column in the best-selling national magazine *To Periodiko* received many questions about hymen-repair operations. Gynecologists I spoke with admitted performing at least two or three such operations a week, for a total of thousands annually on the island.

Tables 6, 7, and 8 summarize some responses from the author’s clinical population of 840 adults. There appears to be quite a range in the frequency of sex, with a fairly even spread between the sexes (Table 8). About two thirds of the sample have sex more than twice weekly, with the remaining third less than once weekly. Remember that this is a clinical sample that has come for sex therapy for some sexual dysfunction or other, which inevitably adversely affects the frequency of lovemaking. This picture may not be so

representative of the general Cypriot population. My guess is that, given our Mediterranean temperament, we Cypriots are generally more hot-blooded than this!

There is a clearly significant difference between the sexes regarding the number of sexual partners in their lifetime (see Table 9). Two thirds of the women tended to stick with only one partner mostly, compared to about 7% of males, while very few women have more than two to three partners com-

**Table 5**

**Ideal Age for Marriage**

	Number	Percent
Already married or engaged	51 (26 males and 25 females)	1.6%
Do not intend to marry	52 (36 males and 16 females)	1.6
At age 18	190	6.0
Between ages 19 and 20	797	25.1
Between 22 and 25	1,455	45.8
Between 26 and 30	360	11.3
Between 31 and 35	43	1.4
Age 36 or older	18	0.6

11 or more	31.9	1.3

pared to males (8% of females vs. 73% of males). Whether this reflects the difference between the sexes or the inhibitions and taboos that exist in the Cypriot culture is not clear; the editor's guess is that the taboo placed upon female "promiscuity" by family and society is certainly a hindrance to moving from one partner to the other. Certainly, females that are likely to have multiple partners that are known in society will be labeled with very nasty names, such as "used," "prostitute," "ethically free," and others. These females tend to have difficulties finding a marriage partner, particularly if their behavior is well known. Usually, when a marriage is about to take place, both sets of parents will begin conducting an informal "character" assessment by asking various individuals in the close community of the prenuptials for a character reference. If the girl has a "bad name" in this community, then this will be reported to the potential bridegroom's parents who will strongly advise their son not to proceed, and will continue to stand as an obstacle until their son "sees sense"! These societal norms and taboos are enough for young girls not to consciously want to repeat one mistake twice or more.

About one third of males and one fifth of females had never experienced giving or receiving cunnilingus (see Table 10). A very small percentage of males tend to dislike giving cunnilingus (7%), whereas a much larger number of females dislike the act (21%), which could be for a variety of reasons. The most common reason cited by women in

Frequency for Males and Females Who Have Engaged in Anal Sex	Male	Female
1-2 times	25 %	31.1%
3-6 times	29.3	35
7-8 times	1.2	0
9 or more times	44.3	33.7

this sample was the partner's inexperience, his ignorance about the clitoris, and his or her belief that the vagina is the most stimulating and sensitive of areas. Also cited were the inhibitions of females who feel that they are dirty "down there," or that coitus is the only "acceptable" form of sex.

Not surprisingly, very few males do not enjoy being fellated—these being in the older age groups, which tend to be a lot more conservative in their sexual behaviors. About a fifth of the women in this clinical sample did not like giving fellatio to their partners, again probably related to taboos and inhibitions rife within the Cypriot community. Over a third of the men and a quarter of the women had never experienced this sexual behavior, but again these tend to be in the older age groups above 50 years old in the lower working social classes. Certainly, one third of the women thoroughly enjoyed it, as did well over half of the men (see Table 11).

A majority of the men and women who reported experimenting with anal sex appear divided about equally between those who tried it once or twice and those who were a bit more persistent, trying it three to six times before deciding not to continue with this sexual outlet (see Table 12). A third of the women and 44% of the men who tried anal sex appear to have incorporated this outlet into their sex lifestyle on a perhaps more regular basis, despite the disapproval of this behavior by the Greek Orthodox Church and despite it generally being considered a "no-no" by most couples. Perhaps one of the reasons for its fairly widespread occurrence among both sexes is the availability and popularity of pornography. Additional questioning of this clinical population revealed that it is mostly the male who will "subtly coerce" his partner into trying it, mostly for the sake of experimentation, after viewing anal sex on a pornographic video. In many cases, the reaction of the wife will determine the frequency of anal sex thereafter.

Unfortunately, there has been no epidemiological study of the sexual behavior of Cypriots. This small clinical sample is the only data available at present and it is limited by focusing on details of sexual functioning among a group of people who at some point in their lives developed a sexual dysfunction. In my opinion, this does not necessarily mean that the sexual histories and behaviors of these particular people differ from those without sexual dysfunctions, as this sample of people were also likely "normal"—without dysfunction—at some point before they decided to seek sex therapy. Their dysfunctions did not exist all their lives. The ideal, of course, is to have a methodologically sound, longitudinal epidemiological study with a substantial random sample of subjects. The lack of funds at present has made this very difficult to impossible.

### *Divorce, Extramarital Sex, Single Mothers, and Domestic Violence*

See comments under Sociolegal Status of Males and Females, Children and Adults, in Section 1A.

## *6. Homoerotic, Homosexual, and Bisexual Behaviors*

### **A. Children and Adolescents**

#### *Previous Homoerotic or Homosexual Experiences*

Many adolescents have some kind of sexual interaction with same-sex peers. This fairly common behavior, particularly among young adolescent males, might best be referred to as "homoerotic" rather than "homosexual." Sorenson (1973) found that about 9% of young people in the United States had one or more sexueroetic experiences with someone of their own sex between the ages of 13 to 19. The likelihood of homoerotic activities in adolescence is signifi-

cantly greater among those who have had same-sex experiences prior to adolescence. Indeed, most adolescents have their first homoerotic experience with another adolescent.

In the Knowledge, Attitudes, Beliefs, and Practices (KABP) Survey (Georgiou & Veresies 1990, 1991), about 34% of the respondents reported having hugged someone of the same sex at least once. Of these students, the majority were girls (722 girls vs. 354 boys). A further 7.9% had kissed passionately and a further 5.3% had petted above the waist—of these the majority were males. Table 13 summarizes the frequency of various sexual activities with a same-sex partner.

The majority of students who reported experiencing same-sex anal intercourse were males (141 males vs. 9 females). It is not clear, however, how these 9 females could be involved in homosexual anal intercourse, unless it was taken to mean anal penetration by a homosexual boy or with a dildo, but the likelihood of this is probably very small. These results are probably because of a misunderstanding of the question, or ignorance regarding anal sex.

When asked, “With how many people of the same sex have you had oral or anal sex?” 88.7% reported never experiencing oral or anal sex with a same-sex partner. An additional 4.3% had attempted homosexual oral or anal sex with between one to two partners (119 males vs. 18 females), and 1.2% had with three to six partners.

It appears that the majority had their first homosexual experiences when they were between the ages of 13 to 16 (see Table 14). During these ages, 5.5% of the respondents reported having their first homosexual experience. There may be a latent period for homosexual experiences at the age of 12, but this cannot be confirmed by the data. It has been shown by Kinsey and his co-researchers that the age of puberty is related to the age of the initial sexual experiences, including homosexual ones. It is not clear from the data, however, when Cypriot boys reach puberty, even though it might be presumed that it is younger than 11 years old for some boys.

**B. Adults**

*A Few Statistics*

The author’s clinical sample of 840 patients cited earlier gives us some idea of homosexual and bisexual behavioral practices in a group of men and women seeking help with some sexual problem or dysfunction. A second bias in this data is the gender balance, with 597 males to 243 females.

The respondents were asked during history taking if they had ever been approached sexually by another person of the same sex. This opening question was chosen as much less threatening than asking whether the client had actual same-sex experiences. If the response was “yes,” then they were asked simply, “What happened?” Of the total number of responses, 12.4% of the sample admitted to some type of sexual contact to orgasm with a same-sex partner; 11.6% were male and 0.8% female.

In order to avoid polarizing the population into “homosexual versus heterosexual,” the following clinical data were collected using the seven-point rating scale of heterosexual-homosexual attraction/behavior devised by Alfred Kinsey (1953).

It seems clear from the data that the majority of people who admitted to some type of homosexual contact or experience were Kinsey 1 or 2 (13.1%), with very few, 1.7%, in Kinsey 5 and 6. This indicates the transitory experiences of these people with a same-sex partner. Indeed, all of the male experiences, with the exception of 18 cases discussed below, were age 18 to 20, the age when all Cypriot males are required to do their National Guard training as a soldier in

an army camp for 26 months. It was during this period in the National Guard that most of these experiences occurred. Most of these young soldiers would be “picked up” by homosexuals “cruising” the scene and taken to their army camp. The deal would be struck in the car, and most of the time they were offered a small sum of money ranging from ten to 15 dollars (US) in exchange for “services,” which meant the homosexual felling the soldier, or the soldier

**Table 13**

**Frequency of Sexual Activity with a Same-Sex Partner**

Behavior	Never	1-2 times	3-6 times	7 or more times
Hugging	62.4%	14.0%	4.5%	15.5%
Deep (open mouth) kissing	88.9	3.7	1.3	2.9
Petting above the waist	90.9	2.3	1.2	1.8
Petting below the waist*	89.8	2.4	1.5	2.8
Sleeping together (without sexual/anal intercourse)	85.0	4.6	1.8	4.8
Sexual intercourse	91.5	1.5	1.3	2.5
Oral intercourse**	91.6	1.5	0.6	1.9
Anal (rectal) sex***	91.6	1.9	0.6	2.3

\*Of the approximately 7% who reported petting below the waist with a same-sex partner, 192 were males and 31 females.

\*\*A further 4% of the respondents reported experiencing same-sex oral intercourse, with the majority of these being males (114 males v. 13 females). It is not known whether the respondents were giving or receiving oral sex. This is an important factor regarding HIV transmission, as the probability of contracting the virus is far higher for the person giving oral sex, particularly if semen is released into the mouth.

\*\*\*The latter numbers probably indicate that there are between 2% and 3% homosexuals on Kinsey’s scale 5 and 6 of his heterosexual-homosexual continuum. This is a little lower than what one would expect, compared with other research. Kinsey and associates (1948) reported that during early adolescence, about 28% of the early-adolescent boys were involved in same-sex activities. Sorenson (1973) in his study of adolescent sexuality reported that 11% of the boys and 6% of the girls in his sample had at least one active same-sex experience.

**Table 14**

**Age of First Experience with Oral or Anal Sex with a Person of the Same Sex**

Age	Percent						
Never experienced oral or anal sex with a same-sex person	91.6%						
Age 11 or younger	2.0%	61 boys	v.	8 girls			
Age 12	0.7	18 boys	v.	3 girls			
Age 13	1.0	29 boys	v.	2 girls			
Age 14	1.6	49 boys	v.	2 girls			
Age 15	1.9	47 boys	v.	12 girls			
Age 16	1.0	21 boys	v.	10 girls			
Age 17	0.3	6 boys	v.	3 girls			
Age 18 or older	0.5	12 boys	v.	4 girls			
<b>Kinsey Scale:</b>	<b>0</b>	<b>1</b>	<b>2</b>	<b>3</b>	<b>4</b>	<b>5</b>	<b>6</b>
Male	82%	9 %	4%	0.9%	2 %	1 %	0.3%
Female	95	0.1	0	0.9	0.9	0.4	0

penetrating the homosexual anally, but not the reverse. With most soldiers, this activity was a one-time experience; with a few, it was repeated two or three times.

The five exceptions that had not had these types of army experiences had encountered homosexuals while studying abroad, and they behaved in a similar fashion to what has been mentioned above. The other 18 males had a specifically homosexual orientation, and their homosexual experiences were more varied and more frequent. These homosexuals had voluntarily entered same-gender relationships, and their interest in opposite-sex partners was very limited. The women were mostly patients who had come to specifically discuss their sexual orientation, and they were involved with a single partner with whom they had fallen in love. All were married at the time.

### *Homosexual Life in Cyprus* ALECOS MODINOS\*

For centuries, this island, which is now an independent country only 100 miles (160 km) from the coast of Lebanon, was a model of social and familial conservatism. Family ties were close, the patriarchal concept was entrenched, and strict social mores were enforced by both Church and tradition. The pattern of life, while not unduly exciting, was extremely stable nevertheless.

Abruptly, in just a few short weeks 25 years ago, the pattern of centuries was destroyed when Turkey invaded and occupied almost 40% of the country. A great percentage of the population lost their homes and jobs, and fled to the southern half of the country before the advancing armies. Thousands were killed or injured and another 200,000 became refugees.

In those short weeks, the entire social fabric of Cyprus was destabilized. Family ties were abruptly loosened or disappeared altogether in the chaos that followed, and even now, 25 years later, there are still over 1,600 missing persons as a result of the invasion. In a small island-state of less than 700,000 people, the effects of the invasion and continuing occupation were profound.

In May 1989, the following headline appeared on the front cover of a popular national magazine and in daily newspapers: "Homosexual Accuses Cyprus to the Council of Europe for Violation of His Human Rights." The article clearly demonstrated how many journalists were not only prejudiced, but knew very little about the subject. Cyprus is one of the few member countries of the Council of Europe that until very recently had not abolished its anti-homosexual laws. The existing criminal law, CAP 154, articles 171-174, considers homosexual acts a criminal offense punishable by 5 to 14 years' imprisonment. This law was influenced by the British Colonial occupation of the island between 1878 and 1960, and was incorporated in our legislation in 1929 in accordance with the British "Criminal Law Amended Act of 1885," a good reflection of the Victorian period! In Britain, the 1885 anti-gay law was abolished with the "Sexual Offenses Acts of 1967," but this had no effect in Cyprus, which by then was an independent state. Cyprus thus was left with an outdated colonial law that Britain had abolished 32 years ago. Homosexuality between women is not a criminal offense, but is completely ignored by the law as if it does not exist at all.

The first discussion on homosexuality was organized by the Pancyprrian Mental Health Association in the fall of 1979. In the spring of 1982, a two-day seminar was organized by the same association on the same subject. About 500 persons

attended; the great majority were women, and the absence of men was obvious! As a result of the second seminar, five gay men began working together. Five years later, after many difficult and laborious efforts, 16 gay men and a lesbian founded the Gay Liberation Movement of Cyprus on December 10, 1987. As of January 2000, less than half-a-dozen persons have come out of their closet, while the remaining hundreds of gay men and women members of the Gay Liberation Movement still remain in the closet for fear of reprisals.

From 1989 onwards, with great caution, two radio stations arranged live interviews with a gay man who answered questions from listeners calling in. Between 1991 and 1992, in a regular weekly radio program titled *Human Sexuality* presented by the main author of this chapter, homosexuality was included as a topic on three separate occasions. After this initial exposure on live radio, homosexuality was more openly discussed on a few other private radio and television stations.

On December 6, 1990, the European Commission decided unanimously, with 15 Commissioners, in the case *Modinos vs. Cyprus*, that Cyprus was violating the human rights of homosexual people. The case went to the European Court, as the Government was reluctant to reform the law. Following a hearing on October 26, 1992, the European Court decided eight to one on April 23, 1993, that Cyprus was violating the human rights of homosexual persons, and ruled that the antiquated anti-homosexual law of 1885 must be abolished. The sole dissenting vote was cast by the judge from Cyprus.

The Greek Orthodox Church bitterly opposed this law reform and was supported by the majority of the members of Parliament. However, after a lot of pressure from the European Council of Ministers over a period of five years, a week before the third ultimatum given to the Government was to expire, the Cypriot Parliament very reluctantly reformed the law in May 1998.

The new law, made to the satisfaction of the Church and the majority of the opposing Members of Parliament, was found unacceptable by Amnesty International, the human rights organizations of the island, practically all the Pancyprrian scientific organizations including the Family Planning Organization, the Gay Liberation Movement, and, on September 17, 1998, by the European Commission. The amended law, which the Cypriot government submitted in early 1999 to the European Council of Ministers, was rejected because it was full of discriminations. The Cypriot government planned to rewrite the law and submit it again in 2000.

The Cyprus government was obliged to revise the 1999 law in May 2000 because of the discriminations that were not accepted by the European Council of Ministers. During the voting procedure in Cyprus, 27 of the 40 Cypriot Members of Parliament walked out, and as the Cypriot media wrote, "it was not for purposes of micturation [urination]!" Of the remaining 13, two were against the law with the remaining 11 passing the amended law. The main points in the amended law included:

- The title, "Licentiousness Against the Order of Nature," has now become "Coitus Between Men."
- The age of consent for homosexuals has been made 18, whereas for heterosexuals it is 16. Cyprus is not the only country with this discrimination.
- Before, it was against the law for more than two homosexuals in the privacy of their homes to engage in sexual acts. This has now been amended to include more than two consenting adults.
- Article 174a stipulates that it is a criminal offense if homosexual males under the age of consent engage in homosexual acts.

\*Note: The following perspective on homosexuality in Cyprus was provided by Alecos Modinos, B.Arch., A.R.I.B.A., president of the Gay Liberation Movement of Cyprus, and a chartered architect.

Homosexuality is still a subject very few Cypriots talk about, despite the great publicity through the media since 1989. Cypriots in general are sympathetic and sensitive people who oppose any violations to human rights. There is, therefore, no organized movement against homosexual persons at present. General attitudes toward gays are slowly changing in a positive way because of the European Court's decision and the great publicity given by the media to the gay law reform. However, parents are very unhappy and bitterly disappointed if they have a lesbian daughter or a gay son. Given the slow progress toward liberalization, there still exists a lot of prejudice and discrimination from all walks of life against lesbians and gay men, and this is why the vast majority still remain in the closet.

Besides the clinical data gathered by the main author, there are some anecdotal data regarding homosexual behavior gathered from members who attended the weekly meetings of the Gay Liberation Movement, but this is not in a presentable format that would make any scientific sense. There is clearly a need for further research on this important topic of human sexuality, but the lack of funding makes this difficult.

The difficulties that homosexual and lesbian Cypriots encounter stem from the great social stigma associated with the limits on open homosexuality in the small Cypriot society, the legal system, which still considers gays criminals, and the powerful Orthodox Church, which considers homosexual relationships "the gravest of sins."

Most Cypriot homosexuals conceal their identity behind the curtain of wedlock; it is estimated that about 80% of homosexual males are married with families. Marriage makes them feel accepted and secure in a patriarchal, very family-oriented society. Homosexual activities outside marriage are usually conducted with other married homosexuals, or indeed, married "heterosexuals" who are willing to "service" the gay partner with anal penetration without this being reciprocated. Other willing partners include tourists who frequent the island; there is a huge choice, given that Cyprus welcomes about 1.5 million tourists annually!

Because Cyprus did not have its own university until recently, a record number of young Cypriots study abroad. Away from home, they are free to join gay groups, become gay activists, take part in gay parades, and thoroughly enjoy a very active gay life, including one-night stands—a way of life forbidden to them at home. Some even develop long-term relationships. After finishing their studies, many settle down abroad. Those who return home have the same predicament that practically all gay people have in Cyprus. Very few of them remain free at home and travel abroad for holidays and business trips; the great majority will get married, have children, and lead a double life.

There are no organized gay bars or clubs on the island. However, there are a couple of bars/pubs in the main towns, usually owned by gay persons, that are known meeting places with a mixed clientele. Beaches, parks, and "cottages" in the main towns are listed in all European gay guides, but are best avoided because many people frequenting these places, especially during the summer months, land in trouble with plainclothes young policemen acting as "provocateurs." Cyprus's many exercise gymnasiums are another popular meeting place. Good cinemas and theatrical productions, recitals and concerts, as well as ballet performances from visiting companies, attract a number of gay men. Often, they socialize with other gay friends over coffee, sometimes for dinner, and most of the time with mixed groups of friends without anybody knowing, perhaps not even suspecting, they are gay.

The great majority of adult gay men and women who remain single and tire of one-night stands want to eventually settle down in a permanent relationship. Such relationships

are much easier to achieve between women than men and are, thus, more numerous. The majority of adult lesbians have a lasting relationship. Cypriot men grow up to be strong and to conceal their emotions, and they find it very difficult to be tender and loving toward another man. The Gay Liberation Movement and specialists trained abroad, enlightened with the latest scientific discoveries concerning human sexuality, have assisted many gay persons who seek counseling, with the result that we now have over 30 male couples who have been living together for six to ten years in the main towns. Very few of these couples have talked this over with their family. For the great majority, there is unspoken understanding and silent acceptance, a practice terribly common between all who have a gay son or a lesbian in their families.

Lesbians are discriminated against both as women and as lesbians. Practically all get married and have children; very few of them will dare or manage to have a special friendship with another woman. In the past, they were active members of feminist organizations or women's groups, without letting anybody know of their homosexual inclinations. Unavoidably, special friendships were formed and, as a result, suspicion and prejudice made all such women's groups slowly disappear. Some lesbian couples in the main towns live together, but most live with their families or in separate flats, even though they have been together for several years. This provides them with good cover for family, friends, and colleagues alike.

The younger generation of lesbians today are somewhat more rebellious and daring. They refuse to get married, even to socialize with other young men as a cover-up, especially if they are economically independent. They usually live on their own, not with their families. They socialize with small groups of five or six other lesbians of the same age on the look-out for a partner. They usually form relationships lasting only a few months. Sometimes, they may meet the right person and settle down to a more permanent relationship, but many of these will have relationships on the side for quite a while before making a final commitment to one person.

Single lesbians, especially those who have given up hope of finding a permanent friend, avoid the company of straight men and often meet and socialize with gay young men who share the same interests. The necessity to socialize with the opposite sex brought many homosexual men and women together, thanks to the Gay Liberation Movement, which helped to disperse the myths and stop the prejudices that existed between them.

Recently, although they still dare not come out in the open, the women of very wealthy families who have studied abroad live their lives and form friendships with other women. They ignore the drawing-room gossip about them, much as that hurts and makes them and their families miserable. They often put up a fight with their own families, who may accept their sexual orientation, but they are concerned about what the other people say.

Practically all Cypriot gay men take holidays abroad, even those who can hardly afford it. They travel alone or with friends. They are out to enjoy themselves and have as many sexual relationships as possible, trying to make up for that which is forbidden for them at home. Greece is very popular, with the gay bars of Athens, the saunas, and the gay beaches of Myconos and other Aegean islands coming first. Amsterdam, Paris, London, and other European cities are always resorts for those who can afford them.

Homosexual men are not accepted or retained in the army if their homosexuality is discovered. Except for half a dozen or so cases, all members of the Gay Liberation Movement have served their national service and have excelled in the posts they were assigned by their officers.

Apart from occasional parties at Christmas and special occasions, where about 50 gay men and some lesbians are invited, there are few gay private parties. The first one was in December 1990 to celebrate the unanimous decision of the European Committee, when the 15 Commissioners condemned Cyprus for violating the human rights of homosexual people. The second took place in April 1993 to celebrate the European Court's decision against the Government for the same reason, and since then, two more to raise money for people with AIDS. About 350 gays attended these huge parties that were considered a great success by all who attended.

Cyprus is a divided country, proud to be a member of the Council of Europe and trying hard to become a member of the European Union. To achieve this, a first necessary step is the equality of all citizens in the eyes of the law. But this is a minimum demand. What must be achieved is true equality in the minds of all people in everyday life. To achieve this, we still have a long way to go!

In the main author's 1990 survey of Greek Orthodox priests (mentioned in Section 1/2B, Religious Beliefs Affecting Sexuality), the priests were asked for their pastoral response to a second situation involving an 18-year-old boy who is having a sexual relationship with another boy, and finding it rewarding and fulfilling. He has heard from someone that it is wrong, and approaches a priest for guidance and advice. The responses chosen by the 130 priests responding to the questionnaire were:

- to terminate this relationship immediately (38.5%)
- to terminate the sexual relationship, but maintain the friendship (10.8%)
- to continue as they are (0.3%)
- to visit a Christian therapist (21.5%)
- something else (28.9%)

The subjective responses given by the 27 priests interviewed face-to-face were analyzed using a thematic analysis consisting of 16 general categories, some of which are included below:

- the two boys should separate immediately (51.5%)
- homosexuality is considered a cardinal sin (40.2%)
- the boys should visit a Christian therapist, because they are sick and need help (27.3%)
- God destroyed Sodom and Gomorrah for the sin of homosexuality (17.4%)
- it would be advisable for this boy to find a woman to marry immediately (12.9%)
- they should visit a Spiritual Father for guidance and confess their sins (12.1%)
- this is an abnormal, unnatural act that can only be considered a disease (9.1%)
- they should remain friends and have no sex; if this is too much of a temptation, then they should separate completely (8.3%)
- God did not create only men or only women, he created both sexes so that they could be united in matrimony (5.3%)
- if the boy truly repents, his sins will be forgiven (3.8%)
- homosexuality was responsible for the spread of AIDS, etc. (2.3%)

The face-to-face interviews elicited more attitudes from the Cypriot priests that were similar to the survey responses cited above. There was a belief that all homosexuals are really promiscuous heterosexuals who choose same-sex partners for fun, as their passions have overrun them, and that this was definitely the work of the devil. The focus appears to be on the homosexual act, as opposed to the homosexual person. This was further reinforced by the belief that

the homosexual person was seen to be the person who accepts being penetrated. This "true" homosexual was referred to by many of the priests interviewed as the *passive* partner, whereas the active penetrative partner was not seen as being homosexual by many priests. This appears to be congruent with St. Chrysostomos's belief of gender expectations, or men behaving inappropriately like women.

## 7. Gender Diversity and Transgender Issues

There is no information available on this topic. There are certainly a few transsexuals and transvestites living on the island, as they appeared in media interviews seven or eight years ago, but little is really known about their situation. The main author has also seen a couple of transvestites and one transsexual in clinical practice, mostly seeking advice regarding sex-change procedures and relationship problems.

## 8. Significant Unconventional Sexual Behaviors

NATHANIEL PAPAGEORGIU\*

### A. Coercive Sex

#### *Sexual Abuse of Children and Incest*

Because Cyprus is a close-knit community, it is difficult to conceal sexual abuse and incest with children. The police statistics cover only a minor portion of what happens within families. For example, there has only been one case of incest reported between 1995 and 1997. In the same period, 15 cases of sexual assault on a minor between ages 13 and 16 years old were reported, with 5 cases of assault on a minor younger than 13 years of age. From a sample of 840 patient interviews (see Section 12, Sexual Dysfunctions, Counseling, and Therapies, for details), 3.6% or 29 females and one male reported sexual encounters with relatives. These encounters were with a cousin (1.8%), uncle or grandfather (1.3%), father (0.4%), and brother (0.1%). This rather small sample of the general population indicates that the problem of incest is far larger than what is reflected in police statistics. It seems reasonable to assume that most such cases are "hushed-up" by the families and by the authorities to avoid shame for the family and having to face all the consequences thereafter. If such incestuous practices were known, the family would be stigmatized, and the chances of the female victim finding an appropriate partner for life would be severely affected.

#### *Rape and Marital Rape*

Of the 25 cases of rape reported to the police between 1995 and 1997, all involved tourist women visiting the island. Some of the rapes were perpetrated by Cypriot males "on-the-prowl," while many others have been by foreigners living on or visiting the island. Most of the female victims were from Scandinavian countries, with a few from Europe. There is no doubt that there have been more such cases that were not reported for various reasons.

Perhaps the most common sexual assault is that perpetrated by husbands on their wives. The author has encountered many such cases, including sexual coercion and abuse. If these cases are reported to the police, they are usually covered up and do not go to the courts for fear of shaming the family and destroying its honor. Many times, the police and family members persuade the wife to keep this within the

\*Note: The editor is grateful to Nathaniel Papageorgiou, Chief Superintendent in the Criminal Investigation Department (CID) of the Ministry of Justice and Public Order, for providing parts of this section on sexual crimes.

family and not to press charges. Even cases that are reported are often “struck-off” the record after intervention by family members concerned about the probable effect on family ties and honor. (See comments at the end of Sociolegal Status of Males and Females, Children and Adults, in Section 1A.)

### *Sexual Harassment*

Sexual harassment is perhaps the most commonly occurring crime in the workplace and by Cypriot men harassing tourist women. Sexual harassment in the workplace has been a frequent topic of discussion by the local media, as this was a way of life here in Cyprus. In the workplace, it involves male supervisors using their position and power against women, or women who want to improve their work status or to obtain a promotion. This type of behavior still occurs, but not on the scale that it was once practiced.

A study involving sexual harassment was conducted in 1997 by the Research and Development Center of Inter-college, a large private college in Cyprus, using 1,500 questionnaires that were distributed anonymously to both men and women. About 85% of the sample felt that sexual harassment was a serious social problem in Cyprus. About 40% of the sample actually knew first-hand of people who had been victims of sexual harassment; most of these took place in nightclubs (cabarets) with strippers (96%), with foreign home workers (73%), in hotels (64%), in factories (38%), in shops and offices (28%), and at schools and colleges (17%).

### **B. Prostitution**

There has not been any systematic study conducted on the rather large population of prostitutes in Cyprus. Apart from the local indigenous prostitutes, there is a growing group of foreign artists who have been specially imported by cabaret and nightclub owners for “entertainment” in their clubs. These girls, from the Philippines, Russia, Bulgaria, and India, are given work-permits and visas by the Cypriot government to work as dancers in these clubs. It is estimated that there are over 1,000 foreign girls working on the island, plus an unknown number of Cypriot women. The latter are probably dwindling because of the growing number of foreign imports who are favored by the Cypriot males who frequent such clubs. These foreign girls are not officially registered to work as prostitutes, but it is often recognized by the authorities that this happens. These girls are monitored for sexually transmitted diseases on a regular basis by the authorities.

In the last few years, there have been cases where the owners of these clubs have been convicted of coercing these women to have sex with customers against their will. These cases are usually reported because of some dispute over pay for services rendered between the women and their boss. Most of these cabarets are frequented by Cypriot businessmen in groups who are out for a laugh and a bit of fun with their friends; most are married.

### **C. Pornography and Erotica**

Pornography and all types of erotica are freely available in Cyprus to those who want it. Before the ban on video piracy which the government implemented about two years ago, there were literally hundreds of video shops where anyone of reasonable age could go and ask for a porno tape “behind-the-counter.” These tapes cover the whole gamut of sexual behavior, from straight heterosexual sex, to anal and oral sex, homosexuality, bestiality, sadomasochism, fisting, and all the other sexual behaviors in between. Cypriots can rent their usual thrillers or soap movies on a regular basis, and while in the video shop, pick up a porno movie to watch while the children are in bed. Many of these tapes were subsequently copied and are still circulating in many

households in Cyprus, often entertaining the children as well, who happen to find their hidden location while the parents are at work.

There were large groups of Cypriots who, out of sheer curiosity and fascination, were requesting harder and harder varieties of porn that consisted of acrotomophilia, anaclitism, anolingus, bestiality, bondage, coprophilia, fisting, klismaphilia, and much more. This surfaced about 12 years ago when the author had the opportunity to interview one of the main suppliers of pornographic material on the island. He mentioned that the more “perverse” or “deviant” the sex he could obtain on video, the greater his business!

### **D. Sexual Crimes**

[*Update 2003*: To the police and the public, sexual assaults, and especially sexual assaults against young children, are a major social concern. In Cyprus, sex crimes are not reported frequently. This is because of the conservatism and closeness of the society in Cyprus. It is believed that the police statistics cover only a minor portion of sex crimes, especially of crimes that are committed in the family, for example crimes of incest and of partner violence.

[Even though changes in the social structure are taking place in Cyprus, it is still considered a shame to a family that experiences a rape case. Many families decide to either “hide” this crime, or to take no legal action, and bring the offender to justice, in order to avoid publicity of the case, and therefore shame. Because of the close-knit community in Cyprus, many people always avoid the possibility of getting stigmatized. This is the case especially for rape cases where the honor of the family is at stake. Therefore, it is assumed that the phenomenon of sex crimes might be larger than what the statistics show.

[There seems to be an increase in the rape rates since 1997. To be more specific, in 2001, 18 cases were reported involving rape cases, compared to 10 that were reported in 1997. In the year 2000, there were 12 rape cases reported and in the year 2001, 18. Out of these 30 cases, only 2 were committed by the partner of the victim.

[The majority of the other types of sex crimes showed a decrease since 1997. Comparing the statistical information of 1997 to the statistical information of the year 2001, there was a decrease in the following categories of sex crimes:

- Seduction of a female under the age of 16,
- Proccuring,
- Indecent assault against a female,
- Indecent offense,

It should be noted that these types of sex crimes all showed a major decrease in the past four years.

[No cases were reported to the police for the following sex-crime categories in the year 2001:

- Seduction of a female between the ages of 13-16
- Pimping
- Solicitation

[The categories that showed relevant increases and decreases between the years 1997 and 2001 were, indecent offense and indecent offense exposure. These two categories have some commonalities between them. The category of indecent offense was the most prevalent of the others throughout the years 1997-2001. For example, in 1997, there were 101 cases of sex crimes reported, 24 of which were indecent offenses. Again, for the year 2001, there were 80 cases of sex crimes reported, 31 of which were indecent offenses. It should be noted that there has been an overall decrease in the cases concerning sex crimes by 20.8% (21 cases) between the year 1997 and 2001.

[Sex-crime cases where the perpetrator is a member of the family or the partner of the victim are rarely reported. For example, in the year 1997, there were only 8 such cases reported, and all of them were indecent assault against a female, while in the year 2001, there was only one case reported where a member of the victim's family was the perpetrator, and this was a rape case. This shows how the family in Cyprus in the 21st century is still afraid to bring a case of such nature in the court of law, or even report it to the police. This emphasizes how the "honor in the family" cliché discourages victims in Cyprus from reporting incest cases, or even rape cases to police, and thus not bringing the perpetrators before justice.

[Even though Cyprus is a small country, and it is not expected to have large numbers of sexual crimes, we believe that there is a dark figure to this category of crimes. In fact, until quite recently, the number of sexual crimes committed each year was negligible (see Table 15). (*End of update by G. J. Georgiou and L. Papantoniou*)]

### 9. Contraception, Abortion, and Population Planning

#### FAMILY PLANNING ASSOCIATION OF CYPRUS\*

[*Update 2003: Mission:* The Cyprus Family Planning Association promotes the development of a society where all people can enjoy the basic human right to make free and informed choices in their sexual, emotional, and reproductive lives:

- Defends, protects, and advocates for the sexual and reproductive rights of all women, men, and young people.
- Provides high-quality informational, educational, and clinical services in the sphere of sexual and reproductive health in an accessible and affordable manner to all people, especially the marginalized, including sex education and family planning.
- Exercises a leadership role in sexual and reproductive health through committed, competent, and skilled volunteers and staff.

**Table 15**

#### Sex Crimes Reported During the Years 1995-2001

Type of Crime	1995	1996	1997	1998	1999	2000	2001
Rape	8	8	10	11	11	12	18
Kidnapping	3	0	3	6	4	2	1
Seduction of a female under 13 years old	1	1	3	2	1	1	0
Seduction of a female from age 13 to 16	6	5	4	3	1	14	1
Procuring	0	11	17	17	7	8	10
Indecent assault against a female	24	14	19	7	16	6	17
Indecent assault against a male	2	3	4	2	3	1	0
Pimping	3	11	15	4	2	2	0
Solicitation	0	1	0	1	0	1	0
Indecent offense	32	20	24	38	20	35	31
Indecent offense exposure ("unethical projection")	8	4	2	7	15	4	1

\*Note: The editor is grateful for information supplied for this section by the staff at the Family Planning Association of Cyprus.

#### [Aims:

1. To enlighten and educate the public on issues relating to family planning and sex education, emphasizing the role and responsibility of the parents to the family and the social welfare.
2. To support and promote means and services for providing advice and help on family planning issues, sex education issues, marital counseling, and other related matters appertaining to the institution of marriage.
3. To increase the understanding of the Cypriot people and government of the demographic issues regarding their own community and those of the world.
4. To advise the public on conception and contraception and to provide voluntary family planning services.
5. To ensure the maintenance of satisfactory standards in the delivery of voluntary family planning services.
6. To promote the provision of family planning information and services through other appropriate organizations
7. To take any and all other appropriate measures to further the above aims.

*"Youth Center": The activities will be carried out in all parts of Cyprus where youth can potentially be reached.*

[*Summary:* The "Youth Center" project aims towards the provision of counseling, informational, and educational services, in the field of Sexual and Reproductive Health, to youth living in Cyprus. In-person counseling will be provided and, at the same time, a hotline will be established so that young people can have access to the psychological support they might need. Young volunteers, members of the "Youth for Youth" group, will receive comprehensive training in order to become able to run the center. Furthermore, youth will be able to obtain information regarding issues in S&R Health through a website. Concurrently, a massive distribution of relevant informational material will take place throughout the project.

[*Objectives:* The Cyprus Family Planning Association has assumed a leading role in the provision of services in the field of Sexual and Reproductive Health over the past three decades. Issues such as unwanted pregnancy, teen pregnancy, sexually transmitted infections, and abortion have surfaced as major social problems, especially among youth, in the past few years in Cyprus. Unfortunately, the increasing magnitude of these problems has not yet been measured scientifically. Expert observations, however, allow for great concern.

[Based on its ongoing effort to target young people, educate them, and provide them with psychological support and information in regards to Sexual and Reproductive Health, the CFPA strongly believes that the creation of a program such as the "Youth Center" will establish a more direct contact, strengthening its existing relationship with youth so that the above services are provided in the most effective way possible. Furthermore, sex education is not currently fully provided by the educational system in Cyprus. The Youth Center project aims to attempt to fill this gap through peer education, a tested and rewarding method of approaching youth. Young men and women, who live in rural areas, do not have easy access to free family planning services. Also, young people who live in tourist areas are more prone to exhibit risky sexual behavior, and therefore may become more exposed to sexually transmitted infections. CFPA will try to approach these youth and provide them with the services, the information, and the attitude needed to sustain a healthy sexuality.

[*Aim of the Project:* The main goal of the “Youth Center” project is to satisfy the unmet needs of young men and women throughout Cyprus with regards to their Sexual and Reproductive Health. (*End of update by G. J. Georgiou and L. Papantoniou*)]

### A. Contraception

In the main author’s clinical sample, 33% reported using the condom and 21% used coitus interruptus. The IUD ranked third at 7.3%, followed by 6.7% for the contraceptive pill. Very few Cypriot women use the diaphragm, cervical cap, or contraceptive foam—only 0.1% for each. Cypriot women tend to have concerns about placing objects in their vagina, not necessarily because they may injure themselves, but because there is a repulsion to placing items in the vagina. This seems to be a cultural attitude reported in the sexual histories taken by the author. “Touching” the vulva seems to be out-of-bounds for most Cypriot women, and this is reflected in the relatively low frequency of women who masturbate. The IUD is slightly more acceptable because this is placed by the gynecologist and does not entail self-insertion. One in five survey subjects reported using no contraceptive, and 3.8% reported sterility. (See Section 5B, Interpersonal Heterosexual Behaviors, Adolescents.)

In the 1990 survey of priests conducted by the main author, the priests were presented with a case for pastoral counseling involving:

a Christian couple with five children. The husband is 35 years old and the wife 30. Only the husband is working and earning a small income, which provides the essentials for the family. Under the circumstances, the couple has decided to use artificial contraceptives (that do not allow fertilization to take place), and go to a priest to discuss the matter. (Georgiou 1990)

The priests responded as follows:

- all contraceptive methods are disallowed (39.2%)
- the couple should sexually abstain (25.4%)
- contraceptives are allowed in exceptional circumstances (8.5%)
- contraceptives are freely allowed (6.2%)
- the couple should make love during the wife’s infertile days (1.5%)
- something else (9.2%)

Older (over 65) and less-educated priests (junior school with additional training in the Theological School of the Cypriot Archbishopric) tended to be more against the use of contraception than the younger, more-educated priests ( $p = 0.0002$ ).

The thematic analysis of the subjective responses included 17 mutually exclusive general categories, some of which are presented below:

- the Orthodox Church considers the use a contraceptive sinful, and therefore does not allow it (37.9%)
- the couple should coitally abstain during the fertile days (25.8%)
- God gave the command to multiply and fill the earth, which means that we should have as many children as possible (18.2%)
- the couple should humbly accept as many children as God sends them (16.7%)
- the idea would be to completely abstain from sexual intercourse, unless one wants to procreate (12.9%)
- there are many large families of eight to ten children who are healthy and content, so why not others? (8.3%)
- contraception is allowed in exceptional circumstances (7.6%)

- we should believe in God’s Providence; He will help us raise our families if we have faith (6.8%)
- God cares for all the animals of the earth, so why would he not care for his people (6.1%)
- the state should provide assistance to large families (4.5%)
- procreation should not be the only goal in marriage (4.5%)
- contraception is freely allowed to be used by all (3.0%)
- the couple should avoid intercourse during the second to the eighth day of the menstrual cycle which are the fertile days [*Comment 2001:* In this self-generated response, the priests revealed their own misinformation about the menstrual cycle, because days 2-8 are not the fertile days. (*End of comment by G. J. Georgiou*)] (2.3%)
- it is better to use contraception than to have an abortion (2.3%)

### B. Abortion

Perhaps the fact that over half of the main author’s sample do not use adequate contraception should lead us to the conclusion that many Cypriots have abortions or have numerous children. The latter is not the case, and epidemiological statistics for abortion are unavailable. Using the same clinical sample of 840 patients (see Section 12, Sexual Dysfunctions, Counseling, and Therapies), 21.5% said they had had an abortion. Examining the statistics from an unpublished Cyprus Family Planning Association study, 20% of the total sample of 496 women reported having at least one abortion during the years 1995 to 1997, with 19% having at least one from 1985 to 1987. Interestingly, in the 1980s, 25% of these women were single, 18% were engaged, and 19% were married, whereas in the 1990s, only 3% were single, with more married women (27%) having abortions than before. It is certainly difficult to be certain about precise figures, but a figure of approximately 20% of the female population during any one year would be a fair estimate of the incidence of abortion. In the same study, about 7% of women had two abortions between the years 1995 to 1997, compared to 11% of women who had two between 1985 and 1987. (See also Section 1A, Sociological Status of Males and Females, Children and Adults.)

It is known that there are about 10,000 births per year, and it has been estimated that there are probably 12,000 to 13,000 abortions yearly. It appears that many Cypriots use abortion as a method of contraception after all else fails. The majority of gynecologists on the island will freely give abortion upon demand, because of a loop-hole in the law amended after the 1974 invasion of Cyprus by the Turks, allowing abortions for women who had been raped by Turkish troops or based on medical grounds with the permission of two medical doctors. This law still exists and allows gynecologists to practice abortion upon demand. There are only two gynecologists on the island whom the author knows that do not perform abortions for ethical and religious reasons.

In the main author’s 1990 survey, Greek Orthodox priests were presented with the following situation involving abortion:

A Christian woman is pregnant with her fourth child, even though her doctor warned her not to have another child as she would be endangering her health. Presently three doctors have told her that if she continues the pregnancy there is a chance that she would die. She has been advised, therefore, to have an abortion. As she is a woman who believes in God, she approaches a priest for advice. (Georgiou 1990)

The responses selected by the priests were as follows:

- she should listen to the doctors and have the abortion (17.7%)
- she should not have the abortion under any circumstances (60.0%)
- something else (19.3%)

An additional 3.1% of the total sample of 130 priests avoided the question.

A thematic analysis of the subjective and “something else” responses produced 14 mutually exclusive general categories, some of which are examined below:

- she should have complete faith in God (43.2%)
- the Orthodox Church believes that abortion is an act of murder and is therefore a cardinal sin (25.0%)
- she should pray and ask for God’s help and make up her own mind (16.7%)
- if the diagnosis is certain, then she should have the abortion so she will not leave her children and husband to suffer alone (15.2%)
- I’ve seen similar cases where the woman and child had both survived (11.4%)
- we must bear in mind that there are many cases where doctors have been proven wrong (10.6%)
- she should have the baby; I am certain that God will help her and the baby survive (9.1%)
- God is the wisest scientist (6.8%)
- the woman should follow the doctors’ orders and she will be forgiven (5.3%)
- it is important not to listen to the doctors in cases like this (3.8%)
- if she presents a letter from her doctor to the Spiritual Father with the facts of the case, then he will allow her to proceed with the abortion (2.3%)
- she should die for the love of her child (1.5%)
- she should have the abortion, and she will be given a heavy penance (1.5%)
- the priest cannot take responsibility for any abortion (0.8%)

### C. Population Programs

The total population of Cyprus was estimated at 746,100 at the end of 1997, compared with 741,000 in 1996, having increased by 0.7%. In 1997, the number of births in the Government-controlled areas (the Greek Cypriot side) declined from 9,638 in 1996 to 9,275 in 1997, giving a crude birthrate of 14.2 per 1,000 in 1997 compared to 14.9 in 1996. Both the number of births and the crude birthrate have followed a declining trend in recent years. The total fertility rate (TFR), which describes reproductive behavior unaffected by changes in the age of the population, is 2.3, slightly above replacement level but declining.

Cyprus has one of the lowest rates of extramarital births in Europe, and fertility is almost exclusively marital fertility. In 1997, only 146 children were born out of wedlock constituting a mere 1.6% of the total number of births. The mean age of women at the birth of their first child was 25.8 years old, while the mean age at birth irrespective of the older child was 28 years old in 1997. Women in rural areas tend to start younger, compared to urban areas: 24.8 years and 26.3 years, respectively.

At the Special Session of the United Nations on Population and Development in New York, June 30 to July 2, 1999, the Cyprus Delegation reported that:

Cyprus is undergoing demographic changes worth mentioning. Fertility is falling below replacement level and shows no sign of recovery. Concurrently, mortality is on

the decline and currently is at 7.9 deaths per 1000 population. Also, infant mortality is 8.0 per 1000 live births, while maternal mortality is practically zero. Moreover, life expectancy is 75 years for males and 80 years for females. These are indications that Cyprus is going through a period of nearly stagnant population growth, 1.0% per year in the last five years, a phenomenon of population aging. Although, aging does not mean an old population, still my Government is worried about the problems that come in its way and in particular the social and economic implications.

Indeed, the government certainly wants to increase the declining population of 600,000 Cypriots on the island, and is giving incentives to this effect. All parents who have four or more children, so-called “multi-sibling” families, receive monetary and social incentives. For example, each child is entitled to a child benefit allowance of about \$60.00 per child per month, and mothers receive a “mother’s allowance.” Also, all health expenses are paid by the government, as well as subsidies on school fees, books, entrance to museums, theatres, low-interest loans for building or repair of existing home, reduction in months spent doing National Service, tax incentives, and others. There is even discussion in Parliament at present to offer a duty-free car of choice, which is a huge incentive for most families, as car duties can exceed 100% of the value of the car.

In Cyprus, reproductive health is integrated into the primary health care system, and is provided free of charge by public sector institutions and at affordable rates by the private sector. The total expenditure dedicated to health purposes, from all sources, is on the order of 6% of GDP, or 16% of all public expenditure. This compares very favorably with most developed countries.

In Cyprus family planning issues are entrusted to specialist doctors in the private sector, but more so to an NGO subsidized mainly by Government. The services provided are not confined within the narrow meaning of population control but also include access to information relating to sexual and reproductive rights, sexual education, including health issues, reproductive choice and gender equality; it also provides counseling on sexual relations and more recently on the prevention of HIV/AIDS. (United Nations Cyprus Delegation, June 30-July 2, 1999)

Some information regarding the work of the Cyprus Family Planning Association (CFPA) is provided in a recent unpublished study. The data were obtained retrospectively by examining 495 patient records of visits to the CFPA between 1985 and 1997. Most of the women visiting the CFPA were married between the ages of 21 and 41. The most commonly requested services were for birth control and cytology tests. The four major services that women requested were Pap tests, IUD insertions, breast examinations, and prescriptions for the contraceptive pill.

## 10. Sexually Transmitted Diseases and HIV/AIDS

### A. Sexually Transmitted Diseases

There are no systematic surveys that have been conducted regarding sexually transmitted diseases, as most of the population with STDs saw private practitioners who do not need to report these statistics. There are, however, some official statistics, which are based mainly on the monthly returns from the dermatology clinics of the four Government general hospitals. Although rare, certain cases may be reported by gynecologists, urologists, and possibly general practitioners in the private sector. The diseases recorded are those that are considered notifiable and reported to the

World Health Organization (see Table 16). The sharp increase in AIDS cases in 1997 is because of the adoption of a new case definition by the United States Centers for Disease Control in 1993. A workshop on epidemic preparedness was held in November 1999, during which the list of notifiable diseases was revised to include other STDs such as chlamydia.

From the KABP Survey on AIDS of 3,176 schoolchildren examining their knowledge, attitudes, beliefs, and practices related to AIDS, there were a few questions regarding STDs that would be worthy of note (Georgiou & Veresies 1990, 1991).

Twelve questions were designed to tap respondents' knowledge about syphilis, gonorrhea, chlamydia, and genital herpes:

- Close to half the teenagers surveyed had heard something about syphilis: 1,498 (844 boys and 654 girls, or 47.2%)
- Had heard something about herpes: 1,432 (700 boys vs. 732 girls, or 45.2%)
- Had heard something about gonorrhea: 965 (517 boys vs. 448 girls, or 30.4%)
- Only 236 (150 boys vs. 86 girls, or 7.4%) had heard of chlamydia, probably because it is not an STD that is often portrayed through the Cypriot media.

Overall, it appears that Cypriot school adolescents are relatively ignorant regarding STDs compared to their American, Canadian, and English counterparts. This relative ignorance, probably related to the fact that there is no formal sex or health education in schools, needs to be addressed.

Asked more specific questions regarding STDs, the great majority of students were "uncertain." Overall, it appears that less than 20 to 25% of the students have correct knowledge regarding ways of transmission, therapy, prevention, and asymptomatic status of STDs. Perhaps the most striking finding is the fact that only about 25% of the students were aware that condoms can protect against gonorrhea. The overwhelming majority (63.1%) were uncertain about the prophylactic use of condoms. There was also high uncertainty regarding syphilis transmission from an asymptomatic person (57.8%), and whether a person who has caught syphilis once can catch it again (64.3% uncertain, with 15% incorrect). It is clear that these issues need to be urgently addressed in any program on human sexuality.

## B. HIV/AIDS

LAURA PAPANTONIOU

[Update 2003: Note: The following data for HIV/AIDS was abstracted by the Editor from the Ministry of Health, National AIDS Programme (NAP) December 2002 report prepared and provided to the Editor by Laura Papantoniou, M.D., National AIDS Programme Manager. Elements of Dr. Papantoniou's summary in the 2001 volume 4 of this *Encyclopedia* have been incorporated into this summary.

**Table 16**

### Summary Statistics for STDs from 1995 to 1998 and for AIDS from 1994 to June 1999

STDs	1994	1995	1996	1997	1998	1999
Syphilis		23	32	32	33	
Gonococcal urethritis		56	48	61	42	
Non-gonococcal urethritis		220	206	166	114	
Herpes genitalis		137	118	122	118	
Genital warts		140	81	77	97	
AIDS	40	49	57	85	91	97

## [Dimensions of the Epidemic

[Our current knowledge of the HIV/AIDS epidemic in Cyprus is based on epidemiological surveillance, which covers the period between the first reported AIDS case in 1986 and the end of December 2002. From 1986 on, this surveillance has included both cases of AIDS and cases of asymptomatic HIV infection. There has been an upward trend in the number of new cases of HIV infection diagnosed in each year until 1994, followed by a slight decrease until 1998. A small increase observed between 1999 and 2002 was mainly because of cases among foreign people and cases of clinical AIDS among repatriated Cypriots, who returned to Cyprus to continue their treatment that had been initiated abroad and was interrupted, mainly because of interruption of the supply of free drugs.

- [A. Between 1986 and December 2002, 392 cases were reported to our program, 229 Cypriots and 163 foreigners. The great majority of the foreigners have left the country immediately after diagnosis, since the test was mainly done in order to obtain a stay permit, for work or studies.
- [B. Among the group of seropositives who are Cypriots or foreign permanent residents, 203 are men and 42 are women, giving a sex ratio of five men for one woman.
- [C. The main mode of transmission is sexual intercourse, which was reported by 91% of known seropositives. Homosexual intercourse was reported in 44.1% and heterosexual intercourse in 46.9% of cases. Blood transfusions accounted for 3.3%, but these are all cases that were diagnosed before 1987 and all of them were transfused or received blood products abroad. Another 1.6% reported illegal drug use and it is possible, though not confirmed, that they were infected through the use of infected needles. This percentage is very low by international standards, but we have to bear in mind that in Cyprus, drugs trafficking and use have increased significantly in recent years, and we need to be on the alert for the implementation of the necessary preventive measures. Perinatal transmission—from mother to child during pregnancy, delivery or breastfeeding—occurred only once in Cyprus, whereas, in four other cases regarding seropositive pregnant women, timely action with the administration of antiretroviral drugs to the mother during pregnancy and to the newborn has averted mother-to-child transmission. In 3.7% of cases, there is no information regarding the mode of transmission. However, these represent cases that were diagnosed at the initial stages of the epidemiological surveillance, when recording of information was less detailed.

[Mean age at diagnosis is rather advanced in Cyprus compared to most other countries, being 34.2 years. A proportion of 73.5% of seropositives were aged between 20 and 40 years at the time of diagnosis, and this is in concordance with the fact that the main mode of transmission is sexual intercourse.

[Monthly epidemiological reporting is based on data collected from the sources shown in Table 17. Table 18 shows the numbers of new cases of HIV infection by year. Since the beginning of the surveillance in 1986, 140 seropositives were AIDS patients at the moment of diagnosis or subsequently developed AIDS. Of those people, 52 subsequently died of AIDS.

## [Preparing Phase Two Response

[When the strategic plan covering the period 1995-1999 ended, a workshop took place in October 2001 to prepare

the next five-year plan, under the guidance of a WHO expert. The Phase Two plan, in its initial stage, is being designed to address the main groups that were identified by the workshop participants as being at risk for HIV infection: drug abusers, youth, and men who have sex with men.

[The evaluation and follow up of the 1995-1999 Programme was based on systematic epidemiological surveillance and on sentinel surveillance in selected populations. Behavioral studies have been initiated among selected sections of the population. *A Study on the Knowledge, Attitudes and Behaviour Regarding AIDS, Sex and Sexually Transmitted Diseases, Among the Adult Population of the Limassol Town and Rural Areas* was carried out in 2001. Preliminary results from this study are described below. Further statistical and sociological analysis of the results is planned. This is considered to be a pilot study that will serve for the carrying out of a nationwide study that will cover the remaining areas of the government-controlled part of Cyprus.

[Despite the low HIV prevalence in Cyprus at present, the potential for increase in the number of new cases is visi-

ble, particularly among persons with risky sexual behavior and among people who are making use of illegal drugs. The study was undertaken in order to obtain quantifiable data on the individual and public risk in Cyprus of becoming infected with HIV and other sexually transmitted diseases and on various ethical and social aspects related to HIV infection.

[This study is of the cluster type, based on WHO methodologies, regarding the sampling of communities and of individuals within these communities. The sampling frame used was the list of cumulative totals of the population of the communities included in the 1992 census, which at the time was the most recent census that has been conducted. The sample selected consisted of 505 individuals—243 men and 262 women.

[Eligible for participation were Cypriots and other permanent residents (over 3 months in Limassol District) aged 18 to 50 years. Foreign workers on contract, foreign students, and Cypriots who live permanently abroad were excluded but are eligible for a different study design that will probably be planned in the future.

[Out of 767 households visited, 601 households were eligible for participation to the study. There were 96 refusals and 505 participations, giving a participation rate of 84%. Results of the study are summarized below:

[*Survey Results: Knowledge.* Cypriots who participated in the *Study on the Knowledge, Attitudes and Behaviour Regarding AIDS, Sex and Sexually Transmitted Diseases* proved to be quite knowledgeable about the modes of infection with HIV, except in the case of perinatal transmission, which 20% of respondents failed to identify correctly. Ways by which HIV is not transmitted are less well recognized, with misconceptions ranging from a low 13.5% of those believing that eating with an HIV-infected person can expose one to the risk of infection with HIV, to a high 66% of those believing there is risk of acquiring HIV infection during the act of donating blood. The percentage of people who believe that insects can transmit HIV is 46.4%.

[When different ways of protecting oneself from HIV are considered individually, knowledge may be rated as medium to high, ranging from 63% for abstinence from sex, to 93.7% for avoidance of common use of needles. Correct condom use is correctly identified as protective against HIV infection by 93% of the respondents.

[Avoiding people who are HIV-positive and using the contraceptive pill (by women) are still considered by 27% and 23%, respectively, as ways of protecting oneself from HIV infection.

[Naming correctly at least two ways of protecting oneself from HIV is used for the estimation of Prevention Indicator a. The level of 90% specified for Prevention Indicator a (P.I.a) is not reached, since the highest percentage for naming correctly two ways of protection is 82%, represented by the combination of "avoiding common use of needles" and "correct condom use."

[Knowledge on the general features of HIV infection is medium to low. As many as 65% of respondents did not know that an HIV infected person can have a negative test for HIV, whereas 26% did not know that it is possible to be infected with HIV but have no external signs of it. A proportion of 83% did, however, recognize that the presence of another sexually transmitted disease increases the risk of HIV infection.

[*Survey Results: Attitudes.* Relatively low proportions of respondents consider that using a condom is a man's responsibility (53%) or a woman's responsibility (56%). (The possibility that the questions may have been misinterpreted should be explored and relevant corrections made before using the questionnaire in future surveys). Eighty-seven

**Table 17**

**Sources of HIV Testing in Cyprus**

Source	Rate*	N
Contacts of HIV-infected people	2.52	714
Suspected AIDS patients	80.22	91
Routine diagnostic testing of in-patients in the public and the private sector	0.03	91,320
Voluntary testing in the government services	0.16	64,324
Routine testing of pregnant women in the public sector and partly the private sector	0.003	37,536
Foreign workers and foreign students	0.32	20,815
Foreign bar girls	0.06	62,137
Blood recipients**	0.08	13,957
Routine testing of STD patients of Government dermatology clinics—sentinel surveillance	0.0	1,394
Universal screening of blood donors	0.003	458,288
Registered Cypriot prostitutes	0.0	1,078
Child from HIV+ mother***	25.0	
Intravenous drug users	0.0	36
Non-intravenous drug users	0.0	48
Prisoners	0.06	6,309
National Guard (recruits, sentinel surveillance, 1998)	0.0	3,423
Premarital testing group for thalassaemia****	0.0	307

\*Rate of infection per 100 persons tested.

\*\*Multi-transfused only are recorded. All known cases were infected abroad before 1997.

\*\*\*Based on 4 known cases of HIV+ pregnant women.

\*\*\*\*1992-1993 sentinel surveillance; we are contemplating resuming sentinel surveillance.

**Table 18**

**Numbers of New HIV Cases in Cyprus by Year**

Up to 1986: 11	1991: 22	1996: 28
1987: 17	1992: 24	1997: 27
1988: 16	1993: 24	1998: 19
1989: 24	1994: 39	1999: 23
1990: 16	1995: 35	2000: 29

percent of respondents (86.4% of men and 87.5% of women) stated that they could get a condom any time they need it. People who believe they can protect themselves from HIV by avoiding risky sexual behavior represent 91% of the respondents. A proportion of 17.3% of respondents believe that a woman who carries a condom in her bag is loose, whereas 34.9% believe that a woman and 14.3% that a man should guard their virginity until marriage.

[It is believed by 85.1% of respondents that alcohol can lead to risky sexual behavior and by 81.3% that the intravenous-drug-related risk for HIV is high in Cyprus. Risk of getting AIDS from foreigners is believed by 83.8% to be increasing in Cyprus. The corresponding figure regarding Cypriots is 60.2% of respondents. As many as 77% of respondents (79% of men and 52% of women) consider that it is acceptable to donate blood so as to have a test for HIV at the same time.

[Positive attitudes towards people with HIV are noted on the whole. However, 6.2% believe that HIV-infected people got what they deserved and 5% believe that they should be isolated away from society. A proportion of 68% (72% of men and 65% of women) stated they could be friends with an HIV-infected person and 91% believe that free care for HIV should be provided by the State.

[Participants were asked to adopt (or reject by not marking) various statements about a) people with multiple sexual relationships, b) morality, and c) factors which control sexual behavior. Further analysis is needed, for better validation of the answers to this type of questions.

[*Survey Results: Behavior.* Data on the behavior of the participants identified various sexual activities and provide limited information on the use of drugs and alcohol. The main findings are as follows:

[Five out of six, 86.5%, of respondents stated that they had had sex (defined as penetrative sexual intercourse in the questionnaire). The proportion of people having had sex increases with age, whereas respective proportions for men and women are 92.1% and 81.4%, presumably because of the earlier onset of sexual activity in men. Mean age of onset of sexual activity is: 17 years for men with a range of 12 to 29 and 20 years for women with a range of 13 to 36. Moreover, 13% of men started sexual activity before the age of 15 and 50% between 15 and 17; 2.5% of women started sexual activity before the age of 15 and 30% between 15 and 17. On average, both men and women tended to have had sex for the first time with an older person than themselves.

[Forty-three percent of people out of those who stated that they had had sex, reported having had sex with a person other than their steady sexual partner at some time in their lives (respective proportions for men and women are 67.8% and 17.3%). (The question does not define what is meant by "steady sexual partner" and does not ask whether the intercourse with a non-steady partner took place while the respondent was in a steady, free relationship or in wedlock. In future surveys, inclusion of these clarifications will be considered).

[Among the people who answered that at some time they had had sex with a person other than their steady partner, 63.5% stated that they used a condom in the last sexual intercourse with a non-regular partner. Reasons cited for not using a condom during the last sexual contact with a non-regular partner include the partner's refusal (5%), not having thought to use one (22%), being dizzy from alcohol drinking (10%), and the belief that it decreases pleasure (58%). (The question did not include options for the participants to state whether they were "embarrassed to buy one" or "embarrassed to ask partner to use one," and this should be included in the questionnaire for future use). Of those having had sex with a non-steady partner, 48.3% stated that

they always used a condom with the non-steady partner, 33.8% stated they used one sometimes, and 17.9% stated they never used one.

[The proportion of people reporting use of intravenous drugs at some time in their life is 1.7% for all categories. For the 18-to-20 age-group category, this proportion is 4.3%. One in 40 respondents, 2.4%, reported having had a sexual partner who was a drug addict at some time in their lives. It is interesting to note that 11.3% of respondents—17.5% of men and 4.9% of women, as well as 25.9% of people aged 18 to 20 years—reported having been led at some time in their life to unchecked sexual behavior because of alcohol consumption. These figures are close to figures obtained from studies on drug use conducted in Cyprus among school youth.

[The mean number of lifetime sexual partners is 14 for men, with a range of 1 to over 100 (the latter reported by four people), and 2.5 for women, with a range of 1 to 20 (also one woman at 45). Some overreporting of sexual activity in men and some underreporting in women is to be expected, because of prevailing social norms and taboos. It is believed, however, that differences in mean number of sexual partners in men and women do exist and that men would tend to have sexual contacts with people not meeting the inclusion criteria to the study, such as foreign bar girls or visitors. This issue would have to be clarified in future research.

[It is interesting to note that the interviewers reported that on some occasions men tended to brag about their sexual achievements, leading presumably to an exaggeration in their recorded answers. Most of these cases concerned men who visit nightclubs and bars on a regular basis. On the other hand, some women seemed shocked that it was even considered possible that they engage in such activities. (It is specified that interviewers were asked to record on separate sheets of paper or to report verbally to us any interesting reactions and situations encountered in the households, and this has led to the collection of very interesting comments regarding the reactions of the participants. This information will have to be evaluated in the course of future study of the survey results. It is, also, reminded that, because of the methods used in data collection, identification of respondents and linkage of information to known individuals are quite impossible).

[Six percent (6.3%) of men and 3.8% of women stated that they had had sex with a person who was of the same gender as themselves at some time in their lives. These figures are very interesting, since the forbidden nature of the subject did not allow for much optimism as to the level of response to the question. It is very encouraging to have obtained even this level of response, though this figure should be considered a clear underestimate of the true level of homosexuality. It is noted, however, that it is comparable to some of the results obtained by Kinsley in his famous study, *Sexual Behavior in the Human Male*, conducted in 1948 in the USA on 12,000 males, at a time when acceptance of homosexuality was probably at similar levels as it is currently in our country. This issue is being examined in cooperation with the Gay Liberation Movement of Cyprus, for a more in-depth evaluation, in light of statistical and sociological information from the extensive international research.

[Six percent (6.3%) of respondents (5.7% of men and 7.0% of women) stated that they had at some time been forced to have sex. The question does not specify whether the event took place within or outside the family. It is interesting to note that in a recent study conducted by the Advisory Committee for the Prevention and Handling of Violence in the Family, 11% of respondents had admitted having been victims of violence in their family, but it is not

specified which proportion had suffered sexual violence. Further evaluation is needed.

[It is very important to note the early onset of sexual activity and the large number of sexual partners reported by relatively large proportions of the respondents, and this information should be taken very seriously into consideration in the preparation of future preventive strategies against AIDS and other sexually transmitted diseases. All this information will have to be reexamined and evaluated, in cooperation with the authorities dealing with the study and management of the drug problem in Cyprus.

#### [Costs and Financing of Treatment and Care

[*Estimated Costs.* Care for HIV-infected persons and people seeking support from the National AIDS Programme includes free medical care (antiretroviral treatment and treatment for opportunistic infections and neoplasms), nursing care, laboratory support for the diagnosis of cases and the monitoring of treatment based on WHO guidelines, and counseling for HIV-infected individuals and their families and for people undergoing examination for HIV. These services are offered free of charge to all citizens of the Republic and for a fee to people who are not citizens of the Republic.

[Table 19 shows the cost of delivering antiretroviral treatment to patients from 1995 to 2002. The cost of other components of HIV/AIDS care include:

1. General treatment costs involving nursing, counseling, laboratory diagnosis and monitoring (including CD4 count and viral load), treatment for opportunistic conditions, and hospitalization costs. The costs for this component of care have not yet been evaluated.
2. Assistance from the Social Welfare Department: according to general terms applying to the general population. Social workers make home visits for social and financial support.
3. Assistance from the AIDS Fund: Christmas bonus per person ranging from £400 to £2,000 (US\$800 to \$4,000), according to socioeconomic evaluation.
4. Assistance from nongovernmental organizations: in close cooperation with the AIDS Programme (employment of a psychologist for AIDS Clinic needs, financial assistance in urgent cases, insurance for the education needs, and tuition fees of children of HIV-infected people).

#### [Financing HIV/AIDS Care

1. The healthcare expenses are covered through the Ordinary Budget of the Republic.
2. The expenses for the support of PWHIV/PWAIDS are covered in part through the AIDS Fund, and in part from the Social Welfare Department and voluntary activities, as mentioned above.

**Table 19**

#### Cost of Antiretroviral Treatments (Delivery Statistics)

Year	Pounds	Dollars
1995	£ 20,114	US\$ 40,228
1996	64,008	128,016
1997	244,908	489,816
1998	317,012	634,024
1999	333,610	667,220
2000	493,090	986,180
2001	612,334	1,224,668
2002	610,405	1,220,810

3. The educational campaigns and the research activities are undertaken in part by the regular personnel of the Ministry of Health and in part in collaboration with non governmental organizations. Preparation of health education material (including purchase of condoms) and research activities are financed through the AIDS Fund, through the Development Budget, and through the Publications Programme of the Public Health Information Office. The AIDS Fund is financed mainly through voluntary donations and in part through the government budget. This arrangement is not always adequate with regard to the basic needs of the NAP.

#### [Future Requirements

[Main concerns at present are linked to risky sexual behavior, which has been the basic driving force of the epidemic until now, since over 90% of cases have been infected through sexual intercourse, and to the increasing use of illicit drugs, which has a potential for a sudden increase of new cases of HIV infection.

[*Health Education.* Based on the international experience that knowledge does not necessarily lead to behavior change, a new orientation is now being promoted, with the development of peer education projects in schools. Despite the fact that the first attempts were highly encouraging and successful, peer education has not yet been applied on a routine basis in schools because of a shortage of staff and time constraints. Most other health education activities are also focusing on the area of behavior change in youth and other sections of the population. Such activities are information kiosks, special events, lectures, messages and programs using mass media, youth meetings, and others.

[It should be noted that health education is facilitated by the fact that sex issues and the subject of condom use may be easily addressed in Cyprus because of the high level of knowledge and sensitization among the population. Opposition from certain society leaders, mainly the Church, is hampering full implementation of effective health education. New material is being constantly developed, such as brochures, booklets, posters, TV spots, videos, and various advertising items (key rings, T-shirts, etc.) as a necessary complement to these activities.

[Health education focuses mainly on sexual behavior, but all other important issues, i.e., compassion and avoidance of discrimination, safe blood donation, dangers of drugs and other habit-forming substances, and the hazards of perinatal transmission, are addressed as well.

[Based on the country situation and the recommendations from WHO/UNAIDS, the immediate requirements for the National AIDS Programme may be defined as follows:

1. Finalization of the next five-year strategic plan.
2. Restructuring of the National AIDS Committee to conform to current needs of the program.
3. Continuing and strengthening the provision of services already provided through the National AIDS Programme.
4. Ensuring a mode of steady financing for the AIDS Fund through the government budget.
5. Improving local expertise through relevant training (clinical, counseling, nursing, epidemiology, laboratory, and health education) and through an increase of the number of personnel where relevant (e.g., health visitors and counseling service).
6. Strengthening intersectoral collaboration by improving and increasing the involvement of key nongovernmental organizations and government services in program activities.

7. Expanding peer education programs to cover all final year students of secondary education and, at a later stage, students of lower grades.
8. Providing information to various groups who are inaccessible for purposes of peer education (Parents' Committees, army personnel, police, etc.), but may be approached through lectures, the media, special programs, and other events.
9. Reaching out to groups that are, for various reasons, difficult to approach (men who have sex with men, drug addicts, and sex workers).
10. Promoting further research in behavioral studies (knowledge, attitudes, and behaviors) and focus-group discussions, in relation to AIDS, sex, sexually transmitted diseases, and drug abuse among the general population and the school youth, in epidemiological monitoring (strengthening of routine monitoring and continuing/initiating sentinel surveillance among youth, adult males, and army recruits), and in evaluating the socioeconomic impact of the epidemic.
11. Strengthening the cooperation with the drug-abuse control program.
12. Strengthening the cooperation with the sexually transmitted diseases control program.
13. Upgrading the legislation with regard to HIV/AIDS.

### [Conclusions

[In the light of the above epidemiological and general information, it is evident that the HIV/AIDS situation in Cyprus is comparable to that in other Western countries. Based on current epidemiological evidence, health education activities are focused mainly on prevention of transmission of HIV through sexual intercourse, with the main emphasis on abstinence, delayed sex, mutual faithfulness, and the correct use of condoms. Peer education in schools and in youth NGOs is being promoted, though at present, it has only been implemented on a pilot basis. Program evaluation is planned according to WHO guidelines and constitutes an integral part of the NAP, but has not been implemented to a satisfactory degree to date. (*End of update by L. Papantoniou*)]

[*Update 2002*: UNAIDS Epidemiological Assessment: This combined epidemiological assessment is for both the Turkish Republic of Northern Cyprus (TRNC) and the (Greek) Republic of Cyprus.

[HIV seroprevalence among blood donors has been reported below 0.01% in Cyprus since 1989. There was no evidence for HIV infection among pregnant women that were tested from 1998 until 2001, with the exception of one HIV case detected among 4,019 pregnant women in 1992 and one case detected among 2,422 pregnant women in 2001. HIV seroprevalence among bar girls remains below 1%. No infection has been detected among sex workers over the years. HIV prevalence among injecting drug users is reported to be between 0.1% and 0.3% between 1993 and 1999. Of clients of voluntary counseling and testing, 0.4% and 0.8% were found to be HIV-positive in 1999 and 2000, respectively.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	< 1,000 (rate: 0.3%)
Women ages 15-49:	150
Children ages 0-15:	NA

[No estimate is available for the number of adults and children who died of AIDS during 2001.

[No estimate is available for the number of Cypriot children who had lost one or both parents to AIDS and were under age 15 at the end of 2001. (*End of update by the Editors*)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

### A. The General Situation

There is scant information on sexual dysfunctions and therapies in Cyprus, mainly because of the lack of qualified, professional therapists who can systematically collect such data. As of 1999, the main author was still the only professionally qualified sexologist with doctoral training on the island. There were a few psychologists who attempted sex therapy using psychoanalytic techniques with very poor results. There were also a number of medically qualified dermatologists, STD specialists, and urologists who advertised as "sexologist," but are not qualified in any form of sex therapy and have no specific training in this field. Their treatments included mostly drugs and papaverine and prostaglandin penile injections for both erectile problems and premature ejaculation, regardless of etiology. In 1999, Viagra was granted an import license, and no doubt this will be used widely. The situation is quite sad really, as many patients fall victim to costly medical treatments without seeing any benefit.

Unfortunately, at present, Cypriot law does not regulate the training, certification, or licensing of sex counselors or therapists. Anyone can advertise freely on their signs whatever they wish, on the condition that they do not use the adjective "specialist." So "dermatologist-sexologist" is a legal sign, but "dermatologist-specialist sexologist" would be illegal if the individual does not have qualifications and clinical training in sexology. Few Cypriots are aware of this distinction and its inevitable consequences for the delivery of effective healthcare in this specialized area.

[*Update 2003*: The medical profession is quite determined to protect their self-interests and will not allow any other profession, even qualified clinical sexologists with doctoral degrees, to practice sex therapy on the island. The law regarding medical practice written in the 1960s and amended in 1979 clearly states that no one can diagnose or treat without being a qualified medical practitioner. The editor and author of this work has been arrested once and taken to court a second time based upon charges brought against him by the president of the Cyprus Medical Association. The charge was practicing medicine without being a qualified medical practitioner. On both accounts, the case was thrown out and nothing further was heard, but the Medical Association is far from happy with this situation. There are frequent "witch hunts" and publications in the local media about 'apparent sexologists' exploiting the public, and being called charlatans along with other 'titles.' This anachronistic legislation will be tested in a court of law in order to bring it in line with European standards. (*End of update by G. J. Georgiou*)]

### B. Some Limited Observations

#### *The Population and Its Problems*

The following observations have been culled from 840 clinical cases of Cypriots with sexual dysfunctions who sought treatment at the editor's Natural Therapy Centre in Larnaca between 1993 and 1996. Some additional insights came from a survey of sexual knowledge, attitudes, beliefs, and practices of 3,176 schoolchildren aged 14 to 18 years old conducted under the auspices of the World Health Organization (Georgiou et al. 1990), a study of the sexual attitudes of Greek Orthodox priests (Georgiou 1990), a 1995 book on the treatment of premature ejaculation by the editor, and *Homosexuality*, a book written in 1982 by the Pancyprian Society of Psychic Health after a seminar on homosexuality.

A quarter of the editor's clinical population were age 18 to 25, 40% between ages 26 and 35, 21% from age 36 to 45,

9% ages 46 to 55, 4% between the ages of 56 to 65, and the remaining 1% 66 and older. One percent of the sample had not completed elementary school, 12% had attended junior high school but not graduated, 12% had attended school to age 15, 40% had completed high school, and about 20% were university graduates. Two thirds of the subjects were married, 12% engaged, 2% separated, 1.5% divorced, 1% widowed, and 18% single. Some of the 840 attending were partnered, but individual histories were taken, and are presented here as such. The sample is quite representative of the spread of occupations on the island, and covers professionals (13%), technical—plumbers, electricians, and so on (9%), business people (20%), clerical (12%), civil servants (10%), housewife (6%), agricultural (11%), unskilled (9%), students (3%), unemployed (1.5%), waiters and hotel workers (5%), and others (4%). All clients completed a sexual-history questionnaire covering 75 topics or questions modeled on Wardell Pomeroy et al.'s *Taking a Sex History* (1982).

In terms of the whole sample of 840 patients, the most common problem was secondary erectile dysfunction (30%), with an additional 2% primary erectile dysfunction. Other male dysfunctions included premature ejaculation (24%), retarded ejaculation (2%), and male sexual desire disorder (5%). Secondary inhibited orgasm (7%) was the most common female complaint, with an additional 3% presenting with primary inhibited orgasm—the total of female inhibited orgasm: 11%. Other female dysfunctions included vaginismus/coital phobia (11%) and female sexual desire disorder (6.5%). One percent presented with problem paraphilias, mostly “flashing.”

### *Premature Ejaculation*

Males suffering from premature ejaculation commonly postpone treatment for years, waiting until the stress and anxiety of the chronic situation makes the problem a lot worse and their marriage is threatened. Only 15% of premature ejaculators seek help within three years of onset. Thirty-seven percent wait four to ten years, 31% wait 11 to 20 years, and 4% wait more than 20 years. In comparison, men with erectile dysfunction are much quicker to seek help, probably because their problem directly threatens their male ego. Ninety-two percent of impotent men sought help within three years of onset, 4% within four to ten years, and 4% in 11 to 20 years. A strong majority of premature ejaculators recall ejaculating quickly from their early masturbatory experiences.

This appears to support Helen Singer Kaplan's (1983) theory of the ejaculatory reflex being conditioned to ejaculate early from the initial sexual experiences. Very few of the males recalled otherwise. Most of the males who came for treatment for premature ejaculation had the problem for many years, on average about ten years, but only decided to seek help when additional stress factors had exacerbated the problems to such a degree that many were ejaculating before intromission. Certainly the majority where finishing in 10 to 20 seconds, to the woman's growing frustration. At this point, additional coercion from the wife resulted in the men seeking help.

### *Erectile Problems*

Many cases of erectile problems began with an extramarital partner, and not with the wife or major partner. This may be because of the tremendous performance anxiety that is again related to the huge Mediterranean masculine ego to “conquer” the woman and show her that one is a “man.” I have also thought that it may have been because of the anxiety related to the pricking of consciences, but having spoken at length to many of these men, this does not appear to

be the case. Indeed, many of them had come to me not so much to improve their relationship with their wives, but to help them “get it up” so that they could “prove” their manhood with their girlfriends. Many actually expressed satisfaction in the wish to “do it just once” with the girlfriend, and that would be enough! The shame, disappointment, anguish, and bruised ego was very apparent in many of these men. The vast majority of them had no sexual or relationship problems with the spouse—their motivation in pursuing an extramarital partner was purely to satisfy their ego, and not much else.

In addition to these psychological problems, I have found causes related to dietary stresses and abuses, smoking, nutritional deficiencies, subclinical hormonal imbalances, subclinical hypothyroidism, reactive hypoglycemia, toxic metal status, systemic toxemia, and others. These causes I would consider as “organic,” but not in the traditional classical medical view of organic. There may not be any obvious pathology that can be measured on blood tests, Doppler, or morphological changes, but there is a continuum of health and disease, with a lot of gray areas in between. Many of these men have malfunctioning organs and tissues, which inevitably will affect penile functioning, unless one holds the view that the penis has its own will and personality and is totally independent of other bodily functions. Cognitive-behavioral sex theory is often quite effective in treating an erectile problem that is strictly psychogenic in etiology, but compound a psychological factor with smoking two packs of cigarettes a day, eating fast foods full of empty calories and fats, working a 12- to 18-hour day, drinking alcohol regularly to “destress,” being anxious and insecure about the future, and so on, as many Cypriot males do, and it is obvious that something more than traditional cognitive-behavioral sex therapy may be indicated, including nutritional and homeopathic remedies.

### *Vaginismus*

A clinical incidence of 11% for vaginal spasms in Cypriot women is much higher than reported in other countries, where the reported incidence ranges between 1 and 4%. The origin of this difference, I believe, lies in the cultural dynamics, and specifically the sexual messages that both sexes receive while growing up in Cyprus. The male child gets messages based around: “You are a male, so it is normal, acceptable, and a sign of your manhood to pursue and conquer females sexually,” whereas the woman gets a very different message: “You are a female and must remain a virgin, as this has direct links with your honor and that of your family—be careful as males are cunning and are only after one thing.” Sixty-nine percent of the women in this clinical sample were virgins until they married, compared to only 9% of the men. The women had limited premarital experiences, and their sexual knowledge was obtained mainly from friends and media—with all the misconstrued ideas and prejudices that are inevitable from such sources, mixed with a high level of anxiety and neuroticism. A large majority of the vaginismic women reported dwelling on the fear of coitus, starting when some friend or cousin shared her initial “painful” sexual experiences, saying that the pain was unbearable, and that they had hemorrhaged. Without exception, these women had high scores on the Spielberger Trait Anxiety Inventory (SPAI), averaging at least one or more standard deviations above the mean for their age group.

### *Dysorgasmia*

There appears to be a problem with the statistics for dysorgasmia, which one would expect to be higher than the

10% reported in this limited clinical sample, particularly when 24% of the males have a chronic problem with premature ejaculation. Again, the answer may lie in cultural values and conditioning. Cypriot women are very reluctant to discuss their sexual lives with a complete stranger, even when that person is a competent professional in the sex field. Also, Cypriot women have been taught not to consider or make a fuss about the quality of their sexual pleasure, given that their male is performing like an *epividoras* (stud). Cypriot women tend to lament in silence, perhaps until things in the marriage get to such a point where frustrations can no longer be tethered. Other causes may include physical and mental fatigue from coping with home, work, and many children, an insensitive husband who is tender only in bed, limited sexual foreplay because of ignorance and inhibitions, marital discord, and certain "naturopathic" organic causes. Similarly, I believe the incidence of female sexual desire disorder, a scant 6.5% in my clinical sample, is not indicative of the actual incidence of female inhibited sexual desire in the general population. Cypriot women are not taught to expect much from their sexual relations, and so they suffer in silence. We simply do not see these people in clinical practice.

### Male Coital Phobia

A recent development in this limited clinical sample has been a three- to fourfold increase over the past two or three years (compared with five years ago) in the incidence of males seeking help with unconsummated relationships owing to their own coital fears. I have no explanation for this fascinating phenomenon, which is certainly worthy of being researched.

The main author's clinical experience with over 10,000 patients in the last 16 years in Cyprus suggests that the treatment of sexual problems in both sexes is getting more and more difficult. Modern Cypriots are more stressed and anxious, more concerned about finances, apprehensive about the future, concerned about personal safety, have less time for relaxation and leisure activities, are more affluent with all the consequences of bad eating and drinking leading to poor health, and more.

## 12. Sex Research and Advanced Professional Education

Certainly there is much research that needs to be done in the field of human sexuality on the island of Cyprus. Lack of funding for such research has left the island literally virgin territory for sexology.

The tertiary educational establishments on the island, and there are many, do not even have a single course geared to human sexuality. Perhaps the administrators and educators see it as unnecessary, or fear that it would take up additional space on a busy curriculum. Perhaps it is the inhibitions of the governing bodies to include such topics in the curriculum. Whatever the case, these topics do not exist, neither in the private institutions that award undergraduate and postgraduate degrees from external universities, nor in the one and only newly opened University of Cyprus. It goes without saying that there are no sexological journals and periodicals published in Cyprus, or indeed any national and regional sexological organizations. It is difficult to set these up with only one member!

Certainly the talent for research exists on the island. We have the second highest rate of university graduates per population ratio in the world, as well as the technology and infrastructure. We also have keen researchers who would love to participate in ongoing research. If someone will fund, research will progress.

## PART 2: TURKISH CYPRUS

KEMAL BOLAYIR and SERIN KELÂMI

### *Demographics and a Brief Historical Perspective*

ROBERT T. FRANCOEUR

#### A. Demographics

In July 2002, Turkish Cyprus had an estimated population of 200,000 out of an estimated total Cypriot population of 767,000. All data are from the authors, and pertain to the Turkish Republic. Readers are invited to compare these figures with those in Part 1, Greek Cyprus, of this chapter.

**Age Distribution and Sex Ratios:** 0-15 years: 29% with 1.04 male(s) per female (sex ratio); 16-64 years: 65% with 1.2 male(s) per female; 65 years and over: 10% with 0.77 male(s) per female; *Total population sex ratio:* NA

**Life Expectancy at Birth:** *Total Population:* 74.03 years; *male:* 73 years; *female:* 75 years

**Urban/Rural Distribution:** NA

**Ethnic Distribution:** 98.7% Turkish and 1.3% Maronites, Greeks, and other nationalities

**Religious Distribution:** 98.7% Muslim

**Birth Rate:** 17 births per 1,000 population. The rate is rather high because of the people who emigrated from Turkey.

**Death Rate:** 8 per 1,000 population

**Infant Mortality Rate:** 9.5 deaths per 1,000 live births

**Total Fertility Rate:** 2.2 children born per woman

**Population Growth Rate:** 0.4%

**HIV/AIDS (2000 est.):** *Adult prevalence:* 0.1%; *Persons living with HIV/AIDS:* 100; *Deaths:* NA. (For additional details from [www.UNAIDS.org](http://www.UNAIDS.org), see end of Section 10B.)

**Literacy Rate:** 94% can read and write

**Per Capita Gross Domestic Product (purchasing power parity):** US\$4,000; *Unemployment:* 19%; *Inflation:* 51% (2001 est.)

#### B. A Brief Historical and Cultural Perspective

Cyprus occupies a very important strategic position in the triangle of Asia, Africa, and Europe. Because of this strategic significance, several countries occupied the island of Cyprus during its history. Among these countries, the most important ones were the Phoenicians in the 10th century B.C.E., the Romans in 58 B.C.E., and the Ottomans, who were there for 300 years starting in the 16th century. After the division of the Roman Empire, the island became part of the Byzantine Empire. Cyprus was ruled by Britain during the Christian Crusades to the Holy Land. Later, the Lusignans and Venetians came to Cyprus.

In 1571, the island was occupied by the Ottoman Empire and ruled by them until 1878 when it was leased to Britain at the Berlin Congress during the Crimean War. In 1914, Britain annexed the island when the Ottomans participated in World War I on the side of the Germans. At the Lausanne conference in 1925, Cyprus became a British Colony and remained so until 1960 when independence was declared and a bi-communal Republic of Cyprus was established.

During the British administration, Cyprus was the scene of disturbances as a result of Greek Cypriots' campaigning and efforts for *Enosis* (the aspiration to unite the island with Greece). The Turkish community strongly opposed the union of the island with Greece. The first major uprising was in 1931 when the Greek Cypriots set fire to the Government House. The second move came in 1955 when again the Greek Cypriots launched the Eoka terrorist attacks.

The colonial government cooperated with the Turkish Cypriots and tried to suppress the Greek violence. The reason why the Turkish Cypriots cooperated with the British was because the only aim of the Greek Cypriots was the union with another country, Greece, not the independence of all the Cypriots.

The Republic of Cyprus had a short life of just over three years. In 1963, the island again became the scene of intercommunal strife, and the regime collapsed. On March 5, 1964, the United Nations (UN) Security Council recognized the Greek Cypriot faction of the government as the official government of the Republic of Cyprus. This UN resolution contributed to the continuation of intercommunal conflict resulting in ten thousands of Turkish Cypriots abandoning their villages and homes in the big cities and living as refugees in restrictive enclaves in the north.

In 1974, the Greek Junta joined hands with the fanatical Greek Cypriot elements and annexed the island to Greece (until the Junta was replaced by a democratic government). Because of this, Turkey exercised her right of intervention under the 1960 agreements and intervened in July 1974. Since then, the two communities have been living separately in two regions, the Turkish Cypriots in the north of the island and the Greek Cypriots in the south. The intercommunal talks for solving the Cyprus issue have not produced any positive results. However, the recent decision of the European Union (EU) to accept Cyprus as a member has perhaps created an opportunity for ending the division of the island. In

May 2003, the borders between the north and south were opened, signaling a new attempt at reunification.

## 1. Basic Sexological Premises

### A. Traditional Turkish Cypriot Family Life and Gender Roles

Since the beginning of the 20th century, Turkish and Greek people of Cyprus have engaged in agriculture and animal husbandry. In the cities, Turks opted to become civil servants, whereas the Greeks engaged in trade alongside with employment in government services.

As in other Mediterranean countries, Turkish Cypriot women traditionally occupied themselves with work at home while the male population undertook the role of the breadwinner. But, in time, these sorts of activities could not secure a prosperous life. It was difficult to have sufficient income and maintain a decent life for the family because of the lack of irrigation water and technical insufficiencies obstructing productivity, especially in the northern rural areas. This shortcoming affected the social life of the family. In due course, in order to obtain a better income, people had to move from villages to the big cities.

In the traditional Turkish community, the man was the head of the family. He was responsible for the protection of the family's honor and dignity and for ensuring a better life for all. The activities at home did not concern him very much. He spent most of his free time at coffee shops and clubs, which were only visited by men.

Women in the traditional Turkish family were responsible for all the work inside the home, looking after the children, cooking, washing, tending the domestic animals, and meeting the husband's various needs. Above all, she had to be honest and dignified and protect the family honor in every respect. Women and grownup girls normally stayed at home and did not frequent places visited by men, but visited other women friends in their homes. In mosques, women occupied specially prepared areas where men could not see them. Sexual relations between husband and wife were strictly secret, even kissing each other was not disclosed to third parties. Only very young girls and mature women could freely go around, as they were not considered to be sexually at risk. Women and grownup girls were fully familiar with the traditional sexual evasion. They knew how to dress, talk, and behave in public places where men were in the majority, without losing their honor and dignity.

Under the traditional Turkish Cypriot gender roles, girls and boys up to the age of 6 could easily play together in the streets. After this age, the parents dictated the conventional conditions to their children. Boys were given more freedom in their activities, while girls were told to be modest and not get involved in any disgraceful activity. They were told that they had to learn traditional behavior in their social life. If a girl was seen talking to a boy who was not her relative, this could have been interpreted as reflecting a sexual desire. The advice of the mothers and fathers to their daughter was that, when a boy looked and/or smiled at her, she should not smile or look back. She should close her mouth with her hand (if she had the urge to smile) and divert her glance elsewhere. A girl who obeyed the traditional rules, honored her family and had a better chance of a good marriage.

In the traditional Turkish Cypriot society, the roles of young girls and boys were very strict. Nowadays, these strict rules have changed, and the relations between the genders have become easier and more modern.

### B. Social Changes and Modernization

The influence of the British colonial administration and the increase of technical facilities around the world have

forced Turkish Cypriots to move to the cities. Some members of the family, usually the main breadwinner and the young boys, try to find job in the cities. In 1950s, the Turkish Cypriots' preference was to get a job either in the British sovereign areas, or to find employment in the mining industry or the civil service. These were good sources of income.

The modernization in the Turkish Cypriot community started after the end of World War II. During this time, the people in the cities had a better source of income and a better social and cultural life. This alone led to the relocation of people from rural areas into the cities. This, in turn, led to increased education and, as a result of increased education, the philosophy of sexual strictness changed and became much more flexible.

Since 1960, important changes have taken place in the family structure. In the Turkish community, employment in the civil service became the most secure area of livelihood for both the male and the female. The significance given to education also increased. In the 1950s, kindergarten education was officially introduced (although there had been private kindergarten facilities long before that). During the late 1960s, the number of boys and girls in both elementary and secondary education was almost equal. However, after 1974, because of the influx of the population from Turkey to the northern part of the island, the number of boys in schools increased, as the Anatolian people traditionally give priority to the education of boys rather than girls.

In 2001, Dr. Ahmet Cavit carried out a research study on the communal structure of the Turkish Cypriots, including the immigrants from various parts of Turkey. According to this research (census of December 15, 1996), the total number of the population in Northern Cyprus was 200,857. Of these, 146,450 were citizens of the Turkish Republic of Northern Cyprus (TRNC), 30,702 were citizens of Turkey, and 5,425 were citizens of other nations.

This study indicates that the immigrants from Turkey also take part in the political life of Northern Cyprus. In the 1998 general elections, four out of 50 Members of Parliament were of mainland Turkish origin. According to the statistics of the Research and Statistic Department of TRNC, 1,108 marriages took place in 1998. One third of these marriages were among the immigrants. Most of the married Turkish Cypriot couples had secondary or higher education levels. TRNC recorded 2,433 births during 1998. A breakdown of this figure indicates that the majority of the Turkish Cypriots preferred private clinics, whereas the immigrants frequented government hospitals because of their low economic position.

Because the immigrants give priority to the education of boys, their daughters rarely have secondary education, as their parents prefer to see them married and having children instead of carrying on to higher education. According to this study, Turkish Cypriots prefer government services, whereas immigrants find employment as manual workers and waiters.

Another important aspect is the increase of women in employment. A 1998 study revealed that 20 out of 100 women were employed outside the home. In 2001, this increased to 28%. Looking at the role of woman in modern life, the mother is still seen as more loving and tolerant than the father and often communicates better with the children. She devotes more time to the family, looks after the children, runs the house, and sometimes contributes to the family budget by working outside the house as well. The man is the breadwinner, head of the family, and has the final say in family affairs. Husbands rarely get involved with domestic affairs and spend most of their spare time at coffee shops or clubs. This is especially true in rural areas. As in most parts of the world, women and men in cities are successfully trying to achieve a sense of equality of the sexes.

### C. Sociolegal Status of Males and Females

Secularization has been an important factor in the life of the Turkish community since the early 1920s, when Kemal Atatürk introduced modern life and secularization in the Republic of Turkey, as well as introducing the right of women to vote. During the last 20 years of the British colonial administration, the family life inherited from the Ottomans underwent important changes. The 1960 Cyprus agreements also contributed to the modernization. Article 28 of the 1960 Cyprus Constitution provides for equality of the male and the female.

In the Turkish Republic of Northern Cyprus, if a foreign individual marries a Turkish Cypriot, he or she becomes a citizen after the lapse of one year from the date of the marriage. Marriage and divorce in the Turkish community is performed under the Turkish family law. It has no connection whatsoever with religious rules.

In Northern Cyprus, abortion is not legally allowed except under very special circumstances. However, it is common knowledge that abortions are possible in private clinics.

### D. Legal Status of Men and Women at Work

In Northern Cyprus, it is not a common practice in the private sector for men and women to receive equal pay even when they perform the same duties. Despite agreements between trade unions and employers to ensure equality for men and women, discrimination still exists. It is different at the civil services. Equality does exist there, and men and women have equal payment and equal chances for promotion. Another reality in the Turkish Cypriot community at the moment is that a large number of labor forces from mainland Turkey accept employment at very low wages, thus increasing the wage gap between the male and female by forcing the female to accept employment at still lower wages. According to Cavit's study, most of these workers are illegal immigrants.

Women in Northern Cyprus do not fight for their rights. The main reason for this is the fact that senior posts and political offices are mainly occupied by men. So far, women's efforts and desires to get a better place in the political arena have not produced any positive results. The existence of only four women MPs out of 50 in the Parliament is a proof of this.

### E. General Concepts and Constructs of Sexuality and Love

Traditional marriages in the Turkish Cypriot community were performed on the basis of *Görücü evliliği*, arranged marriages. The candidate bridegroom and his family visited the bride-to-be and her family to see the chosen woman (sometimes for the first time) and eventually ask for the hand of the woman in marriage. The decision of the youngsters was not of great importance in this system, although most families did at least ask their opinion. The choice of the elders was the decisive factor. Sometimes, a boy requested his parents to go and ask for the hand of the girl whom he had seen and liked physically without knowing her personality and/or educational level. It was always the boys who asked for the hand of the girls, never the other way around.

Usually, the family of the bride was chosen first, because the boy's parents wished for a bride from that particular family. The main criteria for the man's family in these marriages were the social and financial status of the woman's family. It had to be of the same background, rank, and social standing to theirs and occupy a position of respectability in the community.

If the impressions of both of the families were positive, then the marriage was agreed upon and the couple got en-

gaged, usually during a ceremony including family and friends. The couple was seldom allowed to be alone together. Typically, a member of the family, this could even be a child, was sent along with them as a chaperon. The period of engagement was kept as short as possible. The families wanted to have the marriage ceremony as quick as possible. Traditionally, the engagement ceremony was paid for by the bride's family, and the wedding ceremony by the bridegroom's family.

This tradition is still mostly true, although recently, more and more families are sharing the cost, as weddings are getting more and more expensive. The woman was supposed to bring her dowry into the marriage, including all the furniture for the new house, and the man was supposed to supply the house in which they were to live in. At present, this, too, can vary, and there is no set rule, especially in the cities.

It is still customary for the bridegroom to give a piece of precious jewelry to the bride on their wedding day. This stems from the time when the bridegroom was only allowed to see his bride after the wedding ceremony was over. This present was called the *yüz görümlüğü* (to see the face), as it was presented after the bridegroom had lifted the bride's veil, thus seeing her face for the first time.

Until the 1950s, marriages in the Turkish Cypriot community were performed on a religious level by a *Hodja*, a man of religion. After the enactment of the family law during the last years of the British colonial administration, these became civil marriages and were performed by marriage officers. All marriages performed prior to the enactment of the law were considered as performed under the law.

Until the 1950s, the woman's family was very strict with the virginity of their daughters. The girl was not allowed to have sexual relations before her marriage, not even during the engagement period. The men, on the other hand, were encouraged to "gather some experience" before their marriage. The day after the wedding, the bridegroom's family was anxious to see the red blood spot on the sheet, proving the virginity of the bride. This was mostly true in the rural areas and rarely in the cities. However, after the 1970s, this tradition was also widely abandoned, and the virginity of the bride was not the first prerequisite for the continuation of the marriage. But even today, an intact hymen is interpreted as belonging to an "untouched" woman.

After the 1960s, men and women preferred marriages based on mutual love and respect, preferring to choose their partners themselves, but hoping for approval by their parents. Families tolerated the decision of their children without imposing traditional rigid conditions. At present, dating and flirting has increased in the Turkish community. This has been made easier for most by the increased number of men and women studying and working together. Some go as far as to say that flirting is a must prior to marriage. There is even a modern version of arranged marriages, where the families choose the partner but agree to let the man and woman go out dating before they make up their minds. The engagement period can also take as long as it is necessary for the couple to make up their minds. Despite these developments and changes, there are still many people, especially in the rural areas, who believe that virginity is essential in the community. The enlightened youth, though, is starting to believe in the equality of the sexes, including their sex lives before marriage.

A difference is seen in the marriage understanding of the Turks who came to Northern Cyprus from Turkey after 1974. They are more conservative and prefer marriages among themselves, especially between relatives.

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

Religion does not have any direct effect on sexuality in the Turkish Cypriot community. Though adultery, abortion, premarital sex, and homosexuality are a sin in Islam, most people are not influenced by this. During the holy month of Ramadan, sex, flirting, touching each other, kissing, and so on, is not permissible in the fasting time from dawn to sunset every day. In 1990, a respected *Hodja* offered the following advice to young people: "Get acquainted with each other prior to engagement. Afterwards, only get engaged if it is your own decision. It is not a sin for young people to get to know and talk with each other beforehand. Get married only if there are not any problems during the engagement period."

## 3. Knowledge and Education about Sexuality

This section was prepared from a study by Nuri Gökşn, M.D., Chief Medical Officer of the Turkish Hospital in Famagusta.

### A. Government Policies and Programs

In the TRNC, there is no sexual education in schools. The only information about sex given at schools is during biology lessons on an insufficient level. Teachers try to teach the students only the anatomic structure of the genital organs.

### B. Sexual Knowledge in the Turkish Community

To ascertain the level of sexual knowledge among the Turkish community, a three-stage study was carried out. These studies were undertaken at the encouragement of the late Prof. Dr. Alpaz Kelâmi, who was a Turkish Cypriot andrologist/urologist working at the Free University of Berlin, Germany. The first stage was carried out among the 4- to 12-year-old age group by K. Bolayır and N. Cahit in 1990. The second stage was carried out among the 14- to 18-year-old and 18- to 24-year-old age groups by K. Bolayır, N. Gökşn, and E. Emekçi, in 1991. The third stage was carried out among the age group over 30 years of age by K. Bolayır and S. Özyigit in 1992.

In the 1990s, sexuality was not taken up in the media very much. Sexual words, such as "penis" or "in the vagina," could not be written in the newspapers. Teachers were reluctant to give sex education to the children in schools, because they themselves had insufficient knowledge on sexual issues. During the above studies, the schoolchildren made interesting comments when questioned on the subject of biology lessons. They said teachers avoided any reference to genital organs and sometimes boys were sent out of the classroom while a female teacher talked to the girls only, thus compelling the boys to ask the girls questions as to what the lesson was all about afterwards.

- Below are ten typical questions and answers from the 1,000 schoolchildren in the 4-to-12 age cohort: How did you come to the world? Answers: From the belly of my mother: 80%, My mother gave birth: 20%; Down my mother's legs: 5%.
- Do you sleep with your father and mother? 95% no, 5% yes.
- Do you prefer playing with boys or girls? 92% preferred playing with the same gender.
- Why do boys and girls not want to play with each other? 70% simply said 'we don't play' without giving any reason, 20% considered it wrong or because they might be thought of as sweethearts, 10% were afraid to be made fun of.

- To the boys: Were you afraid of circumcision? 10% yes, 90% were proud of it.
- To the girls: Has your mother said anything to you about menstruation? 80% yes, 20% no.
- Which scenes that you watched on TV have you tried on your friends? 20% only kissing scenes.
- What dirty words have you heard from your environment? 80% admitted hearing dirty words, but did not say what they were.
- Have you learned anything from what is written on the toilet walls and desks in school? 60% became acquainted with love affairs between the names mentioned.
- Between which relatives are marriages not allowed? 100% said that marriages were not allowed between brothers and sisters and first-degree relatives.

This study revealed that children are not immensely affected by traditions and taboos. Unfortunately, however, as time goes on, communal pressure will affect these children. During this study, in a TV discussion in 1990 with A. Kelâmi, Telaloglu, and Bolayır, the priority was given to the sex education of the parents and schoolteachers.

In 1991, in the first part of the second stage of this study, 980 schoolchildren 14 to 18 years old were questioned:

- Do you think that both testicles can be felt in the scrotum when a boy is born? 70% didn't know and 30% said yes.
- Can you speak about sexuality with your parents? 90% no, 10% yes.
- Do you have friends of the opposite sex with whom you can discuss sexuality? 75% yes, 25% no.
- Do you know what homosexuality is? 55% yes, 45% no.
- Do you know what sperm and ovum are? 70% yes, 30% no.
- Have you learned anything about sexuality from writings on restroom walls and school desks? 70% yes, 30% no.
- When you play with your sexual organs, do you do this in a feeling of fear and guilt? 70% yes, 30% no.
- Do you masturbate? boys 95% yes, girls 13% yes.
- Do you know that AIDS is the most dangerous sexually transmitted disease? 60% yes, 40% no.
- Do you know that a woman can have a child without having menstruation? 80% don't know, 20% yes.
- Have you watched any porno film? 90% yes.
- Do you flirt? 50% yes, 50% no.
- Do you have sexual education at your school? 98% no.

The second part of the second stage of the study surveyed 1,000 18 to 24 year olds in 1991, including the following questions:

- Can you speak with the older members of your family about sexuality? male: 90% no; female: 80% no.
- Can you discuss sexuality with your friends? 95% yes.
- Can you communicate with your teachers in school about sexuality? 98% no.
- Do you know that in females, menstruation occurs in the uterus and continues for about five days? male: 45% do not know; female: 95% yes.
- Are both testicles palpable in the scrotum when a boy is born? 60% do not know.
- Is the hymen the most valuable thing for girls? male: 60% yes; female: 80% yes.
- Are you against a marriage arranged by your family? male: 75% yes; female: 50% yes.
- Do you think that masturbation is not harmful? male: 87% yes; female: 50% yes.
- Do you think that a married couple should have a baby within a year if they desire so? male: 60% yes; female: 40% yes.

- Are you against premarital sex? male: 85% no; female: 30% no.
- Do you think that abortion should be legally permitted? 90% yes.
- Do you think that the main cause of erectile problems is psychological? 80% do not know.

A 1998 study of 800 persons in the age group over age 30 produced the following results:

- Who chooses the marriage partners in the Turkish Cypriot community? 40% the partners themselves; 60% chosen by the family.
- Do you think menopause is a cause for the reluctance to have sexual intercourse? 60% yes; 40% no.
- Do males continue to masturbate after 30 years of age? 60% yes; 40% no.
- How many women out of ten masturbate until 30? 70% said "2"; 20% said nothing.
- Do you agree that the sex knowledge of a newly married woman is sufficient? 80% yes.
- Do you agree that Turkish Cypriot women learn sex by experience after their marriage? 80% yes.
- Do sexual problems create a cause for divorce in the Turkish Cypriot community? 60% yes.
- How many married women and men out of ten have extramarital sexual intercourse in the Turkish Cypriot community? 70% of married men had one to three affairs; 10% of married men had only one or none; 35% of married women had one to three affairs; 30% of married women had one or none.
- What percentage of married partners discusses sexual problems between themselves? 50%.
- Can a man over age 70 have sexual intercourse? 50% yes.
- Can a cure be found for an impotent man? 50% yes; 50% do not know.
- Do you believe that pornographic films should be freely distributed? 75% yes.
- Do you think that women have as much desire for sexual intercourse as men? 60% no; 40% yes.
- Do you think that the man should always be the initiator of sexual intercourse? 60% yes; 40% do not know.
- Do you believe that the contribution of the woman is very important to the sexual quality and performance? 40% yes; 60% no.
- Is pregnancy possible during the menstruation? 90% don't know.
- Do you think that a spinster should also have a gynecological check-up, just like a married woman? 70% yes; 30% do not know.

Between 1990 and 1998, we examined the level of sexual knowledge in the Turkish Cypriot community. We tried to ascertain how and from where people got their sexual information. The answers given by 6 to 70 years olds reveal that the level of sexual knowledge in the community is very low.

It is a very important finding that 95% of youngsters do not discuss sexual issues with their parents and 98% of boys and girls also do not discuss sexuality with their teachers. Where do these boys and girls get their sexual knowledge? Young people of marriageable age learn about sex from friends, magazines, porno films and similar publications, and the media. In the past, males used to get their sexual experiences in brothels. Nowadays, nightclubs and pubs have replaced these places.

Porno films can be easily bought in Northern Cyprus. From Bolayır's clinical experience, the following are some

of the main complaints of people watching porno films in the Turkish Cypriot community.

- When compared with those in the porno films, they find that their penises are smaller, and ask whether these can be lengthened.
- They also inquire about why their own sexual intercourse does not last as long as that in the porno films.
- He or she is also confused to see that anal sex is brought to the foreground in porno films, and then inquire about the dangers and harms of anal sex.
- Others find themselves in a state of great stress because men in porno films appear to be very powerful.
- The couples in porno films appear to be very energetic and hot blooded, whereas some of our patients say they are not the same when together with their wives.

#### 4. Autoerotic Behaviors and Patterns

##### A. Children and Adolescents

In a 1990 study among 980 young people, it was established that 95% of boys and 13% of girls masturbate. Girls in the Turkish Cypriot community are sexually under greater pressure and control than boys. Therefore, girls who feel guilty masturbate in secrecy and under very secure conditions as if doing something wrong. It appears that parents are always inclined to take great care to prevent their daughters from masturbating, and have a fear that they might lose their virginity if they are allowed to do so. Hence, we see that statistical data for girls are very limited. No clear-cut results have been obtained in these studies regarding the age at which girls and boys start masturbating. Generally, the girls are taught to be shy, which is probably another reason why they could not admit to masturbating. However, it can be said that many girls start masturbating at about the age of 11 years and boys at about age 13 years. As adolescents grow older, masturbation becomes more frequent, especially among boys. Our clinical experience has shown that parents accept masturbation if the child is male. In a sense, the parents are proud of their son's masturbatory behavior, saying their boy is a real man, like his father. Sometimes, parents refuse to discuss the normality of their daughter's masturbation. These parents never accept their daughter's masturbation and punish her as a consequence if she continues.

##### B. Adults

There is no available data about adult masturbation in the Turkish Cypriot community. It is thought to be very rare in both sexes, but it is practiced by a number of married men who have problems approaching their wives because of marital conflict. Turkish Cypriot women say that they do not masturbate when their husbands are abroad or in therapy.

#### 5. Interpersonal Heterosexual Behaviors

##### A. Children

No study on the sexual rehearsal play among children has been made in the Turkish Cypriot community.

##### B. Adolescents

There are no puberty rituals as such in the Turkish Cypriot tradition, but the start of menstruation for the girls and circumcision for the boys are both celebrated as milestones. When the female child starts menstruating, the mother is told. She in turn tells the father, the sisters and brothers, the grandparents, and the aunts and uncles. A great fuss and excitement surround the child, with everyone kissing and congratulating her on becoming a woman. The girl is usually embarrassed by all this commotion around her.

Every young boy knows that one day, he is going to be circumcised and “become a man.” Traditionally, boys are circumcised between the ages of 5 and 7 years. Parents usually like to have the boys circumcised before they start elementary school. In the past, circumcisions were performed without any anesthetic by men called *sünnetçi*, non-medical men specializing in circumcisions. The child was held firmly by two male family members (other than the father) while the *sünnetçi* performed the operation. As soon as the child opened his mouth to cry out, a little piece of *lokum* (“Turkish delight candy”) was put into his mouth and the whole procedure was over in minutes. Although these *sünnetçi* still exist in rural areas, nowadays circumcisions are performed under anesthesia by urologists in hospitals. On the day of the circumcision, the boys are dressed in special costumes and hats. Depending on the family, they may then be taken around the village or the city on horses with accompanying traditional *Davul* and *Zurna* music drums and a kind of clarinet. The children and adults of the family, sometimes in cars and blowing their horns, follow this happy procession. On the eve of the circumcision, a party is given, and all the guests bring presents or give money to the circumcised boy. The boys continue to wear their long white shirts for about a week until they can wear trousers again.

No clear-cut studies have been carried out in the Turkish Cypriot community on sexual behaviors among adolescents. However, Bolayır’s (1991) study of 230 adolescents (age 16 years.) revealed that 80% of the boys and 30% of the girls had experienced hugging, kissing, petting, and sexual intercourse. Boys and girls of this age consider themselves to be mature. Boys try to prove themselves by endeavoring to influence girls. On the other hand, girls are under the influence of physical and psychological changes and want to be loved. At this period, the young do not possess sufficient sexual knowledge, but they put on a brave face and attempt to think and act strongly.

In a 1998 study by Bolayır among 210 adolescents, it was established that 68% of the boys and girls in the 16- to 18-year-old age group had no sexual intercourse, 20% had only one such experience, and 10% more than one. Ninety percent of these youths knew what a condom was and 48% had used and knew how to use a condom properly. To avoid pregnancy, some boys and girls preferred anal sex. However, there is no available data about the extent of this practice.

The male adolescent’s main sexual experience is with women working in nightclubs, pubs, and other entertainment places. These interactions are with payment, and the duration is short. The women in the nightclubs are commonly known as “Natasha.” It is an interesting fact that 50% of the men who have paid for sexual relationships with “Natasha” are married and are mostly fathers. In the community, sexual relationships between Turkish Cypriot men and women and tourists are at a very low level.

### C. Adults

The study made in 1992 among 800 people of marriageable age revealed that virginity was an important phenomenon in the Turkish Cypriot community. According to our clinical findings, 11% of men and 77% of women were found to be virgins when first engaged or married. In the Turkish Cypriot community, one of the reasons for ending an engagement or marriage is when a bride is found not to be a virgin on the first night of her marriage or during her engagement. Sometimes, members of both families insist on a medical examination prior to marriage to prove the virginity of the girl, forcing the girl concerned to be examined by a gynecologist. This is an unfair, unacceptable, and disgraceful position for

the girl. Several families have a hymnography operation—hymen reconstruction—performed on their daughters before marriage. As a result of this, the girl is compelled to have to resort to a deceitful marriage and build her life on unsound foundations. Nowadays, virginity has lost its importance in the cities, but unfortunately not in the rural areas or with the very conservative families.

This study also showed that 3% of the girls and 15% of the boys had their first sexual intercourse before the age of 16, and 75% of these males had their first sexual intercourse before marriage with prostitutes. Nine out of 10 Turkish women had their first sexual intercourse either with their fiancée or husband. It is expected that this rate has increased in recent years and, therefore, new research is necessary.

In the Turkish Cypriot community, 98% of married women and men do not have extramarital sexual relationships during the first years of their marriage. But in this male-dominant community, after a short lapse of time, and probably trying to prove their superiority over their wives, most men do not keep up this good record. The majority of the men who visited nightclubs to have sex insisted that they went there under the influence of alcohol and on the insistence of their friends. Some even infected their wives with sexually transmitted diseases from these extramarital sexual relationships.

In the Turkish Cypriot community, it is acceptable for men to easily and openly speak to their friends about their extramarital activities. They can also unreservedly speak with their doctor, telling him or her how and from whom they got the disease. However, this is not the case with women. Women who have extramarital affairs will possibly be labeled as prostitutes, whereas men are often considered as brave for acting in this way and are easily forgiven in the public eye. This is the traditional mentality of the community. In Northern Cyprus, 75% of the women tend to stick to only one partner in their life, but that is not true of the men, 75% of whom have one or more extramarital relationships.

Our clinical experience shows that 4 out of 10 men and 7 out of 10 women do not like oral sex. Three out of 10 women do not know what a clitoris is or what a clitoral orgasm is. They claim that the vagina is the only source of sexual pleasure. These findings show the level of sexual knowledge of the women in the community.

Another clinical finding is that in the younger generation, 70% of men and 30% of young women enjoy anal sex. Young Turkish Cypriots who are interested in and watch porno films often prefer anal sex.

In a close-knit small community such as Northern Cyprus, confidential information is not easily disclosed, so more funds are required to carry out detailed research.

## 6. Homoerotic, Homosexual, and Bisexual Behaviors

### A. Adolescents and Adults

To establish the ratio of homosexuality in a community of 200,000, it is essential to make a very detailed study. Traditional community principles and family pressure make this sort of study all the more difficult.

In a study made in 1992, clinical samples indicated that there were 16 homosexual cases, 14 boys and 2 girls. The average age was between 19 and 23 years. Eight of these boys were exposed during their military service. These homosexuals coerced their peers to have sex with them in return for money or valuable gifts. As soon as these cases were exposed, the army immediately discharged the involved homosexuals for misconduct.

Our studies show that these male homosexuals not only enjoy anal sex, but also all other sorts of activities, such as deep kissing, hugging, nipple stimulation, non-genital touching, oral-genital kissing, and hand-genital stimulation. Male homosexual orgasm is more commonly achieved by fellatio or mutual masturbation. Briefly, it can be said that not all male homosexuals necessarily engage in anal intercourse. It could also be ascertained that female homosexuals insert different phallus-like objects into their vagina during sex.

Looking at the reports of the Kinsey Institute, it is seen that the differences between homosexual and heterosexual findings are about the same. "The major difference between homosexual and heterosexual sex activities is that homosexuals cannot engage in penile-vaginal intercourse with a member of the same sex."

People in Northern Cyprus dislike talking about homosexuality. However, according to widespread belief among the Turkish Cypriots, this is not so among the Greek Cypriot community. Prior to 1974, parents even advised their children to always keep this in their minds in their relationships with the Greek Cypriots.

In the Turkish Cypriot community, it is a great disgrace to be a homosexual, which makes it very difficult to find out the exact number of homosexuals in the community. It is also very difficult for the homosexuals to seek any rights in the community. They have no clubs or places of assembly of their own. Parents never approve of their children's being gay or lesbian.

Homosexuals in the Turkish community escape from the community by either immigrating to other countries, or staying and struggling to have a place in the community. Those who flee aspire to have a better and easier life and enjoy homosexuality somewhere else. Those who stay and wish to have a place in the community, opt to marry someone from the opposite sex and carry on his or her homosexual activities in secret.

In 1986, when we started to examine the level of sexual knowledge in public schools, we encountered several problems from the Ministry of Education. It was indeed not easy to get permission to conduct this study, simply because the officials of the Ministry were of the opinion that such a study would provoke homosexual feelings among the students. In fact, this is not true. In our opinion, and also according to the Kinsey Institute, homosexuality is not an abnormality, nor an illness or a disorder.

Today, in the Turkish Cypriot community laws inherited from the British colonial administration are still in force on sexuality. Since 1974, the Turkish and Greek communities are living apart in Cyprus as a result of events started by Greek Cypriots in 1963. Negotiations are continuing, and there is hope for a peaceful solution. The Greek side has already enacted the relevant law legalizing homosexuality. The Turkish community has so far not done so. Nevertheless, homosexuality is legal in the European Union, which both communities are trying to join.

## 7. Gender Diversity and Transgender Issues

In Northern Cyprus, there are very few transsexuals. In 1996, five people, three women and two men, who were anxious to change their sex, were interviewed. Although they all wanted to have a surgical operation immediately, they all believed that if they stayed in Cyprus, they could be ousted from the community. All claimed that they could reach their goals easier abroad in developed, large countries.

## 8. Significant Unconventional Sexual Behaviors

### A. Coercive Sexual Behaviors

#### *Sexual Abuse of Children and Incest*

In small communities like the Turkish Cypriot community, any attempt of child sexual abuse can easily be uncovered and can have widespread repercussions. Such events are also given great coverage in the press.

According to the reports of the Criminal Department, only three incest cases occurred during 1995-1996 in Northern Cyprus. On the other hand, there were 12 cases of child sexual abuse. In fact, these figures are probably incorrect. In order to avoid scandals and disgrace, and to protect the family honor, events among relatives are not reported to the police.

#### *Rape and Marital Rape*

According to police reports, cases of rape have increased in the Turkish Cypriot community after the arrival of immigrants from Turkey. These reports claim that the numbers of such cases are 12. However, the opinion is that these do not reflect the real situation, as raped women are afraid of a bad reputation in the community and, therefore, prefer to remain silent.

Marital rape is even more common than anticipated, because violence in the family has always existed in both communities in Cyprus. Some cases of marital rape consist of attempts by men to have anal sex with their wives against their will. In most cases, men usually act only in accordance with their egocentric feelings and desires, and do not take into consideration the psychological feelings of their wives. Sometimes, men go to such extents, that women have no other choice but to complain to the police. However, both the police and the members of the family do their best to avoid going to court. The main reason for this is the fear that during the trial period, family honor will be harmed, and the families of both the husband and the wife will be disgraced considerably.

Irrespective of the belief that the number of such cases may have decreased during recent years, it is essential to continue investigating these cases in the Turkish Cypriot community.

#### *Sexual Harassment*

In the Turkish Cypriot community, sexual harassment of women by men generally occurs at the place of work. The offer of promotion priority and higher payment is used as an excuse to sexually harass and violate the woman employee. Additional dangers await women subjected to this sort of sexual harassment. Other male employees might consider the woman as easy prey, risking the honor of the woman and her family.

In 1994, there was a report in the local press about the sexual harassment of a woman at her workplace. Following this publication, a questionnaire was sent to about 200 female employees in various workplaces. Three out of four women surveyed replied that sexual harassment was rather widespread in the Turkish Cypriot community. Women working as cleaners in private homes and belly dancers were also possible targets. Sexual harassment in schools and in government offices is less common.

### B. Prostitution

Although prostitution is illegal, it was common knowledge that, until recent years, prostitution was practiced in certain houses. However, nowadays, there are no local prostitutes, because girls known as "Natasha" from countries like Russia, Ukraine, Moldavia, Romania, and Thailand are in abundance operating as prostitutes, usually controlled and forced by the nightclub owners. These girls claim that

they only get 25% of the money received from the customers in return for sexual intercourse, with the rest of the money being kept by the bosses.

**C. Pornography**

See survey results at the end of Section 3B, Knowledge and Education about Sexuality, Sexual Knowledge in the Turkish Community.

**D. Sexual Crimes**

The incidence of sexual crimes in the Turkish Cypriot community is very low. This number is so low that it is not worth dwelling on it. Kidnapping of children has not taken place during the last five years. According to police reports, there were 6 cases of rape in 1997, 5 in 1998, and 7 in 1999. Seduction, indecent assaults against women, and indecent offenses were also found to be very rare.

*9. Contraception, Abortion, and Population Planning*

**A. Contraception**

To avoid pregnancy, males have learned to use condoms, and the females hormonal contraceptive pills and intra-uterine devices (IUD). In extramarital sexual relationships, the males prefer to use condoms, as this is a precaution against sexually transmitted diseases and AIDS as well.

In the Turkish Cypriot community, the question as to which one of the couple is mostly responsible for the prevention of pregnancy during their marriage is very important. Is it the woman or the man? In fact, the best method for couples that do not wish to have children is for the man to have a vasectomy operation. This is the simplest and safest method (Kelami et al.). If the couple change their mind and wish to have children again at a later stage, the man can easily have a vasectomy-reversal (vasovasectomy) operation.

In a study carried out in 1996 among 100 couples, it was ascertained that only 2% have had vasectomies and 8% had tubal ligation. The same study showed that 15% of men used condoms and 20% had coitus interruptus, 35% of women used pills and 15% used the IUD. Five percent of the couples took no precaution. In these cases, tests revealed sterility in either the man or woman.

In contrast, most of the immigrant families from Turkey in the Turkish Cypriot community, take no precautions against pregnancy, so many of their families have between 5 to 10 children. However, when questioned about the number of children and their socioeconomic problems, their common reply was: "No problem, God will give the livelihood of the children."

**B. Abortion**

Abortion is the only way to end undesired pregnancies. As stated previously, abortion is illegal except in very exceptional circumstances. However, it is quite possible to get an abortion in the private clinics in Northern Cyprus, despite the fact that this is considered a sin and crime in Islam. In a study carried out in 1999 by Bolayır and Gökşın among 300 women, it was determined that 21% of the women had had one abortion, 15% had had two, and 5% had had three or more abortions. There are no doctors in Northern Cyprus who will not perform abortions for ethical reasons.

**D. Population Programs**

The total population of Cyprus is about one million. There has been no steady increase of the population of Northern Cyprus during the last 50 years. The reasons for this are the political problems and intercommunal conflict. These compelled a large number of Turkish Cypriots to emigrate from the island. However, after the Turkish intervention in

1974 and the agreement to relocate the Greek Cypriots from the North to the South and Turkish Cypriots from the South to the North, there has been a sudden increase in the population in the Turkish community. This is because of the arrival of immigrants from Turkey. In 1974, the Turkish Cypriot population was about 120,000; in 1999, it was 200,000.

In Northern Cyprus, there is no official department of the government to direct family planning. This is done by specialist doctors. People, too, have learned to keep a balance consistent with their socioeconomic condition. However, tax exemptions for children encourage people to have more than one child. Parents with more than one child also enjoy subsidies in school fees and facilities in hospitals.

*10. Sexually Transmitted Diseases and HIV/AIDS*

**A. Sexually Transmitted Diseases**

In Northern Cyprus, people suffering from STD generally prefer treatment by private medical practitioners because they want to keep this a secret. Although it is a legal obligation to report such cases to the Ministry of Health, in general, medical practitioners, urologists, gynecologists, and dermatologists refrain from doing so. Therefore, there are no reliable records on STD in Northern Cyprus, except for AIDS, which is normally reported. The only available data is from our own clinical samples, results learned from our researchers, and from official statistical information given out monthly.

As stated earlier, the study carried out among 100 young people in 1990 confirmed that they had insufficient knowledge on sexually transmitted diseases. Faced with this finding, we were requested by schoolteachers to give talks to the students on all matters related with sex. Up to now, we are doing this task periodically. In the course of these conferences, it was discovered that AIDS was the main topic of interest. For instance, 98% of the participants did not know that the papilloma virus causes warts in the genital region. Another virus, the herpes genitalis, enters the body and remains there for the rest of one's life and causes painful sores on the skin of the genital organs that may reappear from time to time for many years. Also, chlamydia and gonorrhea, if not treated, lead to scarring in the channels of the genital organs. These scars might cause infertility in females and urethral stricture in men, as well as facilitate entrance of the HIV virus into the body.

In Northern Cyprus, men who have sexual intercourse with girls in nightclubs do not know whether the girls are drug users or recipients of blood transfusions, but they should at least know that they are risking exposure to HIV and/or some other STD.

During the period of 1996 to 1998, the number of cases officially reported are shown in Table 20. According to our clinical experience, Turkish Cypriot schoolchildren are anxious to learn more about STDs. But the question is, from whom are they going to receive this information? Although the young have learned to use condoms, the majority do not

**Table 20**

**Official Number of Sexually Transmitted Disease Cases in Turkish Cyprus, 1996-1998**

	1996	1997	1998
Syphilis	13	17	19
Gonorrhoea	40	32	38
Herpes genitalis	98	80	90
Genital warts	110	120	119
AIDS	Total of 15 cases		

know how and/or what type of condoms to use. Neither do they know the exact benefits of using a condom. It is obvious that sex education should be a must in every school. The question is how to introduce this information into the school curricula and train teachers to present the information.

## B. HIV/AIDS

AIDS is a frightful disease in Northern Cyprus as it is in the whole world, particularly because a person with this deadly infection is seldom aware of the infection and continues to have sex, thus transmitting the disease to others. Throughout the world, as well as in Northern Cyprus, there are thousands of undiagnosed individuals with HIV, as this infectious disease takes a long time to manifest itself. Thousands of tourists from various countries of the world visit Northern Cyprus every year, and certainly some of these have sexual intercourse with Turkish Cypriots. Even if only a fraction of these are unknowingly HIV seropositive, their partners can easily be infected.

The only way to find out whether one has AIDS is to have a blood test. The ELISA test (enzyme-linked immunosorbent assay) is generally performed in the Burhan Nalbantoglu State Hospital, but there is no way to require Turkish Cypriots suffering from other sexual transmitted diseases and drug users to have the ELISA test. Such a requirement for arriving tourists is beyond any practicality. However, the application of the ELISA test in Northern Cyprus started in 1986. According to Dr. Tansel Dikengil, the head of the Microbiology Department of the State Hospital, 180,000 people are annually subjected to the ELISA test. This test is applied to every patient undergoing an operation, to newly married couples, and those who apply to become citizens. The test is also obligatory for individuals who are known to have had sexual intercourse with an HIV-seropositive partner. Under an agreement between the Ministries of Health of Northern Cyprus and Turkey, Refik Saydam health institute in Ankara also confirms the result of the tests that are found to be HIV seropositive in Northern Cyprus. The Ministry of Health of the TRNC (Turkish Republic of Northern Cyprus) reports these results to WHO at the end of each month. The results of the HIV-seropositive tests between the years 1987-1999 are shown in Table 21. The most recent number of seropositive persons in the TRNC is 87. Of these, 27 were Turkish Cypriots and 60 were foreigners; 70 were men and 17 women. The average age was 31.8 years. Out of the total 87 cases, 40 were heterosexuals and 47 were homosexuals. Three cases were the result of blood transfusions and five were drugs users.

In Northern Cyprus, of the 15 total cases of AIDS, 12 were male and 3 female. These patients received treatment in medical centers in Ankara and Istanbul. Three patients died in Northern Cyprus. The foreign patients, 80% of whom came from Moldavia, Russia, Ukraine, and the Far East, were sent to their countries at their request. In 1996, Gökşn carried out a test on 2,000 soldiers between the ages of 19 and 23 yrs. No cases of HIV seropositivity were found as a result of these tests. The ratio of 0.1% HIV in Northern Cyprus is rather low compared to other countries.

**Table 21**

**Number of HIV-Seropositive Test Results in Turkish Cyprus by Year, 1987-1999**

1987: 3	1992: 7	1996: 3
1988: 6	1993: 8	1997: 9
1989: 5	1994: 9	1998: 7
1990: 8	1995: 10	1999: 8
1991: 4		

## Treatment, Prevention Programs, and Government Policies

In Northern Cyprus, the Ministry of Health educates the public on AIDS throughout the year, but especially on the first of December, which is worldwide "AIDS Day." Lectures, television and radio panels and interviews, and other activities are organized. The public is continuously reminded that the most important preventive measure for AIDS is the use of condoms. Brochures, leaflets, posters, key rings, and T-shirts are used in the anti-AIDS campaign to stress the fact that risky sexual intercourse without using condoms is the main factor of the AIDS infection, not forgetting blood transfusions and the hazards of prenatal transmission.

Cooperation with the World Health Organization and UNAIDS is an important issue in Northern Cyprus. The main criterion is the prevention rather than the cure of AIDS. The media plays an important role in all anti-AIDS campaigns. However, the difficulty is educating the homosexuals, drug users, and those frequenting prostitutes. It is emphasized that abstinence from sex and the correct use of condoms are very significant in preventing the spread of the disease among the community.

[Update 2002: UNAIDS Epidemiological Assessment: This combined epidemiological assessment is for both the Turkish Republic of Northern Cyprus (TRNC) and the (Greek) Republic of Cyprus.

[HIV seroprevalence among blood donors has been reported below 0.01% in Cyprus since 1989. There was no evidence for HIV infection among pregnant women that were tested from 1998 until 2001, with the exception of one HIV case detected among 4,019 pregnant women in 1992 and one case detected among 2,422 pregnant women in 2001. HIV seroprevalence among bar girls remains below 1%. No infection has been detected among sex workers over the years. HIV prevalence among injecting drug users is reported to be between 0.1% and 0.3% between 1993 and 1999. Of clients of voluntary counseling and testing, 0.4% and 0.8% were found to be HIV-positive in 1999 and 2000, respectively.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	< 1,000 (rate: 0.3%)
Women ages 15-49:	150
Children ages 0-15:	NA

[No estimate is available for the number of adults and children who died of AIDS during 2001.

[No estimate is available for the number of Cypriot children who had lost one or both parents to AIDS and were under age 15 at the end of 2001. (End of update by the Editors)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

### A. The General Situation in Northern Cyprus

During the 1980s the main author and his colleagues carried out a series of research surveys in the Turkish Cypriot community with the support of the late Prof. Dr. Alpay Kelâmi. The results of these studies indicated that the level of sexual knowledge was inadequate and that there were no qualified professionals to treat the individuals suffering from sexual dysfunction. People were mostly ignorant as to which physician was knowledgeable or involved in treating sexual dysfunction of either men or women. Most were inclined to visit general practitioners. In 2003, Cypriots who seek professional help with a sexual problem are limited to a few general medical practitioners, andrologists, and gynecologists who have expanded their interest and expertise to include some professional training in sexual counseling and therapy.

In the traditional mentality of the people in Northern Cyprus, the sexual organs were to be concealed at all times. The sexual organs were considered taboo, prohibited areas of the body that were not exposed or discussed, even with a spouse or physician. When it came to a disease or functional disorder of the sexual organs, nothing is disclosed to close family members. Even visits to the physicians are avoided, with the belief that the disorder may be temporary and might cure itself. If the situation continues for a longer time, the advice of the same-sex elders in the family or close friends of the same sex might be sought. A visit to a doctor is only considered when nothing else works. Sometimes, the treatment is made more difficult through the waste of precious time. If, however, the ailment were in any other part of the body, friends and family would be extensively asked for advice and the doctor visited immediately.

Understandably, the few pioneering physicians who have decided to address sexual issues in Northern Cyprus have come from the well-established fields of urology and gynecology, and the new field of andrology, the diagnosis and treatment of the dysfunction, function, and disease of the male genital organs.

In the field of andrology in general, and contributions to the sexual health of the people of Cyprus in particular, it is a great pleasure to stress the services of the late Prof. Alpay Kelâmi. Turkish and Greek Cypriot urologists attended courses on andrology and urology at the Free University of Berlin organized by Kelâmi. He also played a leading role in organizing numerous International uroandrological symposia in Northern Cyprus. Distinguished doctors, all authorities in their fields, from all over the world attended these international symposia and presented papers and had discussions on relevant subjects. Several Turkish Cypriot doctors, and doctors from Turkey and other countries had the opportunity to exchange views with the participating foreign specialists. Unfortunately, however, the Greek Cypriot authorities did not allow Greek Cypriot doctors to attend these symposia because of political reasons. Prof. Kelâmi also participated in TV and radio interviews after each symposium in Northern Cyprus between the years of 1980-1992 and enlightened the public on sexual issues. His innovative "Art and Andrology" exhibitions during the symposia were additional means of bringing the medical sexual issues to the attention of the lay public.

Having acknowledged the many contributions of the late Professor Alpay Kelâmi to the sexuality education of physicians and to the sexual health of Turkish Cypriots, because he was a urologist/andrologist, his focus in sexuality was on the male, and the treatment of women was more restricted to their procreative role.

## **B. Diagnosis and Treatment of Sexual Dysfunctions**

The first author of this chapter on Turkish Cyprus is a physician specializing in uroandrology with some 20 years experience in treating sexual dysfunctions. An associate professor of urology, he has presented papers on andrology, sexual therapy, and rehabilitation at three-dozen professional meetings and has organized several international conferences on urology and andrology. The observations offered here are based on the main author's clinical practice.

### *Diagnosis and Treatment of Erectile Dysfunction*

For many years, the cause of male impotence was believed to be solely psychological in origin. Even today, some physicians believe that the majority of cases of male impotence have some psychological origin. This is not correct. In fact, more than 80% are primarily of physiological

origin, although many of these patients are affected psychologically later on.

In the past decade, clinical research in erectile dysfunction has demonstrated that penile erection is a vascular and neurological phenomenon. In our clinical experience, when we evaluate a male patient suffering from impotence, we consider that erection appears to be the result of three hemodynamic stages, the proper clinical evaluation and management of which requires an understanding in anatomic and physiologic aspects of these prerequisite events.

An impotent patient in Northern Cyprus is evaluated by a sensitive medical interview. The initial evaluation is based on doctor-patient communication during history taking together with the husband and wife/partner. Unfortunately, however, in Northern Cyprus, the visit of the husband to the doctor together with his wife/partner is an important problem. The Turkish Cypriot community is a small and conservative unit. The traditional mentality is that discussing sexual matters in the presence of a doctor will damage the family dignity. In fact, women are reluctant to discuss these matters with any person. Women in general shoulder so many responsibilities in the family that probably sexual affairs are ignored. In the traditional mentality, the women even refrain from discussing sexual matters with their husbands. So, many women over the age of 50 years never like to visit doctors to discuss sexual issues. However, in recent years, couples are beginning to visit doctors jointly to discuss their problems. This is a good omen for the future.

In taking the sexual history of the patient, Turkish Cypriots use a different sexual terminology than physicians, creating a communications problem that needs to be addressed and resolved. Questions are especially directed to verify the existence of an erectile problem, because sometimes patients describe impotence as lack of libido, or retarded or premature ejaculation. By the end of the interview, the physician should be aware of the patient's problem. History taking leads to identifying psychological and physiological factors that may affect erectile performance. Most cases involve both physiological and psychogenic erectile dysfunctions. These findings are confirmed by intracavernosal injection tests and analyses of blood, urine, and hormones.

One common disease that causes erectile dysfunction in men is diabetes. In the Turkish Cypriot community, when looking at the patients who suffer from physiological erectile dysfunction, the following symptoms are seen; gradual loss of erectile ability, change of rigidity of the erection, and diminished morning erections. In contrast, if the suggestive diagnosis is primarily of psychological origin, predisposed individuals may be affected and the long-lasting rigid erections, as well as morning erections, may diminish and disappear for a long time. Our clinical experience has shown that, as in other communities, purely psychologically impotent men are very rare. Looking at the ages, we see that most of the impotent patients of psychological origin are under age 40 while patients with physiological impotence are over age 40.

When looking at the options of treating patients with erectile dysfunction, it can be seen that many advances have occurred, such as penile prostheses or the "miracle drug" sildenafil (Viagra). Patients with erectile dysfunction in Northern Cyprus received either nonsurgical or surgical treatments. Among the alternatives to surgical treatment for impotent patients are: intracavernosal injections, vacuum devices, hormonal injections, behavioral sex therapy, and sildenafil (Viagra). If all these treatments fail to remedy the erectile dysfunction, then the patient is advised to have surgical treatment. In Northern Cyprus, we apply venous and arterial surgery for vasculogenic impotence or use penile prostheses in these patients. The majority of the impotent

patients who received penile prosthesis in our clinic were diabetic.

Since 1980, 640 males were treated in our clinic for erectile dysfunction: 70% of these were cases of impotence, 17% of premature ejaculation, 7% of honeymoon impotence, 4% of sexual desire disorder, and 2% with retarded ejaculation.

### *Honeymoon Impotence*

This is normally seen in male patients with anxiety and a lack of sexual experience and knowledge. According to our clinical experiences, the custom in the conservative community of expecting a spot of blood on the sheet on the wedding night, plus the expectations of the family members of the bridegroom, can easily cause him increased anxiety and prevent him from having an erection. A few more unsuccessful attempts may lead the young groom to believe he is permanently impotent. An andrologist can easily diagnose this "honeymoon impotence" and the treatment of such cases is very easy in modern medicine. Between 1999 and 2001, 13 cases of honeymoon impotence were treated in our clinic. As all cases were found to be because of psychological impotence, the treatment results were very satisfactory.

### *Early Ejaculation*

According to our clinical experience, the patients who suffer from early or "premature" ejaculation have a good erection initially, but the duration of the erection changes from between 10 to 15 seconds up to 2 or 3 minutes. These patients do not like to receive early treatment, as they believe that this problem threatens their male ego. They prefer to continue to suffer from this situation rather than visit a physician. However, upon increased coercion from their wives, they eventually seek medical advice from an andrologist or sexologist. In these cases, men always visit their doctor on their own. It has to be stressed that sex therapy is very effective with this disorder.

### *Drugs Affecting Sexual Function*

According to our clinical experience, there are diseases that affect erectile dysfunction, such as diabetes, vascular diseases, hypercholesterolemia, alcoholism, heavy smoking, depression, and hypertension. Some of the pharmaceuticals used in the treatment of these diseases may affect erection. They may also affect sexual desire (libido) and ejaculation. Although there are numerous publications, both epidemiological and anecdotal, on the adverse effects of these drugs, many physicians are still not aware of these negative side effects.

### *Dysorgasmia and Anorgasmia*

Very few cases of male dysorgasmia have sought help in our clinic. Those who do are usually men over the age 40.

As noted earlier, women do not like to discuss their sexual problems with strangers, with family members, or with a specialist doctor competent in the field of sex. The majority of these women are unhappy and complain about their lack of sexual satisfaction, despite the insistence of their husbands to make love to them regularly. According to Özyigit, most sexual complaints from the females involved inhibited orgasm, vaginismus (vaginal spasms), and coital phobia, most cases of which can be traced back to negative sexual learning, misinformation, religious inhibitions and prohibitions, or lack of sexual knowledge.

Dysorgasmia among women is more frequent in a long-term marriage. This is believed to be because of the heavy burden of the women, housework, childcare, and the need to work outside the house, as well as contribute to the family budget. Men's insistence on making love whenever they desire, without taking into consideration the feelings of the

women, and their failure to include enough foreplay prior to sexual intercourse, are among the reasons for women's dysorgasmia. In Northern Cyprus, the main cause that diminishes sexual desire for women is the lack of quality in the sexual foreplay. Many Turkish women are deprived of enjoying orgasm, but yet prefer to suffer in silence instead of speaking out. In brief, women avoid revealing or discussing their dysorgasmia or anorgasmia problem, and so suffer without relief.

### *Sex Therapy*

It is common knowledge that one of the most effective behavioral therapies for erectile dysfunction, the sensate focus exercises, is designed to reduce the performance anxiety that is interfering with erectile dysfunction. This requires the cooperation of both of the sexual partners. In Northern Cyprus, behavioral sex therapy is applied to all patients with erectile dysfunction as the initial choice of treatment. Between 1990 and 1994, 90 patients were evaluated, and those diagnosed with erectile dysfunction of psychogenic origin showed a good response to sex therapy.

In 12 out of 20 cases of early ejaculation, a combination of sex therapy and the sildenafil drug produced a very good response. Seventy percent of the patients who did not respond to sex therapy alone, received another type of combination therapy. This included intracavernous injections, vacuum therapy, the sildenafil drug, and sex therapy. According to investigations, these patients' disorder had physiological origins, and most had significant performance anxiety as well. In our cases, very few received sex therapy together with the intracavernous injection.

### **C. Certification and Advanced Education**

In many developed countries, in both Europe and North America, as well as both the Greek and Turkish communities of Cyprus, licensed physicians, psychologists, and psychiatrists can offer sexual diagnosis, counseling, and therapy as part of their healthcare expertise. In many countries, including both Cypriot communities, there is no further regulation, certification, licensing, or required training for sex educators, counselors, or therapists as such, apart from the standard licensing or certification of traditional healthcare professionals. If a political solution is found to the separation of Cyprus' two communities, and the island becomes a member of the European Union, these issues will then hopefully be solved.

## *12. Sex Research and Advanced Professional Education*

Despite the research that has been done in Northern Cyprus since 1980 on sexual matters, we believe that further research is necessary.

Political, social, and economic problems prevailing in Cyprus for the last 50 years have had adverse effects on sexuality. These problems have caused several interfamily discords between the older and young generation. The research studies that we carried out in the Turkish Cypriot community have shown that sexual knowledge is insufficient. The young make use of foreign publications, magazines, journals, and TV programs. Because these publications are produced outside of Northern Cyprus, they address their own communities and do not generally meet the requirements of the Turkish Cypriot community. There is a definite need for periodic publications on sexuality produced within the Northern Cyprus community and similar material addressing the Greek Cyprus community. On the other hand, widespread intersectional research and surveys on sexuality have to be made in order to have reliable infor-

mation for future planning. There is also need for a clear need for family, relationship, and sex counseling.

However, the prevailing political structure in Cyprus has so far prevented cooperation between the two communities. There is need for cooperation in the fields of dangerous diseases, such as AIDS and so on. Laws have to be enacted by both communities on patient's rights in keeping with the WHO requirements. Nongovernmental organizations in both the North and South have to cooperate and work more closely in every field of health. And finally, universities in Northern Cyprus have to contribute more towards sexual education.

### Demographics and a Brief Historical Perspective

ROBERT T. FRANCOEUR

#### A. Demographics

The 30,450 square miles (78,866 km<sup>2</sup>) of the Czech Republic are divided between the very hilly Moravia in the east and the plateau of Bohemia in the west surrounded by low mountains. Germany borders the Czech Republic on the north and west, Austria on the south, Slovakia on the east, and Poland on the north. The Czech Republic is slightly smaller than the state of South Carolina in the United States. From the administrative point of view, the Czech Republic is divided into 13 regions; the capital of the country is Prague.

In July 2002, the Czech Republic had an estimated population of 10.26 million. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 15.7% with 1.05 male(s) per female (sex ratio); 15-64 years: 70.3% with 1 male(s) per female; 65 years and over: 14% with 0.63 male(s) per female; Total population sex ratio: 0.95 male(s) to 1 female

**Life Expectancy at Birth:** Total Population: 74.95 years; male: 71.46 years; female: 78.65 years

**Urban/Rural Distribution:** 66% to 34%

**Ethnic Distribution:** Czechs: 81.2%; Moravian: 13.2%; Slovaks: 3.1%; Polish: 0.6%; German: 0.5%; Silesian: 0.4%; Gypsy: 0.3%; Hungarian: 0.2%; other: 0.5% (1991 est.). The number of Gypsies is universally judged as underestimated because many Gypsies report themselves as Czech. The Gypsy ethnic population consists of about 100,000 people, approximately 1.0% of general population.

\*Communications: Asst. Prof. Jaroslav Zvěřina, M.D., Sexuologický Ústav, 1. lékařské fakulty, Univerzity Karlovy Karlovo nám, 32, 120 00 Prague 2, Czech Republic; jaroslav.zverina@lf1.cuni.cz or zverina@psp.cz.

\*\*Editor's Note: Because there was minimal information about the Slovak Republic in the original chapter in volume 1 of the *International Encyclopedia of Sexuality*, this revised chapter focuses only on the Czech Republic and omits the data on Slovakia.

(CIA 2002)

**Religious Distribution:** Typical for the Czech Republic is the high secularization of citizens, with 39.8% of respondents signing themselves as atheists. Religious affiliation is Roman Catholic: 39.2%; Protestant: 4.6%; Orthodox: 3%; and other: 13.4%.

**Birth Rate:** 9.08 births per 1,000 population

**Death Rate:** 10.76 per 1,000 population

**Infant Mortality Rate:** 5.46 deaths per 1,000 live births

**Net Migration Rate:** 0.96 migrant(s) per 1,000 population

**Total Fertility Rate:** 1.18 children born per woman

**Population Growth Rate:** -0.07%. The birthrate is about 1.13, and the balance sheet of population has remained negative for the last five years (in 2001 it was -18.091). Such a deficit is not fully compensated for with immigrants (about 8,000 people in 2001).

**HIV/AIDS** (1999 est.): Adult prevalence: 0.04%; Persons living with HIV/AIDS: 2,200; Deaths: < 100. (For additional details from www.UNAIDS.org, see end of Section 10B.)

**Literacy Rate** (defined as those age 15 and over who can read and write): Literacy is practically universal with nine years of compulsory education. In 2001, 16.5% of men and 29.1% of women had only a basic education. Meanwhile, 10% of men and 7.1% of women had a university degree.

**Per Capita Gross Domestic Product** (purchasing power parity): IS\$15,300—about 70% of the GDP average within the European Union (2002 est.); Inflation: 5% (2001 est.); Unemployment: 9%; Living below the poverty line: NA. The Czech Republic is a member of NATO and one of the best-prepared candidate countries for the membership in the European Union (EU).

#### B. A Brief Historical Perspective

Probably sometime in the 5th century of the Common Era, Slavic tribes from the Vistula basin settled in the region of the traditional Czech lands of Bohemia, Moravia, and Silesia. The Czechs founded the kingdom of Bohemia, the Premyslide dynasty, which ruled Bohemia and Moravia as the Great Moravian Empire from the 10th to the 16th century. This later became part of the Holy Roman Empire. Charles IV, one of the Bohemian kings and a Holy Roman emperor, made Prague an imperial capital and a center of

Latin scholarship. In the 14th century, Prague was the cultural center of Central Europe.

Early in the Reformation Movement in the Christian Church, the Hussite movement founded by Jan Hus (1369?-1415) linked the Slavs to the Protestant Reformation and revived Czech nationalism, which had previously faded under German domination. After Ferdinand I, a Hapsburg, ascended the throne in 1526, the Czechs rebelled in 1618, precipitating the Thirty Years' War (1618-1648). Defeated in 1620, the Czechs became part of the Austrian empire for the next 300 years. Full independence from the Hapsburgs was not achieved until the end of World War I, following the collapse of the Austro-Hungarian Empire.

A union of the Czech lands and Slovakia was proclaimed in Prague on November 14, 1918, and the Czech nation became one of the two component parts of the newly formed state of Czechoslovakia. In March 1939, when German troops occupied Czechoslovakia, Hitler proclaimed Czech Bohemia and Moravia protectorates and declared Slovakia independent. The former government returned in April 1945 to power when World War II ended and the country's pre-1938 boundaries were restored. Communists became the dominant political party in 1946 and gained control of the Czechoslovakian government two years later. Soon thereafter, the former democracy was turned into a Soviet-style state. Nearly 42 years of Communist rule ended when Vaclav Havel, a highly respected writer and dissident, was elected president of Czechoslovakia in 1989 in what was known as "the Velvet Revolution." The return of democratic political reform saw a strong Slovak nationalist movement emerge by the end of 1991. Independence then became an issue for Slovakia. When the general elections of June 1992 failed to resolve the continuing coexistence of the two republics within the federation, Czech and Slovak political leaders agreed to separate their states into two fully independent nations. On January 1, 1993, the Czechoslovakian federation was dissolved and two separate independent countries were established, the Czech Republic and Slovakia. In March 1999, the Czech Republic joined NATO. The country's next goal in international relations is to gain entrance into the European Union in 2004.

### *1. Basic Sexological Premises*

#### **A. Character of Gender Roles**

The prevailing character of gender roles in the Czech Republic is traditionally European in accordance with the Judeo-Christian culture. Masculinity is connected with social dominance, and the socioeconomic status of women is still under the average status of men. The number of women employed outside the home is high and their role in family and childcare is underestimated. In 2001, about 58% of men and 46% of women were economically active. The employment rate for women is one of the highest in Europe.

#### **B. Sociolegal Status of Males and Females**

Both men and women have the same political rights. In both civil and criminal law, both genders are traditionally equal in the Czech Republic. Basic schools, colleges, and universities are coeducational. The principle of nondiscrimination according to gender and sexual orientation is fully respected in accord with the Charter of Fundamental Rights.

#### **C. General Concepts of Sexuality and Love**

According to the Judeo-Christian tradition, the couple concept of sexuality is dominant. Most couples base their sexual relationships on romantic love. Marriage is still very popular, which is in contrast with the very low fertility rate of 1.18 children born per woman and a negative population

growth rate since 1998. Under the communist dictatorship, erotic and sexuality topics were kept out of the mass media. With the growing impact of HIV/AIDS and the changing political atmosphere after 1989, there has been a shift to more-open discussions about sex and sexual morals.

## *2. Religious, Ethnic, and Gender Factors Affecting Sexuality*

### **A. Source and Character of Religious Values**

Christianity is still a dominant religious influence in the Czech Republic, with Roman Catholics in the majority. The Czech Republic also has an old tradition of Protestantism. In the 15th-century Protestant movement against the Roman Church, Jan Hus and Jan Žižka were very influential religious reformers and martyrs. In 1415, the Council of Constance condemned Hus to be burned at the stake. In the 16th and 17th centuries, Jan Comenius, a Moravian educational reformer and bishop, was a major religious reformer. In today's Czech Republic, religiosity has only a limited influence on the citizens. The country is very secularized, partly as a result of 50 years of atheist communistic propaganda. Forty percent of Czech profess to be atheists. This situation seems not to be changing under democratic government within last ten years.

### **B. Source and Character of Ethnic Values**

In terms of ethnicity, the population of the Czech Republic is very homogenous. Practically all ethnical minorities (Polish, German, Slovak, and Gypsies) have very similar ethical and cultural values. Within the last ten years, more legal and illegal immigrants are living in the country, with most of them coming from countries of the formerly Soviet Union. The Czech Republic now has some communities of people from China and Vietnam.

## *3. Knowledge and Education about Sexuality*

### **A. Government Policies and Programs**

Basic knowledge about sexual anatomy and physiology is provided as part of the basic school curriculum. Part of the official sex education is prevention of STDs and HIV/AIDS. However, information about sexual hygiene, safer sex practices, and contraception are not universally covered within such curricula. Almost universally ignored in sex education are topics like homosexuality, paraphilias, and sexual delinquency.

### **B. Informal Sources of Sexual Knowledge**

As a consequence of the insufficient formal education, children and young people get the major part of their information about sex from peer groups and mass media. Attitudes towards erotic explicit materials are very liberal in the Czech Republic. Most Czech journals and magazines have some columns devoted to sexual topics and problems.

According to our latest findings using a representative sample of 2,003 Czech respondents in 1998, a third of Czechs, 37% of men and 32% of women, listed their peers as their main source of sexual information. Books were the second most common source for 19% of men and 23% of women. Television and the mass media ranked third, for 21% of men and 16% of women (Weiss & Zvěřina 2001). The participation of schools in sex education is growing very slowly.

## *4. Autoerotic Behaviors and Patterns*

In all sources of sex education, self-pleasuring (masturbation) is almost universally presented as an important and natural part of normal human sexuality. Myths about the

unnaturalness and harmfulness of autoeroticism are only rarely mentioned, although letters of readers to sex publications indicate that, despite negative beliefs and fears, people do engage in autoeroticism. This applies to both children and adults. Sometimes, but rarely, parents complain to physicians about the masturbation practices of their children, but medicalization of this phenomenon is very rare.

In a representative sample of 2,003 Czech respondents in 1998, 84% of men and 58% of women reported masturbating sometime in their lives, with the average age of first masturbation being 14 years for men and 17 years for women. Only 5% of men and 10% of women said that masturbation poses some health risk (Weiss & Zvěřina 2001).

## 5. Interpersonal Heterosexual Behaviors

### A. Children

The sexual games of children are usually played in secret and ignored by parents if discovered. They are not the objects of particular sanctions in most Czech families.

### B. Adolescents

#### *Puberty Rituals*

There are no special or institutionalized rituals that recognize either puberty or the initiation of a nonmarital sexual relationship.

#### *Premarital Sexual Activities and Relationships*

First sexual intercourse usually occurs between ages 17 and 18. Criminal law sets the minimum age of consent for sexual intercourse at age 15 for both men and women. This law applies equally to both heterosexual and homosexual intercourse. Premarital sexual intercourse is very common, with 98% of women having had sexual intercourse before marriage. Premarital sex is quietly tolerated, but not openly accepted or endorsed by parents for women under age 18. The average number of premarital sexual partners is one or two for women and two to four for men.

In a representative sample of Czech adults over age 15 years, the average age reported for first coitus was 18.1 years for men and 18 years for women. More than 40% of these first experiences occurred in a cottage or outdoors; without contraceptives for 57% of the men and 64% of the women; and with an "occasional partner" for 34% of the men and 12% of the women (Weiss & Zvěřina 2001).

In 1993, the author of this chapter carried out a representative survey of the sexual life of Prague youths of age 15 to 29 years. Seventy-eight percent of the men and 83% of the women reported having had sexual intercourse, with the average age for first coitus 17.3 years for men and 17.4 for women. In this same survey, sexually active men reported an average of 8.1 coital partners, while women reported an average of 6.6 partners. Nearly two thirds of the men and 73% of the women reported having a sexual partner in the previous year. Nine percent of the males and 18% of the women reported only one sexual partner. One in five males and one in eight females reported having had more than ten sexual partners in their lives. The most common sexual expression was vaginal coitus (96% of sexually active men and 99% of sexually active women). Fellatio was refused by 16% of the women surveyed, while anal heterosexual

intercourse was reported by 22% of the men and 16% of the women (Weiss & Zvěřina 2001).

### C. Adults

#### *Premarital Courtship, Dating, and Relationships*

Courtship and dating customs are similar to those in other European countries and are based on the romantic model. There are no major differences in the dating and courtship patterns of young Czechs living in the cities or rural areas. There are no special courtship customs. Only in very small rural areas in South Moravia persisted in some engagement rituals in folklore.

Under the communist regime, the age of first marriage was relatively low, about 21 years, for most men, with their brides generally being about a year younger. During the 40 years of communist rule, the government supported early marriage with a system of government benefits and loans. Under communism, and down to the present, it has been extremely difficult for a single man or woman to obtain a flat or apartment. In addition, marriage and having a first child is an important social signal of having grown up and achieved adult status. During the 1990s, the average marriage age for men and women gradually crept upward. In 1990s, the age of first marriage was on average 24 years for men and 21 years for women. In 2001, it was 28 years for men and 25 years for women (ČSÚ 2002). This recent evolution has extended the gap between coital debut and marriage. Also more obvious today than ten years ago is the cohabitation of couples who live together without marriage.

In a 1994 study of Czech adults over age 15 years, men reported an average of 12.2 sexual partners, women 5.1 partners, with 1.8 and 1.9 partners, respectively, for the previous year. The average coital frequency in heterosexual partnerships was 8.4 times monthly. Three quarters of the men and 82% of women reported being "fully satisfied with their sexual life" (Zvěřina 1994a). In 1998, a similar investigation found men reporting an average of 10.1 partners and women 5.1 sexual partners in their lifetime at that point, and an average of 1.7 and 1.5 partners for men and women, respectively, in the previous year (Weiss & Zvěřina 2001).

#### *Marriage and the Family*

As in most parts of the world, heterosexual monogamy is the dominant pattern of sexual behavior in the Czech Republic. At the same time, and following the same pattern elsewhere in Europe and North America, serial or successive monogamy is becoming a common modification. The 1990 Czech marriage rate was 8.8 per 1,000 inhabitants; the divorce rate was 40.81 per 100 marriages. The average age of first marriage in 1990 was 23.7 for men and 21.3 for women. During the 1990s, this age has been continuously rising, as shown in Table 1.

Substantial rises in the age by first marriage and the age of mothers at the birth of a first child are indicators of changes in reproductive behavior after the "velvet revolution." Political and social changes have led to an extremely low fertility rate.

Several studies indicate the incidence of extramarital intercourse at between 25% and 35% of husbands and wives, with extramarital sex more frequent for men. Most of these extramarital activities are short-lived and infrequent. Rea-

**Table 1**  
Average Age by First Marriage in the Czech Republic, 1992-2001

Year	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001
Men	24.2	24.4	24.7	25.0	25.4	25.9	26.3	26.7	27.1	27.6
Women	21.6	21.7	22.0	22.4	22.8	23.3	23.6	24.1	24.6	25.0

sons for extramarital sex have not been studied, although it is likely that sexual variety and the attraction of a new experience are common motivations. Eighteen percent of men and 31% of women held that extramarital sex is “ethically unacceptable behavior” (Zvěřina 1994a, Weiss & Zvěřina 2001).

In recent decades, there has been an escalating problem of single-parent families, mostly divorced mothers with children. The divorce rate used to be relatively high—about 40%—with the average duration of marriage about ten years. More than 70% of marriages that end in divorce have a minimum of one minor child. Single mothers have a state-guaranteed minimum standard of living, plus the economic support from the father of their children. Czech and Slovak societies are not hostile to unwed mothers or divorced women. Surveys suggest that coital frequency for most married couples is one to three times per week.

As mentioned earlier, the Czech birthrate is low, with substantial decreases during the 1990s (see Table 2). The birthrate in 1978 was 18.4 per 1,000 inhabitants. In 1992, it had dropped to 12.2 per 1,000, and in 2002, it was under 9.0. The fertility rate was under 1.2 in 2002, one of the lowest in Europe. Most married couples plan to have one or two children. Planning for more than two children in a family is extremely unusual.

#### *Sexuality and the Physically Disabled and Aged*

Sexual behavior and sexual problems of mentally and physically handicapped persons are only rarely mentioned in public. The same is true with sexologists and marriage counselors. Since the dissolution of communist control in the “velvet revolution” of 1989, there has been a growing activity of different nongovernmental organizations (NGOs) seeking to promote the care and well-being of the physically handicapped. Enhanced attention is paid to sexual and reproductive functions of people with transversal spinal injuries (Šrámková 1997).

As elsewhere, there are more single women than single men over age 60. Older women are less likely to find an acceptable partner than older single men. We know that interest in sex in the later years has a direct connection with the availability of an appropriate sexual partner. An additional problem in the republic is that the living standard in state facilities for older persons is not conducive to couples’ maintaining intimate relationships. In most cases, the state facilities for the elderly are based on a collectivist model.

#### *Incidence of Oral and Anal Sex*

Oral sex is widely accepted and practiced by Czechs and Slovaks. Respondents in several surveys indicated that about 70% of men and women engage in oral sex as a part of their sexual intimacy. In a 1994 survey, 74% of men and 67% of women acknowledge experience with some oral sexual practice. Figures from 1998 were similar (Weiss & Zvěřina 2001).

In 1994, 15% of men and 12% of women acknowledged experience with anal sex. In 1998, 20% of men and 17% of women reported experience with anal intercourse. In most cases, where reported, this activity was exceptional and infrequent.

Sexual practices are not the object of legal regulations. The sexual behavior of consenting adult partners is free from any restriction by criminal law.

## *6. Homoerotic, Homosexual, and Bisexual Behaviors*

### **A. Children and Adolescents**

Same-gender sexual experiences are a natural part of the sexual play and exploration of children. However, their prevalence does not appear to be high. Only about 10% of men and 5% of women in the heterosexual population report having had same-gender experiences in childhood and early adolescence. In the population of gay men and lesbians, such experiences are, of course, more common.

### **B. Adults**

Attitudes towards homosexuality among the greater part of the Czech population are hostile or ambivalent. Homophobia and hostility towards homosexual people are more common among people in the lower socioeconomic classes. The pandemic of AIDS has brought some changes, mostly in the attitudes towards gays. It seems there is a greater tolerance of stable gay partnerships and couples, and the existence of gay clubs and associations. However, 33% of men and 41% of women in the 1994 adult survey considered homosexuality a disease. Twenty-two percent of both Czech men and women fully accept homosexuality.

In 1994, 3.4% of the men and 2.6% of the women reported sexual experience with a partner of the same sex. One percent of both male and female respondents self-identified as homosexual with another 1% unsure. In 1998, these figures were 6.2% and 4.4%, respectively. This means that sexual experience with a same-sex partner is becoming more frequent, or that respondents are more comfortable admitting this behavior. In more than 60% of male homosexual coitus, condoms were not used (Weiss & Zvěřina 2001).

In the penal law code, which went into effect in 1990, no distinction is made between heterosexual and homosexual behaviors. The age of legal consent to sexual intercourse was formerly 15 years for heterosexuals and 18 years for homosexuals. Now the age is the same for both heterosexuals and homosexuals, 15 years. This new code revoked the partial criminalization of homosexuality that existed in the previous code. At present, there is a movement to reduce the intolerance and inequities homosexual persons experience socially. These involve paying more attention to the situation of homosexual men and women in the workplace, in schools (both students and teachers), and in the army.

Most gay and lesbian associations are engaged in a movement to legalize the unions or marriages—also called “registered partnerships”—of homosexual couples. Important politicians support some kind of legalization of long-term homosexual partnerships. The attitude of the Catholic Church on homosexuality is, at present, still fundamentally rigid and hostile. Some Protestant Christian churches, on the other hand, are traditionally more liberal and less rigid.

Bisexual behavior is more common among homosexual persons than among the heterosexual majority. About 60% of the homosexual men surveyed and more than 70% of the lesbians reported having had heterosexual intercourse some time in their lives. Among heterosexual men and women surveyed, only 12% of the men and 5% of the women

**Table 2**

#### **Fertility and Abortions in the Czech Republic**

	<b>Births</b>	<b>Induced Abortions</b>	<b>Spontaneous Abortions</b>
1990	130,564	111,268	14,772
1995	96,097	49,531	10,571
1996	90,446	48,542	11,420
1997	90,657	44,471	11,500
1998	90,535	42,959	11,128
1999	89,471	39,382	11,173
2000	90,910	36,300	11,070
2001	90,715	34,500	10,516

reported some same-gender sexual contacts. Most of the same-gender contacts reported did not involve coitus.

While homosexual men tend to be more sexually promiscuous than lesbians, the frequency of anonymous sexual contacts under poor aesthetic conditions is decreasing. One hopes that this is connected with the increasing sex and AIDS-prevention education programs. The prevailing pattern at present is stable, long-term gay and lesbian relationships.

Sexual practices among homosexuals in the Czech Republic are the same as in other parts of the Western world. Among homosexual men, active and passive (receptive), anal intercourse is common. Condoms and lubricant gels are used with growing frequency.

## 7. Gender Diversity and Transgender Issues

Fetishistic transvestitism is a paraphilia with seemingly low incidence among males in both the Czech Republic and Slovakia. In some cases, transvestite males bring their problems to sexological counseling centers. Most of these problems are connected with the partner's/wife's hostility toward the client's cross-dressing and its impact on their sexual practices.

The prevalence of transsexualism also appears to be low, as in other European countries. Interestingly, the sex ratio of transsexuals in the republics' sexological centers is the opposite of what it is in Western Europe. In the records of the Institute of Sexology at the Charles University in Prague, for instance, there are three times as many female-to-male transsexuals as male-to-female transsexuals. In most Western European gender clinics, twice as many male-to-female transsexuals are reported as female-to-male. Colleagues in Poland report a ratio similar to that in Prague. Different social conditions and gender viewpoints in east and west European countries may be a factor in this difference in ratios.

Treatment for transsexual persons follows the common step-by-step practice in respected gender clinics around the world. Initial counseling and screening is followed by months of psychotherapy and sociotherapy. In allowing the client to adapt better to a reversal in gender role, it is possible to change the patient's name to a gender-neutral one; in Czech, the given and family names usually indicate the person's gender. However, some names are gender neutral and the same for either a male or a female.

Following months of hormone treatment, the decision for anatomical sex reversal surgery can be made. Sex reassignment surgery, which involves plastic surgery and gonad removal with consequent infertility, is required for an official and complete sex-reversal procedure.

Sex-reassignment surgery is available for both female-to-male and male-to-female transsexuals as part of the health insurance system. From a medical point of view, transsexuals are seen as people with inappropriate development of secondary sexual characteristics. In the Czech Republic, about eight patients a year request official sex-change surgery.

## 8. Significant Unconventional Sexual Behaviors

### A. Coercive Sexual Behaviors

#### *Sexual Abuse, Incest, and Rape*

The statistics on criminal sexual delinquencies are low when compared with most western European countries or with the USA. Twelve percent of women in the 1994 adult Czech survey reported an experience with rape, while 5% of the men admitted forcing sex on a woman. In 1998, these figures were 13% and 5%, respectively. Most of these assaults were not reported to the police or other authorities.

In 2001, there was a substantial change in the definition of rape in the Czech criminal law. The previous law defined a rape as sexual violence, perpetrated by a man on a woman. The new definition removed the "gender-specific" description and now defines a rape as sexually motivated violence, without reference to the gender of the victim or perpetrator.

Sexological investigations of criminal sexual delinquents requested by the police and courts are generally grouped in three main categories: (1) indecent exposure, (2) sexual molestation or abuse of children and minors, and (3) rape and other sexual assaults.

Approximately 8% of women and 4.6% of men in 1994 stated that they had been the object of sexual abuse as a child. In 1998, it was 10.4% and 7.1%, respectively.

In recent years, greater attention has been paid to sexual abuse and incest. The common experience is that the most threatened individuals in terms of sexual abuse and incest are children in single-parent families. The most frequent perpetrator is a stepfather or the boyfriend of the mother of the victimized child.

The police subject a woman who reports a rape to a very careful and long investigation. Hearings and questioning of the woman can last up to five hours or more. Once a charge is made, the woman cannot withdraw it. Nor can she discuss the accusation with anyone other than the police. If she does, she can be prosecuted for false accusation. At the court hearing, the woman has to answer questions from the court, the defense attorney, and the accused male, in what can be a very traumatizing experience. Similar procedures are followed in cases of child abuse.

At present, there are only a few special centers for counseling and support of the victims of rape and sexual abuse founded and directed by NGOs.

When apprehended, perpetrators of sexual assault are examined both from psychiatric and sexological perspectives. In cases of psychopathological or paraphilic motivation, the court can commit the perpetrator to compulsory treatment in a hospital psychiatric department or in an outpatient clinic. Specialized sexological departments in most psychiatric hospitals are staffed with personnel trained in treatment of dangerous sexual delinquents.

### *Sexual Harassment*

Men can be sued for comments and sexually explicit (dirty language), but accusations and court cases involving accusations of men making sexual advances to women, using indecent language, or sexually harassing women are rare. [Comment 1997: A 1996 report by J. Perlez suggests that Central European countries and corporations are being slowly influenced by Western concepts of sexual harassment. In a high-profile case in the Czech Republic, a manager at a major state bank was dismissed after a secretary filed a sexual harassment complaint against him. In a 1995 case involving the same manager, the bank refused to act. (See additional comments in Section 8A of the chapter on Poland) (Perlez 1996) (*End of comment by R. T. Francoeur*)]

In 2002, the Czech labor law was changed to give the possibility of penalization for sex harassment in the workplace. Experience with the new legal statute is still limited.

### B. Prostitution

Prostitution is a common phenomenon in the Czech Republic. There are probably several thousand prostitutes working in Prague and in other greater cities. Some work in massage parlors and exotic clubs, but most frequent hotels, bars, and restaurants. Since the collapse of the Communist regimes, there has been a migration of Czech prostitutes to the West, and from Eastern European countries to the Czech

Republic. Street prostitution is concentrated at the borderline with Germany and Austria and along the highways. Nine percent of men in 1994 and 14% in 1998 reported paying at some time for sex. No men and only 3% of women had engaged in sex for money in our exploration of the sexual behavior (Weiss & Zvěřina 2001).

Prostitution, as such, in the Czech Republic is not penalized. Pimping and trafficking of people are, of course, criminal offenses.

Some Czech cities have great problems with street prostitutes and their negative influence on tourists and citizens. In this context, the possibilities of legal regulation of prostitution are frequently discussed. Some Czech politicians criticize contemporary abolitionist law. The government is trying to find a solution in partially regulating "sex workers."

Some nongovernmental organizations are active in social, health, and hygienic help for prostitutes, for example "RR" (Rozkoš bez Rizika: "Pleasure Without Risk").

### C. Pornography and Erotica

In comparison with the situation before 1989, the contemporary production and availability of sexually explicit materials has increased significantly. Soft erotica is free from restrictions. Hard-core magazines, book, and audiovisual materials are sold in special shops, which are restricted for minors under 18 years of age.

In our 1994 survey, 4% of the men and 8% of the women thought that pornography should be prohibited; 11% and 20%, respectively, thought pornography to be dangerous. In 1998, these figures were 9% and 14%, and 20% and 21%, respectively. More frequently, however, contact with explicit erotic materials could promote a greater sensitivity and more-negative attitudes.

### D. Paraphilias

Paraphiliacs at present have more opportunities for communication and contact than they had under the communists. Some sexual-contact magazines, advertisement services, and clubs now exist for these people. Most of the interest is in sadomasochism and fetishistic practices. Groups which produce pedophilic pornography, both heterosexual and homosexual, are repeatedly investigated by the police. Some paraphilic erotic materials are accessible on the Internet.

Some people with ego-dystonic paraphilias seek help at the counseling centers and sexological departments. More frequently, sexologists are called on to treat paraphiliacs who have been arrested as perpetrators of some sexual crime. In such situations, consultation with a psychotherapist is required, and treatment can be paid for from the national health insurance.

pist is required, and treatment can be paid for from the national health insurance.

## 9. Contraception, Abortion, and Population Planning

### A. Contraception

The birthrate in the Czech republic is very low. About 49% of all children are not planned, but only 1.4% of all newborns are placed for adoption. The fact that almost half of all pregnancies are unwanted poses a major problem and challenge. In 1990, the most popular contraception in the Czech Republic was coitus interruptus, which 40% of the Czech women relied on at their risk (1991 data). A third of Czech women, 31%, used barrier methods, particularly the condom and IUD. The hormonal contraceptive pill was used by 8% and sterilization by 2%. The low incidence of hormonal contraception and surgical sterilization was a national problem. See Table 3 for a comparison of contraceptive use by men and women in 1994 and 1998.

### B. Teenage (Unmarried) Pregnancies

The number of pregnancies in women under age 15 is low. Slovak and Czech teenage women have limited access to contraception. Contraceptive pills can only be obtained from a gynecologist, and the attitude of many gynecologists toward hormonal contraception for young women is not always a positive one. Hormonal contraception is not paid by health insurance and could be relatively expensive for some young women.

As shown in Table 4, the share teenagers have in the total fertility of the Czech Republic has steadily decreased from 13.0% in 1990 to 5.6% in 2000. The number of pregnant women under age 18 is also low. Table 5 shows the number

**Table 3**

**Contraception in the Czech Republic: Percentage of Men and Women Who Have Ever Used a Particular Method**

Method	1994		1998	
	Men	Women	Men	Women
Withdrawal	79%	75%	76%	64%
IUD	—	31	—	25
Condoms	66	—	70	—
Oral contraception	—	63	—	60
Natural/rhythm	44	41	42	26

**Table 5**

**Number and Share of Children Born Outside of Marriage, 1993-2000**

	1993	1994	1995	1996	1997	1998	1999	2000
Number of children	15,434	15,570	15,013	15,367	16,194	17,284	18,532	19,868
Share of children of all births	12.7%	14.6%	15.6%	16.9%	17.8%	19.0%	20.6%	21.8%

and share of children born outside of marriage in the Czech Republic between 1993 and 2000.

### C. Abortion

The law regulating induced abortion in the former Czechoslovakia was liberalized in 1956. Between 1956 and 1986, women seeking an abortion had to present their request to special "abortion commissions." After 1987, pregnant women could obtain an abortion simply by requesting it. Induced abortion is legal until the 12th week of gestation. Abortion for medical reasons or to protect the woman's health is legal up to the 24th week of gestation. Illegal abortions are rare. In the 1994 adult survey, 60% of women and 58% of the men were fully "pro-choice." This situation was not changing in the repeat survey in 1998. Only 3% of both men and women believed the law should prohibit induced abortion.

In the last two years, the number of legally induced abortions has declined. More than 85% of all abortions are performed in the first two months of gestation as "mini-inter-ruptions." RU-486 is not available.

The number of legally induced abortions per 1,000 women decreased from 1991 to 2001, from 111,268 to 34,500. Such a radical change is, of course, connected with all these dramatic shifts in different segments of the Czech society during the last decade.

From the point of view of the prevention of induced abortions, two things seemed to have great importance: The first is substantially better availability of modern contraception; the second is dramatic change in the value system of citizens, with great influence on the reproductive behavior of people.

### D. Population Programs

In the 20 years between 1970 and 1989, the communist Czechoslovak government made some efforts to promote population growth. All of these efforts utilized economic incentives. Money was provided for the support of each additional child at above the standard of normal living. Families with three or four children received increased support and benefits. All of these efforts had only a temporary effect, and no substantial long-term success.

At present, the state population policy is relatively liberal, based on the free choice and reproductive rights of people. The main goal is to enhance the social and reproductive responsibility of the people. The state supports some sexual educational and healthcare programs. Nongovernmental organizations also sponsor activities, including education programs aimed at improving contraceptive use and lowering the number of legally induced abortions for non-medical reasons.

One of the stable questions within domestic politics used to be state support for young families with children, which is now seen to be insufficient.

## 10. Sexually Transmitted Diseases and HIV/AIDS

### A. Sexually Transmitted Diseases

#### *Incidence, Patterns, and Trends*

At present, the incidence of STDs and AIDS is relatively low. In the young Czech citizens survey, only 7% of males and 16.5% of females reported some experience with a sexually transmitted disease. This is because of 40 years of communist policy, which, in a substantial way, restricted the free movement of people. After the frontiers were opened in 1989, the movement of people into and out of the country increased. This new mobility and migration is already increasing the number of STD cases in the larger cities and in regions near the western frontier.

*Syphilis.* In the 1980s, no more than four cases of syphilis were reported annually per 100,000 inhabitants. In 1991, the rate of new syphilis cases was 1.3 per 100,000, with more women than men affected; in 1995, it was 4.0 and in the 2001 already 12.5. Such a rapid elevation of STD prevalence is conditioned by greater migration, primarily from Eastern Europe, where the prevalence of STDs is very high. In the last decade, some small local epidemics of syphilis, imported from abroad, were registered.

*Gonorrhea.* In the 1980s, the annual incidence of gonorrhea was under 100 cases per 100,000 inhabitants. In 1991, 71% of all cases were men between ages 15 and 24. In 1992, the incidence of gonorrhea increased significantly in some regions on the north and west frontiers and in Prague. This is one of the first signs of a new STD epidemic developing under new social conditions. Contemporary prevalence of gonorrhea is officially very low. In 1991, it was approximately 70 cases per 100,000 inhabitants and in 2000 only 10 cases. This decline is only an estimate, based on the unwillingness of physicians to report these cases.

Actual clinical experience reveals a remarkable increase in the incidence of all other STDs, including genital warts, papilloma virus infections, genital herpes, nonspecific urethritis, pelvic inflammatory disease (PID), chlamydia, cervical dysplasias, and cervical carcinomas.

#### *Availability of Treatment and Prevention Efforts*

The law requires that all new cases of classical venereal diseases be reported to the Ministry of Health Care. Infected persons are also required by law to give health professionals information about all sexual partners. Diagnosis and treatment for STDs is easily available in all the larger cities, at dermatovenereological departments, clinics, and gynecological and urological departments.

The main factor in the primary prevention of STDs is responsible sexual behavior. Sexual education should be started at a very young age and should include information of the health risks of sexual behavior. Some particular groups, "at-risk populations," need special attention with specifically designed sexual education programs. Such programs would promote safer sex information among promiscuous heterosexuals, homosexuals, prostitutes, and highly mobile minorities (tourists and professional drivers). There are many nongovernmental organizations that are active in the sex education and the promotion of STD-prevention efforts. However, sexologists are not completely satisfied with the present situation in sex education. In the Czech Republic, sex education is a compulsory part of the educational programs in schools, but the level and quality of these programs varies widely. The involvement of the mass media, radio, and television in this area is not consistent.

### B. HIV/AIDS

#### *Incidence, Patterns, and Trends*

Thus far, the incidence of HIV infection in the republic is low. At the end of 1992, there were 143 known cases of HIV infection and 32 cases of AIDS in the Czech Republic, 93 of them being homosexual or bisexual men and 30 hemophiliacs or blood-transfusion recipients. Only one IV-drug user has registered. Ten cases involved heterosexual transmission and 9 cases had unknown sources. Of the 143 known cases, 11 were women and 7 were children under age 15.

In 1995, there were 249 HIV-positive cases, including 72 cases of AIDS; in 2001, 501 HIV-positive cases, and 149 cases of AIDS were reported. Most of the HIV-positives are men, approximately 80%, with the main source of infection being sexual contacts with men. Intravenous drug abusers

are very rare in the Czech Republic, with only about 4% of HIV-positive cases being intravenous-drug users.

The low incidence of HIV infection is well demonstrated by the results of several preventive and anonymous screenings for HIV. In 2002, 800,000 HIV tests were conducted in the country, with positive findings in only 70 cases (including 21 foreigners).

Persons with suspected HIV infection or AIDS are protected under a special rule guaranteeing their personal freedom to seek or refuse testing.

For 96% of the Czech men and women, the main source of information about HIV/AIDS is the mass media.

### *Treatment, Prevention, and Government Policy*

The Czech Ministry of Health Care has a special program for the prevention and treatment of HIV/AIDS. This program has a self-contained budget. There are centers for HIV/AIDS investigation and treatment in all regional centers, and in the capital city, Prague.

Anonymous testing for HIV is available in all larger cities free of charge. Government policy fully respects the international standards of the World Health Organization. The national center for HIV/AIDS has been operating by the National Health Care Institute in Prague ([www.aids-hiv.cz](http://www.aids-hiv.cz)) for several years.

The Ministry of Health Care has been coordinating governmental activities with nongovernmental organizations and institutions. An AIDS-Help society, SAP [Společnost AIDS Pomoc], was founded in 1991. Sexual education is actively promoted by the Sexological society and by the Czech Family Planning Association [SPRSV–Společnost pro Plánování Rodiny a Sexuální Výchovu]. Many hotlines and telephone counseling services are operating with varying professional standards.

Programs for training counselors and health professionals are just being organized. Work with “at-risk” populations does not have a long tradition, because the communist government did not acknowledge such groups.

An organization for prostitutes was started in 1992 (RR–Pleasure Without Risk). Propagation of safer sex information among promiscuous homosexual men and promiscuous heterosexuals is possible with the collaboration of gay self-help groups like the Lambda Klub and through erotic magazines and video-rental clubs. SOHO is an NGO, which is trying to represent different gay and lesbian groups in the country.

The author’s 1993 survey of 984 residents of Prague ( $N=485$  males and 499 females) between the ages of 15 and 29 contained 30 questions about past and present sexual behavior designed to elicit information on the risk of HIV infection. The most frequent sources of information about HIV/AIDS were books and magazines (for more than 50% of males and females). Parents and school were the main information source for less than 10% of the respondents. More than 90% of the male and female respondents were appropriately informed about HIV transmission, although 20% believed that insects, kissing, or sneezing could spread the virus. Five percent of the males and 2% of the women believed that hormonal contraception protects against HIV infection. One in four males and females felt threatened by the risk of infection. One in four males and one in five females had changed their sexual behavior as a result of this fear, with a decrease in sexual partners and an increase in condom use being the most common changes. Twenty-nine percent of males and 16% of females stated they would break with a partner if they learned that he or she was HIV-positive. Twenty-three percent of the men and 17% of the women believed persons with HIV/AIDS should be kept in

isolation. Eleven percent of males and 20% of females had been tested for HIV infection at least once.

Preliminary results of the survey of Prague youth indicates that approximately a third of the youth of Prague are at very low risk for the infection, because of their monogamous lifestyle, avoidance of risky sexual practices, regular use of condoms, or complete sexual abstinence. Approximately 5% of the men and women were at high risk because of a combination of sexual promiscuity, risky sexual practices, coitus with IV-drug users, and failure to use condoms. Now that information about this risk group is on the record, it can become the subject of a government-sponsored prevention campaign.

[Update 2002: UNAIDS Epidemiological Assessment: By the end of 2001, a cumulative total of 551 cases of HIV infection had been officially reported. Estimated prevalence and incidence of HIV/AIDS is still relatively low and the epidemiological situation seems stable. However, there are some changes in the pattern of HIV spread in the years 1995 to 1999. No HIV infection has been reported in blood donors since 1995. Heterosexual transmission of HIV is increasing and, as of the end of March 2000, was responsible for 35.7% of all registered HIV cases. The number of HIV-infected women is increasing, now comprising 20.2% of all registered HIV cases. The rate of HIV-infected pregnant women is also increasing, making up 7.1% of all HIV-infected women; during this period, the first two cases of mother-to-child HIV transmission were reported. HIV is also slowly penetrating to the subpopulation of injection drug users; at present, 4.2% of HIV infections are among injection drug users. The number of HIV infections registered among foreigners from Eastern Europe, especially from Ukraine, is increasing. The incidence of notified syphilis cases in the last few years is in the range of 3 to 4 per 100,000 population.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	600 (rate: 0.1%)
Women ages 15-49:	< 100
Children ages 0-15:	< 10

[An estimated less than 10 adults and children died of AIDS during 2001.

[No estimate is available for the number of Czech children who had lost one or both parents to AIDS and were under age 15 at the end of 2001. (End of update by the Editors)]

## *11. Sexual Dysfunctions, Counseling, and Therapies*

The investigation and treatment of sexual dysfunction has a long tradition in Czechoslovakia. Since the founding of the Institute of Sexology at Charles University in Prague in 1921, sexual dysfunction has been one of the main interests. Czech sexologists have adopted a psychosomatic approach to couple sexual problems and sexual dysfunction. Strong emphasis is given to the quality of the therapeutic contact and to psychotherapeutic activities. Sexology was introduced as a particular medical specialization in 1975. Most of the clinical sexologists came into sexology from psychiatry, others from gynecology and urology. Prague has a long tradition of investigating the vascular etiology of erectile dysfunction. One of the pioneers of surgical treatment of vasculogenic impotence is Vaclav Michal from Prague.

The prevalence of sexual problems within the population was repeatedly studied in our survey. Global satisfaction with their own sexual life was expressed in 1994 by 76% of men and 82% of women. In the 1998 survey, overall satisfaction was expressed by 73% of men and only 70% of women. Very outstanding was the decline in the level of sat-

isfaction level for women from 83% to 70%. For such a trend, we have no rational explanation, and further study of this phenomenon is needed.

Medical diagnosis and treatment of sexual dysfunction in both men and women are free of charge at present for all ages and social groups. Some medications, of course, are provided with partial payment by the patients. For example, recently introduced drugs for impotence (sildenafil, tadalafil, apomorphine—Viagra) are not covered from health insurance. Counseling and psychotherapy for sexual problems are available not only at the sexological clinics, but also at some psychological centers in the health system and in social institutions, particularly marriage-counseling centers that operate in all the larger cities in both countries.

## 12. Sex Research and Advanced Professional Education

The main center for sex research has traditionally been the Institute of Sexology at Charles University in Prague, founded in 1921. Research at this Institute has centered on behavioral sexology and on some andrological problems.

The founder of the Czech School of Medical Sexology, Josef Hynie (1900-1989), spent some time at several of the world-renowned centers of early sexology, particularly the Magnus Hirschfeld Institute of Sexology in Berlin. His successor, Jan Raboch (1915-2002), has made important investigations in both andrology and behavioral sexology. In 1977, Raboch was president of the International Academy of Sex Research (IASR). Prague has twice been the site of an annual meeting of the IASR (in 1977 and 1992).

Czech psychiatry is well known for its sexological research. In the early 1950s, Kurt Freund began his studies using penile plethysmography to investigate male sexual orientations. Ales Kolarsky and Josef Madlafousek, at the Prague Center of Psychiatric Research, extended Kurt Freund's work in penile plethysmography with important publications. Research on gender problems has been established at a new center founded by the Faculty of Philosophy of Charles University in Prague. The Czech Sexological Society used to regularly organize scientific conferences at least twice a year. "East-West" conferences on sexual abuse and sexual violence are organized every two years in Prague.

Undergraduate programs in sexology are included in some medical, pedagogical, and law faculties. Postgraduate study is available only in medicine. Admission to this postgraduate specialization is limited to those who have successfully completed the program in psychiatry, gynecology, or urology.

The main sexological institutions in the Czech and Slovak Republics are as follows:

Institute of Sexology, 1st Faculty of Medicine, Charles University, Prague. Address: Karlovo namesti 32, 120 00 Praha 2, Czech Republic. Tel./Fax: +420224966609.

Sexological Society (of the Czech Medical Society). Address: See Institute address above.

SPRSV (Společnost pro Plánování Rodiny a Sexuální Výchovu—National Family Planning Association). Address: Senovážná 2, POB 399, 111 21 Praha 1, Czech Republic.

Gay Initiative in Czech Republic. Address: Senovážné náměstí 2, 110 00 Praha 1, Czech Republic. www.gay.iniciativa.cz.

AIDS-Help (AIDS Pomoc) Society. Address: Malého 3, 180 00 Praha 8, Czech Republic. Phone: +420224814284.

## *Demographics and a Brief Historical Perspective*

ANNETTE FUGLSANG OWENS

### A. Demographics

Once the seat of Viking raiders and later a major European power, Denmark is located in northwestern Europe, with the southern tip of Sweden to its east, Germany to the south, Norway to the north, and Great Britain to the west. Denmark occupies the Jutland Peninsula north of Germany, and the major islands of Zealand and Funen, plus hundreds of smaller islands. The North Sea separates Denmark from Great Britain on the west, while to the north and east the Skagerak, the Kattegat, and the Baltic Sea separate it from Norway and Sweden. With a total landmass of 16,639 square miles (43,094 km<sup>2</sup>), Denmark is slightly less than twice the size of the state of Massachusetts in the United States and half the size of the state of Maine. The terrain is low and flat to gently rolling plains, and the climate temperate, humid, and overcast. Mild windy winters and cool summers predominate, interrupted by the occasional ice-winter, when islands can be reached by foot, and by periods of hot summer days, when air-conditioned facilities are longed for but rarely found. Whenever the sun shines, Danes are out to enjoy it.

In July 2002, Denmark had an estimated population of 5.37 million, with a quarter of the Danes living in metropolitan Copenhagen. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Per Capita Gross Domestic Product (purchasing power parity):** \$28,000 (2001 est.); *Inflation:* 2.4%; *Unemployment:* 5.3% (2000); *Living below the poverty line:* NA

### B. A Brief Historical Perspective

From 10,000 to 1500 B.C.E., the Danish population evolved from a society of hunters and fishermen into an agricultural one. The missionary Ansgar (801-865) and, later, king Harald Blaatand (?-985) Christianized the country in the 10th century. Bishop Absalon (1128-1201) is regarded as the founder of the city of Copenhagen, the Danish capital, situated on the east side of the country.

The Danes formed a large component of the Viking raiders in the early Middle Ages and, for centuries, the Danish kingdom was a major European power. Denmark's power

began declining when Napoleon (whom the Danes supported) was defeated, and the Congress of Vienna in 1815 gave autonomy to Norway and Sweden. Schleswig-Holstein withdrew from a union with Denmark in 1864, although Northern Schleswig rejoined Denmark in 1920. Iceland declared its independence in 1944, ending a union that began in 1380. The Faeroe Islands and Greenland, the latter being the biggest island in the world, are still part of the Danish Kingdom, but with their own home rule. Denmark has been a member of the E.C. (now the European Union) since 1973. A monarchy for more than 1,100 years (one of the oldest in the world), Denmark is currently ruled by Queen Margrethe II. Nine political parties, collaborating in coalitions and led by the Prime Minister, share political power. Medical health is primarily socialized, with a small, but growing private sector.

### 1. Basic Sexological Premises

CHRISTIAN GRAUGAARD

#### A. General Concepts and Constructs of Sexuality and Love

As other Western countries, Denmark has experienced a marked socioeconomic development over the last two centuries: from a classical agrarian society to a modern industrialized welfare state. Along with modernity came profoundly altered concepts of love, intimacy, sexuality, and gender, and broadly speaking, the process of sexual liberation came about in three distinct (yet historically closely intertwined) stages: the late-19th-century feminism, the inter-war sexual-reform struggle, and “the sexual revolution” of the 1960s. Today, Denmark is a peaceful and politically stable democracy, and although women in executive positions are still amply outnumbered by men, gender inequality is nowhere near bleak global figures. On the contrary, it can be argued that the “social gender” of Danes has been gradually obliterated over the past century, and in spite of persisting differences, it is generally acknowledged that males and females are *potentially* capable of discharging similar jobs and societal positions. Specific legislation on gender equality has existed since 1919, and currently the Ministry of Social Affairs is formally responsible for governmental surveillance of gender issues.

Today, Denmark is a predominantly secular country, and although well over 90% of the population belong to the Protestant Church, doctrinaire religious groups are scarce and have very little impact in public debate. In the rural areas of Jutland, however, Christian morals are still kept alive, having an impact on various levels of personal experience and conduct. On a whole, the Danish population is small (1.4% of the EU population), and uniquely homogeneous, and though issues of immigration have been vividly debated in recent years, immigrants and their descendents constitute only 7.4% of the population. Out of 5.3 million inhabitants, one fifth are below the age of 17, whereas 15% are older than 65. Seventeen- to 24-year-olds constitute slightly less than one tenth of the total population. Most Danes live in metropolitan areas.

During recent decades, Denmark, like other Western European countries, has been largely “postmodernized.” Thus, “serial monogamy” has become a prevailing way of life, and a majority of adults cohabit without being married. In 2000, 38,844 marriages were contracted, and the same year, a total of 14,394 couples were divorced. Unfaithfulness is generally frowned upon, but seemingly considerable numbers of Danes have had extramarital affairs: Among 60-year-old Copenhageners, 38% and 22% of males and females, respectively, stated that they had been engaged in extramarital relations at least once (Eplöv 2002ab). A total of 1.4 million

adults live by themselves, and 120,000 (8.6%) of these have children. Thus, a growing subculture of singles has emerged among adult Danes. The availability of pornography has markedly increased since its decriminalization in the late 1960s, and similar to other Western countries, a certain “sexualization” of mass medias, art, and popular culture has occurred during recent years.

#### B. Basic Outlines of Sexual Behavior and Knowledge

Along with profound socioeconomic changes, a gradual relaxation of sexual attitudes and behavior has taken place among Danes: The median age of coital debut among women and men born before 1920 was 21 and 20, respectively, as opposed to 16 for both women and men born in 1960 or later (Jaeger 2000). Similar figures were reported by Fog (1994). For females born before 1920 and after 1960, respectively, the median interval between menarche and coital debut has decreased from seven to three years. The median lifetime number of partners for women and men born before 1920 was 1 and 3, respectively, and 7 for both women and men born after 1960. For women and men above age 75, 1% and 17%, respectively, have had more than 10 sexual partners, as opposed to 42% of both women and men under age 35 (Jaeger 2000). In sum, a marked liberation of sexual behavior has occurred over recent generations in addition to a striking leveling of former sexual gender differences. In 1976, the age of sexual consent was set at 15 for both homosexual and heterosexual relations.

On a legislative level, too, an overall air of sexual *frisind* (Danish for “free-mindedness”) is detected. Sex education in schools has been mandatory since 1970 (see Section 5A, Interpersonal Heterosexual Behaviors, Adolescents), abortion was decriminalized in 1973 (see Section 9B/C, Contraception, Abortion, and Population Planning, Abortion and Teenage Pregnancies), and in 1989, same-sex partners obtained (almost) the same legal status as heterosexual couples (see Section 6, Homoerotic, Homosexual, and Bisexual Behaviors). Moreover, Denmark was the first country in the world to legitimize written pornography in 1967 (followed by pictorial pornography in 1969) (Kutchinsky 1989). Prostitution is no longer a criminal offense in Denmark, and it is estimated that a total of 5,000 transactions with female prostitutes take place every day. Further, 13% of Danish males claim to have been with a prostitute at least once. Among 40- to 44-year-olds, this fraction rose to 17% (Melbye 1992). Equivalent numbers were seen by Jaeger (2000). Male prostitutes are believed to constitute a total of only a few hundred persons. The number of migrant sex workers is apparently low, but internationally, Denmark is sometimes mentioned as a transit country for women who end up in prostitution in neighboring countries such as Germany and Holland. Though not in itself prohibited, prostitution is considered illegal vagrancy if the prostitute has no other means of income. Prostitution of minors is rarely seen.

Generally speaking, sexual and reproductive rights are both acknowledged and appreciated in Denmark, and sexual autonomy is taken for granted by younger Danes. Sexual curiosity of juveniles is widely accepted (many kindergartens have “cushion rooms” for children to fight and cuddle in privacy), although heated debates on the alleged “pedophile threat” have swept over Denmark (as it has in the rest of Europe and the US) during recent years. As previously mentioned, sex education in schools has been obligatory since 1970. The current sexual knowledge of adolescents is supposedly good, even though up-to-date didactic methods are called for. Thus, a quarter of youngsters still don’t use any contraception at their first intercourse (Rasmussen 1999), and

rates of chlamydia and venereal warts among adolescents are a matter of medical concern (see Sections 5A, Interpersonal Heterosexual Behaviors, Adolescents, and 10A/B, Sexually Transmitted Diseases and HIV/AIDS, Basic Figures).

### C. Danish Sexology

Danish sexology was founded in the 1950s, and Dr. Kirsten Auken's 1953 dissertation on the sexual behavior of young women is often considered the starting signal of serious scientific efforts. Foremost, however, it was her protégé, Dr. Preben Hertoft, who—inspired by Masters and Johnson and Helen Singer Kaplan—pioneered modern sex therapy in Denmark. In 1986, a Clinic of Sexology was launched at the University Hospital of Copenhagen (Rigshospitalet), and for more than a decade, Dr. Hertoft functioned as its productive chief physician. Though two more clinics were originally intended, the Copenhagen clinic is currently the only service of its kind in Denmark.

As of early 2003, clinical sexology was not approved as a medical or psychological specialty by central authorities, but recent efforts have been made by the Nordic Association for Clinical Sexology (NACS) to certify and authorize sexological specialists on various levels (see Section 11, Sexual Dysfunctions, Counseling, and Therapies). The NACS hosts annual meetings rotating among member countries and, additionally, the Second Congress of the European Federation of Sexology was held in Denmark in 1994. Between 1983 and 1998, NACS published a periodical, *Nordisk Sexologi* [*Nordic Sexology*], subsequently replaced by the *Scandinavian Journal of Sexology*. Regrettably, this was given up in 2001. Currently, efforts are being made to relaunch a Nordic periodical of sexology.

The first Danish textbook on sexology was published by Dr. Hertoft in 1976. Though not revised since 1987, this book is still commonly used and has been translated into several languages (Hertoft 1987). In recent years, two thorough encyclopedias of sex and sexology have been published in Danish (Graugaard 2001; Hertoft 1989). A useful list of selected publications in non-Scandinavian languages (until 1994) was presented in a special issue of *Nordisk Sexologi* (1994, 12:151-175).

## 5. Interpersonal Heterosexual Behaviors

### A. Adolescents CHRISTIAN GRAUGAARD *Coital Debut and Sexual Behavior*

Classic studies of adolescent sexuality in Denmark were performed by Auken (1953) and Hertoft (1968), but since the appearance of the HIV/AIDS issue in the mid-1980s, several studies concerning sexual knowledge, attitudes, and behavior of youngsters have emerged (Wielandt 1993; Krasnik

1990). In 1999, a comprehensive questionnaire survey was carried out among 7,355 representative adolescent Danes, including more than 500 questions about sexual issues, such as experience and current behavior, use of contraception, sources of information, attitudes, and factual knowledge (Rasmussen 1999). This study provided healthcare persons, sexologists, and sex educators with valuable insights into the sexual world of young Danes, and the following is largely based on the major results of that survey.

The median age of coital debut (sexarche) among adolescent Danes is 16.8 years, and in all age groups from 13 to 25, girls tend to be slightly more experienced and active than boys. The age at coital debut has dropped about two years since the post-war period (Jaeger 2000; Fog 1994), but seemingly it has remained stable over recent decades. At the age of sexual consent (15 years), just about a third of both girls and boys have had their first sexual intercourse, whereas 7% to 8% of 13-year-olds claim to have had sex. At age 20, 8% and 13% of girls and boys, respectively, are still not sexually experienced. Despite Denmark being a small country, marked differences are seen between urban and rural youth—the former being significantly more experienced and active than the latter. Similarly, youngsters with an ethnic background (at least one parent not originally Danish) were considerably less sexually active than their same-aged peers with Danish parents. By far, this tendency was most striking for girls.

The primary motives for first sexual encounter included “being in love” (about two thirds) and “curiosity” (one third), but various kinds of pressure from partner or peers were also reported by around one third. A similar fraction claimed to be drunk at their sexual debut, whereas less than 5% were influenced by cannabis. Not surprisingly, sexual activity increased by age, and 56% of 20-year-old women (43% of men) claimed to have sexual intercourse at least once a week. A third and a half of girls and boys, respectively, had known their partner less than a month at their sexual debut, and similar fractions found it fully acceptable to have sex within a week of the first date. Only a small minority of youngsters had had more than 10 sexual partners—and a vast majority of both girls and boys insisted on (serial) fidelity.

Expectedly, the frequency of orgasm among girls increased with age. One third, reportedly, experienced an orgasm in the year of their sexual debut, whereas 60% considered themselves orgasmic five years later. No knowledge exists as to the masturbation habits of adolescent males, but among 13-year-olds, three fourths reported having ejaculated. Though still somewhat tabooed, masturbation is thought to be highly common among young Danes of both sexes. Less than 10% had anal sex on a regular basis, whereas the frequency of oral sex is unknown. Only about 5% reported having had intercourse with a partner of the same sex. Other same-sex experiences (i.e., petting and mutual masturbation), however, were not investigated and are believed to be quite common.

One fourth of youngsters did not use contraception of any kind at their first intercourse, whereas 61% used a condom; 14% used the pill, alone or combined with a condom. The lack of coital protection is a matter of great educational concern, and during recent decades, various safe-sex campaigns have been specifically targeted at adolescents (Wielandt 1993). The prevalence of unsafe sex decreased with age, and just 12% of all sexually active youngsters abstained from use of contraception on a regular basis. A considerable amount of sexually active youngsters (one third) had experienced failure of the condom, and one fourth of active girls had used postcoital prevention at least once. Just 7% of sexually active

girls had had an induced abortion, whereas 9% and 5% of active girls and boys, respectively, had been diagnosed with chlamydia at least once. The last-mentioned number was considerably higher among youngsters with a minimum of 10 previous partners (see Section 10, Sexually Transmitted Diseases and HIV/AIDS).

### Sex Education

Surprisingly enough, more than half of girls and 70% of boys reported that sexual topics were “never” or “rarely” discussed at home. On the other hand, a vast majority—96%—had received sex education in schools, and a total of 43% considered this both sufficient and relevant. By far, peers constituted the preferred forum for talks and discussions on sexual and emotional matters. As mentioned earlier, sex education has been mandatory in Danish elementary schools since 1970, but there are substantial differences in both quantity and quality of the didactic efforts made by single schools. Unfortunately, sex education only holds a scant priority at most teachers’ colleges, and a majority of educators have actually never received formal pre- or postgraduate education prior to starting their teaching.

During recent years, efforts have been made to supplement official activities and, hence, reach youngsters with information and counseling by alternative means. In 1992, the Danish Family Planning Association launched an anonymous, nationwide hotline service for teenagers—the service is free of charge and it receives around 2,000 calls a year, mainly concerning “basic information” and “sexual problems.” Considering the small population of Denmark, 2,000 calls to the FPA hotline is a substantial response. Moreover, interactive counseling on the Internet is gradually evolving, and a number of private or semi-private websites offer free sexual counseling to adolescents (Graugaard 1998). Gradually, new didactic methods are being developed for school purposes, too, including peer education, interdisciplinary teaching aids, and interactive computer games. The concept of *ungdomsmottagningar* (youth clinics) known in Sweden has not as yet gained ground in neighboring Denmark, but for many years, the Danish Family Planning Association has run a well-attended contraceptive service in downtown Copenhagen. Congenial clinics are found in other major cities.

As in other Western countries, youth culture has become increasingly diverse and polyphonic since the “youth revolt” of the late 1960s. Thus, no predominant or homogeneous trend is currently found within the teenage group, rather an ever-changing variety of mobile adolescent subcultures. Sexually, not least, conduct, codes, values, standards, role models, social conventions, self-staging, and modes of expression widely differ within various adolescent segments—from MTV-viewing “pop girls” to left-radical “autonomous,” from Americanized hip hop boys to well-behaved, timid, middle-class girls. During recent years, concerns have been raised as to the possible pernicious effects of the increasingly “pornification” of mass media and public spaces. However, the genuine harmfulness of late-modern conditions, including the shattering of gender roles and traditional family structures, still remains to be shown. On the contrary, it seems that Danish youngsters are competently coping with—and fully enjoying—the multitudinous cultural wardrobe of the Babylonian “fetish society.” Moreover, teenagers seem to draw a clear line between the sexualized “kitsch” of the outside world and their own personal dreams, hopes, and expectations. Thus, in spite of their ever-increasing sexualized appearances (i.e., diminutive dress codes, defiant piercing, and harsh diction), many youngsters express surprisingly conservative, romanticized ideals and stereotypes, rather than any urge to engage in extreme sex-

ual practices. (See also Sections 1, Basic Sexological Premises, and 9B/C, Contraception, Abortion, and Population Planning, Abortion and Teenage Pregnancies.)

## B. Adults

LENE FALGAARD EPLOV

### Sexual Attitudes

Although officially a Protestant country, most Danes are brought up in a secular tradition with relaxed attitudes towards sexual matters. Only minor provincial communities maintain more-restrictive religious beliefs. The sexual attitudes of Danish people, however, are also influenced by old Nordic traditions, such as “night-courtship.” Thus, for centuries, premarital sex has been common and accepted (Hertoft 1977). Altogether, Danes consider themselves sexually open-minded, and to some degree, this is supported by national legislation. As mentioned in Section 1B, Basic Sexological Premises, Basic Outlines of Sexual Behavior and Knowledge, Denmark was the first country in the world to legalize written pornography in 1967. In 1970, sex education in schools became mandatory. Abortion was legalized in 1973. And in 1989, registered same-sex partners obtained (almost) the same legal status as married heterosexuals.

Despite this liberal legislation, the sexual attitudes of adult Danes, however, cannot be substantiated by comprehensive, cross-sectional studies, and our current knowledge stems from smaller studies only. In 1996, the sexual attitudes of a representative group of 60-year-olds from Copenhagen County were examined. Around 60% of males found pornography to be stimulating. Fewer than 20% indicated that infidelity, group sex, sadism, masochism, homosexuality, transvestitism, transsexuality, and fetishism should be legally banned, whereas a vast majority indicated that zoophilia, pedophilia, exhibitionism, incest, and voyeurism should remain punishable (Eplov 2002a). Among women, 9% used pornography occasionally, whereas 60% claimed to be indifferent towards pornographic material. Around half of the women regarded infidelity as immoral, and 12% indicated that prostitution should be abolished. Practically all women labeled pedophilia, necrophilia, and zoophilia as “perverse,” whereas two thirds labeled exhibitionism so. Around half of the women found sadomasochism, voyeurism, and group sex perverse, but less than 15% regarded homosexuality, transvestitism, and transsexuality as perverse (Eplov 2002b). These data among 60-year-olds cannot be considered representative for the general population, and results from studies among three female birth cohorts living in Copenhagen County indicated that younger women had more liberal attitudes towards sexual topics than older women (Fog 1994; Nielsen 1986ab; Garde 1980).

Sexual attitudes are obviously influenced by many factors, knowledge being one. Presumably, sexual knowledge has increased in the Danish population during the last decades, thus studies on the above-mentioned female birth cohorts (born 1910, 1936, and 1958) established that the fraction of people having received sexual information as juveniles decreased by age: 7% of the 1910 group, 6% of the 1936 group, and 61% of the 1958 group (Fog 1994). A nationwide study of adolescent Danes revealed that in the late 1990s, only 4% of youngsters had *not* received sex education in schools. Contrary to this, nearly a quarter of the girls and more than one third of the boys stated that they had not received sexual guidance at home (Rasmussen 1999).

### Sexual Behavior

In Denmark, the patterns of intimacy have changed considerably over the past decades, from long-lasting marriages to serial monogamy. Figures from the National Statistics Department show that although the number of yearly

marriages was a little over 35,000 in both 1951 and 2001, the number of divorces more than doubled, from around 7,000 to almost 15,000. Around 20% of the persons getting married in 2001 had been married before, and the average duration of a marriage was 11 years. As mentioned, registered partnership was legalized in 1989, and by late 2001, around 3,000 same-sex couples had been registered. Furthermore, an increasing number of Danes live alone, and in late 2001, around 37% of adult Danes, both men and women, lived by themselves (Danmarks Statistik 2002). See also Section 1, Basic Sexological Premises.

Concerning the number of sexual partners, Schmidt (1989ab) reported that 34% to 47% of Danish men aged 16 to 55 had more than five female partners in their life. Within the past 12 months, 64% had had one female partner, 8% had two, 1% had 3 to 5, and 3% had more than five partners. In a study of almost 5,000 adult Danes, the median number of sexual partners was highest for men aged 30 to 34 (eight partners) and for women aged 25 to 29 (seven partners) (Melbye 1992). In a sample of Danes and Swedes, 1% and 17% of women and men over age 75, respectively, had had at least 10 partners in their lifetime. This was contrasted with 42% of both women and men under age 35 (Jaeger 2000).

The sexual behavior of Danes have only been well examined with regard to age of coital debut and risk behavior in relation to HIV/AIDS (Eplöv 2002c). Since “the sexual revolution,” one might expect that the age at sexual debut had decreased gradually, but studies reveal otherwise. Thus, the three female birth cohort study showed a decrease in sexual debut from women born in 1910 (average age at debut 21) to women born in 1958 (average age at debut 16) (Fog 1994). Representative studies among pupils in 9th grade in a municipality in Jutland showed no changes in the age of coital debut over 14 years (Boelskifte 2002b). Similar results were found in two representative studies among 16- to 20-year-old Danes from 1984 and 1989 (Wielandt 1993). In sum, a decrease in the average age at coital debut took place before 1980, with no real change in recent decades. See also Section 5A, Interpersonal Heterosexual Behaviors, Adolescents.

Since Danes have overall liberal attitudes towards sex, one might expect this to be apparent in their sexual conduct. The sexual activity of adult Danes, however, is only briefly illuminated by one nationwide study among citizens aged 18 to 88. This study demonstrated that a total of 81% were sexually active, falling off to 64% in the top age bracket (Ventegodt 1998). The incidence of masturbation, oral sex, and extramarital relations are only examined among metropolitan adults, whereas anal sex and the use of prostitutes are both examined in nationwide studies. Studies among 60-year-olds have shown that 11% of male respondents masturbated weekly or more; 27% masturbated at least monthly, whereas 33% stated that they did not masturbate at all. Among women, 4% masturbated weekly or more, 7% at least monthly, and 75% did not masturbate. The three female age cohort study showed an age-dependent increase in the number of women having ever masturbated—the youngest being the most experienced (Fog 1994). Among 60-year-olds, 55% of men had experienced fellatio, 79% cunnilingus, and 12% anal intercourse. On the female side, 63% had tried fellatio, 80% cunnilingus, and 20% anal intercourse (Eplöv 2002ab).

A national cross-sectional study by Melbye and Biggar (1992) showed that 22% of women had tried anal intercourse, it being most common (36%) among those aged 30 to 34. Further, more younger than older women reported having engaged in anal sex within the last year. The practice of anal intercourse was associated with a high number of male partners. Notably, a study of 23- to 87-year-old Danes

and Swedes revealed that receptive anal intercourse was significantly more common among Danish (17%) than Swedish (3%) women (Jaeger 2000). Among 60-year-olds in Copenhagen County, 38% of males stated that they had been engaged in extramarital relations, while this was true for 22% of females (Eplöv 2002ab). Figures from the three female birth cohorts revealed an increase in unfaithfulness from the oldest to the youngest women (Nielsen 1986ab, Garde 1980). In two representative studies, male use of female prostitutes was examined, showing that 13% to 14% of respondents had had sexual contact with a prostitute once or more in their life (Melbye 1992; Schmidt 1989ab).

As for sexual satisfaction and frequency of sexual problems and/or dysfunctions among grownup Danes, Ventegodt (1998) found that 67% of females and 58% of males were “satisfied” or “very satisfied” with their current sex life. Eleven percent of women and 18% of men were “dissatisfied” or “very dissatisfied.” A review from 2002 documented that even though the frequency of sexual problems and dysfunctions in the Danish population have been the issue of several studies, only one of these could comply with basic methodological requirements (Eplöv 2002c). Subsequently, the frequency of sexual problems and dysfunctions among adult Danes is poorly established. In a representative sample of the Danish general population, Ventegodt (1998) found the following female complaints: reduced sexual desire (11%), pain/discomfort during intercourse (3%), anorgasm (7%), and vaginismus (less than 1%). Common male complaints were: reduced sexual desire (3%), erectile problems (5%), premature ejaculation (5%), and anorgasm (less than 1%).

### C. Sexual Attitudes and Behavior BO MØHL

#### of Elderly Danes

##### *Sexuality in Old Age*

In 2000, the mean life expectancy of Danes was 74 and 79 years for men and women, respectively. Because of improved standards of living, the numerical and relative fraction of old-aged persons in the Danish general population has increased dramatically during the 20th century (in 2000 15% of the population was 65 or older) and to quote the WHO, “years have been added to life” as well as “life to years.” Thus, a growing number of elderly people experience more years in good health. Among 80-year-olds, however, there are five times as many women as men, obviously making it difficult for a widow to find a new male partner.

Despite the fact that modern Denmark holds liberal attitudes towards sexuality, there is a perpetual tendency to look down upon sexuality in old age. The sex lives of older people are often neglected or depicted as ridiculous or even disgusting. The reason is clearly a lack of knowledge, but presumably also because of children’s profound resistance to acknowledge and accept the sexuality of their parents, extending their reluctance to any old person. Elderly people who identify with the cultural prejudices of asexuality will often repress their sexual impulses and desires, resulting in a subsequent loss of sexual capacity and self-esteem.

Only a few studies of the sexuality of elderly Danes exist. Recent surveys among 60-year-old women and men (Eplöv 2002ab), however, describe attitudes and sexual lives of mature, urban people. A majority of both men and women had experienced different sexual practices during their lifetime, and relatively liberal attitudes existed towards sexual preferences such as homosexuality and transvestism. Pedophilia and incest, however, were deemed unacceptable. This is in accordance with the public opinion in Denmark and with the Danish edition of WHO’s code of diagnoses (ICD 10), in which homosexuality and transvestism are no longer considered to be diseases.

Approximately, half of the women still felt spontaneous sexual desire once a month or more, and a similar number had intercourse at least once a month. Despite the fact that they had a partner, 11% of the women had no sexual activity. Further, in a sample of 66- to 75-year-old Danish and Swedish women, 45% were still coitally active, whereas the same was true for just 4% of the over-75-year-olds. A quarter of coitally active women in these age groups were still married. The same study revealed that just 1% and 17% of women and men over age 75 had had at least 10 lifetime partners, as contrasted with 42% of both women and men under age 35 (Jaeger 2000). In the above-mentioned studies of 60-year-olds (Eplöv 2002ab), about half of the men felt sexual desire once a week or more. More than half of them had intercourse at least once a month. Eleven percent of women masturbated at least once a month, and 90% of these were fully orgasmic. Two thirds of men masturbated, 40% once a month or more.

### Sexual Dysfunctions

The most common sexual problem among 60-year-old females was vaginal dryness (29%). Approximately, every tenth man of the same age had serious erectile problems, while 47% had never experienced this sort of problem. Ninety-five percent of women were satisfied with the way they had sexual intercourse; 68% of the men were content with their sexual life in general. Both sexes described a good sexual experience as more than just a matter of physical satisfaction. The contact with the partner and the circumstances surrounding the intercourse were considered equally important. In a study of 70-year-old women, 11% reported having a current sexual problem as opposed to 22% of 22-year-olds and 36% of 40-year-olds. One in ten 70-year-olds expressed a need for sexological treatment or counseling (Fog 1994).

Approximately, 80% of elderly people have at least one impairment or chronic disease (i.e., diabetes, cancer, dementia, cardiovascular, or rheumatic disease), affecting their sexual life and well-being negatively. Besides, many elderly persons take prescription drugs (i.e., SSRIs, anti-hypertensives, or painkillers), which may have negative impacts on their sexuality. Lack of knowledge and misunderstandings about sexuality in old age result in additional sexual problems. The age-related physiological changes of the body make adjustments in sexual practice and coital positions necessary. Especially for old persons brought up with a puritanical and negative attitude to sexuality, a change of deeply rooted habits and routines can be very difficult (Møhl 2002a).

In Denmark, there is a condescending saying about mature/old age: "Forty, fat, and finished." Sexually speaking, however, this motto should be changed to "Eighty, fresh, and fiery," as the chance that an 80-year-old has sexual interests and desires is much greater than the opposite. Though presumably, there are considerable variations in the sexual lives of elderly Danes, the majority are certainly *not* asexual. The contrary might well be the case. A change in attitudes is therefore called for, by laypeople as well as professionals (Møhl 2002b), and during recent years a public debate has occurred as to the sexual rights of elderly in nursing homes.

## 6. Homoerotic, Homosexual, and Bisexual Behaviors

CHRISTIAN GRAUGAARD

### A. A Brief Historical View

During the Middle Ages, sexual same-sex relations in Denmark were solely a matter of church law, but after the Lutheran Reformation (1536), sodomy was tried by secular

courts and punished in accordance with the Bible. Not until the Danish Code of 1683, however, was sodomy added explicitly to national statutes—it was considered a "contra-natural act" and sanctioned by capital punishment. Interestingly, only a few cases of sodomy between males have been documented in the period before the penal code of 1835, and it seems that most sodomy cases were resolved discreetly by administrative means (for an informative overview, see von Rosen 1994). Between 1835 and 1866, 14 men were sentenced, but the death penalty was routinely commuted to hard labor by the Royal Chancery. The new criminal code of 1866 reduced the maximal penalty to six years of imprisonment, but in practice, punishment for sodomy between consenting adults was considerably milder, usually 8 to 12 months in jail. With the Civil Penal Code of 1930, adult same-sex relations were decriminalized, but not until 1976 was the homosexual age of consent lowered to the same level as the heterosexual, namely 15 years. Historically, sexual relations between Danish women have only been considered scarcely problematic and such behavior was never an object of specific legal interest.

As elsewhere in Europe, the early modern *époque* gave rise to "homosexuality" as a circumscribed social phenomenon with a distinct personality and lifestyle of male homosexual persons. Prompted by early continental sexology, the modern homosexual gradually came into being, and in Denmark, too, the views on same-sex relations shifted from a question of morality, sin, or crime to being strictly a medical and/or forensic concern. No longer was homosexual behavior something which deviant people *did*, but rather something they *were*. Inspired by the writings of Richard von Krafft-Ebing (1840-1902), Danish *fin-de-siècle* doctors considered "genuine" homosexuality (as opposed to moral depravation) a degenerative condition of the central nervous system, and most Danish psychiatric textbooks of the period offer detailed descriptions on the concept of "contraire sexual instincts." In the first decades of the 20th century, however, the medical focus shifted towards the internal glands, and ambitious theories about homosexuality as a hormonal disturbance were put forward. In Copenhagen, Dr. Knud Sand (1887-1968) substantiated these through an elegant series of gonad transplantations in rodents and birds. Like Austrian Eugen Steinach (1861-1944), Sand believed that (male) homosexuality could be cured by restoring a proper testosterone balance, and during the 1920s, a number of Danish homosexual men underwent surgical procedures with transplantation of "heterosexual" gonads. This hormonal-deterministic viewpoint culminated in 1929, when the Danish Parliament passed the world's first Act on Sterilisation. The primary aim of the new legislation was to sterilize on eugenic grounds, but the law also warranted surgical castration on sexual delinquents or simply on persons whose sexuality caused them "mental suffering" or "social disparagement." By the late 1960s, just over 1,000 men (and some 10 women) had been legally castrated. Out of these, approximately 100 homosexuals underwent castration solely on the grounds of "mental suffering." (See Sections 7, Gender Diversity and Transgender Issues, and 8, Significant Unconventional Sexual Behaviors.)

Though no way near the proportions of "neighboring" cities like Hamburg or Berlin, a male homosexual subculture (and a modest male prostitution) gradually evolved in late-19th-century Copenhagen. Little by little, certain bars, secret societies, and meeting points became notorious homosexual territories, and one of the central parks of Copenhagen (Ørstedsparken) is still frequently used as an "erotic oasis" for men seeking sex with men. Initially, this was barely tolerated by philistines, legislators, and law-enforcement offi-

cers, and several scandals swept over town before the outbreak of World War I. As late as 1947, an opinion poll revealed that 61% of Danes considered same-sex relations to be worse than drunk driving, burglary, forgery, and rape (Albaek 1998), and in the postwar decades, an overheated moral panic again focused on depraved and subversive gay men. Thus, in 1961, a change of the Civil Penal Code criminalized male prostitution for the paying party, when the prostitute was under 21 years of age. This led to a considerable increase in police harassment and enabled numerous cases of blackmail. This so-called Ugly Law (*Den Grimme Lov*) was abrogated by Parliament in 1965. In 1967, male prostitution, as such, was legalized.

In 1948, the first homosexual organization in Denmark, simply called The Association of 1948, was founded. The Association soon began publication of the periodical *Vennen* [*The Friend*], later succeeded by *Pan*, which is still published. In 1980, the original organization changed its name to Landsforeningen for Bøsser & Lesbiske (Danish National Association of Gays and Lesbians) and though never truly radical, the Association has successfully managed to put various gay-related issues on the political and societal agenda. In the beginning of the 1970s, more activist homosexual groups evolved, and especially Lesbisk Bevægelse (Lesbian Movement), to some extent succeeded in bridging hard-core feminism with a lesbian lifestyle.

## B. Danish Homosexualities

Public attitudes towards homosexuality and homosexual persons have changed considerably since the sexual revolution of the 1960s. Thus, today the human rights of Danish homosexuals are (almost) on footing with heterosexuals. In May 1989, the Danish Parliament passed a pioneer bill on registered partnership between same-sexed persons, and on October 1, 1989, Axel and Eigil Axgil were married at the City Hall of Copenhagen as the first homosexual couple in the world. From 1989 to 1997, just over 5,000 individuals (two thirds males) were officially registered as partners (Frisch 2003). Despite legal equality, homosexual marriages are still not sanctioned by the Danish church. However, the atmosphere among Danish bishops is sympathetic towards ecclesiastical weddings, and priests are free to bless registered partners in their church. Unlike Sweden, Danish homosexuals are still not allowed to adopt (except for their own stepchildren), and following a fiery debate in the Parliament, it was decided that the Danish healthcare system should not assist lesbians in having children, nor should doctors be permitted to perform fertilizations of female same-sex couples. Still, a number of clinics, typically conducted by midwives, offer fertilization to lesbians with anonymous donor semen. The topic is still under debate, and a change of legal statutes is expected within a few years. Danish legislation explicitly bans sexual discrimination, and incidences of severe harassment or “gay bashing” are rarely heard of. In rural areas of Denmark, though, homophobia still abounds, and the Danish National Association of Gays and Lesbians hosts a telephone hotline for youngsters fearing to come out of the closet. Among urban 60-year-old males, 6% believe that homosexuality should be legally banned (Eplöv 2002a).

According to recent studies, only 1.1% and 1.4% of Danish 31- to 33-year-old males and females, respectively, label themselves as homosexuals, while 1.3% and 1.6% claim to be bisexual (Ventegodt 1996). In a study of 18- to 88-year-olds, just 1% reported being homosexual (Ventegodt 1998). Among males aged 18 to 59, an overall 2.7% reported to have had homosexual intercourse. This percentage, however, was almost doubled in men aged 40 to 44 (Melbye 1992). Among Danish teenagers, about 5% of girls and boys reported to

have had intercourse with someone of the same sex (Rasmussen 1999). Despite these marginal figures, the homosexual subculture in Denmark is broad and vivid, and in major Danish cities, several gay-friendly bars, cafés, clubs, saunas, and discotheques exist. Gay Pride Parades (so-called Mermaid Pride) are conducted every summer in the streets of the capital (in 1996, Copenhagen was the official European Pride City), and the World AIDS Day (December 1) is solemnized among both homosexuals and heterosexuals.

As in other Western countries, the gay and lesbian community is dispersed and manifold, with a virtual abundance of lifestyles open to view (Lofstrom 1998). Along with late-modern life conditions and the gradual demolition of sharp, mutually excluding sexual categories, homosexuality is being further de-dramatized. Thus, even though few Danes presently label themselves as homosexuals, it is generally agreed upon that same-sex relations will eventually appear in a more-relaxed manner among younger people considering themselves (and considered by others to be) heterosexuals. The modern homosexual man, therefore, may be a “ghost of the past,” as more flexible and unpredictable sexual life forms evolve. This is a theme thoroughly investigated by the Danish sociologist, Henning Bech (1999ab, 1998ab, 1997).

## 7. Gender Diversity and Transgender Issues

ELSE MUNCK

### A. Brief Historical View

During the second half of the 20th century, knowledge of gender-conflicted persons has increased considerably in Denmark through art, literature, and the news media. Thus, as a predominant late-modern trend, the multiplicity of gendered roles, expressions, and behavior patterns are increasingly accepted, appreciated, and cultivated. Both individuals and subcultural groups are now challenging the traditional stereotypes of gender and curiously investigating and modifying the boundaries of traditional gender roles. Furthermore, transvestites, transgenderists, and transsexuals are no longer objects of prohibitions. There has been no Danish legislation against transgender behavior since 1966. A few years ago, the Ministry of Health even eliminated transvestism from the official diagnostic code.

In 1930, the Danish painter, Einar Wegener (1882-1931) became the first person in the world to undergo a partial sex-change operation in Dresden, Germany. Wegener was a patient of the German sex researcher Magnus Hirschfeld (1868-1935), and soon after the operation, he changed his name to Lily Elbe. Unfortunately, Elbe died following a subsequent operation, and though the circumstances remain unclear, it is possible that her death was caused by surgical complications. The first transsexual surgery in Denmark took place in 1952 on the American photographer George Jorgensen (1927-1988). Jorgensen had Danish ancestors and came to the country for hormonal treatment and possibly to have a sex-change operation. After the operation, she took the name of Christine Jorgensen, and the sensational affair became known all over the world—providing Denmark with a highly exaggerated reputation as a “transsexual paradise” for years to come (Meyerowitz 2002). Jorgensen later described “the Danish connection” in her autobiography (Jorgensen 1967).

### B. Current Perspectives

At present, about five to ten individuals undergo sex-change surgery each year in Denmark. During recent decades, gender-conflicted persons tend to be ever younger when they confront authorities with their desire to change sex, often as young as 16- to 18-years-old. The number of females wanting to change sex is on the rise, and currently,

the male-to-female and female-to-male cases have almost equalized. Previously, the ratio was relatively constant at about three to one. As of early 2003, a total of about 200 individuals have undergone a legal sex-change operation in Denmark. Additionally, an unknown number of Danish transsexuals are operated in other countries, mostly Thailand, Belgium, or England—by personal choice or because they were not legally accepted for surgery by the Danish authorities (Sorensen 1982; Hertoft 1978; Sturup 1976).

No specific legislation for cross-gendered persons exists in Denmark. Access to sex-reassignment surgery is regulated by a law originally from 1929 concerning sterilization and castration (see Section 6A, Homoerotic, Homosexual, and Bisexual Behaviors, A Brief Historical View). This law warrants voluntary castration in cases of potential criminal behavior or a considerable amount of “social disparagement” or “mental suffering.” The person must be at least 21 years of age. By tradition, however, the age of 25 has been recommended before sex-change surgery can be permitted. Admittance to sex-change surgery requires clinical/psychiatric visitation during at least two years, often more. In almost all cases, this takes place at the Clinic of Sexology in Copenhagen, which is the national center for sexological research, counseling, treatment, and education.

On the whole, the visitation for sex-reassignment surgery follows the guidelines drawn by the Harry Benjamin International Gender Dysphoria Association. The applicant is counseled by a multidisciplinary professional team evaluating medical, psychological, and social issues. The object is to ascertain whether the person has a strong and persistent cross-gender identification and a persistent discomfort with his or her assigned sex. During the “real-life diagnostic test”—that is living as the opposite gender during at least one year—the person’s ability to adapt him- or herself to the new gender role is observed. After one year, hormonal therapy may be instituted. Some transsexuals only desire partial surgical correction and some female-to-male transsexuals just want mastectomy and hormonal treatment. The transsexual him- or herself applies to the Department of Civil Law (The Ministry of Justice) for permission to change sex. The Department of Civil Law then consults the Medical-Legal Council (a board of psychiatric experts) before deciding on the matter. If a person is rejected he or she can try again, but there is no board of appeal.

At present, sex-reassignment surgery can only take place at the University Hospital of Copenhagen (Rigshospitalet). All expenses are covered by the state. Prior to the operation, the person may change his or her first name to a gender-ambiguous one. Not until after the operation, however, can identity papers, passport, and civil registration number be altered. The person is now legally considered an individual of the newly assigned sex and shares (almost) the same rights as other Danish citizens. Thus, transsexuals can marry, but would hardly be allowed to adopt children.

There are various Danish organizations fighting for the civil rights of transsexuals, transgenderists, and transvestites—and a number of gender-conflicted persons are affiliated with the FPE-NE, the Danish branch of Phi Pi Epsilon. Transgender people, however, are still quite invisible in public spaces and, though not legally or socially stigmatized to any great extent, the whole area of cross-gendering is still somewhat ridiculed.

An often-debated issue is the legal situation of transgenderists and transsexuals who live as the opposite sex waiting for (or not desiring) a full sex-change operation. For many years, a legal sex change could not take place prior to surgical reassignment. However, in March 2003, it was permitted for people to change their sex-specific civil registra-

tion number, birth certificate, and so on, without (or before) surgical intervention. Moreover, it has been argued that sex-reassignment procedures should be further liberalized and surgical sex change made fully available for persons who are not psychotic or otherwise severely mentally disturbed. This, however, is still a matter of great medical and political controversy.

The medical, surgical, and psychosocial treatment of intersex people is not systematized in Denmark, but in many cases, the Department for Growth and Reproduction at the University Hospital of Copenhagen (Rigshospitalet) conducts the treatment and long-term follow-up of these patients. A nationwide study concerning the overall quality of life of intersex people was initiated at this department in 2001.

## 8. Significant Unconventional Sexual Behaviors

ELLIDS KRISTENSEN

### A. Coercive Sexual Behaviors

#### *Basic Statistics*

In Denmark, just under 3,000 cases of sexual crime are reported to the police every year, and in approximately one third of cases, legal proceedings are instituted. In 2001, a total of 912 charges were pressed: offenses against minors (including 38 cases of incest) 29%, offenses against decency (including exhibitionism) 49%, and rape 22%. Just over half of the charges (497) resulted in a conviction or other legal measures. Only eight charges were raised against women, emphasizing the well-known male predominance in sexual crimes. The charges against female perpetrators concerned incest and offenses against decency, and only two of these resulted in legal measures.

Because of both international and domestic focus on incest and pedophilia, public as well as governmental awareness of this problem has been raised considerably during recent years. Thus, in 2000, a center for treatment of sexually molested children was established at the University Hospital of Copenhagen (Rigshospitalet), and many Danish counties now have professional committees that can be consulted in suspected or factual cases of child sexual abuse. Additionally, many voluntary groups offer support to adolescents and adults who have been sexually abused recently or as juveniles.

#### *Child Sexual Abuse*

A study of child sexual abuse in the Copenhagen area was undertaken two decades ago (Merrick 1985), and two studies have recently been published (Strange 2002; Helweg-Larsen 2000). Moreover, Leth (1988) established that out of 2,000 demographically representative 18- to 50-year-old Danes, sexual abuse before the age of 18 was reported by 14% of females and 7% of males. More than one third of instances were reported to have taken place within the family. Also, the specific problems regarding child sexual abuse in Greenland have recently been evaluated (Curtis 2002). In 1998, a multi-center study of women sexually molested as children was launched at five psychiatric departments—400 women participated in this program and follow-up studies are still in progress as of early 2003.

Decriminalization of pornography in 1967 and 1969 also legalized child pornography, and not until 1980 was sale and propagation of this kind of material prohibited. In 1994, the possession of child pornography, too, was made illegal, and in 2002, additional types of drawings and computer-generated material were criminalized. The correlation between pornography and sex offenses has been studied for decades in a Danish context, and not least in the case

of rape and child abuse, results have indicated that availability of pornography might decrease the number of offenses actually committed (Kutchinsky 1991, 1989, 1973).

### *Rape and Sexual Harassment*

With a total of 202 criminal charges in 2001, rape is still a major problem. The difficulties of producing conclusive evidence in rape cases are illustrated by the fact that only one third of the charges result in a conviction. This is, however, an increase compared to 1975, where only 18% of charges resulted in an actual conviction (Helweg-Larsen 1985). In 2002, the maximum penalty for rape was increased to 12 years of imprisonment. Since 1999, a number of shelters for male and female rape victims have been established. These have led to an upgrading in the medicolegal and psychological management of rape victims. Victim-compensation laws give rape victims the right to compensation for damages in connection with the sexual assault. The frequency of unreported "acquaintance rape" is not known.

In recent years, a number of cases have been brought to court regarding sexual harassment, often conducted by trade unions on behalf of one of their members. Regularly, these cases catch the attention of the public, particularly if they involve politicians or other well-known persons. However, as no controlled studies of sexual harassment exist, it is difficult to estimate the true number of cases. Following the recommendations of the European Union, the Danish legislation was changed in 2002. Earlier, the alleged victim had to prove that sexual harassment had in fact taken place, but now he or she just has to make probable that sexual harassment has occurred, leaving it to the alleged offender to refute the accusation in order to be acquitted of the charge.

### *Treatment of Sexual Offenders*

In addition to normal punitive measures, the Penal Institution at Herstedvester (Copenhagen) for decades has been treating violent sex offenders. Between 1929 and 1970, surgical castration was used in a total of 1,000 cases (Sturup 1971, 1968), but since then, the predominant treatment of sexual offenders has been intensive psychotherapy. Since 1989, a subgroup of sex offenders (3 or 4 annually) has received additional treatment with anti-androgens (Hansen 1997; Ortmann 1980).

The Sexological Clinic in Copenhagen has offered psychiatric/sexological treatment to sexual offenders since its founding in 1986. In 1997, a nationwide visitation and treatment network was established by the Danish Parliament in order to extend the psychiatric/sexological treatment to all those who had been convicted for a sexual crime and were found suitable and motivated. About 100 sex offenders are treated every year. The treatment is based on collaboration between the Department of Justice, the Ministry of Social Affairs, psychiatric-forensic departments in Jutland and Funen, and the Sexological Clinic in Copenhagen (Kristensen 2000). A follow-up report concerning the first five years was in preparation in June 2003.

### **B. Prostitution**

See Sections 1B, Basic Sexological Premises, Basic Outlines of Sexual Behavior and Knowledge, 5B, Interpersonal Heterosexual Behaviors, Adults, and 6A, Homosexual, Homosexual, and Bisexual Behaviors, A Brief Historical View.

### **C. Pornography**

See Sections 1B, Basic Sexological Premises, Basic Outlines of Sexual Behavior and Knowledge, 5B, Interpersonal Heterosexual Behaviors, Adults, and 8, Significant Unconventional Sexual Behaviors.

### **D. Other Sexual Minorities**

CHRISTIAN GRAUGAARD

A Danish association for sadomasochists (SMil) was founded in 1979 and today, it has local branches in several Danish cities. SMil publishes a periodical, offers education and counseling, and hosts SM events of various kinds. Just like other sexual subcultures, sadomasochistic trends have been gradually mainstreamed through art, the media, and popular culture. Thus, public "fetish parties" have become quite popular in major cities during recent years, but it is unknown to what extent adult Danes engage in sadomasochistic behavior. However, it is suspected that mild forms of bondage are quite widespread, and a number of fetish shops have emerged in several Danish cities in recent decades.

Danish transsexuals and transvestites (see Section 7, Gender Diversity and Transgender Issues) are united in FPE-NE (the Danish branch of Phi Pi Epsilon), and associations for every conceivable sexual preference (such as infantilism, swinging, and all sorts of fetishism) abound. Because of the smallness of Denmark, however, these associations mostly have the form of private clubs, and only the Danish National Association of Gays and Lesbians—and to a lesser extent SMil—hold any genuine political and popular impact. A group of Danish pedophiles has launched Pædofilgruppen (Danish Pedophile Association), which hosts a website on the Internet ([www.danpedo.dk](http://www.danpedo.dk)). Though supposedly diminutive, the group has recently attracted vast public attention, and both political and non-political forces are currently trying to have it abolished.

See Section 5B, Interpersonal Heterosexual Behaviors, Adults, for other paraphilic behaviors.

## *9. Contraception, Abortion, and Population Planning*

HANNE RISØR

### **A. Contraception**

Generally, Danish people have good knowledge of contraceptives, and accessibility is satisfactory. The following contraceptives are readily available and commonly used: oral contraceptives (including progesterone-only pills), condoms, IUDs, hormone implant sticks, diaphragms, and oral postcoital contraceptives. High-quality condoms can be purchased at pharmacies, drugstores, supermarkets, gas stations, and from vending machines in many public toilets. In some bars and nightclubs, they are available for free, but normally one has to pay. Since July 2001, postcoital contraceptives ("emergency pills") are sold at pharmacies without a prescription. Subsequently, an increase in use has been detected and by early 2003, around 3,500 therapeutic doses were purchased every month.

No credible statistics exist regarding the use of contraceptives in Denmark, but from sales figures we know that around one third of fertile Danish women use oral contraceptives. Almost half of 20- to 24-year-olds use oral contraceptives. In a representative survey study among adolescents, more than two thirds of respondents used a condom at their coital debut, whereas 14% used contraceptive pills. Sadly, one quarter of youngsters did not use any kind of contraception at their first sexual intercourse—and 43% of sexually experienced boys deemed condoms unpleasant or difficult to use. Moreover, a quarter of sexually experienced girls had used emergency contraceptives at least once (Rasmussen 1999). IUDs and diaphragms are rarely employed by young women, and the general use of IUDs has been declining during recent years. Natural family planning methods are seldom used by youngsters.

If a woman wants personal (prescription) contraception, she must consult her general practitioner (Denmark has a GP for every 2,000 people) or go to a family planning clinic in one of the major cities. Counseling on contraceptive issues is an integrated part of the general health service, but contraceptive devices have to be paid for. Furthermore, Danes aged 25 or more can undergo a sterilization free of charge. Counseling, though, is mandatory prior to surgery. In 1999, 5,470 males and 5,370 females underwent sterilization (2 to 3 per 1,000 inhabitants).

Since 1966, youngsters who want medical counseling about contraceptives do not need the consent of their parents, and any GP can be approached anonymously and free of charge. In addition to obligatory sex education in schools, information about contraceptives are available through leaflets, women's magazines, telephone hotlines, and counseling on the Internet (Graugaard 1998). (See also the end of Section 5A, Interpersonal Heterosexual Behaviors, Adolescents.)

### **B/C. Abortion and Teenage Pregnancies**

The first bill legalizing abortion was passed by the Danish Parliament in 1939. This legalized abortion on tightly regulated medical or social grounds. A second bill was passed in 1971. This law allowed women over age 38 to have an abortion before the end of the 12th gestational week. Younger women who had more than four children under the age of 18, or presented serious medical or social issues, could also have an abortion before the end of the 12th gestational week. These rather restrictive laws forced many women to give birth to children that they could not manage, and for decades, a black market for illegal (and often hazardous) abortion flourished. It is estimated that some 18,000 illegal abortions were carried out annually during the 1950s.

On October 1, 1973, the Danish Parliament legalized abortion before the end of 12th gestational week. After this time, women can still obtain an abortion, but her application now has to be approved by a regional abortion council consisting of a gynecologist, a psychiatrist, and a lawyer. Dispensations are routinely given on medical, social, and psychological grounds. However, legal abortion after gestational week 20 to 22 is rarely approved. Only 2% to 3% of abortions take place after week 12. Adolescents below the age of 18 must have their parents' consent in order to apply for an abortion. Dispensations are sometimes given by the councils (usually on social grounds). All council decisions can be brought before a board of appeal.

Legal abortion must take place at a public hospital and is free of charge. A doctor can refuse to perform abortions on personal ethical grounds, but in practice this rarely happens. Medicinal (mefipristone or RU-486) abortions have been available at major hospitals for a couple of years and currently make up one third of all cases. Abortions are generally accepted and taken for granted, and a survey from 1995 established that 95% of 18- to 44-year-old Danes consider induced abortion before the end of the 12th gestational week a basic human right (Norup 1997). Religious groups regularly protest against the current legislation, but although a pro-life-inspired association exists (Retten til Liv [The Right to Life]), rabid abortion opponents are marginal and seldom heard of. Only one political party (the Christian Democrats, currently holding four of 179 seats in the Parliament) opposes legal abortion.

The number of abortions peaked in 1975 at 27,884, and since then, it has gradually decreased. In 2000, a total of 15,681 women had a legal abortion, a fifth of the total number of known pregnancies. The same year, 1,954 women between ages 15 and 19 had an abortion (abortion rate 14.3 compared to 12.5 in total). The relatively highest number of

abortions is seen among 20- to 24-year-olds (abortion rate 19.9), whereas the abortion rate is around 18 for women aged 25 to 34. The abortion rate is predictably higher among urban women.

The number of teenage pregnancies in Denmark is relatively low, supposedly because of sex education in schools, counseling measures, and availability of contraceptives. Very few pregnant teenage girls want to carry through with the pregnancy, so a majority of these choose to have an abortion. In 2000, 216 women between ages 15 and 19 gave birth to a child, while 1,954 had an abortion. Among sexually experienced teenage girls, around 7% reported to have had an induced abortion (Rasmussen 1999). This pattern is seemingly different among second-generation ethnic minorities, who typically have their first child at a slightly younger age.

### **D. Population and Family Planning**

During the "baby boom" of the 1960s and 1970s, the population increase in Denmark was around 40,000 per annum. In the 1980s, however, it was just a few thousand. Thus, from 1965 to 1985, the number of newborns went down from 85,796 to 53,749. In 2000, 67,081 live babies were born and the population growth was 18,593. In 1800, the population of Denmark was a little less than one million, while it is estimated that there will be 6.2 million Danes by year 2040.

Currently, Danish women have their first child at an average age of 27 years, and on the average, every woman has 1.73 children. In the postwar decades, it was common for women to have their first child between ages 23 and 25, or younger. The current marked postponement is mainly thought to be because of socioeconomic circumstances (better contraceptives, legal abortion, educational changes, and gender equality), but a possible deterioration of the fertility has also been speculated to be of importance (Jensen 2002). In most families, both parents work and the majority of Danish preschool children are in daycare institutions. Family planning is encouraged by free access to counseling on contraceptives, and both sterilization and legal abortion are free of charge. All families with children under the age of 18 receive a government paycheck four times a year.

The Danish Family Planning Association (Foreningen Sex & Samfund) was founded in 1956 by Dr. Agnete Braestrup (1909-1992), and today it conceives itself as a "watchdog" of sexual and reproductive rights in Denmark and abroad. The purpose of the association is to sustain and enhance sexual possibilities and well-being for individuals of all ages and backgrounds, and domestically, STDs, contraceptives, and sex education in schools are among its top priorities. The Danish Family Planning Association runs a telephone hotline and a website targeted at adolescents ([www.sexlinien.dk](http://www.sexlinien.dk)). Moreover, the association hosts a database on abortion and contraceptives ([www.abortnet.dk](http://www.abortnet.dk)), and a clinic offering anonymous and free counseling for Copenhageners. An educational service for school classes is also provided. Over the years, the association has published various information materials in different languages (i.e., Turkish and Arabic), in addition to books on sexual counseling and sex education. Since its foundation, the Danish FPA has been an active member of the International Planned Parenthood Federation (IPPF), and it currently conducts and supervises a number of projects in the developing world.

### **E. Sexual and Reproductive Health and Rights**

Denmark has officially participated in all United Nations' conferences on population and development since Teheran 1968. At the International Conference on Population and De-

velopment (ICPD) in Cairo in 1994, Denmark supported the Program of Action and sympathized strongly with the shift from traditional family planning to more comprehensive notions of sexual and reproductive health and rights. Traditionally, Denmark has been a major donor behind UNFPA and IPPF, and though recently struck by major domestic cutbacks, the governmental aid organization (DANIDA) funds extensive developing programs in the Third World. A number of these aim specifically at the empowerment of women. Unfortunately, there is much less focus on the followup of the ICPD's Program of Action today than in 1994. In general, HIV/AIDS has gotten a much higher priority than more-basic themes of sexual and reproductive health and rights. There is still a lot to do.

## 10. Sexually Transmitted Diseases and HIV/AIDS

CHRISTIAN GRAUGAARD

### A/B. Basic Figures

The incidence of classic sex diseases has been rapidly declining during the second part of the 20th century: Syphilis is hardly ever seen (51 cases in 2001), whereas the number of gonorrhea cases has decreased from over 10,000 in 1983 to just 309 in 2001. When it comes to chlamydia and venereal warts, however, numbers are considerably more worrisome: It is estimated that one fifth of sexually active adolescents are infected with HPV, and the number of diagnosed chlamydia cases has been on the rise for several years. The incidence of the latter was 283 per 100,000 in 2001, and out of 15,150 annually reported cases, two thirds concerned patients aged 15 to 24. It is estimated that 7% of sexually active youngsters currently have a chlamydial infection. (See also Section 5A, Interpersonal Heterosexual Behaviors, Adolescents.)

Like other European countries, Denmark was struck by the first AIDS cases in the early 1980s. Initially, an uncontrolled epidemic was feared, but although more extensive than in neighboring Sweden and Norway (Amundsen 2000), the spread of HIV has remained modest over the years. By June 2002, a total of 3,335 Danes had been diagnosed with HIV, and around 2,500 persons were then receiving treatment at one of five Danish HIV centers. Estimates show that the prevalence of HIV in the general population is 0.1% (0.03% among heterosexuals, 4.8% among homosexuals) (Smith 2003). In 2000, the overall incidence of HIV was 4.8 per 100,000 and in 2001, a total of 304 persons (213 males, 91 females) were diagnosed with HIV. Half of the newly diagnosed were aged 29 to 39, and nearly half resided in the greater Copenhagen area. In 2000, the annual HIV incidence here was 15.5 per 100,000, while it was below 5 per 100,000 in most rural areas. One third of the infected persons were men having sex with men, whereas almost half were infected heterosexually. The remainder caught the disease through intravenous drug abuse, blood transfusion, or from an infected mother. Slightly more than one third of newly infected persons were emigrants (especially from Eastern and Central Africa). One third of heterosexually infected persons contracted the disease abroad. The number of infected persons below the age of 25 has been declining between 1990 and 1999. In 2001, the median age at diagnosis was 37 and 29 for males and females, respectively.

In 1874, it became legally mandatory for venereal patients to seek medical treatment, and throughout the 20th century more or less restrictive laws sought to regulate the behavior and civil rights of persons infected with STDs. In 1988, however, the legislation on STD was completely abolished and Denmark became the only country in the

world to base examination, treatment, and partner notification entirely on mutual trust between patient and doctor. Thus, full anonymity exists regarding STD and HIV/AIDS, the rationality of which is intermittently debated. Following a vivid public discussion, the Parliament in 1994 made it punishable for "known" HIV-positives to deliberately have unprotected sex.

HIV testing in Denmark is anonymous and free of charge and can be performed either by the family physician or at a public Venereal Clinic. In 2000, a total of 134,116 tests were performed. A central surveillance system exists for both STDs and HIV/AIDS, but registration is strictly anonymous (Smith 2003). Since the mid-1980s, several HIV campaigns have been launched by the central health authorities, and contrary to some European countries, it has been paramount to avoid the fear factor in favor of relaxed and matter-of-factly information—not emphasizing sexual abstinence, but focusing on thoughtfulness and the joys of "safe sex" (Wielandt 1993).

[Update 2002: UNAIDS Epidemiological Assessment: By the end of 2001, the cumulative total of 3,255 known cases of HIV infection was reported. An anonymous HIV case-reporting system was implemented in August 1990. Data collection includes information on risk behavior, previous testing and results, and on nationality. The number of HIV tests conducted are reported monthly. No routine screening programs exist except for blood donors. The annual number of voluntary tests done is around 130,000 (2.5% of population) and cross-sectional studies have shown that the rate of retesting is relatively high and increasing. The number of persons below 30 years of age seeking testing is high as well.

[All data indicate that HIV-incidence has been stable for many years, with an overall annual incidence of around 230 (4.3 per 100,000), 2.2 per 100,000 among men who have sex with men, 180 per 100,000 among injection drug users, and 2 per 100,000 among heterosexuals. However, because of the decreasing AIDS-morbidity and -mortality resulting from HAART, the number of people living with HIV is increasing, and reached the highest number ever by the end of 2001, with an estimate of 15 per 100,000 population. The infectious burden in Danish society is estimated to be increasing, although the annual HIV incidence is unknown and very difficult to estimate with the existing surveillance tools.

[Cross-sectional studies on knowledge, attitude, and behavior among men who have sex with men have been conducted since 2000. The first results indicate that many of them were still practicing unsafe sex that may expose them to HIV. Such results may have great implications for prevention work.

[Incidence of syphilis has been fairly low for many years, while the incidence of gonorrhea has decreased since the mid-1980s. But there was a slight increase in the last few years, mainly among men. The annual incidence of chlamydia has not changed in recent years and is still relatively high; it is highest among young women age 20-24, with an annual incidence of around 2.2%.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	3,800 (rate: 0.2%)
Women ages 15-49:	770
Children ages 0-15:	< 100

[An estimated less than 100 adults and children died of AIDS during 2001.

[No estimate is available for the number of Danish children who had lost one or both parents to AIDS and were under age 15 at the end of 2001. (End of update by the Editors)]

### C. Sex Education and Legal Measures

Over the years, mandatory sex education in elementary schools has been tentatively expanded and improved, and surveys among Danish adolescents have continuously revealed a general high level of knowledge and an overall satisfaction with AIDS-education in schools (Rasmussen 1999; Krasnik 1990). However, around one fourth of youngsters still have sex the first time without using any contraception (see Section 5A, Interpersonal Heterosexual Behaviors, Adolescents). A state-funded AIDS hotline was launched in 1986, and in 2002, it received more than 9,000 calls. At the Adolescent Sexuality Hot-Line (run by the Danish Family Planning Association), around 12% of callers inquired on STD and HIV/AIDS related issues.

As in other countries, several organizations and services are specifically targeted at HIV-positive persons. These are increasing in number because of recent advances in antiviral treatment (and subsequent survival). Thus, in 1995, 43 per million inhabitants died of AIDS, compared with just 5 per million in 1998. The World AIDS Day (December 1) is solemnized in major Danish cities, but contrary to the USA, no Act Up movement exists.

## 11. Sexual Dysfunctions, Counseling, and Therapies

GERD WINTHER

### A. Availability of Sexological Counseling

Despite the fact that Scandinavia is often considered to be among the most sexually liberated countries in the world (Graugaard 1997; Rasmussen 1996; Westrup 1993), a fair share of Danes will experience sexual problems of some kind during their lifetime. Unfortunately, only few valid studies have been carried out concerning sexual problems, but some useful cohort studies exist (see Section 5, Interpersonal Heterosexual Behaviors). In these studies, the prevalence of self-assessed sexual problems in various age cohorts was reported to be between 5% and 22%, and one might suspect the frequency of unreported sexual troubles to be substantial.

Since the inter-war period, the Danish Parliament has discussed the possibility of creating public sexological clinics, but it took almost 50 years before the first one was established in 1986 at the University Hospital of Copenhagen (Rigshospitalet) (Hertoft 1991; Spanager 1987). As yet, this is the only clinic of its kind, although it was originally intended that similar clinics should be opened in the cities of Odense and Aarhus. A few other hospitals in Denmark provide minor sexological services free of charge. To some degree, general practitioners offer free psychological counseling to their patients, but only a slight minority of Danish GPs have any formal sexological training. Counseling on STDs and contraceptive issues, however, is almost completely carried out by the family physician. Furthermore, a range of private or semi-private initiatives exist: A nationwide telephone hotline and a counseling clinic are being run by the Danish Family Planning Association, and various sexual subcultures (i.e., homosexuals and sadomasochists) offer free and anonymous counseling, personally or by phone or the Internet. The availability of sexological treatment is considerably better in the metropolitan areas of Copenhagen, Odense, and Aarhus than in more-rural districts of Denmark.

As of early 2003, around 200 Danish sexologists are unionized in the Danish Association for Clinical Sexology (DACS), which offers a multidisciplinary environment for doctors, nurses, psychologists, social workers, midwives, physiotherapists, and occupational therapists. Some members are in private practice, while others work part-time

with clinical, theoretical, and/or didactic sexology. DACS was founded in 1981 at a Copenhagen meeting of the Nordic Association for Clinical Sexology (NACS) (Jensen 1994). More than 400 people have been members of DACS since its foundation. The aims of DACS are to make sexological services more readily available in Denmark, to train professionals, and to provide them with a competent sexological forum through postgraduate courses and seminars, a scientific journal, and annual Nordic meetings (besides Denmark, NACS currently consists of Sweden, Norway, Finland, Iceland, and Estonia, a recent new member).

### B. Views on Sexual Dysfunction

The Danish healthcare system uses the WHO's ICD diagnosis system, but in the middle of the 1970s, when Dr. Preben Hertoft's team began treating people with sexual dysfunctions at the University Hospital of Copenhagen, a supplementary diagnostic system was developed, inspired by Helen Singer Kaplan's and Masters & Johnson's theoretical framework and diagnostic taxonomy (Winther 1990; 1982; Møhl 1988). During the 1970s, the most common sexual problems were female orgasmic dysfunction (61%) and male erectile difficulties (73%) (Spanager 1987; Winther 1982). Throughout the 1980s and 1990s, the situation gradually changed, and a growing number of patients of both sexes now presented various desire problems. A much lower percentage (about 20%) was now women with orgasmic problems, while the percentage of men with erectile dysfunction remained about the same. Cases of premature ejaculation, on the other hand, were far fewer than in the 1970s, and today many of those treated for this problem are born outside of Denmark (Faber 1991). The spectrum of diagnoses and therapeutic procedures outside the Sexological Clinic is unknown. (See also the end of Sections 5B, Interpersonal Heterosexual Behaviors, Adults, and 5C, Interpersonal Heterosexual Behaviors, Sexual Attitudes and Behavior of Elderly Danes.)

Since the early days of modern Danish clinical sexology, the main therapeutic approach has been psychodynamic, especially inspired by the concepts and procedures of Helen Kaplan, supplemented by behavioral instructions *ad modum* Masters and Johnson. Treatments are preferably based on holistic biopsychosocial principles. From the very beginning of sexual dysfunction treatment in couples, marital dynamics have been an integral part of therapy and counseling. The Danish language has a word for the integration of marital and sex therapy, namely *samlivsterapi* ("cohabitation therapy"), which indicates that the total life situation of the couple is focused upon, rather than just their sexuality. Outside the academic world, private "sexological" services of every kind abound—from Tantric techniques to body-centered therapy. Moreover, a few urologists specialize in erectile dysfunction. Just one or two plastic surgeons offer penile augmentation surgery, thus genital reconstruction treatment is scarce and generally frowned upon by professionals.

### C. Sexological Training and Certification

Since 1972, voluntary sexological courses for medical students have been provided at the University of Copenhagen—originally lasting for one week, but later divided in two separate courses (Hertoft 1992; Wagner 1976). Until 1995, the medical school at the University of Aarhus (Jutland) also offered voluntary courses, while the medical school at the University of Odense (Funen) has had a mandatory sexology course since the late 1980s. Preben Hertoft wrote the first Danish textbook of clinical sexology in 1976 (third edition 1987), and this is still widely used. Sexology

is a voluntary elective part of the training to become a general practitioner.

Starting in the late 1960s, psychology students at the University of Copenhagen had access to sexological lectures by Inge and Sten Hegeler (Hegeler 1963), and voluntary courses of basic sexology are still a part of the curricula at the Faculty of Psychology in Copenhagen. Furthermore, several institutions of higher education offer intermittent sexological courses, though a certain decline has sadly been detected over the past ten years. Educators and social workers dealing with disabled or mentally handicapped people typically have to pay for sexological training themselves. However, voluntary postgraduate training is sometimes offered free of charge by various Danish counties (Buttenschon 1994).

DACS has provided postgraduate therapy and counseling courses since 1982. Around 250 postgraduate students have completed such courses as of early 2003. In 2001, NACS passed a joint agreement on common rules for certification in clinical sexology and in sexual counseling (Fugl-Meyer 2001). Since then, DACS has launched a three-step postgraduate education (Basic Sexology, Clinical Sexology I, and Clinical Sexology II), which meets the inter-Nordic demands and is equivalent to two years of full-time university studies. Before achieving authorization in Clinical Sexology, students have to go through a formal psychotherapeutic education. A specialist board under DACS assesses all applications for authorization, and these later must be confirmed by a similar board under NACS. Finally, the student is authorized as Specialist in Sexological Counseling or Specialist in Clinical Sexology.

## 12. Sex Research and Advanced Professional Education

LENE FALGAARD EPLOV, ANNAMARIA GIRALDI,  
and CHRISTIAN GRAUGAARD

### A. Epidemiological Sex Research

Epidemiological sex research in Denmark is scarce despite the fact that conditions for exactly this kind of research are optimal: Every Dane is assigned a 10-digit civil registration number that follows the person lifelong, making register studies and prospective designs highly favorable. Furthermore, the population is small and homogeneous, and national registers of all sorts virtually abound.

Although the amount of epidemiological sex research in Denmark is not impressive, it all started out quite well. When Alfred C. Kinsey made his revolutionary research in the United States, the Danish psychiatrist Kirsten Auken (1953) interviewed 315 young Danish women about their sexual lives. Subsequently, Preben Hertoft (1968) studied the sexual lives of young Danish men. Inspired by the methodology of Shere Hite, Temte (1984, 1983) published two surveys in the early 1980s based on questionnaires distributed by a "word of mouth method." Although historically interesting, these studies do not meet strict epidemiological standards.

Moreover, a long Danish tradition exists as to the sexual attitudes and behavior of adolescents (see Section 5A, Interpersonal Heterosexual Behaviors, Adolescents), and this is naturally reflected in research. A few studies are especially worth mentioning:

- Three representative studies among pupils in 9th grade in a municipality in Jutland (Boelskifte 2002ab; Rasmussen 1994, 1987).
- A study among all pupils in the 8th, 9th, and 10th grades, in high schools, and similar youth education settings in Copenhagen (Rasmussen 1991).

- A nationwide study among adolescents (Rasmussen 1999).
- Two nationwide studies concerning risk behavior in relation to HIV/AIDS (Melbye 1992; Schmidt 1989ab).
- A longitudinal cohort study (The Glostrup Population Study) among adult Danes living in suburban Copenhagen (Eplov 2002abc; Fog 1994; Lendorf 1994; Solstad 1993ab; Garde 1980).

To picture the full scope of sexological epidemiological research in Denmark, a comprehensive review was conducted in 2002 (Eplov 2002c). Altogether, it was possible to identify 49 population studies, 34 of which were found to be representative. Among these, 14 had adolescents as a target group, and in six studies, the aim was to examine sexual behavior of people under the age of 30. Only 10 out of the 34 studies were nationwide, and out of these, six dealt with adolescents. Out of the remaining four studies, three examined risk behavior in relation to AIDS, one study only included men and one study studied mixed Danish/Swedish material. The last study only included five questions about sex.

In sum, it must be emphasized that additional epidemiological sexological research is needed in order to obtain a thorough picture of the sexual lifestyles of Danes. Thus, a comprehensive, representative population survey covering issues of sexual desire, activity, behavior, dysfunctions, and satisfaction is still lacking.

### B. Biomedical Sex Research

In Denmark, a long research tradition exists on reproductive physiology, andrology, urology, and sexology. In the area of male and female genital physiology, one of the pioneers is Dr. Gorm Wagner, who for decades was affiliated with the University of Copenhagen. In females, Wagner's research has focused on vaginal function and the changes during orgasm. This work was carried out in collaboration with Roy Levin from Great Britain. Wagner and Levin developed new methods to measure vaginal blood flow and lubrication, and in numerous articles they have described the mechanism underlying vaginal lubrication (Levin 1985; Wagner 1978). Their work has added tremendous insight into the physiological function of the vagina. In collaboration with a Danish gynecologist, Bent Ottesen, the research was expanded to cover the effect of various hormones, especially Vasoactive Intestinal Polypeptide (VIP) and its possible sexual role and distribution along the genital tract (Ottesen 1987, 1983).

Wagner has also been a pioneer in the area of male sexual function, especially erectile function and dysfunction. He has developed new methods to evaluate erectile function, in addition to research on various aspects of penile surgery and pharmacological agents. Much of this work was done in collaboration with several other prominent Danish researchers, i.e., Thomas Gerstenberg, Anders Uhrenholdt, Jorgen Ebbehøj, Peter Metz, and Giles Brindley from the UK. Over the years, the work done by these researchers has added tremendously to the understanding of erectile mechanisms (Wagner 1989, 1981; Ebbehøj 1985, 1974; Metz 1983). Gorm Wagner was one of the founders of the International Society of Impotence Research (ISIR) and the *Journal of Impotence Research*.

In the field of andrology and reproductive medicine, Niels E. Skakkebaek at the University Hospital of Copenhagen (Rigshospitalet) is one of the leading scientists. His department works in several areas, but especially the investigation of prenatal environmental exposures in testicular cancer and semen quality has attracted international attention during recent years. Skakkebaek's team has shown a low and decreasing sperm quality in Danish men (Auger

2001; Andersen 2000) and linked this to the recent decline in fertility rates in the industrialized world (Jensen 2002).

Fin Biering-Sorensen and Jens Sonksen have done extensive work on men with spinal cord injury, describing their sexual function and developing new methods to treat their erectile and ejaculatory dysfunction. The latter is of great importance in order to prevent infertility in this group of often younger men (Biering-Sorensen 2001).

Finally, an important research area in Denmark is the treatment of torture victims suffering from post-traumatic somatic and psychosexual problems (Lunde 1990; Larsen 1987). ETICA (Treatment Centre for Traumatized Refugees, Migrants, and Danes) offers treatment to torture victims and also participates in education, counseling, supervision, and research. One of their priorities is research on sexual torture.

### C. Humanistic Sex Research

As elsewhere in Europe, scientific sex studies were originally dominated by a biological discourse, and during the inter-war period, Danish investigators were among the pioneers of sex hormonal research (see Section 6A, Homosexual, Homosexual, and Bisexual Behaviors, A Brief Historical View). In the post-Kinsey years, however, new perspectives on sexual behavior and interactions gradually came about, and in 1953, Kirsten Auken published an important thesis on the sexual lives of female adolescents (Auken 1953). Auken was openly inspired by Alfred Kinsey's reports and met with her acclaimed American colleague during his roundtrip of Scandinavia in 1955. Until her premature death in 1968, Auken maintained a sociological/humanistic angle towards sex research issues, and a number of her younger protégés published significant sexological work in the years following her dissertation. Not least, Preben Hertoft (1968) published a doctoral thesis on the sexuality of adolescent Danish men.

In the early 1970s, new approaches to body, sexuality, gender, and sexology emerged and, stimulated by (post) feminist and Foucaultian thinking, numerous constructionist studies of variable form and quality have occurred. Among the prominent sex researchers in the field of sociology and human science are the late criminologist Berl Kutchinsky (the societal effects of pornography), folklorist Karin Lützen (lesbian studies), historian Wilhelm von Rosen (gay studies), historian Bente Rosenbeck (female studies), historian Hans Bonde (male studies), historian Morten Thing (history of pornography), and art historian Rune Gade (aesthetics of pornography). Foremost, sociologist Henning Bech has published extensively on masculinity and male homosexuality (Bech 1999ab, 1998ab, 1997). During recent years, several queer-study-oriented scholars have emerged, and literary historian Dag Heede (2001) has launched an ambitious "queering" of the Danish literary canon—from Hans Christian Andersen to Isak Dinesen (Karen Blixen), from Nobel Prize-winning Johannes V. Jensen to contemporary Klaus Rifbjerg.

### D. Sexological Organizations

Denmark has a good number of special-interest sexological organizations. Four of the more important ones are:

Danish Association for Clinical Sexology (DACS), Gronhojgaardsvej 147, DK-2630 Taastrup, Denmark; tel./fax: 45/43 99 66 19; email: dacs@klinisksexologi.dk; www.klinisksexologi.dk.

The Danish Family Planning Association, Skindergade 28, DK-1159, Copenhagen K, Denmark; tel.: 45/33 93 10 10; fax: 45/33 93 10 09; email: danish-fpa@sexogsamfund.dk; www.sexogsamfund.dk.

Danish National Association of Gays and Lesbians, Teglgardsstraede 13, DK-1007 Copenhagen K, Denmark; tel.: 45/33 13 19 48; email: lbl@lbl.dk; www.lbl.dk.

SMil (sodomasochists), P.B. 691, DK-2200 Copenhagen N, Denmark; tel.: 45/35 83 55 69; email: info.kbh@sado.dk; www.sado.dk.

## Demographics and a Brief Historical Perspective

ROBERT T. FRANCOEUR

### A. Demographics

Egypt is located in the northeastern corner of Africa and the Sinai, a small Asian peninsula between the Middle East and northern Africa. Egypt's borders include a coastline of 1,523 miles (2,450 km) facing the Mediterranean Sea on the north and the Red Sea on the east. Israel is on the northeast border of Egypt's Sinai Peninsula, between the Mediterranean and Red Seas. On the south is Sudan and on the west Libya. Egypt's 386,660 square miles (1,001,450 km<sup>2</sup>) make it about one and a half times the size of the state of Texas. Almost all of Egypt is arid, desolate, and barren, with hills and mountains in the east and along the Nile River. The Nile River and its fertile valley, where most Egyptians live, stretches 550 miles from the eastern Mediterranean Sea south into the Sudan. Three percent of the land is arable and 2% is devoted to permanent crops; 2% of the land is irrigated.

In July 2002, Egypt had an estimated population of 70.71 million. (All data following are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 33.96% with 1.04 male(s) per female (sex ratio); 15-64 years: 62.18% with 1.02 male(s) per female; 65 years and over: 3.86% with 0.84 male(s) per female; *Total population sex ratio:* 1.02 male(s) to 1 female

**Life Expectancy at Birth** (1999): *Total Population:* 64.05 years; *male:* 61.96 years; *female:* 66.24 years

**Urban/Rural Distribution:** 45% to 55%; Cairo: 9.7 million; Alexandria (El-Iskandriyah): 3.6 million (1999)

\**Communications:* Bahira Sherif, Ph.D., Department of Individual and Family Studies, University of Delaware, Newark, DE 19716-3301 USA; Bahira.Sherif@mvs.udel.edu. Hussein Ghanem, M.D., Professor of Andrology, Sexology, and STDs, Cairo University; hmghanem@hotmail.com.

(CIA 2002)

**Ethnic Distribution:** Eastern Hamitic stock (Egyptians, Bedouins, and Berbers): 99%; Greek, Nubian, Armenian, and European (Italian and French): 1%

**Religious Distribution:** Official government statistics cite Muslim (mostly Sunni): 94%; and Coptic Christian and other: 6%. However, several outside authorities claim the Coptic Christian population is actually 15% to 20%.

**Birth Rate:** 24.41 births per 1,000 population

**Death Rate:** 7.58 per 1,000 population

**Infant Mortality Rate:** 58.6 deaths per 1,000 live births  
**Net Migration Rate:** -0.24 migrant(s) per 1,000 population

**Total Fertility Rate:** 2.99 children born per woman

**Population Growth Rate:** 1.66%

**HIV/AIDS** (1999 est.): *Adult prevalence:* 0.02%; *Persons living with HIV/AIDS:* NA; *Deaths:* NA (For additional details from www.UNAIDS.org, see end of Section 10B.)

**Literacy Rate** (defined as those age 15 and over who can read and write): 51.4% (*male:* 63.6%, *female:* 38.8%) (1995 est.); *attendance for nine years of compulsory school:* 95% (education is free and compulsory from age 6 to 13)

**Per Capita Gross Domestic Product** (*purchasing power parity*): \$3,700; *Inflation:* 2.3%; *Unemployment:* 12%; *Living below the poverty line:* 22.9% (2001 est.)

### B. A Brief Historical Perspective

Civilization and urban life were born around 5000 B.C.E. in the fertile valleys of the Nile, Indus, and Tigris/Euphrates Rivers. About 3200 B.C.E., King Menes established the first of many dynasties of pharaohs who gradually unified the country from the Nile Delta to Upper Egypt. The pharaohs produced a distinctive ancient civilization of great wealth and cultural brilliance, built on an economic base of serfdom, fertile soil, and annual flooding of the Nile Valley. The decline of ancient imperial power facilitated the conquest of Egypt by Asian invaders, the Hyksos and Assyrians. The last pharaonic dynasty was overthrown by the Persians in 341 B.C.E. Alexandrian and Ptolemaic Greek dynasties then replaced the Persians, who were in turn replaced by the Roman Empire. Egypt was part of the Byzantine Empire from the 3rd to the 7th centuries of the Common Era, when it was conquered by Arab invaders who introduced the Muslim reli-

gion and Arabic language. (The ancient Egyptian language is still used in the Christian Coptic liturgy.) Around 1250, the Mameluke dynasty, a military caste of Caucasian origin, replaced Arab control. In 1517, the Turks defeated the Mamelukes, and Egypt became part of the Ottoman Empire.

In 1798, Napoleon's armies invaded Egypt and occupied Cairo. His effort to block British trade routes to India and establish a francophone society was ultimately unsuccessful. Nevertheless, Napoleon's invasion had profound repercussions for the Arab and Muslim world, which continue to affect the region's political and social development. This was the first European conquest of a major Arab country in the history of Islam, and it signaled the rapid decline of Islam as a world political power. Some analysts even trace contemporary Muslim fundamentalism to this initial shattering defeat.

The French occupation, defeat, and withdrawal destabilized Egypt and left it vulnerable to an internal political struggle that was won by Mohammed Ali, an Albanian lieutenant in the Ottoman army, who set about modernizing the economic and educational structure of Egypt. However, the expansion ultimately put Egypt heavily into debt, and, at the end of the American Civil War with the resumption of American cotton production, initiated a major recession in Egypt's cotton industry. As a result of the economic crisis, the British began to assume greater control over the country.

The Suez Canal, built by a French corporation from 1859 to 1869, was taken over by the British in 1875. After the British Empire expanded into East Africa and the Sudan, the British established their *de facto* rule in 1882, although Egypt remained a nominal part of the Ottoman Empire until 1914. Egypt became a British protectorate in 1914 and a League of Nations Mandate in 1922. The autonomy of the Egyptian monarchy was strengthened in the Anglo-Egyptian treaty in 1936, although Great Britain continued its military presence in Egypt and its control of the Sudan.

After the heavy fighting of World War II, a growing nationalist movement led Egypt to abrogate the 1936 treaty in 1951. A military uprising the following year forced King Farouk to abdicate. Farouk was succeeded by Gamal Abdel Nasser when Egypt declared itself a republic. British troops were withdrawn from the Suez Canal Zone in June 1956, and the following month, Egypt nationalized the Canal. At the end of October, Israel invaded the Sinai Peninsula, and French and British forces came to Israel's aid. United Nations intervention maintained the peace between 1957 and 1967. Egyptian incursions into the Gaza Strip in June 1967 led to a full-scale war with Israel that continued through 1970, when Nasser died and was succeeded by Anwar Sadat. In October 1973, Egyptian forces crossed the Suez Canal and attacked Israeli positions. Eighteen days later, the Yom Kippur War ended in a ceasefire. Meanwhile, Soviet influence had risen with Russian contributions to the Aswan High Dam, and then waned. In 1974, Sadat's government became increasingly friendly to Western and American investment, and relationships between Egypt and Israel improved.

Sadat's economic "Open Door Policy" encouraged, in particular, the private sector to increase the productive capacity of the economy. However, as the government withdrew its commitment to guaranteed employment for all college graduates, unemployment increased. Women, in particular, were affected by this policy. While there had been an increasing expectation in the 1960s that women would increasingly enter the labor force, the Open Door Policy surprisingly worked against this expectation. The national dialogue about women's work started to shift, and the definition of women as primarily playing a role in the domestic arena gained ground. Justifying ideologies based on sexual divi-

sion of roles began to appear, supported by the newly emerging Islamic fundamentalist groups, which advocated that a woman's place was in the home (el-Baz 1997, 149). Further, a provision was added to Article Eleven of the 1971 Constitution, which declared the state's commitment to help reconciling women's family obligations and their equality to men in the public sphere, "provided that this did not infringe on the rules of the Islamic *shari'a* [the "Way" of Islam, including the law and governance]." The new Constitution represented an important divergence from the secular discourse of the 1960s and created opportunities for Islamic groups to oppose women's rights on the grounds that they were in opposition to Islamic principles (Hatem 1992, 241).

Throughout the 1980s, the Open Door Policy became increasingly institutionalized, eventually leading to the current economic Reform Policy. While this policy has been relatively successful on a macro level, it has had negative consequences for the more vulnerable sectors of society, namely the poor, and specifically, poor women and their children (el-Baz 1997, 149). As key resources, such as healthcare and education, have become scarcer, it has been lower-class women and children who have become least likely to have access to them. Also, affected by the economic restructuring have been individuals who would previously have been classified as middle class, namely civil servants and unemployed graduates.

While the pressures and tensions of a rapidly changing world in the last half of the 20th century have affected all the nations and peoples of the world, these tensions have been more obvious in the Islamic nations of the Middle East and southeast Asia. In particular, the growing Islamic fundamentalist movement symbolizes the tensions and conflicts between Western and indigenous traditions and beliefs. Further, in Egypt, this movement has centered much of its rhetoric around the "appropriate" roles for women in society. Gender issues thus constitute a principal mechanism for understanding issues of marriage and sexuality.

### 1. Basic Sexological Premises

According to Egyptian societal norms, sexuality and the ensuing children are part of marriage and creating a family, and do not, therefore, belong in any other sphere of life. With this ideology in mind, contemporary fundamentalists often point to the West and the "loose morality between the sexes" in order to legitimize their arguments about sexuality and gender roles. The essence of their arguments is that women should not work outside of the home and should instead take care of their husbands and children. The family structure emerges as all-important for maintaining a well-ordered society, practical morality, and channeling sexuality. As will be seen, gender roles, and in particular woman's role at the center of the family, thus acquire social importance and political relevance.

### 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

#### A. The Issue of Gender

Egyptian society is organized on the principle that men and women simply have different natures, talents, and inherent tendencies. This becomes most apparent in the realm of the family, where each gender has a different role to play. Men are created for going out in the world and are responsible for providing financially for the family. Women are suited for remaining within family boundaries, caring for the home, the children, and the husband. Further, women's inherent sexuality is believed to be constantly endangering the social harmony of society (specifically, men) and is, there-

fore, best controlled through women's modesty and women remaining as much as possible within the private sphere of family. This belief is reinforced through cultural and religious norms that increasingly advocate that family roles of both women and men are fundamental in maintaining societal structure. The dominant gender constructions therefore support keeping women in the home and oppose women working and abandoning their primary roles (Macleod 1991, 85). Nonetheless, contemporary images of women as economic assets and providers are rapidly coming into conflict with what are perceived as divinely inspired roles.

Gender roles in Egypt derive much of their legitimacy from the Qur'an. In particular, women are often the focus of quotes that supposedly refer to the appropriate roles and behaviors of women. References to the role of women are widely scattered throughout the Qur'an. Some passages focus on women's unique nature, some on women's place in society, and some on women's role within the general congregation of believers. As Fernea and Bezirgan (1977, 13) emphasize, even though the Qur'an is the central source of Islamic belief, there is considerable controversy about the meaning of each of these passages and their implications for the status of women. Consider the verse:

O mankind! Be careful of your duty to your Lord Who created you from a single soul and from it created its mate and from them twain hath spread abroad a multitude of men and women. Be careful of your duty toward Allah in Whom ye claim [your rights] of one another. (Qur'an 4, 1)

This verse is used by some interpreters as evidence that women are considered equal within Islamic doctrine. Others, however, point to the following verse:

Men are in charge of women, because Allah hath made the one of them to excel the other, and because they spend of their property [to support women]. So good women are the obedient. (Qur'an 4, 3, 4)

They cite this as evidence that women can never achieve equality within Islam (Fernea & Bezirgan 1977, 18). Selectively choosing Qur'anic verses can either undermine or support dialogues concerning the proper role of women.

Verses from the Qur'an, the *Hadith* (traditions about Mohammed, second only to the Qur'an in authority), and theological arguments about their relevance, are often used as empirical data for sociological explanations of a gender hierarchy in which women are subordinate to men (Mernissi 1987; Marcus 1992). Notwithstanding the powerful assertion that Muslim men and women utilize these sources as part of their hegemonic beliefs, contemporary scholarship has shown that, rather than determining attitudes about women, parts of the Qur'an are only used at certain times or occasions in order to legitimate particular acts or sets of conditions that concern women. The Qur'an is part of the way in which the gender hierarchy and sexuality are negotiated and enforced. It does not provide an explanation of gender roles; instead, it is part of a constant process of gender-role negotiation. While central to Islam, the Qur'an is neither the only nor the most important part of the beliefs and practices that influence the daily life of Muslim women and men. Differences between men and women are readily apparent in several aspects of Islamic law, which accords certain rights and capacities to both men and women. A Muslim's legal capacity (*ahliyyat*) begins at birth and ends with death. Legal responsibilities are assumed under one's legal capacity and are distinguished as a "capacity of execution" and a "capacity of obligations." A free Muslim man who is sane and considered an adult has the highest degree of legal capacity. A Muslim woman, even though she has certain rights, generally has

half the legal capacity of a man. This difference only becomes apparent when men and women reach adulthood.

According to the Islamic legal point of view, an adult is a:

legally and morally responsible person, one who has reached physical maturity, is of sound mind, may enter into contracts, dispose of property, and be subject to criminal law. Above all, he is responsible for the religious commands and obligations of Islam. (Lapidus 1976, 93)

When a Muslim man reaches maturity, his legal capacity becomes complete; neither his age nor marital status influences his legal rights, responsibilities, or capacity of execution.

A Muslim woman's legal identity also begins at birth, but in contrast to men, her legal capacity and status undergo various changes throughout her lifecycle. For a woman, her legal coming of age and her achievement of physical maturity do not necessarily coincide. She is a ward of her father or guardian as a child and, as an adult, is restricted in legal decision-making. Her legal persona and social status depend on the state of her sexuality, whether she is a virgin, married, divorced, or widowed. There is, of course, variation in different Islamic societies as to the perception of the different stages of femaleness. At different times in a woman's life she is treated differently both by the law and by the society. Societally and legally, the young woman (*shabba*) is the focus of a great deal of protection, and her freedom of movement is limited. In contrast, an old woman (*aguza*) is able to move with much greater ease, and may also move in places and participate in situations where the young woman is forbidden even to enter. It is, therefore, very important to emphasize the fundamental difference between the stability of mature men's status under the law versus the changing nature of women's status. This legal difference pervades and shapes the lives of women all over the Islamic world.

Existing side by side, and sometimes in contradiction to the reality of women's daily struggles in Egypt, is the cultural religious ideal of complementarity between the sexes. Within this concept, women are not devalued as persons, or somehow considered to be inherently lesser in value than men, or thought to be lacking in abilities. Instead, Egyptian women tend to emphasize that everyone—man, woman, or child—is thought to be part of an interrelated community, and that gender complementarity is part of the message of the Qur'an and *Hadith*. Even though men overwhelmingly act as the public spokespeople for Islam, as *ulama* (teachers and scholars of Islam), or as *sheikhs* (spiritual leaders), women tend to categorically emphasize that they are just as capable of spreading the word of Islam as men.

While women are clearly not always as much in the spotlight as men, they perform their duties in other ways. Women are valued as the first teachers of their children in the ways of Islam, both through their instruction and also by their example in daily life, which extends beyond the home. There are also many examples of women in Islamic history, beginning with the wives of the Prophet Muhammad and in folk Islam, who have become spiritual leaders in their communities (Ahmed 1992).

While both Muslim men and women are expected to be observant practitioners of religious rites, the actual practice of Islam among men and women in Egypt varies. According to the male view of Islam, all believers have the same responsibilities to God and the same duties to perform. This is supported by the Qur'an, which states: "And they [women] have rights similar to those [of men] over them in kindness, and men are a degree above them (2, 228)." In one sense, the Muslim community is made up of equals, and this is supported by the belief that all are equal before God. This doctrine is supported by reference to the Qur'an, and serves as

the foundation for the assertion that Islam is egalitarian. However, while it is stated that all are equal before God, at the same time men are in charge of women. Mernissi (1987, 41) considers the Islamic community, *umma*, to be the male Muslim world, while women's world is the other portion, a kind of sub-universe. However, this is only partially accurate. There is an important distinction between the concept of the *umma* as the imagined moral community to which all people naturally belong, and the society of believers on earth. The two spheres of the moral community and the world of daily life are connected, but in a manner that may not be directly apparent.

## B. The Dangerous Sexuality of Women

A dominant gender ideology is an actively negotiated aspect of many Egyptians' daily lives. Contemporary constructions of what it is to be male or female are only partially shaped by Islamic beliefs. Western images, indigenous feminism, new Islamic views of women, and the requirements of the institutions of family and state all contribute to the creation of the ever-changing image of "proper" woman and man. Nonetheless, an Islamic framework is becoming ever more popular as the foundation for gender discourse in certain segments of Egyptian society. Fundamentalist discourse lends legitimacy and cultural authenticity to all positions in the argument. Much of this gender discourse is based on the "dangerous" nature of women and the evils of unbridled sexuality in society.

The contemporary sociologist Halim Barakat comments that, in the Arab world in general, "the prevailing religious ideology considers women to be a source of evil, anarchy [*fitna*] and trickery or deception [*kaid*]" (Barakat 1985, 32). Throughout Egyptian society, one finds the expression of a pervasive gender ideology that perceives women as posing extreme danger for men.

This same ideology prescribes modesty in the form of dress and behavior for women. Contemporary Egyptian beliefs regarding the modesty of women represent a convergence of ideology with customary practice and modern problems. In Egypt, as throughout the Arab world, descent is traced through the male line, and a woman remains a permanent member of her father's family. Even after marriage, a woman keeps her father's name and returns to him, or to another male relative on her father's side, if she is divorced or mistreated. She remains tied to the prestige structure of her father's family, even though she is incorporated into the household of her husband. The honor of the family is closely bound to the modest behavior of women, and honor is associated with the family group, not just with an individual. Thus, one finds that the actions of one family member affect the honor of everyone in that group. This leads to the complex situation that a woman's dishonorable actions before marriage threaten her father's whole family, but such actions after marriage threaten both her father's and her husband's family. As head of the family, a man must insure the integrity of family honor by watching over the behavior of the women of the group at all times.

One way in which these existing attitudes and practices are reinforced is by the recitation of passages from the Qur'an and *Hadith* that relate to women's modesty, and by interpreting them in a way that underscores the social values of keeping unrelated men and women separated from each other. For example, "And when ye ask of them [the wives of the Prophet] anything, ask it of them from behind a curtain [*higab*]" (Qur'an 33, 53). The word *higab* in some contexts is interpreted variously as a screen or a cloth used as a space divider in a tent, or in a metaphorical sense as modest dress or maintaining a decorous distance between

men and women. A key word relating to the modesty of women is *zina*, which is defined as adornment, ornament, or beauty. The Qur'an states:

And tell the believing women to lower their gaze and be modest and to display of their adornment [*zina*] only that which is apparent, and to draw their veils over their bosoms, and not to show their adornment [*zina*] save to their own husband or father or husband's father, or their sons or . . . And let them not stamp their feet so as to reveal what they hide of their adornment [*zina*]. (Qur'an 24, 31)

This verse has been alternately interpreted as defining *zina* as adornment, such as makeup or jewelry, or all of a woman, except for her face and hands or natural beauty (Hoffman-Ladd 1987, 29). It has become increasingly common in Egypt to hear that a woman must cover all of her *zina* in the name of honor and for the protection of public morals. In a constantly changing world, women have thus become the locus for many of the debates that actually deal with wider issues in the society.

Much of contemporary Islamic discourse on women deals with the underlying preoccupation with what it means to be a Muslim in a changing world. As technological developments in transportation, communication, and the media become accessible to a wider segment of the Egyptian population, some Muslims are turning to the fundamentalist scriptural versions of Islam, which are unfamiliar to much of the population. In an attempt to validate their positions, these Muslims cite the works of medieval jurists as the basis for their views on the appropriate roles of men and women. These works provide some insight into current developments with respect to gender roles.

First, one should note that the Qur'an specifically encourages sexual relations in the following verses addressed to husbands:

And when they [the women] have purified themselves, then go in unto them as Allah hath enjoined upon you. (Qur'an 2, 222)

Your women are a tilth for you to cultivate so go to your tilth as ye will, and send [good deeds] before you for your souls. (Qur'an 22, 23)

Having said this, medieval jurists regarded women as a major site of disruption, *fitna*. This was based, in part, on the specific notion of the potential danger of women's sexuality. In their arguments, the presence of women presented society, i.e., men, with the ever-present threat of *fitna*. Nonetheless, this presence was relational. Even though the danger of *fitna* was located in women, it was not their actual being that represented disorder, but the possibility of their unregulated relationships with men. A popular *Hadith*, frequently cited in contemporary fundamentalist literature, states: "I have not left any disorder [*fitna*] more damaging to men than women." Thus, women's disruptive sexuality presented a constant danger to a harmonious society.

In their socialization of men and women, the medieval societies of the Islamic world presumed that the sexes needed to coexist. Nevertheless, men and women needed to interact in prescribed ways. This was based on an ideology that assumed that women were seductresses and men were susceptible to seduction (Bouhdiba 1988, 20-29). Based on an assumption of their innate abilities, men were accorded the responsibility to set limits for women, who were considered to be below them. Jurists based this assumption on the Qur'anic verses that state: "men are a degree above women" (2, 228). While medieval jurists' emphasis on *fitna* must have affected attitudes toward other concepts relating to women's mod-

esty, these discussions were not by any means original or exclusive to the societies of that time.

The fear of *fitna*, which was posed by the visible presence of women, added an element of vested communal interest to the seclusion of women, an interest which was religiously sanctioned (al-Misri 1994, 512). Not only was women's modesty supposed to be guarded by men, who did so in order to guard the honor of their family, but women themselves were seen to bear a religious obligation to uphold their own modesty (*Ibid.*). Part of a woman's duty was to prevent *fitna*, to prevent men from feeling aroused, for if a man misbehaved as a result of arousal by a woman's physical presence, she, personally, was to blame. Furthermore, this was considered to be a woman's duty, not just toward her own family, but also toward society at large. Thus, Ibn al-Hajj, for example, writing in 14th century Cairo, suggests that in order for a woman not to cause havoc in society, she should leave the house three times in her lifetime: "at the time of her wedding; at the funeral of her parents; and at her own funeral" (1973, 1, 119). Any contact between men and women was deemed as potentially dangerous, as seen in another of his examples, where he warns the water-carrier to lower his gaze upon entering a house, because of the possibility of seeing an unveiled woman (1973, 3, 123). A spontaneous glance, in this case totally without forethought, was quite naturally assumed to lead towards seduction. These examples provide some insight into the underlying issues of gender ideology which are undergoing change in modern Egypt and reveal why women and sexuality remain a central focus of contention in contemporary debates about the centrality of marriage and family.

### 3. Knowledge and Education about Sexuality

#### A/B. Formal and Informal Sources

There is no form of sex education in Egypt. While Islamic culture has a certain fascination with all sexual matters as evidenced in the bawdy nature of *A Thousand and One Nights*, in contemporary Egypt, no sexual issues are discussed, either in schools or in the media. This is also in contrast to Qur'anic teachings, which encourage married couples to have sex both for reproductive as well as pleasurable purposes. This is evidenced by an Islamic law that says that if, on the wedding night, the woman discovers that her husband's penis is smaller than the thickness of three fingers, she may divorce him on the grounds of impotence.

While discussions of sexuality are a common component in Egyptian social life, and part of the role of older men and women is to help younger men and women deal with their sexuality, these informal discussions take place within highly regulated spheres of interaction characterized by gender segregation and, among women, the virgin/non-virgin category.

### 4. Autoerotic Behaviors and Patterns

ROBERT T. FRANCOEUR

For Muslim men, the loss of semen in masturbation and nocturnal emissions is bound up, as is the menstrual flow of women, with the impurity associated with the evacuation of organic wastes, unlawful (*haram*) relations, and specific taboos of the *ihram* (ritual purity and dedication of the pilgrim), violations of which constitute a capital sin against *zina*. The life of an observant Muslim is a succession of states of purity acquired then lost, and of impurity lost and then found again in carefully specified purification rituals. Man is never ultimately purified, nor is he condemned to permanent impurity. Major impurity (*janaba*) results from

any emission of semen, menstruation, or the 40-day lochia (*nafas*, the liquid discharged from the uterus following childbirth). Minor impurity is contracted as a result of any excretion by the urethra or anus.

Faithful execution of prescribed purification rituals, following emission of semen, urination, defecation, and the menstrual flow, enable a good Muslim to face God. Whatever the body eliminates is impure and sullies the body, and that pollution must be cleansed each time. This has nothing to do with sin, because man's very life involves the pollution of elimination and excretion, and nothing else. The serious nature and detailed prescriptions of the various purification rituals following an evacuation of organic wastes are often a surprise to non-Muslims (Bouhdiba 1985, 43-57).

The nature of the purificatory act is of a metaphysical order. It is the act of sublimating the body, of removing pollution and of placing it at the service of the soul and spirit. A material, physical, psychological or moral pollution is never final in Islam and the purpose of the purificatory techniques is to restore man to his original purity. (Bouhdiba 1985, 43)

Not surprisingly, in view of Egypt's Islamic culture and Islam's reticence in discussing sexual issues, female masturbation is not discussed, or even mentioned, in standard references on sexuality in Islam or Egypt. A single reference discovered by the editor in *Sexuality in Islam*, by Abdelwahab Bouhdiba (1985, 31), notes that, while both male and female homosexuality are equally condemned, female homosexuality (*musahaqa*) incurs the same reprimand as incurred by autoeroticism, bestiality, or necrophilia. Whether Bouhdiba would include female autoeroticism in this unspecified mention of masturbation is open to speculation.

### 5. Interpersonal Heterosexual Behaviors

#### A. Children and Adolescents

##### *Gender Segregation of the Young*

An Islamic marriage contract entwines men and women in a set of mutual rights and obligations. The first obligation of marriage is faithfulness and chastity. Any involvement in an extramarital relationship constitutes adultery and is grounds for divorce. This stems from two Qur'anic verses:

And who guard their modesty—save from their wives or the [slaves] that their right hands possess, for then they are not blameworthy. But who so craveth beyond that, such are transgressors. (23, 5-7)

And all married women [are forbidden unto you] save those [captives] whom your right hands possess. It is a decree of Allah for you. Lawful unto you are all beyond those mentioned, so that ye seek them with your wealth in honest wedlock not debauchery. (4, 42)

Traditional practices throughout the Islamic world limit interaction between the sexes, based on the idea that contact encourages adulterous relationships to develop. Contact is thus limited between young boys and girls, and complete separation of boys and girls becomes the ideal after the onset of puberty. These ideals have become extremely difficult to uphold with the advent of large numbers of women working outside of the house, and are presently in a state of negotiation between the sexes.

Faithfulness and chastity also account for the extreme emphasis that families and prospective bridegrooms place on the virginity of the bride. Both sexes believe that virginity guarantees the faithfulness of the woman to the man after marriage: "She will not desire others if she has not known men before," is a common phrase that is bantered about. While customarily, these rules are not applied as

stringently to men, men from “better” families will attempt (at least in mixed company) to portray themselves as very “moral” and as abstaining from women until marriage. It is commonly believed that one is able to predict future behavior based on the past.

Infractions of the moral code of faithfulness and fidelity are more common than is usually admitted by most middle-class Egyptians or than is cited in the literature on women and family. For example, Altorki writes, “In all the families studied, the fidelity of the wives was a principle that was strictly observed, and to my knowledge no infractions occurred” (1986, 63). While Egyptians also adhere to a similar belief system where the issue of faithfulness and fidelity is concerned, the reality may at times differ quite substantially.

## B. Adults

Egyptian society is characterized by a general sense of patriarchy as well as sexual frustration. Men dominate over women in all matters of sexuality, and children are from their first day brought up with very strict sexual guidelines. Girls are expected to be virgins at marriage and are not allowed to ask about sex before their weddings. For many young women (especially the less-educated ones), the actual sex act comes as a complete surprise on their wedding nights and often results in lifelong frigidity because of the shock of the experience. Further, because of cultural constraints, even if a woman comes to enjoy sex, she is not allowed to show this to her husband, who will otherwise become suspicious of her desire and suspect her of having sex with other men. Also, women are not allowed to be the initiators when it comes to sex. Women are expected to initially be completely innocent and then later to “endure” sex in order to be “respectable” in their husband’s eyes.

Men have a different set of challenges. While they are expected to have some “experience” before marriage, men also are faced with maintaining their reputations so that they will be eligible to marry a “morally respectable” girl once they are financially set to do so. This entails secret sexual behaviors, since many men do not marry until their 30s. Further, it is difficult to find women to have sex with. Men, therefore, resort to encounters with prostitutes or with willing married women. However, most of this behavior occurs secretly and a man will never tell his bride about his experiences. Given the sexually repressive atmosphere of the society and the lack of sexual access to women, many men suffer from impotence and are extremely preoccupied with all sexual matters.

In addition, it must be pointed out that there are strong differences in degree between rural and urban areas, as well as class differences, in terms of interpersonal behaviors between men and women in the private sphere. Men from the south of Egypt (Saidi’is) are renowned for their jealous behaviors over their wives. Nonetheless, the rules depicted above apply in some degree to all individuals brought up in Egyptian society.

### Concepts of Beauty

The traditional idea that in order to be attractive, women should be pleasantly plump (*mirabraba*) is still around, but it is changing in the upper strata of society. For example, it is now possible to find diet Coca Cola and other diet sodas in Egypt. Also, hospitals have started treating obesity. There are no reported cases of bulimia or anorexia. “*Hilwa mirabraba*” or “pretty and plump” is a standard phrase, as if the two words are automatically attached. To call a woman “skinny as a stick” or a “drumstick” (referring to drums, not a chicken’s legs) is an insult. Traditional lower-class women use a different insult, “you rusty needle” (*lya ibra miSadiyy*), as a standard insult.

As far as ideals of beauty are concerned, women spend a lot of money straightening kinky hair and trying to whiten their skin using various creams such as “Fair and Lovely” or “Fair Lady.” There are commercials for these products on television all the time. Also, the male ideal of a woman in traditional sectors is blonde, with white skin and blue eyes. Women tend to find men who are somewhat taller, have a full head of hair, and again fair skin, as attractive. However, women do not attach great importance to men’s looks if they have other favorable criteria, such as a job, good education, and respectable family background.

### Intimacy and Nudity

ROBERT T. FRANCOEUR

While the Imams and mullahs of Islam are very clear in their interpretations of the Qur’an and what is permitted and not permitted by tradition, there is often, as Perper points out in the Preface to this volume, a real discrepancy between “proper sex” and “formal values,” what the authorities say should be done, and “smart sex” and “informal values,” what men and women actually do in their private sphere. The comments of Abdelwahab Bouhdiba in *Sexuality in Islam* are a good example of this distinction applied to the issue of nudity. Bouhdiba (1985, 37-38) writes about formal values and proper sex according to the Qur’an:

To be a Muslim is to control one’s gaze and to know how to protect one’s own intimacy from that of others.

However, the concept of intimacy is far-reaching, for we are confronted here with the concept of *’aura*, which tradition divides into four categories: what a man may see of a woman, what a woman may see of a man, what a man may see of a man, what a woman may see of a woman.

Between men and women, and also between men before their own wives, the part to be concealed from the eyes of others stretches from the navel to the knees exclusively, with a greater or lesser tolerance for the lower part of the thighs, especially in the case of youths. A woman must reveal only her face and hands. Between husband and wife sight is permitted of the whole body except for the partner’s sexual organs, which one is advised not to see for “the sight of them makes one blind.” However, this is allowed in cases where it is necessary, for juridical or medical purposes, to examine the sexual organs of the *zani* or woman in confinement.

Certain *fugaha* authorize the partners to look at one another’s sexual organs during intercourse. Zayla’i, armed with the opinion of Ibn ’Omar and Imam Abu Hanifa, even affirms that it increases one’s ability to reach the quintessence of ecstasy.

Total nudity is very strongly advised against, even when one is “alone.” This is because absolute solitude does not exist in a world in which we share existence with the *djinn*s [*spirits lower than angels*] and angels. “Never go into water without clothing for water has eyes,” Daylami observes.

When the editor asked Bahira Sherif to comment on the above description of “proper sex” offered by Bouhdiba, she offered the following comment: “Public nudity in all forms is forbidden for both men and women. The most extreme case of this is that some ultraconservative men will cover their wife’s feet with a cloth when she climbs in and out of a bus. Men and women *are* allowed to be intimate and to see each other’s sexual organs.”

### Islamic Law and Egyptian Marriage

In order to understand sexuality in Egypt, it is necessary to clarify the role of marriage in Islamic law (which remains in effect in all issues related to family in Egypt.) In all schools

of Islamic law, marriage is seen as a contract whose main function is to make sexual relations between a man and a woman licit. The term *'aqd al-nikah* refers to the contract of coitus. A valid and effective marriage contract outlines certain respective legal rights and duties for wife and husband, together with other rights and duties common to both of them. Very superficially, these rights and duties can be summed up as dowry and maintenance for the wife and children, as well as the good treatment of the wife and children by the husband, the mutual right of inheritance between the conjugal couple, and the wife's obedience to her husband in lawful matters. At the time of marriage, other parties can stipulate certain conditions, provided that they are not contrary to the basis of marriage as defined by jurists.

The essential requirements for a valid Muslim marriage in Egypt are:

1. consent of the wife,
2. consent of the legal guardian or *al wali*,
3. two legal witnesses, and
4. payment of dowry or *mahr*.

While each of these elements must be present for a marriage to be considered valid, there are other features inferred from Islamic legal texts, which combine to make a legitimate, socially respectable marriage. Because marriage is a contract, both parties can stipulate certain conditions. For example, one condition may be the wife's right to divorce, but a condition that eliminates the husband's right to divorce would be void. Verma (1971, 97-104) has provided a list of valid and void conditions related to marriage.

Beyond its legal components, marriage is also regarded as a religious obligation and is invested with many ethical injunctions. This can be attributed primarily to the fact that any sexual contact outside marriage is considered fornication or a violation of *zina*, and is subject to severe punishment. Furthermore, Islam condemns and discourages celibacy. In this manner, marriage acquires a religious dimension; it becomes the way of preserving morals and chastity through the satisfaction of sexual desires within the limits set by God (Maudoodi 1983, 6-7). Muslim jurists have gone so far as to elevate marriage to the level of a religious duty. The Qur'an supports this notion in the verse that states, "And marry such of you as are solitary and the pious of your slaves and maid servants" (24, 32), which is commonly interpreted as advocating marriage in order to "complete the religion" (Bousquet 1948, 63). A common *Hadith*, still often quoted, particularly among men, states that "the prayer of a married man is equal to 70 prayers of a single man." Thus, all individuals are encouraged to marry, and societal provisions, such as the importance of family reputation, discourage being single.

Marriage remains at the center of contemporary Egyptian social life. It is the primary focal point in the lives of both men and women, followed only by the birth of a child. From a legal standpoint, the marriage contract establishes a series of rights and obligations between a couple which have a long-lasting effect on many aspects of their lives. An Islamic marriage contract naturally represents more than a mere exchange of money or material goods. It is a form of social exchange and is thus a legal, religious, economic, and symbolic transaction (Mauss 1967, 76). The contract is attended to with utmost seriousness and is preceded by a set of lengthy negotiations, almost all of which center around the material protection of the woman and her unborn children once she enters the state of matrimony. Nevertheless, the marriage contract may include conditions that are advantageous for either or both spouses. Conditions specified in the contract may range from the woman's right to dissolve the marriage,

to an agreement that neither party may leave the town they agree to live in, and even that the husband may not marry another woman. The contract, as a matter of course, also acts as a medium for bringing the various members of the two families together and provides them with the opportunity to discuss in detail the preliminary workings of the marriage. Most importantly, the marriage contract symbolizes the public acknowledgment of the formation of a lawful sexual partnership that will be sanctioned both religiously and socially, and which marks the beginning of a family and the care and upbringing of children.

#### *Mut'a or Temporary Marriage*

While *mut'a* or temporary marriage is not recognized as legitimate by any school of Sunni Islam, its acceptance and practice among the Shi'as highlight the contractual nature of Muslim marriages (Haeri 1989). However, Haeri's argument that all Islamic marriage contracts are basically an exchange of money for sexual intercourse, while thoroughly researched and argued, is incomplete. While that is one element of the exchange, Haeri ignores the other elements of protection of the woman and her children. Even temporary marriages require a contract based on the notion that should a child be fathered, even in a short-term union, the man must claim paternity. This can be observed by the fact that after the short-term-marriage contract expires, the woman is still required to observe the *'idda*, the period of waiting. A *mut'a* wife is not entitled to maintenance, but should children be conceived during a legitimate *mut'a* marriage, they are entitled to inherit from both parents.

For a *mut'a* marriage to be valid, the term of cohabitation must be fixed, and it may be a day, a month, a year, or a number of years; and a dowry should be specified. However, it is still incorrect to draw conclusions about the nature of all Islamic marriage contracts based on *mut'a* marriage contracts. *Mut'a* marriages are outlawed among all other schools of law because they do not fulfill the purpose that the jurists argue is the fundamental reason behind marriage in the first place. While lawful sexual intercourse is one aspect of the contract, the legalities bound up with the relationship, I think, indicate the multidimensional nature of an Islamic marriage. The Sunni jurists emphasize that even under Shi'a doctrine, temporary marriage is not a proper marriage, since it establishes no maintenance or inheritance rights for the woman.

Modern Egyptian legislation dealing with marriage and its actual practice provides insight into the contemporary nature of the founding of an Islamic family through matrimony. Here we can only give a general summary of the issues dealing with marriage and divorce. A general examination of the legalistic intricacies of marriage is relevant to all schools of law in Islam and reveals the rights and obligations of both men and women that are established through the marital bond. It is not within the scope of this chapter to expound on the social and cultural customs that vary across the regions that are today primarily Islamic. While these variations are very important, they are not central to our discussion here, because of the prevailing uniformity of the legal issues. Few fundamental conceptual and legal differences exist among the various schools of Islamic law concerning the basic rights of women (e.g., dowry and financial maintenance), inheritance laws being the exception. Since the legal structure for marriage and divorce, which constitutes most of the laws dealing with women, is described in detail in the Qur'an (especially *suras*, chapters of the Qur'an, 2, 221-41; 4, 3-35; 65, 1-7), they are believed to be immutable. Historically, Islamic societies have avoided making changes to the structure of family law because of its derivation from religious text. Thus, it is of contemporary

relevance to examine some of the legalistic aspects of marriage with respect to their derivations from the Qur'an.

Sources such as the Qur'an and Islamic law represent norms; they do not describe what is or what was, but what should be. They constitute the mechanism of an ideally functioning Islamic society, the goal being to provide for humankind the path to happiness and paradise. However, this does not mean that these sources have no relation to reality. In fact, they do from two aspects. On the one hand, the solutions that they suggest to human questions and problems are often derived, in particular relation to issues about marriage and family, out of the existing circumstances, even in those instances when they seek to change existing conditions. On the other hand, these guidelines influence the given society, leading to changes in social practice, including marriage, family, and gender roles.

### *Sexuality Within Marriage*

Islamic justification of sexual intercourse through the marriage contract can be seen in a variety of provisions (Bousquet 1948, 63-74). For example, a Muslim marriage only becomes completely valid when it has been consummated. If a man declares his wife divorced three times, he can only remarry her once she has contracted a marriage with another man and consummated the new marriage—a *Hadith* refers to this as “tasting a bit of honey.”

[(*Comment 2001*) As Zeynep Gulçat, author of the chapter on Turkey in this volume, explained when asked about this by a graduate student in the Editor's class, this *Hadith* is meant to protect the wife from repeated, impulsive declarations of divorcing a wife for minor irritations and then remarrying her on reflection. (*End of comment by R. T. Francoeur*)]

Also, once husband and wife live together, the marriage is to be consummated within a certain period of time. The different schools of law vary on the specified time period, but one year seems to be the average (al-Misri 1994, 531). A woman may not refuse her husband's sexual advances at any time, even if she is menstruating, unless it will cause her discomfort. She, in turn, has the right, not just to sexual intercourse, but also to sexual satisfaction. It is said that if a woman pleases her husband sexually, she can be assured of paradise, and if she refuses him, she will be penalized both on earth and in heaven. If a man swears an oath that he will not touch his wife any more, then she has the right to divorce him after four months, unless he resumes sexual relations with her again (Qur'an 2, 226). All of these prescriptions indicate how important and potent Islam considers sexuality to be. Both men and women are to be satisfied sexually in order to prevent adultery and consequent chaos in the society.

The importance of sexuality in the married life of Egyptian women is very apparent in their conversations, which are often, by Western standards, very explicit. Married women will not speak of their sex lives in front of other men or unmarried young women. Nevertheless, once they find themselves alone with other married women, the conversations will become very detailed about the various strengths or weaknesses of their married lives. Women will advise one another on all aspects of sex and on how to best “deal with one's husband.”

A major issue among married women is the issue of frequency of sex. Some women feel that their husbands place undue demands on them, given the fact that they work, have children, and are running a household. Interestingly, some other women have the opposite complaint. According to a couple of my informants, several of their husbands kept them on a strict schedule of sex. Thus, the men initiated sex

with their wives regularly but in a limited fashion on, for example, Tuesdays and Thursdays, Thursdays being the most common night for sex before the holy day on Friday. Any attempts on the wife's part to deviate from this schedule were met with great opposition. Thus, women are constantly advising one another on “seductive” techniques to force their husbands to vary the schedule. Men, however, feel that it is necessary to preserve a strict regular sexual schedule in order to keep their wives' sexuality under control. Men tend to fear that, as they age, women may want or expect too much from them, and that once they are not able to perform as well, this could initiate a marital crisis. Furthermore, many men fear that anything beyond basic sexual knowledge could potentially make their wives “promiscuous” and “uncontrollable.” A major complaint on the part of women is their ignorance about sex when they married and their husband's lack of interest in educating them in this matter.

While Thursday night is considered “sex night,” Friday is traditionally known as bath day. This is the day that ritually men get cleaned up to go to Friday prayer. Because of the traditional association of sex with full ablutions required after a major impurity, water is strongly associated with sex. This can even be seen in the term *Imayya suxna*, hot water, a phrase used by parents for something that the children should not be allowed to hear.

Among many Egyptians, part of the role of older men and women is to help younger men and women deal with some of the fundamental aspects of marriage. While sexuality, within the legitimate institution of marriage, is an active, much-discussed component of Egyptian social life, these discussions take place within highly regulated spheres of interaction characterized by gender segregation and, among women, the virgin/nonvirgin category.

To an individual brought up in the West, Egyptian women's discussions of sexuality are striking because of the many allusions to the Qur'an. While many women do not actually know what the Qur'an says, they do know that it urges all individuals to marry and that sexuality is encouraged and considered of primary importance for both men and women. “The Qur'an says it [sexuality] is part of our nature,” or, conversely, “sex is part of their [men's] nature,” are common comments and complaints among women. Especially among older women, jokes and anecdotes about sex and their husbands are afternoon entertainment. Younger women tend to be quite proud of the new power they have over their husbands and again validate these feelings with religious references, such as, “the Qur'an urges us to reproduce—and we are helping them [their husbands] to become good Muslims,” or, “We are helping them to fulfill their religious obligation.” Some of the less-happily married women in my study (in particular the older ones) repeatedly emphasized to me that, even though they were not satisfied with their husbands, “this was God's will,” and that they were trying to please their husbands in all aspects, including sex, “because it is part of our religion and we will be rewarded in the afterlife.” Religious references are used by both older and younger women to validate their positive and negative marital experiences. Nonetheless, none of the women seemed to have concrete knowledge of the actual *suras* or *Hadith*.

The complete social prohibition of young people's sexual activities outside of marriage naturally leads to the almost nonexistence of illegitimacy among this societal group. Illegitimacy is only spoken of in hushed tones and is associated with unusual occurrences, such as a maid getting pregnant through the advances of one of the men in the household. The Western phenomenon of older, educated, unmarried women

having children is unheard of and evoked expressions of extreme surprise among my acquaintances. "That is *haram* [forbidden]. Why would a woman do this to herself!" or "A woman bears children for her husband. Children need a father. How can this be?" A unanimously shared Egyptian belief is that reproduction belongs to the realm of the family and is thus, like sexuality, highly regulated by legal, as well as social rules and responsibilities.

### Divorce

Until 2000, Egyptian and Islamic law provided the wife with a very limited right to initiate a divorce, one of these being the right of the wife to divorce her husband on the grounds of impotence if she discovered when the marriage was consummated that his penis did not exceed the thickness of three fingers.

A major development occurred in late January 2000 when the 454-member Egyptian Parliament voted to allow women to divorce their husbands without first having to prove to a judge that they had been mistreated. Under the new legislation, which was quickly approved by President Hosni Mubarak, divorce will still be more complicated for a woman than a male (Sachs 2000).

[Update 2002: With the new law, enacted after a 15-year campaign, an Egyptian woman now has two choices. A woman can still use the often-protracted procedure, which requires her to have witnesses to provide a family court judge with exacting proof that her husband has committed adultery or has mistreated and abused her badly enough to justify divorce. In the end, the court procedure usually results in a ruling against the wife. The old law gives men appeal rights that can take years to exhaust. Under the old law, as little as an hour with the local marriage registrar is all that it takes for a husband to get a divorce, sometimes without even informing the wife. Prior to passage of the new law of 2000, a Muslim man in Egypt could end his marriage by saying three times, "I divorce you," or by filing with a government registrar a document testifying to his action. Despite these disadvantages, 1.5 million such requests were filed each year under the old law, and 290,000 divorces were granted, according to government statistics. In Cairo, where one fifth of Egypt's 70 million people live, roughly 15,000 women filed for divorce annually under the old law.

[Even with the new law giving women the option of seeking a divorce, and the likelihood that the courts will tie up a case for years examining a woman's claim, it is still preferable for the wife to prove cause, if only to retain the *mahr* (bridewealth or marriage payment) her husband brought to the marriage. The option of the quick divorce demanded by the wife allows the husband to file his own divorce request and make a quick exit with the *mahr*.

[The new option allows a woman to demand a unilateral, no-questions-asked divorce on the basis of incompatibility. The only restrictions are a required court-supervised attempt at mediation and a six-month wait for a woman with children, and a three-month wait if no children are involved. If a judge fails to reconcile the couple in this period and the wife still wants a divorce, the judge has to grant it. However, the woman has to return all money, property, and gifts she received in the marriage from her husband—her *mahr*—and forego alimony.

[One compromise during the debate over the new law eliminated a provision that would have allowed Egyptian women to travel with a husband's or father's permission, because it was too daring. In late 1999, the government repealed a controversial part of the criminal code that allowed rapists to avoid imprisonment if they offered to marry their victims.

[During the 15-year effort to change the old family law, the conservative religious element objected vehemently that the proposed reform would cause major social upheaval and set women at war with men, while advocates of reform argued that reform would make the legal system more efficient and in tune with contemporary concern over women's rights. In the end, a diverse coalition made reform possible. President Mubarak, whose wife has been active on social reform issues, along with legal reform activists, civil libertarians, and supporters of women's rights, all supported the reform. Perhaps most crucial were the Muslim scholars who agreed that there was justification within Islam for the proposed changes. It was, in fact, the justification of the new law on religious grounds that won it approval in a nation where family law, in particular, is seen as deeply rooted in *shari'a* (Islamic code). The activists for reform successfully argued that the Prophet Mohammed meant divorce to be a gender-equal—or at least nearly equal—opportunity for men and women to dissolve an unhappy marriage. When scholars at Cairo's Al Azhar University, the Muslim world's oldest seat of religious learning, agreed, the reform became a reality (Geissinger 2000; Schneider 2000). (End of update by B. Sherif)]

The situation of the 6% of Christian Egyptians remains as burdensome as before, because religious courts, which administer family law, rarely grant Christian women a divorce unless she can prove adultery.

Many leading clerics supported the change, including the government-appointed *mufiti* (legal advisors on religious matters) and the sheik of Al Azhar University, the oldest Islamic teaching institution in the world. Supporters of the change point out that even the Prophet Muhammad allowed an unhappy woman to divorce her husband over his opposition, provided she first returned her dowry.

In the impassioned debate on the new law, opponents argued that Islam gives only men the right to initiate a divorce. Extending this right to women, whom they described both in Parliament and the media as emotionally capricious and vengeful, would lead to a massive breakdown of family life. "This will only lead to more and more splits within the society," Ayman Nour, a member of Parliament claimed; "This law will instigate women to be corrupt. A woman could just get together with another man and agree to divorce her husband."

Establishment of a woman's right to initiate a divorce is a major advancement for women in Egypt in light of the strong fundamentalist movement.

### Polygyny

While polygyny is allowed by the Qur'an, it is virtually nonexistent in Egypt. In contrast to the stereotypical Western image of Muslim men with multiple wives, Egyptian men bemoan the difficulties of supporting one wife in today's economy, and strong social sanctions work against their even considering polygyny as a viable option.

Male and female reactions must be seen in light of a 1979 ruling, also known as "Jihan's law," so named after Sadat's unpopular modernist wife, who introduced a decree outlawing polygyny as an option for men. Considerable debate ensued in the media and among secular and religious elites concerning the Personal Status Laws and their relationship to the *shari'a* (Islamic law). This amendment was eventually partially abrogated on procedural grounds in 1985. However, in June of that year, a similar law (Law No. 100) amending the 1925 and 1929 laws was enacted and is now the law in place (Karam 1998, 145). The new law stipulates that in the case of a polygynous union, the first wife retains the right to seek divorce, but it is no longer an automat-

ic right. Instead, she now has to prove that her husband's second marriage is detrimental to her either materially and/or mentally. Further, the first wife now only has the right to sue for divorce in the first year of the new polygynous marriage. It is socially unacceptable among the middle and upper classes for men to engage in polygynous unions and, in fact, is not seen as an option. The revisions in the law are important on a symbolic level in terms of giving men certain legal rights over women in the context of the family.

### 6. Homoerotic, Homosexual, and Bisexual Behaviors

While there is no public acknowledgment of homosexuality in Egypt, there is a largely hidden but thriving bisexual and homosexual community (Murray 1997c). Nevertheless, families will never acknowledge that one of their members is potentially homosexual. Men will remain living in their natal family for most of their lives and there will never be any public discussion about their reasons for not marrying. Islam condemns male homosexuality and popular culture further reinforces this message. In reality, homosexuality is widely practiced but is divided into two categories: the active versus the passive partner. The active partner has little stigma attached to him, or at least much less than to the *khawal* or passive partner, who is heavily stigmatized. According to one *Hadith*, there are three kinds of male homosexual: "Those who look, those who touch, and those who commit the criminal act" (Bouhdiba 1985, 32).

There is also traditional pederasty between older men and younger boys. Long-term domestic relationships between men are unknown, given social norms that force all unmarried individuals to remain in their natal families until they marry. Since there are many situations in which males can interact with other males, opportunities for male homosexual encounters are available. Egyptian culture, for instance, encourages intimate interactions between men, and it is common to see men holding hands, embracing, or kissing each other on both cheeks without, again, any sexual overtones.

There are no similar venues for women, who are under the constant supervision of their families. Thus, there is no information available on the prevalence of lesbianism in Egyptian society. Also, it is considered quite appropriate for women to interact with other women in very intimate settings (such as helping each other bathe) without there being any sexual overtones to these encounters (Murray 1997b).

After pointing out that the Islamic world rests on the bipolarity of the sexes and their union in marriage, Bouhdiba (1985, 30-33) notes that "homosexuality is a challenge to the order of the world as laid down by God and based on the harmony and radical separation of the sexes."

"God has cursed those who alter the frontiers of the earth." In these terms the prophet condemns any violation of the separation of the sexes. Tradition has it that four categories of person incur the anger of God: "Men who dress themselves as women and women who dress themselves as men, those who sleep with animals and those who sleep with men." Homosexuality [*liwat*] incurs the strongest condemnation. It is identified with *zina* and it is advocated that the most horrible punishment should be applied to those who indulge in it.

In the final analysis, *liwat* even designates all forms of sexual and parasexual perversion. Nevertheless, in Islam, male homosexuality stands for all the perversions and constitutes in a sense the depravity of depravities. Female homosexuality [*musahaqa*], while equally condemned, is treated with relative indulgence and those who indulge in

it incur the same reprimand as those condemned for autoeroticism, bestiality or necrophilia. (Bouhdiba 1985, 31)

[Update 2003: Although most Egyptians view homosexuality as heretical, it is not illegal. In the late 1990s, Cairo was gaining a reputation in Egypt's gay grapevine, and even in some nearby Middle Eastern countries, as having a rapidly expanding gay scene. Bars, discos, and plenty of public meeting places were opening up in the center of Cairo where it was relatively easy to socialize, exchange cellphone numbers, hold hands, and perhaps be more daring. The gay life flourished, either largely unnoticed amid more pressing issues, like terrorism and a government crackdown on radical Islamic activists, or tacitly tolerated.

[That changed dramatically in May 2001, when 52 men were arrested for "debauchery" in a police raid on the Queen Boat, a disco on the Nile known as a gay-friendly hangout. After the defendants were convicted in a November 2001 trial that caused international protests, President Hosni Mubarak ordered a second trial. In March 2003, a Cairo court convicted 21 of the 52 Queen Boat defendants of "debauchery" and sentenced each to three years in jail. Both highly publicized trials were widely criticized by human rights groups and Western governments. While homosexuality is not explicitly outlawed in Egypt, a section of the penal code dealing with "debauchery" that is rooted in Islamic law has recently been used to prosecute gay Egyptians. Activist lawyers and human rights activists estimate that 70 gay men have been arrested in recent months in addition to the 52 arrested two years ago.

[With the gay hangouts and clubs now closed down, gay men have turned to connecting on the Internet. But the police are now using sting operations on the Internet to track down gays. Government officials deny any harassment of gays. They also deny having targeted gays for arrest. However, several Western governments remain concerned about the treatment of gays and have been discussing the matter with Egyptian officials behind the scenes (Kershaw 2003). (End of update by R. T. Francoeur)]

### 7. Gender Diversity and Transgender Issues

There is no information available on transvestites or transsexuals because they cannot come out in public. This topic is not considered legitimate for discussion in Egypt.

### 8. Significant Unconventional Sexual Behaviors

#### A. Female Circumcision

In the West, the most controversial and publicized issue concerning women's health in the Islamic world and Africa is the practice of female circumcision. This practice is extremely widespread in Egypt, especially among the poorer classes and in rural areas. It is considered imperative for girls to be circumcised because of cultural norms that stigmatize uncircumcised girls and prevent them from marrying. Estimates range from 50 to 90% of all Egyptian women are circumcised, but precise figures are not known. A recent study conducted by researchers from Ayn Shams University found that 98% of all girls in the Egyptian countryside and poor girls in Cairo had been circumcised, both Muslims and Coptic Christians, while the estimate for upper-class girls in Cairo was approximately 30% (Botman 1999, 106). The 1995 Egypt Demographic and Health Survey (EDHS-95) indicates that female circumcision is still a common practice despite government portrayals to the contrary. Among women with one or more living daughters, 87% report that at

least one daughter has already been circumcised or that they intend to have the daughter circumcised in the future.

Most circumcisions take place before puberty; the median age at circumcision among both respondents and their daughters was 9.8 years. Traditional practitioners were responsible for more than eight to ten circumcisions among respondents, while trained medical personnel performed more than half of the circumcisions among the daughters of respondents.

The majority of women surveyed (82%) think female circumcision should be continued. Seventy-four percent believe that husbands prefer their wives to be circumcised and 72% believe that circumcision is an important aspect of religious tradition. Relatively few women recognize the negative consequences of circumcision, such as reduced sexual satisfaction (29%), the risk of death (24%), and the greater risk of problems in childbirth (5%).

This clinic-based study, one of the few of its kind, was carried out at five university hospitals, several rural hospitals, and two urban clinics. It included a total of 1,339 women for whom both questionnaires and physical examinations were completed. All clients coming to the sites for family planning or gynecological examinations were interviewed about their experience with female circumcision. In addition to the interview, pelvic examinations were conducted on all the women in the study. As part of the examinations, specially trained gynecologists determined whether there was physical evidence of circumcision and, in the case of circumcised women, the amount of tissue excised during the circumcision.

The results of the study permit a classification of circumcised women according to the type of circumcision performed. Because the interviews were conducted prior to the physical examinations, it was also possible to compare the woman's own report as to her circumcision status with the results of the physical examination. For 94% of the women in this clinic-based study, there was agreement between the reporting of circumcision and the findings of the subsequent physical examination.

While female circumcision is often presented as a requirement of Islam, this is in fact a fallacy. To the great embarrassment of the Egyptian government, the issue was raised at the 1994 International Conference on Population and Development in Cairo. Subsequently, a decree was issued to limit the practice to hospitals. The government refrained from completely outlawing the practice because of pressure by Islamic groups who deem female circumcision as necessary based on a saying by the Prophet Muhammad. Critics, however, point out that the Prophet's own daughters were not circumcised and that circumcision is not practiced in Saudi Arabia, the most conservative Islamic country in the Middle East. In 1997, under pressure from Islamic fundamentalist groups, the government lifted the ban on female circumcision. Despite international efforts to publicize the physical and psychological dangers of circumcision, the practice is gaining legitimacy as Islamists revive the belief that it is religiously mandated. The controversy around female circumcision is indicative of the tension between ingrained cultural values with respect to gender, Islamists' quests for "authenticity," and Western perspectives that advocate universal women's rights with respect to control of their bodies.

## B. Coercive Sexual Behavior

### *Incest*

Although all cultures have some kind of incest taboo, the boundaries restricting who is an acceptable sexual and marital partner vary. In Egypt, for instance, sexual relations and marriage between first cousins is not considered incestuous

behavior and historically was very common. Even today, it is not uncommon for first cousins to marry. In fact, many families, particularly in the poorer and rural areas, consider this form of arranged marriage preferable to marrying outside of the family. The rationale for this includes the idea that one has an insider's knowledge about one's own family and, therefore, knows "what one is getting." Also, first-cousin marriages keep the land and wealth within the family.

### *Rape*

Incidents of reported rape are infrequent in Egypt, because young girls, especially from middle-class and upper-class families are very protected. They tend to only move in the company of members of their families and they themselves take great care to protect their reputations in order to remain "marriageable." Girls from poor families who work as domestic servants are at a much greater risk of rape, because they have little power to protect themselves from the advances of male family members. These cases tend to go unreported and are not of interest to most members of the society. Also, the surge in an underground drug culture has led to a greater risk for women to be sexually exploited.

### *Unconventional Sexual Outlets*

Although there are no recorded cases, some people claim that rural males occasionally use animals, such as sheep, as a sexual outlet. Especially in isolated villages, where sexual outlets for unmarried adolescents are lacking, sexual intercourse with animals is not uncommon.

## C. Pornography and Erotica

Pornography, as well as prostitution, are forbidden by Egyptian law. That said, there are attempts to smuggle in pornography from the West, in particular now through the Internet. A crackdown on this behavior has been advocated by the government to the extent that at Internet cafes, users must sign a form saying that they will not attempt to access or download pornography.

## D. Prostitution

Although information about prostitution in the religiously conservative nations of the Middle East is limited, prostitution is known to exist in most Arab countries, including the urban areas of Egypt (Inhotn & Buss 1993). Even though prostitution is outlawed in Egypt, Cairo is widely known as offering males access to many classes and types of prostitutes. With the increasing conservative climate in Egypt, the social phenomenon is increasingly hidden and not easily observed. Prostitution rings catering to traveling Western businessmen are known to operate out of private apartments, while other prostitutes frequent the large hotels with a high percentage of Western guests. It is difficult to regulate this form of prostitution because Egyptian prostitutes do not exhibit the same overt signals as their Western counterparts. There is no published data on prostitution in Egypt.

## 9. Contraception, Abortion, and Population Planning

Family planning is a problematic area even though Egypt has the longest history of contraceptive initiatives in the Middle East. In 1996, the former Ministry of Population and Family Planning was abolished and a new Ministry of Health and Population was created to underscore the renewed importance the government is giving to issues of population growth. Egypt's population problems are twofold: rapid rates of population growth related to high fertility and an unbalanced population distribution. The highest fertility level is found in rural Upper Egypt, 5.2 births per

woman, compared to a lower fertility level of 2.7 births per woman in urban Lower Egypt (Chelala 1996, 1651).

In order to help curb population growth, the government has consistently advocated the use of family-planning methods. However, the quality of family-planning services is often poor, contraceptives are not readily available, and, especially, poor and rural women are reluctant to use artificial birth control methods, which they have heard rumored are detrimental to women's health. Many unwanted pregnancies end in self-induced abortions because abortion is prohibited in Egypt, except in cases where pregnancy threatens the life of the mother. The 1995 Egypt Demographic and Health Survey, a nationally representative survey of 14,779 married women aged 14 to 49, shows a leveling off of the contraceptive prevalence rate at around 48% from 1991 to 1995. Although contraceptive use in Egypt doubled between 1980 and 1995, from 24% to 48%, most of the increase happened in the 1980s, with no significant change in the overall rate of contraceptive use between 1991 and 1995. The 1995 survey also revealed significant differences in the level of contraceptive use based on region, with women in Lower Egypt showing the lowest contraceptive use. This high discrepancy can be attributed, at least in part, to lower socioeconomic conditions and traditional practices and beliefs.

A primary issue discussed during the International Conference on Population and Development held in September 1994 in Cairo was the relationship between religion, family planning, and women's rights. Abortion turned out to be the most controversial topic. Muslims vehemently argue against abortion as a means of family planning but believe that abortion should be tied to the family unit. They believe that abortion may be practiced in exceptional cases where the health of either the mother or the fetus is in danger. The government's stance is that women must avoid abortion as a method of family planning, but the government does not provide treatment and counseling for women forced to resort to this measure.

Herbal and folk contraceptives are still popular, particularly in rural areas. Midwives are popular sources for information on preventing pregnancies and inducing abortions. Midwives are also often indirectly involved in the hymen-breaking ceremony of young virgins on their wedding night. Should a young woman not be a virgin or be worried about the intactness of her hymen, she may go to a midwife who will arrange for her to place a small sack with chicken blood into her vagina, so that when the marriage is consummated on her wedding night she will bleed.

Infertility, even though it is barely acknowledged or studied, is also an important problem that culturally afflicts primarily women in Egypt. In a society where it is imperative for women of all classes to bear children and, thus, attain social status through motherhood, the inability to bear children leads to serious social consequences. Alternatives to motherhood and domesticity are largely absent, and adoption is not allowed under Islamic law. Thus, for all women, biological parenthood is imperative, especially since under Islamic law a man has the right to replace an infertile wife through divorce or polygynous marriage. While polygyny is not an option that is exercised by upper- and middle-class men, the threat of divorce hovers over childless marriages. Among all classes and educational levels, women are typically blamed for reproductive failings, and they also bear the burden of overcoming this condition through a therapeutic quest that is often traumatic and unfruitful (Inhorn 1994, 5). Further, women face extremes of social judgment, for they are cast as being less than other women, as depriving their husbands and their husband's families of offspring, and as endangering other people's children through their supposedly uncontrollable envy.

## 10. Sexually Transmitted Diseases and HIV/AIDS

### A. Sexually Transmitted Diseases

Information about sexually transmitted diseases in Egypt is scattered and often anecdotal. Nevertheless, evidence suggests that sexually transmitted diseases are widespread in the general population. The only study, which provides some indication of the prevalence of sexually transmitted diseases, is research on reproductive morbidities, including reproductive tract infections, conducted among 502 women in two villages in rural Giza, 1989 to 1990. Sixty-four percent of the women sampled had a reproductive tract infection at the time of the survey, which may be in part because condoms are rarely used in Egypt. While solid data are lacking, the 1995 Demographic and Health Survey reported that only 14% of married women used condoms for family planning. It is, therefore, unlikely that condoms are commonly used in Egypt for disease prevention (Lenton 1997, 1005).

As in many other countries in sub-Saharan Africa, the migration-prostitution-STD triad is operative in Egypt. Studies indicate that, in particular, male labor migration, which is currently over 2 million, brings with it a variety of social ills, including STDs. Given strict cultural norms regarding women's premarital virginity and marital fidelity, Egyptian women find themselves on the receiving end of a variety of sexually transmitted infections. Their husbands, many of whom migrate for extended periods of time, contract gonorrhea, genital chlamydia, and other sterilizing infections, primarily from foreign prostitutes. Emerging studies from both rural and urban Egypt indicate that rates of various STDs are rising in similar proportions to the West. Often men contract STDs from either female or male prostitutes, and, given cultural norms that discourage this form of behavior, avoid seeing doctors. The infection, therefore, becomes chronic in men's prostates and they transmit the diseases directly on the first wedding night to their new brides. Women, thus, may start their marital lives with tubal infections that potentially lead to infertility. This has major societal implications, because infertile women face their greatest threat from their husbands, who have the right under Islamic law to replace an infertile wife through divorce or a polygynous remarriage. Such replacements are often encouraged by the husbands' families, who view an infertile wife as, at best, useless, and, at worst, a threat to the social reproduction of the patrilineage (Inhorn 1996, 4).

Another factor that may influence the spread of STDs is the fact that Egypt remains a popular tourist destination, both for visitors to the pyramids and pharaonic treasures and, more recently, for seekers of sand, sea, and sex who visit Red Sea resorts. Despite the growing conservative fundamentalist movement, Egypt is still more liberal than other Arab states.

### B. HIV/AIDS

According to United Nations statistics, North Africa and the Middle East accounted for less than 1% of the total number of people infected worldwide with HIV. In this region, 27,000 people have died from HIV-related illnesses, compared to 170,000 in Europe and 46 million in sub-Saharan Africa (as of 1997). The National AIDS Program in Egypt recently published the number of units of blood that have tested positive for HIV in each of the seven years prior to 1997. The prevalence of infection is low and there is no real evidence of an upward trend. For example, in 1990, 136,422 blood units were tested and only 4 were positive for HIV; in 1996, a quarter of a million units were tested and only 3 were positive (Lenton 1997, 1005). The data from blood donations is par-

ticularly interesting, because all blood collected in Egypt's public-health facilities is voluntarily donated by family members of patients. There is no evidence of either voluntary or non-voluntary donor referral. Egypt's medical surveillance of blood units is, therefore, a good indicator of the prevalence of HIV in the adult population.

Despite worldwide increases in the AIDS epidemic, AIDS is so far not spreading in any perceptible numbers in Egypt. Nonetheless, factors that contribute to the spread of HIV definitely exist, and anecdotal evidence suggests that other sexually transmitted diseases are widespread in the general population. However, while reliable survey data is not available, Egyptian medical experts claim that the negligible spread of HIV infection and AIDS in the general population is possibly the result of the Islamic moral code, which forbids adultery, sex before marriage, and homosexual practices. This indicates that widespread adherence to this code could mean that, while HIV infection occurs in small groups practicing sexual behaviors that increase their chance of infection, only rarely do individuals in the general population come into contact with at-risk individuals. Nonetheless, research into patterns of sexuality is needed in order to explain the low prevalence of AIDS in Egypt. Also, the lack of reliable data makes it difficult to gauge the real situation from the picture presented by official sources.

[Update 2002: UNAIDS Epidemiological Assessment: Egypt appears to be at a low epidemic level. A small number of sex workers, men who have sex with men, and drug users have been tested yearly and the rate of HIV infection remains very low. In 1999, only one HIV-seropositive case was found out of 236 men who have sex with men who were tested. Likewise, there is still no evidence from reported data that HIV prevalence among injecting drug users is high. However, the problem of HIV and drug use in Egypt, as in many countries of the Eastern Mediterranean, should not be underestimated. In a recent study on the prevalence and patterns of drug use in Egypt, the rate of injecting drugs was around 13% of all practices of drug intake. HIV among sex workers is still below 1%. Clearly, with the current level of reported information about HIV in Egypt, and the obvious gaps in the surveillance system of high-risk groups, it is difficult to draw any conclusive remarks about the situation and the trends of HIV in the country.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	8,000 (rate: < 0.1%)
Women ages 15-49:	780
Children ages 0-15:	NA

[No estimate is available for the number of adults and children who died of AIDS during 2001.

[No estimate is available for the number of Egyptian children who had lost one or both parents to AIDS and were under age 15 at the end of 2001. (End of update by the Editors)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

While there are no official studies on sexual dysfunction in the Egyptian population, it is widely known that Egyptian men are obsessed with enhancing sexual performance. While the men define enhanced sexual performance as prolonging intercourse, all remedies used suggest underlying occurrences of impotence. In recent years, Viagra has become very well known and popular in Egypt. During Ramadan 1999, better varieties of dates, which are very popular as one of the favorite foods for breaking the fast, were being sold under the names "Viagra" and "Monica" dates. Even melatonin, when it initially became popular on

the world market, was seen by Egyptian men as some kind of aphrodisiac, as a means for bringing one's youth back. Other remedies that are thought to be good for men are hashish, tea (but not mint or *karkadeh* or hibiscus tea), and other things which are "relaxing," for example, pigeon, sheep's feet, and also nutmeg. There are other more medicinal remedies available at the traditional pharmacies. In addition, there is *dahaan*, "ointments" of various kinds, local anesthetics also supposed to prolong erection. Many Egyptian men at the time of their wedding will seek advice on sexual aids in order to ensure that everything will "function properly."

Women's medicinal and folk medicinal remedies tend to center around issues of conception, pregnancy, and nursing. While many people are aware that female circumcision may lead to frigidity, as was mentioned above, it is still extremely common. Also worthy of mention is the cosmetic practice of hymen repair. Because of the fact that female virginity plays an enormous role in terms of the honor of a family and the bride involved, some doctors have developed the practice of sewing up ruptured hymens before an upcoming wedding night. This practice is particularly common among upper-middle-class and upper-class families, where the girls have been permitted more freedom in terms of their interactions with men before marriage, but where female virginity on the wedding night remains just as important as among the lower classes.

## 12. Sex Research and Advanced Professional Education

Sexological research is only in the initial stages in Egypt. While issues of family planning, mother and infant mortality, and women's reproductive concerns have been at the forefront of the Egyptian research agenda for quite a long period, other topics concerning sexuality are not. The growing fundamentalist movement further impedes any research that deals with issues of sexuality not directly related to reproductive issues.

There are no sexological organizations or publications in Egypt. The Egyptian Family Planning Association has its offices at: 66 Gazirat El Arab Street, Al Mohandissen, El Giza, Cairo, Egypt. Phone: 20-2-360-7329; fax: +20-2-360-7329.

[Update 2003: The Egyptian Society of Andrology (ESA) and the Pan-Arab Society of Impotence Research and Sexual Sciences (PASIR) are well established and popular societies in Egypt and the Middle East, working in the areas of erectile dysfunction and sexology. Egyptian consultants have also initiated several erectile dysfunction centers in Saudi Arabia and the Gulf area. Since 1985, the Andrology, Sexology, and STD Department at the University of Cairo has offered a doctoral degree, possibly one of the few in the world, in Andrology, Sexology, and STDs. The faculty have numerous publications in both national and international journals, including the *International Journal of Impotence and Sexual Research*. Most sexological work and publications from Egypt over the past 20 years have been done by members of ESA and PASIR—many of whom are members of both societies. Both societies maintain good relations and are supportive of each other's activities ([www.family-clinics.com](http://www.family-clinics.com)).

[Many eminent members of both societies have been active in local media to promote sexuality education and to fend off fundamentalist critics. Many are also working and actively educating against the practice of female genital mutilation (female circumcision), which is sadly still very popular in Egypt and many parts of Africa despite the laws passed against it. Others are working on updating the study

curricula for undergraduate medical students and for postgraduate degrees in Andrology, Sexology, and STDs at Cairo University. ESA and PASIR members provide a variety of educational, scientific, and community services. They are also very popular and respected figures within our scientific community. (End of update by H. Ghanem)]

## *Demographics and a Brief Historical Perspective*

ROBERT T. FRANCOEUR

### A. Demographics

The northernmost of the three Baltic states, Estonia is located in Eastern Europe, north of Latvia and west of Russia. To the north of Estonia is the Gulf of Finland and Finland. Estonia's western border is formed by the Baltic Sea and Gulf of Riga. With a total area of 17,462 square miles (45,226 km<sup>2</sup>), including 1,520 islands in the Baltic Sea, Estonia is slightly smaller than the states of New Hampshire and Vermont combined. The terrain is marshy and lowlands, with maritime, wet, moderate winters and cool summers.

In July 2002, Estonia had an estimated population of 1.42 million, or 1.37 million in the last national census of 2000 (Estonian Board of Border Guard, Statistical Office, <http://www.stat.ee/>). (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** *0-14 years:* 16.4% with 1.04 male(s) per female (sex ratio); *15-64 years:* 68.5% with 0.93 male(s) per female; *65 years and over:* 15.1% with 0.49 male(s) per female; *Total population sex ratio:* 0.86 male(s) to 1 female

**Life Expectancy at Birth:** *Total Population:* 70.02 years; *male:* 64.03 years; *female:* 76.31 years

**Urban/Rural Distribution:** 73% to 27%; 67.4% versus 32.6% in the 2000 national census

**Ethnic Distribution:** Estonian: 65.1%; Russian: 28.1%; Ukrainian: 2.5%; Byelorussian: 1.5%; Finn: 1%; Other: 1.8% (1998). The official language is Estonian, which be-

(CIA 2002)

longs to the Finno-Ugric language family and is closely related to Finnish. English, Russian, and German, along with Finnish, are also widely spoken and understood.

**Religious Distribution:** Evangelical Lutheran, Russian Orthodox, Estonian Orthodox, Baptist, Methodist, Seventh Day Adventist, Roman Catholic, Pentecostals, Word of Life, and Jewish. Since the 16th-century Protestant Reformation, the Evangelical Lutheran Church has played the leading role in Estonia.

**Birth Rate:** 8.96 births per 1,000 population; 9.5 in the 2000 national census

**Death Rate:** 13.48 per 1,000 population

**Infant Mortality Rate:** 12.32 deaths per 1,000 live births

**Net Migration Rate:** -0.73 migrant(s) per 1,000 population

**Total Fertility Rate:** 1.24 children born per woman

**Population Growth Rate:** -0.52%

**HIV/AIDS** (1999 est.): *Adult prevalence:* 0.04%; *Persons living with HIV/AIDS:* < 500; *Deaths:* < 100. (For additional details from [www.UNAIDS.org](http://www.UNAIDS.org), see end of Section 10B.)

**Literacy Rate** (defined as those age 15 and over who can read and write): 100% (1998 est.); compulsory school attendance from 7 years to 16 years of age

**Per Capita Gross Domestic Product** (purchasing power parity): \$10,000 (2001 est.); *Inflation:* 5.8% (2001 est.); *Unemployment:* 12.4%; *Living below the poverty line:* 25% (2000 est.)

### B. A Brief Historical Perspective KAI HALDRE

In the area that now forms present-day Estonia, the first settlements occurred some 11,000 years ago, after the last ice cap retreated. During the 12th century, the Baltic region was in the hands of the Teutonic Knights. Estonia was incorporated into Christendom at the beginning of the 13th century, under the pressure of crusaders from Germany and Denmark. During the 14th century, the power shifted to the Hanseatic League, with several Estonian towns and cities belonging to the League, including Tallinn (Reval), which had received its city charter as early as 1248.

In the first half of the 16th century, the Protestant Reformation reached Estonia. Since that time, Estonia has re-

\**Communications:* Elina Haavio-Mannila, Ph.D., Department of Sociology, P.O. Box 18 (Unioninkatu 35), FIN-00014 University of Helsinki, Finland; [elina.haavio-mannila@helsinki.fi](mailto:elina.haavio-mannila@helsinki.fi). Kai Haldre, M.D., Sexual Health Clinic, Suur-Ameerika 18A, Tallinn 10122, Estonia; [kaihaldre@hotmail.com](mailto:kaihaldre@hotmail.com). mained a part of the Lutheran cultural space. From 1558 onwards, Estonia became the battleground for a war involving Denmark, Sweden, Russia, and Poland. Sweden won the war and Estonia remained under her sphere of influence until the beginning of the 18th century. During Swedish rule, the first university in Estonia was founded at Tartu in 1632. The Great Northern War left Estonia under Russian rule (1721). Estonia became a window through which Peter the Great wished to gain access to Europe.

In the 19th century, the winds of numerous national movements blew through the whole of Europe. In Estonia, the period of national awakening began with the publication of Estonia's national epic *Kalevipoeg* in 1862.

The Estonian Republic was declared on February 24, 1918. At first, this was merely a decision made on paper. True independence was fought for between 1918 and 1920, during the War of Liberation. The struggle was crowned with success, and a treaty was finally signed with Soviet Russia, which revoked in perpetuity all claims over Estonia. During independence (1918-1939), Estonia established diplomatic relations and made its existence felt throughout Europe. Independence was curtailed by the signing of the Pact between Nazi Germany and the Soviet Union in 1939.

Following the Soviet occupation in 1940, Estonia became part of Nazi Germany from 1941 until 1944. The Soviet Union incorporated Estonia in the fall of 1944. A large proportion of the population fled abroad. Many others were arrested and deported to Siberia. Those who remained had to adjust to a new way of life. Estonia succeeded in regaining its independence when the Singing Revolution was signed in 1988, with full independence once more since 1991.

### 1. Basic Sexological Premises

According to the Estonian sexologists Imre Rammul, Olev Poolamets, and Tõnu Ots (2000), the sexological premises behind contemporary sexuality and sexual life in Estonia has deep roots:

Before Christianity, Estonians were quite liberal about sexuality. It was not a sin for a woman to be sexually active before marriage, in some places it was appreciated to have a child already before the marriage as it indicated the reproductive capacity of the woman. Folk merrymakings contained orgiastic elements. Special holy places were defined to carry out fertility rituals, using totemistic items and figures of the Fertility Goddess, *Maaema*. Thunder and rain were connected with male Gods; fertility and the harvest were influenced by female Goddesses.

Something like trial marriage was accepted for a period of one year. However, it was more a trial of reproduction rather than a testing of psychological compatibility.

These liberties were mostly accepted silently for non-married people. Later the society, especially men, tried to keep genetic purity with repressions aimed at those not following the rules. It seems that later as a result of Christian attitudes and traditions, abortions and killing of newborns became more common. Though Estonians have had some gender role models similar to those in neighboring countries, the historical background did not contribute to the opposition between genders. The reason is probably that marriage had traditionally been more like a social agreement rather than a trade. Also, women in the Estonian household had more power than men who were more involved outside the household. Marriage was not complicated by the rule that the manor lord had the right to intercourse with the wife on the wedding night.

Bridal ransom has never been a tradition in Estonia, the reason for that being unclear. It was enough to bring a

bottle of alcoholic drink to the parents of the bride while making the proposal. The parents also considered the economic capability of the man or made him work for the family. Even today the word to depict the son-in-law and the farmhand/servant is the same in Estonian and Finnish *sulane/sulhanen*. On the other hand, the bride was commonly required to have an amount of property—a special box that was called *veimevakk/dowry-chest*. Its contents included different handwork and jewelry and symbolized that the woman was industrious and not poor. In Estonia, many Christian sexual manners were combined with traditional paganistic habits.

Estonia was part of the Russian Empire in 1721-1918. It might sound surprising, but Russia, even before the beginning of the 20th century, was quite liberal in matters of sexuality. Probably, it was because of the early spread of atheistic ideas and later because of the attitude that during communism, everything is common (except one's own wife). Already in 1848, Shavrov issued his research about female sexual satisfaction. Later, Tarnadovski published *Female Sexual Disorders*. However, most research described statistics or deviant sexual behavior, mostly among men. A 1904 presentation by Nenadovitch at Pirogov Institute in St. Petersburg, on "Anaesthesia sexualis mulieris" (including classification of female sexual dysfunction), was an early cornerstone of Russian, and hence Baltic sexology.

A widespread study of students' sexual behavior was carried out by Tshlenov in 1909. It was already influenced by the coming Revolution and remains one of the last studies in the country. The results of the study were confiscated by the police.

The period of independence in Estonia between the two World Wars was a sort of pre-revolution before the real sexual revolution in the 1960s, with contradictory attitudes. There was an increase in prostitution, the coming out of sexual minorities, and the cult of nudity, but this raised opposition, creating moral police and organizations to promote the moral way of life. There were also some medical publications taking a stand against masturbation and polygamy as harmful practices. At the same time, nice romantic literature became internationally popular in *The Ideal Marriage* (1930) by Theodore Van de Velde and other similar works. Meanwhile, sexuality in school and university curricula was limited to its medical aspects.

During the Soviet occupation, human sexuality was a taboo in Estonia as it was all over the Empire until the end of the 1980s. This taboo was illustrated by the TV bridge between the USA and Soviet Union at the end of the 1980s, when one Russian lady announced, "There is no sex in Soviet Union."

In spite of that, already in the 1960s, several people tried to touch on sexual issues. For example, in 1964, urologist Mihkelsoo at Tartu University started to use human ribs to perform operations in the case of erectile dysfunction. At the end of 1960s, psychiatrist Heiti Kadastik from Tartu University started offering lectures on sexology for students. Kadastik also initiated translation and publication of a book by Finnish psychiatrist Martti Paloheimo, *Openly About Marriage*. This book, published in 1974, remained almost the only source of literature about sex for Estonians thereafter and became a cult itself. Psychoanalysis was represented by V. Vahing, who for several years had a private practice as well as taught students. Another key person in the development of Estonian sexology was psychologist Tõnu Ots, who started to answer questions about relationships in a youth magazine *Noorus* in 1971. He used the name Dr. Noormann, which remains a synonym for sexology counselor until today.

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A. Source and Character of Religious Values

The dominant religion in Estonia is Evangelical Lutheranism. Estonians were Christianized by the Teutonic Knights in the 13th century. During the Reformation, Lutheranism spread, and the church was officially established in Estonia in 1686.

At the same time, Estonian culture and politics influenced the traditions of the church. The privileges granted to the Baltic-German nobility by the Russian Czarist powers in 1743 to supervise the church, the schools, and hospitals paralyzed church activities, as the church lost its relative independence. The 1832 ecclesiastical law reduced the Evangelical faith in orthodox Russia to the status of a "tolerated" religion. In 1919, in the newly independent Republic of Estonia, control of the church passed into Estonian hands. Religious freedom was granted to all persons and all denominations. The Estonian Evangelical Lutheran Church with an Episcopal-synodical structure was created and soon grew to be the largest church in Estonia, with 80% of the population as its members. In 1925, the church was separated from the state, but religious instruction remained in the schools and clergymen were trained at the Faculty of Theology at Tartu University.

With the Soviet occupation and the implementation of anti-Christian legislation, the church lost over two thirds of its clergy. Work with children, youth, publishing, and so on, was banned, church property was nationalized, and the Faculty of Theology was closed. Although some church services were tolerated (Sunday church services and presiding over funerals), by the 1970s, less than 10% of Estonians were prepared to publicly state that they were Christians. It was not until 1988 that the state's religious policies became tolerant, and by 1990, repressive legislation was annulled.

Today, the Estonian Evangelical Lutheran Church is the largest church in Estonia, with 169 congregations and approximately 175,000 members. Although Estonia has never had a "state church," the predominant position of Lutheranism is based on a centuries-long tradition. The next in size, also with long historical traditions, is the Estonian Apostolic-Orthodox Church, with 58 congregations and approximately 18,000 members. Other Orthodox in Estonia belong to the Russian Orthodox Church, whose activity has not yet been coordinated with local laws. Third in size is the Alliance of Estonian Evangelical Baptist Congregations, which consists of 89 congregations with 6,100 members. Although official statistics imply one congregation for every 2,700 inhabitants, only 16% of the population has formalized their ties to a specific congregation. Most Estonians do not belong formally to any religious community. According to the Estonian sex survey of 2000, 22% of Estonian-speaking men and 19% of Russian-speaking men, and 37% and 50% of respective women consider religion important in their life.

### B. Source and Character of Ethnic Values

Most of the religious adherents among the country's Russian-speaking population are Orthodox, while the Estonian majority is predominantly Lutheran. There is a deep-seated tradition of tolerance of other denominations and religions. Although the majority of citizens are nominally Lutheran, ecumenical services during national days, Christian holidays, or at public events are common. Tension between the ethnic Estonian and ethnic Russian populations generally do not extend to religious matters.

According to the population and housing census in 2000, there are 1.37 million people living in Estonia. 80% of them are citizens of Estonia, 6% citizens of Russia, 0.7%

citizens of other countries, 0.6% with unknown citizenship, and 12% of the population are with undetermined citizenship. About 83% of Estonian citizens speak Estonian as their mother tongue, 15% speak Russian, and 1% speak other languages. One of the main priorities of the state integration program is to teach the state language, while at the same time creating opportunities for the different ethnic groups to learn their mother tongues. There are more than 140 ethnic groups represented in Estonia, forming around 32% of the population. The largest non-Estonian ethnic groups are Russians, Ukrainians, Byelorussians, and Finns.

The tensions between the ethnic groups in Estonia have culminated in citizenship laws. Estonian citizenship demands officially accepted Estonian language skills shown by a test. Non-citizens in Estonia are guaranteed basic rights under the Estonian Constitution, including the right to unemployment benefits and social services. Although they have no voting rights in Parliament elections, they can vote in local governance elections. This has caused problems in the process of joining the European Union, which will take place in 2004.

## 3. Knowledge and Education about Sexuality

In the late 1960s, a growing demand for sexual counseling initiated an idea to create a family counseling center in Tallinn. In 1975, this center started sexuality education lectures for the adult public and schoolchildren. Sexological counseling was provided by gynecologists, urologists, and psychiatrists. People from different specialties, mainly gynecologists and psychiatrists, could get postgraduate training in sexology in St. Petersburg (Leningrad), Moscow, or in Ukraine at Harkov or Kiev. Being a medical person gave a sort of "permission" to talk about sex. Educators generally lacked an interdisciplinary approach and presented the views of their own background.

Nowadays, sex education is included in the school health education curricula. There are nongovernmental organizations established in the first half of the 1990s, which provide information materials. Young people can visit the 15 youth counseling centers in different parts of Estonia to get individual counseling on reproductive and sexual health issues. Sexologists work in Tallinn and Tartu. Sex education had improved a lot at the end of the 1990s thanks, to NGOs and the empowerment of schoolteachers, the Internet, youth and women's magazines, and many other sources. These rapid recent developments are not yet reflected in statistics or research data. (See Section 5B, Interpersonal Heterosexual Behaviors, Adolescents, for survey data on sexual education and knowledge.)

## 4. Autoerotic Behaviors and Patterns

ELINA HAAVIO-MANNILA

### Children, Adolescents, and Adults

Masturbation is a common harmless practice. Nowadays, men and women with sexual problems are encouraged to masturbate in order to overcome their inhibitions (Kay 1992). People with a high interest in masturbation have been found to be less afraid of intimacy than those with no interest in masturbation (Rinehart & McCabe 1998). The way in which individuals view masturbation is linked to their perceptions of its nature and the consequences associated with it in a given culture, particularly during one's teenage years (Kontula & Haavio-Mannila 2002).

### Prevalence and Frequency of Self-Pleasuring

The Estonian sex survey of 2000 (see Haavio-Mannila & Kontula 2001) shows that 64% of men and 47% of women

respondents had practiced masturbation at some time in their life. In the past month, 33% of men and 22% of women reported having masturbated. In a Multiple Classification Analysis (MCA) with five predictors: gender, age group, type of relationship, education, and national group, Estonian-speaking respondents reported self-pleasuring more often than Russian-speaking Estonians. Younger and more-educated respondents reported masturbating more often than older and less-educated subjects. Type of couple relationship (married, cohabiting, living apart together (LAT), and being single) had no statistically significant association with masturbation. Compared to Finns and Swedes in the 1990s, Estonians were less likely to report masturbation, whereas, compared to people in St. Petersburg (and Finland in 1971), they were more likely to do so.

In 1996, Eesti Kirjandusmuuseum (The Estonian Literature Museum—ELM) in Tartu collected sexual autobiographies in response to advertisements in 17 newspapers and journals. Sixty-two sexual life stories were received. Thirty-eight of them were translated into English. The examples cited here are from the translated autobiographies. In terms of autoeroticism, these Estonian sexual autobiographies, especially those written by men, included a lot of stories about autoerotic behavior. Women less often wrote about autoerotic behavior than men. [This collection of autobiographies was organized by Rutt Hindrikus, supported by a grant received by a grant to J. P. Roos from the University of Helsinki. Merle Karusoo edited 21 of the autobiographies into a book (Karusoo 1997).]

These stories confirmed the common-sense assumption that young Estonian males learn autoerotic behavior from other youngsters:

Once one of my classmates invited me to their sauna. His two brothers, who were studying in technical school, and a boy from next door, would also be there. We five would have a real men's sauna! I went! The sauna was good and hot and soon all the youths were sitting lined up in a row, on the top step of the "stage," all naked of course. My classmate suggested we give ourselves erections and measure to see who has the longest tool. We had a wooden, folding ruler with clear numbers (meters). The erections were achieved with the help of soap and by sliding the foreskin back and forth until my tool was as taut as a bowstring (I felt it would snap any minute). My classmate and I measured 18 cm. His one brother's and the neighbor boy's measured 20 cm. and the third brother's was 22 cm. After we had finished measuring one of the older brothers said, let's jerk off and see whose sperm shoots the furthest. All five boys masturbated to climax and exploded with that great feeling and a huge spurt of white liquid. The first stream landed near the wall at the opposite side of the narrow washroom and every one thereafter increasingly closer until it merely trickled down the head of our shafts: Our tools were all swollen close to bursting—red, and with veins bulging. We were perspiring heavily and silent for a while, while we recovered. Then began the real sauna. We washed, birched and swam in the lake behind the sauna. This was the first time I had masturbated and have done so again later in life. (ELM 1996)

Getting intense pleasure from autoerotism makes the following young woman hypothesize that she will continue self-pleasuring also after marriage:

In about the ninth form (or earlier) I discovered something pleasant! Taking a bath I accidentally found out that it was awfully pleasant to direct the spout of water on my clitoris (at that time I did not know what clitoris was). I felt how

my body became tense; meanwhile the feeling was so strong that I could not direct the spout, and then the frantic end, and I was not able to continue that activity even for a moment. Soon I discovered that when to stop it for a while I could stand the feeling again. I was very happy about that discovery and thought that if the intercourse with a man was as pleasant, it was worth to be desired. I could take a bath several times a day and you may presume that someone might wonder why it took me so much time. I did not tell anyone about that, and even now that I am going to be thirty already I have confided in one friend only. I do not deny that I have to do that also when married. (ELM 1996)

Masturbation compensated for the lack of sexual commitment by men. Married and cohabiting men masturbated less often during the previous month (29%) than single men (40%) and men living in a separate steady relationship (36%). Nevertheless, having had intercourse during the past month was not connected to masturbation in the same time period.

Autoerotic behavior of women seems to be a more private, secret matter than that of men. Contrary to men, autoerotism and heterosexual activity during the past month were associated among women. Women who had had intercourse in the previous month masturbated more often than women who had not had intercourse—27% compared with 15%, respectively ( $p < .003$ ).

The gender difference was also apparent when one looked at the masturbation of women in different types of couple relationships. Twenty-two percent of married and cohabiting women had masturbated during the past month, slightly more than had single women (19%). Women who were living apart together in a committed relationship (LAT) were most active in self-pleasuring. As many as 33% of them had masturbated in the previous month. These connections are partly because of the different age composition of the four couple-relationship types. Separately living and cohabiting women were, on average, ten years younger than the single and married women subjects.

### *Predictors of Masturbation*

Beyond the influence of gender, age, relationship type, education, and nationality on experiences of self-pleasuring during the lifetime summarized above, is our deeper study of how the social background and some characteristics of the present relationship predict recent masturbation using stepwise regression analysis. Because we wanted to explore the impact of relationship factors, we excluded from the analysis people not living in a couple relationship as married, cohabiting, or having a steady sexual relationship without living together (LAT).

We found that recent masturbation (seven alternatives; see Table 1) was connected to mutual oral sex<sup>1</sup> (standardized beta coefficients were, for men .17 and for women .29), and finding pornography arousing (both genders .15).

For men only, being an Estonian-speaker instead of a Russian-speaker (beta .19), dissatisfaction with sexual life as a whole (beta .18), practicing manual sex (.21), frequent use of alcohol<sup>2</sup> (.14), and having had parallel relations dur-

<sup>1</sup>*Oral sex.* A sum scale composed of the five response alternatives in the following two questions: "In the last five years, how often have you had oral sex in your sexual relationships, that is, caressing a man's penis or a woman's genitals by mouth? Partner has/I have done [it] mostly, sometimes, seldom, 1-5 years ago, and not at all" (range 2 to 10).

<sup>2</sup>*Alcohol usage.* The six alternatives were: Daily, twice a week, once a week, a couple of times a month, once a month, and once in two months or more seldom.

ing the present couple relationship (.13) predicted masturbation too.

For women only, masturbation correlated with young age (beta .12), number of sexual partners during the past year (.18), and wanting to have intercourse more frequently in the present couple relationship<sup>3</sup> (.11). In addition, masturbation was associated with low quality of the present couple relationship<sup>4</sup> (.12).

The regression model predicted 29% of the variation of recent masturbation by men and 22% by women. When the influence of all these variables was controlled for, masturbation was not statistically significantly explained by, for example, education and recent intercourse.

These findings indicate that recent masturbation among people having a steady couple relationship is part of a *liberalized and versatile sexual lifestyle* (oral and manual sex, accepting pornography, having had several sexual partners, and frequent alcohol use). It is also connected to *problems in the couple relationship*. For men living in a steady sexual relationship, this can be seen in the association of recent masturbation with dissatisfaction with their sexual life and having had parallel relations. For women in couple relationships, the compensative nature of masturbation emerges as a connection between self-pleasuring and a low quality of the present steady sexual relationship and longing for more frequent intercourse with the permanent partner.

For single people, autoerotism is sometimes the only way to get sexual release, as is evident in the autobiographical passages above. According to the survey data, masturbation did not compensate for the single men's lack of a steady partner. Estonian men without a steady sexual partner practicing self-pleasuring were dissatisfied with their sexual life as a whole (beta .28). Their sexual lifestyle was versatile with recent experiences of oral sex (.30).

Among single women, the young ones (.30), those getting aroused by pornography (.24), and those having practiced oral sex (.24) had engaged in masturbation more recently than other women. Single women with recent experi-

ences of masturbation were as satisfied with their sexual life as a whole as were the women who had masturbated a long time ago or never. For single women, masturbation seems not to be a desperate attempt to cope with the "misery" of not having sex with a partner, which may cause dissatisfaction. In sum, autoerotic behavior is part of a liberated sexual lifestyle more often for single women than for single men.

## 5. Interpersonal Heterosexual Behaviors

### A. Children

There is autobiographical, but no statistical information.

### B. Adolescents

OSMO KONTULA

#### *Behavior and Knowledge*

After the incorporation of Estonia into the Soviet Union, sexuality was a taboo topic for decades, making it difficult to obtain sex information. As a consequence, the state of sex education in Estonia was poor until the 1990s. In the KISS (*Küpsemine Inimsuhted Sõbrad Sesksuaalsus*) survey (conducted in Estonia in 1994 among 1,080 schoolchildren at the 9th grade—15 year olds), a good level of sexual knowledge among Finnish boys was five times as high as among Estonian boys, and among Finnish girls eight times as high as among Estonian girls. In Estonia, the sexual knowledge level of the girls was lower than that of the boys. Adolescents with a low level of sexual knowledge mostly had not discussed these issues with their parents or friends, nor had they sought information from alternative sources (Papp et al. 1998).

Estonian society accepted adolescents' romantic feelings towards the opposite sex but disapproved of sexuality in the relationships of adolescents. Courtship in Estonia has had significantly less sexual intimacy than in Finland. Estonians had much less sexual intercourse in their courtship than did Finnish adolescents. A double standard for males and females was common: 18% of boys and 5% of girls reported that they had experiences of sexual intercourse. For masturbation, these figures were 14% and 6%, respectively. During the occupation, articles published, as well as programs of sex education for schools, presented masturbation to adolescents as a vice and recommended weaning oneself away from it.

In 1999, another KISS survey was conducted among 1,676 students in the 9th grade. In this survey, girls showed a marked improvement in their knowledge compared to 1994. The number of pupils with poor sexual knowledge had been cut in half. Topics concerning sexuality began to be discussed more frequently in schools during this period. However, a fifth of Estonian pupils and half of the Russian pupils said that questions concerning sexuality had not been discussed in the classroom in this or in previous years. As a source of information, video films and pornographic magazines were popular among boys, and articles in women's and youth magazines among girls. Sexual intercourse was experienced by 9% of the 15-year-olds in 1994 and by 14% in 1999. The increase was much more pronounced among girls. Slightly over half of the respondents of Estonian origin had used a contraceptive (mainly a condom) in their first intercourse. Condom use had not increased during the five-year follow-up (Papp et al. 2001).

In a 2000 sex survey of adult Estonians, only 10% of the people who belonged to the middle-age group (35 to 54 years) and an equal proportion belonging to the old-age group (55 to 74 years) reported that they had received enough sexual knowledge from their parents. In the youngest generation, this proportion was almost a quarter. More-open discussion about sexual issues had started in homes, although only in exceptional cases.

According to the responses in the 2000 survey, there has not been much sex education in Estonian schools before the

**Table 1**

#### Time of Latest Masturbation Event, in Percent

Masturbation	Men		Women	
	Estonian speakers	Russian speakers	Estonian speakers	Russian speakers
During the past 24 hours	9	3	4	4
During the past week	15	8	7	6
During the past month	14	11	13	7
During the past year	11	9	14	15
1-10 years ago	9	12	8	6
Over 10 years ago	11	10	4	3
Never	31	47	50	59
Total	100	100	100	100
Number of respondents	301	142	329	192

<sup>3</sup>Wanting to have more intercourse. The four alternatives were: I would like to have intercourse clearly more often, somewhat more often, I am satisfied with the present frequency of intercourse, and I would like to have it less frequently.

<sup>4</sup>The quality of the relationship was measured by a sum scale based on dichotomic variables of happiness of the couple relationship, open communication on sexual matters with the partner. The opposite of low-quality relationship is high-quality relationship, HQR (see Kontula & Haavio-Mannila 2003).

1990s. Only a few percent report that they have received enough knowledge in sexual issues in their school. Even in the youngest generation, this proportion was only around 10%; the comparable figure was two thirds in Finland. Even though the available knowledge and material (including pornography) have increased in the 1990s, there is still a major deficit in sexual knowledge in Estonia.

### Dating

Forty-eight percent of Estonian-speaking men and 43% of Estonian-speaking women had dated before they were 18 years old. For Russian-speaking men and women these proportions were 38% and 41%. The average age for the first dating was 18.2 years for men and 18.3 years for women. This age had decreased for both genders. In the oldest generation (age 55 to 74), the average age at first dating was 20.0 years.

Young Estonian men dated for the first time when they were around 17 years old, about the same age of their Finnish cohort. Compared to their Finnish counterparts, Estonian women dated for the first time at an older age, having started dating, on average, at 17 years old. This was a year later than in Finland. Among Estonian women, the average age of first date was comparable to that one generation ago in Finland.

### Sexual Debut

According to the Family and Fertility Survey carried out in 1994 in Estonia, 40% of those age 20 to 24 had started sexual life by age 18, compared with 14% in the age group 40 to 45 years. The mean age of first sexual intercourse in these age groups was 18.4 and 20.1 years, respectively. According to the Estonian Health Interview Survey carried out in 1996, 40% of women in the age group 20 to 25 and 10% of women in the age group 40 to 45 had had intercourse by age 18 years.

In the 2000 sex survey, 42% of Estonian-speaking men and 29% of Estonian-speaking women had had intercourse by the age of 18. For Russian-speaking men and women, these proportions were 38% and 21%, respectively. A third of Estonian-speaking women and half of Russian-speaking women had experienced first sexual intercourse after they were 20 years old. The age of sexual initiation has been higher for those whose level of education has been higher than average.

The age of first intercourse has been changing in Estonia in much the same way as in most other European countries, only the timing of this transition has been one generation later than in most Western European countries. In the female generation born in 1927 to 1931, the average age of first intercourse was 22.3 years; in the female generation born in 1972 to 1976, intercourse came, on average, at 17.5 years. During these years, the average age of first intercourse had decreased by as much as almost five years. Among men, a similar decrease occurred from 19.7 years to 17.3 years, a smaller decrease of only two and a half years. A couple of generations ago, men had their first intercourse two years younger than women in the same age group. In today's youngest generation, there is no longer as much difference between genders in sexual initiation.

In comparison to the neighboring countries, young men in Estonia experienced their first intercourse almost at the same age as in Finland. The other men in Estonia had had their first experience when somewhat older than men in Finland, but roughly at the same age as men in St. Petersburg.

Estonian women had experienced their first sexual intercourse significantly later than women in Finland. In each age group, Estonian women had their sexual debut on the average of one or one and a half years later than Finnish women. This difference was even bigger between Estonia

and Sweden. The decreasing trend in Estonia has followed the trend measured in Finland, with a 20-year delay. The decrease in the age of sexual initiation started earlier in Estonia than in St. Petersburg.

Estonian women had a higher age for sexual debut than men, and they also married younger than men. In the 2000 survey, the average age at first marriage was 23.8 years for men and 21.8 years for women. This implies that, on the average, women have had several years less sexual experience than men before they marry. Almost half of women and a quarter of men married their first sexual partner. This proportion had been higher among Russian-speaking men and women than among Estonian-speaking men and women. It has also declined from one generation to the next.

The Western sexual revolution that reduced the average age of female sexual debut in Western European countries by two to three years from the 1960s to the 1990s, arrived in Estonia and Russia one generation later than in the West (Bozon & Kontula 1998; Kontula 2002; Kon 1995). This one-generation difference has been found, for example, in attitudes towards sexual activities of teenagers. Sexual initiation in Estonia has been more limited to engagement and marriage than in the other Western European countries, and young men have had more sexual freedom than young women. A sexual double standard still exists in Estonia. However, among the young generation, already four fifths of Estonian men and women approved of teenagers' sexual intercourse, provided they are going steady.

In a European comparison, the age of sexual initiation in Estonia was found to be fairly high, even though trends have followed the Eastern European trends. The Estonian male debut age in the last two generations has been one of the highest in Europe. The Estonian female debut age was as high as in Portugal, which had the highest debut age in Western Europe, but lower than, for example, in Romania, Moldova, and in some cities in Russia (Kontula 2002).

### C. Adults

ELINA HAAVIO-MANNILA

Here, we look at marriage and family structures and patterns in Estonia using several indicators: people's couple relationships at the time of the surveys, and then their lifetime relationship patterns (numbers of marriages, cohabitations, and sexual partners, and experiences of love at work). A brief passage discusses the number of sexual partners in the past year. A considerable part of this section is devoted to parallel or extra sexual relationships and attitudes toward marital fidelity. Finally, we look at the ideal sexual lifestyles of people in Estonia.

#### Sexual Relationships

*Type of Couple Relationship.* More than 40% of the respondents in Estonia were married, one fifth was cohabiting, and one fifth had a permanent sexual relationship without living together—living apart together (LAT). About 20% of men and 30% of women were at present living without a steady sexual relationship. Estonian-speaking men were more often single (26%) than Russian-speaking men (15%). Compared to people in Sweden, Finland, and St. Petersburg, people in Estonia were less often presently married. There was, however, quite a lot of cohabiting and separately living (LAT) people. Thus, the proportion of people in a couple relationship (marriage, cohabitation, or LAT) was about the same as in the neighboring countries.

*Duration of the Present Relationship.* On the average, people in Estonia had lived 15 years in their present couple relationship. According to MCA, there was no statistically significant gender or national difference in the duration of the relationship. Self-evidently, the unions of younger people

were shorter than those of the older ones. The unions of the officially married persons had lasted on the average of 20 years, those of the cohabiting people 11 years, and those of the people with a steady relationship living separately only 8 years. There was a weak association between the education of the respondent and the duration of his or her relationship. The unions of the least educated had lasted longer, 17 years, compared with 15 and 14 years for people with the middle and highest education, respectively.

*Number of Marriages or Cohabitations.* Quite a lot of Estonians were not with their original marital or cohabiting partner. Thirty percent of the ever-married or cohabiting Estonian-speaking men and 26% of Russian-speaking men in Estonia had been married or cohabiting more than once. For women, the proportions were 34% and 28%. On the average, the ever-married or cohabiting persons had been married or cohabiting 1.4 times. MCA showed that there was neither gender nor educational differences in the number of unions. Older, cohabiting, and Estonian-speaking people reported more marriages or cohabitations than the others.

In Finland in the 1990s and in St. Petersburg, fewer people than in Estonia had been married or cohabiting more than once. In the older age groups, multiple marriages were more common in Sweden, Estonia, and St. Petersburg than in Finland.

*Lifetime Sexual Partners.* The average number of sexual partners in a lifetime was 13 for Estonian men and 16 for Russian men in Estonia. In both ethnic groups, women had had, on average, 5 sexual partners. Very few, 12% of men and 22% of women, had had only one sexual partner. A large gender gap can also be seen in the finding that 40% of men and 17% of women had had at least 10 sexual partners. There were no significant age, educational, and national-group differences in the number of partners. Married and cohabiting people had had fewer partners (8) than the separately living (13) and single people (10).

Finding out the large number of partners of her partner was a shock to a 71-year-old woman teacher:

I found his notebook, where he had put down the names and birthdays of his girls, and the dates when the relationship had began. My name occupied the 78th place. I cannot describe the disgust I felt reading that list. It was just as if I had sunk into deep, stinking and sticky mire; the taste of it was in my mouth. Where was the deep and happy first love, which should have given support in all hardships of life? . . . Oh how right had been my father, trying to persuade me to give him up. I told myself that as I had chosen that path myself, I had to bear my cross without letting anybody know about my sufferings. (ELM 1996)

For a 54-year old Estonian man, it was not a big deal to have several lovers:

Anyway, that bottle of cheap, 1.60 rubles wine set me going on a merry-go-round of sex affairs, which did not stop for a number of years and involved a frequent change of partners. There were women whom I did not even ask the name and there were some who I kept seeing for a long time. The older I got, the more "luck" I had with women older than myself and married ladies. I liked the latter because with them there was no need to talk about love or promise to be true to the end of my days (which in fact I never did); it was enough to pay them some compliments and hear the usual story of a drinking, unfaithful or brutal husband and find the words of consolation. (ELM 1996)

The number of sexual partners in Estonia was about the same as in Sweden and Finland. Inhabitants of St. Petersburg

had had fewer partners. In Sweden and Finland, the middle-aged respondents reported the highest numbers of sexual partners in a lifetime, and oldest people the lowest numbers. Contrary to this, in Estonia and St. Petersburg, the number of partners of the youngest people was the largest. This indicates that sexual liberalization has been quite recent and most powerful among young Estonian and Russians in Estonia.

*Sexual Partners During the Past Year.* A majority of Estonians who had had intercourse in the past year had only one sexual partner: two thirds of the men and 85% of the women. One quarter of Russian men and 14% of Estonian men had had at least three partners. In Estonia, having had several sexual partners during the past year was much more common in the younger age group (average 2.1 partners) than in the middle and older age groups (1.4 and 1.6 partners). Married and cohabiting people had fewer partners (1.5 and 1.3) than people living apart together (2.5) and single people (2.6). Education did not predict the number of partners during the past year. In the past year, Russians in Estonia had had more partners (2.0) than Estonians (1.6).

*Love at Work.* In Northern Europe, most women work for pay and there are plenty of opportunities to find interesting love objects in the workplace. About every second Estonian had experienced "falling in love" at work, with a coworker or someone else met at work. Only 2% to 6% of the respondents were in an affair at work at the time of the survey; the others reported past affairs or infatuations. There were no statistically significant differences between men and women or in the type of their steady relationships. Middle-aged people, as well as those with higher education had fallen in love at work more often than the others. Estonian men had experienced a work romance slightly more often (51%) than Russian men, 51% versus 40%. The incidence of love at work in Estonia did not differ from that in Finland or in St. Petersburg.

*Incidence of Parallel Relations.* Having had parallel or extra sexual relationships in addition to a present marriage or cohabitation was more common among men than among women. In Estonia, 35% of Estonian men and 39% of Russian men had engaged in a parallel relationship during their present marriage or cohabitation, compared with only 24% and 21% of respective women. Most of the parallel relationships had been casual. Only 7% of Estonian men and 12% of Russian men in Estonia reported regular parallel relationships; for women it was 6% and 4%, respectively.

Age group, education, and nationality did not predict parallel relations, but the type of couple relationship did. As many as 43% of people living apart together had had a parallel relationship during their current LAT. Only 30% of the married and 17% of cohabiting persons had had parallel relations during their present union. Parallel relations of men were more common in St. Petersburg than in Estonia. The proportion was about the same as in Finland in the 1990s. Women in Estonia and St. Petersburg had been unfaithful more often than women in Finland.

The quality of the couple's relationship predicted faithfulness in marriage or cohabitation. This was especially true for men. For Estonian men with a "high quality relationship"—defined as a happy couple relationship with easy communication and mutual love (see discussion of Sexual Satisfaction below)—only 28% had been unfaithful during their marriage or cohabitation. For men with a poorer quality relationship, as many as 52% had had one or more affairs. For women, the proportions were 24% and 41%. Also in the sexual autobiographies, parallel relationships were often explained as a consequence of a poor marital relationship. The same connection between fidelity and

the quality of the relationship was found also in St. Petersburg and Finland (Kontula & Haavio-Mannila 2003).

Four excerpts from the ELM archives illustrate the varieties of parallel relationships, starting with the most common type: *extramarital relations of men with non-married women*.

The following married male teacher was asked by a single woman to take her virginity and even make her pregnant:

There was a girl from the Faculty of Medicine who was especially keen on helping me, even after her graduation. And what came out, she had been in love with me. She was already twenty-eight years old, but still a virgin. In the end, she asked me to help her to lose her virginity. I had never in my life had sex with a virgin before, I agreed willingly. We drove out of the town, it was June and a very beautiful day. It was near Tartu, on a nice grassy meadow, where we managed to get rid of her virginity. But that was not enough for that girl. Later, she asked me to give her a child; she promised to raise it herself, without bothering me. Now I regret it, but then I agreed. She chose the most suitable time for conceiving and got pregnant from the very first effort. She kept her promise and had a very fine son all by herself! Her son is a grown man already, a bright and energetic person, his mother is still grateful to me. (ELM 1996)

Affairs by *married women with unmarried men* were rare. The following story is from a married woman architect who had had a satisfying extramarital romance while studying abroad:

In summer after my fourth year of university I had the chance to go abroad through the student exchange. We visited the Bratislava Art Institute. Half of the group was from Tallinn Art Institute and half from Kiev Art Institute. It happened somehow that I became friends with a young man from Kiev called Vassili. We went together through the wonderful art galleries of Prague and went walking in the evenings. We had our first sexual intercourse somewhere on the park-bench. I was awfully ashamed because I was married but Vassili said there was no difference if I was with him just once or more and so I went with him also to his hotel-room. Vassili was very good but I understood it really when I went to visit him in Kiev in my fifth year. Vassili liked to sex long and energetically. I do not know where he got his endurance. He trained himself at yoga. Maybe it helped? (ELM 1996)

Men enjoyed when they happened to have ample opportunities to get new women (and good food) through their work. A 68-year-old male teacher took advantage of tourist trips on which he met women traveling alone:

In the Soviet Union I went on the tourist trips that took me all over the country, as a rule, these were quite long ones, and many women were traveling alone. I usually went in August, as the grapes and other fruits were ripe by that time. The fruits were helpful with sex too. And in the southern republics it was possible to taste all kinds of local wines, which was also very helpful in forming relationships. So I met plenty of willing women on those trips. The local women tended to appreciate a man from a Baltic country very much. (ELM 1996)

For some married women, it was difficult to abstain from sex because of the absence of the husband who was working or studying far away. A 69-year-old chauffeur writes about these women as follows:

There is also another group of women and men who have extramarital affairs. These are women whose husbands

are away from home for a long time, they are either taking some courses, in the army or long business trips. They just need a partner who would be alive and there with them. I once met one such woman. She worked in our ministry. Her husband was sent to some course in Leningrad; it had something to do with the Communist Party. One day she dropped me a note to meet at our common friend's place. I went there but my friend wasn't home. The woman had a lot of difficulty explaining that she just wanted to make love. I freed her from tormenting herself. Through my wife I knew that some women have really bad time when they don't have a sexual partner. (ELM 1996)

*Attitudes Toward Marital Fidelity.* Attitudes toward temporary infidelity of a husband were more liberal than toward an unfaithful wife. In Estonia, men were more permissive than women, especially when it was a question of male unfaithfulness. A very clear ethnic difference could be seen in the attitudes of Estonians and Russians in Estonia in permitting temporary infidelity by a husband. As many as 60% of Russian-speaking men, but only 27% of Estonian-speaking men accepted it. On this issue, Russian men in Estonia were even more permissive than men in St. Petersburg. Also, in respect to temporary infidelity by a wife, Russian-speaking Estonians were very permissive compared to Estonians. The results of MCA showed that age group and education did not explain the attitudes of people in Estonia toward fidelity, but the type of couple relationship did. People in LAT relationships were more liberal than the others.

In comparing people in Finland and St. Petersburg, russophones in Estonia were very permissive in regard to marital infidelity. Only men in St. Petersburg were close to them in accepting male infidelity.

The attitudes of Estonians on infidelity were amply expressed in the sexual autobiographies. Most of those who gave their opinion on this issue were quite permissive. A 28-year-old unemployed man reports:

Adultery? On the one hand I consider marriage to be a holy union, but on the other hand I do not think that husband and wife belong to each other only and are each other's property. Sexual intercourse can happen out of love of adventure or of friendship or it can just be a casual act between two people. A person is still a very many-sided creature, and why cannot s/he have friends outside of marriage, with whom occasionally to go to bed with? Simply one's feelings should be under control and not let the situation grow beyond oneself. But I still think that if one of the partners finds a new one for him/herself, there is still something wrong in the relationship and it should be an alarm signal. Before that, one should still think whether the "danger" exists and how serious it is. (ELM 1996)

The same opinion is expressed by a 68-year-old divorced woman worker:

And I am not so negative about extramarital relations—that might sometimes improve the situation, the man or the woman might find that another partner is no better than the old one. (ELM 1996)

But there were also negative attitudes. The following 58-year-old woman teacher was ashamed of her extramarital relations and strongly condemned them.

I, too, at first out of defiance, later simply because of opportunities had some extramarital affairs. . . . I would give much . . . to undo it. Out of my own experience it is perfectly clear to me that the highest value of a woman is her moral pureness, not the number of men whom she can get into her bed. On the basis of present-day attitudes I could

even look for justification. Maybe my marriage did not satisfy me. . . . [But] I am ashamed and regret until now, more than thirty years later. (ELM 1996)

*Ideal Sexual Lifestyle.* The ideal sexual lifestyle of Estonians varied a lot. The most-often-chosen lifestyle was living married without other sexual relationships. It was chosen by about 30% of men and 40% of women. The next-popular lifestyle was living together with a partner without marriage (cohabitation) and without other relationships—about 15% of both genders. Thirteen percent of men, but only 3% of women preferred marriage with parallel relations. Seven percent of men and 2% of women preferred cohabitation with parallel relations. Women were more likely to choose separate living as their favorite sexual lifestyle than were men—12% versus 6%. Surprisingly, 12% of the women did not have any sexual relationship in their life; 4% of the men were also in a celibate lifestyle. The gender differences can be summarized by saying that men preferred marriage or cohabitation with other relations, women preferred separate living or no sexual relations. The differences between Estonians and Russians in Estonia were very small.

Compared to Swedish and Finnish men, Estonian men more often preferred as their ideal lifestyle marriage or cohabitation with parallel relations. Estonian women would choose celibacy as their sexual lifestyle more often than women in Sweden and Finland. (Haavio-Mannila & Kontula 2001, 150-151). This indicates that there may be some problems in the couple relationships in Estonia.

### *Sexual Behaviors*

Sexual behaviors were studied using the time since most recent intercourse, position in last intercourse, attitude toward women taking an initiative in sexual contact, manual and oral sex, orgasm in intercourse, and erection problems.

*Time Since Last Intercourse.* In answering the survey question "When was the last time you had sexual intercourse?" men reported more-frequent intercourse than women. Seventeen percent of the men and 12% of the women had had coitus in the last 24 hours; 34% and 27% in the past 2 days (cumulative percentages); 44% and 38% in the past 3 or 4 days; 56% and 46% in the past week; 66% and 55% in the past 2 weeks; 74% and 61% in the past month; 83% and 67% in the past 3 months, 90% and 73% in the past year; 93% and 78% in the past 2 years; 98% and 89% in the past 10 years; and 2% and 11% more than 10 years ago.

There was very little difference between Estonians and Russians in the time since last intercourse. Fifty-seven percent of the Estonian men and 54% of the Russian men in Estonia had had intercourse in the past week, of the women 48% and 44%, respectively. Younger people were more active than older people, persons living in a steady relationship more active than singles, and Estonian-speakers more active than the others. Education did not make any difference in sexual activity, when the influence of the other factors was controlled for in the MCA. Fewer Estonians had had intercourse in the past month than people in Finland and Sweden and men in St. Petersburg. Especially the older Estonians and Russians had stopped having intercourse when they have grown older.

*Position in Last Intercourse.* The most common position in sexual intercourse was laying face-to-face, man on top and woman underneath. As many as 37% of men and 40% of women in Estonia reported that this "missionary" position was the only position used in their last intercourse. The reverse position, with the woman on top and man underneath, was the only position used by 12% of men and 7% of women. Lying side by side was the only position in the in-

tercourse reported by 8% of both genders; 6% of men and 7% of women used other positions, and 30% of men and 28% of women used two or more different positions.

Using several positions in the latest intercourse did not differ by gender or national group. Young people had used versatile positions more often than the older ones. People in LAT relations had most often used several positions (42%, people with other types of relationships 25% to 28%). More-educated persons were slightly more likely to engage in different positions than the less-educated. People in Estonia used several positions in their last intercourse to the same extent as Finns in the 1990s and people in St. Petersburg (and clearly more than Finns 30 years earlier).

*Attitude Toward Gender Equality in Initiating Sexual Contacts.* In the Western world, initiation of sexual contacts by women has traditionally been rare; women were expected to be passive and men active in sexual interaction. In Estonia, 93% of Estonian-speaking men and 69% of respective women and 86% of Russian-speaking men and 67% of respective women totally or somewhat agreed with the statement: "Women have every right to take the initiative when they want sexual contact with men." Supposedly, it is taken for granted that men have this right. Thus, we take the attitude toward the statement as an indicator of attitudes toward gender equality in sexual initiation.

According to MCA, men were more favorable toward female initiative than women themselves were, young people more favorable than older people, people in a couple relationship more favorable than singles, and Estonian-speakers more favorable than Russian-speakers in Estonia. Compared to Finns, people in Estonia and St. Petersburg were less gender-equality oriented. Only the Finnish female respondents 30 years ago were as reluctant to give women the right to initiate sexual contacts with men as were women in Estonia and St. Petersburg.

*Oral Sex.* A majority of the respondents had engaged in oral sex. This was measured by the question: "How often have you had oral sex in your sexual relationships, that is, caressing a man's penis or a woman's genitals by mouth in the last five years." The response alternatives were presented separately for passive oral sex received from a partner and active oral sex given to a partner.

About 60% of the respondents in Estonia had received or given oral sex in the past five years. Men reported oral sex somewhat more often than women did. There was no difference between the Estonian and Russian speakers in Estonia. Younger people were much more likely to report mutual oral sex (81% of the 18- to 34-year-olds) than middle-aged (53%) and older people (13%). Living in a LAT relationship and having higher education were connected to the practice of oral sex. In Sweden and Finland, mutual oral sex was more common than in Estonia. In St. Petersburg, men reported mutual oral sex as often as in Estonia, but women less often. Among young people, national differences in having practiced oral sex were small. Estonia and St. Petersburg differed clearly from Finland and Sweden in the older age groups, where oral sex was rare.

*Manual Sex.* Giving a partner satisfaction by hands was quite popular in Estonia. Men reported it somewhat more often than women did: only 28% of men, but 37% of women had never given manual sex. Twenty-two percent of men and 16% of women had given manual sex to his or her partner during the past 7 days, 26% and 31% at most a month ago (cumulative percentage), 40% and 40% 1 to 6 months ago, 47% and 46% 6 to 12 months ago, 55% and 54% 1 to 5 years ago, and 62% of men and 63% of women more than 5

years ago. Younger people had practiced more oral sex than the older ones; people living in a LAT relationship more than the those living in the other types of sexual relationships; the more educated more often than the less educated, and Russian speakers more often than Estonian speakers. In Finland, manual sex was somewhat more common than in Estonia, especially in the older generation.

*Orgasm in Intercourse.* Having defined an orgasm as “sexual pleasure ending to relaxation and very good feeling,” the question was: “Have you got an orgasm during sexual intercourse?” Men reported orgasm much more frequently than women did. Only one in ten women reported that they had always reached orgasm in intercourse, of the men about 60%. Russian-speakers reported orgasm more often than Estonian-speakers did.

Frequent orgasm in intercourse was, according to MCA, related to male gender, young age, living in a permanent sexual relationship, and higher education. The statistical significance between the national groups disappeared when the impact of the other variables in the model was adjusted for. International differences in getting orgasm (almost) always were very small, both among men and among women.

In Estonia, Finland, and St. Petersburg, getting an orgasm (almost) always in intercourse was more common among younger than older women, with the exception that in the youngest age group (18 to 24 years), it was not very frequent. In Sweden, however, elderly women reported orgasm as frequently as middle-aged women.

*Erection Problems.* Two thirds of Estonians reported having at least sometimes encountered problems with male erection in their sexual encounters. The question was phrased as follows: “It is not uncommon that a man cannot enter into sexual intercourse because he cannot get erection or his penis becomes flaccid right when sexual intercourse is started. In the last year, has something like this happened to you/your partner?”

Men reported erection problems somewhat more often than women did for their partners. Estonian-speaking men had had more erection problems in the past year (49%) than Russian-speaking men (33%). Female respondents of both ethnic groups reported equally often that their male partner had had erection problems—38% and 32%. Erection problems strongly increased with age. The less educated reported them much more often than the more educated. Type of relationship was not related to erection problems.

Erection problems were a little more common in Estonia than in Sweden and Finland in the 1990s. There was a large regional difference in the share of men with erection problems among the 35- to 54-year-olds. More than 70% of people in Estonia, but only 50% to 60% of Swedes and Finns reported erection problems in the past year. Erection problems were very common among the 65- to 74-year-old Estonian speakers—96%.

Sexual behavior of the Estonian- and Russian-speaking people in Estonia was, in most respects, very similar. Russian respondents in Estonia reported more often to giving their partner manual sex, always reaching orgasm in intercourse, and having less often had erection problems than Estonian-speakers.

### *Sexual Satisfaction*

In the Estonian sex survey 2000, we asked about satisfaction with sexual life as a whole, satisfaction with the frequency of intercourse in the present couple relationship, pleasure derived from intercourse, quality of the steady relationship (happiness of the couple relationship, easiness of talking about sex with the partner, and mutual love), and sex-

ual self-esteem (to what extent the respondent considers him- or herself to be sexually skillful, active, and attractive).

*Satisfaction with Sexual Life as a Whole.* About 25% of Estonian-speakers in Estonia and 33% of Russian-speakers were very satisfied with their sexual life as a whole. Forty-two percent of male Estonian-speakers and 40% Russian-speakers, and 36% and 22% of women, respectively, were fairly satisfied with their sexual life. About 20% found it unsatisfactory. The rest considered their sexual life as neither satisfactory nor unsatisfactory. Russian women in Estonia gave more-extreme responses (very satisfied or not satisfied) than Estonian women, but the average satisfaction of the two female groups was the same.

According to MCA, there was a bimodal relationship between age and sexual satisfaction in Estonia. The younger and older people were more satisfied with their sexual life than the middle-aged were. People with a steady sexual relationship were very much more satisfied than single people. People in Estonia were less satisfied with their sexual life as a whole than Swedes and Finns were. Estonian men of both ethnic groups were as satisfied as men in St. Petersburg. Estonian women were more satisfied than women in St. Petersburg.

In the four research areas, satisfaction with sexual life as a whole varied by age in different ways. In Sweden and Finland, age differences were small. In Estonia and St. Petersburg, there was a sharp decline from the age group 25 to 34 years to the 45- to 54-year-olds, but then an increase toward the oldest age groups.

*Pleasure from Intercourse.* Thirty-five percent of Estonian-speaking and 34% of Russian-speaking men considered their sexual intercourse very pleasurable; of the respective women 19% and 23%. A majority, about 57% of men and 61% of women, reported that intercourse is quite pleasurable. Six percent of Estonian- and 11% of Russian-speaking men, and 18% of women in both ethnic groups evaluated intercourse as not pleasurable.

Younger people in Estonia enjoyed coitus more than middle-aged and older people. Cohabiting and separately living people found intercourse more pleasurable (mean on a 5-point scale was 4.2 to 4.3) than married (4.1) and single (4.0) people. The more-educated people enjoyed intercourse more than the less-educated ones. An international comparison reveals that Finns found intercourse more pleasurable than people in Estonia and St. Petersburg.

*Preferences for Frequency of Intercourse.* Two thirds of men and 45% of women in Estonia would like to have more-frequent intercourse in their couple relationship than they have at present. This indicates that there is a lot of unsatisfied sexual desire in Estonia. Only 1% of men and 6% to 9% of women wanted to have intercourse less often. The rest considered the frequency of coitus to be suitable.

More younger and middle-aged (64% and 60%) than older (46%) people would have liked to have more-frequent intercourse with their steady partner, in spite of the fact that the younger and middle-aged persons actually had had more recent intercourse than older persons. People’s level of aspiration in regard to frequency of intercourse seems to decline with growing age. Also, the generation one is part of may have an impact: In the older generations, people may have had learned to demand or expect less-frequent sexual activity. Type of relationship and education did not predict preferences for frequency of intercourse. Compared with Finland and St. Petersburg, more people in Estonia would prefer more-frequent intercourse in their couple relationship than they have at present. The wide gender gap in the

attitude toward frequency of intercourse was visible in all research areas. Everywhere, men would like to have more frequent intercourse than women did.

*Quality of the Couple Relationship.* Three indicators of the quality of the couple relationship were used in the Estonian sex survey of 2000: mutual love, happiness of the couple relationship, and ease of communication on sexual issues with the steady partner.

About 55% of Estonians of both genders and both nationalities felt that there is a man or a woman whom they really love, and the same proportion thought that they are really loved by some man or woman. The very young ones least often felt love. In the middle-aged and older age groups, the feelings of love decreased with growing age among women, but in the older male groups, love did not decrease with age. On the contrary, the oldest men very often felt love and being loved. This may explain their satisfaction with sexual life, which will be described below.

Married and cohabiting people reported mutual love most often—66% of men and 67% of women. Women in LAT relationships told of mutual love more often (58%) than LAT men (46%). Single people very seldom (men 9% and women 7%) thought that they loved and received love. The feeling of love was equally rare in Estonia and St. Petersburg. In Finland in the 1990s, three quarters of the respondents felt love and being loved. In their lack of love, Estonians and Russians resemble Finnish men 30 years ago.

A 61-year-old woman teacher tells about companionate marital love that has lasted for a long time:

I have been loving my husband for almost 40 years. Our marriage is continuously directed and guided by mutual respect and decency but we have certainly had the moments of excitement, burning passion and exaltation. I have never liked ambiguous conversations on the topics of love and sex. . . . I know that he does not watch erotic shows on TV and is mostly at home. Only his two main hobbies, sports and fishing make him go out. He usually goes fishing with children. For us, mutual understanding, trust and support have been more important than sex. Yet, we have also enjoyed the happiness of a complete unification with a person you can trust as much as yourself. (ELM 1996)

People in couple relationships (married, cohabiting, or LAT) were asked about the *happiness of their relationship*. Men reported happiness a little more often than women did. Twenty-one percent of men and 16% of women considered their couple relationship as very happy, 46% and 44% fairly happy, and 33% and 40% neither happy nor unhappy. There was no ethnic difference in this issue.

*Discussing sexual matters with the partner* was considered not at all difficult by 46% of men and 42% of women. Gender and ethnic differences in the easiness of communication were small.

The indicators of mutual love, happiness of the couple relationship, and open communication on sexual matters correlated with each other. They were combined to an index of High Quality Relationship (HQR). There was neither gender nor national differences in the quality of the relationship in Estonia according to MCA. Younger people rated the quality of their relationship higher than the middle-aged and older people. Married and cohabiting people found more love, communication, and happiness in their present couple relationship than people living apart together (LAT). The more-educated people reported more quality in their relationship than the less-educated.

International comparisons revealed that the quality of the couple relationship was lower in Estonia and St. Petersburg

than in Finland. In all three areas, more younger than middle-aged and older people reported that the quality of their relationship was high. The exception was that, in Estonia and St. Petersburg, the oldest respondents aged 65 to 74 years reported higher quality of relationship than the 55- to 64-year-olds.

### *Sexual Self Esteem*

“What is your opinion about the following statements concerning your sexual life and characteristics: I am sexually skillful, I am sexually active, and I am sexually attractive.” In Estonia, men considered themselves more often sexually skillful and active than women did. Women had a little more belief in their sexual attractiveness than men had. Russian-speaking men considered themselves more attractive than Estonian-speaking men. Otherwise, the ethnic groups were similar. The three indicators of sexual self-esteem correlated with each other. The reliability of the three-item sum-scale of sexual self-esteem was 0.78 (alpha).

In Estonia, according to MCA, men, the younger, and the more-educated people had a higher sexual self-esteem than women, older people, and the less-educated people. Cohabiting and separately living (LAT) persons reported more self-esteem than married and single people. When we compared the three areas in which sexual self-esteem was studied, we found that men in Estonia and St. Petersburg had about as high sexual self-esteem as people in Finland in the 1990s. Women in Estonia had a lower sexual self-esteem than women in Finland in 1999 and in St. Petersburg.

## *6. Homoerotic, Homosexual, and Bisexual Behaviors*

ELINA HAAVIO-MANNILA

### **History**

Male homosexuality was not punishable in the independent Estonian Republic before World War II. In spite of this, there is no information about gay structures in Estonia in that era.

During the Soviet occupation, male homosexual behavior—specifically anal intercourse between men—was forbidden everywhere in the Soviet Union. Homosexuality was considered as a psychiatric pathology. This repressive legislation prevailed until June 1, 1992. However, the situation seemed to be more liberal in occupied Estonia than in most other parts of the former Soviet Union. Gay men who had no public sex or political problems, were not persecuted. Usually, no more than 10 men were imprisoned per year. Up to the mid-1980s, there was an unofficial gay bar in Tallinn. Also, there was at least one cruising area in both Tallinn and Tartu.

A decisive year for Estonian homosexuals was 1990, when the International Scientific Conference on Sexual Minorities and Society in Twentieth Century Europe took place in Tallinn, the first of this kind in Eastern Europe. Also, during 1990, the first advertisements for gay and lesbian acquaintances were published in independent newspapers. The first gay/lesbian organization in Estonia was the Estonian Lesbian Union, founded in 1990, followed two years later by the Estonian Gay League.

According to A. Raudsepp, an expert in the field, the situation of homosexuals has changed with the overall liberation and democratization in Estonia. The position for gay and lesbian youth in 2003 seems to be very different from the situation, for example, at the end of 1980, when some people started to come out as gays. During the Russian occupation, there was no information about homosexuality other than rumors, penal code, and psychiatric manuals. It was very difficult to meet other gay people.

### Attitudes Toward Homosexuality

The ambivalence of the attitudes toward homosexuality is clearly shown in the sexual autobiography of a 49-year-old male chauffeur written in 1996:

In US homos want to become quite official. I just can't understand such people. Once one of my friends told me a story about them. He had a small joint-stock company and went to Cesis (in Latvia) to get some goods. He stayed the night with his Latvian business partner. At night this man came to his bed and behaved the same way that a man does when he starts making love to a girl. My friend tried to push him away but he kept coming back. This lasted half of the night. In the other room there was a nice pretty wife of this man; they probably even had children. I tried to look upon this as some kind of disease that should be cured. During the Soviet times they tried to cure this with prisons but this isn't probably right, except in cases where the other party is a minor. I can understand women who make love to each other even less. But this has been a taboo, so we don't know much about that at all. (ELM 1996)

In Estonia in 2000, 50% of surveyed men and 63% of women agreed with the statement "Homosexuality among adults is a private affair of the people concerned with which officials the law should in no way interfere." Twenty-one percent of men and 12% of women disagreed with the statement. Quite a number of the respondents, 29% of men and 25% of women, found it hard to say what their position was. Women considered homosexuality to be a private affair more often than men did. There was no difference between the national groups in the attitudes toward homosexuality. Younger people were more liberal than older people. Type of couple relationship and education did not affect homosexuality attitudes.

### Sexual Orientation

In 2000, 12% of people in Estonia reported homoerotic feelings, i.e., they were sexually interested in the same sex. Most of these people were also interested in the other sex, that is, they had a bisexual orientation. Only 2% of men and no women were interested only or mainly in the same sex. People with lower education reported same-sex interest more often (16%) than those with middle or higher education (9%). Age, type of relationship, and ethnicity were not associated with sexual orientation.

Compared to Sweden and Finland, homoerotic interest was more common in Estonia and St. Petersburg. The highest rates appeared among Estonian-speaking women in Estonia (13% of the 18- to 54-year-olds) and St. Petersburg women (12%). In Estonia, contrary to the other areas, middle-aged and older people reported homoerotic feelings at least as often as younger people.

### Same-Sex Experiences

In 2000, 6% of men and 8% of women in Estonia had sexual experiences with persons of their own sex. These encounters were more common among younger (14%) than among middle-aged and older people (3% to 5%). Type of relationship, education, and ethnicity did not predict homosexual experiences.

A 55-year-old Estonian unemployed man was not sure of his sexual orientation. He had had sexual experiences with both women and men.

I was still quite helpless in intercourse later, but my kissing had developed much and I would still enjoy it, even on "some other places" . . . A week after our encounter she started suffering from awful pains, which made her scream. She was taken away, and forever—she had leukemia and it

killed her. With her gone, my intimate world collapsed. I buried myself in sport, until the next sexual experience, which was with a man when I was sixteen. It may seem that I have been a homosexual already from an early youth, but that is not true. My sharpest and most exciting memories are still of those overwhelming kisses and the first entry into a vagina. . . .

. . . We were lying on the mattress and talking about all kinds of things. Then he started caressing me, and as I had experienced it already from a man, I was quiet and a sort of expectation came over me. Gradually he moved closer and closer to my genitals, pulled down my underpants and took me into his mouth. A sudden rush of pleasure gave me a start and I almost moaned aloud. He sucked me very skillfully, taking almost the entire length of my penis into his mouth and licked the tip of it. Stroking my balls he put one finger into my anus, which also gave me a new kind of pleasure. I had the feeling that my member would truly explode, it was so full of blood, stone-hard, really painful. He went on, caressing and stroking my penis with his tongue. He felt the throbbing of my member and sucked it deeper and deeper into his mouth. I couldn't stand it any more and ejaculated into his throat. I heard him swallow and his satisfied grunting, and felt myself totally pumped out. He asked me whether I wouldn't want to do the same to him. I suppressed the thought that the same thing is used to urinate; besides, he smeared something sweet-tasting onto his penis. At the beginning it felt disgusting, but he continued rubbing me and I felt a sort of passion arise. His member was very big and veined, my mouth got tired, but he encouraged and taught me all the time. He said he wanted to ejaculate into my mouth too, and if I couldn't (or wouldn't want to) swallow it, I could pass it from my mouth into his mouth, he would swallow it himself. I tried to follow his teachings and do the thing as well as possible. In the end I felt his member grow even more, then it started to jerk and a kind of salty greyish-white slime came out of it like from a fountain. I couldn't help but swallowed some of it, but passed the rest over into his mouth. We kissed for a long time with our sperm-smearing mouths and all this was simply indescribable. I still want to stress once again that actually I am not a gay or bisexual, only the circumstances developed this way. (ELM 1996)

Homosexual or bisexual authors of some sexual autobiographies in Estonia complained about their alienation and mental health problems. One should notice that the majority of the population has a favorable attitude toward homosexual behavior between adults; it is seen as a private affair with which officials and the state should not interfere.

## 7. Gender Diversity and Transgender Issues

KAI HALDRE

*Health System.* After regaining independence, health reform was carried out in Estonia. The Sick Insurance Fund was formed on a solidarity basis—up to every salary (payment to a person), 33% of a sick insurance tax has to be paid. After that, the person becomes insured and can have the majority of health services either free or for a very small payment. All minors up to 18 years old and retired persons are automatically insured. A list of pharmaceuticals is defined, which are compensated to a different extent according to the diagnosis and drug. Together with health reform, a family doctors' system was introduced.

Currently, there is no legal regulation for organizing help for transsexuals. In October 2002, a new law on organizing

medical services was adopted, and all old regulations are not valid any more. Helping transsexuals will be organized in accordance with the principles adopted in the European Council's Parliamentary Assembly session No 41 in 1989.

There is a draft of a new regulation, according to which an advisory committee for helping transsexuals is formed. The task of the committee is to be the final body that makes the proposal to the Minister of Health to change the gender of a person. It can happen only if the person has felt that he or she belongs to the other gender/sex group for at least two years, after any psychiatric illness is excluded and the genetic sex is defined. Then, the Minister gives a decree, according to which hormonal therapy and surgical therapy can be started. Both are not obligatory and the person can stop at any stage. The passport is changed only after two years of treatment. If the person wants to change back to the initial gender/sex, it is done according to her or his written directive.

Transsexuals are entitled to get both psychological help and buy medications in the same way as all other people who have sick insurance. If they decide to have surgery, this cost is not covered by health insurance and they have to pay for it by themselves. Treatment of intersexual persons (both medical and surgical) is covered by sick insurance.

## 8. Significant Unconventional Sexual Behaviors

### A. Coercive Sexual Behaviors

#### *The Legal Situation*

Until the year 2002, the old modified Soviet law regulated legal penalties for sexual crimes. There was a differentiation according to how natural or unnatural a sexual act was. Sexual abuse/coercion performed by woman was not possible. The new law active since 2002 is based on the principle of sexual freedom of the person—a person him- or herself has the right to decide with whom and how he or she has sexual relations.

The penalty for rape is five years imprisonment. If the rape was with a person less than 18 years old, carried out by two or more persons, if the victim's health was damaged or death caused, if the victim has taken to a stage of suicide or attempt of suicide, or if the offender had raped earlier, the penalty is 4 to 12 years imprisonment. If the rape was inflicted on a person less than 14 years, the penalty is 6 to 15 years imprisonment.

In 2000, there were 676 criminal acts against a person. Of these 676, 54 were registered as rape (in 1999, there were 58 cases registered as rape). Out of these 54, 39 person's court decisions were put into force. At the same time, while criminal acts against a person have been decreasing since 1995, rape and attempts of rape have remained the same.

The Bureau of Equality of Rights in the Ministry of Social Affairs and the Estonian Open Society Institute has carried out some research on sexual violence. In 2001, the Estonian Open Society Institute studied the incidence of violence in the family and against women. Twenty-one percent of women and 16% of male respondents answered "yes" to the question "Have you experienced against yourself either physical, mental, or sexual violence during the last 12 months?" According to this study, it is estimated that every day, 252 women experience physical violence and 33 women experience sexual violence. Two thirds of the violent acts take place at women's homes.

In terms of social response, sexual violence still seems to be quite a taboo topic. Many professionals (medical persons, police, teachers, etc.) feel themselves uneasy while meeting the problem. At the same time, a lot of education has been provided to different groups (including police,

medical personnel, etc.) since the mid-1990s. Two children's support centers have been established. They deal with counseling and rehabilitating mistreated children and families. The Children Support Center in Tartu has been active since 1995, while Tallinn's Children Support Center was opened in 1999. The Open Estonia Foundation is financing both centers. Additionally, specialists are being trained to work with children, and a network of specialists is being established for solving cases of child abuse.

A sign of immaturity in the Estonian legislation is perhaps that the law on Equal Gender Rights (*Soolise Võrdõiguslikkuse Seadus*) was not adopted by the Parliament in 2002. Parliament declared it "unnecessary" and some members of Parliament ridiculed it. Since sexual violence is mainly a problem for women, an equal-rights law would help in fighting against it.

### *Child Sexual Abuse, Incest, and Pedophilia*

ELINA HAAVIO-MANNILA

*Incest.* In the Estonian sexual autobiographies, there is a detailed story by a 16-year-old girl about the sexual abuse by her father:

It was winter. I went to school and had my 15th birthday in September. Father drank every day. One night when he came home he appeared in my room. I had heard nothing. I woke up when he touched me. I did not dare even to move and was breathing with difficulties. I pretended to be sleeping and was terribly afraid. My heart was pounding. He touched my breasts and thighs. We sleep on a "double-decked" bunk with my brother and it seems that my brother moved in his sleep. Father went away pulling the blanket over me before that. I could not sleep till morning. I went to school broken and sad; I could not concentrate at the lessons and was terribly tired. A few days passed and everything happened again. I thought I would lose my mind out of fear and was having constant nightmares. I did not venture to speak about all that to anybody. It all went rather far. He began kissing me, taking out his penis and caressing me until it hardened, then tried to enter me but I could not bear it any longer, moved myself and pulled the blanket over my head—I felt myself totally defenseless. Father left. Next night he tried it again, again luckily without any result. At last he satisfied himself between my buttocks. He wiped the sperm off his penis, covered me and went to sleep beside mother in the other room. I was awfully scared. I went to the toilet and wiped myself clean. I wept from fear.

After some days he came again, I pressed my teeth together and thought I now would get up and scream but fear fixed me to the bed, I was afraid, paralyzed by my own ignorance. At the same moment mother came in. I let out an imaginary sigh of relief, at last it was all over. But no, that was but the beginning. It seems mother had felt it strange that father was lingering in the kitchen so long (for my father had a habit of eating at night) and had decided to come and have a look. The only thing she said was: "So it is the child you are at now." That was said with great bitterness. Mother seemed to collapse inwardly as if some huge waves had carried her away. She could say nothing else. (ELM 1996)

*Other Abuse of Children by Adults.* Sexual abuse of children by adults was frequently mentioned in the autobiographies. A 39-year-old Russian-speaking woman writes:

When I was 10 or 11, the other bachelor who was about 20 and half-wittedly asked me to come to his room so that the neighbors would not see me. He promised to buy me

candy when I show him my “thing.” Our life was poor and Mother used to borrow from the neighbors to buy us food. I must have wanted candy so much I agreed to climb in through his window so that the others did not see me. (ELM 1996)

*Peer Harassment.* A married 59-year-old retired male teacher with two children writes about the after-play of peer harassment of girls in his own school-age.

Toilets were the centers of sex lore for boys. When the girls could break off from their tormentors, they ran into the girls’ WC. It was called a sanctuary by angry boys, but the girls themselves also called it so, because it was a safe place. When the boys had touched and pawed girls in the classrooms or corridors, they were quite aroused and ran into the boys’ WC, where they jerked off. It was quick, and then they compared, who could shoot higher. I was 8-9 at the time, and knew everything, watching the “real men” and learning the trade. (ELM 1996)

In addition to schoolmates, the members of youth organizations could harass each other, as the following story by a 40-year-old woman architect shows:

There is also one unpleasant experience from form 7 after a game of pioneers that we had had. All the girls had probably gone home already; I remained there in the wood with boys, to come home together with them. I trusted them; they had always been my good fellows. Then suddenly they dragged me down to the ground and tried to get my trousers off. I didn’t realize at all what’s going on. There was someone holding his hands on my mouth to prevent me from crying and someone climbed over me and tried to stuff something between my legs.

I don’t remember how I escaped from there. I probably began to cry so loud that they had pity on me. Or maybe there was someone with more common sense to stand up for me. The more active ones threatened me that they would catch me with a net the next day after school and take me to the wood. It was such a terrible threat for me that I didn’t dare to go to school for two weeks. Luckily, the boys had lost interest in me by then. (ELM 1996)

*Gang Rape.* Gang rapes of girls occasionally took place in Estonia, even though the formal and informal punishments were very serious. A 60-year-old locksmith told stories of gang rape by peers.

The schoolboys were running after girls too, trying to “make them.” I know an occasion, when an eleven or twelve-year-old girl was caught and gang raped in the forest, the boys were telling about it afterwards. They described how the girl had tried to fight them off, but couldn’t, and later they often visited that girl, she even sort of expected it. So a gang of boys spoilt a girl, who was too afraid to tell about it. (ELM 1996)

### *Adult Sexual Harassment and Rape*

According to the 2000 Estonian sex survey, 2% of men and 14% of women in Estonia had been sexually harassed, 0.4% of men and 8% of women had been raped, and 3% of women had been both harassed and raped. Russian-speaking women in Estonia had been sexually harassed or raped more often than Estonian-speaking women had been—30% versus 22%. Three percent of respondent men and 13% of respondent women reported being the subject of physical violence from a long-term partner.

In the ELM archives, there are many stories on physical violence in relation to sexuality. Kelly (1988) has divided these into five groups: 1) harassment from flassing to assault,

but not attempted rape, 2) pressurized sex against one’s own will, 3) coercive and forced sex involving elements of threat or fear, 4) (attempted) rape, and 5) general mentions about violence including domestic violence. There are not many stories in the sexual autobiographies about the author perpetrating a rape, but most of the authors told about attempting rape of another person or animals.

### *General Family and Sexual Violence*

Violence in the family was sometimes upheld by the older-generation family members. The following 61-year-old Russian-speaking woman teacher writes:

When he came home again, I told him about money [the mother of the author had demanded her to ask money from the husband for the upkeep of the family] but he did not give me any. He simply lived with me, used me and beat me. Whenever he had had alcohol he found a reason to beat me, cruelly, with his feet. Once he beat me on the head with his fists and it seems I even lost consciousness. Mother watched and told him: “It is right to educate her, otherwise she will not listen to me any more and there is nobody who could tame her.” Yes, that was my own mother who allowed her daughter to be beaten in such a cruel way and never came to help me, to rescue me from the drunkard with whom I had refused to go out because he was drunk.

I thank God I was saved from that sadist [the husband was put in jail for killing a man]. I wish he had got death penalty but it was our child that saved him from that. I thought that from now on I could live peacefully but no . . . he began to write me from the prison, threatening me in his letters. I have lived in fear all my life. When I started receiving those letters I must have thought about seeking defense from somebody and also I was fed up with my mother’s scolding. I wanted a home of my own; I wanted to marry, to find a father for my child. (ELM 1996)

Women were more often than men victims of sexual harassment and violence, as can be seen in the lack of autobiographic stories by men on general family and sexual violence.

### **Prostitution**

Since the beginning of the 1990s, combined with fast socioeconomic changes, there was a rapid booming of prostitution in Estonia. Kristiina Luht (2003) estimates that more than 1,000 prostitutes work in Tallinn. Since a prostitute’s working time during the life course is quite short, 5 to 10 years, many more than a thousand women and men are involved.

According to Juri Kalikov (2003), two main tracks can be followed: first, girls go to bigger cities (half of the prostitutes come from Russian-speaking northeast Estonia), and second, women are taken abroad—mainly to Finland, Sweden, Poland, Germany, Denmark, Holland, and Spain. The human trade can appear in different forms: to work as a prostitute, to work as an *au pair*, cleaner, and so on, to work as a dancer (striptease), escort, and so on, and getting married with the aim of making a person work for free or as a sex worker. The local criminal organizations profit from prostitution and work closely together with foreign club or brothel owners.

In the 2000 Estonian sex survey, people gave their opinions on the following statement: “I have nothing against people earning money by selling sexual services (prostitution).” Fifty-five percent of men and 30% of women agreed entirely or almost completely with this statement. There was no difference between the national groups. Young people accepted it more often than middle-aged and older peo-

ple. Type of relationship and education were not significantly connected with prostitution attitudes. Compared to the neighboring countries, Estonia was the most permissive to prostitution. People in St. Petersburg were particularly very much against it. But in the sexual autobiographies, many authors expressed their negative attitudes toward prostitution. The following 71-year-old woman teacher supports legal, controlled brothels:

I do not justify prostitution, but those who want to sell themselves always find ways to do it. But this shouldn't ruin our youth. The ads in the newspapers where girls invite men to have coffee with them, giving addresses and phone numbers should be condemned. When I read the ads in the newspapers where somebody wants to find a boy- or girlfriend for extramarital relationship, I think that these people should be mad.

There should be a house in town, where those who cannot do without it, could find satisfaction. This house should be under medical surveillance and the persons working there should be issued passports of different color than the other citizens. This lush sex is disastrous for the nation. (ELM 1996)

Twelve percent of men and 28% of women in Estonia had been solicited to have sexual intercourse in return for money or equivalent economic advantages, but had refused to take it. Three percent of the Estonian-speaking men and 1% of Russian-speaking men accepted the financial offer, as did 2% and 5% of the women. Younger and Russian-speaking people had been offered money for sex more often than older and Estonian-speaking people. Type of couple relationship and education did not predict persuasion to have sex for money.

Taking money for sex was more common among Russian-speaking women in Estonia and St. Petersburg than in Sweden and Finland. As many as 14% of the 25- to 34-year-old russiaophone women in Estonia had accepted money or other economic advantages for sexual services.

Ten percent of men in Estonia had paid for sexual intercourse. Only 2% admitted that they had been offered money for intercourse, but had refused to take it. Two women, both Russian-speaking, had paid for sex. National differences were not significant. The younger and the middle-educated had offered money for sexual services more often than the older and the least- or most-educated people. Type of relationship did not have any impact on paying for sex.

In Estonia, fewer men had paid for sex than in Sweden (15%) and Finland in 1999 (13%). In St. Petersburg, 10% had done it. Contrary to the situation in Estonia, where mostly younger men had paid for sex, in Sweden and Finland, middle-aged men most often reported having paid for sex.

### C. Pornography and Erotica

During the stagnation times of the Soviet system, before 1991, all sexual literature, sex aids and substitutes, films, and so on, were strictly forbidden in Estonia, and there were legal codes and sentencing procedures for offenders. But it was not totally absent from the society as the following passage of the sexual autobiography by a 45-year-old man reveals:

An acquaintance of two of my classmates was having a birthday party in Tallinn and we were all invited to go. I was sixteen. Nothing predicted the course of following events as it really happened. At the party, we ate and had a few drinks. The walls of the flat of that man were covered with all kinds of pornographic pictures, which excited us all a lot. For the first time I saw all kinds of positions of intercourse, group sex, oral and anal sex. It all had a very strong impact on me and for a long time I saw them in my

erotic fantasies. I don't know from where he had got those pictures, but Finland is only some 80-90 kilometres off Tallinn and it was possible to smuggle things in. (ELM 1996)

After the independence, pornography became legal and easily attainable. The following 27-year-old man uses it as educational material:

Sex magazines, porno films? I don't buy them except when I come across them when I'm alone, I look them through, trying to remain independent. I am more interested in the contents, pragmatical advice that I can share with my wife. I would also like to watch realistic films of deep thoughts and ideas, including erotica elements, in case it does not embarrass my wife. But cheap, downright hardcore porno films I wouldn't watch more than just once. (ELM 1996)

In 2000, attitudes toward pornography were very positive: 68% of men and 55% of women considered pornography very or quite arousing. Young people enjoyed pornography more than the older persons. People in different types of couple relationship, educational, and national groups found pornography equally arousing. Estonians considered pornography more arousing than Swedes and Finns did in 1992. But in 1999, the Finnish attitudes resembled those of the Estonian people.

## 9. Contraception, Abortion, and Population Planning

KAI HALDRE and ELINA HAAVIO-MANNILA

During the last decade of the 20th century, major socio-economic changes took place in Estonia. At the same time, many reproductive and sexual health indicators abruptly changed: The beginning of sexual life took place at a younger age; the number of induced abortions and deliveries, including teenage pregnancies, decreased rapidly; the availability of contraceptive methods improved; and their use increased. Nevertheless, much less contraception is used in the first sexual intercourse than in other developed countries, and often the sexually active people used unreliable methods of contraception—coitus interruptus and the rhythm method.

### A. Contraception

#### General Usage

There are no systematic and accurate data about contraceptive usage in Estonia. According to the statistics given by the Estonian Ministry of Social Affairs, there were 182 users of hormonal contraception and 145 IUD users per 1,000 women of fertile age in 2001. These data are collected only about women who visit state women's outpatient clinics. The definition of which data should be included in statistics is not well defined, and the collection of the data is not on the same level in all of these institutions.

According to the available statistics, the number of women using hormonal contraception has increased about fourfold, and the number of women with an IUD has decreased a little, when compared with the year 1992 statistics of 39 and 209 per 1,000 women of fertile age, respectively. These statistics of hormonal contraception do not tell us whether the figures refer only to the combined oral contraceptive pills or include also usage of other hormonal methods (POP, depo progestogen, or levonorgestrel-IUS). Nor do they tell use about how constant is the usage. The statistics reflect the usage per 1,000 women of fertile age, but do not distinguish how many of these women are in need of contraception.

The Estonian Health Interview Survey carried out in 1996 shows that the usage of different family planning

methods during the previous four weeks by sexually active women in age groups 20 to 24 years and 25 to 29 years was as shown in Table 2. From the EHIS 1996 data, one might conclude that every user of a contraceptive method used only one method at a time. Our practical experience does not support this conclusion, and it was possible to select two main methods while answering this particular question in the interview. One, then, cannot consider the EHIS data reliable. The data depicting contraceptive usage do not reflect how many of these women were pregnant, infertile, or wishing pregnancy at the time when the interview was carried out. No reliable methods were used by one quarter of the women; at the same time, there are no data about their plans in case of pregnancy. Twenty-five percent of the 20-to-24 age group and 21% in age group 25-to-29 did not have intercourse during the previous four weeks.

According to the Family and Fertility Survey carried out in 1994, the usage of different contraceptive methods among sexually active women during the previous month was 58% in age group 20-to-24 and 66% in age group 25-to-29, including, respectively, condom use 21% and 17%, contraceptive pills 5% and 5%, IUD 19% and 34%, coitus interruptus 9% and 7%, and other methods 4% and 2%; 25% and 19% in these age groups did not use any method. During the survey, 8% and 3% were pregnant in age groups 20-to-24 years and 25-to-29 years, respectively; 25% and 19% of women in these age groups did not have sexual intercourse during the last month.

We can compare this 1994 Family and Fertility Survey to the results of a Finnish survey carried out in 1994 of the age groups 20-to-24 and 25-to-29, in which 60% and 52%, respectively, of the sexually active women used contraceptive pill, 17% and 4% used condoms together with either the pill, IUD, or depo progestogen, 13% and 25% condoms alone, and 2% and 6% the IUD. The proportions of those not in need of contraception among sexually active women were 7% and 11% in age groups 20-to-24 and 25-to-29 years (cf. Table 3). Male and female voluntary sterilization is legally regulated by the "Law of Pregnancy Termination and Sterilization," adopted by the Estonian Parliament at the end of 1998. There are no data on how many people have used this possibility, and what is the potential amount of users in the near future.

In the middle of the 1990s, emergency contraception was introduced in Estonia. The prerequisite of successful usage of this method is good information about the method among public and medical personnel, and easy accessibility of the emergency pills.

### Contraception in First Intercourse

According to the Estonian Health Interview Survey in 1996, 62% of women in age group 20-to-24 years did not

use contraception in their first intercourse. According to the Family and Fertility Survey in 1994, the proportion of non-users in the same age group was 67%. Additionally, about half of those who said that they had used the method had chosen "traditional methods" for avoiding pregnancy. We can compare this with the proportion of non-users of contraception at first sexual intercourse found in the KISS study in Finland already in 1988, where it was 27% among girls in the age group 15-to-16 years.

According to the Estonian sex survey conducted in 2000, in their first intercourse, 42% of Estonian-speaking men and 38% of respective women, and only 21% of Russian-speaking men and 33% of respective women had used some contraceptive method. The difference between the language groups was statistically significant for men, 42% versus 21%.

Coitus interruptus was the most-often-used method in the first intercourse. Twenty-one percent of the Estonian-speaking respondents had used it; of the Russian-speaking, only 10%. A condom was used by one tenth of the respondents, and the pill by only 1%. Two percent had used some other technique, and the rest could not remember what method of contraception they had used in their first coitus.

Very few Estonian autobiographers referred to contraception when they wrote about their first intercourse. This is probably because of the fact that no contraception was used, as the findings above indicate. Lack of knowledge on sexual matters, especially contraception, often made the first intercourse an unpleasant experience.

In Estonia, fewer people used some contraceptive in their first intercourse than Finns did 30 years earlier, not to speak of Finland in the 1990s. Only 10% to 13% of people in Estonia had used a condom in their first intercourse, compared with 28% in Finland in 1971, 52% in 1992, and 55% in 1999. Among the 55- to 74-year-olds, Estonian-speaking people (born before 1946) reported as much as, and even more contraception than the Finns did in 1992. This Finnish generation (born before 1937) grew up when contraception was not yet common in Finland.

### Contraception in Most Recent Intercourse

These statistics are more reliable than those for contraceptive usage in the first intercourse. Fifty-two percent of men and 54% of women surveyed—needing contraception and having had intercourse in past year—had in his or her latest sexual intercourse used one or several of the following contraceptive methods: condom, birth control pill, minipill, implant capsule or injections, intrauterine device (IUD), or sterilization. There was no age difference in the use of these contraceptive methods considered as reliable ones.

**Table 2**  
Contraceptive Usage, in Percent

Method	EHIS 1996		FFS 1994	
	20- to 24-year-olds	25- to 29-year-olds	20- to 24-year-olds	25- to 29-year-olds
Total usage			58	66
Condom	22	12	21	17
Oral pill	11	6	5	5
IUD	21	35	19	34
Natural methods	13	16	—	—
Coitus interruptus	5	—	9	7
Other methods	1	—	4	2
No methods	27	24	25	19

**Table 3**  
Usage of Contraceptive Methods During Last Four Weeks: Women, 20 to 24 Years, in Percent

Contraceptive Method	Estonia 1994	Finland 1994
Condom	21	13
Pill	5	60
IUD	20	2
Coitus interruptus	9	
Other methods	4	
Did not use	25	
Condom and pill depo/IUD		17
Pregnant/infertile // no need*	8/1	7*
Did not have sexual intercourse	25	

(FFS 1994; Kosunen 2000)

A comparison of the contraception techniques in the four sexual relationship types shows that cohabiting people had used reliable contraception most often (67%) and single people least often (39%). Married and LAT people were in-between, with 53% and 57%. The higher the educational level, the more often was a condom, pill, IUD, or sterilization used. Of the least-educated persons, 46%, of those with the middle level of education, 54%, and those with the highest education, 63%, had used these reliable birth control techniques. Estonian-speakers had used reliable contraception more commonly (56%) than Russian-speakers in Estonia.

Of the different contraceptive techniques labeled as reliable, condoms were the most popular. Of Estonian-speaking men, 25% reported the condom as the main device used in the latest intercourse, of Russian-speaking men, 22%. For women, the percentages were 10% and 19%. The coil or intrauterine device had been used in the latest intercourse by 18% of Estonian-speaking men and 16% of Russian-speaking men, and by 31% and 19% of respective women. Use of birth control pills, minipills, hypodermic capsule, or injections was rare: 11% of the Estonian-speaking men and none of the Russian-speaking men reported their use, of the respective women, 9% and 3%. Use of contraceptive foam or cream was reported by no men and by 4% of Estonian- and 3% of Russian-speaking women. Three percent of the respondents told that they or their partner had been sterilized.

One reason for the infrequent use of reliable birth control techniques is exemplified in the following passage from a 53-year-old woman chauffeur in a cooperative farm:

I had made a promise not to have more children. I had not enough strength any more. It was hard time to tell my husband so I went to a gynecologist and had a diaphragm entered but my body rejected it. I worked like a horse: when the baby was born on 4 September, I had to be in the field ten days later, harvesting potatoes, milk pouring down from my breasts. What a life! (ELM 1996)

Of the less reliable methods, 15% to 16% of the survey respondents had in their last coitus used coitus interruptus. About 7% of men and 15% of women had applied the rhythm method ("safe days"). Of Estonian-speaking men, 6%, and of Russian-speaking men, 6%, and of the respective women, 5% and 14% had used no contraception, even though they needed it. The rest, 1% to 4% of the respondents, did not remember what kind of contraception they had used in their last intercourse.

Lack of contraceptives in intercourse was very often mentioned in the Estonian sexual autobiographies reporting on sexual life after the first intercourse. For a steady-going couple, pregnancy was mostly not a catastrophe, as a 60-year-old male mechanic shows:

From the beginning we agreed that I would not interrupt coitus but I would shoot ahead and if she got pregnant we would have a child in the family. We had sex constantly for three months until she told me that her menstruation had stopped. It was clear we had started a family. Once we tried to have sex with a prophylactic but didn't like it. It was artificial! (ELM 1996)

A 69-year-old male chauffeur writes about the successful use of the less-reliable birth control techniques, abstinence, and moralism in the social networks, in preventing unwanted pregnancies.

In the thirties in Virumaa it was a matter of big shame when a single woman had a child. Although knowledge of sex was scanty boys and girls knew how to regulate their sex-life so that there were no love-children, or if there

were, there were just very few. Single people also didn't live so active sexual life and I had never heard that someone had divorced because of sex. I think life was much more private in these older days. When someone did something that was forbidden by popular law then there was much more putting to shame, reproaching and condemnation than now. (ELM 1996)

Compared to Finland, the surveyed people in Estonia needing contraception and having had intercourse in the past year had rarely used reliable contraception in their last intercourse. In St. Petersburg, middle-aged and older people used them even less often than the respective people in Estonia. There was no gender difference in the likelihood of having used reliable contraceptive techniques. In all research areas, the use of the condom, pill, IUD, foam, or sterilization was least common in the age group 55-to-74 years.

### *Worry About Unwanted Pregnancy*

Most people, especially women, in Estonia had in their lifetime been worried about unwanted pregnancy. For men, the proportion was 70% and for women 80%. Estonian-speaking men had been more often (74%) worried about unwanted pregnancy than Russian-speaking ones (61%). These proportions include the 44% of men and the 59% of women who had been worried at least sometimes; the rest had been worried scarcely ever.

## **B. Abortion**

### *Legislation and Statistics*

In the Soviet Union, abortion was prohibited from 1936 to 1955. In Estonia, it has been legal since November 23, 1955. There was no abortion law until 1998, although it was regulated by a decree of the Ministry of Health (now Social Affairs). Since 1994, abortion is partially paid by women having health insurance. Approximately one third of the cost of abortion is paid by the woman—currently 330 EEK. The main method is vacuum curettage; mifepristone is not available.

The 1998 Estonian abortion law states that abortion is allowed on request up to 11 weeks of pregnancy and for medical reasons up to 21 weeks of pregnancy. Therapeutic abortions and treatment for spontaneous abortions are free of charge. Abortion for girls up to 15 years and women over age 45 are also free of charge. Abortions are performed only in state or private-owned institutions having a special license for that procedure. Filling in an abortion form for the Abortion Registry is obligatory (including so-called mini-abortions—termination on an outpatient basis up to 21 days of absent menses). The Abortion Registry started in 1994 and data are available from the registry from 1996 on. In 1998, the quality of the Registry worsened when, for political reasons, it was not allowed to write the personal identification code on the registration forms.

Until 2000, more pregnancies ended with termination than with birth. The rates of legally induced abortions and the birthrate have both decreased remarkably in Estonia during the last 10 years. According to the data of the Estonian Abortion Registry and Medical Statistics Bureau, there were 69.6 induced abortions per 1,000 women of fertile age in 1992; the figure was 34.0 in 2001. The fertility rate per 1,000 women of fertile age was 48.6 in 1992 and 36.8 in 2001, according to the Estonian Medical Birth Registry.

During the last ten years, the proportion of repeat abortions among abortion patients has remained the same—in 1996 to 2001, about 68% of women had terminated two or more pregnancies. This is a high proportion compared to Finland in 1997, where the proportion of repeated abortions was 30%.

The proportion of teenagers among abortion patients has increased during the last 10 years, being 11% in 1992 and 13% in 2001. The proportion of teenage mothers has decreased during the last 10 years, being 15% in 1992 and 10% in 2001.

### *Incidence and Consequences of, and Attitudes Toward Abortion*

Of the male respondents of the 2000 sex survey who answered the question about abortion, 38%, and of the respective female respondents, 66%, reported that they themselves or their partner had had an abortion. There was no significant difference between the language groups. Thirty-three percent of the women who had had an abortion reported that they had had only one abortion, 34% two, 16% three, 6% four, 5% five, and 6% six or more abortions. Two women reported 26 abortions.

Compared to Sweden and Finland, the abortion rates in Estonia and St. Petersburg were very high. The discrepancy in the replies of men and women found in Estonia (men reported much fewer abortions than women) did not emerge in Sweden, Finland, and St. Petersburg. Estonian women may have kept their abortions secret from their partners, because of shyness and traditional Protestant morality. One explanation given to the consistency of the replies by men and women in St. Petersburg is that the father candidate had to pay part of the cost of abortion in the Soviet Union. Thus, it was necessary for a woman to reveal their pregnancy to her partner.

Reactions to and feelings about abortion varied by gender. In most cases, the surveyed women reported more consequences of abortion than men did.

Quite a number of both women (44%) and men (39%) who/whose partner had had an abortion reported that abortion made them feel guilty. Guilt feelings were more widespread among Estonian-speaking (men 42% and women 50%) than Russian-speaking people (men 30 and women 33%). According to a multiple classification analysis, young people had suffered from guilt feelings more often than older people had. Type of the relationship and education did not predict the guilt feelings of the respondents from abortion.

In Estonia, more women (19%) than men (7%) thought that an abortion had been degrading. Women considered abortion painful much more often (48%) than men did (10%). Russian-speakers reported pain in connection with abortion more often than Estonian-speakers did (Russian-speaking men, 20%, and Estonian-speaking men, 6%, and the respective women, 58% vs. 42%). Very few respondents (7% of men and 3% of women) reported that their or their partner's abortion had been easy.

Thirty-six percent of men legitimized the abortions of their partners by saying that they had been natural in the partner's situation. Of the women, only 22% stated that the abortions had been natural in their situation. There was no difference between the national groups in this respect.

The decision to have an abortion was often a difficult one, as a 39-year-old Russian-speaking woman told of deciding again an abortion at the last minute:

When he learned about my pregnancy, he decided to go to sea, said he needed big money and told me I could do whatever I wanted—bear the child or not to bear. My colleagues learned about my pregnancy too and advised me to make an abortion. It may be he had even advised everybody to tell me that. One of my colleagues took me to the hospital and went to negotiate with the doctor. Until they discussed things in the doctor's study, I spent time reading the posters that hung on the walls. I learnt that if a woman

aborted her first pregnancy, she would risk being childless for the rest of her life. But I wanted to have children. So I gave up the abortion plans and bore the child. I was 17 when I bore my first child. (ELM 1996)

Another 40-year-old woman architect avoided abortion in spite of the request of her partner. Later, she anyway had an abortion. She seems to have had guilt feelings, because she thought that she was punished for it.

The father of my child did not want any children but as I was 26 myself already, it was the last moment for me to become a mother. And I really did give birth to a sweet lovely boy, exact copy of his father. [Later] I had won a prize at an architectural exhibition and it included a voucher for a trip to Finland. Giving birth to a baby was an obstacle. My conditions to [my partner] were as follows: I shall bear the third child if he will marry me and we shall live together. He didn't agree on marrying and I had an abortion. . . . I had a bitter revenge from destiny for destroying this embryo. In June 1987 an inborn dilatation of a blood-vessel (aneurysm) that was predicted to break at the age of 30, broke in my head. It was God's providence it didn't happen during the birth of my children. (ELM 1996)

In the 2000 survey, attitudes toward abortion were measured by the statement "I do not accept free (legal) abortion." The responses were quite evenly distributed between the five alternatives ranging from agree entirely to disagree entirely. The average score for men was 2.9 and for women 3.1; women were thus slightly more favorable toward free abortion than men were. There was no statistically significant difference between the ethnic groups. In Estonia, 35- to 44-year-old people accepted legal abortion better than younger and older people. The higher the educational level, the more likely were the respondents to permit abortion. Type of the relationship was not associated with abortion attitudes. Attitudes toward abortion were more restrictive in Estonia than in Finland in the 1990s, and especially in St. Petersburg.

### **C. Getting and Caring for Children**

From the 1950s until the end of the 1980s "Singing Revolution," Estonia's annual birthrate was quite stable—about 20,000 births per year. In the aura of liberation at the end of 1980s, the birthrate increased, and then suddenly and dramatically decreased during the socioeconomic transformation of the 1990s. In the last year of the 20th century, 1999, Estonia saw a small blip in the annual number of births and the birthrate per 1,000 women of fertile age. Between 1992 and 2001, the average maternal age increased from 25.5 years to 27.1 years, and the age of first birth from 22.7 to 24.1 years. The total fertility rate is below replacement level: 1.27 children per fertile woman and 1.33 in 2001.

While it is assumed that the maternal age will continue to increase, Estonia can expect an increase in birthrates when it reaches the level of Nordic countries, as in Finland, Sweden, Iceland, and Norway. In the past decade, most deliveries in these Nordic countries were in the maternal age group 25-to-29, in Estonia in 2001, only 30% were in age group 20-to-24 and 30% were in age group 25-to-29; previously, the biggest group of mothers were of age 20-to-24. The perinatal mortality rate also decreased markedly from 20.1 in 1992 to 8.0 per 1,000 live births in 2001. Since the decreasing birthrate and an aging population are pointed out by different groups in society as main concerns, many political parties have tried to introduce their "population programs," none of which have been implemented effectively until now.

In Estonia, most children have not been deliberately planned. In earlier times, when reliable contraception was

unavailable, many children were, nevertheless, likely to be born. Pregnancy was often a joyful event.

The autobiographies contained also stories about problems in becoming pregnant. A 69-year-old male teacher writes about the best position in intercourse for begetting a child:

I have noticed that when using this position [see below], the woman conceives most easily, as the sperm directly reaches the orifice of the womb, which is very important. I was quite worried in the first years of my marriage, as all our efforts to have children were in vain. Then we discovered this position, which also gives much pleasure. Woman is on her belly and man on her back, in the end woman lifts his bottom. This position led us to the desirable results. I have given this advice also to my pupils when teaching the class of family and sexual education. I have even received some thanks from the people whom it has helped, there was a couple who had tried to have children for several years, and they followed my advice, and had one child after another, all in all five of them. I have talked on this subject with my former pupils, who have been of the same opinion. This is the position, which the animals use, that is why I call it an animal-position. (ELM 1996)

A high proportion of the surveyed people in Estonia, about 70% of men and 80% of women, had their own children. Of Estonian-speaking men, 21%, and of respective women, 20%, had at least three children; of the Russian-speaking men, only 12%, and of the respective women, 8% had at least three children. The average number of children for Estonian-speakers was 1.6, and for Russian-speakers, 1.3 (childless people were included in this calculation). The difference between the language groups may be related to the ardent campaign to increase the number of the Estonian-speaking population in the 1990s, after the independence.

Middle-aged and older people had more children than younger people. The obvious reason is that they had had more years for childbearing. Married and cohabiting people had more children (1.8) than LAT persons (1.3) and singles (1.0). The number of children for the less-educated people was higher (1.6) than for the middle-educated (1.5) and highest-educated people (1.3).

The international comparison shows that in Finland in 1999, there were more childless respondents (34%) and less respondents with only one child (15%) than in Estonia, where 25% had no children. Twenty-one percent of Estonian-speakers and 30% of Russian-speakers had one child. In St. Petersburg, more people (41%) than in Estonia and Finland had only one child. In Finland in 1999, 23% had at least three children, compared with 21% among Estonian-speaking people.

In comparing age groups, Swedish data have been included. In the age groups below 45 years, people in Estonia and St. Petersburg more often than those in Sweden and Finland had their own children. This was the case in spite of the high abortion rate in the areas of the former Soviet Union.

During the Soviet regime, the social conditions for having children were unfavorable. A 28-year-old university-educated unemployed woman tells about her own birth as follows.

I was born in one of the small towns of Estonia in 1968, during the deep Soviet regime. At that time women had to complete their work tasks equally to men. Everybody was supposed to follow the example of the leading workers—women truck drivers, astronauts (Valentina Tereskova) etc. The main task and function of women at that time was neglected. After the birth of a child, women could stay home for 2 months only, not more. And also the occasions

when the mother could stay home with a sick child were rare. Work was the most important thing. (ELM 1996)

In the 2000 survey, we asked parents of children in Estonia how the birth of the last child had affected their life. People reported more positive than negative consequences of getting a child. The most popular response was, "I became happy." Of men, 43%, and of women, 49% felt happiness on the birth of the child. This autobiographical sketch was by a 73-year-old medical nurse:

In July 1949 the baby boy was born and we called him Viktor, considering that the name should suit both Estonian and Russian environment. The baby brought new feelings into our life; our happiness was more complete than ever. Now we already had a family! When the baby was two months old, I had to go back to work. Juhan's mother agreed to baby-sit. To ease the burden of the nanny and to get free days, I was willing to have night duties. At night Juhan looked after the baby and the boy slept well, too. So far I had breast-fed my child but when I went back to work, difficulties arose. The hospital was two kilometers away. To feed the baby, I had to walk home. Sometimes, because of the patients, I could not leave the hospital on time and when I reached home I found a fed and sleeping baby.

We lived in a small bachelor's flat where my mother-in-law's bed was only a few meters away from ours. Moreover, she suffered from sleeplessness. Even the slightest movement made our wooden beds squeak. We had to enjoy sex, trying not to breathe. It often happened at the sweetest moments of love that she began to sigh and turn over in her bed. In the morning she used to tell us how she had not slept a wink at night. For me it was most embarrassing when she tried to advise me, saying that one had to have sex in moderation, and the norm she offered was twice a week, otherwise it might happen that later the husband had no potency left. (ELM 1996)

Thirty percent of the survey respondents of both genders felt themselves as a real man/woman as a result of the birth of the child. The term "real woman" was actually used in the story of a 53-year-old woman former chauffeur in a *kolhose* (a leading worker of the socialist society) with three older children.

On an evening I felt pains inside, I was taken to hospital where I gave birth to a baby boy. It was a hard delivery; the child was in its mouth position. I was in despair, it is all over, the child's breathing disappeared, and there was no pressing, my own blood pressure 180. The doctors were hopeless, at that Kunda hospital. I was thinking, I gave myself a command, Aino, you are a woman, and you are a creator. Pull yourself together! I exerted all my strength. And really, as a result of it, a boy was born. I was so happy! I felt a real woman, a mother. Everything ended well, in a few days we were back at home. There I had to cope with everything, and I did.

Twelve percent of the surveyed women were satisfied because they did not have to go to work.

But the birth of the last child also had negative effects. Twenty percent of both men and women respondents of the survey reported that their economic situation worsened considerably because of the birth of the last child.

Fourteen percent of the survey respondents felt that the relationship with the partner suffered because of the birth of a child. The following autobiographical passage was written by a 68-year-old retired woman worker:

Until the birth of our first child we lived really well, although we had only a borrowed stool and a mattress in our

hostel room. We spent all free time embracing each other and talked about how nobody had ever been so much in love. We obtained more furniture but it seemed like with every new piece we lost something of our feelings. When our child was born I felt that I was not paid so much attention any more and I did not understand that a part of me now belonged to my child. My husband started to be away from home, another child was born in a year, and after that I had an abortion. (ELM 1996)

Nine percent of female and 1% of male survey respondents felt that the child took all their energy.

Twenty-seven percent of the men surveyed and 31% of the women had children who needed daycare. When listing the usual caregivers of their children needing care, the respondents were allowed to mention several types of persons.

One third of men and 44% of women reported that, in their family, the wife usually takes care of the children, and one sixth that the husband does it. In every tenth family, parents or grandparents of the respondents were the main caregivers. In 1% to 2% of the families, the children or grandchildren took care of the children. Only 1% of the respondents reported that there were other caregivers in the family. The caregivers in Estonian- and Russian-speaking families were almost exactly similar.

The parents seem to be the main caregivers of children in present-day Estonia. The extended family is not such a support as one might have expected on the basis of the autobiographies. The following story by a 34-year-old woman reveals the truth about traditional gender roles in childcare:

After the birth of the child everything vanished, no tears and hysterics any more, no more humiliating scenes. We still matched well in bed, but that was the only thing that kept us together. I went to work when the child was three months old. My husband wanted to sleep late, so I had to drag the child, the carriage and a bag with the bottles and nappies all through the snow to the nanny we had. Our love diminished more and more. When I was again two months pregnant, my husband was taken to the army. We wrote each other long letters. My grandmother, with whom we had been living, told me that I was a fool. I was the fool, and gave birth to the second son. (ELM 1996)

The low birthrate in Estonia has been and remains a national worry. After the independence, public daycare services were neglected—but supported again since the late 1990s. Thus, it is no wonder that less than half of the parents in Estonia reported happiness because of the birth of a child. One in five had serious economic problems because of it. Nevertheless, from the perspective of sexual life, it is encouraging to learn that only 14% of the parents reported that their relationship with the partner had suffered with the birth of their latest child.

To illustrate the changing family model and value system, we can report that, according to the Medical Birth Registry in 1992, 66%, and in 2001, 43% of mothers were in a registered marriage. At the same time, the proportion of deliveries attended by the father (sometimes another family member) was 13% in 1992, when the possibility to do that became available, and 56% in 2001.

## 10. Sexually Transmitted Diseases and HIV/AIDS

KAI HALDRE

### A. Sexually Transmitted Diseases

Source data for this chapter are derived from healthcare institutions whose area of work includes the diagnosis and treatment of dermatological and venereal diseases. In 1999, there were 97 such institutions in Estonia. HIV-related infor-

mation is from the Merimetsa Hospital and Health Protection Inspectorate. The increased incidence of syphilis and other predominantly sexually transmitted diseases is characteristic of many states that became independent after the collapse of the USSR (Health in Europe 1997). Major socioeconomic changes (unemployment, a boom in prostitution, growing drug abuse, expansion of borders, and increase of tourism) create a good soil for the spread of diseases.

For the third time after World War II, an increased incidence of syphilis poses a problem for Estonia. The greatest incidence rates in the postwar period were registered at the end of the 1940s (149.2 cases per population of 100,000 in 1949), the smallest in the 1960s and at the end of the 1980s, respectively, 2.0 to 4.6 (Communicable Disease Statistics in Estonia 1998). In the 1970s, a second wave of syphilis incidence occurred (42.4 in 1976), which can partly be explained by the peak of the organized inflow of labor at the turn of the 1960s and 1970s (Population 1997). Thirdly, the second-largest increase period has been the past ten years, in which the incidence rate has increased by 20 times, from 3.6 per 100,000 persons in 1989 to 72.4 per 100,000 persons in 1998, before starting to decrease to 30.6 in 2001.

Gonorrhea incidence has, in the past decades, been relatively stable (together with some fluctuations), although the trend has been downward from 1993 to 2001—from 233 registered cases per 100,000 persons to 50 cases, respectively. Compared with other European countries, the incidence of gonorrhea has always been very high in Estonia (Nordic/Baltic Health Statistics 1998). Since Estonia started to register cases of chlamydia in 1991, the upward trend of the first half of the 1990s represents an improvement in diagnostic facilities. The downward trends observed in the past years with several STDs (gonococcal infections, trichomoniasis, etc.) can partly be explained by changes in sexual behavior. The problem of the quality of registering incidences (STDs are under-registered) must be noted. The system that for years worked requires a new approach in the changing healthcare system.

One of the autobiographical stories in the ELM collection is told by a 34-year-old woman who tells about a STD, which she got at the age of 14, and about the problems she encountered in getting treatment.

One night, when I was sleeping naked, as the night was so hot, I woke up feeling somebody touching me. It was my cousin who was gently fussing with me. . . . Some time after this incident my periods started, and together with this came a brownish foul-smelling flow. To hide the smell I poured plenty of perfume over myself, being childishly naive. This, of course, made the things worse. I didn't dare to tell my aunt or to ask anybody for help. I couldn't wash my panties clean, so my aunt started to suspect something. She took me to town to see a doctor the diagnosis was trichomoniasis. Back home the interrogation started: where?, with whom?, when? We had never talked about private things with my aunt, so I told her nothing. She still suspected her son. I denied everything. The very first moment was when my cousin called me a stink bomb. I was alone with my trouble and sorrow. My aunt had given me the medicine and told me to treat myself. Unfortunately, I didn't manage, the large flow stopped, but I didn't get entirely well. My aunt didn't take me to the doctor again, it was such a shame to go to a gynecologist with such a young girl. (ELM 1996)

### B. HIV/AIDS

The first HIV infection was discovered in Estonia in 1988 and HIV diseases in 1992. As of December 31, 1999, there were 62 HIV-positive patients in Estonia, 54 men and 8 women. Five people (all men) diagnosed with AIDS were

alive and 15 (one of them a woman) had died. Fourteen HIV patients had left Estonia. Although, only a couple of the HIV-positive patients were infected because of drug injections (*Health Promotion in Estonia 1997-1998*), increases in viral hepatitis, syphilis, and drug abuse are warnings of an increased spread of the HIV infection. The year 2000 marks the beginning of the explosive increase, as by the middle of December, more than 350 new virus carriers, mostly drug addicts, had been registered. Since then, the number of HIV patients reveals an explosive increase of 0.6 in 1999, 28.5 in 2000, and 108.1 cases per 100,000 inhabitants in 2001.

[Update 2002: UNAIDS Epidemiological Assessment: HIV testing is mandatory among blood donors and prisoners. HIV surveillance is done through screening and through a national HIV case-reporting system. Prevalence data come mostly from ongoing testing programs. UAT is not authorized in the country. By December 1999, 96 HIV cases had been reported, most of them living in the capital area. No HIV cases had been reported among injection drug users; numbers of cases among homo-/bisexual men and persons infected through heterosexual contacts were comparable. Women represented a small proportion of infected patients (16% in 1997 to 1999). Incidence of syphilis cases increased dramatically from less than 10 cases per 100,000 in 1982 to 190 to 70 per 100,000 in 1995.

[In 2000 and 2001, the situation has become extremely alarming. In 2000, 390 HIV-positive cases and 3 AIDS cases were reported. In 2001, 1,470 new HIV-positive cases and 7 new AIDS cases were reported. Men make up 76% of the HIV/AIDS cases reported in 2001. New HIV/AIDS cases are concentrated among the young; 76% of all positives were among 15 to 24 year olds, and 89% among people under age 30. Of the cases reported in 2001, over 25% (382) were among prisoners. The cumulative totals for the country, at the end of 2001, are 1,940 HIV-positive cases and 7 AIDS cases.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	7,700 (rate: 1.0%)
Women ages 15-49:	1,500
Children ages 0-15:	NA

[An estimated less than 100 adults and children died of AIDS during 2001.

[No estimate is available for the number of Estonian children who had lost one or both parents to AIDS and were under age 15 at the end of 2001. (*End of update by the Editors*)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

Sexual dysfunctions are diagnosed according to ICD-10. People with sexual dysfunctions can get help mainly from psychologists, psychiatrists, urologists, gynecologists, and sexologists. Those involved in treating sexual dysfunctions have received additional education in sexology besides their basic discipline.

There is currently no system of sexology education in Estonia. Postgraduate three-day courses about basics in sexology for gynecologists and family doctors are organized at Tartu University Medical Faculty (Department of Obstetrics and Gynecology).

After becoming members of Nordic Association of Clinical Sexology, those in the field have made attempts to start to implement the Nordic system of sexology education in Estonia.

The drugs for treatment of erectile dysfunction are not supported by sick insurance and people have to pay the whole price themselves. The same was true concerning oral

contraceptive pills; sick insurance started to reimburse part of the cost only in the second half of 1990s. A majority of the cost of pills is reimbursed to women three months after an abortion and one year after delivery, and to school and university students. Surgical phalloplasty and prosthesis are available.

## 12. Sex Research and Advanced Professional Education

### A. Graduate Programs and Sex Research

Some institutes and programs for sexological research are presented in Section 1, Basic Sexological Premises.

### B. National and Regional Sexological Organizations

At the annual meeting of the Nordic Association for Clinical Sexology in 2000, Imre Rammul, Olev Poolamets, and Tõnu Ots presented the activities of the Estonian Academic Society of Sexology. According to them, there was a lot of sex and little information and discussion about sex in Estonia a couple of decades ago. Now sex is discussed everywhere and constantly in Estonia, but less sex is taking place in the bedroom. At least this can be speculated, looking at one aspect of heterosexual sex—the number of pregnancies has decreased many times during the last decade. To study the situation and promote sexual and reproductive health and rights, the Estonian Academic Society for Sexuality was founded in 1998, connecting different specialists: medical doctors, psychologists, teachers, lawyers, writers, and so on.

Rammul, Poolamets, and Ots intentionally used the word “academic” to stress the competency and reliability of the members. Since there is still a lot of “trash” information that is naturally mostly consumed by the youth, there is some inconsistency in legislation; sometimes specialists do not know how to find their colleagues and people in need of help do not know where and how to find help. All this provides a reasonable need for more reliable information and analysis of the situation.

Sexual violence and the sexuality of the disabled have been among the topics discussed at meetings of the society. Members of the society have also presented seminars with colleagues from Finland. Collaboration between the society, Tartu University, and the Family Planning Association has resulted in regular training in sexuality for medical doctors. In 2000, the Estonian Academic Society of Sexology became a member of the Nordic Association for Clinical Sexology.

The two main sexuality organizations in Estonia are:

Estonian Academic Society of Sexology, Suur-Ameerika 18 A, Tallinn, Estonia 10122; email: [kliinik@amor.ee](mailto:kliinik@amor.ee); [www.hot.ee/eass](http://www.hot.ee/eass).

Estonian Family Planning Association, Kotka 2, Tallinn, Estonia 11315; email: [eppl@amor.ee](mailto:eppl@amor.ee); [www.amor.ee](http://www.amor.ee).

## Demographics and a Brief Historical Perspective

ROBERT T. FRANCOEUR

### A. Demographics

Finland lies in northern Europe where Russia, Sweden, and Norway are its neighboring countries. It is also bordered by the Baltic Sea, the Gulf of Bothnia, and the Gulf of Finland. With a total area of 125,182 square miles (324,220 km<sup>2</sup>), Finland is slightly smaller than the state of Montana. The terrain is mostly low and flat to rolling plains interspersed with lakes and low hills. The climate is cold, potentially subarctic, but comparatively mild because of the moderating influence of the North Atlantic Current, Baltic Sea, and more than 60,000 lakes.

In July 2002, Finland had an estimated population of 5.18 million. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 17.9% with 1.04 male(s) per female (sex ratio); 15-64 years: 66.9% with 1.02 male(s) per female; 65 years and over: 15.2% with 0.64 male(s) per female; *Total population sex ratio:* 0.95 male(s) to 1 female

**Life Expectancy at Birth:** *Total Population:* 77.75 years; *male:* 74.1 years; *female:* 81.52 years

**Urban/Rural Distribution:** 64% to 36%

**Ethnic Distribution:** Finn: 93%; Swede: 6%; Sami: 0.11%; Roma: 0.12%; Tatar: 0.02%. The population is ethnically very integrated. Separate cultures are not very conspicuous within Finnish society.

**Religious Distribution:** Evangelical Lutheran: 89%; Greek Orthodox: 1%; none: 9%; other: 1%

**Birth Rate:** 10.6 births per 1,000 population

\**Communications:* Osmo Kontula, Ph.D., Population Research Institute (Vaestontutkimuslaitos), P.O. Box 849, Iso Roobertinkatu 20-22A FIN 00101 Helsinki, Finland; osmo.kontula@vaestoliitto.fi; Elina Haavio-Mannila, Ph.D., Sociology Department, Box 18 (Unioninkatu 35), University of Helsinki, FIN 00014 Helsinki, Finland; elina.haavio-mannila@helsinki.fi.

(CIA 2002)

**Death Rate:** 9.78 per 1,000 population

**Infant Mortality Rate:** 3.76 deaths per 1,000 live births

**Net Migration Rate:** 0.62 migrant(s) per 1,000 population

**Total Fertility Rate:** 1.7 children born per woman

**Population Growth Rate:** 0.14%

**HIV/AIDS** (1999 est.): *Adult prevalence:* 0.05%; *Persons living with HIV/AIDS:* 1,100; *Deaths:* < 100. (For additional details from www.UNAIDS.org, see end of Section 10B.)

**Literacy Rate** (defined as those age 15 and over who can read and write): 100%

**Per Capita Gross Domestic Product** (purchasing power parity): \$25,800 (2001 est.); *Inflation:* 2.6%; *Unemployment:* 9.4%; *Living below the poverty line:* NA

Social services are well developed in Finland. People receive free counseling in contraception for family planning at the communal health centers, expectant mothers have been given free guidance in childcare centers for decades, mothers of small children have paid maternity leaves, and there are

inexpensive communal daycare places for children and financial compensation for childcare given at home, as well as child benefits until the age of 18. As a result, Finnish women play as active a part in paid employment as Finnish men.

In 1992, the sexual life of the Finns was studied using nationally representative data on the 18- to 74-year-old population in Finland (Kontula & Haavio-Mannila 1993). The response rate for the 2,250 Finns in this FINSEX survey was 76%. Each of the respondents was interviewed personally and asked to fill out a questionnaire about the most intimate sexual matters. The questionnaire responses were not shown to the interviewers. The results of this study have been compared with a corresponding 1971 study (Sievers et al. 1974) to provide a detailed picture of Finnish sexual attitudes and behaviors in recent decades. Worldwide, the 1971 study was only the second population survey based on nationally representative data of sexual matters. (The first nationally representative sexual study was done in Sweden in 1967.) The results of this most recent FINSEX study will be discussed in different sections of this chapter.

[*Update 2003*: In 1999, the authors conducted a follow-up to the 1992 survey by a mailed survey (Haavio-Mannila, Kontula, & Kuusi 2001). This sex survey had 1,496 respondents. Because of this new data-collection technique, the response rate was 46%. By analyzing the distributions of several identical retrospective questions measuring sexual issues in different birth cohorts in the three Finnish surveys, Kontula (2001) showed that the low response rate in 1999 did not bias the recorded sexual histories of those who were under 55 years old. In the age group 55-to-74, the male respondents were more monogamous than those participating in the two earlier Finnish sex surveys. (*End of update by O. Kontula*)]\*

## B. A Brief Historical Perspective

There is archeological evidence that Finland was inhabited already at least 50,000 years ago. In a better-known history, the early settlers of Finland probably arrived about 2,000 years ago from the Ural area to the southeast. Swedish settlers brought the country into the Kingdom of Sweden in 1154, where it remained until 1809, when it became an autonomous grand duchy of the Russian Empire. A strong national spirit emerged, with Finland declaring its independence in 1917 and becoming a republic two years later. Finland was invaded by the Soviet Union in 1939, forcing the Finns to give up 16,173 square miles (41,888 km<sup>2</sup>) of territory. Further cessions were exacted by the Soviets after World War II. Finland became a member of the European Union in 1995.

### 1. Basic Sexological Premises

#### A. The Character of Gender Roles

Historically, Finland has a longer tradition of gender equality than most other countries of the world. This can be seen in the realm of politics, paid work, and in the division of labor at home.

In 1906, Finnish women gained parliamentary voting rights, second in the world after New Zealand. Finnish women also were the first in the world to gain the right to serve in Parliament. These rights were immediately implemented. In 1907, 19 women were elected to a Parliament of

200 members. At present, 39% of the MPs in Finland are women. In the 1994 presidential election, the female candidate got 46% of the votes, indicating that a woman can reach the highest positions of power in this country. [*Update 2003*: In the 2000 presidential election, a woman candidate was for the first time elected President of the Republic. (*End of update by O. Kontula*)]

Women in Finland are gainfully employed nearly as often as men. In 1991, some 72% of the women in the working-age population and 78% of the men were part of the labor force. In Finland, both women and men work on a full-time basis. In 1991, the proportion of women working part-time was 10% and that of men 5%.

The large proportion of gainfully employed women is also reflected in their high percentage of the entire labor force. In 1991, 48% of the labor force were women, and women made up 51% of the salary and wage earners. Unlike most European countries in the 1980s, Finland had a lower rate of undisguised unemployment for women than for men. However, the rate of unemployment among women over 55 has been higher than the rate among men of the same age.

Public offices are equally open to women and men, and under the Equality Act, no vacancy in the private sector can be announced exclusively for women or men on any other than weighty and acceptable grounds relating to the nature of the work. Nevertheless, the Finnish labor market remains somewhat gender-segregated. Women comprise approximately 60% of the labor force in the service sector, while the industrial and building sectors are dominated by men. The segregation extends to occupations and specific tasks. No dramatic change has taken place in the gender segregation of the labor market, although employees who have made nontraditional choices have entered practically every occupation dominated by the other sex. Another illustration of the gender-segregated labor market is the differences in the positions that women and men occupy in the official hierarchies. Men advance rapidly and attain higher positions than women (Haavio-Mannila & Kauppinen-Toropainen 1992).

Recent studies indicate that the quality of working life for women has deteriorated considerably in some respects. Time pressures and stress have become a more prevalent feature of jobs held by women.

The differences between women's and men's earnings diminished both proportionally and in real terms in the 1970s. In 1983, this development shifted, and the pay differentials between women and men began to grow in real terms in most sectors. In 1991, women's pay was 80% of men's pay.

Women are slightly more-often unionized than men, and their daily working hours, as well as the time spent working during a lifetime, are nearly the same. The characteristics of women workers—unionization, rise in educational standards, full-time work, and very short absences from the labor force—have not served significantly to narrow the pay differentials between the sexes.

As most women work for pay, it is necessary that men share household work with them. In international comparison, gender equality in the division of housework is high (Gershuny 1990). Nevertheless, women still do more domestic work than men, even though their share of it has declined from 67% in 1979 to 64% in 1987 (Niemi & Pääkkönen 1989). In the United States, the percentage was 67% in 1987 (Robinson 1988).

#### B. Sociolegal Status of Males and Females

As the number of children in the families is small, children are valued as individuals. Even though there is a slight tendency to prefer boys when asked which gender one

\**Editor's Note*: Because most of the updates to this chapter are brief inserts to add the results of this third national survey in 1999 (Haavio-Mannila, Kontula, & Kuusi 2001), we indicate these only with brackets to avoid breaking the reader's attention; longer updates are in our standard format, i.e., beginning with *Update 2003* and ending with the updaters' names.

wishes the future child to be, girls are taken care of and loved as much as boys.

The provision of daycare for children is a municipal responsibility. The Day Care Act of 1973 aims at providing communal daycare for all children in need of it. Since 1985, parents have been able to choose between placing their child in communal daycare or receiving a homecare allowance for taking care of their child at home. This allowance may also be used to cover some of the costs of private daycare. Taking care of one's child at home with the help of a homecare allowance does not terminate employment or, since 1991, lower employee pension.

When the educational level of the entire population is examined, it is discovered that women and men are now at the same level. In 1989, half of those who had completed senior secondary school or vocational education or had a university degree were women. Women have reached a high level of general education. In the working-age population, women have a senior secondary school diploma more frequently than men, a circumstance that will prevail in the future, because 60% of senior secondary-level students are women.

Men still have the majority of masters' degrees (60%), but women are quickly catching up; since 1986, the number of women graduating from universities has exceeded that of men. For example, in 1989, women represented 54% of students who obtained a master's degree and 34% of those with a higher degree. The proportion of women who have a doctorate has been steadily increasing since 1976. The percentage of women in the senior faculty of universities remains small.

The choice of fields is segregated by gender. The proportion of women is the largest in healthcare, and quite considerable in the fields of pharmacy and veterinary science. Similarly, students in teacher training are predominantly women. At the university level, clearly the smallest proportion of women can be found in the mathematical and technical fields.

The dropout rate at the basic level of education is very low nowadays. The law provides for compulsory education until the age of 16. The dropout rate at the upper secondary level was 7% in 1988. Somewhat fewer women leave school prematurely than men.

Leisure pursuits are differentiated according to gender. Girls are more interested in arts, boys in sports. Attempts to achieve equality in training are made by offering girls and boys the same opportunities to engage in various kinds of arts and sports.

Women are more active than men as consumers of cultural services. They go to the library, theater, concerts of classical music, museums, and art shows more frequently than men, and form the majority of students in voluntary adult education. Men go to sports competitions more often than women, and somewhat more often to the cinema and to concerts of popular music.

Gender differences in drinking alcoholic beverages have diminished; women have started to imitate the drinking habits of men. This applies particularly to women working with men (Haavio-Mannila 1992).

While men and women are, in principle, equal in Finland, the position of men in the public sphere—in politics, work, and the economy—is still better than that of women. In the private sphere, at home, women have more power than men, but it also means a heavier workload there.

## C. General Concepts of Sexuality and Love

People in Finland have a positive attitude toward sexual behaviors as a health promoter—they do not see it as a threat to health. In 1992, 88% of Finnish men and 79% of women

thought that sexual activity promotes health and well-being. A clear majority, 74% of men and 70% of women, believed that masturbation does not endanger one's health. [In 1999, these figures were 81% and 76%, respectively.]

Sex is considered to be an important aspect of a steady relationship. In 1992, most Finns, 86% of men and 78% of women, considered sexual life very important or important for happiness in their relationship. Among women, the strength of this opinion had declined from 1971 to 1992. In 1971, 40% of women aged 18 to 54 considered sexual life very important for happiness in their relationship, while only 21% held this view in 1992, a development that reflects the strong public preoccupation with sexual liberation 20 years ago. [In 1999, this figure had increased to 29%.]

Women are expected to be more restricted than men in their sexual behavior. These expectations are rationalized by referring to gender differences in sexual needs. In 1992, 51% of Finnish men and 61% of women thought that a grown-up man has a clearly or somewhat stronger sexual need than a woman. Forty-one percent of men and 33% of women considered the sexual needs of men and women as equally strong. Only 7% believed that the sexual needs of women are stronger.

In the case of marital fidelity, a double moral standard is not very strong. In 1971, 34% of men and 29% of women aged 18 to 54 said that one must be able to accept a husband's temporary infidelity, and 28% of men and 30% of women would accept a wife's temporary infidelity. In 1992, the corresponding liberal attitudes in regard to a husband's infidelity were 19% of men and 21% of women, and to a wife's infidelity by 22% and 23%, respectively. [In 1999, the corresponding figures were 23% and 13% related to a husband's infidelity, and 21% and 15% related to wife's infidelity. Women's approval of sexual infidelity had decreased significantly.]

Even though attitudes toward many aspects of sexuality, for example, adolescent and homosexual sex, have liberalized with the course of time, attitudes toward marital unfaithfulness have become more conservative in the last 20 years. This may be because of the fear of AIDS, or to a general increase in familism in the society. It is easier to be liberal in issues not directly tied to one's own life than in matters related to the personal relationship.

[Update 2003: The trend toward increasing expectations of marital faithfulness represents a renaissance of romanticism in a time of increasing individualism. Sex belongs currently to a romantic script in which sexuality is highly valued. According to this approach, individual pleasures are integrated into romantic relationships. Romanticism does not mean an orientation toward the partner at the expense of oneself. The romantic ideas highly valued in traditional female culture have become transformed into valuing the relationship between the partners. This has happened especially among women and in the youngest generation. (Kontula & Haavio-Mannila 2003.) (End of update by O. Kontula)]

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A. Religious Factors

In terms of religiosity, Finland is a uniform country, for about 87% of the people belong to the Evangelical Lutheran Church of Finland and about 50,000 people to the Orthodox Church. Both churches are considered state churches. Only a few thousand people at the most belong to each of a few other religious groups. About 8% of the Finns do not belong

to any religious communities. The religiosity of the Evangelical Lutherans is, in most cases, rather passive; only a small percentage attends church services regularly. The influence of religion and religious values has declined significantly during the last few decades. Religious thinking does not have much meaning in the sexual lives of people, especially the younger generations.

Marriage is no longer considered a prerequisite to having a sexual life in Finland. The quality of the relationship has become more important than its religious or civil form. Sexual relations are accepted in steady dating relationships and most couples live together before marriage. A significant number of cohabiting people do not get married even after years of living together as a couple. The sexual life of single persons is also widely accepted. The percentage of single persons has gradually increased, with about 30% of the middle-aged not living with a sexual partner. One third of these single persons have a steady relationship with a person with whom they do not live.

## B. Cultural Factors

It is an essential principle in recent Finnish legislation concerning sexual issues that people may and can do privately all they want when it does not involve forcing another person. In this regard, Finnish legislation aims to respect the individual's right of self-determination. This was a decisive principle in the reform of Finnish legislation around 1990. This principle is also strong in the general population where liberal sexual attitudes prevail among the secularized and independent-thinking majority. This liberalization of sexual attitudes is a significant change, because those with liberal attitudes on sexual issues are usually more satisfied with their sexual life than are others.

The interval between publication of results from the 1971 national survey (Sievers et al. 1974) and the FINSEX survey (Kontula & Haavio-Mannila 1993) was marked by a great change in attitudes, values, and practices that began in the sexual revolution of the 1960s. Public discussion about the sexual revolution at the beginning of the 1970s in Finland concerned, to a great extent, the increased availability of sexual material and its commercial use in advertising and mass communication in general. The change could also be seen in legislation where the individuals' liberty to decide about their own sexual matters was increasingly recognized. While increased open discussion about sexual issues in society continued the erosion of some of the still-existing old taboos, a clear step was taken towards more-accepting attitudes to sexual issues as a whole. Today, the sexual life of unmarried people is almost as accepted as that of married couples.

A major factor in this shift to more-liberal attitudes has been a rise in the level of education, but even without this, the changes would have been significant. More-positive attitudes about the sexual rights of adolescents, women, and homosexuals have been matched by more-liberal attitudes regarding the acceptability of casual sexual relationships that are not based on love.

In 1971, two women out of three set the promise of marriage as the condition for beginning a sexual relationship; in 1992, only 16%, [and in 1999, only 11%] of Finnish women were of this opinion (see Table 1). Among adolescents, the revolution is even more apparent. Dating has replaced marriage as an institution, with sexual intimacy almost as accepted during dating as it was earlier only within marriage. As a consequence, very few young people marry their first sexual partners any more. As late as 30 years ago, 60% of women married their first sexual partners.

Attitudes have also become more positive towards casual relationships (see Table 2). About 70% of Finns think that

even a casual sexual relationship can be happy and satisfying. The necessity of love as a premise for sexual intercourse has also diminished. Sexual intercourse without love was considered wrong by 42% of men and 64% of women in 1971. In 1992, the corresponding shares were 29% and 43%. [In 1999, they were almost unchanged: 28% and 42%.]

Still, 70% hold that living in a steady relationship in which sexual fidelity prevails is most desirable, compared with 10% who believe that living apart is most desirable. Twenty percent of men and 4% of women would like to maintain several concurrent and continuous sexual relationships. So, as far as their hopes are concerned, women are more monogamous than men.

Finns also take a more liberal attitude than before toward sexual relationships that are outside their own steady relationships. This shift is linked with the greater acceptance of sexual relationships among unmarried and single persons. Attitudes toward homosexual relationships are also significantly more accepting than before. In 1971, close to half of all Finns, 44% of males and 45% of females, regarded homosexual behavior between adults as a private affair with which officials and legislation should in no way interfere (see Table 3). In 1992, this opinion was supported by 59% of men and by 72% of women. [In 1999, the corresponding figures were similar: 58% and 72%.] On the other hand, attitudes toward extramarital relationships of spouses and pornography have become somewhat stricter, but only among women. Two thirds of the men and one third of the women considered watching pornography sexually arousing for themselves. The quite-free sale and distribution of pornographic films and videos were supported by 51% of men and by 24% of women.

Based on attitudes towards sexuality, equality of gender has made remarkable progress in Finland. Women's right to be the initiators at sexual intercourse when they want it so,

**Table 1**

**Percentages of Men and Women by Age Who Think Adolescent Sexual Intercourse Is Acceptable in a Regular Relationship, 1971 and 1992**

Age	Men 1971	Men 1992	Women 1971	Women 1992
18-24	75	91	59	91
25-34	64	94	40	93
35-44	52	88	20	86
45-54	38	80	14	71
55-64		72		49
65-74		56		43

1971: *N* = 2,139, with 738 men and 1,401 women

1992: *N* = 2,244, with 1,101 men and 1,143 women

**Table 2**

**Percentages of Men and Women by Age Who Think That an Entirely Casual Sexual Relationship Can Be Happy and Satisfying, 1971 and 1992**

Age	Men 1971	Men 1992	Women 1971	Women 1992
18-24	77	74	52	73
25-34	66	82	44	73
35-44	50	73	35	63
45-54	51	68	24	56
55-64		65		34
65-74		48		35

1971: *N* = 2,132, with 741 men and 1,391 women

1992: *N* = 2,239, with 1,101 men and 1,138 women

was supported by 94% of men and by 90% of women in 1992. This is a significant increase, especially among women. [In 1999, these proportions were still higher: 97% and 94%.] Three out of four women were of the opinion that a respectable woman could openly show her interest in sex.

The cohort analyses show that part of the changes in attitudes do not concern the oldest people at all, especially not the women. Women aged 55 to 74 approve of women initiating a sexual relationship, casual relationships, and sex without love as rarely as they did 20 years ago when they were 35 to 54 years of age. On the other hand, the attitudes towards gays and sexual relationships between steady-going adolescents have become more liberal in all the gender and age groups.

The differences in sexual behavior between Finland and the U.S.A. are not very big. However, Finns are significantly more liberal than Americans, at least, in their attitudes towards the beginning of sexual life with adolescents, homosexual relationships, and pornography (Smith 1990). A corresponding difference was observed 20 years ago between Denmark and the U.S.A. (Christensen & Gregg 1970).

### 3. Knowledge and Education about Sexuality

#### A. Government Policies and Programs for Sex Education

Legal restrictions designed to control sexarche, the beginning of sexual coitus, which prevailed in Finland until as late as the 1800s, were gradually replaced by the moral education given by the Church and the school. This education with its religious morals gradually changed, giving way to medical views on sexual matters. In sexuality education, the main attention gradually turned from teaching about what is immoral and a sin to focusing on the prevention of pregnancies and the ill health effects caused by sexual relationships. Contrary to the custom in many other countries, giving information, advertising, or distributing contraceptives have never been officially prohibited in Finland.

In the 1920s and 1930s, sex education was considered a family responsibility. There was no sex education in the schools as yet. In 1944, the National Board of Education sent a letter concerning sex education to the schools, directing teachers of biology, hygienics, Finnish, and religion to give instruction in sexual matters.

In 1948, an expert board set up by the Ministry of Education produced a program for instruction and education in sexual morals. The program contained guidebooks both for teachers and students. These guidebooks were distributed to schools, colleges, municipal officers of health, church registry offices, and youth organizations at the public expense. Apart from information about personal relations and

sexuality, the program, with the guidebook to accompany it, also contained moral views about conditions in which sexual life was considered appropriate for young people.

In the early 1960s, the first summer university courses were held for teachers on family education. In the schools, sex education was still very scarce. In the 1970s, the National Board of Education set up a working committee to make a curriculum for the education in personal relations and sexual matters for the comprehensive school. The work was finished in 1976, but it did not lead to any wider reform of teaching. Instruction in contraception was, however, given in most schools.

From the 1950s on, Finnish municipalities have arranged equal school healthcare for all students, and sex education was already a part of this care prior to the 1970s. In practice, however, sex education has—and continues to be—concentrated on the anatomy and physiology of sexuality, contraception, and sexually transmitted diseases. Its outcome has largely depended on the personal interest of those teachers of biology and health education, together with physicians and nurses, who are responsible for the planning and the implementing of the educational experiences, most of which are aimed at the 15- to 16-year-old students in the 9th grade. However, in comparison with the 1960s, all young people have been included in this program, and other sources of information have also been available.

Since the early 1970s, the number of unwanted pregnancies and abortions among adolescents has decreased considerably. In part, the increased liberalization may have contributed to the decline in sex-related research efforts at the end of the decade.

Since 1972, the Primary Health Care Act has required municipalities to organize contraceptive counseling for all who want it, including schoolchildren, who were given access either to public clinics or to school physicians and nurses. When a physician or school nurse has found it necessary, girls have been provided with contraceptive pills.

In 1996, a comprehensive national study of sex education was started at the upper stage of the comprehensive school (grades 7 to 9). A questionnaire was mailed to the biology teachers in all upper-stage schools in Finland ( $N = 603$ ) in February 1996. A total of 421 acceptable responses were returned from 70% of the target population.

The survey came during a period of transition in school sex education, for, in many schools, significant reductions have been carried out in the lesson hours reserved for Health Education. Family Education is about to disappear altogether and new self-governed curricula of the schools have recently been implemented.

Prior to the survey, sex education had been included in the curricula of most of the schools. Only 6% of the teachers reported otherwise. It has been given by a filtering method in connection with several other school subjects.

In the 9th grade, the biology teachers usually discuss the subject in connection with biology and the home economics teachers in connection with family education. In the 8th grade, the boys' and the girls' physical education teachers take up the subject in connection with health education. In addition, approximately half of the schools use school health nurses in sex education (as instructors in contraception) in each of the upper-stage grades.

In the 7th grade (aged 13 years), half of the schools had given instruction in the developments in puberty and menstruation. In the 8th grade, new items were: sexual intercourse, "the first time," contraception, sexually transmitted diseases, dating, and emotions, which had been dealt with in every other school. In the 9th grade, in addition to the above subthemes, nearly all the schools' sex education dealt with

**Table 3**

#### Percentages of Men and Women by Age Who Think That Official and Legal Interference in Homosexual Behavior Is Wrong, 1971 and 1992

Age	Men 1971	Men 1992	Women 1971	Women 1992
18-24	49	60	54	74
25-34	53	66	54	77
35-44	37	59	33	75
45-54	31	52	25	62
55-64		52		55
65-74		44		40

1971:  $N = 2,126$ , with 742 men and 1,384 women

1992:  $N = 2,242$ , with 1,101 men and 1,141 women

genitals and their functioning, ejaculations, conception, pregnancy, birth, and abortion. Other generally discussed new subthemes were sex roles, sexual minorities, sexual morals, sexual terminology, and sex life in adulthood.

Almost all the schools had used videotapes or films in the 9th grades. Textbooks had been used by four out of five, brochures of different kinds had been distributed by two out of three, and condoms had been given at least for examination in every other school. In one third of the schools, visits had been arranged to contraception or family planning clinics; and every tenth school had made visits to youth offices and/or to the congregation. A special event or happening related to sex education had been arranged in 16% of the schools within the school year.

According to the survey, the most important objectives of school sex education were directing the growth to responsibility, transmission of correct information, promoting the growth of personality, and learning easy attitudes towards sexuality. On the other hand, teaching abstinence, finding the sexual experience nice and stimulating, as well as learning that casual relationships were unsatisfactory were considered the least important objectives. The chosen objectives emphasized promoting adolescents' readiness for couple relationships and sexual life. The teachers wanted to avoid moralistically intervening in adolescents' own choices or "feeding" them their own moral values. The teachers did not want to warn against sex too much; neither did they want to advertise it.

One of the objectives of the survey was to explain the possible differences in sex education across the country. As a whole, these differences were not strikingly great or systematic between the provinces. The perceived differences were mainly explained by the local governments' activity in arranging further training in this field or various campaigns.

The greatest problem in the Finnish school sex education is its timing: It comes too late for the stage in the adolescents' development. The present sex education given to the 9th graders (aged 15 years) should be provided two years earlier. Both the students themselves and the experts in this field agree unanimously that sex education in its full extent should already be given to the 12- to 13-year-olds. According to the latest news, the syllabi of biology will cover sex education for the 8th graders (aged 14 years).

The strength of school sex education in Finland comes from the school healthcare, which brings out sexual matters in connection with annual physical examinations. Over a third of the girls and a fifth of the boys go to the school health nurse even at other times to talk about sexual matters. In most schools, they also give contraceptive pills. According to the survey, school health nurses also give proper lessons in sex education in at least every other school. Without the contribution of the school healthcare, the level of adolescents' knowledge of sexual matters would be significantly lower than what it is now.

[Update 2003: In 2002, health education was prescribed as a compulsory subject of the national primary school curriculum. Sex education was integrated in health education. This will harmonize and improve sex education in Finland.

[Teenage sexual knowledge was tested in Finland in 2000 (Kontula et al. 2001). Fourteen- and 15-year-old students of the 8th grade responded to the national sexual health knowledge survey. It was organized as a competition between schools. The survey had 30,000 respondents. It revealed that the quality of sexual knowledge was much poorer among the boys than among the girls. On the average, boys got 48 points and girls 57 points of the maximum 80 points. Girls had better knowledge in all areas of the sexual health topics. Because of more-limited sources of information, sex education

provided in the school is more important for the boys than for the girls. (End of update by O. Kontula)]

No detailed and effective public program for the development of sex education or other public services related to contraception can take credit for the quite-effective system of school sex education and the low teenage pregnancy rates in Finland. Rather, we would credit the liberal climate around adolescents and their sexuality for the teachers' natural willingness to teach the subject. Adolescents' need for information about sexual matters has been taken for granted. When sexual relationships between adolescents are accepted, it is clear that they are entitled to be prepared and well informed about various matters related to sexual life.

Public healthcare plays a significant role in sex education and advising on contraception. The system of maternity and childcare of the public health centers covers the whole country for almost all the expectant mothers and families with children. In the maternity centers, sexual life during pregnancy and contraception are discussed, among other things, and mothers and fathers are psychologically prepared to welcome the baby.

A liberal attitude towards sexuality may be reflected in the condom advertising found in the mass media, especially during the summer months. Women's magazines have also contained numerous sex-related articles that are read by both sexes.

## B. Informal Sources of Sexual Knowledge and Education

In the FINSEX study (Kontula & Haavio-Mannila 1993), people were asked if they had gotten information about sexual matters in their childhood homes in their youth or sex education at school. At the same time, the people were asked to evaluate the sufficiency of the information and education they had received and their willingness then to receive such information about sexual matters in general. Similar questions were asked both in 1971 and 1992.

Discussion of sexual matters has gradually increased both in the homes and in the schools. In their childhood home, information had been received about sexual matters by 39% of men and by 41% of women in 1971, and in 1992, correspondingly by 61% and by 64%. Ten percent of men and 14% of women in 1971 regarded the information received at home as sufficient. In 1992, the percentages were 29% and 32%, respectively. Until recently, most people have, thus, not been getting very much information about sexual matters at home, even if these matters have been more talked about.

In 1971, 28% of men and 33% of women reported having received sex education at school, and in 1992, 64% of males and 74% of females. [In 1999, these proportions were already 78% and 81%.] In 1971, 7% of men and 8% of women considered this information sufficient; in 1992, the percentages were 25% and 32% [and in 1999, 36% and 43%]. This shows that sex education in the schools has clearly improved, although only around 40% of the respondents considered the education sufficient. Close to 5% of the people said that they would not even have wanted such education. Slightly more people would have wanted to receive more education from the school than from the home.

Young people report clearly more often than others of having received sufficient information concerning sexual matters from the school or home (see Table 4). This suggests that speaking and teaching about sexual matters has clearly become more common, at least with those people who lived their youth in the 1980s. During the past 20 years, there was an especially clear increase in dealing with sexual matters. After 1971, the share of those who had received sex education in the school increased nearly threefold. Only a

few people in the oldest age groups reported they had talked enough about sexual matters in their homes or at school.

The school has often tried to avoid taking the responsibility of giving sex education, maintaining that it is a question of family privacy with which the school should not interfere. This has been an attempt to cover the teachers' own feelings of insufficiency about the teaching of sexual matters. The homes again have shuffled off the responsibility upon the school. The young people in this awkward situation have had to find the information they needed from the most diverse sources. Such sources have been the mass media and sex-related literature, from which the information received has been spread from one to the other in the circle of friends. Boys often use sex magazines as a source of information—often as their only source—where they have found actual information about sexual practices. The girls again have been more interested than the boys in the medical facts about becoming pregnant and contraception. This information has often been found in the readers' queries sections of magazines.

The attitudes about the school's sex education are fairly trusting in Finland nowadays, since at least 63% of the men and women reported that they did not think sex education in the schools would induce the young to start their sexual life too early. Only 19% of the men and 22% of the women feared that sex education would induce young people to have intercourse too early. Those who supported this opinion were strongly concentrated in the over-55-year-old age group, where one in every two held this opinion. Since the people of this age group have had their say in the decision making of sex education in the schools up to now, it is no wonder there are still some deficiencies in the teaching.

#### 4. Autoerotic Behaviors and Patterns

##### A. Children and Adolescents

According to Kontula and Meriläinen (1988), between 2% and 3% of both the boys and the girls reported having started masturbating already before age 10. In childhood, touching genitals to cause pleasure cannot very often be connected with masturbation. In addition, adolescents often dare not report it in a survey such as this. The researchers, therefore, believe that the percentage of children practicing masturbation at an early age is surely more than 2% or 3%.

In the follow-up of the same survey (Kosunen 1993), 13- to 17-year-olds were asked if they had ever practiced masturbation and if they had masturbated during the last month. Of the 13-year-olds, 36% of the boys and 23% of the girls reported that they had sometimes practiced masturbation; of the 15-year-olds, 67% and 45%, respectively, reported this practice; and of the 17-year-olds, 79% and 59%. About 40% of the boys had masturbated during the last month and about 20% during the last week. With the girls, the corresponding figures were 20% and 5%. With age, the masturbation activity of the young increased.

**Table 4**

**Percentages of People by Age Reporting That They Received Sufficient Sex Education at Home and at School, 1971 and 1992**

	18-24	25-34	35-44	45-54	55-64	65-74
School 1992	58	37	18	7	3	1
Childhood home 1992	52	34	19	17	9	7
Childhood home 1971	21	12	7	8		
School 1971	17	5	3	2		

##### B. Adults

The proportion of adults engaging in self-loving, clearly more common among men than women, has definitely increased during the last 20 years, according to the FINSEX study. There has been an increase in the practice of self-loving both during the previous month and during the past year. In 1971, 28% of the men and 16% of women reported masturbating during the previous month. In 1992, the corresponding shares were 42% and 25% [and in 1999, already 60% and 37%]. The strength of the change can be seen in the percentage of women who had masturbated during the previous year. In 1992, this figure for women was higher than the corresponding data for men in 1971.

With the spread of a more-natural attitude towards self-loving, fewer and fewer people abstain from it entirely. In 1971, 49% of the women and 26% of the men had never tried this sexual outlet. In 1992, the corresponding figures were 23% and 10% [and in 1999, 14% and 6%]. So, a large majority of both women and men have engaged in self-loving at least some time in their life.

Self-loving is considerably more common with the young than with older people (see Table 5). This, however, is not so much because of age differences as it is to changes in the times. People seem to keep the frequency pattern of self-loving they adopted in their youth throughout their lives. There are no obstacles to this, since masturbation is in no way dependent on the presence of a partner. With the aging of the present middle-aged people, the incidence of self-loving will increase further in the population.

The increase in self-pleasuring is explained by the fact that fewer and fewer people believe in the unfounded arguments that it entails health risks, as booklets on sex education maintained as late as the 1950s. Two thirds of the women and over one third of the men who still believed in these risks, or were at least uncertain about them, had never engaged in this sexual activity. Very few of these women had masturbated during the last month. On the other hand, half of the men who had totally lost their belief in the health risks of masturbation, and nearly 30% of the women, had engaged in self-pleasuring during the last month. The spread of accurate information had been a major factor in encouraging people to feel free to enjoy their sexuality with self-pleasuring.

Having a steady sexual partner somewhat diminished the need for self-loving: The unmarried, the divorced, and the widowed engaged in self-pleasuring more regularly than did married people. The better-educated people engaged in self-loving more often than others. Religiosity did not relate to the incidence of self-loving, but those who consumed more alcohol were more likely to masturbate than others. During the past 20 years, the differences in the incidence of self-loving among the different age groups has disappeared, while the differences between the marital-status groups and alcohol-user groups had grown.

Young low-income men and women engage in self-pleasuring more often than others. This relation of the mas-

**Table 5**

**Percentages of Men and Women by Age Reporting That They Had Masturbated During the Past Year, 1971 and 1992**

	18-24	25-34	35-44	45-54	55-64	65-74
Men 1992	77	71	57	43	25	18
Men 1971	64	44	30	14		
Women 1992	61	53	43	26	13	11
Women 1971	45	28	16	11		

turbation frequency to low income persists in middle-aged men. Further, this higher incidence of self-loving is related to the observation that low-income men enter into steady relationships less frequently than others. Masturbation thus serves them, at least in part, as a substitute for an intercourse-centered sexual life.

[Update 2003: One important finding of the current study is that masturbation does not necessarily decrease during the course of one's life. In fact, the three surveys in Finland show that masturbation remained almost at the same level in every birth cohort from one survey to another. This implies that the masturbation habits, which each generation adopted in its teenage years, tend to remain very similar throughout life, even over a 27-year time span. This tells us how important a generational approach is to understand differences between age groups in sexual attitudes and behaviors. Comprehensive sex education for teenagers would help new generations enjoy their sexuality free from unnecessary fears and anxiety (Kontula & Haavio-Mannila 2003b).

[According to studies of the sexual autobiographies of ordinary people, fears related to masturbation have been common among many generations in Finland, Estonia, and St. Petersburg. Several authors of the sexual life histories have been afraid of the negative consequences of masturbation after reading warnings in publications or after hearing about them from others. Fears (of becoming insane) and guilt related to masturbation were common especially before the 1970s. Some people explained how they had tried to stop masturbating because of these fears, usually unsuccessfully. Even among women in the youngest generations, feelings of guilt remained common (Kontula & Haavio-Mannila 1997; Haavio-Mannila et al. 2002). (End of update by O. Kontula and E. Haavio-Mannila)]

The use of pornographic materials has remained almost the same among men but decreased among women between 1970 and 1990. Even when sex videos were included in the printed publications in 1992, fewer people, on the average, had viewed such material during the previous year. During the past year, 50% to 60% of the men in the different age groups, and from 15% to 20% of the women, had watched a sex video or read a sex magazine.

Obviously, interest in pornographic publications was exceptionally high in 1971, because open nakedness had come, for the first time, into the pictures of the sex magazines at the end of the 1960s in Finland. The charm of novelty and the taste of "the forbidden fruit" made this material especially attractive. More recently, this high excitement and attraction have settled down. Besides, the so-called soft pornography is now within everyone's reach, for example, in the pictures in the afternoon tabloids, although it is no longer referred to as pornography.

[Update 2003: In 1999, the popularity of pornography had again increased: 64% of the men and 21% of the women had looked at sex magazines during the last year. For sex videos, these proportions were 57% and 27%, respectively. (End of update by O. Kontula)]

## 5. Interpersonal Heterosexual Behaviors

### A. Children

Small children often play sexual games (doctor games) and masturbate, during which they examine the genitals of both their own and the other sex. According to the KISS study conducted in Finland (Kontula & Meriläinen 1988), sexual games have been played by at least 40% of the young adults in their childhood, half of them more frequent than one or two incidents. These games may also include imitating and trying the sex habits the children had seen adults us-

ing. This cannot, however, be regarded as an actual initiation of sexual life, because it is not yet conscious activity that could be interpreted as sexual. Sexual meanings are not generally understood before approaching adolescence and the effects of pubertal hormones on the brain. Puberty brings a quite new kind of interest in sexual matters.

### B. Adolescents

#### Puberty

By age 13, about four out of five girls have had their first periods of menstruation and about 60% of the boys their first ejaculations. As a result, many young people show considerably more serious interest in the opposite sex than before. Over half of the boys of this age and one third of the girls have already viewed sex magazines and sex videos, and more than half of both boys and girls have kissed, according to the 1992 data. Many have experienced caressing over the clothing. Almost half of the 13-year-olds are ready to accept sexual intercourse in their peers' relationships. About as many report having already had a dating relationship with the opposite sex. Mostly, this means going around together with the dating partner as part of a group of young people. Sexual intercourse has been experienced by about 5% by the age of 13.

Between ages 14 and 15, most Finnish adolescents go to a confirmation class, a one-week church-sponsored camp, after which they are confirmed. This has become a kind of initiation rite for becoming a sexual adult.

Adolescence is a time of rapid changes, and, with age, sexual experience quickly grows. In Finland, the greatest changes in adolescent sexual behaviors occurred between 1960 and 1970. In 1992, Finns between ages 18 and 54 reported they had kissed for the first time, on the average, at the age of 14, had started dating at 17, and experienced their first sexual intercourse at the age of 18. Young people with a long education began sexual intercourse later than others.

Nowadays, young people mature, both physically and mentally, earlier than before. Because of the increased economic well-being, they live in a more grown-up way at a fairly young age, when they build their sexual identity through a multinational youth culture. As a result, the age of sexual initiation has fallen. On the other hand, the time spent in education has lengthened and the age of entering into marriage has risen. This explains why young people have more relationships, both successive and casual, today, and why marriage has been displaced by cohabitation, at least before having children.

In the 1992 FINSEX survey, one third of the 18- to 74-year-old women and a quarter of the men reported dating (going steady) by age 15. About four out of five had experienced kissing, and two out of three caressing over the clothing. Petting under the clothing had been experienced by one of every two younger Finns. Sexual intercourse before the age of 16 had been experienced by 31% of the girls and 19% of the boys according to the 1992 data (see Table 6). On average, Finnish girls begin having intercourse somewhat younger than the boys. This is quite understandable, because girls

**Table 6**

#### Percentage of 9th-Grade Pupils (15-Year-Olds) Who Had the Indicated Experiences, 1992

	Boys	Girls
Masturbation	67	45
Kissing on the mouth	72	81
Light petting	66	70
Heavy petting	45	53
Sexual intercourse	19	31

often date boys from two to three years older than they themselves are. The boys are more eager to have intercourse than the girls, but the girls have better opportunities.

### *Early Noncoital Experiences*

The sexual life of young Finns does not generally begin with sexual intercourse, but with kissing and caressing. These behaviors are often associated with first dating relationships. It has been observed in Finland that four years, on the average, elapse from the first kisses and caresses of the young people to the first sexual intercourse (Kontula 1991). These experiences are surely as important to the young as the first intercourse. In the past, when a great number of people wanted or had to put off beginning sexual intercourse until marriage, kisses and caresses were the only forms of sexual life before entering matrimony.

A great number of people have already kissed before their first steady relationship, according to the 1992 FINSEX study. After the mid-1970s, about 60% of the men and 70% of the women were dating before the age of 18. About 40% of the present-day under-35-year-olds had had a steady dating relationship before the age of 16. Before the 1950s, it was quite unusual for women of this age to date. Nowadays, only 3% of the over-25-year-olds have never had a dating relationship. Since the 1980s, there have not been great changes in the onset of dating.

The age of sexual initiation has clearly fallen during the past few decades. Both first kisses and dating relationships are experienced at a younger age today than in the past. Four out of five have kissed before the age of 16, and two out of three have been going steady before the age of 18.

Characteristic of those adolescents who initiate a sexual life earlier than the others is a lifestyle that emphasizes a break with the norms of childhood and an orientation towards a freer social life. To these young people, free social life represents a means rather than a goal. The reverse is true for those who have less self-confidence and fewer sexual experiences. The acquired values and moral codes, such as associating love with family, lose their importance after sexual initiation.

Based on the KISS study (Kontula 1991), it can be said that the values associated with starting a sexual life early are today often connected with symbolic opposition or rebellion to authorities. Extended education with its upper-class values is ideal for arousing such opposition.

Sex is used to sell things and ideas to the young, but sex itself is rarely sold to them. Society and parents rarely provide adolescents with interpretations of sex (scripts) that would give a positive and an enjoyable picture of sexuality. Thus, adolescents, girls in particular, do not expect much good of their first sexual experiences, especially of sexual intercourse. Normally, organized education and instruction only provide warnings about the risks of getting pregnant, being infected with an STD or the HIV virus, getting a bad reputation, and similar dangers.

Moral values concerning reproduction and marriage have gradually been replaced by the values of satisfying one's social needs. This shift has contributed to a widening of interpretations relating to sexual interactions guided by strict Christian and conventional scripts towards "games," in which various tactics to achieve first sexual experiences are possible. The morals of satisfying social needs, which emphasize the importance of sexual life, give young people permission to initiate a sexual life in various practical situations. This widening of the sexual script towards "games" is one important reason for an earlier sexual initiation among Finnish adolescents during the last few decades (Kontula 1991). Tactics, interpretations, and values, which are all

part of sexual interactions, are, however, still strongly regulated socially and culturally.

### *Dating*

The age of first dating, like the age of first kisses, has lowered in recent years. In the 1930s, only half of the under-20-year-old people had dating relationships; currently, more than four fifths of the under-20-year-olds are dating. This increase stopped in the 1980s.

In the Finnish-Karelian culture area, "night courting or prowling" was a common way for young people to become acquainted until the early 20th century. In rural areas, it was customary for groups of boys to visit several girls during a single outing, since the girls belonged to the same social group. In going to the girls' sleeping quarters, "night courting" constituted a formal social venture or endeavor, with identifying knocks, introductions, overtures, seductive lines, and poetry. The choice of a conversation partner was made with the help of night proposal rites. The many customary rules and norms in night courting were aimed at the preservation of morality (Sarmela 1967). In their classic study *Die Einleitung der Ehe [The Introduction to Marriage]* (1937), K. Rob and V. Wikman divided night prowling into two main types: organized-group and individual courting. In group prowling, the boys watched, often very strictly, over each other's behavior. The girls could not refuse the visits of such groups. It was, nevertheless, in the power of the girls to decide which boys in the group would be allowed into their sleeping rooms in the storehouse or building where they were spending the summer.

### *Sexarche*

Sexarche, first sexual intercourse, requires finding an appropriate partner and becoming sexually aroused. What a person defines as "appropriate" is closely associated with the interpretations given by society. "An appropriate partner" may be understood as a partner with whom one has a love relationship and a relationship in which both partners feel "ready" for sexual intercourse. The importance of these social conditions is emphasized by the fact that about 20% of the 15-year-olds with steady partners would have liked to have sexual intercourse, but, for some reason, they had not had that experience. They had had both the chance and the willingness; nevertheless, all the social conditions had not been fulfilled.

At the age of 15, adolescents usually accept the sexual intercourse of their peers on grounds of love. Thus, an important condition for starting a sexual relationship is that two people love each other enough. The importance of love in legitimating sexual relationships of the young people is somewhat greater among farmers and the upper-middle class. This applies to both youths and their parents. This emphasis on love is closely connected with the demand for faithfulness.

Girls tend to value sex less, to masturbate less frequently, and to report considerably less desire for sexual intercourse than boys of their age. Girls who have never had a steady relationship with a boy are less likely to report a strong sexual desire. A female culture that emphasizes love does not attach a high value to sexual enjoyment in the expectations of Finnish girls. The dating institution, however, diminishes the effect of this romantic value that delays sexarche. Among the girls, the importance of sex quickly increases with an increase in experience. Dating clearly brings the expectations of sexual life closer to each other in boys and girls.

Twenty percent of Finns currently experience sexual intercourse before the age of 16, and approximately 50% by age 18. [*Update 2003*: According to the latest results (2003), about three quarters of women and over half of men experi-

ence sexual intercourse before the age of 18. The mean age of first intercourse was 17.6 years for women and 18.1 years for men. (*End of update by O. Kontula*)

Seventy percent of the women and half of the men reported that they had had their first experience of sexual intercourse with a steady partner. Only 60% of the women and 50% of the men reported being in love with their first sexual partner (see Table 7).

Among the older Finns surveyed, nearly half of the women had their first sexual intercourse after the age of 20. With the men, the corresponding share was about one fifth. Among younger Finns, about 10% have their first intercourse after age 20. Two percent of the over-30-year-olds reported that they had never had sexual intercourse.

The age of first sexual intercourse does not differ significantly in the provinces of Finland. Nor is it related to population density, although people living in the rural areas start having sexual intercourse somewhat later than urban youth, probably because rural living provides fewer opportunities for making social contacts.

A significant change has also occurred in the extent to which sexual intercourse is involved in the first dating experiences. When ages of first dating relationship and first sexual intercourse are compared, it appears that, as late as the 1930s, sexual intercourse was not generally a part of a steady dating relationship. Less than a third of the women who had been dating at a particular age had had sexual intercourse at that age. After the 1930s, there was a continuous even growth in the proportion of the women who experienced sexual intercourse while dating. By the end of the 1970s, the proportion of women dating who had had sexual intercourse grew to nearly 90%. During the 1980s, it dropped a little and is now about 80%.

Women's greater sexual initiative and willingness at the first intercourse has contributed to this change. However, for many women the first experience of sexual intercourse is still painful and a disappointment. Many women go through their first experience expecting it as a necessary routine in order to be able to start really enjoying their sexual life after this "puncturing."

The decreasing gap between the willingness of men and women to initiate sexual relations in the interval between the 1970s and 1990s is statistically very significant. In two decades, the share of the women who were reluctant at their first sexual intercourse fell from 40% to 10%. This increasing equality between women and men has been matched by an increase in equality in other sectors of life, such as education, work, politics, family, and leisure time. Part of this change may be because of the more-honest reporting of both men and women to these questions than before.

### Early Contraceptive Use

The use of contraception at the first intercourse has increased considerably in recent decades (see Table 8). Only a

few percent of the over-55-year-olds had used contraception at the first time, and about 70% had been entirely without contraception. Withdrawal was the most common contraceptive method. The use of the condom as a contraceptive method at the first intercourse increased significantly with the under-55-year-olds, especially among the young after the middle of 1960s. In the 1970s, the use of the condom decreased slightly, according to age-group comparisons, but increased again in the 1980s, obviously because of the condom campaigns against AIDS. In the recent years, 60% of the men and 65% of the women had used the condom at the first intercourse. About 15% used no contraception at all. These proportions correspond well with results of the most recent surveys among adolescents.

## C. Adults

### Single Adults

In 1992, 30% of Finnish men ages 18 to 74 and 34% of women were not married or cohabiting. One third of these had a steady sexual relationship. In the whole population covered by our survey, 11% of both men and women had a steady sex partner with whom they did not live.

The proportion of single adults, i.e., not having any steady sexual relationship, is highest in the youngest and oldest age groups (see Table 9). A large proportion of people under 30 years have not yet started to live together with a partner but will probably do so later. Many of the women over 60 years are single because of widowhood and the shortage of older men. Among men, singlehood does not increase with age because they less often get widowed and have more potential partners available.

Singlehood in Finland does not mean celibacy. A large proportion of single people have a regular sex life: 40% of all single men and 28% of single women had not experienced periods of at least six months without sexual intercourse over the course of the previous five years. On the other hand, 8% of single men and 30% of single women had not engaged in sexual intercourse during the previous five years.

More single adults never had engaged in sexual intercourse, 14%, compared with 3% of the total population. Single women started their sexual activity at a later age than other women, but for men, singlehood was not connected to the age of initiating sexual intercourse.

Single men have a more-varied sex life than single women. Forty-six percent of single men and 20% of single women reported sexual intercourse during the previous month. Thirteen percent of the single men and 3% of the single women had engaged in sexual intercourse at least once a week during the previous month.

Measured by the number of partners, the sexual life of single adults is also livelier than that of married and cohabiting people. Close to half of all single men and more than a

**Table 7**

Women 1971	6	18	21	34		

**Table 8**

**Percentages of Men and Women by Age Who Used No Contraception at the First Sexual Intercourse, 1971 and 1992**

Age	Men 1971	Men 1992	Women 1971	Women 1992
18-24	26	17	24	13
25-34	39	24	46	22
35-44	58	29	60	18
45-54	57	40	60	42
55-64		67		68
65-74		82		70

1971: *N* = 1,919, with 669 men and 1,250 women

1992: *N* = 2,048, with 1,002 men and 1,046 women

third of single women had had more than one sex partner during the previous year.

For single adults living without a steady sexual relationship, their last sexual partner was usually a sexually unaffiliated person. Fourteen percent of single women and 9% of the men said that their last partner was a spouse or steady partner of somebody else. Of single men, 2% said that their last partner was a prostitute. One tenth of single men had, during their lifetime, had intercourse with a prostitute. This is the same proportion as for married or cohabiting men. No single women reported contact with a paid sex partner.

Single people do not use as varied sex techniques as cohabiting couples and other people having a steady relationship. The positions used in last intercourse resemble those of married people: the missionary position with the man lying on top and the woman underneath. In the casual sexual relationships of single people, the love play and coital positions are fairly traditional: There is little oral sex and stimulating of a partner's genitals by hand.

For women, the incidence of orgasm in sexual intercourse varies according to having or not having a steady sexual relationship. However, 26% of single women did not recall whether they had an orgasm during their last intercourse, perhaps because this may have been several years ago.

Single adults reported less satisfaction with their last intercourse than other people. Single adults also reported less satisfaction with their sex life as a whole than people having a steady sexual partner. Single people have a lower sexual self-esteem than other people; this may be one reason for their lack of sexual partner. People not having sexual relationships do not receive positive sexual feedback, which might strengthen their self-esteem.

Slightly more single men have had some homosexual experiences during their lifetime than attached males, 7% compared with 4%. Single men also are more likely to have a homosexual identity or identify themselves as bisexuals than other men (see Section 6 on homosexuality and bisexuality). Single women are not more often lesbians than other women.

Masturbation is more common among single adults than other adults. Half of single men and one fourth of single

women reported self-loving during the last month, twice as high as married people. Self-loving is most common among single people living with their parents. Most of these are young people.

In addition to using self-loving to compensate for not having a steady sexual partner, singles watch sex videos. Forty percent of single men had watched sex videos at least a couple of times during the previous year. This is the same frequency as cohabiting men and more than married men. Only 5% of single women had watched sex videos during the year, less than cohabiting or married women had done. Similar differences were found in the use of pornographic books and magazines. Women with steady partners may get invitations from their partners to watch sex videos or read pornographic materials. Single women seem to be too shy to buy or borrow sex materials to use alone.

Sex toys and aids are generally not used as substitutes for sexual relations (see Section 8 on unconventional sexual behaviors). Vibrators are not used more by single than by other women—about 5% of all women had ever used them.

Alcohol is associated with the sexual life of single adults more than it is for affiliated persons. As many as 58% of single men and 26% of single women reported drinking alcoholic beverages before their last intercourse. For single men, this proportion is almost double that of other men, perhaps because the casual relationships of single adults often begin in restaurants and other social situations where alcoholic beverages are served.

Even though single adults suffer from feelings of loneliness more than people living in a couple relationship, not all of them long for a sexual partner. Many deny the importance of having sex or living with somebody.

### Cohabiting Adults

All over the world, families and couple relationships have changed in recent decades. In the developed countries, children move away from the parental home earlier than before, cohabitation has become a common form of starting a marriage, divorces have increased, and the number of children has declined.

Because of the higher standard of living, adult Finns today live less often with their parents than in earlier times and more often alone (see Table 10). The increase in unmarried cohabitation has decreased the proportion of married people in the population. In 1971, 64% of the respondents ages 18 to 54 lived together with their spouse and only a few percent with their fiancées or steady partners. The rapid growth of cohabitation can be seen from the 1992 survey: 16% of the 18- to 54-year-olds were cohabiting and only 53% of the population in this age cohort were married. [In 1999, 15% were cohabiting and 50% were married. Living apart together (LAT) relationships had increased; their proportion was already 13%.]

The increase in cohabitation has not meant that there are more couples living together than earlier. When one adds the percentages of married and cohabiting people together, their proportion only grew from 66% in 1971 to 69% in 1992. The main change is that nowadays more people delay or do not

**Table 9**  
Percentages of Men and Women by Age in the Given Type of Couple Relationship, 1992

Type of Relationship	Age, Years					Total

Marriage	4	44	71	77	76	74	57
(n)	(159)	(249)	(266)	(203)	(308)	(96)	(1103)
<b>WOMEN</b>							
No couple relationship	32	11	15	13	29	49	23
Steady sexual relationship without living together	32	11	8	9	6	3	11
Cohabitation	28	22	13	7	4	1	13
Marriage	8	56	64	71	61	47	53
(n)	(164)	(233)	(250)	(191)	(157)	(149)	(1114)

enter a formal marriage, and maintain an official status as single. In the past 20 years, the proportion of never-married people among the 15- to 54-year-old Finns rose from 35% to 40% for men and from 27% to 36% for women.

The developmental cycle of the present union greatly varied by age in 1992 (see Table 11). In the older age groups, 55 years and over, a large majority first moved in together after the wedding. In the age category 25-to-44 years, half of the people first lived together and then married. Four fifths of the less-than-35-year-old people living together with someone were cohabiting without marriage. At present, most Finns start their marital life as a cohabiting couple.

In 1992, the age at moving in together was for men aged 15 to 64 years, on average, 0.9 years lower than age at marriage in 1971, and among women 0.6. The increase in cohabitation thus made men, in particular, more inclined to move in together with their partner relatively early. Twenty years ago, the average age at first marriage was 24.6 for men and 22.3 for women—there are no data on when couples moved in together from that era. In 1992, men initiated cohabiting, or married for the first time, on average, at age 23.7 years, women at age 21.8. [The mean age of women at first marriage in 2000 was 28.0 years. This difference is because of the fact that, practically speaking, everybody cohabited before they married.]

Of all the men interviewed in 1992, 79%, and of the women, 83%, had lived in a matrimonial relationship. In the oldest age group, 65 to 74 years, there was a gender gap: 7%

of men and 13% of women never had cohabited or married. This is partly explained by the fact that single men die young and single women live long.

A longer life expectancy and the growing divorce rate have contributed to the fact that people have time to enter several unions during their lives. According to the 1971 study, 5% of the ever-married men and 6% of the women had been married at least twice. In 1992, the proportions were 17% and 22%, respectively, [and in 1999, 26% and 25%].

Cohabitation does not always lead to marriage, particularly among young people. One fourth of the 1992 respondents had been cohabiting without getting married to the partner. Among people under 35 years, the proportion was more than half.

*Marital, Extramarital, and Postmarital*

*Sexual Behaviors*

*Sexual Intercourse.* The frequency of sexual intercourse 20 years ago was almost as high as nowadays. Finns have sexual intercourse usually once or twice a week. The share of people who had had sexual intercourse during the last two days among the people ages 35 to 54 was higher in 1992 than in 1971 (see Table 12). Sexual relations seem nowadays to remain consistent and regular later in life than they did 20 years ago. The frequency of sexual intercourse does not decrease significantly until after the age of 55, especially among women. Even this change does not necessarily follow from aging but from generational differences.

[Update 2003: In the 1990s, the frequency of sexual intercourse had not changed significantly. In 1999, the number of intercourses per month in the age group 18-to-54 years was 6.3 for men and 5.9 for women; the annual totals for men was 75.9 and for women 70.3. (End of update by O. Kontula)]

Sexual intercourse has become more varied. While in 1971, as much as 68% of the most recent occurrences of sexual intercourse among 18- to 54-year-old people were the missionary position, in 1992, the proportion was 43%. The proportion of those who had used many different positions during their most recent sexual intercourse had increased in a very significant way, from 16% to 32%. [In 1999, this proportion was even higher: 44% of men and 36% of women.]

Twenty years ago, it was usual that the man was the sole initiator of sexual intercourse in 49% of the incidents. In 1992, only 37% of the most recent experiences of sexual intercourse were initiated solely by the man. Fifteen percent of the male respondents said that the woman was the initiator of the last sexual intercourse, but this figure was only 10% according to the women's responses. Women were slightly more likely than men to report that both partners took an equal role in initiating intercourse, 51% compared with 45%. Women may find it more difficult to admit that they have taken an active role in coitus.

Alcohol consumption before the last sexual intercourse became slightly more frequent in the past 20 years. In 1971, alcohol had been used by 21% of the men and 11% of the women; in 1992, this figure was 25% and 16%, respectively, [and in 1999, 34% and 23%, respectively]. This reflects an increased consumption of alcohol among Finns in general.

*Sex Styles.* Sexual satisfaction can be attained in many ways. Following a factor analysis of the 1992 data to measure vari-

ables associated with different sexual habits and partners, three sex styles were identified:

1. Sex in a sexual-intercourse-centered steady relationship (frequent sexual intercourse with a steady partner);
2. sex in casual relationships (many sexual partners, including relationships with foreigners and prostitutes); and
3. alternative sexual habits (anal and oral sex, manually stimulated satisfaction, acquaintance with sexual aids, the use of different sex facilities, and masturbation).

The connection of the social background with these sex styles was examined by regression analyses. As explanatory variables in the simple linear regression model, there were gender, age, place of residence, type of marital relationship, years of education, income, days on working trips, religiosity, and two variables about alcohol consumption: the frequency of alcohol use and of getting intoxicated.

Sex in a steady relationship, meaning frequency of sexual intercourse and familiarity of the last sexual partner, relate naturally to living in a steady relationship, but also to youth and high income with a lower level of education. This sex style is typical of ambitious couples. The regression model explained 41% of the variation in the steady-relationship sex.

Those who practice casual sexual relationships, or people who have numerous sexual partners and/or sex with foreigners and paid partners are men, city residents, well-paid, who travel a lot for their work. They are indifferent to religion and often consume alcohol. The people cohabiting or in a steady noncohabiting relationship more often than other people had transient sexual relationships. The typical male practitioners of casual sexual relationships may well be called “rich good-time boys” for their social background, even if they can be found in all age and gender groups. The regression model explained 18% of the variation in the casual sexual relationships.

Alternative sex was related to male gender, youth, frequency of alcohol consumption, and frequency of intoxication. The married and the single people did not engage in alternative sexual habits as much as the people living in cohabitation or in steady sexual relationships. Alternative sexual habits are related to the lifestyle of young go-ahead men. As much as 43% of the variation in alternative sex was explained by these social factors.

*Sexual Partners.* For Finns ages 18 to 54, the average number of sexual partners during their lifetime has risen from 7 to 10 during the last 20 years. In 1971, women of all ages had about 3, men about 11 partners, and in 1992, correspondingly, 6 and 14. In 1992, the male respondents between ages 25 and 44 years had the most partners, between 40% and 50% had at least 10 partners; of the women in the same age cohorts, about 18% had at least 10 partners (see Table 13).

[Update 2003: The number of sexual partners had somewhat increased in the 1990s. In 1999, the mean number of sexual partners was 16 for men and 7 for women; 43% of men and 25% of women had had more than 10 sexual partners in their lifetime. (End of update by O. Kontula)]

In both surveys, the large number of sexual partners is related not only to gender and age, but also to marital status, according to a Multiple Classification (multivariate) analysis: The married people had fewer partners than the un-

married, widowed, and the divorced. Those alienated from religion, as well as the frequent consumers of alcohol, had more sexual partners than the religious and temperate people. Those who had passed the matriculation examination had fewer partners than the less educated; this difference, however, was no longer statistically significant in 1992.

Worldwide, in all the sex surveys, men claim to have had more sexual partners than women. This survey refined this general data by separating out data on Finnish men and women who had foreigners, homosexuals, or prostitutes as partners. When those who had, at some time in their life, at least one foreigner, one homosexual, and one prostitute as a sexual partner, were separated from the data on under-56-year-old men and women, the men still had at least 10 sexual partners—about twice as many as the women. One explanation of this might be that the Finnish men subconsciously overestimate the number of their partners, while the women underestimate their contacts. Another possibility is that many of the men with multiple sexual partners who responded to the survey have as sexual partners a small group of women who, for the main part, were left outside the survey and were among the nonrespondents of the questionnaire.

Finns report a somewhat higher number of sexual partners than Americans (Laumann et al. 1994). This may partly be explained by the fact that in the United States, a greater proportion of survey respondents left the question concerning the number of partners during their lifetime unanswered.

In addition, during the prior 12 months, the Finns more often than the Americans had more than one partner. During the previous year, 21% of the Finnish men and 11% of the women had had two or more partners; the corresponding figure for Americans was 17% and 7%, respectively. Only 4% of the Finnish men and 7% of the women reported that they had had no partners at all during the prior year; in the United States, the proportions were 13% and 24% (see Tables 14, 15, 16, and 17).

These results suggest that the sexual life of the Finns is at least as active as that of the Americans. Indeed, fear of AIDS and traditional sexual attitudes may restrict the number of sexual partners in the United States more than in Finland.

*Extra or Concurrent Sexual Relationships.* The partners in the most recent sexual intercourse have mostly been steady

partners or spouses in marriage or cohabitation. In 1992, only 6% of the men and 4% of the women in a steady sexual relationship had had someone other than the steady partner as the last partner. However, a greater and greater share of people have experiences of sexual relationships alongside their steady sexual relationships. Sexual relationships of this kind, including extramarital relationships, are called extra or parallel sexual relationships in the study.

The number of extra sexual relationships has approximately doubled during the 20 years among the Finns between 18 and 54 years old. In 1971, 24% of the men and 9% of the women who were married at the time of the survey stated that they had had sexual intercourse with some persons other than their spouses during their marriage. In 1992, 44% of the men and 19% of the women who were living in cohabitation or marriage had experiences of parallel sexual relationships during their cohabitation or marriage (see

(Kontula 1993)

Table 18). [In 1999, these proportions had somewhat decreased among men, but increased among women.]

In 1992, the respondents were also asked how many parallel sexual relationships they had had while in their steady relationship with their then or earlier partner. Of all the people aged 18 to 74 years who had sometimes lived in a steady relationship, 52% of the men and 29% of the women admitted having experienced at least one relationship of this kind. Even if the incidence of parallel sexual relationships has increased, attitudes to parallel sexual relationships have become stricter during the past 20 years. This discrepancy between liberated actual behavior and tightening attitudes may be related to the fear of AIDS and the growing conservatism in the society in general (Haavio-Mannila et al., 1997). [Comment 2003: It may also imply higher expectations for permanent couple relationships and a renaissance of romanticism in the 1990s. (End of comment by O. Kontula)]

*Incidence of Oral and Anal Sex.* In the 1992 data, stimulation of the partner's genitals (e.g., fondling and stimulating by hand) in order to give him or her satisfaction without sexual intercourse is a common form of petting and love play. It may or may not be linked to vaginal intercourse. A large majority, 86% of men and 76% of women, had at least sometimes during their lifetime stimulated a partner's genitals. [In 1999, these proportions were 84% and 81%.] During the past month, this had been done by half of men and more than a third of women. More than one year had gone by since the last incidence of stimulation by hand for 26% of men and 42% of women. Women thus have been less active than men in giving satisfaction to a partner without sexual intercourse. Maybe some men offer fondling and stimulation by hand to their partners who otherwise do not have an orgasm in intercourse.

Young people stimulate their partner's genitals by fondling much more commonly than do older people. Of women and men over 55, half of the women and 30 to 40% of the men have never done it, whereas the proportion among 25- to 34-year-olds is only 5%. This huge age gap indicates that fondling the genitals was not considered a part of a "normal" sex life to satisfy one's partner when today's older generation was in their youth. Vaginal intercourse was then the main sex technique.

Anal sex (sodomy) has been practiced throughout history for pleasure, birth control, and to avoid breaking a virgin's hymen. Including the anus in sexual activity is taboo in some cultures.

Clinically there is no difference between stimulation of the mouth, ears, nipples, feet, or anus in the production of pleasure sensations to the brain. None of these activities have a direct role in reproduction so it seems inconsistent for people to accept some and not all points of arousal in sexual activity. (Love 1992, 10)

In Finland, anal intercourse is not illegal. Nevertheless, it seems not to have been an acceptable sex technique in earlier generations, as older people rarely admit having prac-

Women	69	5	11	9	4
Men	68	15	15	21	16

ticed it. According to the 1992 survey, only 20% of men and 17% of women reported having ever practiced anal intercourse. Eight percent of men and 6% of women had done it several times. It had most often been practiced by 25- to 34-year-old persons, 31% of the men and 29% of the women. In this age group, one in ten had had anal sex several times. Only 2% of the women over 55, and 5% of the older men, had ever tried this sex technique.

[Anal sex had become much more prevalent in the 1990s. In 1999, 28% of men and women reported having ever practiced anal intercourse. In the age group 18-to-34, one third has practiced anal intercourse several times.]

Cunnilingus and fellatio are very common sexual practices throughout cultures and history. In the Finnish questionnaire, experiences of oral sex were inquired by the following question: "In the last five years, how often have you had oral sex in your sexual relations, that is, fondling a man's penis or a woman's genitals by mouth?" Men reported to have done cunnilingus to their partner more often, 78%, than women had done fellatio, 67% (see Table 19). More than half of the men and 42% of the women had done it often or sometimes. Men also had received oral sex more often, 73%, than women, 64%.

Oral sex was much more common among younger than older Finns. In the age group 18 to 34 years, almost all had done and received oral sex, whereas in the age group 55 to 74, only 35% of men had received it from and 46% had done it to the partner. Only one in five women admitted it either

way. The discrepancy in older men's and women's reports of oral sex may be because of the more common experiences of extra sexual relations with prostitutes and perhaps a less-inhibited extra partner.

The wide age differences in the practice of oral sex are connected to the varied sex practices of young people in general. Young people use more-varied positions in sexual intercourse, satisfy each other more often by hand and mouth, and have more often experimented with anal sex than older people. The liberated sexual behavior of younger people may be one explanation for their greater sexual satisfaction.

*Sexual Satisfaction.* Perhaps the most positive result of the Finnish sex survey is the observation that young Finns are more satisfied with their sexual lives than their elders are. Sexual intercourse was more generally regarded as pleasant in 1992 than it was in 1971. The amount of love play was considered more adequate, the steady relationship was experienced as happier, discussing sexual matters with the partner was more open and easier, and sexual life as a whole was estimated to be more satisfying than in 1971. Women had experienced orgasm somewhat more often in their last sexual intercourse, and men had had less problems with getting erections during the prior year.

From the viewpoint of sexual equality, it was remarkable that women considered their experiences of sexual intercourse clearly more pleasant than 20 years ago and nearly as pleasant as men. The gender gap in experiencing sexual intercourse as pleasant or as unpleasant decreased significantly. Men enjoyed their sexual life as a whole more than women, but in the pleasantness of the last sexual intercourse, there was no difference between the genders.

Women are now able to enjoy sex partly because there is practically no fear of an unwanted pregnancy. Only a quarter of the women reported that they had been pregnant when entering into marriage or cohabitation; 20 years ago the share had been 45%. The number of marriages-of-necessity has decreased as sexual education and contraception became more common.

[*Update 2003:* Respondents were less satisfied in their sexual life as a whole in 1999 compared to that in 1992. This was evident, although sexual intercourse was considered more pleasant than before, and sexual self-esteem had improved. This finding was explained by strongly increased desire to experience more sexual intercourse. As the frequency of sexual intercourse did not increase in the 1990s, satisfaction in one's sexual life also diminished, on the average of 5 to 10 percentage points. (*End of update by O. Kontula*)]

Sexual satisfaction as a whole is a combination of emotional and physical satisfaction. According to our 1992 survey results, the two aspects are equally important. Among women, the correlation between general sexual satisfaction and finding intercourse pleasant—measured by the sum of finding them in general pleasant and considering the last intercourse as pleasant—was 0.47 and 0.40 for men. Happiness in the present steady relationship, meaning emotional satisfaction, correlated with sexual satisfaction as a whole for women at 0.44 and for men at 0.36.

Happiness with life was more strongly connected to emotional sexual satisfaction—for men 0.52 and women 0.59—than to physical satisfaction—0.23 and 0.20, respectively. Emotional satisfaction prevents feelings of loneliness—for men 0.27 and women 0.30—more than physical satisfaction—0.16 and 0.15, respectively.

Sexual satisfaction is a socially constructed phenomenon. It is related to emotions, sexual practices, and relation-

ships. In Table 20, correlation coefficients between emotional, physical, and overall sexual satisfaction, and a number of variables related to sexual feelings, practices, and partners are presented. Perhaps this analysis gives hints as to how to improve sexual life so that it will be more happy and enjoyable.

Loving and being loved is important for emotional, physical, and overall satisfaction in sexual life. Women in particular need love in order to be happy in their steady relationship. A loving relationship greatly increases satisfaction with sexual life as a whole. The quality of the present

steady sexual relationship also has an impact on sexual satisfaction. People for whom talking about sex with their partner is not difficult at all, but open and easy, are emotionally, physically, and generally satisfied with their sexual life.

The number of persons one has really fallen in love with only correlates with the unhappiness of men's, but not women's steady relationships; that is, men who have fallen in love often are not very happy in their present relationship. Perhaps they have known too many women with whom they can compare their present partner in order to feel totally happy with her. Or maybe falling in love very

many times in life is an indicator of problems in getting really attached to anyone.

Sexual self-esteem is also more important for women's than men's sexual satisfaction. Women who consider themselves as sexually active, having great sexual skills, and being sexually attractive are happy in their steady relationships, and especially satisfied with sexual intercourse and sex life as a whole. Men can consider their steady relationship quite happy irrespective of their own opinion of their sexual capacity. But for men's physical and overall sexual satisfaction, it is important to have a high sexual self-esteem.

The role of sexuality in life is connected more to women's than to men's sexual satisfaction. Considering sexual life as an important part of life is associated with emotional sexual satisfaction to the same extent for both sexes. Valuing sexuality counts more for women's than men's satisfaction with intercourse and, to some extent, their sex life in general. Denial of sexuality in life may prevent women from enjoying sexual intercourse, or vice versa; women who do not like physical sex, may undervalue sexual life as part of their whole life. The subjective experience of an increase in sexual desire in the last five years is more closely correlated with women's than men's sexual satisfaction.

Happy people enjoy their steady relations and also sexual intercourse. The relationship between happiness and sexual satisfaction is probably reciprocal: satisfactory sexual life contributes to feelings of happiness, and happy people are likely to find joy also in sexuality. Sexual partners are often good social companions. Thus, it is understandable that sexual satisfaction diminishes feelings of loneliness.

Sexual habits or practices have a stronger effect on physical than emotional sexual satisfaction. Most of them correlate more with women's than men's satisfaction. From the point of view of sexual satisfaction, the following sexual habits have a positive outcome: frequent sexual intercourse, equal activeness in initiating it, a suitable amount of kissing, petting, or other love play in connection with coitus, and use several positions in intercourse (applies to men only).

In addition to practices related to sexual intercourse, the study also investigated other techniques aiming at sexual satisfaction. Stimulation by hand and oral sex clearly increase women's emotional, physical, and overall sexual satisfaction, and also to some degree, men's physical and general, but not emotional satisfaction. Anal sex, masturbation, and use of sex materials and aids are only to a small degree related to sexual satisfaction. People, particularly men, who masturbate often, are not satisfied with their sexual life as a whole. Women who use sex materials—sex movies and programs on TV, videos, magazines, and wall calendars with naked pictures—are somewhat more satisfied with intercourse than women who do not use them. Perhaps sex materials help women to adopt new, more-rewarding sex techniques.

Orgasm during sexual intercourse is very strongly connected to finding sexual intercourse pleasant. The correlations are higher for women than for men. Also, general sexual satisfaction, and to some degree, happiness of the steady relationship, correlate with experiencing an orgasm during intercourse.

It is not uncommon that a man cannot enter into sexual intercourse because he cannot get an erection or his penis becomes flaccid when sexual intercourse is started. One's own or one's partner's erectile problem decreases physical sexual satisfaction for both sexes. It is also connected to the emotional dissatisfaction of women in their steady relationships.

The number of sexual partners during a lifetime does not correlate with sexual satisfaction except at one point: Women who have had many sexual partners report more dis-

satisfaction with their sexual lives as a whole than other women. Traditional gender roles may make women uncomfortable with a life in which sexual partners change frequently. This lifestyle probably includes a lot of brief casual relationships that women do not take as lightheartedly as men have been socialized to take them.

The number of extra sexual relations during present or previous steady relations is connected to unhappiness of the present steady relationship, but not to physical nor overall sexual satisfaction. Parallel relations indicate a wish to escape the unhappiness of the steady relationship, or they may cause jealousy on the part of the steady partner that might deteriorate the relationship.

Determinants of physical sexual satisfaction have earlier been analyzed by using path analysis (Haavio-Mannila 1993). In the path models developed for explaining satisfaction with intercourse for men and women, some more-general social factors than those presented in Table 20 were included. Some of them only had an indirect influence on sexual satisfaction, but some also had direct effects on it. The social factors studied contributing to physical sexual satisfaction were: irreligious and sexually open childhood home, early age at starting sexual life, liberal attitudes toward sexual issues, short duration of the present steady relationship, and young age. These social background factors correlated with the sexual variables increasing sexual satisfaction: the value of sexuality in life, sexual assertiveness, love, use of sex materials, frequency and variety of intercourse, and orgasm.

### *Divorce and Remarriage*

In 1986-1989, there were 11.6 officially recorded divorces per 1,000 mean population of married women, compared with 5.3 in 1966-1970. In 1989, 47% of marriages ended in divorce. The increase in divorces can also be seen in the survey data. In 1971, only 3% of the respondents were divorced or separated from their spouse at the time of the survey; 20 years later, the figure was 8%. [Altogether, 30% of both genders had experienced divorce, based on the results of the 1999 survey.] Even changes in the structure of families with children reflect the increased incidence of divorces. In 1971, 90% of the respondents reported that their parents had lived together throughout their childhood; 20 years later, the figure was 88%.

Cohabitation does not always lead to marriage; separation of cohabiting partners is relatively common, especially in the younger age groups. One in four respondents interviewed for the 1992 study had had a cohabitation relationship that had not continued as a marriage. This share was more than one in two in the age groups 35 or younger.

The increased lifespan and increasing occurrence of divorce allows people time to marry several times. According to the 1971 study, 5% of married men and women had been married at least twice. Two decades later, 17% of presently or formerly married or cohabiting men and 22% of the corresponding women had had at least two such relationships. [In 1999, these proportions were 26% and 25%.] Women had had a higher number of such relationships before age 54. In older age groups, men had been married more times than women.

### *Sexuality, Disability, and Aging*

There are no serious obstacles concerning values and attitudes in dealing with the sexual needs and activities. In 1992, only 5% of the respondents believed that elderly people should not establish sexual relationships. Most Finns, 75%, held that people in residential facilities ought to have a privacy room for intimate meetings. Although the majority

also approve of sexual relationships for physically and mentally challenged persons, no actual studies have been carried out on sexual issues and the disabled.

There is currently some kind of generation gap between elderly and young Finns on sexual issues. Elderly people, especially women, are more conservative in their attitudes toward adolescents' sexual relationships, casual relationships, relationships without love, and women's right to take sexual initiatives. Elderly people have lived their childhood in a world where restrictions against free sexual pleasure were enormous. They have learned that sexual issues are not really important and that they have to be careful in order to avoid the problems and risks associated with fulfilling their sexual images and fantasies. They never had any knowledge and education, for instance, on how to satisfy the needs of their partners, such as young Finns have nowadays. They initiated their dating and sex life much older than the younger generations because sexual activities were interpreted to be as a part of marriage only. Many of them were, in practice, forced to abstain while married because there were almost no contraceptives available.

The frequency of sexual intercourse is increasing among older Finns. Most retired men have had intercourse during the past month, and they report their experiences to be as pleasurable as the younger ones. Elderly people are still not as actively engaging in sexual relationships as the younger people. More than half of retired women abstain from sexual intercourse because they are widowed and are not able or willing to engage to some new relationship—there is also a lack of older men. Old women are many times sexually quite inactive, because they have learned that sexual initiatives are men's duty.

The coital positions of elderly people do not vary very much and they quite seldom engage in oral sex, anal sex, or manual stimulation. They even abstain quite often from masturbation and pornographic products. Only 18% of men and 11% of women over 65 years have masturbated during the past year. [In 1999, these proportions were already 28% and 20%, respectively.] The sexual inactivity is explained only partly by aging and illness; the education and generation gap is the more-important reason for this finding. This can be seen, for example, in the data on the number of sexual partners during a lifetime that are much lower among elderly people. Elderly Finns have had much more time to engage in sexual relationships than younger Finns, but they seldom have experienced multiple relationships.

Because of their health status, elderly people have more sexual dysfunctions—lack of desire, and problems with having vaginal lubrication, erections, and orgasms—than younger generations. These problems will be discussed later in this chapter.

### 6. Homoerotic, Homosexual, and Bisexual Behaviors

Finnish homosexuals were studied by the snowball method in 1982 (Grönfors et al. 1984). More than 1,000 homosexuals answered a relatively extensive questionnaire. Two thirds of the respondents were men and one third were women. About 60% of the respondents reported that they were exclusively homosexual in their feelings and about 70% in their behavior. Finnish homosexuals were quite similarly distributed into Kinsey's categories (Kinsey et al. 1948, 1953). Feelings and behavior were in most cases consistent. However, it is not always possible to combine feelings with practice in real life. There were people who identified themselves as only or mostly homosexual, but behaved only or mostly heterosexually.

In the Finnish sex survey of 1992, there were ten questions about sex with same-sex persons. They refer to sexual identity, sexual experiences with persons of one's own sex, age at first homosexual experience, type and frequency of these experiences, number of same-sex partners, and orgasm in homosexual intercourse.

Homosexual identity was measured by a five-point scale ranging from exclusive homosexuality to exclusive heterosexuality (cf. Kinsey et al. 1948). The question was phrased as follows: "Besides being sexually interested in the opposite sex, people are sometimes also interested in their own sex. Are you at the moment sexually interested in only the male sex, mainly the male sex, both sexes equally, mainly the female sex, or only the female sex?"

In the population aged 18 to 54 years, the proportion of persons interested only or mainly in people of the same sex was 0.8% in 1971, in 1992 only 0.6%, [and in 1999, 1.1%]. When one takes into consideration all people who have at least some interest in people of the same sex, the proportions were 7.6% and 6.5%, respectively. When all people aged 55 to 74 years who were studied in 1992 are included, the proportion of the exclusively or mainly homosexually oriented persons was 0.7%, and that of at least partly bisexually oriented 6.4%. Men more often than women identified themselves as homosexuals, whereas there was no gender gap in the proportion of bisexually oriented people. Same-gendered experiences are more common than homosexual identity. According to the 1992 survey, 4.0% of the Finnish men and 3.8% of the women had had same-sex partners during their life. [In 1999, these proportions were 6.5% and 5.3%, respectively.] In the United States, in 1991, the proportions were 5.0% for men and 2.7% for women (Laumann et al. 1994). The gender difference is thus larger in the United States than in Finland where there is hardly any gender gap. American women may be shyer than Finnish women in admitting their lesbian behavior, or they may avoid lesbian practices deliberately in order to avoid the social stigma attached to them. In Finland, the liberalization of attitudes toward homosexuality in the last 20 years may have helped lesbians acknowledge and report on their homosexual experiences.

The number of homosexual partners during one's lifetime was on the average of 7.4 for men and 1.6 for women. Compared with the number of sexual partners in the whole population (10.6), these figures are small. This is because of the fact that most homosexual encounters only have taken place with one person: 53% of men and 72% of women had had only one same-sex partner. [These proportions were almost equal in 1999.] Many homosexual contacts took place a long time ago. Only 29% of the same-sex contacts of people ever having had one had happened during the last 12 months. During the last year, 1.3% of the Finns and 1.6% of the Americans had had a homosexual relationship. [In 1999, 2.6% of men and 1.3% of women had had a homosexual relationship.] This question had been left unanswered by a significantly greater proportion (23%) of the Americans than of the Finns (8%). This again suggests that there are more social taboos regarding homosexuality in the United States than in Finland.

The first homosexual experiences took place at the same age as first sexual intercourse—that is, on the average at the age of 18.3 years. Men started somewhat earlier than women. Eight percent of these experiences were probably sexual play as children, since they took place when the respondent was less than 10 years old.

The most common type of homosexual experiences were arousing fondling without touching genitals (54% of people having had homosexual experiences), stimulation of

genitals by hand or rubbing genitals against partner's genitals (also 54%), and oral stimulation of the genitals (29%). Only 19% of men with homosexual relations had been engaged in anal intercourse.

Thirty-eight percent of men and 26% of women had had orgasm in homosexual intercourse. This is less than the proportion of orgasm in heterosexual intercourse (see Table 28 in Section 11, Sexual Dysfunctions, Counseling, and Therapies). Homosexually oriented and/or experienced men considered their sexual life as a whole somewhat less often very or quite satisfying (75%) than bisexually or mostly heterosexually oriented men without homosexual experiences (87%) and exclusively heterosexual men (85%). For women, the percentages were 77%, 61%, and 83%, respectively.

The lower sexual satisfaction of homosexuals may be related to the prevailing conceptions about the superiority of heterosexual love and sex (Jeffreys 1990). It may be more difficult to enjoy homosexual experiences as freely as heterosexual experiences because of their ambivalent status in sexual culture. This can be concluded on the basis of the fact that 28% of men and 38% of women interested in their own sex have sometimes been bothered personally by or fearful and worried about their own sexual deviation. This is three times as common as in the population on the average. Of men with homosexual experiences, 38%, and of women, 19% have felt that kind of fear. This fear still prevails, even though the attitudes toward homosexuality have liberalized during the last 20 years (see Table 3 in Section 2B, Religious, Ethnic, and Gender Factors Affecting Sexuality, Cultural Factors).

[*Update 2000/2002*: In December 2000, the government of Finland proposed legalizing gay partnerships, but with some limitations. In Parliament, the five government parties holding a majority were expected to approve the proposal. The Finnish Evangelical Lutheran Church, to which 85% of Finland's population of 5.2 million people belongs, opposed giving gay partners the same rights as married couples. However, Archbishop Jukka Paarma admitted that "the legal position of homosexual and lesbian couples should be improved."

[In April of 2002, gay partnerships were legalized, but without allowing them to adopt children or share a surname. Finland joined the four other Nordic countries, Sweden, Norway, Denmark, and Iceland, in legally recognizing gay partnerships. Denmark, Sweden, and Iceland also allow gay couples to adopt children under certain circumstances. Same-sex couples 18 years or older are able to make their union official in a civil ceremony, comparable to matrimony but nevertheless "a separate legal institution." Registered gay couples have the same rights as heterosexual couples who are married when it comes to inheritance and divorce. (*End of update by R. T. Francoeur and O. Kontula*)]

## 7. Gender Diversity and Transgender Issues

### A. Sociological Status, Behaviors, and Treatment

In Finland, the most conspicuous gender minority group has been the transsexuals, because their situation requires both therapeutic and juridical measures to be resolved. Society has indeed taken concrete measures to draft legislation and to develop a functioning healthcare system to meet this need. The Ministry of Social Affairs and Health has been preparing the legislation since 1991.

The National Research and Development Center for Welfare and Health (STAKES) gave the first report on the matter in 1992 and the second at the beginning of 1994. The second report had been drafted by a working committee that

had been set up to develop a support and care system for the transsexuals in Finland. The aim is to create legislation to secure healthcare services for transsexuals, create a special expert healthcare system, and provide juridical protection for their gender reassignment and privacy. The legislation will also define the criteria for gender reassignment.

In Finland, there are an estimated 300 people who would benefit from sex-reassignment surgery. So far, the treatment of transsexuals has been quite haphazard. The information about the possibilities and places of treatment varies. The transsexuals get this information through their associations. As of early 1994, sex-reassignment operations were being postponed until the law comes into force. Male-to-female transsexuals have their operations abroad, mainly in London. Of necessity, female-to-male operations may be performed in the homeland, because Finns cannot obtain these operations abroad.

So far, the cost of the surgery has been paid by the patient, but it is the aim of the proposed new law to extend public healthcare to cover the cost of these operations. Those who have sought this corrective gender surgery have had to apply for a castration permit before having plastic surgery on their genitals. A psychiatrist's and an endocrinologist's certificate must be attached to the application. Because the castration law was not designed for use with transsexuals, attempts have been made to have it removed from their procedure.

Various sexual organizations have become active in support of sexual minorities. In Finland, SETA or Sexual Equality, a registered association, was originally a national organization for homosexuals and lesbians, but during recent years, it has also worked actively on behalf of other sexual minorities. SETA arranges group evenings for transsexuals and transvestites, where other sexual minorities have been welcomed. In addition, SETA has vigorously promoted some juridical matters for the sexual minorities, such as allowing a change of one's name and identity number as part of gender reassignment.

TRASEK, the transsexuals' own association, offers advice on the medical process in gender reassignment and surgery. It also provides a support person for those who need one and gives practical help in writing applications. Providing information by transsexuals who have been through the procedure is a major service of TRASEK.

[*Update 2003*: The Transgender Support Center (TSC) was established by SETA in 1994 with the financial help from the Finnish government. By close networking with the authorities and other relevant organizations, the expertise of the TSC has been an important part of the ongoing process of creating the new professional practices and consensus in medical, juridical, and psychosocial services.

[TSC gives psychosocial support services for people with transgender experiences. The clients are transsexuals, transvestites, and people between genders, as well as their partners and families.

[Psychosocial support has been arranged, both on a professional basis and by organizing volunteer individual and group self-help support. The TSC has played a significant role in strengthening the networking of the transgender community.

[In 2000, STM (the Ministry of Social Affairs and Health) started to give instructions for treatment and recommendations for legislation on transsexuals' legal status. Internationally, in 2002, a very progressive law and instructions for treatments were confirmed. They were then implemented at the beginning of 2003.

[The medical and juridical sex-reassignment process in the public services includes:

- psychiatric evaluation and diagnosis in Helsinki or Tampere (at least 6 months)
- hormone treatment
- psychiatric follow-up (2 to 5 years)
- treatment plan
- juridical change of name and social security number, together with a psychiatric follow-up (people can choose the right moment for the change of juridical name and social security number, but usually it is required for the Real Life test)
- possible treatments: epilation therapy, speech therapy or phoniatic surgery, breast mastectomy, and supportive psychotherapy
- consultation on the surgery and a place in the queue for surgery (1.5 to 3.5 years)
- castration and corrective genital surgery (2 to 6 operations) and surgery for silicone implants if needed (1 to 2 years)

The total period of treatment varies from 5.5 years to 11 years. In the future, the period of treatment is expected to be shortened to a maximum of 5 years. (*End of update by O. Kontula*)

## B. Specially Gendered Persons

There are actually no *hijra* or *berdache* communities in Finland, but a so-called gender community that includes people from different gender groups, such as transsexuals, transvestites, transgenderists, and gender-blending people, does exist. There are so few people of each of the groups that they have not formed any subgroups of their own.

## 8. Significant Unconventional Sexual Behaviors

### A. Coercive Sex

#### *Sexual Abuse, Incest, and Pedophilia*

Finnish women have been sexually abused as children more often than men: Under the age of 18, 17% of women and 8% of men had been sexually harassed by peers, other boys or girls, parents, or other adults. There was no clear age difference in the incidence of child abuse. Women most often were harassed by male peers and men, and men by female peers and women. Two percent of women had been sexually abused by their fathers. No reports of sexual abuse by a mother have been made.

#### *Sexual Harassment and Rape*

Incidence of sexual harassment was studied by using the following question: "In the last five years, has anyone laid hands on you or touched you in an offensive way (with a sexual purpose) either in your apartment or elsewhere, e.g., in a restaurant, workplace or at school?" Affirmative answers were given by 3% of men and 9% of women. Younger women reported more sexual harassment than older women. For men, age made no difference. Sexual harassment in most cases was described as approaches (men 88% and women 69%), but 0.4% of all women described the incident as rape, and 1.1% of all women defined it as attempted rape. Of all men, 0.2% described the harassment as attempted rape; no men reported actual rape. Regression analysis showed that becoming an object of sexual harassment was connected with being sexually abused as a child, young age, and female gender. Persons who were sexually harassed were more likely than other persons not to have steady sexual relationships and to have had extra sexual relations and homosexual experiences. Drinking to intoxication and having many sexual partners was also related to having been sexually harassed.

The harassers were mostly men. About half of the respondents knew the harasser before the incidence. Very few of the harassed—6% of the harassed men and 7% of women—had informed the police about the incident. The most common reason for not reporting sexual harassment to the police was that it was considered to be of minor importance. The second reason was that the respondent personally resolved the matter.

Becoming an object of sexual harassment increased sexual fears and worries. Other social factors influencing sexual fears were female gender, young age, lack of steady relationship, stress symptoms, casual and extra sexual relations, and sexual practices alternative to intercourse. One third of the variation of sexual fears was explained by these factors. In order to diminish sexual anxiety, it is worthwhile to discuss and control sexual harassment publicly.

### *Prostitution*

Prostitution itself is not illegal in Finland, but it is against the law to organize prostitutes' services, for example, by maintaining a brothel. Until the beginning of the 1990s, prostitution was scarce (Järvinen 1990). One of the consequences of the fall of the Soviet Union was that many Estonian and Russian women came to Finland to earn money as prostitutes.

Attitudes toward prostitution differ greatly by gender. In 1992, men more often (51%) than women (21%) had nothing against people earning money by selling sexual services in Finland. This activity was opposed by 34% of men and 65% of women. People over 50 years were most negative toward prostitution. [In 1999, 64% of men and 24% of women had nothing against people earning money by selling sexual services. Men had more favorable attitudes towards prostitution than before.]

There has been recurrent public discussion about establishing brothels under the control of the state as there were in the beginning of the 20th century in Finland. Brothels might be a means to fight problems connected with prostitution: i.e., liability of clients and prostitutes to venereal diseases and connections to criminality, particularly drug dealing. Approval of state-controlled brothels was greater among men than women: 42% of men, but only 17% of women approved public brothels, while 41% and 67%, respectively, opposed them. Middle-aged people were most favorable to brothels. Support for public brothels has clearly increased since a 1972 survey. At that time, only 20% approved establishing state-controlled brothels (Markkula 1981). [In 1999, 60% of men and 26% of women approved of establishing brothels under the control of the state. The proportions were higher than before.]

There is a certain amount of demand for paid sexual services in Finland. Twenty percent of women and 8% of men had during their lifetime been persuaded to intercourse by being offered money or similar economic advantages. [In 1999, the corresponding proportions were 17% of women and 11% of men.] Women under 35 years of age most often reported having received these kinds of offers. This indicates that they have increased with time. Only 0.2% of Finnish women and 1.5% of men admitted that they had complied with the request.

Men use paid sexual services more than women. Eleven percent of Finnish men and 0.3% of women had offered money or similar economic advantages for intercourse. One percent of all men and women said that their initiatives had not led to sexual activity. [In 1999, 15% of men had offered money for intercourse in their lifetime.] For Finnish men, traditionally, buying sexual services starts at about age 40 when men begin to have the economic resources for it. Having sex with prostitutes was connected with having many sexual

partners, extra relationships, sex with foreigners, high sexual self-esteem, and few homosexual experiences. Using paid sexual services was not related to sexual satisfaction nor sexual fears.

[*Update 2003*: A quarter of the men who had bought sexual services in their lifetime, had done so during the last year. This means that: 4% of men had visited prostitutes during that year, 72% of men had visited foreign prostitutes abroad, 11% foreign prostitutes in Finland, and 14% Finnish prostitutes in Finland. Altogether, 4% of men had paid for sex in Finland, and 71% of men reported that they used a condom in the latest sexual intercourse with a prostitute.

[In 2002, there was a lively public discussion on the human rights problems related to the pimping of Russian prostitutes in Finland. This has led to proposals of criminalizing buying prostitute services in a similar way to what was done in Sweden some years ago. It is assumed that the government will give this amendment to Parliament in 2003. (*End of update by O. Kontula*)]

### *Pornography and Erotica*

In Finland, between 1971 and 1992, women's attitudes toward pornography became somewhat more negative, whereas men's attitudes have remained unchanged. This may be related to the contents of pornography becoming "harder" and less satisfying to women's expectations than before. The consumption of pornographic products has remained almost the same among men, but has decreased among women. Even when sex videos are included with the printed publications, fewer women, on the average, used pornographic materials during the year in 1992 than in 1971.

Interest in pornographic publications was exceptionally great in 1971 because open nudity had only recently become available in pictures in sex magazines. The charm of novelty and the taste of the forbidden fruit made people anxious to have and use them. Since this initial interest, the greatest excitement and attraction have settled. Besides, the so-called soft pornography has come within everyone's reach—for example, in the pictures of the afternoon tabloids. Such material, however, is no longer referred to as pornography. There are legal restrictions against hard pornography in Finland, but soft pornography and erotica are shown even on public television.

[*Update 2003*: Consumption of pornographic products increased in the 1990s. Use of sex magazines and sex videos was 5% to 10% more common in 1999 than in 1992. Pornography was also more valued than before. Four fifths of men and two thirds of women judged pornography sexually very stimulating. This proportion was even 25% higher among young women in 1999 than what it was in 1992.

[In 1999, phone sex was also studied. Of the men who were younger than 35 years, 15% reported using phone sex during their lifetime and 8% during the last year. Among young women, these proportions were 4% and 1%. (*End of update by O. Kontula*)]

Sex magazines published in Finland are forbidden by the Ministry of Justice to present pictures of anal and oral sex, sexual violence, sadomasochism, sex with children, sperm, paraphilias with sex models, and close-up pictures of genitals. All movies and video films are inspected by state authorities, and hard-core pornography, as listed above, is not allowed to be presented in cinemas or to be rented in video markets. However, in practice, hard-core videos can be bought or leased from specific sex shops. Films presented on TV are not under any legal regulations.

[*Update 2003*: In 2001, new legislation was implemented in Finland. Practically speaking, it gave legal status to pornography. The only exceptions are pictures that are

related to pedophilia, sexual violence, and sex with animals. These forms of sexually explicit material are now defined as illegal. (*End of update by O. Kontula*)]

### *Paraphilias*

In Finland, the use of sexual aids and toys, such as a vibrator or vibrating penis, lubricants, pills or substances increasing potency, erection rings, a penis enlarger with a pump, ropes or gags, an artificial vagina, sexy underwear, sex dolls, and whips or handcuffs or fetters in masturbation or in sexual intercourse by the respondent or his or her partner is fairly rare.

Sexy underwear was the most commonly used aid: One fifth of people told about using it. In the younger age groups under 35 years, the proportion was about one third, and in the oldest age groups only a few percent. Lubricant was the next most popular aid: 17% of men and 15% of women had used it. Lubricant use increases with age, because it lessens problems connected with vaginal lubrication during intercourse.

Vibrators or vibrating dildos were used by the respondent or a partner according to the replies of 7% of men and 6% of women. These were most popular among those around 30 years old (10%). The interest of young people in vibrators indicates that their use will increase in the future. The other sexual aids listed above were each used by less than 2% of the respondents.

Use of sex aids did not correlate with sexual satisfaction except in one case: use of a pump penis enlarger and sex dolls was related to women's unhappiness in steady relationships. These devices are meant for fighting impotency or for compensating for lack of a human sexual partner. As mentioned in the section on sexual satisfaction, impotency and lack of partner indicate an unhappy steady relationship.

[*Update 2003*: In 1999, 8% of men and 7% of women reported that they had practiced bondage plays in their lifetime. Among young persons, this proportion was around 15%. Sadomasochistic experiences had been experienced by 3% of men and 1.5% of women. (*End of update by O. Kontula*)]

## *9. Contraception, Abortion, and Population Planning*

### **A. Contraception**

A decline in birthrate has been a common phenomenon in most West European countries and in all the Nordic countries during the past several decades. In Finland, the birthrate was at its highest after World War II; for instance, in 1947, as many as 108,000 children were born. After this, there was an even decline, so that, after 1968, the birthrate has been lower than the replacement birthrate, which would be about 70,000 births per year. At its lowest, in 1973, the birthrate was 56,787 births. In the 1990s, it has been about 65,000 children per year. Unless immigration increased, the population had been estimated to grow until 1999, after which it would begin to decrease. [*Update 2003*: In the latest prognosis, the population is estimated to increase until 2013, after which it will slowly decrease. (*End of update by O. Kontula*)]

Contraception has been well taken care of in Finland. Young people may obtain contraceptives from their school healthcare services. The law or other regulations require that those who have given birth or had an abortion be given counseling in contraception. Generally, counseling and even the contraceptive methods themselves are easily available. There is also a variety to choose from, thanks to the development in the research and production of contraceptive methods. From an international viewpoint, Finland is considered a model country in organizing contraception.

In 1988, contraceptive use among 13- to 17-year-olds was surveyed (Kontula & Rimpelä 1988). No contraception

had been used at the first intercourse by 27% of the 15-year-olds. Most of them, 66% of boys and 71% of the girls, had used a condom during the first intercourse. A few percent had used the pill. At the most recent intercourse, use of the pill was reported by 17% of the girls and 7% of the boys. At the same time, the proportion of those who used the condom had diminished to 59% with the girls. The share of those with no contraception had remained almost the same as at the first intercourse, about one in four.

Use of the contraceptive pill quickly becomes more common among the young as they settle into a relationship. As many as 44% of the 17-year-old girls in Helsinki had used the pill at their most recent sexual intercourse; the proportion using condoms remained at 45%. Nationwide, the proportion of 17-year-old boys relying on the pill was 25%; for girls, 56%. The differences in these responses stems from the fact that the girls usually have intercourse with boys some years older than themselves.

[Update 2003: In 2002, 61% of 15-year-old boys and 51% of girls had used a condom during the last sexual intercourse. Twelve percent of boys and 26% of girls had used contraceptive pills, while 18% of boys and 16% of girls used no contraception. Among 17-year-olds, these proportions were 27% and 43%, and 11% and 8%, respectively. (End of update by O. Kontula)]

According to the 1971 sex survey, only about 3% of those who needed contraception did not use any method. According to a study conducted in 1977, one in ten women who needed contraception did not use any method (Riihinen et al. 1980).

In 1992, 29% of the men and 18% of the women did not need contraception at their last intercourse (Erkkola & Kontula 1993). About one fifth of the middle-aged people reported that they did not need contraception. A very important reason is that about 12% of the 35- to 54-year-old women had undergone hysterectomy, which becomes more common with age.

The prevalence of contraceptive methods was surveyed by a question about the method used at last intercourse. Slightly over 3% of the men who had thought they needed contraception in their steady relationship had not used any method at their last sexual intercourse. No method had been used at the last intercourse by 5% of the 18- to 54-year-old women who thought they needed contraception.

The condom and contraceptive pill are popular with young people (see Tables 21 and 22). After the age of 30, the

pill loses most of its users, although about one tenth of the women still use it after that age. This is in part because of the health officers' recommendations. The condom, however, holds its popularity fairly steady among users of all ages. This may be because of the protection the condom affords against diseases.

Use of the intrauterine device (IUD) increases considerably around the age of 30, at the same time as the popularity of the pill wanes. The IUD maintains its popularity until the age of menopause, after which it is naturally no longer needed. The IUD is used by about one third of women. The use of sterilization as a contraceptive method increases a little later than the use of the IUD. Sterilization is mostly used around age 40 years, with about 25% of middle-aged women using this method. Based on generation comparisons, it seems likely that the use of sterilization will clearly increase in the coming years.

The pill, IUD, and sterilization had been used by 59% of women; 27% had used the condom. Only slightly over 3% had used withdrawal or the rhythm method ("safe period"); the latter had been used by only a few women. About 4% of the female respondents had used two methods at their last intercourse, mostly the condom with some other method.

[Update 2003: The use of condoms decreased somewhat in the 1990s among the adult population: 27% of men and 28% of women had used a condom in their last intercourse. Also in temporary relationships, condoms were less popular than before. About half of the men and women used a condom with their last temporary partner. (End of update by O. Kontula)]

Laws relating to sterilization were enacted in 1970 and 1985. The spirit of the latter law is quite liberal, for, in practice, any person over age 30 may be sterilized if he or she so wishes. This law caused sterilization to rise threefold compared to previous years.

Regional differences in contraceptive methods used are fairly insignificant. There are hardly any regional differences in the use of the pill and the IUD, but the condom has been more used in the big towns than in the smaller localities, according to the women's responses.

Finns who had their last intercourse with a steady cohabitation partner or spouse and needed contraception had used the condom less frequently than others, 32% of the men and 27% of the women, compared with 46% and 28%, respectively, for those who had had their last intercourse with

some other steady partner, and 68% and 45% of those with someone other than a steady partner. The condom was most often used at the most recent intercourse by men, 71%, and women, 39%, who had no steady partners. No contraception had been used by 5% of men and 10% of the women with the latest not-steady partner, although they reported that they needed contraception. The pill had been used by 28% and the IUD by 10% of the women with their latest not-steady partners. Slightly over 40% of those men and women who had had their last intercourse with somebody else's spouse or steady partner had then used the condom.

**Table 21**

**The Contraceptive Method Used During the Most Recent Intercourse Among Men Who Need Contraception and Have Had Intercourse, 1992**

	18-24	25-29	30-34	35-39	40-44	45-49	50-54	55-59	60-64	65-69	70-74
Condom	53	42	45	38	24	30	36	50	50	56	38
Pill	44	45	28	13	8	15	7	4	7	6	0

Sterilization	0	0	7	19	28	25	18	14	18	10	0

Having children changes quite decisively the type of contraceptive method used. This is most apparent in the shift away from the pill, the most common contraceptive method before having children. In many cases, the pill is replaced by the IUD, which is almost solely used by women who have given birth to a child. As the number of children rises, the percentage of those who have undergone sterilization considerably increases, and the share of the condom users decreases.

### B. Teenage Unmarried Pregnancies

Women under age 20 account for about 2,000 pregnancies each year, about 3% of the total number of 65,000 pregnancies. Teenage pregnancy and live births have been relatively one of the lowest of the whole world. The number of live births to unmarried women has been growing fast and is nowadays about 20,000 a year. The proportion of unmarried women giving birth is about 30%, a share that has doubled during last 20 years. There are no separate statistics of unmarried, noncohabiting couples. The estimated figure has been, according to surveys, about 5% of annual live births.

[*Update 2003*: The teenage fertility rate declined throughout the 1990s, slower in the second than in the first half of the decade. For 19-year-olds, the pregnancy rate continued to decrease until 1996, while among younger girls (aged under 18 years), the decrease leveled off two years earlier. Starting from 1997, the pregnancy rate has increased every single year in every age group among teenagers. In 2000, the mean age of women at the birth of their first child was as high as 27.4 years. (*End of update by O. Kontula*)]

### C. Abortion

In the earlier decades when prevention of pregnancies was poor and abortions illegal, the women in their despair resorted to infanticide in Finland. Nowadays, the situation is considerably better in this respect, but there is still discussion of the justification of abortions. In Finland, the situation is exceptionally good, for abortions had clearly decreased because of the improved contraception during the last 20 years, and abortions are exceptionally few by international comparison.

The current law regarding termination of pregnancies, which was preceded by a fierce debate, was enacted in 1970. As a result of this liberal law, abortion became practically free, and illegal abortions were believed to have almost entirely ceased. With the new Primary Health Care Act instituted in 1972, the cost of abortions was essentially paid by the municipalities.

A 1978 amendment to the abortion law required permission of the Central Administrative Board for termination of a pregnancy after 12 weeks. The latest law concerning abortions came into force in 1985, making it possible to terminate pregnancy prior to the 24th week of pregnancy on the grounds of the illness of the fetus, instead of the earlier 20th week. If the mother's life or health is at stake, termination of pregnancy is permitted at any stage of pregnancy, even after the 24th week. In practice, termination of pregnancy has been without restriction, at least prior to the 12th week of pregnancy, for the past over 20 years.

In the 1992 FINSEX survey, 57% of the men and 53% of the women supported free abortion, disagreeing with the statement, "I do not approve of free abortion (termination of pregnancy)." [In 1999, these proportions were 62% and 59%, respectively.] Agreement with this statement was expressed in 1992 by 28% of the men and 34% of the women [and in 1999 by 22% of the men and 29% of the women.]. Most abortion opponents were in the older age groups.

Opinions on abortion did not vary much in the other age groups, or between men and women.

There are hardly any opponents of abortion in Finland when the pregnancy would seriously endanger the woman's health or the child would probably be born abnormal. Mostly, people understand free abortion as the right of the married people or sexual partners to decide about having the child when the pregnancy is unwanted.

Men's attitudes on abortion mainly reflect their religious views and their general sexual liberality. With women, the acceptance of abortion relates to the modern urban lifestyle, which emphasizes women's right to self-determination in sexual matters. Free abortion is generally accepted by women with a long education and a white-collar background who live in big population centers. Again, free abortion is opposed by religious and conservative women who have had only one sexual partner in their lifetime. These women connect sexual intercourse with a faithful marital relationship that they had entered young; they do not regard women's sexual initiative as proper and they often use unsafe contraception. Becoming pregnant is generally not experienced as a problem when it happens in a steady marital relationship (Kontula 1993).

In 1992, 18% of the women of fertile age thought that they would terminate their pregnancy if they just then found out that they were pregnant. One in two women thought that they would not want to terminate their pregnancy. If a pregnancy had been a current problem, 16% of the men would have supported their partner's abortion and 69% would have opposed it. Women want to have abortions clearly more often than men, especially after the age of 35. Women's desire to have children is clearly concentrated within narrower age limits than with men—around the early 30s. With women, wanting to have an abortion is most centrally related to their age. Almost half of the young women under 25 and women over 40 years of age want to have their pregnancy terminated.

As a result of the 1970 law, the number of abortions rose quickly, reaching its peak of over 23,300 abortions, about 41% of the births, in 1973. After that, the number of abortions declined evenly to 11,200 abortions, about 17% of the births, in 1992. Since the early 1980s, the relative number of abortions has been about 30% lower in Finland than in the other Nordic countries (Ritamies 1994). With young people under 20, abortions have also decreased after the early 1970s. Abortion is more than twice as common among young women in the United States than it is in Finland, 44 per 1,000 compared with 9 per 1,000.

[*Update 2003*: In 1995, the number of abortions fell below 10,000, varying thereafter between 10,000 and 11,000. In 2001, the number amounted to 10,696 or 8.8 abortions per 1,000 women aged 15-to-49 years. The most common reason for performing an induced abortion has been social (about 85%), meaning that the birth of the child would cause considerable strain to the mother in view of her living conditions. About 94% of induced abortions are performed before the end of the 12th week of gestation.

[Since 1994, the relative number of abortions among those under 20 has increased by 43% and the corresponding proportion under age 17 by 23%. The rise in both pregnancy and abortion rates from 1997 to 1999 strongly suggests that unplanned teenage pregnancies are increasing. (*End of update by O. Kontula*)]

Twenty percent of the women who had at some time been pregnant reported having had an abortion, 80% of these women having had only one. Thirteen percent had had two abortions; 4% three abortions; and 2% four abortions. Twelve percent of the men reported that a pregnancy resulting from their sexual relationship had been terminated. Six-

teen percent of these men reported two or four abortions. The data suggests that in nearly half of the cases, the woman had an abortion without the man's knowledge.

In the big towns, about one third of the pregnant women had undergone an abortion. In smaller localities, only one in five pregnant women had an abortion.

Concerning the possible effect of abortions on the degree of gratification gained in sexual life, women who had had an abortion experienced orgasm at their last intercourse more often than women who had not had an abortion. Age was not a factor in this. The sexual life of the women who have experienced abortion is quite satisfying, according to these results.

#### D. Population Control Efforts

Because of the low birthrate, Finnish population policies are directed to support families with children, not to limit the number of children. Child allowances, paid parental leaves, parents' right to stay at home for childcare without losing their job or pension benefits, high-quality municipal daycare service for children, and other family policies aim at encouraging childbirth. The birthrate has remained relatively stable, [the total fertility rate being 1.74,] and in the future, the population will decrease if fertility does not grow. There is some discussion about the compensation for the lack of births by loosening the strict immigration laws in order to avoid a population decline.

### 10. Sexually Transmitted Diseases and HIV/AIDS

#### A. Sexually Transmitted Diseases

The 1992 FINSEX study shows that 15% of the men and 11.5% of the women surveyed had contracted gonorrhea, syphilis, chlamydia, condyloma, or the HPV, and/or genital herpes during their lifetime. Three percent of the men and 2.8% of the women had experienced at least two of these diseases. During the prior year, 0.7% of the men and 1.5% of the women had an STD infection. Based on the total population, these numbers suggest that 450,000 Finns had at some time suffered from an STD, more than one STD had been contracted by about 100,000 people, and during the year, about 38,000 people had been infected.

For the time being, the STDs have been somewhat more common with men than with women. Based on the under-35-year-old women's responses, women's morbidity is likely to surpass that of men's in the future. This change is because of the considerable spread of chlamydia and condyloma among young women. Among men, those who have had an STD appear rather evenly distributed in the different age groups because of gonorrhea, which has been prevalent among men since World War II. However, other STDs have replaced gonorrhea as the leading infections.

Compared to the corresponding study of the year 1971, morbidity among men only slightly rose; with women, the rise was fivefold. This can be explained by the fact that in 1971, only gonorrhea and syphilis were surveyed and diagnosed. In 1992, reports of chlamydia and condyloma greatly enlarged the share of the women who had experienced an STD.

One in ten middle-aged and older men has had gonorrhea. In the younger age groups, especially the under-25-year-olds, gonorrhea is significantly decreasing; none of these men had contracted gonorrhea during the prior year, and only 0.2% of the women. Earlier, gonorrhea had been relatively infrequent among women, but it has become more common in the younger age groups with the spread of other STDs. Genital herpes remains less frequent

than gonorrhea. The responses to the survey suggest that only a few thousand Finns had suffered from herpes during the prior year (see Table 23).

While data on chlamydia are not available for older Finns, one in ten of the under-35-year-olds has had this infection. During 1991, 1.3% of both men and women had been infected by chlamydia. This share very well corresponds to the statistical observation of about 12,000 chlamydia infections per year.

Condyloma is also mainly a problem for young adults. It is more common among women than among men. Only a few of the older Finns have had it during their life. Among the under-35-year-old women, one in ten has suffered from condyloma. During the prior year, condyloma has centered on men around 30 years of age and on women under 40. Of all the women, almost 1% had been infected by HPV during the prior year, and 0.5% of the men. This means about 25,000 infections for the year in the total population.

Of those who had at some time suffered from an STD, 8.3% had had an infection during the year prior to the survey. All men who had been infected by an STD, excepting herpes, during the prior year were under age 35. With women, there were infected women in all age groups under the age of 55, with the highest incidence among 18- to 24-year-olds and 35- to 44-year-olds. Condyloma and chlamydia were clearly the most frequently contracted diseases.

Those men who had had at least ten sexual partners during their lifetime had had 81% of the men's infections. The women of the corresponding group had 43% of the STDs. The women's lower number comes from the fact that only 15% of all the women had had more than ten partners, while 44% of the men had had that many partners. About 2% of the people had contracted an STD, although they had had only one partner during their lifetime. Keeping to one sexual relationship only does not always guarantee safety against the STDs.

Of the men who had had sexual intercourse with at least ten partners during their life, 29% had at some time had an STD and 7% had had more than one STD. With women who had more than five sexual partners, the corresponding figures are 35% and 14%. Half of those who had had 20 or more partners had been infected with an STD. Thus, in reality, most Finns have been spared an infection in spite of multiple partners.

Still, the number of sexual partners is directly linked with the risk of contracting an STD. The probability of the men's being infected by chlamydia or condyloma clearly increases after five partners; after ten partners for gonorrhea; and after as many as over 50 partners for herpes (see Table 24). In the group with over 50 partners, one half had had gonorrhea. Yet, even in this group, most of the people had escaped the other STDs.

With women, the risk of contracting chlamydia, condyloma, or gonorrhea grew significantly already with those who had had more than five partners (see Table 25). Almost one fifth of those who had had more than ten partners had had all the above-mentioned STDs.

**Table 23**

**The Percentages of Those Men and Women of Two Age Groups Who Had at Some Time in Their Life Been Infected with Different STDs**

Age	Gonorrhea		Chlamydia		Condyloma		Herpes	
	Men	Women	Men	Women	Men	Women	Men	Women
18-34	2.8	4.1	9.6	10.3	6.9	7.7	0.8	2.8
35-plus	11.5	2.0	2.3	1.5	1.9	3.1	11.9	1.0

About 40% of those who contracted an STD during the last year had had only one partner during this time. Only one in ten had had more than five partners. This suggests that a great part of the STD infections still come from the steady partner and only a small share from people who continuously have many sexual relationships.

The reports of the men and the women on the sources of infection differ from each other greatly. The women suspect, more often than the men, that they had gotten the infection from the steady partner. The men estimate, more often than the women, that they got the infection from a casual partner or a prostitute. It seems obvious that a significant share of the infections the women got from their partners came from prostitutes. The number of prostitutes is not very great, but they often have infections. The large number of their partners offers them many occasions for spreading infections.

With women's sexual liberation and willingness to initiate, the sources of infection have been "equalized." More and more women are infected by casual partners or friends/acquaintances, and men by their steady partners. Almost half of the under-30-year-old women have been infected by casual partners. One third of the under-30-year-old men, again, have been infected by their steady partners. This reflects a change, particularly, in women's sexual behavior.

In earlier times, a significant part of the men's infections were contracted from foreign women. During the past few years, these infections have increased also with women. Twenty-nine percent of men and 27% of women who had at some time had sexual intercourse with a foreigner while in another country had had an STD. Seven percent of these men and 11% of these women had contracted more than one disease.

Fourteen percent of middle-aged men who reported an STD said they had been infected by a foreign woman, either by an acquaintance on a vacation or a prostitute. A foreign prostitute was the source of infection for 29% of the men who had had sexual intercourse with more than 50 partners during their life and had at some time undergone an STD.

The anxiety about AIDS had caused about one tenth of all the people to decrease the number of sexual partners, and a little more than one tenth reported that they would find out more about the people they were going to have sexual intercourse with. This opinion was supported by 34% of the men and by 39% of the women who had had several partners dur-

ing the year. The risk of HIV influences people's sexual life even if they did not restrict the number of their partners. One tenth of the people had felt fear of AIDS during the last year. Even the people who have no actual risk of becoming infected are often afraid of AIDS.

One fifth of the people reported that they had kept to only one partner more strictly than before. These people were, however, not always those with only one sexual relationship. One third of these men and women had had several partners during the year. Certain sex practices, obviously most often anal intercourse, was avoided by 8% of all the men and 5% of the women.

The use of the condom had, as reported, increased with 20% of men and 12% of women. An increase in condom use was reported by 30% of those under age 25 years. Among those who increased their use of the condom because of AIDS, not all use it regularly. Only 46% of the men and 40% of the women who reported they had increased their condom use actually used a condom in their last intercourse.

About 30% of men and women under age 35 who had experienced an STD reported having decreased the number of their partners for the fear of HIV infection. Every other man and one third of the women reported increasing their use of the condom for the same reason. The condom had been used as the contraceptive method in the most recent sexual intercourse by 25% of the men and 20% of the women who had at some time undergone an STD. With the other men and women, the corresponding shares were 32% and 24%.

Of the men who had never been infected with an STD and whose sexual partner in the most recent intercourse had not been a steady partner, 67% had used a condom on this occasion. The corresponding share was 57% with the men who had at some time had an STD. Of the corresponding groups of women, 45% and 38% reported using a condom. Those who had at some time had an STD did not much deviate from others in their habits of condom use in casual relationships. A previous infection did not seem to "teach" anyone the use of the condom.

About half the men and women who had experienced an STD reported that a physician had advised them in connection with the treatment on how to avoid STD infection. One third had been left completely without counseling. About one tenth had been given a brochure, and about 5% had received counseling from a public-health nurse or a nurse. So, there is still much to improve within the public healthcare system on STD prevention.

[Update 2003: In the 1990s, the prevalence of STDs in a lifetime had increased by 2% to 3%. This increase was attributed to both chlamydia and condyloma. The proportions of gonorrhea and syphilis remained the same as before. Looking at the annual numbers of new infections in the 1990s, chlamydia was the most prevalent STD. After the mid-1990s, there was a slight increase in chlamydia infections. Similar increases have been found in syphilis and HIV, although the numbers are rather low. Gonorrhea decreased fast until the mid-1990s; in the second part of 1990s, these numbers have been stable (see Table 26). (End of update by O. Kontula)]

## B. HIV/AIDS

The first public statements about AIDS in Finland were issued in 1983, with a general discussion following in 1985 and 1986. Health officials were immediately involved, concentrating their efforts on general information about AIDS and its transmission and about other sexually transmitted diseases, strongly recommending the use of condoms in casual sexual

**Table 24**

**The Percentages of Men Who Had Been Subjected to Different STDs During Their Lifetime According to the Numbers of Sexual Partners During Lifetime**

Partners during lifetime	Gonorrhea	Chlamydia	Herpes	Condyloma	(n)
1-3	1.6	0.3	0.3	1.0	(307)
4-9	2.3	3.3	0.5	3.3	(214)
10 or more	17.4	10.9	2.7	6.7	(403)

**Table 25**

**The Percentages of Women Who Had Been Subjected to Different STDs During Their Lifetime According to the Numbers of Sexual Partners During Lifetime**

Partners during lifetime	Gonorrhea	Chlamydia	Herpes	Condyloma	(n)
1-3	—	1.1	0.4	1.8	(541)
4-9	2.7	8.1	2.4	7.5	(295)
10 or more	14.1	16.2	5.6	20.4	(142)

contacts. At the same time, together with communal health organizations, health officials also directed an effective information and support campaign for groups at special risk of AIDS. In schools, the AIDS issue was—and continues to be—associated with general sex education and the prevention of sexually transmitted diseases.

Public discussion and education concerning AIDS was at its strongest from 1986 to 1988, but the tone was considerably calmer than, for example, in the United States or the United Kingdom. By September 1990, the cumulative AIDS incidence rate per million of population was 14.3, compared with 66.3 in the United Kingdom.

By 1994, about 600 HIV infections had been diagnosed, and about 100 people had died of AIDS. The proportion of the HIV-infected in Finland has remained fairly small by international comparison. This is partly because of the scarcity of prostitution and intravenous drug use in Finland. [Update 2003: At the end of the 1990s, IV-drug use had become more popular in the Capital area. This caused some increase in HIV infections. In 2001 and 2002, this epidemic was already rather well controlled by the health authorities. (End of update by O. Kontula)]

In the FINSEX study, 6.4% of the men and 7% of the women reported having taken the HIV test on their own initiative by the beginning of 1992. [In 1999, these proportions had already about doubled to 12%.] Multiple tests were reported by 30% of these men (1.9% of all men) and by 16% of the women tested (1.1% of all women). At the beginning of 1992, about 250,000 Finns had been tested for HIV, and about 50,000 of those had had themselves tested several times. Multiple tests were most common among 30-year-old women. The young age groups had had themselves tested more frequently than older Finns. One tenth of young adults had taken the test.

Some of the HIV-tested had not had very many partners during their lives. One fifth of the men and one fourth of the women tested had had three partners at the most. About half of all the males tested had had at least 20 partners. Of the women tested, 40% had had at least 10 partners. Eleven percent of the men and 17% of the women with more than one partner were tested during the prior year. This shows that, with the risk of infection rising, women were quicker to have themselves tested.

Seven percent of current or past intravenous drug users and 16% of men and 19% of women with a previous STD infection had taken the HIV test on their own initiative. Of the other men and women, the test had been taken by 6%. Of those who had reduced the number of sexual partners or increased their use of the condom because of anxiety experi-

enced because of AIDS or HIV, from 16% to 18% had taken the HIV test. Of the people who had sometimes used drugs intravenously, 7% had themselves tested for HIV.

[Update 2002: UNAIDS Epidemiological Assessment: As of the end of 2001, Finland had reported a cumulative total of 1,301 cases of HIV infection. Of 222 HIV cases reported in 1998 to 1999, 100 were injection drug users, which suggests a recent outbreak among this population. HIV testing is mandatory for blood donors but otherwise voluntary. Diagnosed HIV infections are recorded in a national HIV case-reporting system, using an identification code. Other data come from screening programs. An UAT survey in all pregnant women has been conducted nationally since 1993. Of five positive women identified through unlinked anonymous testing, three were already identified through voluntary testing. UAT surveys have been done also among injection drug users. The incidence of syphilis decreased from 2 to 1 case per 100,000 between 1985 and 1987, and remained stable until 1995. In 1996 to 1998, an epidemic of syphilis had occurred, and most cases identified were imported cases from neighboring countries.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	1,200 (rate: 0.1%)
Women ages 15-49:	330
Children ages 0-15:	< 100

[An estimated less than 100 adults and children died of AIDS during 2001.

[No estimate is available for the number of Finnish children who had lost one or both parents to AIDS and were under age 15 at the end of 2001. (End of update by the Editors)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

In Finland, sexual dysfunction can be treated—depending on its causes—using sexual counseling, sexual short-term therapy, intensive therapy, medicines, and/or surgery. Sexual advice is given both in communal healthcare centers and in medical and therapeutic service centers specializing in counseling. It is possible to get sex therapy all over the country.

In the FINSEX study, the prevalence of different kinds of sexual problems was surveyed, as well as the help sought to resolve these problems. Half of the men and 26% of the women in a steady relationship reported no lack of sexual desire during the prior year. Fifteen to 55% of women in a steady relationship in different age groups experienced a lack of sexual desire fairly often. The women had succeeded in concealing this lack of desire in many cases, since clearly fewer men than this, when asked about their partners' lack of desire, had experienced their partners' lack of desire as a problem in each of the age groups. The men's reports on their own lack of desire and the women's opinions about their partners' lack of desire fit well together. Five to 20% of the men had experienced a lack of sexual desire at least fairly often. [In 1999, this variation in different age groups ranged from 7% to 19% of men. Among women, it ranged from 27% to 56%. Lack of one's own sexual desire increased especially among middle-aged women.]

Married women clearly suffered from a lack of sexual desire more often than the women in other steady relationships. According to their own responses, 35% of the married women had experienced a lack of sexual desire at least fairly often during the prior year. For women in cohabitation and other steady sexual relationships, the corresponding share was 15%. A similar perception, though slighter, could be found in the men's responses, where 18% of the

**Table 26**

**The Annual Number of STDs and HIV Infections in Finland in 1990-2000**

Year	Chlamydia	Gonorrhea	Syphilis	HIV
1990	12,567	2,326	32	89
1991	11,245	1,426	37	57
1992	11,462	993	33	93
1993	9,883	781	48	62
1994	8,289	493	63	69
1995	9,317	331	122	72
1996	9,438	182	148	69
1997	10,175	218	172	71
1998	10,654	269	187	81
1999	10,660	243	116	143
2000	11,731	287	212	145

husbands, 13% of cohabiters, and 8% of the men in some other steady relationship reported that their partners had had a lack of sexual desire at least fairly often during the past year. Partly, these differences are because of the fact that the married people are older, on the average, than those in other relationships, and a lack of sexual desire is noticeably frequent in over-55-year-old women.

In sexual therapy, it is presumed that love, trust, and security are generally needed as essential elements in the creation of sexual desire. Anxiety has been observed to inhibit sexual arousal from taking place (Kaplan 1987). Why then was there less desire in marriages that would appear more secure than other relationships? Important causes are certainly found in the effects of aging on sexual desire, the facilitation of marital relationships, and, in some cases, a sexual life changing into an obligation. Many speak about marital relationships turning into boring routine. Most passion has been observed in new and, in some respect, insecure relationships. Particularly longstanding marital relationships may be regarded as already too secure, thereby lessening the sexual excitement (Hatfield & Rapson 1987).

During the prior year, 58% of the women and 52% of their male partners reported some problem with vaginal lubrication. In this respect, the women's and the men's responses corresponded very well to each other. On the other hand, 15% of the women reported suffering fairly often, often, or regularly from insufficient vaginal lubrication, while only 5% of the men reported this problem. This suggests that it is sometimes difficult for men to notice the woman's problems with vaginal lubrication. Men notice only what affects the insertion of the penis, but, obviously, they do not actually know how much pain and discomfort insufficient vaginal lubrication may cause the partner during sexual intercourse.

With women, vaginal lubrication problems increased considerably with age. About one tenth of the middle-aged women reported fairly frequent problems with vaginal lubrication; after age 50, this rose to about a third, with hormonal changes a prime factor.

Many of the women who suffer from problems with vaginal lubrication experience intercourse as painful. Intercourse had fairly often been experienced as painful by 29% of the women who had suffered from vaginal dryness at least fairly often during the year. The corresponding proportion is 16% with the middle-aged and 40% with the aging. Of the same women, two out of three had experienced their sexual intercourse as painful at least sometimes during the year.

Almost half of the women who had suffered from problems with vaginal lubrication at least fairly often during the year, had obtained lubricant cream to facilitate intercourse and to remove the possibility of pain, according to both the women's and the men's responses. Lubricants had been of evident help, for a greater number of the women who used lubricants experienced orgasm during the last intercourse than those who did not use lubricants.

On the average, 3% of the under-45-year-old women had consulted a physician for problems of lubrication, and of the older women, more than 10%. About nine out of ten seekers felt they had been helped. The problem is thus quite easily resolved in most cases with the help of a lubricant.

Problems with vaginal lubrication have a strong connection with sexual desire and its possible deficiency. Half of the women who had experienced a lack of sexual desire at least fairly often during the year had also at least fairly often had problems with vaginal lubrication.

For the 1992 survey, 49% of the men who had intercourse during the prior year reported that they themselves

had had at least some problems with having an erection during that year; 47% of the women reported the same about their partners. Six percent by the men and 9% by the women reported this as a fairly frequent problem, a fairly good convergent appraisal, although men obviously tend to conceal their more difficult erectile problems. Comparatively, it seems that men's erectile problems are slightly less frequent than women's problems with vaginal lubrication.

Two clear observations emerge when the results of the years 1971 and 1992 are compared: On the one hand, erectile problems seem to have diminished during the 20 years and, on the other hand, they are very much age-bound. In 1971, 4.3% of the under-55-year-old men reported having experienced erectile problems during the last year, and in 1992, 2.2%. The corresponding figures with women about their partners were 6.2% and 4.4%. Both vaginal lubrication and erectile problems become clearly more common after the age of 50. In the age group of the 70-year-olds, almost one third of the couples had at least fairly often suffered from them.

[Update 2003: In 1999, there was some increase in erection disorders compared to the 1992 survey. Of all men, 7% reported having had erection disorders at least quite often in the last year. Among women, the equal proportion (of their partners) was 12%. In the age group 55-to-74 years, these proportions were 19% of men and 32% of women's partners (of the respondents who had sexual intercourse in the last year). (End of update by O. Kontula)]

According to the 1992 survey, men's erectile ability is strongest around the age of 30, when two men out of three have no problems having erections, as reported by both the men and women. With the 50-year-olds, the corresponding share is about 40%, and with the 70-year-olds, about one fifth. So, a significant number of men live throughout their lives without experiencing any problems with having erections. Here, it may be of great importance what kind of partners men have intercourse with, among other things, and how healthy they themselves are.

Men were also asked about their experience with continuous erectile dysfunction during their life. The continuity was not defined except by options of varying spans of time, the shortest of which was the option of "a few weeks' time." Fifteen percent of the male respondents reported experiencing a continuous erectile dysfunction for a span of at least a few weeks at least once (see Table 27). The incidence of erectile problems increased significantly for those over age 50. Half of the 70-year-olds had experienced continuous erectile dysfunction. While erectile dysfunction remains a very common problem, it did decrease slightly between 1971 and 1992.

Fifty percent of all Finnish men had experienced no erectile problems during the prior year, nor a few weeks' continuous dysfunction prior to that. On the other hand, 5% of the men had fairly often had erectile problems during the past year as well as at least a few weeks' continuous erectile dysfunction during or prior to that time. About 9% of the men had had no erectile problems during the past year,

**Table 27**

**Percentages of Men by Age Who Reported Having at Some Time Experienced Continuous Erectile Dysfunction, 1971 and 1992**

	18-24	25-34	35-44	45-54	55-64	65-74
Men 1971	7	7	16	19		
Men 1992	3	7	7	18	35	53

although they had suffered periods of erectile dysfunction prior to that time.

Slightly under 4% of all men in 1992 had consulted a physician for erectile problems, about one third of the men who had reported having sometimes experienced continuous erectile dysfunction. Nearly half of the men who had suffered from at least half a year's continuous erectile dysfunction had sought a physician for help. In 1971, fewer men than at present, 16%, had talked about the matter with a physician. More than half of the men who sought help in 1992 and about one fifth of the men who sought help in 1971 felt that they had been helped. So, seeking treatment, and the efficiency of this treatment, improved during the 20 years.

Of the men whose partners had had problems with vaginal lubrication at least fairly often during the last year, 31% had themselves had problems with obtaining or maintaining an erection at least fairly often. Twenty-three percent of the women who had had problems with vaginal lubrication reported that their partners had fairly often had problems having an erection during the same time. So, one's partner's sexual problems had obviously had an effect on the other's sexual responses. If the partner does not seem really eager to have intercourse, one's own excitement may easily die halfway.

About 5% of the men who had at least occasionally suffered from erectile dysfunction told that they had sometimes used some substances or pills that increase potency. Rings to maintain erection or penis enlargers with pumps, on the other hand, had not been much used by the men who had erectile problems. Neither had vibrators or vibrating dildos been used by these men with their partners more often than by the others. These devices had not been sought to substitute for deficiency in obtaining an erection.

Experiencing orgasm is a focal matter in view of the gratification of sexual life. This is true even though the FINSEX study shows that many women reported enjoying their sexual life although they had not experienced orgasm or had seldom experienced it during intercourse. However, those who had experienced orgasm more regularly were clearly more satisfied with their sexual life and their partners than the others.

About half of the men and from 6% to 7% of the women reported, irrespective of age, that they always experienced orgasm at sexual intercourse. This shows that only a small share of women experience orgasm very easily and that orgasm is not a self-evident matter even for men, for instance, if—from their point of view—their coitus is interrupted. With women, having no orgasm is often a consequence of the quickness of their partner's "coming," after which the love play ceases.

Most men have orgasm during sexual intercourse, either always, almost always, or, at least, mostly. Less frequently than this, orgasm had been experienced by 8% of the 18- to 24-year-old men and 19% of the 65- to 74-year-old men. In the other age groups, from 1% to 2% of the men obtain orgasm during intercourse less frequently than "mostly." Thus, men remain without orgasm during intercourse mostly at the beginning of their sexual life and at retirement age when their physical condition is declining.

With women, experiencing orgasm is much more occasional than with men. Orgasm is experienced at least mostly during sexual intercourse by slightly over half of the women and by about 60% of the middle-aged women. When the incidences of women's orgasms in the 1971 and the 1992 surveys are compared, the regularity of experiencing orgasm had slightly increased with the over-35-year-olds. With women younger than this, no change had hap-

pened. At least mostly, orgasm had been experienced during intercourse by 53% of the under-55-year-old women in 1971, and in 1992, by 58%.

Comparing orgasm data of 50-year-olds in 1971 with the 70-year-olds 20 years later in 1992, experiencing orgasm had not decreased in spite of aging and the increased morbidity (see Table 28). So, the preconditions for sexual satisfaction seem to have improved in this respect. On the other hand, since a considerable number of women do not experience orgasm during intercourse, it is a clear sign of the many restraints that still are obstructing women on their way to enjoyment. And if the woman does not find real satisfaction in sexual intercourse, the man cannot enjoy himself to the full either.

A third of a percent of the men had not experienced orgasm during intercourse, and of the women, 4.4%. This is a relatively small percentage when one looks at the United States, for instance, where about 10% of women do not have orgasm during intercourse (Darling et al. 1991).

Orgasm during intercourse had been experienced seldom or never by 0.7% of the men and 10% of the women according to the 1992 data on 18- to 74-year-old Finns. In 1972, 12% of the women under 55 years old had experienced orgasm seldom or never. In 1992, 9% of the women under age 55 reported orgasm never or seldom; quite-seldom orgasm had been experienced by 30% of the women between the ages 18 and 74 years. Thus, sexual satisfaction has remained significantly deficient for a large number of women, and little improvement has been observed in this regard between 1971 and 1992.

Achieving orgasm reportedly is decisively important to finding sexual intercourse pleasant. Of the men who report that they always experience orgasm at intercourse, half consider sexual intercourse very pleasant, while only 18% of the men who have orgasm approximately on every other occasion or less frequently regard intercourse as very pleasant. With women, the corresponding shares are 65% and 15%. Some women considered intercourse very pleasant, although they had never experienced orgasm.

Ninety-two percent of the men and 56% of the women reported having experienced orgasm in the latest intercourse

**Table 28**

**Percentages of Women by Age Who Reported Having at Least Mostly or at Most Seldom Experienced Orgasm During Intercourse, 1971 and 1992**

Age	Mostly 1971	Mostly 1992	Seldom 1971	Seldom 1992
18-24	52	50	16	12
25-34	58	59	8	10
35-44	51	64	9	9
45-54	44	56	17	5
55-64		44		8
65-74		45		16

1971: *N* = 1,231; 1992: *N* = 1,031

**Table 29**

**Percentages of Women and Men by Age Who Reported Having an Orgasm at the Most Recent Intercourse, 1971 and 1992**

	18-24	25-34	35-44	45-54	55-64	65-74
Men 1992	92	99	99	98	98	81
Women 1992	62	69	62	57	34	33
Women 1971	58	65	50	41		

(see Table 29). There was a rise in this level of experiencing orgasm for all the women's age groups between 1971 and 1992. In 1971, 56% of the under-55-year-old women had experienced orgasm at their last intercourse, and in 1992, 63%. The possible change concerning men is not known, for in 1971, only the women had been asked questions about experiencing orgasm. With women, the level of experiencing orgasm had stayed at 60% until the age of 50, after which it had fallen to about one third.

[Update 2003: The frequency of orgasms in sexual intercourse had remained almost unchanged in the 1990s. In the last intercourse, orgasm was experienced by 62% of women and 94% of men. Two or more orgasms during that intercourse was experienced by 10% of women and 7% of men. Fifty-seven percent of women usually experienced an orgasm, while 5% of women had never experienced orgasm. Eighty-eight percent of men and 66% of women reported having orgasm via masturbation. (End of update by O. Kontula)]

Fifty-five percent of the married women, 71% of the cohabiting women, 64% of the women in other steady relationships, and 41% of the women with no steady relationship experienced orgasm in their latest intercourse. Perhaps it is surprising that orgasms are experienced less frequently within marriages than in other steady relationships, for it has been presented that having orgasm is in an important connection with the feeling of security experienced in a relationship (Kaplan 1987).

The regularity of the orgasms experienced by women in sexual intercourse is clearly related to their sexual desire and to the quickness of the partner's "coming" (see Table 30). The women who had reported having themselves suffered from a lack of sexual desire during the last year experienced orgasm less frequently than the other women. Also a great number of the women who feel that their partner "comes too fast" are usually left without orgasm.

The orgasm experienced in the most recent intercourse was about as strongly related to a person's own sexual desire as to the quickness of the partner's "coming." An orgasm had been experienced by 24% of the women who had very often felt a lack of sexual desire during the year, and by 73% of the women who had not had any lack of sexual desire at all. If the partner's "coming" was not felt to be too soon, 70% of the women reached orgasm in their most recent intercourse. If the woman herself is desirous and the

partner "considerate" in his speed, the woman mostly achieves orgasm.

The partner's sexual desire is also connected with the woman's orgasm. Only 38% of the women whose partners had at least fairly often suffered from a lack of sexual desire during the last year had experienced orgasm during intercourse at least mostly. That is clearly fewer women than average.

The orgasms experienced by women during their most recent intercourse have a clear connection with the sexual practices applied. The best practice at sexual intercourse, in this respect, had been using two or three positions; the second best had been the "woman-on-top" position. The shares of the women who had experienced orgasm in these cases was 72% and 67%, respectively. In the "man-on-top" position, 49% of the women had experienced orgasm. Practicing varying positions at intercourse and the woman's own activity thus greatly increase the probability of her experiencing orgasm.

A number of people experience their first orgasms before their first sexual intercourse during various kinds of petting experiences. Most of the men, however, have their first intercourse-related orgasm at the same time they have their first sexual intercourse. Less than a third of the women reported achieving an orgasm in their first intercourse. Half of the women and one tenth of the men had not experienced their first orgasm until a few years after their first experience of sexual intercourse. There has not been much change in this timing even in the younger age groups. With one tenth of the women, more than ten years had elapsed between their first intercourse and their first orgasm. Four percent of the women reported no orgasm at all.

With respect to sex therapists, there have been some informal courses for them in order to provide them some professional skills. However, anyone can start working as a sex therapist without any special training, certification, or licensing.

[Update 2003: After several years of educational discussions, the general assembly of the Nordic Association for Clinical Sexology (NACS) in September 1997 appointed a committee of three representatives from each of the countries, Denmark, Norway, Sweden, and Finland, to work on a Nordic educational project. The purposes were: to design and offer qualitatively high-standing educational programs structured into different levels and comparable between the different Nordic countries, and, to provide regulations for sexological authorization [certification] and act for authorization of those who are clinically active within the field of sexology. The Nordic Council ("Nordplus") supported the project financially.

[Between 1997 and 2000, the committee—which *per se* regarded itself as a network—met ten times. Analyses of the current sexological educational situation in the Nordic countries, as well as in other European countries and the United States, were performed. Thereafter, analyses of expected requirements, seen from the viewpoints of the prospective students of each country, the different countries, and the NACS followed. Consensus for Nordic educational programs for clinical sexologists took shape. These programs were, in 1999, approved at the NACS Annual Meeting in Grimstad, Norway. The Nordic training program has three levels: Sexology I: Basic sexology (20 points), Sexology II: Clinical sexology: Sexological counseling (20 points), and Sexology III: Clinical Sexology: Specialist in clinical sexology (40 points). This training has started in Finland.

[In order to secure the (basic) quality of sexological education and the clinical practice of sexologists, the NACS

**Table 30**

**Percentage of Women Reporting Orgasms During Intercourse by Their Sexual Desire and the Quickness of Partner's Coming, 1992**

	Orgasm at least mostly	Orgasm every other time	Orgasm at the most quite seldom	(n)
<b>Lack of sexual desire</b>				
Very often	26	14	60	(62)
Quite often	45	18	37	(161)
Quite seldom	62	17	21	(370)
Never	73	13	14	(205)
<b>Partner "comes too soon"</b>				
Very often	28	11	61	(36)
Quite often	35	23	42	(141)
Quite seldom	62	17	21	(350)
Never	73	12	15	(250)

Annual General Meeting in 2000 (in Helsinki, Finland) approved the authorization [certification] procedure based on the Nordic Association of Clinical Sexology's education requirements. In 2002, the first specialists in sexual counseling and clinical sexology were authorized in Finland, Sweden, Denmark, and Norway. This gives more official status to these professions. (End of update by O. Kontula)]

## 12. Sex Research and Advanced Professional Education

### A. Institutes and Programs for Sexological Research

In Finland, sexological research is conducted by individual scholars working at universities and research institutes or projects financed mainly by the state. A bibliography of sex literature for the time period 1549-1989 includes over 2,000 authors (Turpeinen 1991). Most of the articles and books listed are written by medical doctors, but some important sociological studies on sexual behavior were also published in the last century. [Update 2003: An updated bibliography covers years 1990-2000 and is available at: [http://www.seksologinseura.net/Palvelut/body\\_palvelut.htm](http://www.seksologinseura.net/Palvelut/body_palvelut.htm). (End of update by O. Kontula)]

### B/C. Post-College Sexuality Programs and Sexological Publications

None currently exists in Finland. [Update 2003: A newsletter, *Seksuaaliterveys*, is distributed to the members of the Finnish Association for Sexology and to other persons belonging to the network of sex education and family planning. (End of update by O. Kontula)]

### D. Sexological Organizations

Three sexological organizations are active in Finland: SEXPO Foundation (Säätiö). Address: Malminkatu 22E, 00100 Helsinki, Finland; [www.health.fi/sexpo](http://www.health.fi/sexpo).

Seksuaalinen Tasavertaisuus SETA ry (Sexual Equality Association). Address: Hietalahdenkatu 2 B 16, 00180 Helsinki, Finland; [www.seta.fi](http://www.seta.fi).

[Update 2003: The Finnish Association for Sexology (FIAS) (Suomen Seksologinen Seura ry). The aim of FIAS is to improve qualifications of sexologists and to serve as a network for professionals who have an interest in sexual issues. FIAS is a member organization of the Nordic Association for Clinical Sexology (NACS), the European Federation of Sexology (EFS), and the World Association for Sexology (WAS). Address: Population Research Institute, Family Federation of Finland, P.O. Box 849, FIN 00101 Helsinki, Finland; [www.seksologinseura.net](http://www.seksologinseura.net). (End of update by O. Kontula)]

### *Demographics and a Brief Historical Perspective*

ROBERT T. FRANCOEUR

#### A. Demographics

France's position in western central Europe has made it a major cultural force in European history for 2,000 years. France's neighbors are Belgium and Luxembourg on the north, Germany, Switzerland, and Italy on the east, the

\*\**A Note from the Editors:* This chapter came into being after a ten-year frustrating search for a French sexologist to recruit and coordinate a team of experts to write a chapter about sexuality in France. Our breakthrough finally came in late 2001, six months after the Fifteenth World Congress of Sexology was held in Paris. The Congress was widely recognized for its strong therapeutic, psychoanalytic, and medical/pharmacological tenor, a good example of *le mirage complémentaire* of French culture in general, and French sexology in particular. In early 2002, Dr. Michel Meignant accepted our invitation. Despite a tight editorial schedule, Dr. Meignant managed to recruit a team of France's leading sexologists and therapists.

At the Paris World Congress, Dr. Ludwig Fineltain, a neuropsychiatrist and psychoanalyst, reminded us that:

(CIA 2002)

Mediterranean Sea on the south, Spain in the southwest, and the Atlantic Ocean and English Channel on the west. With a territory of 211,210 square miles (547,030 km<sup>2</sup>), France is about 80% of the size of the state of Texas in the United States. A wide plain covers more than half of the country. The northern and western regions of the country are drained to the west by the Seine, Loire, and Garonne Rivers. France's eastern border is marked by the Rhine River. A mountainous plateau, the Central Massif, marks the center of France. The Alps form France's eastern border with Switzerland and Italy, while the Pyrénées mark its border with Spain in the southwest.

In July 2002, France had an estimated population of 60 million. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 18.5% with 1.05 male(s) per female (sex ratio); 15-64 years: 65.2% with 1 male(s) per female; 65 years and over: 16.3%

The history of French sexology has been closely linked with the beginnings of the Société Française de Sexologie Clinique. The idea arose between 1970 and 1974. Where? At La Couple, of course. In Paris, it is well known that great ideas are born in the literary *cafés* between Saint-Germain-des-Près and Montparnasse.

As with all our contributors to *IES* and *CCIES*, Dr. Meignant and his team received our detailed eight-page chapter outline and guidelines, translated into French. The chapter on sexuality in France has its own unique flavor and gourmet accent. It is very different from the other chapters, with a very strong didactic, analytic, and ideological focus. That, in itself, is informative. Several years ago, when Dr. William Prendergast, one of our editorial consultants, analyzed the information on coercive sexual behavior (Section 8A) for the 32 countries in volumes one to three, he ended with an important observation relevant to all the information in the *Complete International Encyclopedia of Sexuality*, and particularly relevant to this chapter: "Often what is not said in these chapters is more informative than what is said."

The French texts provided by the eight creators of this chapter were ably translated by Genevieve Parent, B.A., M.A., a double graduate of the Sexologie Programme at the University of Quebec in Montreal (UQAM). She has held several positions as a sexuality teacher, clinical sexologist, psychotherapist, and certified sexual abuse counselor. Because this chapter is a composite created by eight different French sexologists, R. T. Francoeur, the editor, assumes responsibility of redacting the translation and integrating the different parts of the chapter.

with 0.69 male(s) per female; *Total population sex ratio*: 0.95 male(s) to 1 female

**Life Expectancy at Birth:** *Total Population*: 79.05 years; *male*: 75.17 years; *female*: 83.14 years

**Urban/Rural Distribution:** 74% to 26%

**Ethnic Distribution:** Celtic and Latin, with Teutonic, Slavic, North African, Indochinese, and Basque minorities. Following the breakup of its overseas empire, France received immigrants from its overseas colonies, particularly Vietnam, Morocco, Algeria, and Tunisia, and several Caribbean nations.

**Religious Distribution:** Roman Catholic: 83% to 88% (at least nominally); Protestant: 2%; Jewish: 1%; Muslim (North African): 3%; unaffiliated: 4%

**Birth Rate:** 11.94 births per 1,000 population

**Death Rate:** 9.04 per 1,000 population

**Infant Mortality Rate:** 4.41 deaths per 1,000 live births

**Net Migration Rate:** 0.64 migrant(s) per 1,000 population

**Total Fertility Rate:** 1.74 children born per woman

**Population Growth Rate:** 0.35%

**HIV/AIDS** (1999 est.): *Adult prevalence*: 0.44%; *Persons living with HIV/AIDS*: 30,000; *Deaths*: 2,000. (For additional details from www.UNAIDS.org, see end of Section 10B.)

**Literacy Rate** (*defined as those age 15 and over who can read and write*): 99%; schooling is free and compulsory from age 6 to 16

**Per Capita Gross Domestic Product** (*purchasing power parity*): \$25,400 (2001 est.); *Inflation*: 1.7%; *Unemployment*: 8.9%; *Living below the poverty line*: NA

## B. A Brief Historical Perspective

Traces of 400,000-year-old covered wood shelters created by Neanderthal-type humans (*Homo erectus*) have been found in Nice, along with stone and ivory sculptures from 25,000 years ago. The remarkable, sophisticated wall paintings in prehistoric caves of southern France and northern Spain, particularly Lascaux and Altamira, date back to the Upper Paleolithic about 18,000 years ago and are evidence of some of the earliest modern-type humans (*Homo sapiens sapiens*). The Celtic tribes of ancient Gaul were conquered by Julius Caesar in 57 to 52 B.C.E., and remained under Roman rule for 500 years. The Franks, a Teutonic tribe, reached the Somme from the east around 250 of the Common Era. By the 5th century, the Merovingian Franks had ousted the Romans and defeated the Huns under Attila. Under Charlemagne (742-814), Frankish rule extended over much of Europe, including what is now France and Germany, as well as parts of Italy, Spain, and Austria. Charlemagne's grandsons fought over the empire, and in the peace of Verdun (843), divided the kingdom with Lothar becoming the Roman emperor. Pepin I became the king of Aquitaine, Louis II took over Germany, and Charles the Bald ruled France. The absolute monarchy reached its apogee in the reign of Louis XIV (1643-1715), the Sun King, whose brilliant court was the center of the Western world. The French Revolution of 1789-1793 overthrew the monarchy and plunged France into a bloodbath that ended with a new absolute rule under Napoléon Bonaparte, who became First Counsel in 1799 and Emperor in 1804. The defeat of Napoléon and the 1815 Congress of Vienna sought to restore the pre-Napoléonic order in the person of Louis XVIII, but industrialization and the middle class fostered under Napoléon pressed for change until a revolution in 1848 drove the last of the Bourbon kings into exile.

Napoléon's nephew, Louis Napoléon, declared the Second Empire in 1852, taking power as Napoléon III. His op-

position to the rising power of Prussia ignited the Franco-Prussian War (1870-1871) and ended in his defeat and abdication.

France emerged from World War I as the continent's dominant power, but political instability and economic chaos stemming from the devastation of the war, plagued the postwar Third Republic. During World War II, northern France was occupied by the Nazi troops while southern France remained free. After World War II, as all the European empires with overseas colonies began to collapse, France withdrew from Indonesia in 1954, from Morocco and Tunisia in 1956, and from most of its African territories, including Algeria, in 1958 to 1962. Today, a few small overseas Departments and Territories remain part of France: the island of Corsica in the Mediterranean off the coast of Italy, French Guiana on the northeast coast of South America, the islands of Guadeloupe and Martinique in the Caribbean, and French Polynesia in the Pacific (see the chapter on French Polynesia in this volume).

## 1. Basic Sexological Premises

### A. Sexology in France

SERGE GINGER and MICHEL MEIGNANT

Sexology was born at the end of the 19th century with the publication of *Psychopathia Sexualis* by Richard von Krafft-Ebing in Suttgart in 1886. Havelock Ellis' work, *Studies in the Psychology of Sex* (1898, Philadelphia, USA), and Sigmund Freud's *Three Essays on Sexuality* (Vienna, Austria, 1905) were published around the same time, but showed very different conceptions of sexuality. This accounts for the hesitations of newborn sexology. In 1919, Magnus Hirschfeld created his famous Institute in Berlin. It was one of the first buildings to be plundered and burnt down by the Nazis in 1933. In the eyes of the Nazis, Magnus Hirschfeld had two reasons to be persecuted: He was Jewish and a homosexual. Pioneers in sexology have always had to confront conservative, racist, and fascist attitudes. In 1926, in the context of the liberal and democratic Netherlands, Theodore Van de Velde published *The Perfect Marriage*, endorsing the replacement of sex as a "conjugal duty" with an emphasis on sexual pleasure and happiness. The book was widely published in many countries, and in translations as recently as 1965, in about 50 editions.

In 1966, William Masters and Virginia Johnson published *Human Sexual Response*, documenting their revolutionary research, which became the foundation for modern scientific sexology. Masters and Johnson were the first to observe the physiology of sexual function, in the same way that Claude Bernard had observed the heart, respiratory, and digestive functions. In their laboratory, transformed into a fortress, 694 men and women masturbated or made love in front of cameras. They were heterosexual or homosexual. The subjects were fitted with electrodes and all sorts of sensors in order to record their heartbeat, rhythm of their breathing, and blood pressure. The erection of the penis, of the clitoris, of the breast and nipple, and the color of the skin were, among other things, also measured. Masters and Johnson then moved to the clinical phase of their work, with their book, *Human Sexual Inadequacy*, published in 1970. Following my experience in supervising the French translation of Masters and Johnson's *Human Sexual Inadequacy*, my own therapeutic methodology moved from experimental and behaviorist sexology into a humanistic sexology and a humanistic analytical sexology, to finally become a modality known as Amorology, with the publication of *L'Amourologie*, in 1992. The resulting methodology replaced the therapy of sexual function with a therapy of the

love relationship. The symptom was thus set in the global context of the subject's relational problems.

In France, sexuality is not considered to be a specific method of psychotherapy. Since its creation in 1974, the French Society of Clinical Sexology (Société Française de Sexologie Clinique—SFSC) has chosen an eclectic approach, under the coordination of Charles Gellman, Gérard Vallès, Michel Meignant, Georges Teboul, and others.

Thus, various trainings and specializations have developed in parallel, some inspired by psychoanalysis (Gérard Vallès and Georges Teboul)—enriched by “sexoanalysis” (Claude Crépault, from Montreal); some inspired by cognitive-behavioral therapies, following the work of Masters and Johnson (Mireille Bonierbale, and Robert and Claire Gellman); others inspired by Gestalt Therapy (“Sexo-Gestalt”—with Charles Gellman, Martine Masson, and Chantal Higy-Lang), and others inspired by hypnotherapy or the systemic approach.

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

No information given.

## 3. Knowledge and Education about Sexuality

The Family Planning Association, France's national branch of Planned Parenthood/World Population, is the nation's main agency in providing sex education. The approach taken is a “preventative” approach, linked with the curricula in biology, health, and/or natural sciences. The model consists of pregnancy and STD prevention, teacher training programs, and lectures to the youth in the context of “Life Education.” In 1994, in terms of public attitudes toward sexuality, using a scale of 1 for “opposed” to 9 for “well accepted,” the Family Planning Association rated France as a 5 (Vilar 1994; Caron 1998, 68).

## 4. Autoerotic Behaviors and Patterns

No information given.

## 5. Interpersonal Heterosexual Behaviors

### [A. A French/U.S. Comparison: Comment 2003

TIMOTHY PERPER

[This comment briefly describes statistics relating to couple status and sexual partnering among men and women in France and in the United States for four age groups—19- to 29-, 30- to 39-, 40- to 49-, and 50- to 59-year-olds.

[The results are based on two large-scale and representative probability samples, both from 1992. The U.S. sample contained 3,432 adults, ages 18 to 59, from the *National Health and Social Life Survey* (Laumann et al. 1994). The French sample contained 4,580 adults, ages 18 to 59, from the *Analyse des Comportements Sexuels en France* (cf. Spira, et al. 1994). The French sample was obtained by telephone interviews, whereas the U.S. sample was obtained by face-to-face interviews. Readers interested in statistical and methodological details are referred to the original publication (Gagnon, et al. 2001).

[For the French sample, the percentage of men and women living in couples is lowest among 19- to 29-year-olds (38% for men, 46% for women) and then rises to a plateau among older men and women (from 82% to 89% among 30-, 40-, and 50-year-olds). In France, the percentage who are unmarried but living with a partner is largest among 19- to 29-year-olds (22% among men, 21% among women). These percentages drop steadily with age (16% among men, 12%

among women for 30- to 39-year-olds, and then to less than 10% among 40- and 50-year-olds). Comparable data from the United States show similar effects—proportionally more younger people (19- to 29-year-olds) are single or, if coupled, then unmarried, than among older people.

[These differences among age groups may have several causes. One is a cohort (or “generational”) effect that might represent mores having changed in the youngest generation towards a decreased valuation or even avoidance of marriage (or coupling of any kind) among people born after 1970. Another possibility is an effect of age, in which couple formation normally occurs primarily among older rather than younger individuals. If so, then members of the youngest group will begin to marry when they reach their 30s. Both factors may play a role. Further research is needed to clarify these possibilities.

[Concerning sexual activity in these coupled individuals, in the French sample, the percentages reporting no sexual partner within the last year differ among the age groups. For coupled men, the percentage without a sex partner rises steadily from a low of about 2% for 19- to 29-year-olds to a high of 6% for 50- to 59-year-olds. Although small, the increase is statistically significant. For U.S. men living in couples, men reported a similar (and small) increase in living without a sex partner.

[However, the percentages of coupled women in the French sample who report no sexual partner changes very little with age—in fact, the lowest percentage reported (1%) was among the 50- to 59-year-old women. Unlike French women, U.S. women reported a steady increase with age in living without a sex partner. The origin of this national difference is unknown.

[In French men and women, a U-shaped relationship exists between age/cohort and the presence of a sexual partner. For men and women in France, 30- to 39-year-olds most frequently report having a sex partner, with younger and older individuals both less likely to report having a sex partner. This effect may represent two different processes—a tendency for younger people to live singly and to lack partners, plus a tendency for older people to remain coupled but celibate. However, these hypotheses require further study.

[By contrast, in the U.S. sample, the percentages of coupled men and women who report living without a sex partner increases steadily with age for both sexes. It is unknown why the French sample shows a U-shaped form whereas the U.S. sample does not.

[We turn next to sexual activity among coupled and non-coupled men and women of different ages. For the French and U.S. samples, most coupled individuals (more than 90%) report living monogamously with the partner in all four age groups. However, a far more complex pattern emerges for individuals not living in a couple. In the 20-, 30-, and 40-year-old ranges, about 30% of men in the French sample and about 50% of the men in the U.S. sample report having more than one sexual partner within the last year (both percentages decrease among 50- to 59-year-old men). So it seems that in both nations, a fair proportion of the younger non-coupled men tend to have had more than one sex partner within the last year.

[However, both age/cohort and national differences occur among women not living in a couple. In the French sample and across all four age groups, between 10% and 20% of uncoupled French women report having more than one sex partner in the last year. This is about one-half to two-thirds the rate reported by French men. In principle, for heterosexuality within a closed population, the number of partners must be equal for men and for women. It may be that men

exaggerate and women minimize their self-reports about sex partners, or it may be that men and women define sex partner differently. Again, only further research can clarify these possibilities.

[Among uncoupled U.S. women across the age/cohort groups, the youngest women (19- to 29-year-olds) are most likely to report more than one sex partner in the last year (42%). This percentage decreases steadily among 30-, 40-, and 50-year-olds, to a low of 15% among 50- to 59-year-old women. These percentages are less than reported by U.S. men, again raising the question of why the percentages among men and women are not equal. Furthermore, the percentages of uncoupled U.S. women reporting more than one partner in the last year are consistently higher than percentages reported by French women. The origin of this national difference is unknown.

[The survey results indicate that most coupled respondents in France and in the U.S. report that their primary sexual activity was with their partner. However, complex differences between men and women, between France and the U.S., and among the age groups occur for uncoupled individuals. The most robust finding appears to be that for the youngest men and women in both France and the U.S., sexuality is not limited to marriage or living with a partner. Only further research and time will reveal what these patterns imply for the future of marriage and sexuality. (End of comment by T. Perper)]

## B. Heterosexual Behaviors in an Ethological Perspective

CHARLES GELLMAN

This chapter will mainly discuss sexual behaviors, using a behavioral and ethological approach. The study of ethology is done through the observation of animal behaviors, and is based on factors, which lead animals to adopt specific behaviors. The word “ethology” is very similar to ethnology, which is the study of human relations in a given society. Ethnology also provides a better knowledge of a variety of societies and cultures.

In order to write this section, we used a scientific approach without any preconceived ideas. We have been quite surprised to notice that very few French studies have been published on heterosexuality, all authors referring to homosexuality, often in a polemic manner. We consider it is possible to study heterosexuality on its own.

We will discuss later on the contention that homosexuality is not the opposite of heterosexuality. We consider heterophobia as the opposite to heterosexuality.

Also, a common mistake lies in the consideration that heterosexuality is a sexual identity. In fact, *sexual identity* or *gender identity* or *gender* refers to the male or female gender identity *and not to sexual orientation*. Male or female gender (or a neutral gender) is not an indication of the heterosexual or homosexual orientation, or of any other orientation. Identity and sexual orientation are two different concepts. On the other hand, once the sexual orientation is defined, it may become a part of the person's identity, but surely not of one's gender!

### Sexual Behavior

Sexual behavior includes all the actions surrounding sexual attraction (for example, the sexual parade [response]) and leading to the sexual act. In most species, sexual behavior serves reproduction purposes only. The human race and some monkey species are not only reproduction oriented. While the sexual act allows the fertilization of the egg, sexual behavior also includes certain parental roles, such as nest making and care of the newborn. Sexual and parental behaviors are caused by specific physiological states, such as

gonad maturation and certain hormones, all controlled by the nervous system.

Human sexual behavior has three aspects:

- The instinct: sexual urge or libido;
- The attachment bond, which influences interpersonal activities; and
- The passion: love.

### Pairing Up (Intimacy Between the Sexes: “What's Different Comes Together”)

The search for sexual partners serves the purpose of heredity for both animals and humans. Many different mechanisms are used to facilitate interaction between sexes.

*Attraction*: the attraction of the male for the female. The female animal signals its interest to the male in an extraordinary variety of ways. Women, on their part, use perfumes, makeup, clothes and underclothing, jewels, tattoos, piercing, singing, and vocalization.

*Proceptivity*: the female search for the male. Different behaviors demonstrate the active female search for a male partner: closeness (females are more bodily active during estrus), hops, and facial expressions. The female then readjusts according to male signals. This phenomenon can also be noticed in nightclubs, where men and women mainly interact in a nonverbal way, despite the loudness of the music.

*Receptivity*: when the female accepts copulation, for example, lordosis in the female rat and a woman granting access to her vulva.

*Estrus*: the period during which mammals look for copulation; the state of being during this same period (female in rut = female in heat, from *rugitus*, roaring). It is the ovulation period.

### Heterosexual Orientation

As mentioned earlier, we should differentiate between heterosexual orientation—being sexually attracted by someone of the opposite sex—and one's gender identity. A person who has a male sexual identity can be either homosexual or heterosexual, depending on different factors. The heterosexual orientation can be expressed in different ways:

- Global heterosexual orientation;
- Partial heterosexual orientation, interest for specific body or psychological characteristics of the opposite sex (breast, buttocks, musculature, or personality traits, such as calmness, kindness, or aggressiveness);
- Strong orientation, or on the opposite, weak, fragile, or uncertain orientation;
- Positive orientation; or
- Defensive heterosexual orientation: homophobia.

All these concepts account for the different variations in the time and life of individuals.

Kinsey's report (1948), followed by Masters and Johnson in 1979, considers sexual orientation on a scale of seven, from an exclusive heterosexual orientation, to an exclusive homosexual orientation, with gradient bisexuality an in-between.

Bisexuality can be considered as either sequential or transitional (from 7, an exclusive homosexual orientation, to 0, an exclusive heterosexual orientation, or vice-versa, and the return to the primary orientation). It is considered “contemporary” when a person has sexual partners of both sexes within the same period of time. According to Berkey, Perelman-Hall, and Kurdek (1990), bisexuality can be serial or concurrent (simultaneous—with sexual intimacy at the same time with both a male and a female partner). These studies are limited in that they define sexual orientation through sexual behaviors.

Other studies refer to the self-identification process (identifying oneself as heterosexual, bisexual, or homosexual).

On the other hand, Klein (1985) considers sexual orientation as a dynamic process including different sexual variables: attraction, behavior, fantasies, emotional preference, self-identification, and lifestyle/affiliation.

Relying on Klein's concepts, Berkey, Perelman-Hall, and Kurdek identified six categories of bisexuality to replace the levels 3, 4, and 5 of Kinsey's scale. These categories are:

1. From an exclusive homosexual orientation to an exclusive heterosexual orientation;
2. From an exclusive heterosexual orientation to an exclusive homosexual orientation;
3. A primary homosexual orientation (frequent homosexual contacts or desires with a few heterosexual contacts or desires);
4. A primary heterosexual orientation (frequent heterosexual contacts or desires with a few homosexual contacts or desires);
5. A shared sexual orientation towards both sexes (desires and contacts are as frequent for both sexes within the same period of time): concurrent bisexuality; and
6. A shared sexual orientation towards both sexes (exclusive homosexual orientation followed by an exclusive heterosexual orientation), or a sequential bisexuality.

All this is rather complex, since homosexuality, following Kinsey and Masters and Johnson, is conceptualized as the opposite of heterosexuality. In this conceptualization, homosexuality and heterosexuality are located on the same scale.

We suggest the representation of this clinical reality is more accurately represented as being on *two different scales*. Accordingly, the opposite of heterosexuality is not homosexuality, but *heterophobia*. Again, the opposite of homosexuality is not heterosexuality, but *homophobia*.

This conceptualization underlines that these two scales exist in all human beings. An individual's heterosexual orientation is not something intangible, but rather a demonstration of his or her position in a given period and environment on these two scales. This conceptualization highlights also a defensive heterosexuality, as a consequence to homophobia.

### *The Process, from Unconscious Fantasies to Sexual Intercourse: "Psychosexual Axis"*

The source of our sexual life is in unconscious fantasies. They can be of multiple origins and can only be understood through psychoanalysis, psychotherapy, or with regression techniques (hypnosis, rebirth, or meditation). Many of these fantasies stem from childhood erotic experiences or from "first times" (first love, first masturbation, or first sexual contact). Unconscious fantasies vary depending on cultures, since they are compromises between taboos and cultural and religious interdicts.

Finally, some of the fantasies are genetically transmitted archetypes:

1. *Night dreams*: the royal way to the unconscious;
2. *Day dreaming and erotic fantasies*: sexual imagery which can be similar or very different from the behavior;
3. *Plans and projects*: the rational behind sexuality;
4. *Behaviors*: from thought to action; and
5. *Aptitudes and abilities*: because of its complex and unpredictable nature, sexual intercourse needs a learning, a special attention to the partner and the process, a capacity for adjustment, and creativity; in summary, a sexual intelligence.

### *The Duration of Heterosexual Systems*

*Monogamy*: The couple is stable at least until the children are fully grown up. Only 1.5% of mammals are monogamous (gibbons and wolves). In human beings, 10% of children are not fathered by the putative father. Social monogamy is facilitated when both parents are necessary for the youths' upbringing, for example, in the case of a premature baby.

*Polygamy* refers to two different situations: *polyandry* (several males for a female) and *polygyny* (a male with several females).

The second situation reflects *promiscuity*, meaning many copulations without real engagement. Out of 854 societies representative of all earth regions, we note 0.5% practice polyandry (in Tibet, the woman marries all the brothers of a same family, one after the other), 55% maintain monogamy, and 44% practice polygyny. In most monogamous societies, polygyny is tolerated.

## *6. Homoerotic, Homosexual, and Bisexual Behaviors*

PIERRE DALENS and LAURENT MALTERRE

In recent decades, the evolution of homosexuality in France called for a clear distinction between homosexuality and bisexuality. This distinction requires a definition of these two realities, but first one needs to explore the real meaning of sexual activity.

Sexual activity can be consented if both individuals are not family or biologically related. In homosexuality, both individuals share the same gender. In bisexuality, the object of desire varies, sometimes being the same gender, sometimes being of a different gender. Pleasure is the primary concern, over procreation. However, the emotional and affective aspects play a major role in homosexuality as in bisexuality. In most cases, the homosexual relationship fulfills important affective and emotional needs. There are several degrees between sensoriality and affectivity.

The age of consent for homosexuals is 15 years of age. In 1985, France made it illegal to discriminate against homosexuals. France also prohibits discrimination against homosexuals and lesbians in the workplace. In late 1993, the French government directed insurance companies to accept joint insurance coverage for nonmarried couples.

### **A. Homosexuality**

Homosexuals are sexually attracted by individuals of the same sex. Some heterosexuals may have this fantasy but will never act on it. The reverse is also true for homosexuals: Some will have heterosexual fantasies but will never act on them. We can distinguish between an actualized homosexuality and a fantasized or latent homosexuality. We also have to consider whether the homosexuality is primary or secondary, or transitory. These concepts are particularly important in adolescence and early adult life, while the individual is still exploring his or her lifestyle and orientation. The partner choice is either homogender or heterogender. In this case, we define a reverse homogenderism as being a gender different from the biological identity. In summary, we consider the affective demonstrations and the sex of the partner, similar or different from the biological sex.

Up to now, no study has shown a neurological imbalance responsible for homosexual orientation. The physiological theories seem to apply only to a small number of individuals with a hormonal imbalance. The vast majority of homosexual behavior would be conditioned by psychosociological factors.

There is no difference between homosexuals and heterosexuals in the sexual response, which denies a genetic origin for homosexuality. The behavioral differences are high-

lighted in foreplay, being much more varied in homosexual couples than in heterosexual couples, partly explained by a coital preference in heterosexual couples.

## B. Bisexuality

Bisexuality is defined as the capacity to experience erotic feelings and have sexual desire for both sexes, with an uncertainty concerning the actual sexual orientation. Bisexual people act out their dual fantasy (heterosexual and homosexual), depending on the circumstances. The bisexual is clear with his object of desire and his sexual preference, but has ambivalence regarding his sexual orientation.

Ambisexuals or bisexuals emphasize the sexuality rather than the sex of the person. In all these homosexual and bisexual people, there is a triangulation between the object of desire, the desiring subject, and the rival model, which goes back to an unresolved preoedipal conflict. This situation is similar to the heterosexual preoedipal structure. The bisexual is considered incomplete and therefore in search of both the male and female identity, as in androgyny. The threat does not lie in homosexuality, but rather in the loss of gender identity. The bisexual is stuck in an unclear frontier between homosexuality and heterosexuality.

Even if bisexuality is still considered taboo, we should not think of it as being unclear. It is a variation in sexuality, not necessarily socially accepted, but at least more common or usual than in previous times.

Although fragile, this homeostasis possesses its own specificity, and should not be submitted to repressive and normative models, as other aspects of human sexuality were.

This homeostasis suggests a fragile equilibrium for bisexuals through their erotic investment in both sexes. Erotic is here taken in its global meaning, such as what brings two individuals together in terms of affects, emotions, senses, and the mind. It is not specifically limited to the sexual aspect. There are passages from the heterosexual states to the homosexual states. A state can be overly invested in bisexuality when there is a cleavage between the "archaic," the impulse and the senses, and, on the other hand, the affects, the emotions, and the mind. Bisexual maturity is attained when the individual recognizes his or her dual desire for same-sex and opposite-sex people, while considering the specificity of each relationship in terms of eroticism, affects, and emotions. This is why we believe that the term "bi" should be carefully used and defined in terms of the unique nature of each love story.

Bisexuality can take many faces. When an individual has difficulty acknowledging his dual desire, it will evolve in an interior battle. When a married person is sexually attracted to same-sex people, then feelings of guilt and shame through this experience may threaten his or her heterosexual identity, to the extent of unsettling couple relationships and family unity.

- It may be expressed in the avoidance of ambiguous behaviors and attitudes in a search for normalcy, which leads the individual to shut himself out with his suffering.
- It may be a married man living his secret life as a homosexual with difficulty.
- It may be a heterosexual man who constantly denies his sexual fantasies of being anally penetrated.
- It may be a man who considers himself homosexual and who relives his first love and sexual experience with a woman. The sensations and erotic codification are new and surprise him. Touches, contacts, odors, glow, and body forms are to be rediscovered. In this case, it is a bisexual identity hiding a strong homosexual orientation.
- It may be a love and affection between men and between women which brings them to question their identity.

They feel a psychological dissociation and ask themselves: "Who am I?"

- Finally, it may be this man or this woman who has no real desire for either sex, sometimes seducing males, sometimes females, questioning where his or her actual desire lies.
- It may also be the man experiencing repeated failures with women, who question his male condition and, consequently, his sexual desire and sexual normalcy.

## C. Sociological Aspects

The sociological aspects of homosexuality are worth studying because of the high incidence of HIV, the suicide rate among teenagers, and in the first years of active sexual life, the search for relational stability among homosexual couples. In France, a national cooperative of homosexual and bisexual associations, PACS (Pacte Civil de Solidarité), is major resource both for researchers and for individuals with a homosexual or bisexual orientation seeking to discover and eventually achieve a more stable orientation.

Since the sexual liberation movement in the 1970s, new lifestyles have emerged, which have led the French to rethink their identity again in building their community. This has given birth to the craziest [*sic*] and most-varied homosexual associations, the adoption of health issues as their own concerns—as in the battle against HIV, the emergence of a gay culture with its own novels, magazines, critiques, and studies, its goods, clothes, and underclothing specific to the gay community, the Techno music, and a rainbow flag. PACS: the Pacte Civil de Solidarité, coupled with a new gay ideology, has led the fight against the discriminations the homosexual community has always been victim of. The gay liberation movement asks for civil rights: In 1998, the rights of homosexual couples were fully recognized in terms of social rights, lodging, and fiscal matters.

However, this gay liberation movement has not enabled the gay community to be freed from its provocative myths and visibility concerns, since it is so worried about being assimilated by the heterosexual majority. There was a risk of being caught in a cultural ghetto, with no freedom concerning behaviors and discourse. The gay community does not consider the plurality of homosexuality, where some individuals are bisexual and others previously married. Bisexuality is not well-represented in French society, having only one association called BI. Thus, bisexuals are far from being seen and heard. The bisexual community runs the risk of repeating the same mistakes the gay community has made, namely to consider the group rather than the individual. In reality, each individual has to construct his own identity with his own sexual specificity.

## 7. Gender Diversity and Transgender Issues

PIERRE DALENS and LAURENT MALTERRE

The roots of ambiguity in the sexes can be found in organic or psychological problems, which lead to transgenerism or intersexuality.

### A. Intersexuality

The morphological division between the sexes may cause certain dysmorphological states: the intersexual states caused by problems in the biology of embryogenesis. Such pathologies are infrequent.

The intersexual pathologies are a type of organic pathology and show some dysfunction in the neurological and hormonal systems. In the embryological development of human sexuality, there could be dissonance between the biological sex and the physical appearance of the person.

There also exist other undifferentiated states. All these syndromes prevent an appropriate genital functioning. A real hermaphroditism, being male and female, does not exist.

More frequently, there are difficulties in the process of gender development, and sometimes to the extreme of transsexualism.

### B. Transsexualism

We define transsexualism as follows: The irresistible need for an individual to belong to the opposite sex, totally convinced that there was a mistake with his or her biological sex. Contrary to the transvestite, the transsexual is not sexually aroused by dressing up in the opposite-sex clothing. He is looking for a real sensorial and sexual transformation. The transsexual looks for a change in his morphological sex.

Transsexualism also includes individuals whose gender identity and sexual expression are unfixed and go beyond dual representation of male and female identity.

### C. Transgenderism

This category includes transgender and transvestite behaviors, either in a social way or in a fetishistic way, or in a search for physical comfort. There also exists some transgender individuals who have both male and female characteristics (androgyny), in order to feel comfortable. There are marked differences between transvestites, androgyns, and non-operated transsexuals. The latter live their life in the opposite gender identity without undergoing the sexual operation. On the other end of the continuum are the operated transsexuals who can only live their gender identity by undergoing the sexual surgery.

Gender dimorphism exists when a person experiences too few specific traits of an individual similar to his sex or too many specific traits similar to the opposite sex. There is then a dissonance between the body and the sociocultural realities. This amounts to a disturbance in the gender evolution. Only a few cases of transsexualism are what we would call "primary," unaffected from birth by the parents or society. Most transsexuals are secondary, from the age of 4, according to Stoller. This would often have to do with the mother's regret in not having a child of the opposite sex. The mother is most often the one to trigger the transvestitism. Slowly, the personality structures and the behaviors become seriously affected. This is when the fantasy evolution leads to the surgery, following predetermined steps ruled by the psychiatric norms in France. It is not possible to set a standard procedure, because each case is different.

With the male-to-female transsexual, one needs to consider the emphasis put on the female attributes and the return to an archaic androgyny. The mother-son relationship excludes any sexuality, but includes an asexual intimacy. This explains the low level of heterosexual desire for some operated transsexuals. On the other hand, female transsexualism has different motivations for the daughter. It may be that the female-to-male transsexual considers the male role to be more glorious?

Transsexualism is, therefore, an experimentation of personal identity and of relational and sexual psychology.

### D. Psychosociology

In French society, the transsexual's request to be considered according to his psychological identity and his gender identity, is often considered foolish, since we categorize individuals according to their biological sex. For the transsexual, the individual's gender identity should be given more importance than the biological factors. His discourse resembles the violence he is ready to endure in order to be castrated and, therefore, become incapable of experiencing pleasure. He claims there is a dissonance between his body

and spirit. This raises the question of which should be given primacy: the anatomical sex or the gender identity. In the name of making men and women equal, can we transform a man into a woman and a woman into a man? Is sex a legal matter? In terms of achieving equality, do we give priority to sexual differentiation, or to gender differentiation?

In France, an estimated one in 5,000 is a transsexual. These numbers do not include the castrated and the eunuchs who have their own specific identity. The transsexual is totally convinced that he belongs to the opposite sex and not to his own sex. He or she asks for sex reassignment. There are other cases where people are uncomfortable with their social status and claim the social recognition of their psychosocial sex. In 1992, the European Court in Strasbourg said that it was an invasion of the private life to deny the right for sex change in civil matters. This modification of the sexes in civil matters has to be sorted out and evaluated by psychiatric expertise, which takes three years in France. The purpose is to establish whether it is a paranoid psychosis or a primary transsexualism. Statute law remains perverse, since it obliges a transsexual to undergo the sex surgery even if they do not want to have surgery in the first place. A transsexual does not need to be castrated to belong to the opposite sex; the clothing and the social appearance may satisfy their wish to be considered one of the opposite sex.

All this contributes to the emergence of a new conceptualization: the queers, the drags, and the transvestites are in a transhomosexuality, meaning that they go beyond global expressions of homosexuality. This new conceptualization avoids the bi-categorization, the dichotomizing, which leads to stress in many individuals who do not fit in. This is why it remains important to consider each case as different and deal with it according to its specificity. We should remember that etymologically, sex in Latin is *secare*, meaning "cut in two." This "sex-tion" pushes the individual to search for the other part of his missing "self." This search allows him to be in touch with his sex and the emergence of his desire in his quest for the other, for the encounter, and eventually, for the relationship.

## 8. Significant Unconventional Sexual Behaviors

FRANCE PARAMELLE

### Introduction

This section is a review of the different sexual infractions as described in the French criminal code.

France has experienced a significant increase in the charges of sexual assaults. Also, there has been an increase in the severity of the sentences that take into consideration the actual facts of the sexual assault reported, its circumstances, and the victim's state of being. There has also been an improvement for the victims of sexual crimes. Youths under the age of 18 are now protected by legislation, even within their family. Also, the rights of both men and women are given more consideration. The procedure of reporting and prosecuting is also facilitated by the sensitization of the police forces to the victims and the accusations made. Victims now play an active role throughout the whole procedure. If they wish to, they can assist in the whole procedure and make appeals concerning certain facts. They can also benefit from psychological support throughout the whole procedure. Indemnification funds have also been made available.

Even though all these measures may help the victims, the associations for victims' defense find these efforts insufficient. They state that most victims will not make accusations, in part because of all the media publicity around such cases, and also because they fear the offender will take re-

venge. Representatives of victims' support associations can attend the court with the victims if they wish to.

The court and jury are also preoccupied by the presumption of innocence. Because a person is considered innocent until proven guilty, the defense rights of the accused have also been amplified.

### A. Coercive Sex

Sexual aggression, in general, is defined in French law as every sexual attempt committed with the use of violence, force, threat, or surprise. French law makes a distinction between sexual aggressions with or without penetration. A second distinction is the adult or minor status of the victim. A subdistinction is made for a minor victim under age 18 and a minor under age 15, either of which is considered as an aggravating factor.

#### *Crimes Against Minors*

*Child Sexual Abuse.* The corruption or sexual abuse of a minor occurs when the minor is induced to participate in "obscene acts." This definition does not include the seduction of a minor for the adult's satisfaction.

Article 227-22 deals with corruption acts towards minors under 15 years old. Whether or not the youth was corrupted before does not affect or cancel the accusation. The perpetrator cannot evoke the unawareness of the victim's age, unless he demonstrates his non-responsibility for this mistake. This crime is not necessarily related to monetary issues; the matter is considered to be a crime whether or not money exchanged hands. Criminal intent is the criterion for this offense, as the following examples illustrate:

- A woman who commits obscene acts in front of a minor girl to introduce her into the prostitution milieu.
- An adult or many adults who engage in sexual activity in front of children in order to initiate them.

Whether this happened once or many times, this offense is punishable by a sentence of 5 years in jail and a 500,000-franc fine. The following aggravating circumstances lead to a 7-year jail sentence and a 700,000-franc fine:

- The author met his victim by telephone or the Internet.
- The crime was committed in an educational establishment or in its surroundings.

The corruption attempt is also punishable. The corruption offense is different from the crime of sexual aggression and from attempted sexual aggression.

*Pedophilic Pornography and Minors.* Article 227-23, adopted June 17, 1998, addresses the recording and transmission of pornographic images of a minor. The transmission can be done in a variety of ways. Importing or exporting such images is punishable in the same way as the actual production or transmission of pornographic images involving minors.

Normally, the penalty is a 3-year jail sentence and a 300,000-franc fine. The use of a telecommunication network used by the general population to transmit the juvenile pornographic images is an aggravating circumstance calling for a 5-year jail sentence and a 500,000-franc fine. Unfortunately, this does not prevent the transmission through videotapes or the Internet, which in terms of statistics, represent real traffic.

*Messages Not Permitted for Viewing by Minors.* Article 227-24 concerns the fabrication, transport, and transmission of a violent or pornographic message, which can lessen human dignity when viewed by a minor. The sentence is 3 years in jail and a 500,000-franc fine. An example of this offense would be posting a violent or pornographic message without any precaution to keep a minor from seeing it. The analysis

of the message and of its criminal character is judged by the court, which will apply the statute based on the mores and opinion of the time. Messages supporting sexual contacts between adults and minors are incriminating.

*Sexual Attempts on Minors.* This offense relates to the 1998 law and Article 227-25 of the criminal code. It applies to an adult who attempts to engage in sexual activity with a minor of 15 years old without the use of violence, force, threat, or surprise. The sentence is more severe than what it used to be. Currently, the penalty is a 5-year jail sentence and a 500,000-franc fine. This article also punishes any accomplice, including a person who introduces a minor to an adult perpetrator. Again, the unawareness of the victim's age is not excusable, unless the author demonstrates he is not responsible for this mistake.

Aggravating circumstances are detailed by Article 227-26 as follows:

- The perpetrator is a relative or an authority figure.
- The perpetrator abused authority given by his professional functions.
- The act was committed by a group of people, authors, and accomplices.
- The act involves a monetary payment, in which case the sentence is 10 years in jail and a 1,000,000-franc fine.
- The author met his victim by a telecommunication network for the general population (e.g., the Internet). The same aggravating sentence just mentioned applies here also.
- The same text of law is applied to minors of more than 15 years of age who are not married. The sentence is 2 years in jail and a 200,000-franc fine in the following cases:
  - The perpetrator is a relative or an authority figure.
  - The perpetrator abused the authority given by his professional functions.

The notion of authority is considered essential by the law and underlines the vulnerability of the victim.

#### *Sexual Aggression and Rape*

*Sexual Aggression Without Penetration.* Article 222-22 of the criminal code covers nonpenetrative sexual aggression. The law penalizes the aggression against another person and not the sexuality in itself. The facts represent a sexual action on a person, without her consent. The perpetrator can surprise his victim in order to have a sexual contact with her, without her consent and without penetration. This article also applies when committed by a French citizen in another country, according to a law enacted June 17, 1998.

The penalties for conviction are 15 years in jail plus a 500,000-franc fine. A more severe sentence can be imposed in the following circumstances:

- There were injuries or lesions.
- The perpetrator was a relative or an authority figure.
- The perpetrator abused the authority associated with his professional functions/status.
- The act was committed by a group of people, both leaders and accomplices.
- When a weapon or the threat of a weapon was used.
- When the victim met the perpetrator by a telecommunication network for the general population (e.g., the Internet).

These aggravating circumstances stipulated in the Article 222-28 call for a jail sentence of 7 years plus a 700,000-franc fine. The law also considers the vulnerability of the victim when the victim is under age 18 or under age 15. Vulnerability may also be a factor when the perpetrator knows or should suspect the victim's old age, obvious sickness, physical or psychological disabilities, infirmity, or preg-

nancy. In these circumstances, the sentence is also 7 years of jail and a 700,000-franc fine (Article 222-29).

Article 222-30 of the criminal code states a 10-year jail sentence and a 1,000,000-franc fine when the aggression is committed on victims described in the Article 222-28:

- Resulted in physical injuries or lesions.
- The perpetrator is a relative or an authority figure.
- The perpetrator abused of the authority given by his professional functions.
- The act was committed by a group of people: initiators and accomplices.
- When a weapon or the threat of a weapon was used.

The attempted sexual aggressions corresponding to Articles 222-27 to 222-30 are all sentenced the same.

Of interest for doctors, especially gynecologists, is a 1997 case in which a doctor was sentenced for having sexually caressed a female patient during a medical exam. The court stated that the accusation was true for two reasons: It was admitted by the doctor since he did not appeal, and the victim's friends testified they heard her scream "no" many times while they were in the waiting room. This example should lead doctors to adopt a rigorous code of ethics to prevent false accusations from being made.

### *Rape (Sexual Aggression with Penetration)*

The definition of rape, or sexual aggression with penetration (Article 222-2), is very important. Technically, this act involves any act of sexual penetration, of any nature, committed on another person with the use of violence, force, threat, or surprise. In the simplest terms, rape is any act of sexual penetration involving the vagina, mouth, or anus. "On another person" implies either a man or a woman. Oral penetration is considered a rape by the law, whether the person submitted or was forced to act. The act of penetration can be performed with the penis, the fingers, the tongue, or an object with a sexual connotation, for example, a vibrator or a stick, as long as it has a sexual connotation. For example, the statute law recognized as rape a penetration performed with a stick with a condom on its extremity. If the stick had been used alone, it would have been qualified as an act of torture or barbarism.

The absence of consent is essential. The following situations have been stated as non-consenting:

- The victim was paralyzed by fear and could not escape or run away.
- The mental state of the victim (depression) led to the same consequences.
- The victim was under the authority of the perpetrator, in a state of vulnerability.
- An employer was sentenced for having raped a female employee known as timid and inhibited.
- Another example would be the vulnerability of a patient facing her doctor, during a medical exam, or in relation to a nurse in a hospital.

The law also accepts the reality of marital rape, as long as it can be demonstrated that force and coercion were part of the act. For rape, the intention of the perpetrator is a crucial element. The accused can be acquitted if he has mistaken the victim's intentions. On the other hand, statute law recognizes paralyzing fear and neurotic state as possible reactions for the victim, which enable her to express her non-consent.

Attempted rape is also considered. An "attempt" is usually defined as the intending and trying to force someone into a sexual act or to assault someone in a sexual way. Article 121-5, states: "The attempt is considered as is when in the process of execution, an act was stopped or enabled because

of independent circumstances of its author." For example, an attempted rape exists when the perpetrator, after he had put on a condom, tried to penetrate his victim and only a momentary erectile deficit led him to give up on his project. The judges stated that the beginning of execution and the non-voluntary desistance justified an accusation of attempted rape.

The punishment for the rape crime is 30 years in jail when the victim dies following the aggression. Article 222-26: The rape crime brings a life sentence when torture or barbarian acts were committed before or during the rape. The torture and barbarism are defined as exceptionally severe acts, which led to severe suffering or pain. The acts also have a moral component: a wish to deny the human dignity within the victim. For example, the statute law named as barbarism forcing a victim to have penetration with a dog.

### **B. Prostitution, Pimping, and Procuring**

Prostitution, defined as having physical contacts to satisfy someone else's sexual needs in return for financial payment, is not a legal offense in France, but procuring for prostitution or benefiting from it is a crime. A prostitute is the only person who can benefit from her business transactions. She cannot use her earnings to purchase food or residence for her husband, children, or anyone beside herself. If she does, the beneficiaries of her trade can be prosecuted for procuring. Prostitutes are not allowed to solicit on a public highway. This tolerance accounts for many problems, such as the traffic of human beings, especially minors.

Article 225-5 deals with procuring or pimping (proxenetism). This applies to the action taken by anyone, in any way,

- To help, assist, or protect a person who is engaging in prostitution.
- To make money from the prostitution of a person, to share the benefits of it, or to receive subsidies from a person practicing prostitution.
- To hire, lead, or pressure a person to prostitute herself.

Proxenetism carries a sentence of 5 years in jail and a 1,000,000-franc fine.

Article 225-6 deals with proxenetism and designates similar punishments. It covers the action of anyone, in any way,

- Who panders between the person who prostitutes herself and the person who pays for the prostitution.
- Who helps to pander to justify fictive resources.
- Who is unable to justify resources concerning one's lifestyle, while living with a person who practices prostitution, or to be in relation with people living by prostitution.

This includes an unemployed married man who maintains his lifestyle with money his wife gets from prostituting herself. It also applies to someone who rents a room for someone who does prostitution or who acts as the pander, even if not paid.

Article 225-7: Conviction for proxenetism carries a sentence of 10 years in jail and a 10,000,000-franc fine when the criminal activity is committed:

1. With a minor.
2. With a particularly vulnerable person in terms of age, physical or psychological disabilities, sickness, infirmity, or pregnancy.
3. With many people.
4. With a person who was recruited for prostitution outside France or before her arrival to France.
5. By a relative or an authority figure of the person, or someone who abuses the authority given by his professional functions.
6. By a person whose mandate is to fight against prostitution, protect public health, or maintain public order.

7. By a person carrying a weapon.
8. By the use of force, violence, or physical injuries.
9. By many people acting as authors or accomplices, without being members of an organization.
10. By the transmission of messages through telecommunication networks used by the general population (e.g., the Internet).

Article 225-8: The penalties for proxenetism described in Article 225-7 above increases to 20 years in prison and a 20,000,000-franc fine when committed within an organization. Article 225-9: The proxenetism committed with torture or barbarism carries a life sentence and a 30,000,000-franc fine.

Article 225-10 provides a sentence of 10 years in jail and a 5,000,000-franc fine for a person who, directly or with the help of someone else:

1. Owns, manages, exploits, or finances an establishment for prostitution.
2. Owns, manages, exploits, or finances a public establishment, while accepting or tolerating one or many people to prostitute or search for clients within the establishment.
3. Sells or rents rooms not used by the general population, knowing they will serve for prostitution

Article 225-11 provides similar punishment for a person who attempts to commit crimes related to proxenetism. Article 225-12 states that moral persons can be found criminally responsible for offenses described in Articles 225-5 to 225-10.

The laws against proxenetism are severe and aim to fight the Mafia traffic quite common in France and its territories. In practical terms, the owner of residential apartments can be charged with proxenetism if he rents to people without knowing they will do prostitution, and does not report this activity to the police or take action to stop the criminal activities when he becomes aware of them.

### Conclusion

French legislation is concerned with the protection of minors, vulnerable persons, and the dignity of human beings. Laws are enacted to maintain public order and to protect the victims of pedophilia, pornography, and proxenetism. The fight against organizations behind these crimes is not easy and requires specific training of police forces and collaboration between different state agencies. Ignorance of the law is not an excuse in the eyes of the French law.

Article 122-1 mentions some causes for non-responsibility or diminished responsibility. The person who is affected by psychological or neuropsychological trouble, which would interfere with her judgment while engaged in a crime described in the above articles, is not criminally responsible. Such a person will still be sentenced, although her disability will be considered when the sentencing occurs.

For recidivists in sexual offenses, therapy can be suggested and will have a positive impact on the sentence. The psychiatrist can advise, but the accused remains free to accept or refuse the treatment. The psychiatrist will also judge the accused's responsibility in his actions.

### C. Pornography

[Update 2003: The legal age for viewing pornography in France is age 18. (Reekie 1994) (End of update by the Editors)]

### D. Exhibitionism and Sexual Harassment

#### Exhibitionism

Article 222-32 defines exhibitionism as the exposure of the sexual parts to a non-consenting person in a public place

or an area which can be seen by other people. Sexual acts can be committed in public and private places. An example of a public place would be a sauna accessible to all after payment of an entry fee. An example of a private place would be a hotel room where the door was not completely closed, but half-opened so anybody could come in.

#### Harcèlement (Sexual Harassment)

This law was enacted in 1998 and defines harassment of another person as ordering, threatening, forcing, or severely pressuring in order to obtain sexual gratification, by a person who abuses the authority given by his professional functions. Conviction carries a 1-year jail sentence and a 100,000-franc fine.

## 9. Contraception, Abortion, and Population Planning

### A. Contraception

[Update 2003: In 1993, France reduced the price of condoms to encourage young people to use them. More than two thirds of French women take the hormonal birth control pill. In 1996, the French Roman Catholic bishops broke with Vatican directives and approved the use of condoms to help reduce the spread of the HIV virus (Caron 1998). (End of update by the Editors)]

### B. Minors and the Availability of Free Morning-After Pills

[Update 2003: In November 2000, the French Parliament enacted a new law that allows school nurses to distribute the morning-after pill in junior and senior high schools. As of 2002, French pharmacists were authorized to provide teenage girls with RU-486 (mifepristone), the "morning-after contraception pill," free and without a prescription or parental authorization. In a decree published in the *Official Journal*, the government required that pharmacists speak briefly with the young women before giving them the pill to make sure they are using it correctly and in the right time frame. All girls under age 18 are eligible for the free pills. The pill is taken within 72 hours following intercourse and prevents pregnancy by blocking the implantation of a fertilized egg in the uterus. The government journal said pharmacists who distribute the pill should offer advice about regular birth control and encourage women to see a doctor regularly. (End of update by the Editors)]

### C. Abortion

[Update 2003: Abortion until the 10th week of pregnancy has been legal in France since 1979 and the cost of abortion is covered by national healthcare insurance. Parental consent is required for unmarried minors. In the early 1980s, Roussel Uclaf, a leading French pharmaceutical company, researched and marketed RU-486 (mifepristone), also known as "the morning-after pill." One in six of all abortions in France are performed with RU-486. Each year, more than 2,000 French women go to England for an abortion, many of them because they have passed the time limit for abortion in France (Henshaw 1996). (End of update by the Editors)]

## 10. Sexually Transmitted Diseases and HIV/AIDS

### A. Sexually Transmitted Diseases

No information given.

### B. HIV/AIDS

[Update 2002: UNAIDS Epidemiological Assessment: AIDS surveillance: A significant decline in AIDS-case incidence has been reported since 1996, primarily because of the

wide-scale introduction of HAART, the anti-viral cocktail. Since 1998, the decrease in new AIDS cases has continued, although at a slower rate, among homo-/bisexual men and injection drug users. However, the decrease is no longer apparent among cases attributed to heterosexual contact. The stability of the heterosexual group is explained by an increase of AIDS cases among foreigners, especially among persons coming from sub-Saharan African countries who relocate mostly in the Paris area. More than 75% of AIDS cases diagnosed actually could have possibly been delayed or prevented by testing or access to treatment for those aware of their HIV-positive serostatus. Persons infected by heterosexual contact are more represented among AIDS cases resulting from a lack of access to care, more than a third of them originating from sub-Saharan countries.

[HIV testing: A national HIV reporting system has not been set up in France yet. Despite a stabilization of the HIV-screening activity in free and anonymous testing sites since 1995, the number of HIV-positive diagnoses has increased since 1998 among men and women in Paris. This increase concerns especially persons originating from sub-Saharan countries infected by heterosexual contacts. Other indicators give evidence of a relapse in behaviors in recent years. An increase in gonorrhea has been observed since 1998 through a national laboratory surveillance network. The number of syphilis cases increased in 2000 in Paris among gay men, half of whom were HIV-positive. The results of the study carried out in 2000 in gay venues in Paris show a high level of risky behavior; 30% of respondents with casual partners had unprotected anal sex with them. Several nationwide surveys among injection drug users, including a study carried out in 1997 and 1999 in over 1,000 social and medical centers specializing in the care of injection drug users, consistently found levels of prevalence in the range of 15% to 20%. These surveys were based on self-reported HIV status.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	100,000 (rate: 0.3%)
Women ages 15-49:	27,000
Children ages 0-15:	1,000

[An estimated 800 adults and children died of AIDS during 2001.

[No estimate is available for the number of French children who had lost one or both parents to AIDS and were under age 15 at the end of 2001. (*End of update by the Editors*)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

ROBERT GELLMAN and CLAIRE GELLMAN-BARROUX

### A. Amourology Group Psychotherapy

SERGE GINGER and MICHEL MEIGNANT

#### Methodology

Amourology is meant to give support to individuals and couples who are searching for love and happiness. The main aim is to increase one's capacity for love, in order to reach a properly adequate level. It is a group process, with individual sessions in between the group sessions. There must be at least one individual session between every two group sessions, sometimes more, depending on the desire of the person, the clinical needs, or the hazards of life (a breakup, a death, an accident, or professional problems).

Amourology, according to Wolberg's definition, is: "a treatment in which emotional problems are dealt with thanks to psychological means. During this treatment, an experienced person has a professional relationship with a patient in order to suppress, change or diminish certain existing symp-

toms, alter disturbed behaviors; and encourage positive growth and the blossoming of personality."

A child naturally discovers the whole range of feelings in his family. Amourology incorporates this obvious aspect of the human condition into the context of group therapy, and thus offers many possibilities for experimentation.

#### The Psychotherapists

The therapeutic team is composed of:

- Two Amourologists. The referent psychotherapists are in charge of half the group, a male psychotherapist with male clients in the group, while the female therapist works with the female clients in the group.
- Two other Amourologists, who offer couple psychotherapy, run the couples groups and give personal sessions between the group sessions to people who come as a couple. Once a year, during the 9-day summer seminar, they run the practice of behaviorist exercises from the Masters and Johnson method. This practice is offered only to people who come for couple therapy.
- a person trained in the Milton Trager method.
- a psychotherapist specialized in creative methods. This practice is offered to individuals during the summer seminar, while couples are doing Masters and Johnson behavior-talk therapy.
- Trainee psychotherapists who come to work as assistants.

#### The Therapeutic Context

Each therapist (client) signs, before the therapists and the whole group, a contract by which he or she commits himself- or herself:

1. To participate in all the workshops programmed for the group:
  - Seven 24-hour weekends that take place in a venue equipped with a 32°C swimming pool for mind-body work.
  - Three 3-day groups: "Becoming a Man, Becoming a Woman, Becoming a Couple," during which couples work in a couples group and individuals work in a male or female unisex group.
  - A 3-day group for sexual education, with films from the National Sex Forum of San Francisco.
  - A 9-day seminar, which offers practice of the Masters and Johnson behavioral therapies for couples, creative and audiovisual work for individuals, and Trager Work for all.
  - A 6-day ecological workshop, experienced individually on one of two themes: "The humanist sea" and "The humanist island."
  - For couples only, on top of the individual ecological workshop, a 4-day workshop titled "The couple's humanist island."
  - A Christmas weekend retreat.
  - Two 8-hour groups of Trager Work, experienced individually.
2. To participate in evening workshops from 6:30 p.m. to 8 p.m. every week, if the clients live in the Paris area and can free themselves to come.
3. To have at least one individual session between each weekend workshop.

The clients or therapists also commit themselves:

- not to see each other or write to each other or phone each other in between workshops.
- not to have erotic games or sexual intercourse during the workshops.

- not to drink alcohol during the workshops, and not to smoke inside the rooms or on the boats.

The first two restrictions naturally do not apply to people who come for couple therapy. The length of the therapy is not predetermined. It can vary from a few weekends to several years.

### *The Therapists*

Currently, there are about 50 trained Amourology therapists, roughly about 25 male and 25 female. They are between ages 18 and 70, come from 15 different countries, and belong to various races and religions. Most of them are heterosexuals, but there are some homosexuals. More than half of the group consists of people who work as couple therapists.

### *The Therapeutic Methods Used*

Amourology uses a variety of therapeutic modalities:

- Sexologic.
- Behaviorist (Masters and Johnson method).
- Analytical, based on Jungian as well as Freudian concepts.
- Humanist (using concepts and practices that belong to humanistic psychology: gestalt, bioenergy, and koula)
- Mind-body therapy (the Milton Trager method, sensitive massage, and work in swimming pools).
- Music therapy, using operas by Mozart, but also by Rossini, Verdi, and Offenbach, and Celtic and other kinds of music.
- Self-fulfilling (dance, creativity, music, and singing).
- Audiovisual. Each year, the therapists see more than 20 feature films and around 10 short films. The therapists are filmed during the ecological workshops, while they explore the Ponant Islands (Hoëdic, Houat, Belle Ile en Mer, and Groix), the Bay of Quiberon, and the Gulf of Morbihan.

All workshops are residential: They take place either in a seminar center or on a camping site. A lot of the work is actually done during the breaks, the meals, and by the very fact of living together 24 hours a day during the ecological workshops.

### *The Trager Work*

In 1975 and 1978, a group of 50 French participants attended to training session in California that consisted of:

- a video-gestalt-therapy workshop with Barry Goodfield in San Francisco.
- a Sexual Attitude Restructuring (SAR) workshop at the National Sex Forum, San Francisco.
- a bioenergy workshop with Alan Schwartz or a gestalt workshop with Betty Fuller at the Esalen Institute, Big Sur.
- a sensitive Californian massage workshop and an erotic massage workshop with Margaret Elke in her La Fayette Institute.

During the 1978 workshop at the Esalen Institute, California, Betty Fuller introduced us to the Trager Work, a very specific massage that integrates transcendental meditation. The massage is not at all erotic; however, it does bring the therapist (client) to a delicious and tender regressive state. When practiced in a group, it is a gift to the giver as well as to the receiver. It is a way of differentiating need and desire. Eroticization is one of the major drawbacks of sensitive massage in the context of a group where sexual intercourse between the therapists is forbidden. The Trager Work is a solution for the eroticization-frustration dilemma.

After a 1979 meeting in Hawaii, Milton Trager accepted an invitation to give two training sessions in France. A few years ago, a Trager Work school was created in France.

### *The Amourology Workshop Cycle*

This therapeutic regime includes:

1. *Residential weekends for groups*: In the early years, the therapeutic process consisted of one marathon weekend of 24 hours each month, with nothing in between. These weekends, therefore, constituted the core of the work. During this weekend, we offer an experience in hot water, adapted from Big Sur in California, where the mind-body work takes place in the natural 40°C hot springs of the Indian tribe of Esalen. This work can be regressive, but is most of the time playful and based on tenderness and relaxation. There is no erotic induction. Music that supports emotions or encourages dancing is also used. A general feature film is used as a basis for analytical group psychotherapy, not to debate the film, but to become conscious of one's emotions and identifications in viewing it. Each participant studies his own reactions, compares them with others', especially with the reactions of participants of the other-sex participants.
- Now that other workshops have been incorporated in the process, there are only seven of these weekend workshops, evenly distributed throughout the year. They take place at a venue where we have a 32°C hot water swimming pool for the mind-body work and that is close to a cinema complex for showing films.
2. *"Becoming a Man, Becoming a Woman, Becoming a Couple" workshops*. In these 3-day workshops, offered three times a year, couples work in a couples group and individuals work in unisex groups of men or women. Everyone has the opportunity to experience the Trager method in a group. A feature film or a documentary is shown each night and used as a basis for therapy. Working in unisex groups gives the therapists the opportunity to express their feelings even more freely, without the fear of hurting or embarrassing someone.
3. *A Sexual Attitude Reassessment/Restructuring (SAR) workshop*. These 3-day sexual education workshops use films from the National Sex Forum of San Francisco, that are sexually explicit and educational but not pornographic. After seeing the film, there is a group discussion in which clients explore their emotional reactions and responses to the films.
4. *A July workshop*. This 9-day workshop enables participants to work with the Masters and Johnson method and with the Trager Work. Each night, a feature film is used as a basis for therapy work. It is the most powerful workshop in the process, mainly because of its length. Regression is more intense, and watching many films on the same topic reinforces the impact of the films. Sometimes films by Marcel Pagnol or Ingmar Bergman, and operas by Mozart, Verdi, or Rossini are used in the visual mix.
5. *A 4-day individual workshop* designed for individuals who choose to do both "the humanist sea" and "the humanist island" experiences.
6. *The Christmas workshop*, just before the New Year, involves working on giving with a spiritual therapeutic experience, a Celtic music concert, a conference on Buddhism, a meeting with a Tibetan monk, and a Christmas liturgy with a Dominican monk. Each participant has the opportunity to express his beliefs. This workshop takes the form of a party, and people can share their culinary skills cooking for a 'Christmas eve' supper.

7. *Evening workshops* are offered for therapists who live in the Paris area. The workshop consists of a group talk preceded by 20 minutes of listening to Mozart.
8. *Individual and couple sessions* in between groups consist of face-to-face talk without mind/body work:
  - at least one individual session with the referent Amourologist between two workshops. Often the therapists choose to have a weekly session.
  - each couple has at least one meeting with the couple Amourologists between the big groups they attend together.

*The Humanist Sea* was the first ecological workshop we created, but clients have the option between sailing and the "Humanist Island" experience, which takes place on Hoëdic Island, in Brittany, off the northwest coast of France. The Humanist Sea actively brings nature into the therapeutic process. In the past 20 years, we have offered the sea experience 36 times. Absolute priority is given to safety, with professional staff from the Cruising Training Centre (CFC) based in La Trinité-sur-Mer (Morbihan).

The workshop lasts for 6 days, during which the therapists sleep and eat on board the ships. They form teams of 5 to 8 people, according to the size of the boat. A skipper chosen among the therapists is in charge of each boat and all therapists have their functions. The rocking of the sea invites deep sleep and is favorable to dreaming. The therapist writes down his dreams in a personal notebook for later discussion and analysis.

Specific rules and safeguards have been developed to protect and enhance the therapeutic process.

- The therapists never sail in the same boat as the therapists (clients).
- The sailing instructors have as little contact as possible with the therapists. They only see each other for the sailing lessons and when boats are under sail. We ask the instructors to stay away from the therapists during free time and meals or evenings. The instructors live on the staff boat, with the therapists.
- During times in port, the therapists themselves try to put some distance between them and the instructors. This is done by sleeping on shore as often as possible and by avoiding dining with the instructors. This ensures that each person's specific professional attributes and identity remain clear.
- The analytical work is done in small discussion groups. For example, if the fleet is composed of four boats hosting five therapists each, two small groups of 10 are created and they meet in one of the boats under the supervision of one psychotherapist. This short working time is sufficient. It can be used to do analytical group therapy, or to work on life on board. It might deal with relational problems that have emerged because of living together, or it could be about maneuvers necessary to navigation.
- During the cruises, each therapist has a notebook that provides a double record of dreams and impressions. The therapist keeps the original and gives the copy to the psychotherapist, who can then follow the therapeutic process of each person.

The sun, the sea, the rain, the swell, the beauty of the landscapes, the call of the birds, meeting dolphins, the friendship, all this creates the context for an unforgettable psychological and therapeutic experience.

*The Humanist Island.* This workshop takes place on a small Ponant Island, the Island of Hoëdic (which means duckling in Breton). It is two and half kilometers (1.55 mi.) long and one kilometer (0.62 mi.) wide. There are about 100 inhabit-

ants. The workshop lasts 6 days, including the 8-hour travel from Paris. Hoëdic is a bit like the end of the world. The therapists' camp has *gîtes* (simple shelters) in which to cook, wash, and get warm if the weather is bad. The sea is always present, in the minds as well as in the activities. The therapists are in small groups with a leader and someone responsible for supplies in each *gîte*. Those who do not want to camp out can have a bed in a room of a *gîte*.

### Conclusion

Amourology is one of several therapeutic modalities born on the American continent after World War II. At first, these methods seemed to question the principles of psychoanalysis, but in fact they use some of its tools. The therapists who practice these new methods have themselves undergone an analysis. Their practice was then transformed, through their personal work and through training. Just as doctors who practiced in Africa noticed that they had better results if they mixed traditional methods with European medicine, some psychotherapists have noticed that they had better results if they mixed a psychoanalytic approach with mind-body therapy and behaviorist methods.

### B. Couple Therapy

PIERRE DALENS

Can therapists establish a relation between the notions of desire, pleasure, and love, what makes the love relationship possible within a couple, and what is its evolution in time?

The beginning of a relationship is often characterized by passion, through affective, emotional, and sexual components, which define an "unconscious couple." On the contrary, when the evolution of the couple results in a love relationship, a certain stability can be achieved, with less idealization, but with more durability and social adaptation.

We have to admit that the search for passion is very tempting, compared to the love relationship, which is a more-grounded notion.

We believe that the dysfunctional couple should not be considered as having a marital sickness, which needs to be cured because of physiopathological dysfunctions. Rather they should be viewed in the context of *Relational Eros*, an in-between of the honeymoon, which characterizes passion, and the maturation of an "unconscious couple."

Sexuality can only be integrated through the symbolic acceptance of what pushes a person towards another person, and where the affective, emotional, and sexual components define what will lead to a love relationship, a long-term stabilization.

The body-mind approach is well suited to understand these two relational levels. The psychological-sexological-somatotherapeutic analysis looks at the individual and relational dynamics and the way the emotions and affects are symbolized in the interrelations. The sexological-psychotherapeutic consequences will show in terms of relational dysfunctions and individual *sexoses*.

The goal of group sexotherapies is to establish a new body sensuality through the energetic approach and role play, the neo-Reichian and Gestalt techniques. This will allow the patients to integrate love better in their lives and feel even more alive.

In sexual dysfunctions, the sexual desire is often repressed, either by a denial of any erotic manifestation, by an indifference towards sexuality, or by an inhibited sexuality. On the opposite side, the loving state of being will lead the individual into a search for pleasure and exchange.

The genuineness of the pleasure leads to a real delight, in relation with the individual structure and the integration within the existential life, what G. Abraham called the *sensitive metabolism*, compared to the *fantasmatic metabolism*. The sensitive metabolism can be defined as the search

for an experimentation of the sensation, which correlates the imaginary, the mental representations, and the dreams. The fantasmatic metabolism will mostly consider the imaginary. We are often preoccupied by the lack of sexual desire, called "*erotic aphasia*" by G. Abraham.

We would like to emphasize the problems of communication within the couple. When the love is still fixated at a sadistic-anal stage, it is characterized by possession and impulsiveness. On the contrary, a mature eroticism could relate the desire to the expression of feelings and affects.

Sexual dysfunctions, called sexoses, are considered as an imbalance within the symbolic and imaginary, emotional and pulsional functions. But the couple often puts into play the interaction between the neurotic aspects of the individuals and the repression of pregenital systems. (*Pregenital systems* here refers to the early embryonic "androgynous" stage lasting about 6 to 8 weeks from conception to development of the male and female genitals.) When there are dysfunctions and incompatibilities within the individuals, we can often observe problems in terms of communication, power and control issues, emotional dependency, and stress—and most often in terms of erotic and sexual disagreements within young couples. The marital relationship will be considered as having a durability over time, but also as having a confrontation through exchanges. The search for long-term durability will involve the search for the expression of sexual desire and pleasure through an erotic and passionate exchange.

If we use a *biological* metaphor, it is the indication of different modalities succeeding one another in sensation and sensuality, just as fantasies will coincide with a shared desire. Even if we often use technical and logical approaches to deal with couple difficulties, we will here emphasize the role played by individual structures.

### *The Individual Structures*

Prior to committing to a couple relationship, each individual had developed his own personal history and traumas. Each partner has a basic structure with which the other person will be confronted. Different typologies were created to explain these structures of character. We will consider two, the first one being the *bioenergetic structure of Lowen*, and the second being the *primary and secondary notions, as well as the introversion and extraversion notions of C. G. Jung*. The partners might experience more or less difficulties in accommodating these structures.

The structures of character as defined by A. Lowen consider the impact of the personal history, the couple entity, and the environmental influences on each other. They also study the impact of the lack of affection in the first months of a person's life on his psychosexual development. We associate the different neo-Reichian steps of Lowen, such as schizoid, oral, psychopathic, masochistic, and rigid, to the couple structure through the energetic unification and affective maturation of partners in marital relationship.

### *Biopsychological Theory*

The notion of marking by Konrad Lorenz defines the importance of the early relational programming. The initial marking is biologically understood as the cerebral sex, induced by cerebral sexual hormones and cerebral chemical mediators in the first weeks of the fetal life, combined with maternal stimuli. This neurobiological determinism can be reinforced later on a psychosociological level through the notions of gender identity and role identity. The notion of archaic psychological inscription refers to the individual mark in the couple as a mutual modeling of two identical marks.

Partners are brought together because of this first original inscription in the body. In the dyadic relationship, there

would be two identical marks, but with different mind-body components. We then come up with a crossed identification of a unique bi-sexed being. This neurobiological mark retrieved in the couple brings up the understanding that a part of my own neuropsychological equipment is also in the other person. In the bi-sexed being that we are, it is the lost part of the androgyn we look for in the partner. We can therefore consider the romantic encounter as the start for this twin bonding. The couple becomes the ground for all the future symbolic projections.

### *Psychoanalytic Theory*

This therapeutic modality emphasizes the choice of the total object from the choice of the partial object. The unconscious initial choice of the partner and later on, the development of the couple dynamic, will create the internal structure of the couple based on the interactions between the ego and the unconscious of each partner.

The selection of the partner is based on the choice of sexual impulses as part of vital functions or on the choice of the narcissistic object, a search for the ideal ego. The emotional security, influenced by parental images or pregenital impulses, is very important in the establishment of the marital structure. Through crises, the couple will be confronted by the gap between desires and reality; the partners will have to resign themselves to accepting the distance between them and the reemerging of the repressed.

The crisis will happen when the subject expectations confront the object desires. The cultural and social background might add to the crisis, although this crisis can lead the couple to restructure their relationship, as long as each partner has a solid ego to facilitate autonomy for both partners.

The narcissistic partner can project his own desires on the other person, blocking the other person's impulses. This partner is actually searching for a bonding resembling the one he used to have with his mother as a child-mother relationship. The world of the castration and the oedipe is confronted by the symbolic and imaginary sublimation of the absorbing relationship with the partner. There appears a transitional period where the self does not exist, and the androgynic reunion will only become possible through orgasm.

When the intimacy becomes too intense, there is a need for distancing in the couple. This will modify their unit dynamic and preserve the self of each individual.

All the archaic desires will need to be expressed in the couple dynamic: *the oedipal desire* by assimilation of the partner as a parental figure, *the latent homosexual impulses* in the couple, and *the bisexuality concept* by a better understanding of the male and female polarities in each partner.

The pregenital stages in the psychosexual development are often expressed in the foreplay, such as in sadomasochistic, voyeuristic, and exhibitionist plays. These impulses can be definitively repressed or be expressed in fantasies; this repression is necessary to the stabilization of the couple union. The partners will be confronted to the idealization of the other and to the creation of an intimacy not available to the external world, as well as other possibilities for the couple and the partners to enter in relation with the external world.

### *Homeostatic Relations Within the Couple*

The choice of the partner is influenced by the value we put into love and its relation to the individual unconscious and to the social and cultural conditions. From the start, the couple will be faced with (confronted by) socioeconomic norms imposed by the social group.

The couple can serve as a refuge by overcompensating affective and emotional lacks of the individuals and be the

center of communication and exchange. Fidelity and autonomy are components of a non-official contract about a physical and impulsive sexuality, as well as a fleshly and spiritual love.

The couple can be formed where the economic function and familial projects meet. It cannot be based on passion, since passion is of short duration. It is only after the passion is over that the partners can consider their capacity to form a couple together. The bond will be established with a narcissistic comfort and an erotic satisfaction. When two people form a couple, they can live their archaic issues through the other person with a certain distance of the self, allowing autonomy rather than isolation. The collusion of the partners gives an image of “couple personae” to the external world, while the shadow of this same couple lies within the marital desire.

All these structural and energetic factors within the dyadic communication make a certain “marital contract” possible, and even before, a “corporal contract.” In the Middle Ages, this kind of contract existed between spouses, implying a certain debt in the sexual life of the couple.

### *Marital Eroticism*

Marital eroticism refers to nudity and the body relations. To be satisfying, the relationship has to integrate the physical and emotional sensations to lead to arousal, sensuality, and affective exchange. Marital eroticism puts the partners in contact with all the pleasurable body sensations from past experiences. All this exploration will bring more satisfaction within the couple sexuality, since the sexual exchange is not reduced to sexual intercourse. The beauty of the body will also play a role in seduction, which will bring a certain liberation of the body and a liberation of the mind within the couple relationship.

The marital contract implies pleasurable notions as well as a sexual responsibility. Here, sexual fidelity and extramarital affairs, both extremes of the same pole, have to be negotiated by the couple. The marital relationship involves a total commitment and an agreement on rules for both partners; on the other hand, extramarital affairs can also serve as an escape from responsibility of this same commitment. The corporal contract refers to a commitment to pleasure, within the couple, on affective and erotic aspects. When the couple has trouble exploring its sexual intimacy in different ways, it is a symptom that both individuals are incapable of facing the other person's needs.

The notion of commitment is a challenge to the value of liberty: How can we manage to introduce other people completely and significantly into our relationship? The answer will depend on the couple's maturity and on the corporal contract. The commitment will therefore clarify the notions of liberty, the allowed sexual liberation, with the feelings of jealousy and possession. In this context, researchers need to further explore the relationship between the need for emotional security and the sexual intimacy.

### *Marital Conflict and Extramarital Sex*

These can be understood in different ways. There are different aspects that have an impact on both the sexual and the sociocultural plan. Marital dysfunction will lead to sabotaging behaviors on different levels—sexual, affective, and relational—with the final consequence being an imbalance between the partners' desire.

The sociocultural level will condition competitive social structures in a narcissistic society where the most concrete consequences can be seen in the vicious cycle of “marital sickness,” through manifestation of infidelity and jealousy. The nature of the extramarital affair can be based on

the affinities two people share and their reciprocal identification. The affair can be seen as a complement to the marriage, but most often, it will lead to divorce.

The partner may admit having an affair without realizing it, but unconsciously pressured by guilty feelings. This can allow the couple to look for the deep causes and eventually find a compromise. There are many couple problems nowadays, but extreme jealousy can be found because of resentment towards the partner, needs for possession, and narcissistic devaluation of self-worth. This is the oedipal pathology to the extreme.

It is often one of the partners, usually the most suffering or the most demanding, who asks for help, either to do couple therapy with the partner or to deal alone with the couple difficulties. These therapies usually involve communication problems, and affective or sexual difficulties. Often, these requests are made too late, which makes results difficult to obtain.

For the last 20 years, we have offered groups for couples in a body-mind approach with the use of different body and psychological techniques to help the development of body energy, a body re-sensitization, a corporal and affective exchange through role play, neo-Reichian techniques, the emotional gestalt, and with the psychodrama, in the *psychosomatodrama* of W. Zaruchas. These groups for couples use both verbal and corporal analysis, suggesting an individual therapy as a complementary between the monthly group sessions. The evolution of couples is generally positive.

Masters and Johnson created co-therapy for couples, with two therapists, a man and a woman, as the “model couple.” In France, only Robert and Claire Gellman from Paris still apply this type of analytical couple therapy.

The nature and function of sexuality make us wonder about the affective components of sexuality: Is the sexual union an exclusive and necessary condition? The answer would vary depending on the point of view, whether it is more traditional or liberal. It appears necessary that each partner keeps an intimate time for himself without feeling guilty; this rule should apply to both partners and be respected.

### *A Clinical Example*

In order to illustrate the different theoretical approaches discussed earlier, we will present the case of “Diane.”

Her husband works in computers, she has two children. She lives in a beautiful property in the country and works in a laboratory. She wants to take better care of herself and express herself freely, give up her artificial role of entertainer, and stop living in someone else's shadow. This was her initial request for help.

Diane felt she was getting protection from her husband and intellectual challenge from her lover. After a couple of sessions, she admits having difficulty sexually initiating with her husband and being fulfilled with her lover because of the loving friendship they were living together. She decides to commit to an analytical psychotherapy in addition to a somatotherapeutic group.

She suffers from the lack of emotional expression in this stable and grounded family. Her husband represents an important “social personae.” She complains about not receiving any tenderness outside the genital sexuality. She handles with difficulty the passive role her husband plays in their marriage, whereas he takes on such an active role outside their marriage. She realized they had made the agreement that she was “the chief” in the family. Because her behavior does not reflect her existential wishes in life, she wonders how she and her lover can live their love together.

Frustrated by the lack of affection, she looks for a different love, a manifestation of her oral impulses. Her bipolar

ity is expressed in her activity and feelings through archaic impulses on one side and an external and conscious masculine position on the other side. She is balanced between her fear of being abandoned and not being protected anymore, and her need for liberty and autonomy, which she prioritized over her fears. She feels the precariousness of her relationship with her lover, especially concerning the wife, who considers Diane as a friend and confidante, a strong and dynamic woman she has admiration for. Diane feels stuck between her lover, Robert, and his wife. She thus starts feeling guilty. She gets the impression of still waiting for something, which will not happen, just like she used to do in her childhood. She progressively loses interest for the lover and the couple, which allows her to get more autonomy. She meets a new friend from a different background who deals with things simply and naturally, and who does not make her feel inferior.

She leaves her husband, sells the property, and asks for a divorce, which she associates with her liberty. On the other hand, she is insecure about her new life, but feels a strong need to build a new existence. At first, she has difficulty to balance herself in the new couple between her fear of abandonment and the happiness she cannot find.

Through the relational exchange Diane experienced, she was dissatisfied both ways, with her husband being unable to fulfill her affective needs, since he prioritized the financial security, and her lover being unable to fulfill her erotic needs, since he prioritized the intellectual part.

The therapy made Diane realize all the lacks of affection she suffered in the past and the essential role they will play in her new relationship. This search for marital happiness will end with a stabilization of the couple in time, all initiated by Diane.

### Conclusion

The search for love and happiness implies a rediscovery of our archaic desires and our individuality, since joy is something we have little control over. Therefore, we find ourselves facing a hidden reality. The *love history* leads us through a transformation process, which will never end—a wisdom of the soul impossible to attain. It is an affective ritual of exchange through a symbolic operation to recreate *the mystic androgyny*. It is the energy behind this image that makes the external reality concrete.

### C. Therapeutic Model for Gender and Orientation Difficulties LAURENT MALTERRE

All human problems can be summarized as the attempt to reunify opposites. We can assume that most people go through this resolution of opposites in sexuality first, since it is probably the most extensive ground for polarities. It is the principal source of conflicts and a place for reunification of opposites, while allowing for all kinds of male and female expressions. While their interdependency is obvious, this does not mean that its resolution will be achieved necessarily through orgasm, but more through a search for a whole identity.

These polarities can be expressed through different forms, such as bisexuality, real or repressed homosexuality, or a desire for sex change often expressed through transvestism, or erotic interest in the breast or the anus. For others, this uncertainty between the two polarities will be expressed through sexual orientation problems.

#### Objective

What kind of therapy can we offer to patients who suffer from sexual orientation and gender-identity problems? How do we help an individual to integrate a stable image of himself when all he sees is a fragmented, complex, and imprecise

image. This calls for an ongoing evolutionary process through individual and group therapy with experimentation, understanding, and integration of fundamental steps, such as the androgyny, the psychological bipolarities, anima and animus, which synthesis is the love dimension.

#### The Methodology

The individual and group therapies use approaches referring to diverse disciplines: analytic, somatotherapeutic, and sexologic. For each discipline, different authors are recognized as pioneers: Freud, Jung, and Lacan for the analytic approach, Masters and Johnson, Stoller, and Crepault for the sexologic approach, and Lowen, Reich, and Singer for the body-mind approach. All these approaches are used to form the whole therapy we offer:

- The somatotherapy and gestalt therapy work on the energy, the body sensations, the emotions, the affects, and the relations. They aim at repairing the affective lacks and traumas, to empower the individual in his expression of affects in the here and now, and to pass from a closed attitude to a relational opening.
- The bioenergy works through the analysis of body and character rigidity. Once the person learns to focus on her- or himself and to be in relation with others, she or he will become familiar with her or his emotions and sensations and be more in contact with both his or her body and pleasure.
- Sexoanalysis will study the orientation and identity difficulties through the analysis of the erotic imagery. The person develops capacities to symbolize and better integrate their erotic imagery and unconscious image of her or his body.
- Psychoanalysis will deal with the unconscious, the psychological functioning, the symbolism, the dreams, and archetypes. Words will serve to verbalize the sexual history and the affects and emotions related, in order to have a better understanding of the self.

This therapeutic framework allows for both the affective intimacy through role play, body contacts, relational touching, and the psychological intimacy through active listening of the partner's history, one's emotions and feelings, and the mental representations of the actual exchanges.

The goal of these therapies, whether they are done in individual or in group, is to facilitate the improvements and the reinvestment in one's existence: *How to be in contact with the self, the experiences, the sensations, and the emotions, to feel as a man or a woman, and to be in relationship with the partner without losing one's identity?*

These therapies aim at progressively reconstructing the imprecise or fragmented identity, the emotions, the affects, and the symbolization. This search for identity will lead the individual to transform his relationship and his perception of himself through the exploration of his internal representations of what it is to be a male or a female or an androgyn. This process is what the human being usually goes through in his psychosexual development. It will help the individual to gain a more realistic image of himself, a new identity, and eventually, a new way of loving.

A caring and secure environment will facilitate the emerging of real or latent homosexuality, bisexuality, or ambisexuality through transvestism and transgenderism.

#### The Androgyny

The androgyny is opposed to the genital, and fights against the sex differences. It is oriented towards a narcissistic completion and a symmetrical illusion. It means to have both sexes. Plato defines the androgyn as being neither

father, mother, man, or woman. It is all at the same time. It is a denial of differences and opposites.

The transsexual is considered the modern face of androgyny. He defends himself against the sex differences by disinvesting his own sex. In doing this, he tries to reunify the opposites by abolishing the duality between sexes. In being asexual, he avoids being confronted by the dual experience, that of being a man or a woman.

The bisexuals and transhomosexuals also go through a gender variability just living as transvestites, drags and queers, named trangenders. They often experience relational failures when facing the illusion they can reunify with their opposite.

In therapy, we work on the androgyny by:

- The integration of the body image, the body being often considered as asexual, in-between, or immature. All this variation in degrees between the male and the female poles can be seen through the gender dysphoria, the disgust of the body, the narcissistic fragility, and the desire to cross-dress. Each individual will identify his male and female components and look for his secret sexual identities. The therapist will help his patient to feel more grounded in order to reunify all his different components.
- Exploring this symmetrical view of a double of the self, referred to as homosexuality. The individual will learn to invest both an identical and different vision of the other. This way, the individual is able to recognize his own limits regarding his ideal self. It shows that the partner heals the feeling of emptiness by providing a feeling of continuity. Here, homosexuality and bisexuality tendencies may appear.

### *Male and Female Polarities*

Identity and sexual orientation develop through identification processes with male and female components.

In order to feel at peace with one's identity, the individual has to find the equilibrium between the male and the female poles. This is very difficult to achieve nowadays, since the female entity is seen as the total antagonist to the male entity. All the male qualities are developed and privileged over female qualities, which is a real disaster!

In summary, as a society, we need to get rid of the phallogocentrism, by giving the repressed female entity all the importance she deserves. It is a long road for both men and women. The man overemphasizes his male traits through macho and misogynist attitudes, as well as patriarchal structures. The female part of the woman is treated as being inferior, responsible for all sins. There has to be a serious awareness that the female component is an essential psychological reality. The male and the female components should work in harmony to contribute to the unification of the individual with himself. We need to get rid of all the male and female stereotypes in order to consider the resemblance between the sexes as a common psychological bisexuality.

The man can see the female entity through the anima. Some well-known models can portray this image, such as Eve, Sofia, Penelope, Marie, the Amazon, the Mother, Diane, the muses, and the fays. There also exist negative images, such as the prostitute, the witch, the employer, or the son's lovers. In these situations, the men are no longer in contact with their female entity, their Jungian anima. They are completely cut off emotionally and intuitively. They are those "rough" men, who degrade as soon as there is no maternal or female presence around. They are those no-land men, with no ambition, the criminals. They can remain close to their animal impulses and block any expres-

sion of tenderness. They collect women to avoid being intimate with only one.

The male entity in the woman can be seen in the Jungian animus. These images can appear in dreams and through body expression. Often, the first animus images are quite negative. They refer to captured animals, criminals, and truckers. In these situations, their animus is opposing the man. When the images are ones of fragility, vulnerability, or castration, women cut themselves off from their sensitivity, and their female entity gets disguised in men caricatures. These women want to be in the head office. Fortunately, images change to become more positive animus, such as Tarzan, the knight, the teacher, the wise man. All these images are a reflection of a man being in contact with his female entity: his eroticism, his romanticism, his mental, and his spirituality. They also reflect women whose animus communicates openly and tenderly with the man's anima. The relationship is more human.

Each individual carries Eros, scars which are opened when a new partner arrives. The individual will have to re-establish the dialogue with Eros in order to overcome:

- What separates the man from his female entity and the woman from her male entity?
- Can the man accept that he will never be his female entity, and can the woman accept she will never be her male entity?
- Nowadays, on which figures do we project the female entity in the man and the male entity in the woman?

These questions about the female entity within the man and the male entity within the woman lead us to consider the question of entity as a whole. In fact, when the individual gets closer to his other half, does the relationship become stronger, deeper, and more human or, on the contrary, more destabilizing and fragmented?

We have to be aware of these male and female archetypes in order to integrate them into the psyche. The male and female entity within each individual can fluctuate over time, and be variable and varied in terms of proportions. The final result will be, according to Jung, "a union without fusion between the anima and the animus in the living individual."

The therapies provided allow the participants for the first time to put into play their male and female polarities, especially through psychodrama. It brings the individual through a scenario asking for different language, behaviors, and attitudes, to play fantasies, or situations related to homosexuality, bisexuality, androgyny, or transvestism.

These therapies also allow for an exploration of the body dynamic, the imaginary, and the balance between the male and female polarities, in order to come to terms with a unified identity. The opposite sides of gender identity, their complementarity, and variability will be explored.

On another level, the transvestite will experience his capacity to fit in the opposite-sex entity. He projects himself in the image he has of the opposite sex. Each individual will name his new personae, changing his attitude and his body movement in order to be in relation with someone who has opposite or complementary polarities.

Through his behavior, the transvestite will be able to explore:

- The variability in male and female polarities.
- The similarities and differences between the imaginary body and the real body.
- The way others perceive him, where feelings of attraction, repulsion, and fear can be experienced.
- The possibility to imagine, for women, they have a penis and, for men, they have a breast.

- The emerging of new and different sensations, through the investment of the opposite-sex body, the transvestite can be in contact with other secret identities.
- The role of one's sexual fantasies at a conscious and pre-conscious level in his relationships.
- One's place on the sexual continuum (heterosexual, bisexual, transhomosexual, asexual).

It is a deep transformation within, where the esthetical appearance is not a finality. While working on one's mental representations of what is male and female, the individual can recognize his or her own identity value. At first, the body image is fragile, imprecise, and becomes strong, powerful, assertive, seductive, erotic, and a new self, an erotic self. It is the search for the erotic self in homosexuality and transgenderism, which explains a loss of the self.

#### *Synthesis of Polarities: The Road to Love*

This imaginary relation will allow the individual to develop a strong self-image, to repair his identity uncertainties, and to experience the emerging of desire. Relational difficulties will perpetuate themselves as long as the individual will not come to peace with his identity and orientation. Self-growth then becomes impossible. The relationship will make the individual aware of the partner's limits and his own limits, especially through sexual intercourse. In experiencing relational, emotional, and affective situations, both partners will learn to meet their own needs, while considering the ones of the partner, to achieve a certain harmony in their capacity to love and be loved.

The emphasis will be on the exploration of fusion, separation, and resolution experiences. Exercises on projection of aggressiveness, on domination, submission, and independent relations, will clarify the relational dynamic. Triangulation with a rival, and the jealousy and possessiveness it involves, refers to the unresolved oedipal triangulation.

#### *Conclusion*

Between the group therapy sessions, we have to emphasize that the patient will work on his personal dynamics in individual therapy. All the emotions experienced in the group sessions will be explored in individual sessions.

The multiplicity of factors in homosexuality and transgenderism are considered in the individual and group therapies. Bisexuality, next to heterosexuality, comes to terms with a whole structured identity. All the other sexual problems, such as lack of desire, erectile dysfunctions, sexual addictions, love disorders, and marital conflicts, can also be resolved through a similar work than the orientation problems, meaning an exploration of the female and male internal representations and of the androgyny. Each individual will construct his own realistic image of himself.

As Freud said in *The Schreber President*: "All human beings balance between heterosexual and homosexual feelings; a deception or a privation on one side has the individual balance on the other side."

#### **D. Therapist Training & Certification**

ROBERT GELLMAN and CLAIRE GELLMAN-BARROUX

The medical universities and nonprofit organizations specialized in teaching and ongoing education are responsible for therapist training and certification. The first sexology training in France was created in 1974 at the Necker Hospital in Paris. The French School of Sexology is partly responsible for the creation of the University Teaching at the René Descartes-Paris V University.

There are other sexology certification and training in the most important universities in France. They offer diplomas of Sexology Practitioners to doctors, and sometimes to psy-

chologists having a DESS in Clinical Psychology. Under the same conditions, diplomas in sexology can also be earned by paramedical workers (nurses, social helpers, kinesiotherapists, marriage counselors, educators, etc.).

[*Comment 2003*: Recently, a distinction has been proposed between medical doctors, physicians, "sexologists," and "sexotherapists," which include non-medical specialists who are psychotherapists, psychologists, marriage counselors, social workers, nurses, midwives, and so on. Professional training is available in several universities in Bobigny, Toulouse, Nantes, and Paris, as well as in private associations, such as SFSC and the Gestalt Institut de Neuilly.]

[Most of the practitioners incorporate biomedical or endocrinology interventions, behavioral therapies, studies of profound psychological problems, both intra- and interpsychic, as well as relationship-oriented problems of the couple. A particular variety of Sexotherapy is represented by the work with couples, notably within Gestalt Therapy (Anne and Serge Ginger, Charles Gellman, and Martine Masson). In order to emphasize the important role of the emotional and relational dimension within Humanistic Sexology, Meignant has proposed the term "*Amourologie*" (*End of comment by S. Ginger and M. Meignant*)]

### *Demographics and a Brief Historical Perspective*

ROBERT T. FRANCOEUR

#### A. Demographics

French Polynesia encompasses five administrative areas representing five archipelagos with 130 islands and atolls in the South Pacific, approximately 5,000 miles (8,050 km) east of Australia. The Society Islands, the Gambier Islands, the Austral Islands, and the Marquesas are primarily volcanic islands, while the majority of the Tuamotu Islands are atolls. Oceania is divided into three broad cultural groupings, with Melanesia and Micronesia to the west and Polynesia to the east. French Polynesia as a political entity is situated within the indigenous culture area of Polynesia, which includes all the islands in a "triangle" stretching from Easter Island in the east to the Hawaiian Islands in the north and New Zealand in the southwest. It incorporates diverse societies of Polynesian peoples colonized by the French and declared a French Protectorate in 1842 (Stanley 1992). In 1957, this area became officially known as *Polynésie Française*. It is important to note that French Polynesia is not an indigenous or cultural subdivision, but is rather a modern neocolonial political subdivision.

The Society Islands consist of 14 atolls and volcanic islands and include the Windward Islands of Tahiti (1988 population 131,309), Moorea (population 8,801), Maiao, Tetiaroa, and Mehetia; and the Leeward Islands of Huahine (4,479), Raiatea (8,560), Tahaa (4,005), Bora Bora (4,225), Maupiti (96), Tubai, Maupihaa/Mopelia, Manuae/Scilly, and Motu One/Bellingshausen. Tahiti has a mountainous interior surrounded by a fertile coastline where cane and coconut are grown. Over half of the indigenous French Polynesians live on the island of Tahiti, along with French, Chinese, and genetic intermixtures of these groups.

The Marquesas Islands, popularized by Melville in *Typee*, consist of 11 islands, six of which are inhabited (1988 population 7,358). Gauguin is buried on Hiva Oa, the

(CIA 2002)

most populated of the Marquesas Islands. Other inhabited islands include Tahuata, Fatuiva, Ua Pou, Nuku Hiva, Ua Huka, and Hova Oa. The Tuamotu Archipelago, which means "cloud of islands," situated north and east of the Society Islands, spans an arc of 80 coral atolls covering 1,100 miles (1,770 km), with a population of 7,547. Included among the 78 atolls in this group are: Tepoto, Napuka, Pukarua, Takarua, Manihi, Rangiroa, Raroia, Rotoava, Tatakoto, Hao, Reao, and Pukapuka, among others. Copra and mother-of-pearl are important exports. The Gambier Islands are southeast of the Tuamotus and include three inhabited islands, of which Mangareva is best known (Suggs 1960). According to a 1987 report, it is estimated that only 1,600 speakers of Mangarevan remained on the inhabited islands, a result, in part, of heavy out-migration. Their livelihood consists of horticulture, with crops such as coconuts, taro, and bananas, along with fishing (HRAF 1991, 172).

The Austral Islands include five inhabited volcanic islands with a population of 6,509. One of these is Tubuai, and the group is sometimes called the Tubuai Islands. Islands include Rimatarua, Rurutu, Ra'ivavae, and Rapa. The Rapanese cash crops are coffee and potatoes, which are exported, while farming and fishing are primary subsistence activities (Hanson 1991, 274). The Austral Island peoples are well known for their indigenous arts and temples.

It is difficult to ascertain the precolonial population of these five island groups, because European contact resulted in a massive population decline throughout French Polynesia, both indirectly through disease and directly through European attacks, e.g., in 1595, Mendana's crew was responsible for killing over 200 Marquesans. Thomas (1991, 188) estimates that the population of the Marquesas declined from 35,000 to 2,000 between the 18th century and the 1920s. By the mid-1980s, the population had increased to about 5,500. The Mangarevan population may have once been 8,000 people, but by 1824, it was only 1,275 (HRAF 1991, 172). According to Hanson (1991, 273), the island of Rapa, at contact, had a population of 1,500 to 2,000, but by 1867, it reached a low of 120. Today, there are only an estimated 400 remaining Rapan speakers. The population of the Tuamotu Islands was estimated at 6,588 in 1863, but declined by almost 2,200 by the 1920s. A report in 1987 establishes the Tuamotuan population at 14,400, with 7,000 of these in the Tuamotu, but most

of the remainder living in Tahiti. The Raroian population declined from 260 in 1897 to 60 in 1926. It rose to 120 in 1950 (HRAF 1991, 276). Tahiti's population is believed to have declined from a 1767 estimate of 35,000 to 16,050 in the first missionary census in 1797. By 1869, it had declined to 7,169 (Oliver 1974, 1989, 67, 117). Stanley (1992, 5) cites the 1988 population of French Polynesia at 188,814, and the CIA *World Factbook 1999* estimated the total population as 253,506 (CIAO).

In July 2002, French Polynesia had an estimated population of 257,847. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 29% with 1.04 male(s) per female (sex ratio); 15-64 years: 65.7% with 1.09 male(s) per female; 65 years and over: 5.3% with 1.01 male(s) per female; *Total population sex ratio:* 1.07 male(s) to 1 female

**Life Expectancy at Birth:** *Total Population:* 75.23 years; *male:* 72.88 years; *female:* 77.69 years

**Urban/Rural Distribution:** NA

**Ethnic Distribution:** Polynesian (*Mā'ohi*) 78%; Chinese 12%; local French 6%; metropolitan French 4%. This ethnic-identity breakdown has been critiqued and remains a major obstacle to interpretation of the data.

**Religious Distribution:** Protestant 54%; Roman Catholic 30%; other 16%

**Birth Rate:** 18.17 births per 1,000 population

**Death Rate:** 4.49 per 1,000 population

**Infant Mortality Rate:** 8.95 deaths per 1,000 live births

**Net Migration Rate:** 3.04 migrant(s) per 1,000 population

**Total Fertility Rate:** 2.23 children born per woman

**Population Growth Rate:** 1.67%

**HIV/AIDS:** *Adult prevalence, Persons living with HIV/AIDS, and Deaths:* NA

**Literacy Rate** (*defined as those age 15 and over who can read and write*): 98%. About 87% of Polynesians are literate in French and 64% to 68% are literate in one of the Polynesian languages. The official languages of French Polynesia are French and Tahitian or *reo Mā'ohi*. (The Tahitians refer to themselves as *Mā'ohi* or *Ta'ata Tahiti*.) Indigenously Polynesian languages form two major divisions: Western and Eastern Polynesian. In 1987, educational institutions included 176 primary schools, 7 secondary schools, and 18 high schools; the Université Française du Pacifique was established in 1987. The curriculum in public and private church schools alike is a French one.

**Per Capita Gross Domestic Product** (*purchasing power parity*): \$5,000 (2001 est.); *Inflation:* 1.5% (1994 est.); *Unemployment:* 15% (1992 est.). Of the 64,000 persons counted in the 1988 census as "having employment" out of the total population of 188,814, two thirds of the employed were men and three out of four worked on the Windward Islands of Moorea and Tahiti. In the outer Leeward Islands, 80% of the women and no more than 73% of the men had jobs. Most employed *Mā'ohi* work either as civil servants or in the tourist industry. All Tahitians, even in the rural areas, are involved to varying degrees in the market economy, either in independent enterprises such as craft production, periodic wage labor, and/or cash cropping (Hooper 1985, 161; Elliston 1997).

European culture has had an impact on the indigenous culture of French Polynesia in a number of ways for over 200 years. This chapter presents an overview, integrating historically situated accounts of the traditional culture with perspectives on the influence of colonization and missionary activity on the expression, beliefs, and values related to

Polynesian sexuality over the course of time. When available, contemporary sexual data will be presented. The focus is specifically on the sexuality of the indigenous peoples of French Polynesia and does not address that of the Europeans or the other minorities, unless otherwise stated.

## B. A Brief Historical Perspective

The beauty of these islands has been captured in the paintings of Paul Gauguin and the writings of Herman Melville, Robert Louis Stevenson, Jack London, and W. Somerset Maugham, among other notables. Early explorers, such as Captain James Cook (1769) and Captain Bligh of Bounty fame (1788-1789), contributed to Tahiti's reputation as a sexual paradise. Indeed, the peoples of the area, particularly the Society Islands, became distinguished for their sex-positive attitudes and known by Europeans for taking a casual approach to sex. Although the Polynesian sexual mores varied greatly from those of the Europeans, they were not unregulated. Polynesians had clearly defined cultural rules structuring sexuality and marriage, including exogamy, hierarchy, chiefly structure, genealogy, and incest rules.

The Polynesians' ancestors arrived in the frontier areas of Fiji, then reached Tonga and Samoa about 3,300 to 5,000 years ago (Oliver 1974, 1989, 67, 117). Eastern Polynesian occupation occurred by 200 B.C.E. The Tuamotu Archipelago was probably occupied by voyagers from the Society Islands by about the 9th century, as were the Austral Islands (Suggs 1960, 140-141).

The 1,609 square miles (4,167 km<sup>2</sup>) of area became a French overseas territory under the French constitution in 1957 and is currently administered by a French High Commissioner assigned by France, and a 48-member Territorial Assembly, both in the capital city of Papeete on Tahiti, the largest of the Society Islands. The Territorial Assembly is composed of locally elected representatives from the Windward and Leeward Islands of the Society Islands, the Austral Islands, Tuamotu Islands, Gambier Islands, and the Marquesan Islands (Elliston 1996). "The Territorial Assembly has been granted more powers over internal affairs over the past 20 years, as a result of Tahitian calls for more 'internal autonomy'; the French High Commissioner, however, retains the right to overrule or modify any Assembly decision" (quote from von Strokirch 1993; Henningham 1992; Elliston 1996).

The islands that now constitute French Polynesia are linguistically of the Eastern division and originally included proto-Marquesan and proto-Tahitian. Dialects of Tahitian are spoken on the Austral, Tuamotu, Gambier, and Marquesas Islands. (Tahitian is part of the Austronesian language family that spread and diversified 6,000 years ago.) This linguistic division is also replicated in terms of two cultural groupings: Western and Eastern Polynesia, with the Marquesas and the Society Islands identified as the cultural epicenters of Eastern Polynesia (Goldman 1970, xxvii). Robert C. Suggs suggests that these two archipelagos were centers of population dispersion for the other islands in Eastern Polynesia (1960, 107, 137).

## 1. Basic Sexological Premises

### A. Character of Gender Roles

Because cultures operate as integrated systems, the basic sexological premises, such as gender roles, social status, general concepts, and constructs of sexuality and love, must be considered within the broader Polynesian cultural context. Research on the status of women in traditional Polynesian societies supports the view that their position was regarded as high (Howard & Kirkpatrick 1989, 82-83). High status prevailed in the face of a *tapu* system in which

women and men were segregated and women were regarded as less powerful. (See Section 2A, Religious, Ethnic, and Gender Factors Affecting Sexuality, for a discussion of the concepts of *tapu* and *mana*.) In addition, although there was a division of labor between Polynesian women and men, it was different from the traditional Western gender bifurcation of public/domestic or inside/outside. In traditional Tahiti, men hunted pigs and fished, engaged in warfare, and built temples, while women fished for shellfish, gardened, and produced mats and bark cloth (Oliver 1974). However, role flexibility was differentially enacted among the various Polynesian societies (Howard & Kirkpatrick 1989, 82-83). To fully understand women's position in precolonial Polynesia, the context of the "chiefly structure" must be considered. Chiefly status could take precedence over gender, and consequently, women could also assume positions of power as chiefs (Elliston 1996).

Levy's work among the Tahitians from 1962 to 1964 suggests a culture in which attention to gender distinctions continues the precolonial trajectory (1973, 230-237). Evidence of this is found in the Tahitian language in which gender is linguistically underplayed. While gender-specific occupational divisions do occur, there is a great deal of role pliability and cross-over, e.g., although women do not hold office in the formal political sector, they have an important voice and interest in politics (Levy 1973, 233). The high position of Tahitian women continues a pattern reported early on by explorers. The traditional descent system of reckoning through either matrilineal or patrilineal lines provided women access to powerful positions in the social order. Levy's research concluded that a blurring of gender boundaries continues as a contemporary pattern in rural Tahiti. However, he found that in the more urbanized and Westernized setting of Papeete, this pattern of gender equality and blending was becoming polarized by the wage-labor economy in which men are the breadwinners and women the homemakers (Levy 1973, 232-237). Elliston (1996) suggests that this pattern has not come to fruition, but rather women's employability is increasing while men's is decreasing.

Some researchers have proposed that in traditional times, in Eastern Polynesia (including the Marquesas and Society Islands), women's status was considered low because they were *noa*: common, impure, and polluting in regard to *mana*. Shore's examination of the literature suggests this may be an oversimplification. He cites considerable evidence to the contrary (1989, 146-147). For example, Hanson and Hanson argue that women's menstruation was not regarded as "simply polluting, but as inherently dangerous because it represents a heightened time of female activity as the conduit between the worlds of gods and human" (1983, 93 in Shore 1989, 147).

In-depth discussions of gender roles in recent times are presented in Douglas Oliver's *Two Tahitian Villages* (1981), Greg Denning's *Islands and Beachers* (1980), and Robert Levy's *Tahitians: Mind and Experience in the Society Islands* (1983), among others.

Thomas (1987) has discussed Polynesian gender roles in order to highlight the dramatic effect of colonization and missionization on contemporary Marquesan women and men. Depopulation has had an impact on the Marquesans, as has the introduction of wage labor, which, in some areas, continues today as a mixed economy with subsistence, occasional copra sales, and/or intermittent wage work. The work of Marquesan women is *haka ha'e propa*, which means "to make the house clean." This includes a variety of domestic chores, childcare, clothes washing, and cooking. Men engage in agriculture and horticulture, fishing, cutting coconuts for copra sales, and/or paid manual work. The di-

vision of labor is flexible, and women may work in gardens or collect Tahitian chestnuts, while men may do some work in the house which consists primarily of cooking. Unlike Western practices, cooking, washing dishes, and clothes washing in the nonurban areas are done outside the home. Even if a family has a gas stove or washing machine, this is placed outside the home.

But this model of gender roles that continues in more-rural areas is changing in the more central, Westernized, and urbanized island locales, where the presence of schools, hospitals, post offices, and other administrative services, as well as greater opportunities for continuous employment, affect traditional patterns. Women participate in the workforce in these areas to a high degree, particularly in clerical positions, while men are employed primarily in the highway department with road maintenance. Women's pattern of employment is typically one in which they quit work to have children, but may later return to part-time positions. In contrast, men have a more consistent pattern of long-term, wage-labor employment (Thomas 1987).

Thomas (1987) suggests that these gender-role patterns and the division of labor is more likely a result of colonialism than a traditional Polynesian cultural pattern. The traditional pattern of gender roles in the early contact period (1790-1830) was quite different, according to Thomas. Like Polynesian societies generally, the *tapu* system was an important part of the social organization of the Marquesas, and it frequently involved segregation of the sexes.

Traditional activities for men included fishing from canoes, which continues today, while traditional women's activities included gardening, preparation of bark cloth, and making mats. Prior to missionization, women had other opportunities for enhancement of their status. Coexisting with a class of male chiefs and priests was a class of women shamans whose importance varied throughout Polynesia. In the Marquesas, these women priests occupied a privileged position in society as curers and diviners who received food or pigs as payment for their services. The old Marquesan role parameters provided women with opportunities and access to prestige and power.

The Western disparity in gender roles delineated by separate but unequal domains of the public and the domestic was not expressed in traditional Marquesan gender roles. The *tapu* system also mitigated against such a Western public/domestic split, since typically men ate meals with men, not with women. As Thomas (1987) has noted, today Marquesan gender roles reflect Western tradition and the imposed Christian gender polarization of men-public-provider and women-domestic-nurturer. The demise of the *tapu* system occurred unevenly, but seemed to have been eliminated by the 1880s, facilitated by French colonial rule in 1842, the political efforts of the Catholic and Protestant missions, and the decline of the indigenous population. Colonialism and missionization disrupted the hierarchical aspects of the social system and eroded the chiefly structure, along with the system of *tapu* and *mana* that sustained it (Elliston 1996). By the late 19th century, polyandry, which was probably only practiced by the highest-ranking females, had become almost extinct (Thomas 1987).

Major changes in the political economy resulted in the replacement of traditional landholding units and mechanisms of redistribution by autonomous groups engaged in their own subsistence. Missionaries felt that the traditional Marquesan practice in which women gardened was improper and unseemly to their sex. According to Christian dictates, the women should be confined to their homes while the men should work as the cultivators. This was successfully imposed on the Marquesan peoples and others in

French Polynesia. Lockwood reports a similar pattern in the division of labor, in which men are the farmers while women are responsible for the household and childcare on Tubuai (1989, 199).

The impact of Western missionization on gender roles was particularly effective in French Polynesia because of the large-scale disruption in the indigenous way of life. All these factors converged to influence indigenous gender roles. Yet, the continuity of women's precolonial status vis-à-vis men cannot be underestimated (Elliston 1996). However, this does not now mean that women cannot surmount the Christian ideologies that place men at the head of the household. Lockwood observes that Tahitian women are "socially assertive and are frequently willing to challenge male authority when in a position to do so." Oliver's description of ancient Tahitian women as "anything but a passive, deferential, submissive lot; certainly not in domestic matters and often not in 'public' affairs either" (1974, 604) could be applied equally to contemporary Tahitian peasant women (1989, 207).

## B. Sociolegal Status of Males and Females

The sociocultural status of Polynesians throughout the life course varies in terms of ages and expectations. Oliver's (1981) and Levy's (1973) work on Tahitian life stages is particularly valuable in this regard. The infant, an *'aiu* ("milk eater"), gradually becomes a child (*tamāri'i*) between 1 and 3 or 4 years old (also *tamaroa*, boy child, or *tamāhine*, girl child). Childhood is followed by *taure'are'a*, the period of pleasure. This stage is ushered in by signs of approaching puberty. Between the mid 20s and early 30s, one becomes *ta'ata pa'ari* ("a wise or mature person"). Old age is *rū'au* (old) and/or if an individual becomes senile, he or she is *'aru'aru*, "weak and helpless" (Levy 1973, 25), see also Oliver (1981, 340-400).

Traditionally, the status of individuals in many areas of French Polynesia was defined by a hierarchical pattern of genealogical ranking, sustained by the belief in *mana*, and encountered through the *tapu* system of behavioral rules and restrictions. The Polynesian system of genealogical ranking was one in which the firstborn child was of higher status than his or her siblings. Those in such a position, regardless of their gender, were in a state of *mana* and, according to some reports, were therefore secluded for certain periods. The aura of *mana* also extended to a lesser extent to other siblings as well.

In traditional Polynesian societies prior to disruption of the *tapu* system, children were regarded as highly potent and potentially dangerous. As a result, they had to undergo certain rituals to prepare them to interact in the secular world. All upper- and lower-echelon children were apparently imbued with this divinity. The Polynesian cosmology regarded this sacredness as a highly charged force that required precautions lest harm could befall the unprotected individual.

Jane and James Ritchie (1983) noted that the precolonial pattern of early-childhood indulgence, community concern, and an extended-family concept of parenting has continued, especially in the more traditional areas at the time of their research. Children learn to be autonomous and responsible for tasks and chores at an early age. This transition to responsibility and autonomy occurs when the child is around 2 to 3 years old. By the middle years of childhood, peers are accountable for most of the childcare. Polynesian groups, and French Polynesia is no exception, were noted for a pattern of fluid child adoption. This pattern still occurs today. Adoption may occur informally through kin net-

works that may bypass the legal adoption process. (See discussion below of marriage and the family.)

Gender was also conceived as an integral part of generalized Polynesian hierarchy, genealogy, and the status of the individual as adolescent and adult. Thomas (1987) has described Marquesan men as traditionally having *mana*, while women were *me'ie* (common or free of *tapu* in relation to men). The term *noa* is used in other parts of Polynesia. However, there were numerous situations in which women could become subject to *tapu* prohibitions. This represents the contextual aspects of the *tapu* system described earlier. Such contexts required precautions as well as certain restrictions on the individual, his or her possessions, and tasks. Certain kinds of activities were segregated by sex and locale, e.g., women learning a new chant, men making a net, or a woman placing herself under *tapu* to conceive or prevent a miscarriage. This kind of *tapu* involved communal eating, sleeping, and prohibitions on sexual activity for a particular period of time, or until the project was completed.

Thomas (1987) has also pointed out that *tapu* and *me'ie* were relational constructs, and that in the Marquesas, a man who was *tapu* in relation to a particular woman might be *me'ie* in relation to other men who were in a *tapu* grade above him. This same man would be *me'ie* in relation to women of chiefly status.

In addition to the elites in the Polynesian hierarchy, there were people who were low-status servants of the elites, as well as those who were nonlandholding tenant farmers. It was the commoners in the Marquesas who were most affected by the *tapu* restrictions, e.g., common men could only eat what was produced by women. Persons at the lowest level of the hierarchy were not affected by the *tapu* on food, since they were the servants and produced food for not only themselves, but for the elite they served. The elite were less affected, because they neither produced nor prepared the food they ate.

## C. General Concepts of Sexuality and Love

While sailors on the early European exploring ships regarded Polynesia as a sexual paradise, the missionaries they brought viewed the same cultures as dens of debauchery. Oliver (1989) cites a 1778 report of J. Forster who stated: "The great plenty of good and nourishing food, together with fine climate, the beauty and unreserved behavior of their females, invite them powerfully to the enjoyments and pleasures of love. They begin early to abandon themselves to the most libidinous scenes." Tahitians specifically, and Polynesians generally, became known for their sex-positive attitudes and open valuing of sexuality, although the cultural structuring and tacit rules for sexual expressions were not apparent to the Europeans. Sexual experience and expression for many Polynesians began early and continued throughout the life course.

Needless to say, the various explorers and colonial ship crews visiting the islands misunderstood Polynesian sexuality. For example, in the Marquesas, young naked girls swam out to the ships to engage in sexual trysts with the sailors. While the sailors took advantage of the sexual liberation of these young girls, they experienced some ambiguity, because their own Western sexual paradigm had no comparable framework or referent. While Polynesian girls were similar in some respects to the prostitutes or sex workers who typically greeted these sailors at other ports, they were also very different because of their youth, nakedness, and willingness to swim out to greet the boats. In addition, not all young women swam out to the boats or engaged in sex with the sailors. The young girls that came out to the ships were outside the *tapu* classes, so their relations with

the visitors provided them access to status and wealth that they would not normally have. Foreign sailors and observers were not aware of the situational and contextual factors behind this behavior (Dening 1980).

Others who swam out to the ships were the Marquesan *Ka'ioi*. These were adolescents who were separated at puberty in order to be educated in the social conventions and skills necessary to become singers and dancers at *koina* (feasts). For girls, this was a period of intense sexual play and display. It involved learning songs and dances for the feasts, as well as the art of beautification, which included the application of oils and bleaches. High-status girls were not educated as *Ka'ioi*, nor did they swim out to the ships. However, it was this behavior among the Marquesans that also contributed to the Western stereotype of Polynesian sexual license (Dening 1980).

In their massive cross-cultural review of the ethnographic literature, Ford and Beach (1951) classified the Mangarevans, the Marquesans, and the Pukapukans as "permissive societies," characterized by tolerant attitudes toward sexual expression in the lifespan of the individual. According to Gregersen (1983), Polynesia is known for "public copulation, erotic festivals, ceremonial orgies and sex expeditions," which had disappeared by modern times. It should be pointed out that this does not imply a sexual free-for-all by any means, as noted by Douglas Oliver's account in *Ancient Tahitian Society* (1974). While missionaries were immediately struck by the Polynesian variance from Western Christian standards of sexual morality, it should not be assumed that Polynesian sexuality was without cultural rules. Like sexuality everywhere, Polynesian sexuality was structured and bound by norms, regulations, and sanctions—although these were different from those of the explorers, missionaries, and colonials. It was primarily the young and unmarried people who had the greatest sexual freedom; married people and the elite class had much less.

Although Polynesian societies condoned premarital sexual expression, access to partners was strictly structured. Gregersen (1983), for example, reported that on the island of Raroia in the Tuamotu Archipelago, there were only 109 people in 1951. Such a small population meant that seven of the nine women of marriageable age were prohibited from having sexual partners because of incest regulations. In the neighboring atoll of Tepuka in the 1930s, the young people were all related and had to journey to other islands or await the arrival of visitors to find a partner.

Specific laws were enacted with French colonization. In 1863, for example, the French administrators banned much of the traditional cultural practices that involved *tapu*, the religion, traditional songs and dances, warfare, naked bathing, wearing of perfumed oils, polygyny, polyandry, and other practices at variance with Christian morality. These laws did much to repress the precolonial culture, but, as Elliston (1996) points out, "Polynesians found ways around both the Church teachings against sex-outside-marriage, and against French laws."

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A. Source and Character of Religious Values

Polynesians today are primarily Christian, with 54% Protestant, 30% Roman Catholic, and 16% other, including Mormon, animist (the indigenous system), and Buddhist. The impact of missionary activity in the Pacific is reflected in the high percentage of Christian religious affiliation. Depending on the particular historical situation, different denominations may predominate in an area, e.g., the Mar-

quesas Islands are over 90% Catholic; Protestantism dominates the Austral Islands and the Leeward Islands, while the Tuamotu Islands are two-thirds Catholic and one-third Mormon. Although Thomas (1987) suggests that Catholicism's antagonism to contraceptive use has resulted in typically large families, large families are more probably a continuation of an earlier pattern that existed prior to depopulation, rather than as the consequence of Catholic religious attitudes.

It is important to remember that once the Europeans arrived in Polynesia, the traditional culture began to undergo major change and disruption. Archival and historical research can provide important clues in unraveling the traditional patterns that have persisted despite European colonialism and missionary activity. Broadly speaking, the various denominations of missionaries found the Polynesian sex-positive cultures repugnant. They were appalled by the Polynesian joy of sex, and repelled by the marital practices that allowed for polygyny and even polyandry.

In discussing religion, it is inappropriate to segregate the sacred aspects of indigenous Polynesian life from the wider culture, since these societies are unlike the West, where there is a clear division between the sacred and the secular. In contrast, the sacred and secular are interwoven in an integrated fashion within Polynesian cultures. An attitude in which sex was highly valued was reproduced as part of the synthesis of the social and the sacred in Polynesian life. Sacred aspects of sexuality incorporated beliefs about reproduction, fertility, and fecundity that were symbolically expressed through ceremonial sex. Marshall (1961) reports evidence of public sex associated with sacred temples on the Island of Ra'ivavae. This was also recorded for Tahiti. Among Tahitians, the sacred temples, or *marae*, served as the center of daily life. The religious system was based on beliefs in spirits and gods. Humans and gods were in a relationship that permeated all aspects of the Tahitian's daily life. Even the gods were regarded as joyous and sexually playful in concert with the positive sex ethos of the culture.

The *tapu* (taboo) system regulated social behavior. It was based upon an important religious element, *mana*, a fundamental principal of divinity and sacredness, that has been likened to electricity, prevalent among some Polynesian societies. *Mana* provided a relational and contextual structure, as well as demarcated sacred boundaries around class, time, events, space, and people. "Theoretically *mana* is an inherited potential, transmitted genealogically, with greater proportions going to firstborn children. It is therefore a matter of degree—a gradient ideally coincident with kinship seniority. Ultimately it stems from the gods" (Howard & Kirkpatrick 1989, 614). *Mana*, however, must be demonstrated through acts and activities of an individual. Success demonstrated the strength of one's *mana*, while failure signified weak *mana* (Howard & Kirkpatrick 1989, 64). *Mana* was also associated with fertility, fecundity, and abundance—both reproductive and agricultural, according to Shore (1989, 142).

Shore suggests that this aspect of *mana* may account for the traditional Polynesian emphasis on the genitals of the chief. In the *mana*, relational and contextual construct power was somatically embodied in the head and the genitals, which were regarded as sacred. For the Marquesans, these were the bodily sites for the protection of the self (Dening 1980). Linton reports that in traditional times, "there was constant mention of the genital organs of the chief, which were given names indicating their vigor and size" (Linton 1939, 159, in Shore 1989, 142). The Marquesan concepts of sacred personhood and the autonomy of the individual apparently also transcended class and gender in some respects. All individuals were credited with an inherent divinity that

granted them inalienable social respect. However, in terms of ranking, the chiefly group held a higher position, because it was believed that their personal *mana* far exceeded others. Nevertheless, regardless of rank or status, the individual was endangered if the *tapu* regions around the head and groin were violated.

Bradd Shore (1989, 137-173) has described *tapu* in depth. *Tapu* is a difficult concept for Westerners to understand. It is not directly translatable into our concept of taboo. *Tapu* has multiple referents. According to Shore,

First, the term has two quite distinct usages, one active, the other passive. As an active quality, *tapu* suggests a contained potency of some thing, place, or person. In its passive usage, it means forbidden or dangerous for someone who is *noa* [not divine, common]. Moreover, it seems to combine contradictory properties, suggesting on the one hand sacredness, reverence, and distinctiveness and, on the other, danger, dread, and pollution. (1989, 144)

When people were engulfed by *tapu*, they were in sacred states, and consequently, restrictions and prohibitions were placed on their behavior as well as their person. *Tapu* was the system that structured behavior in relation to *mana*. For example, according to Nicholas Thomas (1987), females were considered *me'ie*, common or free of *tapu* in relation to men. This classification, however, did not mean that women could not have a high status or could not enter *mana* states. However, *mana* was a fundamental spiritual rationalization for segregation of the sexes that resulted in *tapu*, or restrictions on the interaction between the genders in certain domains.

Marquesan women were also regarded as potentially dangerous when menstruating, which provided them with certain kinds of power. For example, a woman could curse an object by naming it for her genitals or by placing the object beneath her buttocks. Similarly, *tapu* could be assigned to an object by naming it for one's head or placing the item above one's head. Among the Marquesans, who believed women were potentially dangerous, sexual restrictions were also placed on intercourse at various times. According to Thomas (1990, 67) "some aspects of femaleness seem to be at the center of the *tapu* system." This was not, however, a universal pattern in French Polynesia.

The religious aspects of indigenous sexuality were also evident in the Tahitian *arioi* cult (discussed later in greater detail and described by Oliver (1974).) Members of the *arioi* society, an organization of traveling Tahitian entertainers, dancers, and athletes, were permitted unrestricted sexuality. Their roles as entertainers included sexual titillation and celebration for the public. The sexual element of this cult was permeated by the religious, as the *arioi* were dedicated to the Tahitian god, 'Oro (Oliver 1974).

## B. Source and Character of Ethnic Values

The peoples of French Polynesia are part of the larger culture area of Polynesia, sharing linguistic and many other cultural characteristics (Burrows 1968, 179). However, in precontact times, there was much cultural variation and diversity among the five island groups making up French Polynesia. Today, unification by the French has provided "the Polynesians living in these different archipelagos and islands . . . new grounds for relating to one another, including the use of French and Tahitian languages" (Elliston 1996). However, it should not be assumed that variation has been lost. For example, Oliver's study in 1954-55 of two Tahitian villages, one on Huahine and the other on Mo'orea, led him to state: "I came to recognize that there were almost as many subspecific varieties of Tahitian societal cultures as there were communities" (1981, xii). In Elliston's (1996)

words, "Polynesians throughout the archipelagos continue to have a very strong sense of their own locally-based identities by which I mean that their contemporary identities are strikingly based on their islands and archipelagos of origin." Elliston explains this as "in part because Polynesians associate different characters, economic practices, even different cultures with different islands and archipelagos; where one is from encodes a great deal of information in the local signifying systems," noting that Polynesians themselves generally see a great deal of diversity in the islands.

Oliver spearheaded a research project in which the social organization of eight Tahitian communities were studied, two each by Douglas Oliver, Ben Finney, Antony Hooper, and Paul Kay. The social organization of these island peoples varied, as did their methods of food production, as adaptive responses to different environmental riches. In Eastern Polynesia, as in Western Polynesia, social organization was a ranked system. The precolonial social system was a chiefly structure and within it variance occurred. Therefore, unlike Western Polynesia in which rank was graded, Eastern Polynesia was stratified by class (Burrows 1968, 185). Four major kinds of socioeconomic ranking or "degrees of stratification" existed in the traditional chiefly structures of what is now constituted as French Polynesia.

Tahiti had a very complex ranking system that usually included hereditary statuses consisting of *ari'i* (aristocracy), *ra'atira* (gentry), *manahune* (commoners), *teuteu* (servant class), and a small nonhereditary slave class of *titi*, captured during warfare. The people of Mangareva had "two basic status levels with tendency to form a third," while the Marquesas had "two status levels," and the Pukapukans "two status levels; the upper containing very few members" (Sahlins 1967; Stanley 1992; Ferdon 1991). While class stratification continues in modern times, the traditional categories have been abandoned (Oliver 1981, 37).

These hierarchical aspects of Polynesian society were permeated with religious meaning since the chiefs and other elites were regarded as divine and rich in *mana*. *Tapu*, *mana*, the *arioi*, and a hierarchical chiefly structure were interconnected as aspects of the sexual system. For example, in Tahiti, as elsewhere, hierarchy was mandated by the gods and manifested in all levels of social organization. The kin-congregation or extended family had small *marae* to make offerings to spirits. Extended-family households were organized into neighborhoods that had larger *marae* with the chief's *marae*, which was the largest and most potent (Scupin & DeGorse 1992). It was believed that "the highest ranking chiefly family . . . was . . . descended from the first humans created by the creator god, Ta'aroa," and was, therefore, the most powerful spiritually (Scupin & DeGorse 1992, 31).

The bilateral kinship system was one in which the chiefly status and sibling order (first-born siblings ranked in status above others) determined one's social position. This was not necessarily limited through the patrilineage. Women, like men, could have access to chiefly positions. The practice of bilateral reckoning provided for flexibility in status and rank, facilitating affiliation through either the paternal or maternal line (Scupin & DeGorse 1992, 313). As a result of colonialism and Christianization, the traditional social-political organization of inherited rank no longer exists (Hooper 1985, 161).

## 3. Knowledge and Education about Sexuality

### A. Government Policies and Programs

Because Tahiti contains over 70% of the population, public health efforts are focused in this area. Not currently available at the time of this writing is information from a

sexual survey conducted in Tahiti in November 1993 under the auspices of La Direction de la Santé Publique.

### B. Informal Sources of Sexual Knowledge

Informally, spatial organization and sleeping arrangements may contribute to sexuality education of the young. Ford and Beach (1951) reported that among the Pukapukans and Marquesans, families often slept in one room, thereby providing children an opportunity for sexuality education through clandestine observation. This, however, must be placed in cultural context. Parents were not putting on an open display for children; but, because families slept in close proximity, this provided children an opportunity to secretly observe their parents copulating. In these societies, discussions about sex with children were also very open and frank as part of a pattern of sex positiveness. For example, among the Ra'ivavaens studied by Marshall (1961, 241), children were aware of orgasm, the role of the penis (*ure*), and the clitoris (*tira*) in sexual arousal.

Other avenues for sexuality education included practices around childbirth. Oliver (1989) recounts that on old Raroia in the Tuamotu Archipelago, childbirth was a social event in which the whole community attended, including children, and even male members who also assisted in childbirth. This custom of including males in childbirth as assistants is notable, for in many parts of Oceania, as elsewhere, men are prohibited from participating in childbirth.

Indigenous beliefs about conception in French Polynesia are part of the informal system of education. In a study of the Marquesas in the late 1970s, Kirkpatrick (1983) reported the then-current belief that, although babies were conceived through the copulation of males and females, this was not sufficient. Divine intervention was also a necessary component.

The Tahitian ethnotheory of conception asserted that the fetus received physical and divine characteristics from both parents. The infant's sacred attributes were regarded as cynosure of its birth. In Old Tahiti, the genealogical system of ranking reckoned that the degree of divinity in each child was directly proportional to the degree of descent from his or her ancestral deities. The firstborn inherited more divinity or *mana* than the subsequent children, so that a genealogical line consisting of all firstborn children had more divinity than others. The amount of divinity was also synergistic, so that a firstborn of parents of equal divinity possessed more sacredness than either parent.

F. Allan Hanson (1970, 1444-1446) has written on the "Rapan Theory of Conception." This analysis focuses on the Rapanese ethnotheory that conception is most likely to occur in the three to four days following menstruation when it is believed women are most fertile. In order to prevent pregnancy, Rapanese couples abstain from sex during this three- to four-day period. While this practice is not an effective method for limiting family size, it can be understood as articulating with Rapan theories of physiology and reproduction.

The Rapanese woman, based on Hanson's survey of 85% of the population, has an average of 6.3 births and raises about five children per woman. This is considered burdensome by the Rapanese who would like to reduce family size to ideally two to three children. The Rapanese say that:

a fetus is formed when semen enters the uterus and coalesces with the blood harbored there. The existence of ovaries, Fallopian tubes, and ova is not recognized. Menstruation ceases after conception, because all the blood goes to building the fetus. If conception has not occurred, the blood becomes stale after a month, is expelled in menstruation and is replaced with a fresh supply. The uterus

opens and closes periodically, opening each month to allow the old blood to flow out. . . . Semen cannot enter when the uterus is closed, so there is no possibility of conception during the greater part of the cycle. (Hanson 1970, 1445)

This theory is also found in the Tuamotu Archipelago on Pukapuka. In the Huahine and Mo'orea villages studied by Oliver (1981, 334), as elsewhere in Tahiti, children were highly valued. Problems in conception were treated by a woman specialist who used an indigenous medication of hibiscus and green coconut.

## 4. Autoerotic Behaviors and Patterns

### A. Children and Adolescents

Among the Pukapukans, Mangarevans, and the Marquesans, during indigenous times prior to Christianization, a tolerant attitude was taken toward childhood sexual expression. Among the Pukapukans, children masturbated in public with no opprobrium. The parents apparently ignored their behavior (Ford & Beach 1953). Levy's research among Tahitians from 1962-1964, cites early explorer and missionary accounts of masturbation among adults and children (1973, 113-116). His work among rural Tahitians indicates children masturbate, although the Tahitian term used to describe masturbation refers to males, since it includes the morpheme for uncircumcised penis. Levy notes that "the emphasis on prepubertal male masturbation is striking" (1973, 115). It is considered a boy's activity outgrown with adolescence. However, adult censure of masturbation does occur and seems to be centered on the fear that the boy's foreskin might tear. Masturbation by post-superincised males is criticized as an indication that he cannot attract a female.

### B. Adults

According to William Davenport (1973), in traditional pre-Christian Tahiti, masturbation was sanctioned positively for young women and men.

## 5. Interpersonal Heterosexual Behaviors

It needs to be noted here that the three Euro-American developmental stages of childhood, adolescence, and adulthood may be of limited utility when encountering non-Western peoples. Adolescence is a fairly recent Western construct whose relevance and meaning cross-culturally will vary. For example, Kirkpatrick (1983) notes that the contemporary Marquesas islanders have an ethnotheory that encompasses four stages of human development: infancy, childhood, youth, and age.

### A. Children

During the traditional times, the Pukapukans, Mangarevans, and Marquesans permitted children open sex play (Ford & Beach 1953). The cultural practices of Marquesans and Pukapukans not only allowed open sex play among children but, as mentioned earlier, provided children clandestine opportunities to observe adult sexual behavior because of the sleeping arrangements. According to Oliver (1974) on Tahiti, coital simulation became actual penetration as soon as young boys were physiologically able. The Tahitians found children's imitation of copulation humorous. Other evidence suggests that young girls may have engaged in copulation before age 10 (Gregersen 1983).

Kirkpatrick's research (1983), based on 25 months of fieldwork in the Marquesas (primarily on Ua Pou and Tahiti during the late 1970s) provides much information on the lifecycle, gender identities, and the integration of traditional patterns with new cultural influences. According to

John Kirkpatrick, babies are massaged with oils and herbal lotions to make their skin smooth, and baby girls are given vaginal astringents to make the genital area sweet smelling. Such treatments for girls continue through puberty and include menstrual preparations as well. The application of fragrant oils, and the concern with cleanliness and personal hygiene, is tied into a wider Polynesian valuing of beauty and the body embedded in the traditional precontact culture. Suggs (1966, 25) comments that in traditional Marquesan society, girls may have had their first coital experience by age 10, and boys were circumcised between 7 and 12 years old.

Oliver's (1981) ethnography includes in-depth discussion of infancy, childhood, and other life-course stages in Tahiti (see the chapter on "Passing Through Life," pp. 342-400). In this regard, he notes that children played in mixed-gender groups until 13 or 14 years old. The Tahitian attitudes to children playing at copulation was one of amusement (1981, 366). However, as children approached the age of 11, adult parental attitudes shifted in regard to young females but not males. Oliver points out that parents objected to girls engaging in sex prior to marriage, an ideal that coexisted with an open and sex-positive attitude. Given Atean and Fatatan flexible definitions of marriage and the cohabitation of young people as a kind of trial marriage, the ideal of chastity in veiled-bride weddings accounted for only 8.9% of Atean and 22.5% of Fatatan weddings.

## B. Adolescents

In discussing adolescents, it is especially important to avoid ethnocentrism. Adolescence is a Western construct with specific age and social concomitants that is of limited use cross-culturally. A more culturally relevant approach for a discussion of Polynesian sexuality is marital status and hierarchy rather than age.

### *Rites of Passage*

Puberty rituals were practiced in traditional times among the Polynesians, including ceremonies in which male genitals were altered surgically, and females and males were both tattooed. These rituals defined the individual as having reached the age of procreation. Traditionally, superincision, along with tattooing, occurred some time after childhood, but before adulthood in the Society Islands.

Superincision continues to be part of contemporary Polynesian practices among some societies. One of the functions of the superincision is to make the penis hygienic and clean, just as vaginal astringents are used for cleanliness in young girls. This is part of the continuing traditional Polynesian cultural emphasis on beauty and cleanliness. It is believed that clean and sweet-smelling genitals make one more attractive as a partner (Kirkpatrick 1983).

However, the puberty ceremonies were and continue to be much more than male genital surgery. They are markers of a process of social-identity transformation as the youth approaches competence and adulthood. Kirkpatrick (1987) discusses Marquesan superincision as a "freeing or enabling event. It results in emergence into the world, rather than the incorporation of the subject into a new group or status" (1987, 389). Young Marquesan males take pride in being superincised for these reasons. Additionally, it is not considered proper for an unsuperincised male to have intercourse. In the Old Society Islands, Oliver (1974) notes that sex was allowed prior to the completion of the tattooing or superincision.

The superincision was traditionally done in the Marquesas by a local indigenous specialist. In the Old Marquesas, the superincision was performed after puberty, al-

though Kirkpatrick (1983) found that in the late 1970s, the age of superincision was expanded to include 11- to 18-year-old boys. Frequently, a boy or group of boys would request that a superincision be performed.

Levy (1973) describes Tahitian superincision in very similar terms. Superincision among Tahitians is part of a boy's *entré into taure'are'a* ("the time or period of pleasure"). Levy points out that this precontact pattern continues in modern times because of its association with Christian circumcision. Peer pressure, such as teasing about smegma, is the reason boys gave when asked why they pursued superincision. Reinforcing this is a belief that superincision enhances sexual pleasure. Linguistic evidence includes an indigenous term for "skin orgasm," which describes the unsuperincised male's orgasm as quick and unsatisfying (Levy 1973, 118-119).

In superincision, the foreskin is cut, various preparations may be applied on the wound, and then the penis is exposed to heat and salt water to heal. Young men will go to rock pools in the sea and expose their penis to the heat from sun-warmed rocks and then alternately bathe in the sea. When the incision is healed, the boys may return to their daily activities and wear shorts. This pattern is similar to the Tahitian regimen that has changed very little from traditional times. A group of boys gets together and asks a man known for his ability to operate on them. Parents are not told beforehand of the boys' plan to do this. A razor blade is now used to cut the skin, followed by bathing in the sea and application of herbal medicines. A fire is made with leaves, and the boys heat the penis from the vapors and then bandage it (Levy 1973, 118-119).

Marshall (1961, see below) reports that superincision, practiced among the ancient Ra'ivavaens, included sexuality education by a priest, as well as a training component in which the superincision scab was removed by copulation with an experienced woman. A boy cannot become a man, even among contemporary Ra'ivavaens, without the superincision. While specialists performed the superincision traditionally, any male with knowledge of the procedure may do so today. However, traditional elements persist in the technique, as well as in the removal of the scab through intercourse with the older experienced woman (Marshall 1961, 248).

Superincision is a characteristic Polynesian practice. Although the foreskin is only slit, the outcome of exposing the boy's penis is the same as in circumcision, according to Davenport (1977, 115-163). Although Davenport maintains that the dramatic ritual aspects of superincision have been lost, the genital operation continued at the time of his writing in 1976 in Polynesia.

Generally speaking, in the Polynesian area, women were not rigidly isolated when menstruating as in Melanesian groups. Like female puberty rituals throughout the world, the Marquesan girl's rite of passage is more continuous and less dramatic than the boys. Reproduction readiness was recognized by the growth of pubic hair. Kirkpatrick (1983) notes that if a menstruating female climbs a breadfruit tree, it is believed that the fruit will have blotched skin. In the Old Society Islands, there was no ritual around menstruation, although at puberty, girls did receive tattoos on the buttocks. Menstruating women were not to enter gardens or touch plants. Levy reports in his early 1960s research that some traditional beliefs persist regarding menstruation among Tahitians. Apparently, young women who were menstruating were told to avoid getting chilled or eating cold foods, as this could result in *ma'i fa'a'i* (the filled sickness). It is believed that if a girl does not menstruate, and/or if she remains a virgin, the blood will fill her body and head and make her crazy, also leading

to *ma'i fa'a'i*. One act of intercourse was believed necessary to ensure good menstruation (Levy 1973, 124-126).

### *Premarital Sexual Activities and Relationships*

Among traditional French Polynesian societies, and for Polynesia generally, there were two standards for premarital sex that varied by status and rank, according to Davenport (1976). For example, among the Tahitians, firstborn daughters in lineages of firstborns were very sacred. As a consequence, their virginity was valued and protected until a marriage with a partner of suitably high status was arranged. Among these elite daughters, virginity was demonstrated, for example, by the display of a stained white bark cloth following coitus. Subsequent to the birth of their firstborn child, females of high rank were permitted to establish extramarital liaisons. On Pukapuka, according to Marshall Sahlins (1967), the chief kept a sacred virgin in his retinue as a symbol of his spiritual power.

Among the Margarevans and Marquesans, the only apparent restrictions on adolescent sexuality were incest, exogamy regulations, and/or the upper-class status of certain females. Premarital virginity was required for a chief's daughters but not for other youths. This pattern, according to Kirkpatrick (1983), continues even today, where concern for rules of exogamy and relatedness still persist among Marquesans. However, Marquesan youths may not be aware of their degree of relatedness to a potential partner when they begin a relationship, a source of concern to their elders.

Marshall's study of Ra'ivavae (1961), based on reports from the archives of ethnographer J. Frank Stimson, his own ethnographic research with elderly consultants, archeological, and linguistic analysis, presents a picture of a highly eroticized Tahitian culture that has been largely dismantled by colonialism and Christianity.

The clitoris, among ancient Ra'ivavaeans, received a great deal of cultural attention. Marshall reports that the clitoris was elongated by the child's mother through oral techniques as well as tying it with an hibiscus cord. An elongated clitoris was considered a mark of beauty. According to Marshall's research, the king would inspect a girl's clitoris to see if it was sufficiently elongated for her to marry. The girls who were ready for marriage would display their genital attributes at a sacred *marae* (Marshall 1961, 272-273). Both cunnilingus and fellatio were practiced among traditional Marquesan youth and adults (Gregersen 1994, 272; Marshall 1961). Suggs (1966, 71-73) describes contemporary Marquesan sex as including virtually no foreplay and lasting five or less minutes.

For the indigenous population of French Polynesia, the *taure'are'a* period in the lifecycle is demarcated as a special status. *Taure'are'a* is part of a traditional pattern that continues today primarily in rural areas. In the Marquesas, adolescence includes a category known as *taure'are'a* that operates as a transitional period between childhood, *to'iki* (kid), and adulthood *'enana motua* (parent person). Kirkpatrick describes it as "errant youth" (1987, 383-385). *Taure'are'a* are characterized by their sexual adventures and same-gender peer orientation. *Taure'are'a* are known for brief sexual liaisons in contrast to adult sexuality, which is integrated within the larger context of domesticity. As a period in the lifecycle, *taure'are'a* is characterized by its pleasure-seeking goal and is looked back upon fondly by adults (Kirkpatrick 1987, 387). *Taure'are'a* is regarded as a temporary status that gradually evolves into adulthood. It is one in which brief sexual encounters are replaced by relations and cohabitation with their partners (Levy 1973, 123). It has also been argued that *taure'are'a* is a time of "testing

relationships" through cohabitation with one or more partners serially (Elliston 1996).

According to Kirkpatrick (1983), peers are very important for the Marquesan youth, especially the finding of a confidant with whom one can share secrets, including sexual ones. Of apparent equal interest is the establishment of heterosexual relationships. These sexual liaisons must remain secret because of the rigid Christian sexual prohibition against premarital sex. For example, if pregnancy were to occur, the girl would be either forced into marriage or her relationship would be ended, although this is not true of Tahiti or other areas of French Polynesia. Peer relations are not severed with marriage, although one's behavior is expected to mature. Sexual gossip is considered normal for youths but not for adults. There is some expectation of a double standard for youthful males and females. Youthful females are expected to act more coy than their male counterparts. In the Marquesas of the late 1970s, males were the sexual initiators, while it was considered inappropriate for girls to take the lead. However, it is a cultural value that both partners should desire and enjoy sex.

Levy also reports on the *taure'are'a* period among rural Tahitians. *Taure'are'a* for Tahitians during the 1960s was very similar to that described for the Marquesans. For girls, *taure'are'a* status converged with menstruation and the development of secondary sexual characteristics. According to Levy, the girls' *taure'are'a* period is less distinctive than the boys in terms of role contrast with childhood norms (Levy 1973, 117-122). For boys, *taure'are'a* status does not begin with superincision, but occurs gradually over the next year or two following it.

In Piri (a pseudonym), Levy notes that most youngsters had sexual intercourse between 13 and 16 years of age. Virginity was regarded as unusual for *taure'are'a* males and females, although shifting demographics, with the migration of *taure'are'a* girls to Papeete, seems to be having an impact on the prevalence of virginity. At the time of Levy's research (1962-1964), the *taure'are'a* male was the initiator in terms of making the arrangements for a sexual encounter (Levy 1973, 122-124).

Douglas Oliver's *Two Tahitian Villages* (1981), historically situated in 1954-1955, offers a detailed ethnography of social life, life stages, sexual behavior, courtship, marriage, and relationships in two rural villages on Huahine and Mo'orea. Oliver's male Tahitian consultants began having intercourse between the ages of 12 and 15 years old. According to Oliver, the standard position was male on top. Male foreplay, which typically lasted from five minutes to half an hour, included: "breast fondling and kissing, clitoral manipulation, and cunnilingus; mutual orgasms were expected and . . . nearly always achieved" (1981, 274).

Night crawling/creeping is a traditional practice that continues even today in various forms throughout Polynesia. It is known as *moe tolotolo* among Samoans and *motoro* among Manganians and Tahitians. There is some controversy among anthropologists as to the function and meaning of this institution. Oliver (1989) regards night crawling/creeping as resulting from sleeping arrangements in which family members shared the same sleeping quarters. It seems to be embedded in the *taure'are'a* pattern for adventure by both females and males.

Night crawling is characterized by the efforts of a young man to sneak into the house of a sleeping young woman and copulate with her without her parents finding out. Apparently, this could be accomplished either with collusion from the young female or without her prior consent. In the latter case, the belief was that the suitor would penetrate the young female while she was asleep; and, if she awoke, she

would enjoy it so much she would not want to scream and alert her parents. Oliver (1989) offers a different explanation, suggesting that the parents may have abetted the situation if their daughter was without suitors by making arrangements for a young man to sneak into their home, and then deliberately catching the couple and forcing them to get married. Levy reported that *motoro* continued among Tahitians in Piri at the time of his research, but that the pattern was on the decline (1973, 123).

### C. Adults

#### *Cohabitation, Marriage, Family, and Sex*

Adult interpersonal heterosexual behaviors, like other aspects of French Polynesian sexuality, must be placed within its cultural context. Oliver (1974, 1981, 1989) has reported that the traditional Tahitians, both premaritally and maritally, experienced sexuality with great joy and gusto, and that this value was expressed in the wider culture through styles of interaction and verbal banter, religion, entertainments, mythology, and so on. This ties in with William Davenport's analysis of the "erotic codes" of Polynesia, defined as those symbolic aspects of culture that "both arouse sexuality and enhance its expression" (1977, 127). Davenport's 1977 essay on "Sex in Cross-Cultural Perspective" is very useful in summarizing this cultural framework and describing intracultural variations.

Marriage was traditionally restricted between individuals by status in the chiefly structure and lineage. Upper ranks were not permitted to marry lower ranks. Formal marriages were relegated to the upper and perhaps middle echelons (Oliver 1989b). Although couples of disparate status were not usually permitted to marry, they could cohabit, although they were dissuaded from having children (Oliver 1974). Divorce was traditionally handled flexibly with the couple returning to her or his own family. They were then free to remarry. There was no formal legal divorce in premodern Polynesia, according to Weckler (1943).

Beauty and sex were closely linked in Polynesia, although in Old Tahiti it was most pronounced. In Tahiti, because large size was a symbol of beauty, higher-ranked boys and girls were secluded, overfed, and prevented from exercise so that they could put on weight. Subsequently, they were displayed in all their pale and fat beauty so as to attract a potential spouse. According to Ford and Beach (1951), Pukapukans also liked plump builds on men and women. Apparently, the Tahitian's value on beauty was reiterated in the belief that a baby could have several biological fathers who would contribute their respective physical traits. Since extramarital, as well as premarital sex was accepted, women would select attractive and athletic young men as sexual partners. In the traditional Marquesas, Ford and Beach (1951) noted that elongated labia majora were considered attractive. Levy has uncovered an ethnotheory of relationships that suggests couples must have a physical compatibility. This is in contrast to one-night trysts in which one person may be as good as another (1973, 129).

In the mid-1950s Aeta and Fatata, Tahitian attractiveness norms favored physical types that were neither too thin nor too fat. Aside from the veiled-bride weddings in which chastity, or at least evidence of strong parental control over the daughter's social behavior, was a prerequisite, previous sexual experience was not unexpected (Oliver 1981, 291-292). See below for Oliver's (1981) typology of Tahitian weddings.

The sexual practices of indigenous French Polynesians include cultural-religious institutions. Gregersen's (1983) review of Oceanic sexual practices makes note of the *arioi* cult. This was an organization of Tahitian men and women

divided into sects, located throughout the Society Islands, who traveled within the archipelago as singers, dancers, athletes, and sexual exhibitionists. Eroticism pervaded the Tahitian songs and dances of the *arioi* entertainers. The *arioi* members were allowed free sexual expression on their journeys, but they were not allowed to marry or have children. This organization was embedded with religious meaning and has been interpreted as a fertility cult. The *arioi* practiced abortion and infanticide, because having children was not permitted for the member. Should an *arioi* become a parent, he or she was humiliated and their participation in the cult limited. The *arioi* were well known for their sexual pursuits with one another and with noncult members encountered on their journeys. Members were selected on the basis of physical beauty and talent that transcended chiefly boundaries to include commoners as well.

Sex and eroticism were made public in other ways as well. Linton's 1939 report of the Marquesans revealed that naked dancing, along with public group copulation, was practiced as part of feasting and festivals as a pre-Christian traditional pattern. Linton disclosed that women would pride themselves on the number of men they had sex with. In ancient times, Pukapukans of the Tuamotu Archipelago would reserve places called *ati*, where men and women could go for sex parties. These were organized by a person who also acted as a guard, to prevent conflict by angry ex-lovers and husbands (Gregerson 1983).

One of Marshall's (1961, 273) Ra'ivavaen consultants contended that, in traditional times, public sex followed men's prayers in the sacred temples. According to this particular consultant, various positions were used, cunnilingus was practiced, and "sperm was smeared upon the face and in the hair as a kind of *mono'i* (coconut oil)" (Marshall 1961, 273; Elliston 1996). Ceremonial copulation was integrated within the spiritual ethos, which, according to Marshall, was saturated with eroticism as a central theme. The erotic was related to fertility, reproduction, and the sacred.

Polynesian societies have been distinguished by a position for coitus at variance from the Western "missionary" position, as the Polynesians refer to the male-prone-above-prone-female position. According to Oliver (1989b), the "Oceanic position" was traditionally far more popular than the missionary position. The "Oceanic position" is one in which the couple sat facing each other. Other positions included the man squatting or kneeling between the woman's legs and pulling her toward him, lying side-by-side facing one another, or with the woman's back to the man's front. In the Marquesas, a sitting position was reported where the woman sat astride the man's lap or assumed a side-to-side lying position. A variety of sexual positions were used, although the woman on top seems to have been the more-prevalent position related to the generalized Polynesian concern for the sexual pleasure of women. The most common position taken today seems to be the missionary position, which is undoubtedly a result of Christian missionary efforts (Gregersen 1983).

Delayed ejaculation for the man was considered a valued expertise in Old Polynesia because it facilitated the female partner's pleasure. Multiple orgasms were valued by both partners in traditional Polynesia as well. Although there was a lesser emphasis on foreplay and more concern with intercourse, the Marquesans were known for practicing cunnilingus and fellatio. Coitus interruptus was also reported among the Marquesans. According to Ford and Beach (1951), the Pukapukans had no preference for sex during the day or at night; each was just as likely.

Kissing among Polynesians is a Western custom. The traditional Tahitian/Polynesian kiss (*ho'i*) consisted of mu-

tual sniffing and rubbing of noses on the face. According to Levy (1973, 128),

kissing on the mouth is still considered a mild perversion. Contemporary Tahitian foreplay according to younger male Pirians includes: "kissing, fondling the woman's breasts, and occasionally cunnilingus." Fellatio was considered a practice of "bad girls" in Papeete. (Levy 1973, 123)

Intercourse among Pirian youth continues the traditional pattern that emphasizes the female orgasm. A man is humiliated by not bringing his partner to orgasm. The role of the clitoris in women's pleasure, as in traditional times, still is part of people's sexual knowledge. In Piri, it is referred to as *teo*. Linguistic evidence provided by the term '*ami'ami*' suggests a precontact focus on eroticism. It is considered a unique capability of some women who can contract and relax the vaginal muscles during coitus (Levy 1973, 128). Elliston (1996) notes that Sahlins makes reference to the Hawaiian term '*amo'amo*' in *Islands of History*, writing: "Girls were taught the '*amo'amo*[,] the 'wink-wink' of the vulva, and the other techniques that 'make the thighs rejoice'" (p. 10).

Surveys on the frequencies of sex for traditional indigenous French Polynesians at various points in history are sparse, although qualitative reports found in the ethnographic literature are available for some of this area. Suggs's 1956-1958 study, *Marquesan Sexual Behavior* (1966), combines qualitative and quantitative data. Frequencies for Marquesan adolescents are sometimes said to be more than ten times in a single night. This may be compared to frequencies for older married couples that are reported of from five times a night to two to three times a week. Questions of accuracy and bias must be considered in evaluating this data. Levy's Pirian male consultants reported that sex occurred daily in the first year or two of a steady relationship, but dropped to about one to three times a week, declining after several years to once every two or three weeks or once a month. A sex-positive attitude is evident as there is no indication of sanctioning of sex among the elderly. Sex continues up to two to three weeks prior to childbirth and is resumed in one to two months. However, sex is prohibited during menstruation (Levy 1973, 125-126).

Data on contemporary sexuality in French Polynesia are not abundant. A sexual survey was considered in Tahiti under Le Direction de la Santé Publique in 1993, but had not been initiated as of early 1997. Spiegel and colleagues (1991) have provided recent sexual data collected between October and December 1990 on 74 sexually active women between the ages of 18 and 44 who were working in bars or nightclubs. It must be noted that this sample is not at all representative of the population at large. The median number of sexual partners among this group was 3 (range 1 to 200), and the median number of sexual encounters was 104 (range 12 to 1,095). This segment of the population is important because of their risk for contacting and spreading sexually transmitted diseases.

Marriage patterns in traditional French Polynesia included monogamy, serial monogamy, polygyny, and polyandry. For example, Oliver (1974) observes that elite chiefs were required to engage in monogamy; lower male chiefs could have two to three wives, although only one wife's children could inherit titles and property. The middle and lower classes of Tahiti were known to have been polygynous. The Marquesas were known for polyandry. An elite woman's household might include a primary as well as secondary husbands (*pekio*). The secondary husbands were subordinate to the primary husband and performed menial

duties, although as members of elite households, they had privileges associated with the aristocracy (Goldman 1970, 142). According to Thomas's 1987 review of gender in the Marquesas, polyandry is better understood as part of domestic relations rather than conjugal relations *per se*. However, Goldman asserts that an unequal sex ratio of 2.5 men to one woman may account for the pattern (1970, 142). Commoners practiced cohabitation rather than the formalized marriages of the privileged classes.

The Marquesans traditionally engaged in a ritual in which the husband was required to have intercourse with his wife almost immediately after childbirth. Following expulsion of the afterbirth, the wife would bathe in a stream. It was believed that intercourse should then occur while the wife was in the stream in order to stifle the flow of the bleeding.

In contemporary French Polynesia, marriage is legitimized by the Church although most people are not formally married. The Protestant Marquesans must be married before membership in the Church is granted. The transition from the secret liaison to marriage signals a dramatic change from youth to adulthood (Kirkpatrick 1983). On Ra'ivavae, Marshall found that of 31 marriages, 29 couples had cohabited (1961, 275). This continues the traditional pattern of premarital sex despite a Christian overlay.

Nonlegalized adoption, a common pattern throughout Polynesia, must be interpreted in the context of the social organization of the family. Kirkpatrick (1983) has noted that the traditional Marquesans had a pattern of large multi-couple households that included not only extended families, but also others not closely related. Such households may have been indicative of wealth. This pattern would also include children whose biological parents were unable to raise them for a variety of reasons. Although this kind of adoption or fosterage is not legal in colonial French Polynesia, it is socially instituted and informally practiced. It represents an old and more widespread Polynesian pattern of fluid adoption that may include close kin, more-distant kin, and even those not directly related.

The trend in the Marquesas in the late 1970s was toward nuclear conjugal family dwellings. This represents the influence of Catholicism as well as broader Western trends. However, the traditional pattern of foster parents and casual adoption still continues today. Kirkpatrick (1983) found that on Ua Pou, 19% of the individuals in the households were unrelated to the household head. Tahitians have a similar pattern of fosterage. Levy reports that 25% of the Tahitian children were not residing with their biological parents at the time of his research (1973, 474-483).

Polynesian childrearing patterns have continued to persist despite the social disruption caused by exploitation, missionization, and colonialism. The Ritchies (1983) have identified several common themes delineating traditional Polynesian childrearing. Among these are fosterage and adoption as part of a wider pattern of community investment in children. Because the community was traditionally composed of lineages of related people, parenting was a collective endeavor, unlike that in the West where it is exclusive to the nuclear family. Howard and Kirkpatrick note that adoption continues today to function as a mechanism to foster relationships between families at the community level and to create alliances at a more macro level (1989, 87). There are economic and ecological implications as well. Adoption of children may help a family with domestic labor since children have certain tasks to do. As they mature, they become important economic contributors for a household. Adoption is also "a powerful adaptive mechanism for equitably distributing people relative to resources, including land, in island

environments" (Howard & Kirkpatrick 1989). In addition, early indulgence of infants was followed by an expectation of autonomy for children beginning around 2 to 3 years of age. Peer socialization began with sibling care and responsibility for younger siblings, and included larger community groups of peers who spanned a broad age range from 2 to 20 years old.

### Extramarital Sex

Extramarital sex was also part of precolonial French Polynesian cultures. The Pukapukans celebrated a successful fishing expedition with extramarital sex. Apparently, women would initiate sexual joking as the men returned with their catch. This was followed by trysts in the bush. Both single and married people participated in these extramarital opportunities with no opposition from their spouse, provided they respected class and incest prohibitions (Oliver 1989b). Among the Tahitians, restrictions on sexuality occurred for upper-class women, sometimes before as well as after marriage, although men and women of common status were free to participate in extramarital sex (Oliver 1989b; Davenport 1977).

There were, therefore, two standards in effect for traditional Tahitians—one for commoners and others, and one for the very elite. Firstborn children, in genealogical lines of firstborns, were regarded as very high ranking and sacred. Purity of the genealogical line was important and controlled through rules against premarital and extramarital sex until, at least, the woman gave birth to a successor. Then, she was permitted extramarital freedom. For example, Douglas Oliver notes that married *ari'i* women were notoriously promiscuous (personal communication with Oliver 1994). Elite women were known to separate from their husbands and to establish their own residence and have lovers (Oliver 1974). Men and women of common status faced no restrictions on extramarital sex (Davenport 1976, Oliver 1989).

On Tahiti, according to Sahlins (1976), a male chief who produced an illegitimate heir practiced infanticide unless measures were taken to alter the status of the mother to be equal to that of the chief. On Mangareva, the chief's power was such that the rule of prohibition against marriage to a first cousin was often disregarded.

Extramarital sex was also institutionalized in the Society Islands in terms of sexual hospitality. Male *taiō* participated in a form of formal friendship relations where sexual intercourse was permitted with one's married *taiō*'s wife. *Taiō* of the opposite sex were not permitted intercourse because their relationship was a social siblinghood and prevented by the incest taboo (Oliver 1974; Ferdon 1981). Sexual hospitality is regarded by some researchers as a widespread Polynesian pattern (Gregerson 1983).

Among the Pukapukans, adultery was believed to cause delayed delivery, and women in such situations were expected to confess (Gregerson 1983, 255). Kirkpatrick (1983) did not find extramarital affairs practiced on Ua Pou, although Suggs (1966) reported that extramarital affairs were common in the Marquesas during his sojourn there. However, according to Goldman (1970, 585) precontact adultery could have dire consequences, resulting in murder by jealous husbands and possible suicide by the wife of an adulterous husband. Suggs (1966, 119-120) reveals that at the time of his research, although adultery was condemned, it still occurred. However, it caused jealousy and hard feelings among both sexes if found out.

Although adultery was the primary cause of breakups and divorce in Aeta and Fatata in the mid-1950s, it was not reason enough by itself. Oliver's Tahitian consultants regarded adultery as something any Tahitian, given an oppor-

tunity, would be likely to do (1981, 317). While church pastors in both villages declared adultery as a sin and cause for expulsion, the Tahitian attitude was more relaxed, reflecting a double standard of greater tolerance of male adultery than female (p. 334).

## 6. Homoerotic, Homosexual, and Bisexual Behaviors

### A. Children and Adolescents

Some Tahitian upper-class men, according to Douglas Oliver, kept boys in their household for sex, although this was not a widespread practice. Suggs (1966, 24) states that homosexual experiences among boys, and possibly girls, were common among Marquesan adolescents.

### B. Adults

Since first colonial contact, the indigenous peoples of Polynesia have been engaged in culture change and transformation. Indigenous systems of homosexual options may be influenced, or even reinvigorated, by the advent of Western homosexual identities. For French Polynesia, it is necessary to point to this complexity in order to understand homosexuality/bisexuality from a cultural perspective that is not a Western-based psychological model.

There were two forms of homosexual behavior in ancient Tahiti. Some Tahitian *ari'i* men, according to Oliver (1989), kept boys in their household for sex. The other context for homosexual expression was associated with the *māhū* status. The *māhū* was a transvestite tradition that included homosexual practices with nontransvestite males. It is important to note that since the *māhū* is a transgendered category, the term homosexual is not really an appropriate descriptor for *māhū* sexuality. Swallowing semen was believed by Tahitians to foster masculine vigor (Gregerson 1994, 274). The indigenous pattern of the *māhū* is not an equivalent to Western subcultural homosexuality or Western transvestism, but was an integrated part of the wider Tahitian culture. The homosexual aspects of the *māhū* status were not its most significant features, but rather it was the cross-gendered aspects of dress and behaviors that identified one as a *māhū*. The *māhū* is reported throughout Polynesia and was found among the Marquesans, where it was very similar to the Tahitian form, according to Oliver (1989). Ferdon (1981) found evidence that the *māhū* began dressing in women's attire while very young. (See Section 7 on gender diversity for further discussion.)

Data on Western-type homosexuality in contemporary French Polynesia is sparse. Chanteau et al. (1986) distinguish the presence of a male homosexual community of Polynesian men that frequented hotels, bars, restaurants, and nightclubs of Tahiti (presumably in Papeete). This population was considered at high risk for LAV/HTLV-III infection by Chanteau et al. who conducted a serological survey. (See discussion on HIV/AIDS below in Section 10.) The population recruited for the serological survey consisted of 50 transvestite homosexuals known as *raerae*. Forty percent of this population had only one partner and frequency of intercourse was once a week. Eighty-five percent of this group had intercourse only once a month. Some of this population had had plastic surgery and female hormone therapy. It is difficult from this report to assess the character of this population, since there are a number of possible gendered identities.

Spiegel and colleagues (1991) collected data from 156 male homosexuals aged 13 to 54 between October and December 1990. The annual median number of sexual partners was 9.5 (range 1 to 600) and the median number of sexual encounters was 156 (range 2 to 5,810). Of this population,

56.4% were transvestites. Unfortunately, it is not possible to place the transvestites in the cultural milieu, as sampling information was not provided by the researchers. Nor is it possible to determine the social identity of the transvestites in terms of the *māhū*, Western gay transvestism, a modern synthesis of both patterns, or some other identity (Williams 1986, 255-258). These transvestites are employed in bars, hotels, and nightclubs. Apparently a *raerae* subcultural expression is found in the Miss Tane and Miss Male beauty contests. It should be noted here that the Western term *transvestite* is not really appropriate in describing the complexity of transgendered identities and homosexualities of French Polynesia.

Levy also records the introduction of the term *raerae* to refer to homosexual and lesbian behavior. While Pirians maintained lesbian behavior (oral and mutual masturbation) did not occur on Piri, it was believed common in Papeete in the bar scene. It was not considered part of a lesbian orientation but rather context-specific. Women who engaged in lesbian encounters were not stigmatized, according to Levy (1973, 139-141), but more-recent research indicates that lesbian lifestyles are problematic in Tahiti (Elliston 1996).

## 7. Gender Diversity and Transgender Issues

In discussing transgendered individuals among indigenous populations, Western-based terminology, such as "transsexualism" or gender dysphoria, are inappropriate, since they refer to 20th-century Western psychiatrically derived categories. The expression of cross-gender or transgender roles needs to be understood in the socio-cultural context and not viewed from the Western perspective as "deviant" behavior. Levy (1971, 1973) has provided some of the most significant research on this subject in his study of the *māhū* of Tahiti. The *māhū* was a transgendered role for males who dressed and took on the social and occupational roles of Tahitian women including taboos and restrictions. According to Levy, the *māhū* tradition has continued from precontact times, although attributes of the status have changed somewhat, so that today the *māhū* no longer cross-dresses, but still engages in work that is considered traditionally female, such as household activities. Levy considers the *māhū* a role variant for men. An interesting parameter of the *māhū* in rural Tahiti is that a man can be "*māhū*-ish" without being *māhū*. *Māhū* are regarded as being "natural," yet one does not have to remain *māhū* throughout the life course. There is a conception of effeminacy associated with *māhū*. *Māhū* are not stigmatized nor are their heterosexual male partners. According to Levy, "a *māhū* is seen as a substitute female" (1973, 34). In Piri, the *māhū* are not believed to practice sodomy, but are fellators of other men.

As mentioned previously, this institution was widespread throughout Polynesia. The *māhū* engaged in fellatio with nontransvestite male partners, but these partners were not considered *māhū* or homosexual. *Māhū* were also reported to have been sex partners of chiefs. This suggests that the Polynesian gender paradigm is one in which sex and gender are discrete categories and the *māhū* identity functioned to highlight gender differences. Levy suggests that the *māhū* may be analyzed as an embodied warning to other males on how to avoid nonmale behavior.

In neo-Tahiti, the *māhū* continues to be regarded as a natural phenomenon. While various explanations are offered for its occurrence, the *māhū* is generally a non-stigmatized status and accepted within wider Tahitian soci-

ety. According to Kirkpatrick (1983), the Ua Pou Marquesans note that there are no *māhū* in their area today because the *māhū* have migrated to Tahiti. Kirkpatrick describes the *māhū* as an ambiguous or disvalued status. The Marquesans also have a more recently introduced term, *raerae*, which is used interchangeably with *māhū*. The Marquesan *māhū* are not considered women, but rather men who want to act as women. The significant attributes for the Marquesan gender paradigm in terms of *māhū* status relate to occupation and appropriate peer relations, rather than homosexual behavior *per se*.

Kirkpatrick (1983) reports on the Marquesan *vehine mako*, or shark woman, which is a gender-variant identity for females. Unlike the *māhū*, the *vehine mako* is not based on relational or occupational criteria. Instead, the shark woman is characterized by an aggressive and vigorous sexuality. The defining feature of *vehine mako* woman is that she is a sexual initiator, an activity defined as masculinity. Thus, both the *māhū* and *vehine mako* are defined in terms of the reversal of gender-role attributes. However, *vehine mako* is not a female equivalent of the *māhū*, or recognized as a form of female homosexuality. Levy regards the institution of the *māhū* as a boundary-maintenance mechanism that identifies the limits of what is considered conventional male and female gender behavior, i.e., masculinity and femininity. Whether this applies to the *vehine mako* must be determined by further research.

[Update 2002: In the text above written in 1996, I raised a cautionary note concerning the use of "Gender Conflicted Persons" as a subheading, which was used then for this section, because of its ethnocentric bias. That caution is even more important in light of the emergence of intersexed and transgendered persons in North America and Europe during the 1990s. It is even more important today that researchers avoid biased and ethnocentric wording that is rooted in the Greco-Roman philosophical dualism of male and female genders/sexes. The concept of "gender conflicted" is intertwined with Western medical/psychiatric derived categories whose applicability in the cross-cultural record remains to be determined. I have suggested substituting the terms "gender diversity" or "gender variance" generally, and the indigenous terms specifically, following Sue Ellen Jacobs recommendation for replacing the term *Berdache* with "two spirit" in reference to Native American gender diversity (1994, 7). The trend among anthropological researchers is to use less "culture-bound" terminology and to seek to understand gender variance within the extant gender paradigm.

[In the original text above, I reported on Robert Levy's (1971, 1973) substantial research on the Tahitian *māhū*. Levy considered the *māhū* a role variant for men, which operated as a negative identity for Tahitians in a society where there was little gender disparity in roles. The *māhū*, according to Levy's interpretation, serves as a clear model of what not to be. Although this research and argument are compelling, it is important to note that this research has not gone unchallenged. In his discussion of "Polynesian Gender Liminality Through Time and Space" (1996, 285-328), Niko Besnier makes a strong and persuasive argument that the *māhū*, although clearly not a third gender as found in the cross-cultural records elsewhere, is nevertheless something more and outside of a variant role for men, as Levy claims. Besnier suggests that the *māhū* is part of a wider Polynesian pattern of gender liminality (threshold) or gender-liminal personhood that occurs within a dimorphic gender paradigm. Besnier makes several important points regarding the Polynesian *māhū* in general, but argues for a historical particularistic interpretation of the *māhū* as gender liminality. He argues that although gender liminality:

is best viewed as a borrowing process rather than as a role or identity, it does give rise secondarily to a rather loosely defined identity. Fundamentally counterhegemonic, it can be a means through which some individuals stake a claim on certain forms of prestige, but at some cost, as evidenced in the low status with which it is associated in the politics of sexual encounters, for example. (Besnier 1996, 327)

[Thus, Besnier takes issue with Levy's functionalist interpretation of the *māhū* as located in Tahitian low sex-role disparity. Rather, Besnier points to a clear division of labor by gender in Tahiti and argues that the *māhū* "blurs gender categories rather than affirms them" in a society where "... gender boundaries are anything but blurred." (Besnier 1996, 307). The question of the character of Tahitian gender roles is an important one that has influenced subsequent research. Thus, Levy's perspective that Tahitian gender roles are relatively androgynous has informed subsequent literature on men's and masculinity studies, such as David Gilmore's *Manhood in the Making*, specifically his chapter, "Exceptions: Tahiti and Semai" (1990, 201-219). Gilmore provides a cultural-ecological explanation for Tahitian gender roles, wherein it is argued that in environs where resources are abundant and where there are no enemies and serious environmental challenges, Tahitian men have nothing to prove and no reason to separate their roles as radically different from women. Besnier (1996) argues against this view that Tahitian gender roles have little gender differentiation and rejects Levy's explanation of the *māhū* as related to androgynous gender roles.

[Besnier regards the *māhū* status as an extremely complex positioning that simultaneously incorporates ambiguity, conflict, and contestation. It is articulated within the Polynesian, and specifically Tahitian, concept of personhood as context oriented (Besnier 1996, 328; Nanda 2000, 70). While Besnier (1996) notes that the gender liminality is porous, it may be adopted as a temporary position. Elliston's research in Tahiti finds that long-term participation in gender liminality facilitates its legitimization (1999, 236).

[While commonalities may occur throughout Polynesia, there are also regional differences that prohibit the view of the *māhū* as a monolithic Polynesian presence, as testified in the work of Levy and Besnier. Indeed, further research is needed to understand regional context, but also the gender crossings with Western-derived identities such as gay and transgender. There is far less evidence of liminal females and that the identity may be of more recent origin (Besnier 1996, 288; Elliston 1999). Indeed, there is little research on this subject, most notably Kirkpatrick's (1993) ethnographic research of the *vehine mako* in the Marquesas, and recently, Elliston (2000) in Tahiti.

[However, Besnier reports "copious early accounts of *māhū* in Tahiti, ... Hawaii, the Marquesas and New Zealand ..." (1996, 294), and argues that there appears to be historical continuity in contemporary gender liminality, although she cautions that this needs more ethnographic and ethnohistorical research. For example, the *māhū*, whether in rural or urban settings, has proclivities towards occupations and tasks associated with women. The *māhū* is thought to have exceptional expertise in these areas. For example, in urban settings, *māhū* demonstrate skill as secretaries and as domestic workers. While some intermittent cross-dressing occurs on special occasions, such as dances, permanent cross-dressing is not reported among *māhū*. However, Elliston's (1999, 236) research indicates that most Tahitian *māhū* men wear a *pareu*, a clothing item worn mainly by women. Gender-liminal persons also span social backgrounds. Historically, *māhū* have been reported as part of chiefly retainers,

acting as confidants to persons of chiefly rank and offering sexual services for male chiefs, although it is not clear if the *māhū* are actually of chiefly rank themselves (Besnier 1996, 297-298).

[According to Besnier (1996, 300), "sexual relations with men are seen as an optional consequence of gender liminality, rather than its determiner, prerequisite or primary attribute." Levy (1973) reports that the Tahitian *māhū* engages in fellatio with non-*māhū* men, who in return view the *māhū* as an accessible and unencumbered alternative to women for sexual release. However, same-sex relations with non-liminal men do not define the *māhū* (Elliston 1999). In contemporary Polynesia, erotic encounters with *māhū* do not commonly occur once a man has married, suggesting that sex with liminal men is a second choice to sex with a woman (Besnier 1996, 301-303). Thus, the meanings associated with sex with *māhū* vary from that of the heterosexual ideal, such that it is "viewed as promiscuous, transient and lacking in significance," contesting Levy's (1973) stance that the *māhū* is "non-stigmatized" (Besnier 1996, 302). Sex with liminal men can be conceived as embedded in wider Polynesian ideologies of illicit sexuality. *Māhū* sexuality is further complicated by Western-style gay identities, known as *raerae*, currently emergent in urbanized areas. This is considered a French importation (Nanda 2000, 65). Both Levy (1971, 1973) and Besnier (1996) offer provocative interpretations of the *māhū* in French Polynesia that deserve careful review before conclusions can be drawn. Serena Nanda (2000) provides an overview in "Liminal Gender Roles in Polynesia" that integrates Levy (1971, 1973), Besnier (1996), and Elliston's (1999) research. (*End of update by A. Bolin*)]

## 8. Significant Unconventional Sexual Behaviors

### A. Coercive Sex

Douglas Oliver's (1974) intensive research could not find evidence of rape in the precolonial Society Islands, and according to J. E. Weckler, "rape is practically unknown in (traditional) Polynesia" (1943, 57). However, today, rape does occur. According to one anthropologist with a research background in Tahitian culture, first encounters with a young girl are often forced by the young man. Levy's consultants argued that *haree* (rape) may have occurred in the past on Piri, but it does not occur today. Levy found no reports of violent rape on the island of Huahine in which Piri is located (1973, 124). More recently, Elliston (1996) reported rape and attempted rape on Huahine and in Papeete.

### B. Prostitution

Oliver reports that prostitution, as defined in the West, was associated with European contact and exploitation of the Pacific. In Old Polynesia, there were opportunities for women in the royal courts to entertain visitors sexually. These positions were not stigmatized in the least. One consultant reports that today, in the Westernized and urbanized city of Papeete, prostitution is not uncommon, although statistics were not available at the time of this writing. Stanley also reported that today there is evidence of male prostitution among some transvestites (1992, 34).

### C. Pornography and Erotica

Information was not available at the time of this writing. The sexual survey of La Direction de la Santé Publique (1995) is expected to address this (see address in Section 12B, Sex Research and Advanced Professional Education, Major Sexological Surveys, Journals, and Organizations).

## D. Paraphilia

It is especially important here to specify the culture of derivation in discussing unconventional behaviors. What is unconventional from Western perspectives is not necessarily regarded so from the indigenous view. Generally, the Pacific peoples have a low incidence of Western categories of paraphilia. In fact, Gregersen's review of the literature of Oceania revealed only the two rather suspicious reports described below. Archival data on which these reports are based may be inaccurate and even fanciful. It is with caution that these are presented here.

According to Gregersen (1983, 1987, 278), among the precolonial Pukapukans, a form of sexual contact with corpses was said to have occurred. In this group, a strong aversion to corpses was expressed in *tapu*. Contact with corpses was prohibited and friends were not even permitted to look at the dead. This *tapu* was mitigated in certain circumstances by the belief that the "grief of a cousin will be naturally so intense that the tabus will be broken—not only by looking at the corpse but even embracing it and sometimes having intercourse with it." This violation of the corpse *tapu* was referred to with a special term, *wakaavanga*. Although contact with corpses was *tapu*, such behavior was expected of cousins. Archival data on which this report is based may or may not be inaccurate and is subject to Western and historical bias.

Gregerson (1983) also notes that sexual contact with animals occurred among the Marquesans when partners were unavailable. Men were known to have sex with chickens, dogs, and even horses, while women were said to have lured dogs into performing cunnilingus on them. However, this account may also be in need of further investigation of its accuracy.

From the vantage of the indigenous peoples of French Polynesia, there was one behavior that was considered sexually deviant. The celibate role of the priest is considered at great variance with male Marquesan ways of being, according to Kirkpatrick (1983). This role is considered distinctive and deviant with the nature of Marquesan masculinity.

## 9. Contraception, Abortion, and Population Planning

### A/B/C. Attitudes, Practices, Teenage Pregnancies, and Abortion

In precolonial Tahitian times of the latter 1700s, discussion of teen pregnancies must be situated within the cultural and historical context. The *taure'are'a* was a period of sexual freedom during adolescence, and this, combined with fosterage, testifies that teenage pregnancy was not problematic and should not be interpreted in terms of Western concerns over teenage pregnancy, where the cultural ideal is delayed pregnancy until young adulthood. It was not unusual among traditional indigenous societies for pregnancy to occur during the teenage years; in many cultures, it was the norm. Today, according to one consultant with Tahitian cultural experience, grandparents may adopt the child, while teenage marriage is much rarer.

The precontact Tahitians practiced infanticide and abortion on occasion. The stratification by class was castelike and intermixing was strictly prohibited. The offspring of parents who were respectively from an upper- and lower-class status was strangled at birth. The *arioi* society members were prohibited from producing offspring, since children would be a hinderance to the many religious activities required by cult membership (Ferdon 1981). Abortion and infanticide were practiced not only by *arioi* members, but also in cases where *arioi* couples of two different class levels conceived. In these

cases, infanticide had no connection with population control, but was practiced instead to counter a violation of interclass marriage. This was tied to the status system in which titles and positions were inherited through chiefly lineages. Infanticide was practiced in situations in which either a woman's child was conceived with a male of lower rank or in which a man's child was conceived with a woman of lower rank. Although, according to Goldman, male infanticide was more common on Tahiti, Marquesan female infanticide was prevalent enough to result in a ratio in which men far outnumbered women (1970, 563).

In the villages of Aeta and Fatata, mixed attitudes were voiced on contraception, although few, if any, used contraceptives regularly. According to Oliver, only "some [from both villages] . . . knew of the existence of contraceptive devices, mainly condoms" (1981, 341).

While attitudes about abortion was varied in these two Tahitian villages, it was generally viewed as the concern of the individual. A folk abortifacient, a blend of green pineapple and lemon juices, was available from older women specialists and believed to cause miscarriage within two months (Oliver 1981, 34).

## D. Population Control Efforts

Information could not be obtained by the author at the time of this publication. See La Direction de la Santé Publique "Sexual Survey" (1995; see address in Section 12B, Sex Research and Advanced Professional Education, Major Sexological Surveys, Journals, and Organizations).

## 10. Sexually Transmitted Diseases and HIV/AIDS

### A. Sexually Transmitted Diseases

In Tahiti, testing for sexually transmitted diseases is available at STD and maternity public clinics. There is a dearth of information on the epidemiological study of chlamydia in the Pacific Islands, with the exception of one study in New Caledonia. Chungue et al. (1988) have examined the rate of *Chlamydia trachomatis* in three populations of at-risk individuals in order to illustrate the importance of specific diagnostic testing for monitoring of this infection. Chlamydia was found in 53% of 53 bar women (ages 15 to 45), 24% of 75 women attending a public maternity clinic for routine care (ages 14 to 40), and 37% of 71 men attending an STD clinic with acute or subacute urethritis (ages 17 to 37).

*Neisseria gonorrhoea* infection was associated with chlamydia infection in 11.4% of the bar women and 18.3% of the men with urethritis. Of the chlamydia-positive women, 58.3% of the bar women and 23.2% of the women at the maternity clinic were without clinical complaints. Eight bar women (15%) were infected with *Trichomonas vaginalis*. This study proves that *Chlamydia trachomatis* is common in Tahiti and warns that asymptomatic women who are chlamydia-positive may be vectors for the spread of the disease. The authors have proposed routine testing for *Chlamydia trachomatis* in STD or maternity clinics.

According to a 1984 public health report by John A. R. Miles, in 1971, three cases of syphilis were reported, but by 1977, the rate was 23 per 10,000. The rate of gonorrhea is 27 per 10,000.

### B. HIV/AIDS

#### *Incidence, Patterns, and Trends*

Several important surveys have been conducted regarding HIV in the French Polynesian population. Chanteau et al. (1986) conducted a serological survey screening for anti-LAV/HTLV-III antibodies using Institut Pasteur and Abbot Laboratories immunoassay kits. Four populations consid-

ered high risk were tested. These included 80 homosexual and transvestite men of low-SES (socioeconomic status); 37 homosexual/bisexual men of Polynesian, European, and Chinese ethnic background of middle- or upper-SES, 35 female prostitutes, and 33 blood-transfusion patients. Four positive results were obtained from the group of 37 homosexual/bisexual men; three Europeans and one Chinese were positive. This group was a highly traveled population that appears to be the source of the introduction of LAV/HTLV-III in French Polynesia. Nicholson and colleagues (1992) measured the prevalence of HTLV-I using the ELISA test and confirmation by Western Blot in 19,975 blood samples from Australia and the western Pacific. No antibody was detected in the 198 sera from the French Polynesian population. However, a 1989 study by Alandry et al., a 1991 report by Spiegel et al., and research by Gras et al. (1992) all report evidence of HIV and AIDS in French Polynesia.

These researchers suggest that HIV was introduced in French Polynesia as early as 1973. Factors contributing to the introduction and spread of HIV include blood transfusions prior to August 1985, tourism primarily from continental France and the United States, and certain groups of individuals whose behaviors put them at risk.

The Allandry (1991) report on HIV is based on data collected over three years. In June 1988, 27,000 HIV tests were given, including to 16,881 blood donors. Of the 27,000, 45 were seropositive; none of the blood donors were HIV-positive. While an additional two children not older than 18 months were HIV-positive, these were not included in the study *per se*. The age breakdowns for the HIV-positive individuals are: 18 months to 6 years, 1; 20 to 29 years old, 24; 30 to 39 years, 10; 40 to 49 years, 8; 50 years and over, 2.

Of the 32 HIV-positive men and 13 HIV-positive women, 22 are of Polynesian ancestry, 19 are European, and 4 are Asiatic. Twenty-two are homosexual or bisexual males (48.8%), 12 are polytransfusions recipients (26.6%), 6 are partners of HIV-positive people (13.3%), 3 are heterosexuals with multiple partners, and 2 are former drug users. Based on this data, the rate of HIV-positives is 2.4 per 10,000.

Only 1 (0.7%) of the 147 homosexuals screened by Spiegel et al (1991) showed a positive result. A subsequent screening of 156 male homosexuals, among whom 56.4% are transvestites working in hotels, nightclubs, and restaurants, and 74 sexually active females working in bars, was conducted between October and December 1990. Among the male homosexuals 13 to 54 years old, 3 (1.9%) are positive for HTLV-I. Among the 74 females 18 to 44 years old, 3 (4.1%) are positive. The median number of sexual partners was 9.5 and the median number of sexual encounters was 156 in male homosexuals, while for the female population, the median number of partners was 3 and the median number of sexual encounters was 104 for the period of October to December 1990. Among the total population of 230 subjects, 2 are IV-drug users, but both are HTLV-I negative. The authors concluded that the risk for HTLV-I infection among male homosexuals is increasing, and the infection is also present in a female population at risk.

Gras et al. (1992) reported on 96 cases of HIV-positive and AIDS-infected persons. Of these, 78% were between 21 and 40 years old, 72 of the 96 had acquired HIV through sexual contact, and 94% live in Tahiti. The sex ratio was 2.8 males to 1 female. Fifty-five percent were Europeans, 38% Polynesians, and 7% Asiatic. Gras estimates the rate of new HIV infection at 20 new cases per year in a French Polynesian population of 200,000, with 150 cases of AIDS per 1 million inhabitants. The rate of prevalence of HIV-positive cases between 1987 and 1990 per 100,000 was a mean of

9.45, a median of 9.65, and the extremes of 7.2 and 11.4. As of June 21, 1993, 30 cases of AIDS were reported for French Polynesia, according to the regional office for the Western Pacific of the World Health Organization (1993, 9). Twenty-two cases were reported for 1979-1990, five AIDS cases for 1991 with a rate of 2.7, and three in 1992 for a rate of 1.6, with no cases reported as of July, 1993.

The ELISA test can be performed in only six laboratories on the Island of Tahiti. A Western Blot confirmation test is required for the HIV-positive cases. HIV-positive patients are provided sex education on condom use, and follow-up of asymptomatic individuals continues for six months. Treatment may be either by a private physician or under the Chef du Service de Medecine du Centre Hospitalier Territorial. A medical exam for the occurrence of opportunistic diseases is also available. Individuals with AIDS may be treated with AZT and pentamidine.

#### *Availability of Treatment and Prevention Programs*

Government policies contribute to the tracking of HIV through readily available testing at hospitals and public health centers. Testing may be done at the following centers: Le Centre de Transfusion Sanguine, Le Centre Hospitalier Territorial, L'Institut Territorial de Recherches Medicale Louis Malarde (Centre des Maladies Sexuellement Transmissibles, Centre de Lutte contre la Tuberculose). La Direction de la Santé Publique en Polynésie Française has been mandated by the Bureau d'Education to teach safe-sex practices. A December 1985 law requires testing of blood donors. In 1986, a consulting commission for HIV was formed, along with efforts at follow-up. Since 1987, condoms may be imported tax-free. In 1990, free and anonymous testing was made available to the public. In monitoring HIV, the French Polynesian Public Health Service and health authorities have implemented HIV-serum surveillance following World Health Organization guidelines. Twenty thousand screening tests for both HIV I and HIV II are done on a population of less than 200,000. Thus far, only HIV I has been found.

[Update 2002: There is very little information on current French Polynesian sexual behavior and HIV/AIDS available, with the exception of high-risk populations of *raerae* and bargirls (Beylier 1998). Confusion over terminology of *raerae* exists in the literature. Anthropologists, including Levy (1973) and Besnier (1996), define *raerae* as Western-style homosexuality in reference to a person "who does not perform a female's village role and who dresses and acts like a man, but who indulges in exclusive or preferred sexual behavior with other men" (Levy 1973, 140). However, in the report *Sexual Behavior and AIDS Prevention in French Polynesia* summarized below, "*raerae*" are referred to as transvestite or transsexual males (1999, 7).

[This confusion was recognized as a problem by the French Polynesian Health Department in its efforts to evaluate and direct HIV-prevention activities for the community-at-large. A study was conducted with the approval of the Territorial AIDS Control Committee in November 1998. The report was published in November 1999 by the Ministry of Health and Research, Health Department, and the Messager Contre le SIDA association, under the title: *Sexual Behavior and AIDS Prevention in French Polynesia. Papeete, Polynésie Française*. The objective of this invaluable research was to "describe sexual and prevention-related behavior in the population residing in French Polynesia and to gather information in an attempt to understand the social logic which leads certain people to protect themselves, but others not, when faced with a possible risk of infection" (1999, 2).

[The population surveyed included 1,043 people, 523 males from 15 to 35 years old and 520 females from 15 to 35 years old on Tahiti, Moorea, and the Leeward Islands. Respondents ranged from those with no schooling through those with senior high school education or higher. All ethnic groups and mixes thereof were included (1999, 6). Areas covered included lifetime number of partners, sexual orientations, first sexual experience, forced sexual activity, recent sexual activity including new partners and occasional partners, social acceptance of infidelity, social acceptance of homosexuality, preventative behavior with regard to AIDS and STDs including condom use over the lifetime, opinions about condom use and other preventative behaviors, screening for HIV antibodies among the population surveyed, knowledge and attitudes about AIDS, sources of information about sexuality, contraception, pregnancy, and abortion, comparing 1993 and 1999, and sexually transmitted diseases. Some of the important findings are listed below:

- “Over the last five years, almost half of young people used condoms during their first sexual experience” (1999, 3).
- The highest level of protection was with those most at risk, those who have intercourse with occasional partners, and homosexual or bisexual men.
- “The non-use or intermittent use of condoms with occasional partners by more than half of the subjects was a particularly high risk” (1999, 3).
- Men were most often the ones to take the initiative in condom use whereas women gave preference to relationship-based models of risk management, which tend to utilize careful selection of partners than on reducing risks with condom use in sexual intercourse (1993, 4).
- “People with little education had less access to prevention information” (1993, 4). Regardless of age group, the cost of condoms was regarded as an obstacle by half those surveyed.

[According to the World Health Organization, 54 cases of AIDS were reported for the years 1979-1996, with no cases reported for 1997 and 1998 (WHO Report 1999, 1). (End of update by A. Bolin)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

### A. Concepts of Sexual Dysfunction

Sexual dysfunction must be considered within the cultural context. For example, sexual dreams with orgasm among Levy's rural Tahitians were thought to be the work of spirits and were regarded as “dangerous” (Levy 1973, 129). The concept of “dangerous” is not translatable as a sexual dysfunction, but neither is it considered desirable.

Hooper (1985, 158-198) collected ethnomedical data in two rural Tahitian communities on the Iles Sou-le-Vent, a group of islands northwest of Tahiti in the 1960s. Indigenous folk medicine continues despite the cultural disruption caused by missionization and colonialism and the introduction of Western medicine. Hooper describes a form of “ghost sickness” with sexual implications. Ghost sickness, *mai tūpapa'u*, is a special category of illness that is believed to be caused by *tūpapa'u*. Such illnesses are characterized by their “bizarre” aspects and can only be cured by an indigenous healer, a *tahu'a*. *Tūpapa'u* is an incorporeal aspect of the self, distinct yet coexisting along with the Christian notion of the soul. Each person has a *tūpapa'u* that can travel during one's dreams. When an individual dies, his *tūpapa'u* continues to remain in the vicinity watching over his kin.

The *tūpapa'u* is regarded as having a personality and can be protective, but also vengeful and playful.

One form of ghost sickness entails visitations from *tūpapa'u* of the opposite sex. While erotic dreams are regarded as encounters with *tūpapa'u* of the opposite sex (no mention of same sex was made) and are therefore not really dreams at all, these are not regarded as problematic if they are occasional and the partners are varied. However, illness can occur if an individual becomes obsessed with a particular visiting *tūpapa'u*. In such a case of ghost sickness, the individual may lose weight, refuse sex with his or her spouse, and may be seen chatting and laughing with invisible *tūpapa'u*. Hooper describes the case of B, who refused sex with her husband. “She would bathe in the evenings, put on scented oil and special clothes, and lie on a separate bed, talking and laughing with a *tūpapa'u tāne* (male ghost).” A healer was called in who “commanded the *tūpapa'u* to leave and never return. B slept soundly for the rest of the night and had no more dealings with the male ghost again. According to . . . the healer . . . the ghost was ‘ripped up’ by his familiar” (Hooper 1985, 178).

Levy's Pirian consultants reported that frigidity and impotence did not occur. The only conditions acknowledged as leading to impotence were illness or getting chilled. The Tahitian theory of sexual attraction may explain this, and clearly points to the importance of a relativistic perspective when regarding Western categories of sexual dysfunction. A Tahitian man who does not have an erection with a woman in an intimate situation, assumes that he must not want to have intercourse (Levy 1973, 128-129).

## 12. Sex Research and Advanced Professional Education

### A. Sexological Research

Sexual research concerning indigenous peoples of the area of French Polynesia includes the work of Richard Levy (1971, 1973), as well as Douglas Oliver (1989ab, 1974), I. Goldman (1970), W. H. Davenport, R. Linton (1939), and R. C. Suggs (1966), among others. In addition, contemporary sex research with a focus on HIV and at-risk sexual behaviors has been conducted by G. Alandry et al. (1989), C. Gras et al. (1992), and Spiegel et al. (1991). La Direction de la Santé Publique conducted a sexual survey in November 1993. The results were to be available in 1995, but were not published at the time of this writing. The interested reader is encouraged to write for the survey. There is no organized advanced education in sexuality in French Polynesia.

### B. Major Sexological Surveys, Journals, and Organizations

A major sexological survey is the following:

Ministry of Health and Research, Health Department, and Messenger Contre le SIDA Association. *Sexual Behavior and AIDS Prevention in French Polynesia*. Papeete, Polynesie Francaise. November 1999.

Journals and periodicals in which sexological information, research, and reports on French Polynesia may be found include:

La Direction de la Santé Publique “Sexual Survey,” Epistat CMRS Laure Yen, BP 611, Papeete-Tahiti, Polynésie Française.

Council Economique Social et Cultural, Avenue Bruat, BP 1657, Papeete, Tahiti, Polynésie Française.

Ministry of Social Affairs, P. O. Box 2551, Papeete, Tahiti, Polynésie Française.

Institut Territorial de la Statistique, BP 395, Papeete, Tahiti, Polynésie Française.

Service d'Information et de Documentation, BP 255, Papeete, Tahiti, Polynésie Française.

Institut Territorial de Recherches Médicales, Louis Malarde, BP 30, Papeete, Tahiti, Polynésie Française.

*The Medical Journal of Australia*, Australasian Medical Publishing Company, 1-5 Commercial Road, P. O. Box 410, Kingsgrove, New South Wales, 2208 Australia.

*Medecine Tropicale*, Institut de Medecine Tropicale, Marseille Armeec, France.

Oceania University of Sydney, Oceania Publishing, Mackie Building, Sydney, New South Wales, 2006 Australia.

*Bernice P. Bishop Museum Bulletins*, 1525 Bernice Street, Box 19000-A, Honolulu, HI 96817-0916, U.S.A.

*Journal of the Polynesian Society*, University of Auckland, Anthropology Department, Polynesian Society, Private Bag, Auckland, New Zealand.

*Journal de la Société des Océanistes*, The Association for Social Anthropology in Oceania.

*The Journal of Pacific History*.

*Pacific Studies*.

*Australian and New Zealand Journal of Sociology*.

### Acknowledgments

I am deeply indebted to Dr. Douglas Oliver who gave generously of his time in reading and commenting on this manuscript. His expertise and many works have been an invaluable source of knowledge and inspiration to me. I would also like to thank Dr. Victoria Lockwood and Dr. Paul Shankman for their helpful suggestions for researching this subject. Dr. Deborah A. Elliston provided an extremely detailed commentary on this paper. Her research among the Tahitians has been critical in this review, as she provided thoughtful and up-to-date feedback. I am grateful to Linda Martindale for manuscript preparation, editing, computer magic, and reference research.

Acknowledgments for updates: I would like to thank Dr. Bruno Hubert, Medecin Coordinateur pour les Maladies Transmissibles, Direction de la Santé, Papeete, Polynésie Française, for making available to me a crucial document for this update: *Sexual Behavior and AIDS Prevention in French Polynesia* (Ministry of Health and Research, Health Department, and Messenger Contre le SIDA Association, Papeete, Polynésie Française, November 1999). Thanks are due to Robert Francoeur for taking on and continuing this admirable endeavor of the *IES* and for being a wonderful mentor and friend. Special thanks to my intrepid Elon student researcher, Hillary Sherman, for locating the recent data on HIV and AIDS in French Polynesia.

## Demographics and a Brief Historical Perspective

ROBERT T. FRANCOEUR

### A. Demographics

Located in central Europe, Germany embraces 137,847 square miles (357,021 km<sup>2</sup>) and is slightly smaller in size than the state of Montana. Denmark and the Baltic Sea mark its borders on the north, the Netherlands, Belgium, Luxembourg, and France on the west, Austria and Switzerland in the south, and Poland and the Czech Republic on the east. Germany's terrain includes lowlands in the north, uplands in the center, and the Bavarian Alps in the south. The climate is temperate and marine.

In July 2002, Germany had an estimated population of 83.25 million. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 15.4% with 1.05 male(s) per female (sex ratio); 15-64 years: 67.6% with 1.03 male(s) per female; 65 years and over: 17% with 0.64 male(s) per female; Total population sex ratio: 0.96 male(s) to 1 female

**Life Expectancy at Birth:** Total Population: 77.78 years; male: 74.64 years; female: 81.09 years

**Urban/Rural Distribution:** 85% to 15%

**Ethnic Distribution:** German: 91.5%; Turkish: 2.4%; other, mostly Serbo-Croatian, Italian, Russian, Greek, Polish, and Spanish: 6.1%

**Religious Distribution:** Protestant: 38%; Roman Catholic: 34%; Muslim: 1.7%; unaffiliated or other: 26.3%

**Birth Rate:** 8.99 births per 1,000 population

**Death Rate:** 10.36 per 1,000 population

Rudiger Lautmann, Ph.D., Bremen University FB 8, GW 2, B 1460 28334 Bremen, Germany; LautmannHH@aol.com. Professor Dr. Kurt Starke, Hauptstr. 6 A, 04774 Zeuckritz, Germany; kurt@starke.luu.net.de. Jakob Pastoetter, Ph.D., Eichborndamm 38, D-13403, Berlin, Germany; Magnus Hirschfeld Archive for Sexology at Humboldt University, Prenzlauer Promenade 149-152, 13189 Berlin, Germany; jmpastoetter@compuserve.de.

(CIA 2002)

**Infant Mortality Rate:** 4.65 deaths per 1,000 live births  
**Net Migration Rate:** 3.99 migrant(s) per 1,000 population

**Total Fertility Rate:** 1.39 children born per woman  
**Population Growth Rate:** 0.26%

**HIV/AIDS** (1999 est.): Adult prevalence: 0.1%; Persons living with HIV/AIDS: 37,000; Deaths: 600. (For additional details from www.UNAIDS.org, see end of Section 10B.)

**Literacy Rate** (defined as those age 15 and over who can read and write): 99%, with 100% attendance in nine or ten years of compulsory schooling

**Per Capita Gross Domestic Product** (purchasing power parity): \$26,200 (2000 est.); Inflation: 2.4%; Unemployment: 9.4%; Living below the poverty line: NA

### B. A Brief Historical Perspective

Julius Caesar defeated Germanic tribes in 55 and 53 B.C.E., but Roman expansion north of the Rhine River was stopped in 9 of the Common Era. After Charlemagne, ruler of the Franks from 768 to 814, had consolidated Saxon, Bavarian, Rhenish, Frankish, and other lands, the eastern part became the German Empire. The Thirty Years' War (1618-1648) split Germany into several small principalities and kingdoms. After Napoleon, Austria challenged Prussia's dominance in the area, but Prussia prevailed. In 1867, Otto von Bismarck, the Prussian Chancellor, formed the North German Confederation. After Bismarck managed the defeat of Napoleon III, he formed the German Empire in 1871 with King Wilhelm I as Prussian German emperor or Kaiser. The German Empire and its colonial possessions reached its peak just before World War I. The Republic of Germany (1919-1933) faced a disastrous economic collapse brought on by war reparations to France and its allies. The National Socialist German Workers' (Nazi) Party came to power with Adolph Hitler in 1933, and started World War II. In the aftermath of the war, Germany was split into an eastern portion under Communist control, and a western democratic republic.

The unification of the Federal Republic of Germany (West Germany—the "Old Lands") and the German Democratic Republic (East Germany—the "New Lands") in 1990 caused serious economic problems for the whole popula-

tion. The long-lasting tension between richer and poorer regions will mask the remarkable differences that have developed in sexual habits. Possibly the unexpected unification, together with the increasing immigration, will lead to new turbulences on the sexual front.

Germany, as well as the predominantly German-speaking countries of Austria and Switzerland, has always received large numbers of immigrants. For many centuries, its geographic situation in the middle of Europe meant that the country functioned as a transit land and clearinghouse for people of other nations. Fascist rule with its tenet of Aryan purification interrupted this mobility for a dozen years and the Iron Curtain for four decades. Apart from these historic peculiarities, the German-speaking countries have always fulfilled the paradox of a “cosmopolitan province.” Exportation and importation of ideas and persons created a melting pot. Diverse cultural traditions and ethnic backgrounds currently form a contradictory mixture, apparently productive as well as unstable.

In this region, the following events occurred within the 20th century: the invention of sexology, a sexual repression of extreme cruelty, and most recently, a fundamental sexual liberation. The leadership in sexual reasoning was suddenly lost when the Nazi government annihilated the symbiosis with the Jews, who until then had fruitfully and uniquely assimilated themselves into German culture. The leaders of German sexual science included Albert Moll (1862-1939), Iwan Bloch (1872-1922), Magnus Hirschfeld (1868-1935), and Albert Eulenburg (1840-1917). The German-speaking sexual science has never recovered from this loss of genius.

## 1. Basic Sexological Premises

### A. Character of Gender Roles

The structure of and changes in gender differentiation in Germany resembles that of other Western countries. The long-term trend, since the first feminist movement in the 1880s, exhibits an egalitarian tendency with regard to political, economic, as well as sexual participation. The trend was interrupted by the Nazi regime, which tried to push women back into household and nursing activities. The policy of “a child as a donation to the Fuehrer” was a remarkable failure. World War II brought women back into the industrial workplaces and to autonomous decision making in all social domains.

Today, there are many endeavors to emancipate women (and, possibly, men). Political rights and the wording of laws and official texts are strictly gender neutral. Affirmative action, quotas, governmental subsidies, and similar programs support and proclaim an egalitarian policy. But there are numerous barriers to putting these incentives into everyday practice (Lautmann 1990). Equality remains a task for generations to come. Still, the actual progress—sometimes in the economic, but mainly in the private sphere—is noteworthy.

### B. Sociolegal Status of Males and Females

Jurisprudence says that every human being from birth on is granted a status as a person with their own rights. Attention is even paid to children’s decision making, according to their level of maturity. Family jurisdiction has to orientate itself around the child’s welfare as its highest principle. Corporal punishment is strictly forbidden, abrogating a traditional customary right of adults. In practice, the children’s autonomy contradicts their factual dependency and older ideas of “parents’ property” and parental rights.

Formal education is gender neutral. Girls and boys are given equal opportunities at schools. The principle of coeducation has been implemented thoroughly. Some feminists

are currently recommending a partial return to gender-specific classes in order to overcome certain problems in the learning of mathematics and technical subjects.

After puberty, men and women enjoy a high level of sexual autonomy. Some youngsters leave the parental house before majority (age 18) to share a flat with other adolescents.

The perception of gender roles is clear for many adolescents. They fixate on these roles, while other factors and, above all, their individuality, are neglected as one-sided. The actual or intended relationship between men and women is partly seen as threatening, especially in the west. The proportion of women with a habitual feeling of disadvantage on account of their sex is much greater in the west. At the same time—and this only appears to be a contradiction—girls in the west also reflect the advantages of their sex more than girls in the east.

Adolescents in the east see themselves to a lesser extent than in the west as men or women, and experience relations between the sexes as less conflict-ridden. Feminist thinking was hardly disseminated in East Germany and did not influence girls as they grew up to develop a critical perception of men, who in turn did not experience a resulting feeling of insecurity. They attribute events in their lives, their success and failure, less to their membership of one of the sexes and more to their overall personality.

[Update 2001: In terms of *Gleichstellung* (the promotion of equal status of men and women), the percentage of women in jobs increased from 47% in 1960 to 56% in 1998. However, in 1989, 81% of the women in the German Democratic Republic had a job. After the *Wende* (Union), the percentage of working women in the New Lands (former East Germany) decreased to 74% in 1995 because of a high unemployment rate.

[Although the percentage of women with *Abitur* (the highest school diploma) increased from 32.8% in 1950 to 39.4% in 1975 and reached 54.1% in 1998, and the percentage of female students at universities increased from 19.7% in 1950 to 44.3% in 1998, Germany still has few women in management positions. German women experience no discrimination in their academic or training period. They also do not have problems securing a good job. However, some time between their 30s and 40s, especially qualified women do experience an “invisible glass ceiling” and their career advancement stops. Because lower positions in the corporate hierarchy receive proportionately lower compensation, the “glass ceiling” means that women in the Old Lands (former West Germany) earn about 78% of the gross salary per hour that men receive. In the former East Germany, where many more women held full-time jobs and were paid equally before the Union, their salaries are now about 89.9% of male compensation. Although the share of female professors at German universities increased in the 1990s, they still constitute less than 10% of all professors. Only 5.9% of the university professors in the highest and best-paid rank of C4-professor are women.

[In recent years, more and more German women have formed networks to overcome the difficulties of an employment world that is marked by male interests and male work structures, like long work hours and few possibilities to combine job and rising children at the same time. In the 1990s, the number of “contact markets” and support groups for women organizing for equal rights in the business world increased from 75 to more than 300.

[Gender equality has also not penetrated family life. Although possible paternity leaves are often available to men, only 1.5% of *Erziehungsurlaub* (unpaid vacation with job guarantee) are taken by men. Men cite a variety of reasons for their disinterest in these leaves, including fears of dam-

aging effects to their career, possible loss of their job, and the financial cost of an unpaid leave. German women can expect little help when it comes to running the household: 58% of working women between ages 25 and 45 say that they have to care for the household and children; the same is true for only 10% of men in the same age group.

[After the European Court decided early in 2000 that women cannot, in general, be excluded from armed units, the Ministry of Defense proposed that all careers in the armed forces would be opened to women beginning in 2001. As of 2000, women accounted for only 1.3% of the German Army, 4,300 out of 340,000 in active service, and these women were only in medical and musical units. (*End of update by J. Pastoetter*)]

### C. General Concepts of Sexuality and Love

In Germany, the basic ideologies and configurations of the erotic world do not differ very much from those found in western and northern Europe and in the WASP population of the United States of America. With respect to sexual behaviors, the most important cleavage runs between the two principles of Romantic Love versus Hedonism. Romanticism binds together personal love and sexual attraction. Without a "harmony of hearts," no orgasmic fulfillment is possible. This principle is founded in the Christian idea that the spiritual community dignifies the genital encounter. The prosaic concept of hedonism emphasizes the erotic quality of the body and the satisfaction of desires. The sexual drive is a natural need. One may give way to it without making many preconditions, calculating only costs and gratifications.

Similarly, there are two ideal types of intimate partnership. *Affective solidarity* is the principle of a stable and universal relationship between two human beings whose individual disparities are balanced through a mutually complementary performance. On the other hand, *contractual partnership* is based on a calculation of mutual benefits. The relationship lasts as long as the balance remains positive for both participants. The contractual element allows for negotiations about sexual relations.

Sexual phenomena are generally conceptualized from a naturalistic point of view developed in the 19th century. The average person and most experts—outside sexology, of course—follow a version of naive biologism that reflects this naturalistic viewpoint. In this view, innate programs, hormones, and so on direct the sexual response. Psychoanalytic and sociological approaches are not prominent, with the exception of a behavioristic learning theory.

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A. Source and Character of Religious Values

Since the Reformation in the 16th century, Germany has been the arena of fierce conflicts between the two main religious denominations, including long wars. Not until the 20th century could the two churches find an arrangement for coexistence—today 45% of the population are Protestant and 35% Catholic. A growing proportion of the population has left the Church—roughly 18%—and even more are only nominal members without much belief (but still paying the not-so-insignificant Church tax).

Thus, the sexual morals of Protestantism and Catholicism exist side by side with all their differences and similarities. Many surveys show that the sexual teachings of the churches do not effectively direct the behaviors of the sexually active population, although they may have some effect on the attitudes. Instead, the churches exert a considerable influence on sexual politics. They are accepted as an expert voice in moral debates, but to a diminishing extent. In the

new, controversial legislation since 1970, no-fault divorce, liberalization of abortion, and sexual autonomy, the ecclesiastical positions were overruled.

### B. Source and Character of Ethnic Values

The current growing immigration rate, which includes, for example, 1.7 million Turks now resident in Germany, may lead to new conflicts. The Islamic and paternalistic view of family values, gender differentiation, same-sex relations, and the like is opposed to the secularized Western view. Immigrants of the second generation experience tensions between intra- and extrafamilial worlds. Moreover, in combination with low social prestige, an explosive mixture arises, bursting with violence against women, gays, and other persons defined as weak.

## 3. Knowledge and Education about Sexuality

### A. Government Policies and Programs

The parental family and the school have the mandate to give the necessary instructions about sexuality. To a certain degree, both institutions are reluctant to perform that task. They mutually suspect each other of being inefficient in advising and/or of being dangerous with respect to the contents. Sex education, if publicly discussed, immediately becomes a political controversy, where the right-left continuum corresponds to the poles of repressive versus emancipative doctrines.

School curricula provide for the instruction of sexual issues from the first elementary class onwards. Since there is no special course, the matter can be addressed in various fields, such as biology, religion, politics, and so on. The outcome, in spite of existing detailed syllabi, is a sporadic sex education. The teachers think of themselves as not being competent enough. As a matter of fact, the academic training is entirely insufficient; only a tenth of the pedagogic students are offered suitable courses. The parents' attitudes are of a similar uncertainty. They hesitate to speak frankly to their children; and many parents wish that teachers would refrain from doing so (Glueck 1990).

### B. Informal Sources of Sexual Knowledge

As in other Western countries, the mass media and peer-group conversation are the primary sources for spreading sexual knowledge. The censoring of magazines, books, and films does not occur, except for pornographic material. There are laws to prevent minors from being exposed to sexual matters, but the general media are full of instructive articles and illustrated stories. Public television has developed a high standard of feature programs dealing with sexual issues. Sex-related problems and questions are presented to audiences and discussed by experts. Presumably, these widely watched features and talk shows have raised the level of knowledge and value consciousness about most variants of sexuality.

## 4. Autoerotic Behaviors and Patterns

Nine out of ten men and seven out of ten women in Germany admit to having performed masturbation. Female activity in this field has been rising rapidly within the last decades (Clement 1986). Boys start mostly during puberty, girls during adolescence. Today, the majority of parents and teachers accept masturbation of young people as a normal and important experience (Glueck 1990).

The social construction of masturbation has undergone a radical change during the 20th century. Around 1900, the meaning of masturbation was associated with ideas of pollution, removing sexual tensions, depletion, risks for health,

and moral dangers. Today the meaning of masturbation is principally satisfaction, to work out sexual fantasies, and to maintain inner balance; it bears no risks for physical and moral development. What has been considered to be a surrogate is now appreciated as a sexual expression in its own right.

### 5. *Interpersonal Heterosexual Behaviors*

The following findings are derived from various investigations of a social-scientific and sociosexual nature—in particular the relationship studies headed by Kurt Starke among 11,313 people aged between 16 and 48, and an east-west comparative survey of youth sexuality (Starke et al. 1984-1989; Starke 1991; Starke et al. 1993).

#### A. Children

Children explore each other's intimate parts in games like doctor/nurse-patient. Even if informed parents know what their children are doing, these games are surrounded by a certain suspicion that they may be too early, or the fear that the children may become oversexualized. Picking up on these silent messages, the children tend to hide their encounters and games from their parents. Since there is no discussion of the morality of these activities, and their expressions have not been subjected to empirical investigation, one knows very little about their reality.

#### B. Adolescents

##### *Puberty Rituals*

No significant rituals mark the passage from childhood to adolescent or young adult.

##### *Premarital Sexual Activities and Relationships*

Nowadays, young people become sexually mature on an average of three years earlier than at the beginning of the 20th century; menarche occurs at approximately the age of 12.8 years, while the ejacularche takes place at around the age of 13.9 years. This physical acceleration has been accompanied by a mental acceleration marked by the earlier inclusion of adolescents in adult society in terms of consumption and information. Young people now have a more dynamic lifestyle; their plans for life are becoming more diverse and open and, at the same time, more short-term and unpredictable. The perspectives of life are expanding with the increase of not only opportunities and alternatives, but also risks and imponderables. Sexual behavior, which is an integrated part of a personality's all-around behavior, is thus social behavior, and is learned in the same way. Sexual self-discovery, the search for a partner, and partner relationships represent important socialization factors and promote the personal development of adolescents.

Ninety percent of Germans at the age of 16 have already been in love. This feeling of being in love quickly brings with it an urge for reciprocation and the establishment of a pairbond. Infatuation without trying to organize further contact or vigorous efforts to achieve interaction are no longer characteristic. Being in love is not suppressed, hidden away, or enjoyed secretly, but is institutionalized (as long as mutuality is present).

Adolescents in Germany enter into steady relationships at an early age. About 80% of 16-year-olds have experience of a relationship, and at any one time a quarter of the males and half the females aged 16 have a steady boyfriend or girlfriend. This proportion used to be higher in East Germany. These days, young males in particular want to live without firm ties for the present, preferring to wait a while so that they can be open and flexible when planning their lives and careers. They do not necessarily long for the joys of having a partner and would rather avoid any risks, hassle, or pres-

sure. However, even among those not currently involved with a long-term partner, the majority yearn for love and desire a steady relationship.

This is not merely the case among youngsters, but also true of older unattached people. The main reasons for being involuntarily single are that Mr. or Miss Right has not yet been found, or that one has not yet gotten over a recent broken relationship. People often hold themselves responsible for this; they expect too much or have contact problems and are less likely to see the causes in the objective circumstances of life. Those who are voluntarily single explain their lifestyle particularly by a shortage of time and the pressure to achieve good results at school or work. A good quarter of the males and exactly half of the females with no fixed partner say that they do not want to give up their sexual freedom, or even their freedom as a whole.

Emotional bonds in steady relationships are close. Even at the beginning, phrases like "I don't know" or "a feeling of ambivalence" are almost never used to describe emotional ties, and "we like each other" only occurs rarely; "being in love" or more commonly "love" are the order of the day. Most young Germans only enter into a bond and seek closeness and intimacy when they can classify the relationship as "love." Both males and females have a mental attitude of expectation and then a feeling of certainty that their partner is also at least as equally committed as they are. Finding a partner purely out of boredom or loneliness, in order to bolster one's own self-confidence or prestige, or for other reasons—sexual, for instance—has become completely untypical.

Relationships among adolescents are, as a rule, romantic attachments of a high standard and of very definite qualities. The dominating and overriding criterion, and simultaneously, the chief motive for the establishment of a pair group is mutual trust. This includes being able to trust one another, mutual empathy, harmony of the heart, mental and physical communication, and affection—all connected with mutual respect for the other person, recognition of her or him as an individual, and the acceptance of the other's need for personal freedom. By contrast, differences in desires, quarrelling, fear of the other, the domination of one partner by the other, latent or actual interference in the other's affairs, and chiefly sexual liaisons are immediately regarded as negative and detached from love, and are rejected as unbearable.

It is not "any old relationship," but love that characterizes young couples. Love is also verbalized: Around 90% have already told their partner they love them and have, in turn, themselves heard the phrase "I love you." Young love in modern Germany, both in the east and in the west, is not silent, but rather a communicative relationship.

The romantic question, "Do you wish to spend your whole life with your partner?" was answered by half of the males and females asked in both eastern and western Germany with a hearty "Yes." However, a difference is to be observed among the other half. Whereas in western Germany, the more common answer is "No," those asked in eastern Germany give the answer "Undecided." This corresponds completely to a general strategic concept of life in the eastern regions—most youngsters, around 80%, want to remain with one and the same partner as long as possible, while the remaining 20% plan partner mobility. Hardly anybody wants to abstain from having a relationship their whole life long.

##### *Love as Condition for Sexual Intercourse*

Throughout Germany and equally among the sexes, love is not only the most important motive for a relationship, but also the decisive condition for sexual intercourse. Sexual intercourse without love is, particularly among females, just

as much of an exception as anonymous sex. The major sexual experiences are not exotic and anonymous (although such do occur), but are shared by young people with a chosen partner. A steady romantic attachment is regarded as the ideal setting for sexual activity. In this sense, love and sex closely belong together in the thoughts and feelings of German adolescents. Despite the variety of lifestyles and current exceptions, their real behavior and sexual experience, their hopes and fears, and the prospective meaning of life and probable disappointments, are also determined by it.

A renaissance of romantic love is currently to be observed in Germany. In both east and west, the ideal of the one great love, exclusive and lasting a lifetime, is predominant. Adolescents do not fall in love temporarily or in order to try it out—they search for a steady, lasting relationship and devote themselves completely and unconditionally to their chosen partner, to whom they also intend to remain faithful. The ideal of eternal love is supplemented by the ideal of current fidelity. Partner mobility consequently does not represent a rupture of the idea of love and faithfulness, but a consequence of it (see the second subsection under Section C, Adults, below for a discussion of partner mobility). Similarly, the modern unwillingness to form close ties cannot be regarded as a countertendency. It, too, is a consequence of the ideal to allow oneself to get involved with just one particular beloved and loving partner.

### *First Coitus*

Romantic attachments quickly lead to sexual contact, including sexual intercourse. Longer-term phases of petting for its own sake are uncharacteristic, especially in eastern Germany. The first instance of sexual intercourse occurs among approximately half of males and females within the first three months of their going out together. Almost all adolescents tolerate premarital coitus and also practice it. Virginity is not regarded as a stigma, a success, nor as something special to be preserved. Sex has freed itself from the institution of marriage, but not, however, from a romantic attachment.

The first instance of sexual intercourse is based on love or being in love and 75 to 85% of the time takes place within a steady relationship. It is only rarely that sexual intercourse first takes place anonymously, by chance, or casually. Although the general tendency is for partners to be of the same age, the first coitus partner (especially among the girls in eastern Germany, who also start earlier) is usually a little older. The older partner, usually male, in many cases is equally sexually inexperienced.

Eight percent of 17-year-old males with experience of coitus from western Germany have had sex with a prostitute; the corresponding figure for males from East Germany is 0%. But, experience with a prostitute is almost never the first experience of sexual intercourse. Ideally, the intimate partner is the object of one's love, making the first instance of sexual intercourse an event that is mutually striven for and desired by both parties. If this is not the case, then young people would rather abstain from sexual intercourse.

The average age at which young males and females have sexual intercourse for the first time, about 17, has remained constant for about a decade. One difference that is to be observed is that boys in western Germany and girls in eastern Germany start somewhat earlier; in fact, one third of the latter have their first experience of coitus before their 16th birthday. Members of the lower classes start particularly early in western Germany, whereas the upper classes and future intellectuals are somewhat slower.

In both eastern and western Germany, young people have a place where they can be with each other undisturbed, ex-

change affection, and sleep together; this is nearly always their own room in the parental home or else their partner's home. Adolescents usually enjoy a close emotional relationship with their parents. The mother, and to a lesser extent the father, is the chief person in whom young people confide and the preferred communication partner, including in matters of love. Two thirds of young males and females say that they can often talk to their mother openly about sex. By contrast, communication between father and daughter is often either disrupted or only rarely touches on intimate topics, and only one quarter of daughters can talk openly with their fathers about sex. Most parents accept their children's partner relationships, allow them to sleep together, and know about their sexual contact. Sex does not take place somewhere outside in secret, but cozily in one's own bed.

## C. Adults

### *Premarital Courtship, Dating, and Relationships*

Men and women aged 22 have sexual intercourse around nine times a month; the frequency among 17-year-olds is six or seven times (six times for males, eight times for females). The figure falls only marginally among the over-30s and over-40s. Psychological and social factors are mainly responsible for intrapersonal and interpersonal differences in the frequency of sexual intercourse, especially the nature of the relationship, as well as external circumstances, such as separation from one's partner and living conditions. People who are happily in love have sexual intercourse more often.

The proportion of women experiencing orgasm increased sharply in the 1970s. About 75% of 16-year-olds, 90% of 18-year-olds, 95% of 22-year-olds, and 99% of 27-year-olds have experienced orgasm. The rate of orgasm during sexual intercourse and other intimate behavior has also increased. The sexual satisfaction of both men and women is judged as an invariant component of sex within a relationship. Affection is the most common aspect associated with love and sex, and sexual sensitivity is expected and appreciated. Sexual contact without a feeling of desire is generally not even undertaken by women.

Young women and men have partnership concepts of sexual relations and want their partners to be desirous of sex as well. People still experience being forced or pestered, and this is regarded as harassment; however, pestering or force have since come to contradict the morals of most young men. The initiative for sexual intercourse hardly ever comes from the man alone, and, in fact, it is now more common for the woman's desire to be decisive. Sexual interaction in a relationship among young people is rarely controlled by the male, but quite often by the female.

One in ten acts of coitus takes place outside a steady relationship. Four out of ten adults have had sexual intercourse with somebody else during their current relationship. In the 1980s, sexual contact outside the main relationship became more common—this increase being especially true of women—and the number of females experiencing sex outside their steady relationship quadrupled in this decade (whereas the figure for men merely doubled). There are no differences in this respect between married and unmarried people. Men have had an average of seven sex partners; women have had five on average, with a fifth having had only one and another fifth having had more than five. Apart from sex, other factors that affect the various numbers of previous sexual partners include conditions of origin and development, as well as of age. Furthermore, partner mobility is higher in an urban environment than in rural areas. In the past year, three out of ten men and two out of ten women have had more than one sex partner. Younger women are more mobile than older men.

The frequency of orgasm has not changed in keeping with sexual liberalization, but the attitude towards it, its experience, and its function within a relationship have changed. The sexist emphasis on male and female potency measured in terms of orgasm has become fragile, and the compulsion to have orgasm is being resisted. There is a growing aversion to orgasm achieved with all manner of tricks and used as a measure of male or female performance, celebrated as a victory in joint conflict, and feared as a stress-obsessed prestige event. Instead, the individual quality of a steady relationship is sought, linked with closeness, trust, warmth, carefree pleasure, and unpredictable, uncalculating, uncalculated affection within the total erotic form. Cuddling is back in fashion; compulsive or cheap commonplace sex is out.

There are many common aspects in partner and sexual behavior between western and eastern Germans. However, noticeable differences continue to exist. These differences are not so much on the level of behavior as on the level of desire, the experience of sex, and sexual attitudes. More eastern than western German females look forward to their first sexual intercourse and they start somewhat earlier. Sexually inexperienced boys and girls in eastern Germany clearly want to have more sexual experiences than those in the west. Females from eastern Germany begin sexual relations earlier than those of the same age in the west. Western German males, on the other hand, link sexual intercourse more firmly than males from eastern Germany to a steady relationship; then again, twice as many have sex with occasional partners. It is possible that they are quicker than eastern German males to detach sexuality from a person or relationship, at least occasionally.

More adolescent females in eastern Germany regard their sexual activity to be gratifying and enjoyable. This refers both to masturbation, which they experience with more pleasure, and especially to sexual intercourse. About 30% more young females in the east say that their latest incidence of sexual intercourse was enjoyable, was sexually satisfying, was a great experience, and that they were happy. The differences are not the frequency of orgasm, but rather the sexual experience, the joy of sexual arousal, the subjective quality of the entire erotic form, and the feelings of happiness experienced during intimacy. In both eastern and western Germany, young females are less appreciative of their latest incidence of sex if they did not achieve orgasm; however, the experience of eastern girls not experiencing orgasm is hardly less positive than that of western girls who do experience orgasm. In the west, some adolescent females feel sexually unsatisfied during sexual intercourse and are not happy, even though they had an orgasm. In eastern Germany, on the other hand, women are also sexually satisfied and happy, even if (on the last occasion) they did not experience orgasm. They are apparently less "fixated" on the orgasm, but are by no means less able to achieve orgasm. On the one hand, female adolescents in eastern Germany are more "conservative," in the sense that they (without disregarding other forms) are more strongly centered on sexual intercourse and orgasm with their lover. By contrast, they are not so strongly centered on the "autonomous" orgasm. At the same time, they are more "liberal," as they begin earlier than their western German counterparts. In addition, it can be seen that among eastern German adolescents, virtually all the differences between the sexes, as regards the experience of sex is concerned, have been dispelled, whereas they continue to exist among western German adolescents.

### *Partner Mobility in Lifestyles*

Four tendencies in the pattern of relationships that individuals adopt are to be observed:

1. **Serial Monogamy**—having a succession of steady relationships, especially at a young age. This is part of learning exercised by young people as they mature. It is connected with practicing partnership and sexual behavior—the search for the optimal liaison with high demands being made on its quality. The high demands also lead to the end of one relationship and the commencement of the next. This succession of relationships is an expression of increased sovereignty in the treatment of sexuality as the basis of social developments, which have led to a liberalization of sexual norms. Changing one's partner one or more times during the course of one's life is connected to the ideal of the unity of love and sex. Such a romantic love morality adheres less and less to the traditional model of life-long marital monogamy, even though, or precisely because, great importance is attached to faithfulness within each relationship.
2. **Sexual Nonexclusivity**—sexual relations are entered into outside a steady relationship, either occasionally or continually. One reason for this—along with a thirst for adventure, an urge to undergo new experience, curiosity, and many other factors—is an unsatisfactory sex and emotional life in the primary relationship. This behavior has increased in the past 10 to 20 years, something that should be neither celebrated as an expression of libertarian norms, nor condemned as a violation of the traditional command of exclusive monogamy. It is self-contradictory and, above all, a product of the problems of long-term relationships. Having sex outside a relationship has traditionally been a male privilege. However, in modern society, where women enjoy a considerable amount of emancipation and independence, particularly in the professional sphere, the situation has been balanced out. Sexual contact outside the primary relationship almost always takes place with close acquaintances or friends. Anonymous sexual contact is a rare exception and is usually rejected.
 

By and large, a moral assessment of either item 1 or 2 above cannot be based on the number of partners. Neither large nor small quantities of partners can provide a general expression of quality, performance, stability, satisfaction, or happiness. In addition, people's personalities and their activity in life's various situations are too different. If one follows these findings, then the appeal for fidelity in view of AIDS is just as justified as it is out-of-touch and repressive. Partner mobility alone does not constitute a risk in terms of AIDS, especially when the comarital relationships involve intercourse more than intercourse, as frequently occurs in such responsibly nonmonogamous relationships, as couples move beyond the raging hormones of youth. Hardly anybody sacrifices happiness in life for the sake of abstract faithfulness.
3. **Commercial Sex**—new partners can easily be obtained in the form of disposable items without the assumption of mutual responsibility, and lust can be quickly satisfied without any complications. Although forms of male prostitution exist, mainly for homosexuals, but also for women, female prostitution is the predominating form. The entire sex industry, including pornography, is chiefly aimed at men, and as a result, these sexual relationships, including long-term relationships and regular clients, are far more common among men than among women.

In terms of prostitution, men can be divided into three habitual groups. The first group has no contact whatsoever with prostitutes, the second visits prosti-

tutes occasionally, while for the third group, prostitution is an integral part of their lives. These groups are clearly separated from each other in terms of their sociological and psychological profile, and the borders dividing them are not fluid. The size of the groups varies among the various social subgroups, and also geographically.

4. Promiscuity. This refers to the very frequent change of sexual partners and the lack of a steady relationship. Further forms of partner mobility within a steady, long-term relationship include partner swapping and group sex.

### [The Single Life

JAKOB PASTOETTER

[Update 2002: In 1999, only one in 25 Germans lived in a household with five or more individuals, while at the beginning of the 19th century, 44% did so. In the same time span, single households quintupled. In 1999, 36% or 13.5 million Germans were living alone. A third (12.6 million) were living with one other person, 15% (5.6 million) were living with two others, 12% (4.4 million) with three others, and only 4% (1.7 million) in households of five or more. Most of the latter are located in small communities of less than 5,000 people; most of the former live in the big cities with more than 500,000 people. Nearly half of the 1.2 million Berliners between 25 and 45 are single. In all of Germany in the early 1990s, 20% of Germans between ages 25 and 35 lived in a single household; in 2000, this rose to 25%. It appears likely that by 2010, a third of this age group will be living alone. In 1998, 17% of all children under age 27 lived with a single parent.

[Since the 1970s, Germany's modern postindustrial society has resulted in growing abundance, plenty of apartments, increasing urbanization, decreasing importance of marriage, sexual liberalization, integration of women into the workforce, increasing pressure for mobility to get a job, and last, but not least, better education for more people. Single females are more likely to earn the highest academic degree (*Abitur*), have a job, and a higher paid one. Single males and females live in bigger apartments than their married peers. Interestingly, they have about the same social network as married couples, and keep closer contact with their parents. In the New Lands, only 15% to 30% enjoy their single lifestyle enough to not wish to find a partner. Nearly half of them are convinced that it is important to have a family and children. One third experience the single lifestyle as being forced on them.

[Not being married or cohabiting is a high-risk factor for little sexual activity. In the New Lands, the 20- to 30-year-olds have sexual intercourse less often than the 50-year-olds. Ninety percent of all heterosexual sex acts take place in long-term relationships. About 50% of singles have no sex at all, according to the most recent survey by Gunter Schmidt (2000). Eighty percent of people in a steady relationship described the quality of their sexual relations as "high," in comparison with only 40% of the singles. As Schmidt notes: "The sexual world of the singles is rather depressing; they spend lots of time, energy, and money for little sex, and this sex is not very satisfying." Besides sex, the other major problem is loneliness. Here one finds that men have a harder time dealing with loneliness than their female counterparts because of their less-developed social and emotional skills, and their inability to make their apartment *gemütlich* (cozy).

[Catchwords and headlines like "Onianisation of Sexuality" (Alexander Schuller) and "Does Society Break Up into a Bunch of Masturbating Monads?" (*Der Spiegel*) reflect the uncertainty of German society in dealing with this development. The "Pioneers of the Modern Age" (Ulrich Beck),

once stylized as self-picked masters of the art of living, are now seen as narcissistic egoists unable to act responsibly. Although the number of longtime singles is quite high, the truth might be in between, since many are only living temporarily as singles. In 1991, 47% of the 25- to 55-year-old singles had had no partner for more than six years, 18% had been alone for four or five years, 20% for two to three years, and only 15% for a shorter period. (More recent numbers are not available.) (End of update by J. Pastoetter)]

### [Singles in Their Later Years JAKOB PASTOETTER

[Update 2002: A certain uneasiness exists regarding aging. In the near future, hundreds of thousands of singles will reach an age where traditionally younger family members take care of the older members. Although Germany has had a national nursing insurance for several years, many doubt it is sufficiently funded. Voluntary solidarity communities are an alternative, but the question is whether people who have lived their life for a long time alone will be able to share responsibility in a larger group. (End of update by J. Pastoetter)]

### Cohabitation Patterns

Most people who maintain a steady sexual relationship will live together in one residence, although not all men and women who share a residence are necessarily having sex with each other. The housing situation in Germany allows living together. Frequently, occupational mobility may lead to a separation of partners.

[Update 2001: In mid-1999, 2.1 million Germans were cohabitating, an increase of 47% since 1991. Increasingly, German couples, especially in the New Lands, prefer cohabitation to marriage. In mid-1999, 12% of all couples living together were cohabiting without being married. Both partners in 46% of all cohabitating couples were under age 35, and 29% were raising children. In cohabitation, women have more freedom to build their own career, especially if they are also childless. Eighty-seven percent of cohabiting women support themselves and 80% of those with children work outside the home. At the same time, 92% of all husbands hardly share the household work; 87% have never ironed clothes, 79% have never done the laundry, and 75% have never cleaned the windows. Meanwhile, public opinion is shifting in favor of cohabitation. Fifty-six percent of Germans would like to see equal status for couples with and without a marriage certificate, while 71% of young women between 16 and 29 cannot see any argument for a different status for married and unmarried couples. (End of update by J. Pastoetter)]

### Marriage and the Family

As regards the current family, the following model is preferred: "Man and wife both pursue their own profession and are equally responsible for housework and bringing up the children, so that both have the same amount of time for their career." Having one's own family with children remains a high aim in life, and only a few do not wish to have any children at all. Since unification, however, both the number of marriages in eastern Germany and the number of newborn children has drastically declined—within three years, the birthrate had fallen by 60%. Adolescent mothers and female students with children have suddenly disappeared as if by magic. The once-low marriage age has rapidly risen and is set to reach that prevalent in western Germany, with the result that the establishment of families is being delayed. What remain unchanged are the attitudes coordinating parenthood/family with career/employment.

Female and male adolescents in eastern Germany are more likely to have grown up with both parents employed

full-time than their counterparts in western Germany, and this is, thus, the model on which they base their own lives. (Before unification, the number of women working full-time in East Germany was over 90%, compared to over 50% in West Germany.) Men and women have become accustomed to their respective partner's professional activity and regard it as an important aspect of life. The compatibility of parenthood and work does not at all only mean for them the adaptation of family necessities to the parents' work, but also the consideration of the family at work and the repudiation of the complete dominance of the job. Work and family are not seen as alternative, mutually exclusive values, but are only acceptable when organized in conjunction with each other. This is a demand being made on both society and the relationship.

[*Marriage and Divorce* JAKOB PASTOETTER

[Update 2002: In April 1999, 39 million Germans lived as married couples. For the first time since 1991, the number of weddings in 1999 rose over the previous year: 430,000 couples married in 1999, an increase of 3.2% (13,500 couples) over 1998. In the Old Lands (former West Germany) the increase was 2.2%; in the New Lands (former East Germany), the increase was 10.3%. Experts suggest the increase was not the start of a new trend, but a blip because of the magic of the date 9/9/99, even though couples who marry on a *Schnapszahl* (funny number) date have an especially high risk of divorce.

[Married people encounter two disadvantages in the job market. Potential employers still regard married women as "being provided for," while "flexible" single men have better opportunities in the job market. The reasons for marriage have changed dramatically in the last ten years; love and partnership are no longer the most important factors, having yielded to economic stability. Couples without children also have a higher per capita income and a higher standard of living than couples with children.

[At the same time, there is a countertrend toward a "new high regard of the family as an emotional home," according to the Delphi-Study of value orientations by the Heidelberg Gesellschaft für Inovative Marktforschung (September 2000). Other surveys confirm this with findings that 72% hope to find Mr. or Miss Right, and 33% think that finding an ideal partner is the most important thing in life. Ninety-four percent of young people say they believe in true love, 70% hope for a single lifelong relationship, and only 4% say they are not interested in an intimate relationship (see Table 1).

[Television soaps depicting happy family life attract an average of 25 million fans. Sociologists and psychologists think that more and more people have learned through experience that a successful job life is emotionally less fulfilling than a satisfying relationship in filling the emptiness of their private lives. While the *Kettenehe*, chain marriage or serial monogamy, is popular, few German couples believe any longer that filing a declaration of divorce as soon as major marital problems occur is the only remedy for relationship problems. They realize that they will not only get rid of a husband or wife, but also of a good deal of their life together, friends and relatives included. The number of therapists who special-

ized in marriage therapy has increased significantly over the last 15 years. Catholic-sponsored offices for marriage therapy rose from 282 in 1985 to 349 in 2000 in the Old Lands. The Protestant Diakonische Werk now has 349 offices that offer free counseling. The share of divorced Old Lands people who remarried rose from 8% for men and 6% for women in 1960 to 21% for men and 24% for women in 1997.

[On the other hand, the probability of a marriage ending in a divorce increased by fivefold in the Old Lands since 1978, while in the New Lands, divorce decreased by a quarter. The New Lands divorce rate peaked in 1986 with 128.5 divorces per 10,000 marriages. The highest divorce rate in the Old Lands came in 1987 with 87.6 divorces per 10,000 marriages. The 1998 divorce rates were 85.7 in the New Lands and 105.7 in the Old Lands. Overall, the 1998 divorce rate rose by 2.5% over 1997. More than half of the divorces involved minor dependents. Four of five divorced husbands had another partner within ten months, while half of all women were still single after three years. Two thirds of all divorce petitions were filed by wives. According to sociologists, factors for the growing rate of divorce include a decline in the social stigma of divorce since the sexual revolution in the 1970s and the growing financial independence of gainfully employed women. Couples without a church wedding or children, and couples who do not own their home are more likely to divorce, with infidelity cited as the most frequent reason. Nine of ten German women and two thirds of German men hold fidelity as the most important value in a relationship. But the same percentage believes that it is not possible to remain faithful to the same person all life long. (End of update by J. Pastoetter)]

[*Living Apart Together (LAT) Relations*

JAKOB PASTOETTER

[Update 2002: Since two thirds of all singles have a stable relationship with another single, one needs to address the issue of LAT (Living Apart Together) relationships. This new term actually refers to a very old and traditional way of life. In the agricultural world of Old Europe, few newlywed couples possessed the financial means required to establish their own household. Only wealthy farmers, burghers, and aristocrats could afford to pay the brideprice or supply their daughters with a dowry sufficient for the newlywed couple to establish their own household. Most others fell into the mass of poor farmers, day laborers, and servants, the younger sons and daughters of aristocrats who in earlier times had to join a monastery or convent, the voluntary or involuntary spinsters and bachelors, and those who were allowed to marry but not to set up their own household. In a sense, LAT relations are only new if we forget history.

[The economy is the main factor for the growing number of LAT relations today. If a couple can only find work in different cities, it may well be more economical to maintain two separate households instead of absorbing the time and cost of daily commutes. LATs also include singles who share a committed relationship, but prefer to maintain their separate modest household, in which each has privacy and the flexibility of being together or apart. In Germany, more than 15% of all couples, married as well as unmarried, have this kind of "weekend relationship." Higher education and flexibility make it more likely that couples will live apart together. (End of update by J. Pastoetter)]

[*Incidence of Oral and Anal Sex*

Oral stimulation of the genitals, both fellatio and cunnilingus, has become a customary practice. Since hygienic standards and opportunities are high, there are no longer aesthetic scruples. For example, at least 60% of German

**Table 1**

**Happiness of Germans by Marital Status**

Status	"Very Happy"	"Happy"
Married couples	23%	51%
Unmarried couples	17	45
Single persons	10	33

students have practiced fellatio or cunnilingus. Anal intercourse has remained quite rare; less than 20% report this experience, most of them only occasionally. Personal hygiene education in early childhood blocks the unaffected dealing with this aperture of the body.

## 6. Homoerotic, Homosexual, and Bisexual Behaviors

### A. History and Legal Status

Same-sex genitality as an institution is rooted in a changeable history. Before the advent of Christianity, German tribes repressed such acts with capital punishment. From the Middle Ages on, there were meeting places in some metropolitan cities, such as Cologne, which, however, were not large enough, compared with London or Paris, to develop an urbanity suitable for a real subculture. From the early 19th century, Swiss and German writers gave expression to the voice of love between men. The term *homosexual* was created, interpretations of same-sex relations were published, and civil liberties for homosexuals were demanded.

The foundations for the modern concepts, lesbian and gay, were laid in Germany. In 1933, this hopeful development was suddenly interrupted by the Nazi government. The persecution was based on racial-biological and demographic beliefs. Enforced with jail and concentration camps, it was the fiercest ever seen in modern times. It was not until the 1970s that the gay and lesbian existence could recover from this knockout blow.

Today, homosexuality is societally established as never before in history. Not even the menace of AIDS has reversed the trend. Despite the numerous victims of HIV, one may say that the life chances of homosexual and bisexual people continue to be enhanced. Same-sex relations between consenting adult men were completely depenalized some 20 years ago. Same-sex relations among women were only criminalized in Austria in earlier decades. Currently, any differentiation between homosexual and heterosexual has been removed from the penal code, as is the case in Switzerland since 1992 and in the former East Germany since 1988. Contemporary political demands include an antidiscrimination amendment to the Constitution and the legalization of marriages of same-sex couples.

The state has long since abstained from open denial of rights and privileges, e.g., against teachers or civil servants, in the judiciary, public administration, social security, and the like. Many politicians, even conservatives, hasten to confirm that they will not “discriminate.” That does not mean that the politicians are willing to grant equal rights to homosexuals. They are given as much equality, meaning tolerance, as necessary, but not as much equality as possible in terms of integration.

Residual discrimination remains in niches like the military and the Church. And it is difficult to intervene in the antihomosexual policies of the private sector of the economy. Homosexual lifestyles are possible even here, as long as they are restricted to the private sphere.

### B. Children

Children, before they “discover” the other sex during or after puberty, naturally look for friends and intimacy within their own sex. So there are many occasions for homoerotic feelings, even for sexual encounters between friends. The passage through such a temporary “youngster homosexuality” is no predictor of adult homosexuality. Most youngsters with homoerotic experiences will follow the path of “normalcy,” with the sole difference that their antihomosexual prejudices are less negative than those of the general population. The same-gender contact of youngsters has been re-

duced, but has not disappeared, in the last decades, because of coeducational schools and acceleration, including the earlier start of heterosexual coitus (cohabitarche). Moreover, the age of coming out for homosexuals has been getting ever lower, so that today this often occurs during adolescence.

### C. Adult Psychology and Lifestyles

Turning to gender roles, the theory of the third sex proposed by Magnus Hirschfeld has faded away. Today, gays are thoroughly masculine, lesbians quite feminine. Sometimes, they play with the possibilities of cross-gender behavior, onstage or in subculture situations. But their personal identity is confined to their biological sex. One is a “faggot” for fun, for provocative purposes, i.e., in a voluntarily chosen role. In lesbian subculture, the rigid separation into butch or femme has diminished.

Uncertainties of gender, intergenerational longings, and love relations between the social classes are no longer the prerequisites of a homosexual preference. Transgression of class, generation, and gender frontiers contributed to earlier sex scandals, and even constituted their kernel. Today, the only and really subversive moment in homosexuality is its negation of compulsory heterosexuality.

The homosexual desire as it has crystallized throughout the 20th century signifies precisely the same-sex relationship. By this, homosexuals were confronted with the possibility and necessity of forming lasting partnerships. Meanwhile, a considerable portion of this population follows a quasi-conjugal lifestyle. Two men or two women establish one household, and share income, leisure time, and friends. Their descent families consider them as a pair; the partner of one’s own offspring, after a certain time, will be treated as child-in-law and vice versa. The couple, especially a lesbian one, may enlarge to a family with children from a former marriage, sometimes from adoption or fostering.

There is no separation of rights, duties, and prestige according to the traditional roles of husbands and wives. Gay and lesbian couples attach great value to egalitarian decisions. On the other hand, their stability is endangered by the lack of institutionalization and public recognition. Too many details of daily life have to be negotiated. Most couples admit some form of sexual contacts with third parties. This sort of “legitimate infidelity” gives rise to erotic flexibility as well as a certain burden of jealousy.

Homosexuality as an accessible form of erotic preference enjoys a high degree of social visibility that was increased but not generated by the public reaction to AIDS. There are more occasions than ever before to learn about homosexuality, to discuss it, and to confront oneself with such experiences. In many sectors of everyday life, the questions of homosexuality are addressed: at school, in the family and peer group, at work, and during leisure activities. So a latent desire can quite easily manifest itself, and one can look for possible partners.

Many doors open to the homosexual world. A lot of newspapers—public or subculture—have a rubric for contact ads. Special guides list the commercial and the hidden places where homosexuals meet. Today, each city with more than 50,000 inhabitants has at least a gay bar and an anonymous meeting point in a public park or lavatory (“tea room”). Bigger cities have baths, numerous bars for special interests, bookshops, voluntary groups, and a “gay switchboard.” The opportunity structure for a lesbian/gay lifestyle has an extraordinary density.

Nationwide associations address cultural and professional interests for Christians, adolescents, teachers, medical people, writers, and the like. On the one hand, only a tiny minority of this minority affiliates with such an organiza-

tion. On the other hand, these few people operate as a real avant-garde to improve homosexuals' life chances.

Homosexuals have conducted numerous experiments with gender roles, forms of coupling, and techniques of sexual outlet. Some of their inventions have gained significance for nonhomosexuals: the social autonomy of women explored in the economically independent existence of lesbians; body image and sensitivity of men explored via some feminine components in gay performance; the remasculinization of men in the 1980s experienced in the so-called clone style. Homosexual relations, of course, are not a model for the general public; nevertheless, they give a striking example for the plasticity of erotic configurations.

[Update 2002: After the 1994 removal of §175 of the German Penal Code, which prohibited male homosexual activity, a second revolution took place on November 10, 2000, when the German Bundestag, with the majority of the Social Democratic Party (SPD) and Green Party coalition, approved a governmental legal initiative that homosexual couples should be treated equally with married heterosexual couples as far as certain legal rights are concerned. (Female homosexuality had never been prosecuted.) The law is already widely seen as "historic," since for the first time, homosexual couples can officially register their relationships in a way that comes quite close to traditional marriage. Since Article 6 GG of the German Constitution states that (heterosexual) marriage and family have to be especially protected by the state, the new family-law institution is called *Eingetragene Lebenspartnerschaft* ("registered partnership through life").

[According to sociologist Michael Bochow, about half of all German homosexuals already live in cohabitation, and although not all such couples will decide for an *Eingetragene Lebenspartnerschaft*, the legal possibility is widely seen as a good thing. The argument is that all social commitments and responsibilities should be strengthened in a time of progressive social fragmentation.

[The individual states (*Länder*) of the Federal Republic have the authority to decide where the couples have to go to get registered. The most probable choice will be the registry office (*Standesamt*) where all heterosexual marriages must be performed to be legal. The *Eingetragene Lebenspartnerschaft* will include such fundamental rights and obligations as the right to choose a common family name, the legal status of next of kin, the right to see the partner in hospital, the obligation to pay maintenance, a so-called *kleines Sorgerecht* (small law of custody for children in the partnership), and rulings for divorce, rent law, and inheritance. A homosexual foreign partner will have the same rights as a heterosexual foreign partner with regard to permission to work and immigration of family members.

[Still being decided are all regulations not subject to federal but to state legislation, such as the tax advantages of *Eingetragene Lebenspartnerschaften*. Income and inheritance tax laws, as well as laws pertaining to tax advantages for maintenance payments when a couple gets divorced, fall within the sovereignty of the 16 German states. Laws pertaining to these matters have to pass the second chamber, the German Bundesrat, where the conservative Christian Democratic Union/Christian Social Union (CDU/CSU) had the majority. On December 1, 2000, the Bundesrat, with its conservative majority, rejected the second law involving these ancillary rights. The main law was, however, passed in the Bundesrat. As for the ancillary rights, the ruling "Red-Green" coalition is prepared to further divide these, so that parts of their proposal can be passed.

[Most Germans see themselves as tolerant towards homosexuals. More than 70% of Germans under age 40 ac-

cept homosexuality, and already in a 1996 survey, 49% said they were in favor of a registry-office marriage, 93% wanted homosexuals to have the same job opportunities, and two thirds suggested a law to protect homosexuals against discrimination. (*End of update by J. Pastoetter*)

#### D. Bisexuality

Bisexuality, in the narrow sense of having homosexual and heterosexual relations during the same phase of a sexual biography, occurs quite often, presumably more often than exclusive homosexuality. Nevertheless, the concept is obscure and psychologically underdeveloped.

Most experts agree with the thesis that they have never seen a genuine bisexual, i.e., someone who reacts with equal sexual appetite to women and to men. Since this judgment refers mostly to a population of therapy clients, and since the universe of bisexual people has not yet been empirically investigated, the question of what types of bisexuality really exist remains open.

There are quite a few sexual biographies where phases of intimate relations with a woman alternate with relations with a man. Such a "successive bisexuality" is frequently reported by women, and there is no reason to suggest a "latency" of either homosexuality or heterosexuality.

### 7. Gender Diversity and Transgender Issues

For transvestites, there are no institutionalized roles in German society. The dichotomy of two and only two sexes is highly crystallized. So transvestites very seldom gain public attention. They are generally considered deviants, but do not constitute a social problem. The phenomena of transvestism, transsexuality, and homosexuality are today clearly separated. Behaviors of cross-dressing and making-up as the other gender do not irritate public opinion, and the individual reaction contains a greater degree of amusement than of worry. Furthermore, since the 1980s, some transvestites have won high prominence as entertainers in stage shows.

For some people, transgressions of the valid definitions of gender lead to a considerable amount of hostility. Transgenderists and transsexuals are, therefore, marginalized even today, when legislation, medicine, and the mass media have acknowledged their right to live as they are and accommodate their outward appearance to their gender identity.

German law provides some procedures for people who wish to change the sex designation ascribed to them shortly after birth. They may choose between officially changing their name or also altering their sex status. The second step presupposes the surgical adaptation of the genitals. In addition, the surgery presupposes expert evidence given by a psychologist or physician testifying that the person is able to live in the long term in the chosen gender role. Several hospitals in the country have specialized in this sort of medical support and are quite willing to deliver it.

At present, several juridical initiatives are being directed towards normalizing transsexuality. Support groups have been organized and receive state subsidies. New sociological research describes the life world of gender-changing people (Hirschauer 1993; Lindemann 1993). The leading German sexologist is pleading for depathologizing the phenomenon (Sigusch 1992). But this will remain a utopia as long as transsexuals themselves apply for medical help, psychotherapy, hormonal treatment, and surgery to gain a healthy condition.

[Update 2002: Since 1981, Germany has had a special law for transsexual issues, the *Gesetz über die Änderung der Vornamen und die Feststellung der Geschlechtszugehörigkeit in Besonderen Fällen Transsexuellengesetz TSG*;

*Transsexuals' Act*. It provides for two possibilities, which may be applied either successively or independently of each other. The first possibility is for a transgendered person to change his or her first name without changing the assigned sex. For this so-called "small solution," the law requires two expert opinions confirming the diagnosis of transsexualism for the past three years. The second possibility entails legal recognition of gender reassignment in all official documents including passport, birth certificate, and so on. This so-called "major solution" requires not only two mutually independent expert opinions, but also sex-reassignment surgery. Moreover, the applicant must be unmarried and must be permanently incapable of reproduction. Between 1981 and 1990, 1,422 judicial decisions were rendered in Germany on this basis, 683 of them involving the "small solution" and 733 the "major solution." Hence, one can estimate the frequency of transsexual applications within these 10 years as being between 2.1 and 2.4 per 100,000 German adults. The male-to-female/female-to-male ratio was 2.3 to 1 (Weitze & Osburg 1996).

[It is obvious that sociocultural factors (*Zeitgeist*) have a tremendous impact on the accessibility and acceptance of legal and medical procedures for changing the assigned sex in Germany (Hirschauer 1993). After decades of desperately split discourses between essentialists (see, for instance, Dörner et al. 1991) and constructionists (see, for instance, Sigusch 1992) regarding the origin of transsexuality, a biopsychosocial approach to the understanding of this phenomenon has been accepted in Germany (see, for instance, Bosinski et al. 1997; Beier et al. 2000). (*End of update by H. A. G. Bosinski*)]

## 8. Significant Unconventional Sexual Behaviors

### A. Coercive Sex

#### *Sexual Abuse of Children and Incest*

The criminal law prohibits sexual acts with young people under age 14 and under age 16 if the acts are exploitative. Moral crusades initiated by some feminist groups argue with increasing numbers of child sexual abuse cases. With some lag, the figures in the official statistics rose after decreasing for three decades. Actually, it is only the public and private awareness that has changed, and child abuse is a more or less stable phenomenon—about 60,000 cases per year. The common construction and terminology throws together three distinguishable interactions: parent-daughter (incest), men-children (abuse), and intergenerational love (pedophilia) (Lautmann 1994). These forms vary in ingredients and consequences.

#### *Rape*

Sexual violence against women is the other big topic exciting the public opinion during recent years. The punishment of rape in the roughly 2,000 convictions per year is quite severe. But many women do not go to the police even though officers have recently been taught sensitivity in dealing with victims. Legislation has hesitated to criminalize marital rape.

Many young people are afraid of sexual violence. A quarter of the 16- to 17-year-old males in western Germany, compared to a tenth of those in the east, and more than half of adolescent females in the west, compared to a third in the east, reported that they had personally experienced sexual violence, sexual molestation, or sexual interference. In the east, 4% of women said they were forced to engage in sexual intercourse against their will the first time they experienced coitus. The figure among homosexual men is 2%. A

fifth of women in eastern Germany have experienced rape or attempted rape.

### *Sexual Harassment*

There are many cases of verbal and bodily molestation of women. Some women train in techniques of self-defense. The majority of men have not yet learned to pay complete respect to a woman's No.

Sexual molestation in the workplace or elsewhere is penalized as an insult, but seldom prosecuted. Some feminists are campaigning for legal recognition of a special offense of sexual harassment. However, the German legislature usually resists the demands to adapt the penal code to social problems addressed by moral crusades.

### B. Prostitution

More than 100,000 women offer sexual services to men, either as a professional or casual job, or to obtain money to buy drugs. The organization of the activity varies. The most respected form is to use an apartment with a telephone and to receive the visitors there after having advertised in a paper. Working in a brothel provides less autonomy for the women, but perhaps equal comfort. Other women wait in bars or hotels for clients. Dangerous, hard, and least profitable in comparison with the other forms is soliciting on the streets.

Male homosexual prostitution is not as common, but it is organized in quite similar ways. Some call boys offer their services equally to men and women. The demand from lesbians is extremely small, if any.

The social prestige of prostitutes has improved to a certain extent since they founded interest groups for "whores." They argue that, if they have to pay income tax (and they do), then they may claim social security and recognition for their vocation.

The law forbids prostitution only under special circumstances, in certain areas, in the neighborhood of schools, and the like. It is also forbidden to further prostitution and to recruit minors. These statutes are enforced in a very incomplete and selective way.

### C. Pornography and Erotica

All forms of sexual, pornographic, and/or obscene material are easily available in Germany—the soft variety from newsstands and television, the harder types in numerous shops where even the most extreme examples are available under the counter. The law forbids hardcore pornography that includes violence, children, or animals, and the sale of all sorts of sexual materials to minors. The debate about the character and danger of pornography has also taken place in Germany (Lautmann & Schetsche 1990).

[*Update 2002*: Germany leads all other European countries in the production of pornographic movies, with about 600 new German titles hitting the market every month. Consumption is also quite high, with more than 78 million hardcore videotapes rented in 1999. Eighty percent of the videotapes rented and purchased are of American origin. Germany is also the European leader when it comes to more explicit sex shows on television: *Liebe Sünde* [*Dear Sin—Love Sin*], *Peep!* and *Wa(h)re Liebe* [*True Love, Love as Consumer Item*] have been in competition for viewers since the early 1990s, with documentaries that mix sex education, voyeurism, and sensationalism. (*End of update by J. Pastoetter*)]

## 9. Contraception, Abortion, and Population Planning

### A. Contraception

Contraception is regarded positively and for the most part is correctly practiced throughout Germany. All but 1%

of Germans accept the prevention of unwanted pregnancy, without any differentiation as regards age, sex, origin, qualifications, or profession. Around 80% of women used contraception the first time they had sexual intercourse, and at least 90% used some method of birth control during the last incidence of coitus. Three quarters of 16-year-olds and nine tenths of 18-year-olds have experience with the contraceptive pill. Some sexually inexperienced females take the pill as a precautionary measure, while others prefer to refrain from sexual intercourse because they are not on the pill. Similarly, many male adolescents also avoid sexual intercourse if a condom is not available. Only 5% of those who have experienced sexual intercourse have never used contraception. Almost everybody regards contraception as a joint responsibility. The current types of contraception are well known among adolescents.

The most popular contraceptive is the pill, favored by 99%. The IUD and diaphragm are less popular. Ninety-four percent of eastern German women aged between 30 and 44 have taken the pill, usually over a protracted period of time, and 52% continuously. (The pill was easily accessible and free of charge in East Germany; it was prescribed by doctors, even to 14-year-old girls.) Two thirds have used condoms; one fifth have used the IUD. Another fifth prefer the rhythm method, a method half of all women have never exercised.

Although hormonal contraception is not decreasing in significance, and acceptance of the pill has actually increased among both men and women, the condom, which was completely out of fashion in East Germany, has been rediscovered as a result of AIDS. However, the condom has not become a rival to the pill or the IUD. It is normally used as an additional means of contraception, and also as a means of protection. The condom is, in fact, the preferred method in certain situations, but regular users are rare. What are sometimes referred to as "natural methods," such as the rhythm method, have decreased in popularity. Coitus interruptus is also widely shunned.

Safe contraception these days, even more than a decade ago, is regarded as an indispensable condition for sexual intercourse. The degree of care exercised, especially in eastern Germany, has actually increased as a result of the changes in values and the social risks, and a significant number of men and women in eastern Germany have taken the opportunity to be sterilized, something that has only been possible since German unification.

## B. Teenage Unmarried Pregnancies

Not more than about 1% of all live births are to minor mothers (under age 18), and half of these are unmarried. A considerable number of teenage pregnancies are terminated by abortion.

[Update 2002: Whether born in- or out-of-wedlock, German children are on equal legal status since 1998, when the last discriminations regarding custody, inheritance, and birth legitimacy were abolished. There is a large discrepancy between the numbers of out-of-wedlock births in the Old and New Lands. In the Old Lands, the rate is between 13% and 27%; in the New Lands, out-of-wedlock births account for up to 51%. In the former West Berlin, 29% of births are out-of-wedlock, while in the former East Berlin the figure is 52%.

[One reason for this development is a strong mistrust, mainly but not exclusively in the New Lands, against middle-class values and the romantic-marriage ideal, since many young adults know from experience in their own families that marriages are often unhappy in the long run—mainly for the woman—or lead to divorce. In addition,

there is hardly any material advantage in being married if one does not keep to the traditional role model of the husband earning the family income. On the other hand, there are many advantages in raising children as a single mother: social security, rent rebates, and other financial support by the state. Another factor in this demographic difference is the different self-awareness of women in the east who are less likely than women in the west to define themselves through their partner, and less likely to perceive a child as a reason to marry. In the New Lands, it was much easier to have a child out-of-wedlock, since the state also promoted lifestyles other than marriage. Single mothers got certain advantages, like smaller taxes and extra vacation. Ninety-five percent of women had children in the New Lands, compared to only 76% in the Old. (End of update by J. Pastoetter)]

## C. Abortion

The acceptance of contraception contains a critical, negative assessment of abortion as a method of birth control, although the principle of the legal option of the termination of pregnancy is supported. Only 2% are in favor of the complete prohibition of abortion, and the majority of Germans are in favor of at least allowing abortion within the first three months. A quarter of eastern German adolescents and a tenth of their western German counterparts are totally against any form of criminal legislation governing abortion. Most German youngsters support the concept of self-determined pregnancy and liberal legislation. Planned childbirth remains the ideal.

[Abortion and Donum Vitae JAKOB PASTOETTER

[Update 2002: In 1998, 131,795 abortions were registered in Germany, for a ratio of 169 abortions per 1,000 live births. Eight of 1,000 women in childbearing age had had an abortion. This corresponds to 14% of all pregnancies, with West Germany reporting 12% and East Germany 23%. Most of the women in West Germany were between 18 and 24 years old and had no children; in East Germany, most women were between 30 and 34 years old and had already one or two children. One of the reasons for this discrepancy might be seen in the fact that East Germans do not worry as much as West Germans do about providing the government with more-or-less confidential information about themselves, as long as the government pays in part or in full for their medical costs, including abortions.

[The government supports consultation offices for pregnant women who are considering an abortion, since women need a *Beratungsschein* (proof of consultation) before getting a legal abortion. The consultation offices are run by the two main churches, the Protestant and the Roman Catholic, most of the latter by organizations like Caritas or the Social Service of Catholic Women, and ProFamila, the German offspring of Planned Parenthood. In January 1998, Pope John Paul II advised the German bishops to find a way to stop the practice of issuing *Beratungsscheine*. The German bishops agreed to an alternative, but still allowed the more than 260 consultation offices to issue the proofs. In September 1999, when the Pope ordered the addition of the phrase, "This Proof may not be used for carrying out an unpunished abortion," the bishops decided to obey. This prompted Catholic laypeople, with the support of the CDU/CSU and SPD politicians, to found a new organization, Donum Vitae [Latin for "Gift of Life"], to continue the pre-abortion consultations and the issuing of *Beratungsscheine*. On January 1, 2001, when all dioceses (except for Limburg) stopped the consultations, 90 offices of Donum Vitae were ready to carry on. (End of update by J. Pastoetter)]

#### D. Population Control Efforts

A negative population growth holds only for “native” Germans. The secular trend of a sinking birthrate began here at the end of the 19th century. It has various causes, many of them grounded in the rationalization of the social structure and private life. Many children born in Germany do not become German citizens, because their parents are immigrants. The laws of citizenship follows the principle of *jus sanguinis* instead of that of *jus soli*.

Unification of Germany has unexpectedly resulted in the sharpest drop in birthrates in modern world history. Birthrates have been very low in West Germany for many years. In the last several years, slightly more west Germans have died than have been born. Birthrates in all five states of east Germany have fallen sharply. In Brandenburg, births have fallen by more than two thirds, from nearly 38,000 in 1989 to barely 12,000 in 1993. Birthrates are down by more than half in the other four states in the same period. In late 1994, Brandenburg announced it would begin immediately to pay parents \$650 for every new child they have. This is in addition to both the national health insurance, which covers obstetric and other medical expenses, and a monthly allowance, called *Kindergeld* that is awarded on a sliding scale based on income. *Kindergeld*, which has been distributed in western Germany since 1955, can reach a monthly cap of \$420 for a family of four (Kinzer 1994).

War, famine, and plague are the usual factors triggering such a precipitous drop in the birthrate. In Germany today, the rising rate of unemployment increasing the threat of poverty is the cause for the free-falling birthrate, which is accompanied by a drop in the rate of marriage and a more than tenfold increase in sterilizations. “Young people in east Germany used to think that the most important conditions for marriage were love and a good partnership,” a recent report noted, “Now they are seeing that the crucial condition is a secure job.” Prior to unification, the Communist system provided jobs and daycare for all and a strong social safety net prevented anyone from falling into poverty. If the current trend continues to 2010, there could well be fewer than half as many children in eastern Germany as there are today.

Nearly all the former Communist countries in Europe have experienced drops in their birthrates, though none match the drop in east Germany. Some countries, including Hungary and Poland, provide payments to the families of newborn babies, but they are much smaller than those initiated in Brandenburg. In the West, Belgium, Luxembourg, and Portugal pay the parents of new babies.

[Update 2002: Two phrases are relevant to any discussion of population programs in Germany: *Überalterung*, or the increase in the percentage of old people, and *kinderfeindliche Gesellschaft*, or the child-hostile society.

[According to a study of the United Nations published in early 2000, Germany would need an influx of an additional half million immigrants each year to keep the number of 15- to 64-year-old social security contributors at the level of 1995. To stabilize the number of people living in Germany, 17 million immigrants would be needed in the next 50 years. On the first of January, 1999, Germany had a population of 82.1 million. In all of 1999, 767,000 children were born (765,000 in 1995), while 844,000 people died (885,000 in 1995). In 1998, for the first time, the number of deaths surpassed the number of immigrants, 67,353 compared with 47,098, reducing the population of Germany by 20,000. Germany's birthrate was 1.35 per fertile woman in the west and 1.10 in East Germany, one of the lowest rates worldwide. At the end of 1998, 22% of the German population was age 60 or older; the average age was 39.1 years.

[Reasons for this development can be seen in a growing life expectancy, in the decline of immigrating younger people, and last, but not least, in what is referred to by Germans as *kinderfeindliche Gesellschaft*, or our “child-hostile society,” meaning the combination of factors that make it difficult for young adults to think about having children. These factors include a high social pressure to give priority to one's career, difficulty in finding part-time jobs, and a society and environment that are perceived by aspiring parents as non-supportive or even hostile and dangerous to children. The latter includes the often-mentioned aversion against noise caused by children's play, a pessimistic outlook to the future in general, the high costs of raising children, gangs and drug use in the schools, and finally, high traffic-accident and death-toll rates. Children are even seen as “women trap Number One” that prevents self-fulfillment through job and leisure time. Especially in the east, many parents feel left alone, in comparison with the full-time care children received in the former German Democratic Republic.

[The German government tries to improve the financial and social position of parents with certain allowances and other privileges. Primary among these are the *Erziehungsgeld*, a child-support allowance with a maximum of US\$300 per month paid until the child's second birthday, and the *Kindergeld*, a child allowance of about \$130 a month for the first and second child, \$150 for the third, and \$175 for subsequent children. The *Kindergeld* is normally paid until the child reaches age 18, but it may continue to age 21 if the young adult is still without job, until age 27 if he or she is still in education, and lifelong if handicapped. There is also the right of *Erziehungsurlaub*, or unpaid vacation with job guarantee. In addition, the government has increased by \$15,000 per child the amount of money a couple can invest tax-free into a special savings account to be used to build or purchase their own townhouse, condominium, or apartment. In Germany, and elsewhere in Europe, only 15% of couples own their own residence, while 85% rent. This is the reverse of the situation in North America, and the German government hopes that its *Eigenheimförderung* incentive, linking home ownership with family size, will encourage couples to have more children. (End of update by J. Pastoetter)]

### 10. Sexually Transmitted Diseases and HIV/AIDS

#### A. Sexually Transmitted Diseases

The incidence of sexually transmitted diseases is incompletely known, since there is a legal obligation to report only four of the 20-some diseases. Presumably, the incidence of STDs equals that observed in other Western countries. That means it has remained quite high in spite of medical and hygienic progress. Within the medical profession, venereology is associated with dermatology. National and private health insurance pays for the cost of treatment.

[Update 2001: The figures for STDs have remained quite low in Germany for several years. In 1995, 4,061 new cases of gonorrhea were reported; this decreased to 2,412 cases in 1998. The largest drop came between 1984 and 1990, before Union, when the number of cases in West Germany decreased from 42,045 to 6,614. The same trend can be seen for other STDs, like syphilis, which decreased from 4,250 in 1984 to 868 in 1990. The annual number of new cases of syphilis increased to 1,138 in 1995 and has remained at this level since. The influx of prostitutes from Eastern Europe is likely to reverse this trend, since in the Russian Federation alone, the number of newly infected

persons with syphilis has jumped to several hundred thousand. (*End of update by J. Pastroetter*)

[*Update 2002*: In the first half of 2002, Germany recorded 1,116 new cases of syphilis, compared with 756 cases during the same time period in 2001, according to the Robert-Koch-Institut, the German equivalent of the American Centers for Disease Control. The increase in the number of new cases of syphilis was similar to that for other sexually transmissible diseases in the same time span. Health experts interpreted this as an “early warning” of an impending increase in new HIV infections, because it indicates a willingness by people to engage in unprotected sexual contact. Young people who did not witness the “AIDS shock” of the mid-1980s and do not fully comprehend the need to use condoms, appear particularly susceptible.

[Because advances in HIV/AIDS treatments have created false hopes of a cure among many people, health officials warn that prevention efforts must be redoubled. However, funding for HIV/AIDS programs in Germany has remained steady over the last three to five years, even though the number of new German AIDS cases has been increasing steadily. The growing concern is that a kind of “prevention fatigue” may reduce prevention efforts at the very time these efforts need to be increased, not just in Germany, but also in other European and North American countries (Stafford, Reuters Health, September 9, 2002; Kaiser 2002). (*End of update by R. T. Francoeur*)]

## B. HIV/AIDS

Among the people diagnosed as HIV-positive, men with homosexual experiences constitute the biggest category, about 70%, followed by IV-drug users, about 15%. Consequently, in Germany, AIDS is essentially understood as a venereal disease. The prevalence up to 1993—about 10,000 cases of AIDS—is lower than in some other European countries, not to mention the United States. Women constitute 10% of the cases. Eastern Germany is as yet a sort of developing country for HIV infection following the fall of the Iron Curtain, which served as a preventive measure.

The comparatively low incidence is a result of a policy that emphasized rational recognition instead of repression and denial. Campaigns in the mass media, at schools, and by street workers delivered preventative messages. Homosexual men changed some of their practices (Bochow 1993; Dannecker 1990). Since the rules of safer sex are not observed completely, some new infections still occur.

Because the official information applies to the whole population instead of just to special risk groups, it is understood that sexuality in general will be affected by the AIDS crisis. It may be that the recently identified return of young people to the ideal of romantic love results partly from official condemnation of promiscuity.

Approximately one tenth of adolescents with experience in sexual intercourse say they have on at least one occasion shunned some sort of sexual activity for fear of being infected with the HIV virus. For most young people, sexual contact is not normally connected with a current fear of being infected with AIDS, and when it is, there is some obvious reason, such as a suspected at-risk partner or unprotected intercourse. Despite the very different epidemiological situations reigning in eastern and western Germany—there are hardly any AIDS patients in eastern Germany and most of these are in Berlin—AIDS has produced equal degrees of consternation. This anxiety is rarely fear for one’s own health or behavior, but rather a more general sense of concern, including sympathy for those infected by HIV and PWAs (persons with AIDS). Somewhat older and more-experienced young people, in particular, do not see themselves

in danger as a result of their partnership activity and sexual behavior and know how to protect themselves in doubtful cases. The fear of AIDS among younger adolescents results from uncertainty, ignorance, and a lack of experience. It represents a sort of “mental barrier” to the adoption of sociosexual contact, which is subsequently dissipated during the relationship. The real dangers are often suppressed in daily sexual life.

Autistic concepts of safer sex are out of fashion, especially among younger people and, in particular, in eastern Germany. Sexuality is not idealized as aseptic sex without contact if at all possible (with the “enemy”), or as an anonymous service, or as isolated desire, but rather as firmly linked with the (beloved) partner. Both heterosexuals and homosexuals love a concrete person, enter into a relationship, and have sexual contact with them. The rates of masturbation are comparatively low. Although masturbation is accepted as a sexual activity, and inhibitions in this respect have been dispelled, partnership sex is still preferred.

[*Update 2001*: In 1999, 2,100 Germans were newly infected with HIV, about the same number as in 1998. Also the number of people diagnosed with AIDS (568) or died (close to 600) has remained constant in recent years. This marks a decrease from 1995, when 2,045 AIDS patients died, and is mainly because of improved medical treatment. According to an estimate from the Robert Koch Institute, Berlin, in 1999, an estimated 37,000 Germans were infected with HIV: 29,000 men, 8,000 women, and about 400 children. (*End of update by J. Pastroetter*)]

[*Update 2002*: UNAIDS Epidemiological Assessment: By mid 2001, a cumulative total of 16,769 cases of HIV infection had been reported in Germany. HIV testing is systematic among blood donors and recommended for pregnant women, with an estimated coverage of 50% to 80%. Since 1993, laboratories and, since 1998, clinicians report anonymously newly diagnosed HIV infections to a national HIV database. Clinician reports are provided for over 90% of cases and contain a name-based code to allow for detection of duplicate reports. Among cases reported in 1997 to 1999, 38% were homosexuals, 30% heterosexuals, 11% injection drug users, and 20% were reported with an undetermined mode of transmission.

[UAT of all newborns has been conducted since 1993 in Berlin and Lower Saxony and since 1995 in Bayern. HIV prevalence is low in the general population, in particular outside metropolitan areas. In Berlin, the city with the highest cumulative AIDS incidence, HIV prevalence in pregnant women is below 0.1%. No significant trends could be detected between 1993 and 1995. Since 1985, prevalence has decreased among injection drug users entering drug treatment centers; and varied in 1992 to 1993 from 6% to 4%. Other data, partly based on self-reported test results, showed a prevalence around 20% among users of syringe vending machines or storefront units (1992 to 1993). As in other Western European countries, prevalence in non-injection drug-using prostitutes is similar to that in the general population.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	41,000 (rate: 0.1%)
Women ages 15-49:	8,100
Children ages 0-15:	550

[An estimated 660 adults and children died of AIDS during 2001.

[No estimate is available for the number of German children who had lost one or both parents to AIDS and were under age 15 at the end of 2001. (*End of update by the Editors*)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

### A. Concepts of Sexual Dysfunction

Real fears of sexual joys exist. The most common fear in connection with sex among males and females and throughout Germany is that of unwanted pregnancy. Sexual diseases and AIDS are, by contrast, currently regarded as worry factors of lesser importance. Other fears refer to the anticipation of sex and the experience of sexuality.

Only one quarter of 16- to 17-year-old, sexually inexperienced females in western Germany have a desire for more sex, and only 10% of them want to have their first experience of sexual intercourse. They are afraid of disappointment, they are fearful of not finding the right partner who will meet their expectations, they are occasionally conscious of an aversion to men in general, not wanting to become a man's sexual plaything, and they are rather wary of both abstract and direct involvement in sex.

Male adolescents, especially those from western Germany, often abstain from sexual contact: Their sex drive is not that great. During their first incidence of sexual intercourse, only a good half of males from western Germany, compared to 80% from eastern Germany, said that a strong sex drive was a motive. They link sexual intercourse with a steady relationship and having a faithful girlfriend, and certainly do not want to get involved in something "wishy-washy," unpredictable, restrictive, or vexing only in order to establish a close bond or for reasons of sex.

Sexual experience: By no means do all females experience their sexual activity to be pleasant and enjoyable, especially those from western Germany. This refers both to masturbation, which they often do not find gratifying, and above all to intimacy with their partner and sexual intercourse. Half are sexually unsatisfied after sexual intercourse, and only the remaining half derive any pleasure from it at all. It is only a great experience for a quarter, and only a quarter have the wish to repeat it soon. Among eastern German females, almost two thirds find sex a great experience. This appraisal is acted on, as girls from eastern Germany have sexual intercourse more often than their counterparts from the west.

Men in the west suffer, in particular, from mental problems connected with sexual competence, sexual performance, their own attractiveness, and frustrations in love and sex, and these are connected with failure to cope with the pressure of norms or a fear of not being accepted without bias, but rather having to first fight as a man against a barrage of devaluation, mistrust, and prejudice.

[Update 2001: Impotence and lack of sexual desire are rapidly growing phenomena in Germany. The number of men without sexual desire quadrupled from 4% in the 1970s to 16% today. Most couples seem relieved when they learn that intense sexual libido rarely survives beyond the first few years of an intimate relationship. Most men and women also seem to accept the fact that having good sex means hard work: keeping in shape and learning from and respecting one another. In everyday life, the stress of work and the time and energy consumed in hobbies also affects the level of libido.]

[For most couples, sexual satisfaction is less a matter of sheer lust and ecstasy as it is showing each other affection and love. Emotional intimacy, tenderness, and the feeling of belonging together are increasingly more important than sexual satisfaction. On the other hand, a trend towards less sexual activity, especially in long-term relationships, is not as new as it might look at a first glance. Early in the 20th century, psychoanalyst Carl G. Jung and the German poet and physician Gottfried Benn agreed that "marriage is an institution to paralyze the sex drive." At the end of the 20th

century, three quarters of German wives married for 30 or more years reported a strong decline of the sexual interest of their partners. Only 12% of all couples think that sexuality is important or very important, and four of ten couples have stopped sexual intercourse all together. (End of update by J. Pastoetter)]

### B. Availability of Counseling, Diagnosis, and Treatment

Counseling and therapy in sexual matters is offered by a range of public institutions and private practitioners, most of them psychologists. However, this scene is not as widespread as it is in the U.S.A. Special certifications and licenses for sexual therapists do not exist. National and private health insurance pays a considerable portion of the costs.

### [C. Redefining the Meaning of Sex

[Update 2002: German men and women are becoming more and more similar in their attitude toward sex, as well as the quantity and quite-high satisfaction both get from their sexual activity. The percentage of women who say they have masturbated increased from 50% in the 1960s to 86% in 2000. The percentage of males who masturbate has been above 90% for decades. For 90% of Germans, love and sex belong together; only one in ten persons says that love is not decisive for sex. For 60% of Germans, touching, tenderness, and petting are the most important sexual behaviors. Overall, only one in three—50% of men and 25% of women—says coitus is the most important aspect of sex. (End of update by J. Pastoetter)]

## 12. Sex Research and Advanced Professional Education

### A. Advanced Education and Research Institutes

Funding and support for sexological research in Germany are deplorably low considering the public demand for knowledge and the gravity of social and individual problems with sexuality. The funds available are far less, proportionately, than in the U.S.A. Consequently, Germany is throwing away its great tradition in sexology.

There are some small institutes within the medical departments of the universities of Frankfurt/Main, Hamburg, and Kiel. Empirical sex research is mainly conducted in Leipzig, pedagogical in Landau, and sociological in Bremen. Ideological cleavages cause controversies, which means that researchers do not cooperate very much. Frequently, they ignore and despise each other. The small sexological community is split into five organizations—which, in turn, contributes to the political weakness of the profession.

Postgraduate training exists at only one or two medical faculties. Graduate-level programs for the advanced study of human sexuality are unknown. Some private institutes for family counseling and birth planning offer courses for interested adults, that is, at the college level. What the Federal Bureau for Health Information (offices in Cologne) can do depends on the ruling party. The conservative government, in power since 1982, had an information pack destroyed soon after it had been developed by their liberal predecessors. This symbolizes how the evolution of sexology in Germany is impeded by the public moralization of sexual matters, even in the time of AIDS.

### B. Sexological Publications and Organizations

Only one sexological journal, a quarterly founded in 1988, is published in Germany: *Zeitschrift für Sexualforschung*. Address: Enke, Box 101254, Stuttgart.

National sexological organizations include:

Deutsche Gesellschaft für Sexualforschung, based at the Universities of Hamburg and Frankfurt/Main. Address: Martinistr. 52, 20251 Hamburg, Germany.

Gesellschaft für Sexualwissenschaft (Leipzig). Address: Bernhard-Goering-Str. 152, 04277 Leipzig, Germany.

Gesellschaft für Praktische Sexualmedizin (Kiel). Address: Hospitalstr. 17-19, 24105 Kiel, Germany.

Deutsche Gesellschaft für Geschlechtserziehung (Bonn/Landau). Address: Westring 10A, 76829 Landau, Germany.

Deutsche Gesellschaft für Sozialwissenschaftliche Sexualforschung (Düsseldorf). Address: Gerresheimer Str. 20, 40211 Düsseldorf, Germany.

### Germany's Immigrants

JAKOB PASTOETTER

[Update 2002: Germany has 7.5 million immigrants: Turkish citizens account for 2.1 million (28.8%); citizens from the former Yugoslavia, 9.8%; and Italians, 8.4%. About one third have lived in Germany for 20 years or longer; about 20% were born here. The jobless rate for immigrants is about double that of native Germans. A major factor in this unemployment, according to the last biannual *Report of the Situation of Migrants in Germany* (3/2000), is the decreasing level of education among immigrant students. Another subgroup that deserves more interest is the rapidly growing number of senior immigrants, with half a million now over age 60.

[The immigration rate of Aussiedler, people with German heritage resettling from host countries like Russia, Poland, and Rumania after having lived there for several hundred years, has remained relatively constant, with 104,916 registered in 1999 and 103,080 in 1998. Meanwhile, the number of people becoming naturalized Germans increased rapidly from 61,709 in 1994 to 106,790 in 1998.

[Specific medical problems, like a higher rate of sexually transmitted diseases. and sexual problems, like inhibited ejaculation, are often the result of highly traditional gender roles and sexual traditions colliding with the values of a postindustrial, Western society. For people living in the conservative and patriarchal traditions of Islam, of Catholic Poland, or of the village societies in rural Eastern Europe, the confrontation with liberal sexual attitudes is a shock. It seems that immigrant males have more problems with the devaluation of their often highly ritualized and privileged position within their family, as well as in society. Women, however, experience the individual freedom of choosing their own lifestyle. German social workers, sex educators, and physicians have started to see some of these conflicts as cultural problems, and are trying to find cultural answers. For example, a German doctor would normally ask to see a male patient alone without the male friend or relative who accompanied him. Turkish men, however, are accustomed to have a male friend or relative present with them during the whole visit to the doctor. Another culture-related problem is the sex-information leaflets, which use a formal, impersonal German style and language, whereas Turkish men tend to prefer an informal and personal form of address.

[Migrant women and men alike tend to be less informed about sexual facts. They also have more difficulty in speaking about sex in general. Immigrant women, particularly those from the former Eastern Bloc, often see abortion as the preferred contraceptive; some have had as many as ten abortions during their reproductive years. Their men, in turn, have a strong dislike for condoms. Polish surveys find the same high level of double moral standard as in the United States; women are expected to enter marriage as virgins while men are expected to have multiple sexual "experi-

ences." That sexual experience male immigrants can achieve with German women at *Salsa* parties in discos and bars, which have developed as rendezvous places over the last ten years. This also sheds some light on how German women view their fellow countrymen as intimate partners, and on their high regard for Latin looks and temperament, which makes German women leaders in sex tourism to the Caribbean. As sex tourists, German men travel mainly to South East Asia.

[Sex education in school can only be a success with immigrant children if the parents are not informed in advance, because many parents do not allow their children to learn about sexuality at all. They regard the German culture as being unchaste and immoral—for Muslims even to talk about sex is "impure." Sex education for immigrant adults also runs into difficulties, because the women, in particular, fear that their peers, parents, or husbands will criticize them. Solutions for this information deficit and culturally conditioned hostility may be found in developing a range of cultural sensibilities and introducing peer-education strategies. (End of update by J. Pastoetter)]

## Demographics and a Brief Historical Perspective

ROBERT T. FRANCOEUR

### A. Demographics

Ghana, on the southern coast of West Africa, is a land of 92,098 square miles (238,533 km<sup>2</sup>), slightly smaller than the state of Oregon or about the size of the United Kingdom. Ghana has fertile plains of luxuriant vegetation in the forest zone in the south and much sparser savanna, woodland, and scrubland in the north. The south supports the growing of cash crops, like cocoa—the main export commodity—rubber, coffee, kola nuts, and coconut, and food crops such as maize, cassava, and plantain. The north is particularly suited for cereal cultivation and cattle rearing. Although the official language is English, Ghana's neighbors are all French-speaking nations: Burkina Faso on the north, Togo on the east, and Côte d'Ivoire (the Ivory Coast) on the west.

In July 2002, Ghana had an estimated population of 20.24 million. These estimates explicitly take into account the effects of excess mortality because of AIDS. This can result in lower life expectancy, higher infant mortality and death rates, lower population and growth rates, and different changes in the distribution of population by age and sex than would otherwise be expected. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 40.4% with 1.03 male(s) per female (sex ratio); 15-64 years: 56.1% with 0.98 male(s) per female; 65 years and over: 3.5% with 0.91 male(s) per female; *Total population sex ratio:* 0.99 male(s) to 1 female

**Life Expectancy at Birth:** *Total Population:* 57.24 years; *male:* 55.86 years; *female:* 58.66 years

**Urban/Rural Distribution:** Slightly less than one-third are urban while a little over two-thirds live in rural areas

**Ethnic Distribution:** Black African: 99.8% with major tribes: Akan: 44%; Moshi-Dagomba: 16%; Ewe: 13%; Ga: 8%; European and other: 0.2%

\**Communications:* Augustine Ankomah, Ph.D.: Not available. Beldina Opiyo-Omolo, B.Sc., Department of Health, East Stroudsburg University of Pennsylvania, East Stroudsburg, PA 18301 USA; [bopiyo@yahoo.com](mailto:bopiyo@yahoo.com).

(CIA 2002)

**Religious Distribution:** Indigenous beliefs: 38%; Muslim: 30%; Christian: 24%; other: 8%

**Birth Rate:** 28.08 births per 1,000 population

**Death Rate:** 10.31 per 1,000 population

**Infant Mortality Rate:** 55.64 deaths per 1,000 live births

**Net Migration Rate:** -0.74 migrant(s) per 1,000 population

**Total Fertility Rate:** 3.69 children born per woman

**Population Growth Rate:** 1.7%

**HIV/AIDS** (1999 est.): *Adult prevalence:* 3.6%; *Persons living with HIV/AIDS:* 340,000; *Deaths:* 33,000 (For additional details from [www.UNAIDS.org](http://www.UNAIDS.org), see end of Section 10B.)

**Literacy Rate** (defined as those age 15 and over who can read and write): 64.5% (male: 75.9%, female: 53.5%)

**Per Capita Gross Domestic Product** (purchasing power parity): \$1,980 (2001 est.); *Inflation:* 25% (2001 est.); *Unemployment:* 20% (1997 est.); *Living below the poverty line:* 31.4% (1992 est.)

### B. A Brief Historical Perspective

Ghana was named for an African empire that existed along the Niger River between 400 and 1240 of the Common Era. The country was ruled by Britain for 113 years as the Gold Coast. In 1956, the United Nations approved the merger of the Gold Coast with the British Togoland trust territory. In 1957, it emerged as the first country in black Africa to achieve independence from a European power. Since that time, Ghana has witnessed a seesaw of political power shared between military and elected governments.

In the years immediately following independence, schools, hospitals, and roads were built, along with hydroelectric power plants and aluminum plants by President Nkrumah, but the economic situation deteriorated between the 1970s and late 1980s. J. J. Rawlings, a flight lieutenant who took over the administration of the country through a military coup in 1979 and again in 1981, won the national election and was sworn in as president in 1993. However, Rawlings was defeated in a landslide victory in the 2000 presidential elections by the current President, John Agyekum Kufuor.

## 1. Basic Sexological Premises

### A. Character of Gender Roles

In Ghana, the human world is basically a “man’s world.” Women are in a subordinate position in terms of decision making within the household. Women work both inside and outside the home. At home, they are responsible for mothering, cooking, washing, food storage, and processing. Outside, they participate in agricultural activities and farm different crops, but few hold titles to land. It is in the sphere of trading that the ingenuity of Ghanaian women is most displayed and apparent. Traditionally, they have maintained an autonomous economic role as market traders, and some of them in Accra and Kumasi are perhaps among the most independent women in Africa. Although women who work in the informal sectors may support themselves, their children, and sometimes the husband, decision making on sex and reproduction is still regarded as a man’s prerogative. In 1988, three in ten households were female-headed, yet these heads have to refer issues relating to their children to the male kin. It can be said that in Ghana, women can achieve considerable economic autonomy, but the female power and prestige accruing from her economic independence at the societal level is unable to affect, to any considerable extent, the power relations within marriage.

### B. Sociolegal Status of Males and Females

#### Children

On the whole, Ghana is a pronatalist country and the value of children inestimable. To suggest that children are the *raison d’être* of marriage is an underestimation: They are the *raison d’être* of life. The specter of childlessness is indescribable, and it is felt by both men and women as the greatest of all tragedies and humiliations. Children are the sign of a woman’s normality, femininity, and healthiness. Among some Akan groups in the not-distant past, a public ceremony of congratulation was performed for a couple when they had ten living children. A woman who has no children is open to various suspicions. The two most common are that she or a relative is a witch who has “killed” all her children or that she led an immoral life when she was young. The changing social and economic conditions have not diminished the traditional desire for children, although the number of children women consider as an ideal family size has been considerably reduced. For example, the ideal family size was found to be 6.1 children in 1979-80, but had dropped to 5.3 by 1988, both of which are still higher than actual current fertility. Today, the status of a family, to a very large extent, depends on how well they are able to support their children, rather than on the absolute number of children.

Unlike in some developing countries where sex preference is very strong, with dire consequences for the “unwanted sex,” Ghanaians do not appear to have any strongly held bias for a particular sex. Ideally, every parent would like to have boys and girls in certain proportions, depending on whether the society is matrilineal or patrilineal. For example, among the matrilineal Akan, since descent and inheritance are reckoned through the mother’s side, women provide the continuity of the lineage. A man without sisters is haunted by a sense of frustration.

There is no evidence of sex bias in the feeding or mothering of infants. A government survey in 1988 based on anthropometric measures found no differences between males and females. However, male children under the age of 5 years were more prone to illness and injury than their female counterparts.

An increasing number of school-age children roam the streets and lorry parks of Accra and other cities. This is grad-

ually becoming a social problem. Children at risk include those from broken or extremely poor homes and migrants. Very little has been done in terms of research on these street children. The Ghana National Commission on Children (GNCC) was established in 1977 in response to the United Nations General Assembly’s Declaration of 1976, which set 1979 as the International Year of the Child. The GNCC is the sole coordinator of issues relating to the development of children. In order to support such children, GNCC in 1987 established the Child Education Trust to enable needy dropouts to continue their education. Sustaining breastfeeding and promoting the use of locally produced weaning food products has also been one of the commission’s achievements, as well as putting on the public agenda issues relating to child labor.

#### Adults

Although there are no legal barriers to female education, employment, and other formal aspects in the public sector, situational factors put females in a disadvantageous position. Parents are more likely to educate boys beyond basic education than girls who, it is thought, will soon get married or can earn a living through trading. Consequently, the proportion of females in secondary schools is about 30%; in the universities, the percentage has always been around 18%. Through education, many women have been able to embark on careers that were considered to be for men.

In Ghana, professional women—doctors, lawyers, administrators, headmistresses, and judges—are highly respected, and in their societies serve as role models. Parents are proud of such daughters and may boast to colleagues and friends about them. Women earn the same salary and have the same conditions of service in employment as their male counterparts, although there is a tendency for men (and some women as well) to feel reluctant to work under a woman boss. In general, women occupy subordinate positions in the Ghanaian society and are not regarded as equals of men, who still monopolize most positions of influence.

Given that the early socialization process is modeled along distinct sex roles, every Ghanaian grows up with the knowledge that it is the woman who cooks, does the washing up, and the laundry, and indeed is responsible for all household chores. Notwithstanding her level of education, profession, or schedule of work, a woman does not expect her husband to share in household chores. A few men in highly educated homes may occasionally assist their wives in the kitchen, but many will abandon whatever they are doing when there is a knock at the door, for it is considered disgraceful for outsiders, especially from the man’s family, to find a man engrossed in feminine roles, such as cooking or washing up. Yet, it is the man who always has the lion’s share. There is unequal allocation of food between husband and wife in the home, especially in the rural areas. Men are given the prime cut of meat, for example. The patriarchal nature of the Ghanaian society also has negative implications for the health of women.

### C. General Concepts of Sexuality and Love

The sexual culture of Ghana can be described as a paradox. Sexual matters are among the popular topics for conversation and gossip, but there is less evidence of serious societal debate about sexual issues. Though many cultural artifacts, Ghanaian traditional and “high life” music, dances, jokes, and gibes, are frequently woven around sex, the topic hardly comes into the forefront of any formal discussion, and blunt questions about sexual matters may encounter opposition. It must be stated that Ghanaian sexual mores, as elsewhere in Africa, can be well understood if one keeps in mind that sexual facts are significant, since they af-

fect other spheres of life. In most traditional societies, there was a seemingly inseparable link between the sexual and the social.

In Ghana, public exhibition of emotions by lovers through kissing is frowned at. This does not imply that there is no love in Ghanaian sexual relationships as some foreign writers claim; however, love alone is not enough to persuade parents to approve of a relationship.

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A. Source and Character of Religious Values

There are three main forms of religious practice in Ghana: traditional indigenous (38%), Muslim (30%), and Christian (24%), with 8% other (CIA 2002). In terms of religion, Ghana is a very tolerant country. There is little or no evidence of religious intolerance and fanaticism as are known in some African countries. As with most African countries, Ghanaians believe in the existence of one Supreme Deity, known by different names, whom they regard as far greater than any other being. Atheists are very rare.

In every Ghanaian town there are churches everywhere. The largest Christian denomination is the Catholics. There are Protestant churches like the Methodists and Anglicans, and also a growing number of Pentecostal and charismatic churches. Many members, especially those of the orthodox churches, still maintain some traditional practices that are unacceptable to their churches—such as polygyny—although more and more churches are becoming tolerant. Since it lacks literary documents, traditional religion is not systematic in doctrine. However, one basic characteristic is the belief in the spirits of the ancestors who influence the living in every conceivable sphere of life, and apply rewards and sanctions where appropriate. There are also lesser gods or deities with different powers who represent the Almighty God on earth. Compared with other West African countries, the proportion of Muslims in Ghana is low. Most of Ghana's Muslims are Sunnis, although there is a substantial group of Ahmadi Mission who are well established in Saltpond in southern Ghana. Apart from northern Ghana, the biggest concentration of Muslims is to be found in the two largest cities of Accra and Kumasi.

In a recent study in an urban center in southern Ghana, it was observed that religion has no relationship with female sexual behavior in terms of number of sexual partners and age at first sexual intercourse, although Catholics are more likely than other religious groups to have first sexual intercourse late in life.

### B. Source and Character of Ethnic Values

With over 90 ethnic groups, there is relative diversity not only in language, but also in customs, including sexual norms. The Akan, consisting of several tribes with closely related languages, are by far the largest. Inhabiting most of central and southern Ghana, they form 44% of the total population. The southeast is inhabited by the Ewes (13%). In northern Ghana, the ethnic situation is more diverse, and relatively few groups have been extensively studied. Other ethnic groups include the Moshi-Dagomba (16%) and Ga (8%).

One basic difference with significant implications for sexual values exists between the Akan and other ethnic groups. The Akan is a matrilineal group and the others patrilineal. In matrilineal societies, descent is traced through the mother's line and a person is therefore legally identified with his or her matrikin. A person inherits from the mother's line and thus children hold no claim whatsoever to their father's estate. As in many matrilineal groups, conjugal ties are weak and considered less important than blood ties. Con-

versely, in patrilineal societies, descent is traced from the father's line and children inherit from their fathers. The "luckiest" Ghanaian children are from intertribal marriages where the father comes from a patrilineal group and the mother from a matrilineal society. The reverse (father from a matrilineal and mother from a patrilineal) is the "worst" match, since children cannot inherit from either side. While all the matrilineal Akan groups generally share similar sexual values and norms, within the patrilineal societies there are striking variations in premarital, marital, and extramarital sexual ethos. Generalizations on "Ghanaian sexuality" is, therefore, very hazardous. As far as possible, where differences are striking, attention is drawn to them in this chapter.

## 3. Knowledge and Education about Sexuality

### A. Government Policies and Programs for Sex Education

The government's attitude toward sex education in Ghana, as in several other sub-Saharan African countries, can be described as ambivalent. In a survey in 1987, it was found that all the teachers agreed that there was a need for sex education in schools. When surveyed in 1991, secondary schools in Accra revealed some disturbing findings showing a high degree of ignorance, especially on questions relating to menstrual cycle and pregnancy. In a study by the Health Education Division of the Ministry of Health conducted in 1990, when junior secondary school (JSS) students were asked whether one can get pregnant the first time one had sex, 47% thought it was not possible. The situation is expected to be worse in rural schools. Yet, some people have argued that the Ghanaian society is open and that the children are not ignorant of human sexuality, and hence, it is unnecessary to handle the subject matter in the formal school setting. Others from a religious point of view are worried that sex education is likely to encourage sexual experimentation among sexually quiescent adolescents.

Theoretically, sex education should be covered, but in practice few schools have a comprehensive program on family life education. Policymakers, perhaps for the fear of arousing religious opposition, are ambivalent on issues concerning sex education. On the one hand, sex education is part of the school curricula in order to acknowledge official interest, yet on the other hand, most officials feel unconcerned that it is not effectively taught, thus pacifying the moral and religious critics. The establishment of junior secondary schools, which marks a radical change in Ghana's educational system, may result in a new approach towards the teaching of sex education. With the new educational structure, family life education at both junior and senior secondary school levels is to be covered in a new subject called Life Skills, and again at the senior level within Home Economics. [*Update 2003*: Despite a national reproductive health policy with specific provisions for adolescents, actual access to information and services is severely limited by adults' judgmental views of sexually active youth. Many community organizations have taken an interest in sex education. The Young Women's Christian Association is working with the U.S.-based Center for Development and Population Activists to involve parents and church leaders in counseling. (*End of update by B. Opiyo-Omolo*)]

### B. Informal Sources of Sexual Knowledge

Though a child's own relatives (mostly grandmothers, in the case of females) were responsible for his or her upbringing, they did not have exclusive right in the traditional society. The society as an entity had a system of preparing

and training the young children for every aspect of future life, including sexual life. The training was given by traditionally recognized instructors, usually the elders. In most Ghanaian societies, the initiation or puberty rites were occasions where guidelines and instructions were provided. This was the traditional approach to sex education.

Rapid urbanization, increased mobility, education, and other agents of change have together undermined the traditional channels of sex education. With very limited access to sex education both at home and in the schools, coupled with long periods of schooling in an unmarried state, the gap between sexual and social adulthood has widened, and the modern Ghanaian adolescent faces a sexual dilemma. When in 1991, students in two secondary schools in Accra were asked to state their sources of knowledge on reproduction, the most frequently mentioned source was teachers—apparently as part of biology lessons. On the broad issue of sexual knowledge, students most frequently get their first information on sex from friends, and further from their teachers and relatives. According to Bleek's study in 1976, girls more than boys tend to rely on relatives, especially their mothers, for their first knowledge on sex education. Boys generally receive this information from male friends. The role of teachers appears to be equal for both sexes. In the urban centers, students also report magazines and books as an important source of sex information.

#### 4. Autoerotic Behavior and Patterns

Information on self-pleasuring is hard to come by in Ghana. Kaye, in his impressionistic survey in the 1960s on how Ghanaian children are brought up, noted that parents strongly disapproved of their children engaging in self-pleasuring. They are sternly scolded or severely beaten. Even small boys who play with their genitals are warned to cease. Rattray, who wrote extensively in the 1920s on the Ashanti, an Akan subgroup, described the phenomenon with a phrase, *owo ne kote afeko* (he makes a pestle of his penis). In Ghana, self-pleasuring is not considered an alternative means of sexual expression and is abandoned or forgotten after childhood. This is supported by Bleek's study of schoolchildren in the 1970s, during which he did not observe the slightest hint of self-pleasuring. Adult male self-pleasuring is extremely rare, and local terms for this sexual behavior are hard to find.

#### 5. Interpersonal Heterosexual Behaviors

##### A. Children

The genitals of children, especially females, are not referred to directly. Special attention is given to children's genitals during bathing. The penis and vagina are washed clean to avoid sores. This is almost universal in Ghana. Warm water is dribbled into the girl's genitals (the opened vulva) and sometimes ground ginger is applied in some traditional homes to prevent disease, or sometimes as punishment for misbehavior.

Sex games in which children play the role of mothers and fathers are commonly practiced in Ghana. The games are not forbidden, but sexual exploration in the form of mutual examination of genitals may not go unpunished. Until puberty, boys and girls play together freely, and in towns and villages, especially on moonlit nights, clandestine affairs are sometimes reported.

##### B. Adolescents

In traditional Ghana, as in most other African countries, the sexual transition from infancy to adulthood was not only a physiological phenomenon, such as onset of menarche, but

also social. Adolescence as a reality, where a person is neither a child nor an adult, did not exist. Puberty in girls is a sign of approaching womanhood and special nubility rites for girls are performed after the first menstruation. The sociological function of initiation rites and ceremonies is to usher the child to adulthood without the period now called adolescence. In Ghana as a whole, girls' initiation ceremonies are culturally more widespread, interesting, and complex than boys' initiation. Girls' entry into womanhood, especially among the Krobo, are marked with complex ceremonies involving elaborate preparation and rituals. Generally speaking, Ghanaian boys enter manhood quietly: There are no initiation ceremonies or public ceremonies for boys.

At the end of the girl's initiation, she is gorgeously dressed and beautifully decorated. The initiate sets out with her retinue to thank all people in her village or town. She is now regarded as marriageable. If she is betrothed, her "husband" (*fiancé*) is formally informed to perform the marriage rites and take her as his wife as soon as practicable. If she is not already "engaged," then bachelors have a chance to have a closer look at her. During the initiation period, "sex education" lessons were provided by recognized older women who serve as custodians of instructions on motherhood. The sexual instructions given included: how to "sleep" with the husband, menstrual taboos, how to recognize pregnancy, and personal hygiene, especially of the genitals.

Unlike parts of East Africa, where there are cycles of initiation periods and ceremonies are performed for groups of persons, in Ghana with few exceptions, initiation ceremonies are mainly individual affairs, although two or three girls may begin their rites on the same day in one village. But, even here, the ceremonies are often separate, except where the neophytes are either closely related or are close friends. While puberty rites are still performed in some rural areas, they have lost a great deal of their pomp and pageantry, perhaps with the exception of the Krobo, the rural Ga, and the Adangbe, where it is still popular.

##### Circumcision

Female circumcision is ritually unknown among all Akan groups in Ghana. On the whole, the practice is fairly common among the Frafra and other groups that inhabit the regions of northern Ghana. The practice is also reported in the areas in the city of Accra, such as Nima and Madina, with a large concentration of migrants from the north. In these societies, it performs a social function as a puberty rite. It is claimed by the local people that it is a precondition for marriage and a test of virginity. Most doctors are of the view that circumcised females stand a higher chance of experiencing problems during childbirth, and female circumcision has always been cited as one of the cultural practices negatively affecting women's health in Ghana.

There are significant differences in the practice of male circumcision among the various ethnic groups in Ghana. For example, the Ga of Accra and the Krobo have traditionally been practicing circumcision. A Krobo parent will not give her daughter in marriage to an uncircumcised man (apparently from an Akan tribe). Traditionally, among the Akan groups, however, male circumcision was not practiced, since it was considered as mutilation of the human body. The Akan have a rule that no one who has a scar can be elected a chief, and one already selected can be "destooled" (deselected) as soon as it is found that he has been circumcised—apparently because his body has been maimed in a way that disfigures him.

In spite of the traditional mores, male circumcision has become very popular. In boarding schools, uncircumcised boys feel shy and are unable to join others in the bathrooms,

as they are constantly ridiculed and called *koteboto* (uncircumcised penis). They lack the confidence to profess love, since girls are known to shun them. The pressure may be so great that many young men are compelled to undergo a painful adult circumcision. These days, however, a great number of boys are circumcised shortly after birth.

### C. Adults

#### *Premarital Courtship, Dating, and Relationships*

In Ghana, traditional norms involving attitudes to and acceptance of premarital sexual relationships differ from society to society. Among the Kwahu (a subgroup of the Akan), girls were not to engage in sex before they were married, and certainly not before their first menstruation. Rattray, who wrote in the 1920s, also stated that among the Ashanti, premarital coitus was forbidden. The official code on premarital sexuality was rather strict. In olden times among the Akan, a girl was killed, or both parties banished, when she engaged in sexual intercourse prior to her puberty and initiation. In most societies in southern Ghana, since girls were usually married shortly after their initiation, many entered the conjugal union as virgins.

Among the communities in northern Ghana, the situation was different. Prenuptial chastity was not particularly valued. It is reported that among the Kokomba, for example, many women were already pregnant before marriage. The Tallensi, also of northern Ghana, explain that copulation and marriage are not the same thing. It can be said that while premarital sexual relationships have been permitted in most societies in northern Ghana, it arrived in the south as an influence of modernization. Chastity can mean two things in Ghanaian sexual mores: chastity before puberty rites and chastity after initiation, but before marriage. In olden days, both were thought important among most ethnic groups of southern Ghana. The attitude towards postpubertal but premarital chastity, however, has undergone substantial changes in many parts of Ghana.

The force of social change in Ghana resulting from education, increasing urbanization, and monetization of traditional economic systems, among others, have blended to produce changes in sexual culture. In Ghana today, it is clear that, even in societies where premarital relationships were not openly permitted, they are now at least condoned. In Ghana as a whole, the onset of sexual activity is fairly early. The median age at first sexual intercourse for females is 17 to 18 years, although one survey puts the mean age at 15. Although a substantial minority have multiple partners, for females, premarital serial monogamy with frequent partner-switching is the norm. Durations of sexual relationships are generally short and women do not appear to be worried about frequent partner-switching. In a study in one town in 1991, the mean duration of relationships was 13 months.

The underlying issue that shapes the duration of sexual relationships is basically pecuniary in nature. For many single women, especially in the urban areas, sexual relationships are means of additional income. A recent study in a town in southern Ghana has shown that personal sociodemographic variables are not significantly associated with parameters of sexual behavior, including the number of sexual partners and duration of sexual relationships. The strongest predictor of sexual behavior is women's attitude to material recompense for sex. Several anthropological studies in southern Ghana, especially, have shown that for women, economic pressures, among others, provide the background for most premarital sexual relationships. At present, the consumerist nature of premarital sexual relationships (but not formal prostitution) is generally acceptable, and it is its absence, rather than its presence, that is strange. It is interest-

ing that most Western researchers mistakenly label this phenomenon as prostitution, apparently because some women obtain money and other gains from sexual relationships.

Premarital sexual relationships are essentially secretive in nature, although secrecy is always a matter of degree. Public show of love and affection through kissing and holding of hands while walking is hardly seen among lovers. This often misleads researchers from other cultures to misinterpret this to mean lack of love in Ghanaian "lover relationships." In Europe or America, dating couples may agree on the nature and extent of their relationships, for example, whether it is to be sexual or not. In most premarital relationships in Ghana, there is no such decision to be made. In both traditional and modern societies, premarital relationships are primarily sexual. Implicitly, male-female relationships are never nonsexual.

#### *Sexual Behavior and Relationships of Single Adults*

Until recently, the term "single adult" was a misnomer in the Ghanaian sense. The puberty rites marked a graduation from youth to adulthood, and a woman was usually married out soon after into a relationship sometimes contracted by the couple's families prior to the initiation. The transition from childhood to adulthood was, therefore, definite and clear-cut.

The modern young adult is in a different social milieu. Modern schooling keeps boys and girls longer in an unmarried state. Some people after school spend some years looking for decent jobs. This has widened the gap between sexual maturity and married life. However, since the social position of a person, especially a woman, is often dependent on marital status, single adulthood as a chosen option is hardly acceptable. The normal pattern of Ghanaian life is to marry and have children. Any alternative lifestyle is highly questionable. Within the past few years, however, an increasing number of women do not conform to social norms and remain single.

It is worth noting that most of the few voluntarily single women are not without children. Some had unwelcome pregnancies at early ages, while others with experience from previous unions find married life distasteful and men untrustworthy. The fact that most single women choose to do so after having had children underscores the importance Ghanaian women attach to their reproductive roles.

The position of a male single adult, compared with the female, is perhaps even more untenable. While a single female adult can have children, and in the process, exhibit her fecundity to her family and indeed the entire community, the single man has no way of demonstrating his virility. Men who continue as single right up to late ages are viewed with suspicion, and may even be thought to be impotent. A middle-aged man who cooks on his own, or eats outside his home, is in an awkward position, because society does not tolerate his position as a single adult. In villages, children may refuse to go on his errands—a Ghanaian child is trained to go on errands—and some impertinent children can boldly tell him to have children of his own if he requires the services of those younger. He is normally regarded as irresponsible: He cannot assume responsibility of a wife and children. This may impair his social esteem, and can become an issue for gossip at his workplace, especially if he holds a responsible position.

#### *Marriage and Family*

Marriage, perhaps the most important social institution in Ghana, is almost universal. Age-specific marital rates are very high and increase rapidly through successive cohorts. According to the Ghana Demographic and Health Survey of

1988, 98% of all women aged between 30 and 40 years were in marital unions. The median age at first marriage is around 8 years, and there has been no significant change since the 1970s. The national figure, however, conceals regional variations. The northern regions of Ghana together exhibit the highest rates, with over 84% of all women aged 15 to 19 in marital unions.

As elsewhere in Africa, marriage is not an individual affair, but rather a union between two families. Even today, highly educated urbanized men and women will go to great lengths to persuade an unwilling mother, but especially the father, to agree to their marriage. Costs involved in marriage differ from society to society and between families, depending on the status of the couple or their parents. On the whole, marriage among the matrilineal peoples is far cheaper. Bride-wealth is considerably smaller, compared with the patrilineal groups, where husbands may be asked to pay dozens of fowls or cattle, which in terms of money is quite substantial.

In Ghana, there is legal pluralism of marriages. There are four basic ones: customary marriage; marriage under the ordinance; Christian marriage; and Muslim marriage. Eight out of every ten marriages are under customary law, under which a man can marry many wives (polygyny). Marriage under the ordinance is a British colonial legacy, which introduces attributes of legitimacy, monogamy, and inheritance into the Ghanaian context. To many, this has caused ambiguity in Ghanaian marriage law. For example, it precludes the husband from the practice of polygyny. In fact, only a small minority of Ghanaian marriages are contracted this way. Marriage types are not necessarily mutually exclusive. Persons who marry in church or in a registrar's office under ordinance do so only after they have performed the necessary customary rites.

In Ghana, as in other parts of Africa, a man, his wife or wives, and children do not constitute a family. Although the Western concept of the nuclear family can be distinguished, it is not the basis of social organization and community living. The extended family network consists of a long list of kinsmen who are matrilineally or patrilineally delineated.

In Ghana, cohabitation as a practice may be better referred to as a consensual union. In very many instances, marriages under customary practice do not take place as a single, definite event. It is rather a process that involves a series of presentations by the man's family to the family into which he proposes to marry. These presentations may be made at once, as among the Kokomba, or over a period of several years, as among the Akan. After the first presentation, a marriage may begin as a consensual union approved by parents of both partners and accepted as a proper marriage for all practical purposes. However, such unions have some drawbacks: For example, under customary law, the husband cannot claim damages if his wife commits adultery. This type of marriage is called *mpenawadie* (concubine marriage), and is less respected, and wives will put pressure on husbands to perform the final rites.

### *Polygyny*

In almost all Ghanaian societies, polygyny (where the husband has two or more wives) is socially accepted, and is even desirable. It is practiced in all the different customary marriage patterns. Although there are some variations, it is practiced in both urban and rural areas, and by literate and nonliterate people.

Many reasons are put forward to explain, if not to justify, polygynous marriages. These include long periods of postpartum sexual abstinence from anywhere between three months and two-and-a-half years. It is common for the pregnant wife to leave the husband's home in order to de-

liver among her kinsmen; she does not return until the baby is able to walk. To satisfy his sexual desires, a man is allowed to marry more than one wife. In the not-too-distant past, social status and economic prestige were the motivating factors. The large number of children from the different wives was useful in the husband's occupation, which was basically farming.

Polygyny demands some domestic residential arrangements. The most uncommon arrangement is the situation where all wives live separately from the husband who arranges periods for visits. Another solution is that in which the husband lives with all his wives in one house. This is not highly desirable, given the embedded rivalry and tension among cowives, which not infrequently results in brawling. The most favored option is that one wife (usually the first) resides with the husband, and the other(s) live on their own or with kinsmen. Cooking, "sleeping," and other wifely duties are arranged by the husband.

Polygyny is commonly practiced. Ghana's 1960 Population Census showed that 26% of all married men had more than one wife; in 1979-80, according to the Ghana Fertility Survey, 35% of all married women were in polygynous homes. The figure for 1988 was 33%. Younger women are less likely to be in polygynous unions than older women. Given that in Ghana an unmarried woman is an anomaly, polygyny affords all women (who desire) the opportunity of being attached in marriage to a man (who, unlike in the past, may not be necessarily supporting her in full). Ironically, polyandrous marriages (where one wife is legally married to more than one husband) is not practiced in Ghana or any studied society in Africa.

### *Divorce*

Marriages among the matrilineal groups in Ghana, strictly speaking, do not promote stability. The children and their mother are considered "outsiders" by the man's matrilineage. After the husband's death, the wife and the children are allowed up to one year to live in the deceased's property, after which they can be forcefully ejected—and many are. The man's children, until the introduction of the Intestate Succession Law in 1985, had no claim to their father's property. Given that the woman and her children are always welcomed back into their lineage after divorce, and the bride-wealth, even where refundable, is fairly small, the incidence of divorce in matrilineal societies is higher than in patrilineal societies.

Under customary law, divorce is common, simple, and easily obtained. Both husband and wife can initiate divorce. Divorce in Ghana can result from several causes—the key culprit being infertility on the part of either partner. Other frequent reasons to merit divorce are: bad conduct, neglect of marital duties (such as a man's failure to provide money for food and family upkeep, popularly called "chop-money"), gossiping and tale bearing (usually on the part of the woman), laziness, accusation or suspicion of witchcraft, and interference in lineage affairs or lack of respect for in-laws. Adultery of a woman is grounds for divorce, but in customary law, the wife cannot enforce divorce on the grounds of her husband's adultery or his marrying more wives. The practice is that before an additional wife is married, the first wife is informed by the husband, who pacifies her with money or in kind.

There is usually a small and simple ceremony or ritual performed to legalize divorce. Among the Akan, it consists of the sprinkling of white clay before the woman's feet, thus formally loosening her from her former matrimonial bonds.

Although it cannot be exaggerated how easily and rapidly marriages dissolve with little trouble, it must be pointed out

that, because marriage is a union between families, most divorces are preceded by family "arbitration." The aggrieved party will have to state his or her case before responsible men. The arbitrators deliver their finding after hearing each party, and then attempts are made to reconcile the couple. Unlike the matrilineal groups, traditionally among the patrilineal groups, especially the Ewe, there usually was stability of marriage. However, there have been significant changes due largely to the curtailment of the power of traditional authorities, which used to enforce the sexual morality of the people. Now, divorce is common among the Ewe, but perhaps not as frequent as it is among the Akan.

It appears the proportion of divorced persons is on the decline. In 1960, up to 20% of women aged over 44 years were divorced, compared with 13% in 1988. It is difficult, however, to obtain any useful idea of the frequency of divorce by examining the proportion of divorced persons in the population. Studies have shown that few women spend long intervals between marriages. They are usually in the process of contracting another marriage before the previous one has been formally terminated. Remarriage rates are, therefore, high, given that the society looks down upon single women.

### *Extramarital Sexual Behavior*

Among the Akan, extramarital relationships have been very common traditionally, and today are still practiced by married adults of both sexes and by people of all socioeconomic groups. There are some circumstances that are especially conducive to this phenomenon. Differences in status or age may demand different sexual or social habits that the partner is unable to provide. Given the high cost of living in Ghana today, some women engage in extramarital liaisons for material recompense, especially if the husband is unable to provide support. In a society where procreation is the main reason for marriage, the husband or wife may indulge in extramarital sex in the hope of having children when the other is infertile. Broadly speaking, women engage in extramarital relationships less than men.

An extramarital relationship by a married woman is regarded as adultery and both male and female culprits are liable to punishment and ridicule. Among the traditional Ga, for example, a man caught in the act of adultery with a married woman is severely beaten there and then by the family of the injured husband, their friends, and helpers. In villages, the distinctive sound of an adultery-hoot may be heard all over. A crowd gathers around the house where the adulterous act is claimed to be taking place. People begin hooting—*huu huu huu*—to emphasize the shameful behavior of the woman. The guilty man sensing danger may jump out the window. If he is lucky enough to avoid a severe beating by escaping into the bush, his family has to pacify the aggrieved husband in his absence. For his own safety, the male adulterer may avoid any public appearance until his family has completed all necessary rites to pacify the husband.

A wife's adultery, especially among the Ewe, is believed to cause not only her own death, but even that of her husband. Among the Anlo Ewe, for example, husbands, including highly educated ones, know well the risk to their lives of the infidelity of their wives. To prevent these misfortunes, many men have charms which help to strike terror in wives with adulterous intentions. Sometimes, adultery is believed to make childbirth difficult, and unless confession is made before or during childbirth—and some women do so in the rural areas—the adulteress may die with the child.

In Akan customary marriage, where a married woman is seduced, her seducer is bound to pay the husband, as damages, an amount which is fixed by law (called *ayefare* by the

Akan), although one could seek divorce outright. Today, *ayefare* is not routinely claimed by men because of the shame attached to its acceptance. Many prefer that their wives' extramarital affairs are kept secret, but once it comes out in the open, divorce is sought rather than the claim of damages that may be considered embarrassing. The societal attitude to the extramarital affairs of men can be described as a double standard. The philandering of married men is generally accepted until a point is reached at which a wife feels she is suffering a grievous hardship; then she may ask her husband's family to restrain him. A woman who seeks divorce because her husband has an affair with another woman is considered to be overreacting, and she cannot expect much sympathy, let alone support, from her relatives, unless there is compelling evidence that the man is financially not supporting her and the children.

### *Levirate*

Levirate marriage, in the strict sense of a man marrying his deceased brother's wife and bearing children with her for the dead person, is practiced in very few ethnic groups in Ghana, among the traditional Ga, for instance. As a rule, levirate does not exist among the Anlo Ewe, where the husband's sexual rights are personal, nontransferable, and end with his death. His widow is then free to remarry any man of her choice, including the deceased's agnates. What is customary among the Akan groups, and is currently practiced in a few instances, is widow inheritance. Here, the brother of the dead man becomes the real husband of the widow, but the children by that marriage belong to him and not the deceased brother. Sororal polygyny, where a man marries two sisters of a family, is unheard of in Ghana.

### *Sexuality and the Disabled and Aged*

Ghana's 1984 population census recorded that about 3% of all the population aged 15 years and over were disabled, with the number of women twice that of men. No studies on the sexual adaptations of this segment of the population have been undertaken.

Very little, if at all, is known about the sexuality of the aged in Ghana. It is not uncommon to find an old man married to a young woman, although many of such women may still have sex with their former lovers or with other young men. In most villages, however, some situational factors may inhibit sexual relations of aged couples. As they grow old, children may be asked to sleep with the grandparents to give privacy for the young couple. This makes it difficult for the aged couple to have sexual intercourse, and they, therefore, slowly drift apart. While young widows normally remarry, remarriage for women over 50 is rare. They are unlikely to find marriageable single men, and many at this age are unwilling to be married as second or third wives to polygynous men. Secretive sexual exploits at this stage are very rare: it is considered disgraceful, not only to the aged person, but also to the children and grandchildren.

### *Incidence of Oral and Anal Sex*

Penile-vaginal penetrative sex with little foreplay is the normal sexual style in Ghana. Although among the well-educated youth, some form of foreplay is introduced, fellatio or cunnilingus is abhorrent. Even among prostitutes, vaginal sex is the norm; very few practice oral sex. Genital manipulation is hardly accepted and, traditionally, women feel shy to touch the penis—and most men are not interested in having their genitals manipulated anyway. Anal sex is considered a sexual depravity and is reserved for animals. It is abhorrent even to prostitutes. In a recent study in Accra, the capital city, only one respondent reported that she would engage in anal intercourse if the price was right.

## 6. Homoerotic, Homosexual, and Bisexual Behaviors

Any form of same-sex activities is hardly mentioned in Ghanaian society. Homosexual activities among boys is exceedingly rare. Even where homosexual activities are practiced by boys, they are considered basically "presexual," and are quickly abandoned as they mature. The situation may be different for female homosexuality. It is practiced in girls' boarding schools by a few students "who want to release tension," but are either afraid of getting pregnant or have no access to male partners, given the strict rules regarding male visits to girls' schools. But here too, it is basically situational and not an alternative means of sexual expression. It is quickly forgotten once the girls leave school. In Bleek's study in the 1970s, he observed that no reference whatsoever was made to homosexuality and no word gave a hint of its occurrence. It is the impression that homosexuality is so rare in Ghana that people hardly have any idea of it, even on university campuses. Young male adults may dance together at nightclubs, and may even imitate a couple, without any inhibition. If there existed a secret or clandestine practice of homosexuality, this would not be possible and boys would be too embarrassed to behave in such a way. It is virtually impossible to prove that homosexuality does not exist: What can be said is that homosexuality as a means of adult sexual expression hardly exists in Ghana, and it is not listed as a sexual offense because self-identified gay men are virtually unheard of.

## 7. Gender Diversity and Transgender Issues

There is no knowledge of gender-conflicted persons. Adult homosexuality is so rare that the sociolegal status of a homosexual is unthinkable. Transsexuals are virtually unheard of in the Ghanaian society.

## 8. Significant Unconventional Sexual Behaviors

### A. Coercive Sex Sexual Abuse

Child sexual abuse is very rare in Ghanaian society. Those who engage in it may be regarded as perverts. Even in societies where daughters could be given in marriage at a very tender age in a form of betrothal, sexual intercourse is precluded until after the girl has undergone the initiation rites. Domestic maids often brought into the cities by middle-class families may in some instances be sexually abused by unscrupulous husbands, especially if there develops a marital discord or the maid becomes more and more beautiful as she grows up in the city.

### Incest

Incest, sexual intercourse between parents and children or between full siblings, is abhorred, extremely rare, and culprits are severely punished. An incestuous act may be wider than imagined, depending on whether the society is endogamous (the Dagaaba of Upper West and the Ewe, for instance) or exogamous (the Akan), where sexual relationships within the large clan are prohibited.

The sexual mores defining what relationships are incestuous may appear strange to an outsider. For example, among the matrilineal Akan, while it is incestuous for a man to have sexual intercourse with his mother's sister's daughter, he is enjoined to marry his mother's brother's daughter or father's sister's daughter. Among the Ga of southern Ghana, it is so repugnant that in the early days, an incestuous man was punished by drowning and the woman driven

away into the bush. To make sure that the practice was not condoned by the family, none of the relatives of the offenders was allowed to hold any post of importance for one generation. Today, it still is a family calamity. An offender is denied from using the family name and is forbidden to attend public festivals.

### Sexual Harassment

Traditionally, a woman's body is considered special, and care should be taken in the way a man handles it. To pull or play with a woman's nose, ear, or any other part of the body, or tickle the palm of a woman's hand is considered highly indecent and immoral. If this is done to a married woman, it could be likened to adultery and the aggrieved husband may claim damages. In contemporary Ghana, few single women will consider any of these as sexual harassment. Rather, they are signs of a man showing interest, but lacking the courage to say so because "he has a mouth that is sewn."

It is, however, common to hear reports of young women, especially typists and secretaries, being sexually harassed by their bosses, or student girls by their teachers. Given the subordinate role of women, coupled with the fear of losing their jobs or being denied promotion when they tell others or decline the sexual advances, women are put under tremendous pressure. Some women are compelled to give in or blow the matter up by exposing the boss, who may become a reference point for public ridicule. It must be stated that sometimes the advances may also be made by women who think they can materially gain from a sexual relationship with the boss.

### Rape

In Ghana, as elsewhere, indecent assault and rape are criminal offenses. Rape is defined in Ghana's Criminal Code as an unlawful carnal knowledge against any female, and when the assaulted woman is physically incapable of resistance to force, rape does not have to be proved. Its occurrence in Ghana is very rare, and a woman walking alone in a city late in the night may be afraid of mugging, but would hardly think of rape.

Very little research has been done on the issue. In 1977, 273 cases of assault and rape were reported. The victims were mostly house girls, babysitters, and were, like the offenders, mainly in the lower social class. The minimum sentence for rape is 12 months, which is considered too lenient by women activists. An attempt in 1993 by female members of Parliament to increase the minimum sentence to three years was opposed. The main national newspaper, the *People's Daily Graphic*, described the men's behavior as "sheer display of male chauvinism and lack of respect and understanding of women's sensitivity."

There is a variant of unconventional sexual behavior that is fairly common in the villages. This is an attempt to seduce a woman while she is sleeping in the night, not infrequently with the connivance of the woman, especially if she is married. Consent of the woman is immaterial if they are caught. The man can be so ridiculed that he may be compelled to move out of the village.

### [Female Ritual Slavery

[Update 1997: In the isolated farming villages along the Volta River in southeastern Ghana, several thousand young women are caught in a religious tradition that condemns them to a form of perpetual ritual slavery. The *trocosi*, as they are known in the Ewe language, or "slaves of the gods," work in local religious shrines to appease the fetish gods for crimes committed by their relatives. In the local culture, justice and punishment are viewed in communal rather than individual terms. Thus, a young female who has

no connection with a crime, and may not even know what it was, may be sent by her family to atone for a (male) relative's crime by serving the local fetish priest. Because the priest is a spiritual intermediary between worshipers and deities of the area's traditional Ju-ju religion, the *trocosi* can appease the fetish and keep them from punishing her whole family. Her life becomes one of unquestioned service to the priest, cooking, cleaning, weeding the shrine's farm, growing yams, manioc, and corn, and providing sexual favors to the shrine's priest. The *trocosi* gain nothing personally from their service; their families must even provide them with food. The people are convinced that without the protection provided by the *trocosi*, the gods may wreak vengeance on their entire extended family or community (French 1997).

[The *trocosi*, who must begin their service as virgins, can only be freed by the priest. A *trocosi* usually gains her freedom only when she is middle-aged, has borne the priest many children, and has lost her sex appeal. But freedom for one *trocosi* means enslavement of another virgin from the same family who must replace her. Thus, the slavery continues generation after generation in perpetual atonement.

[This form of ritual slavery, which is also found in neighboring Togo, Benin, and southwestern Nigeria, is deep-rooted in a very powerful superstition that will be difficult to eradicate. A government law banning the practice would have no effect, since the whole community is in agreement with the custom and firmly believes their survival depends on their freely sending a "scapegoat" *trocosi* to serve the local fetish priest when someone commits a crime. Recently, there has been increasing criticism from international human rights advocacy groups and from women's rights groups within Ghana. Individual women's rights advocates and private groups within Ghana have had some success in stopping the practice by negotiating with paramount chiefs and other prominent local leaders. One local group, International Needs, has persuaded several fetish priests and their shrines to abandon the custom in return for a gift of ten cows, a bull, a corral for the priest's new cattle, and cash given to the surrounding villages (French 1997). (End of update by R. T. Francoeur)]

## B. Prostitution

From the onset, it is necessary to distinguish between sexual exchange and prostitution in Ghanaian sexual culture. These two practices are often misunderstood by outsiders, who consider them as the same. Sexual exchange, a recent phenomenon, is a socially acceptable and pervasive practice in which sexual relationships, both premarital and extramarital, are contracted for material recompense. While implicit pecuniary gains underlie the relationship, it is worth noting that in sexual exchange, material rewards, especially money, are not given directly after sexual intercourse, as is the case with prostitution. The giving and receiving of gains is separate from the act of coitus. A girl is likely to be offended for being thought a prostitute, if she is given money immediately after sexual intercourse. Unlike prostitution, in sexual exchange, it is not the sexual act that is rewarded, but the relationship.

Prostitution, the exchange of sexual acts for money, is illegal in Ghana, and women who practice it are often harassed by the police and other officials of city or local councils. Nevertheless, it is openly practiced in many cities and towns. In Accra, for example, an area called Korle Wokon is noted for its prostitutes. Unlike sexual exchange, prostitution is unacceptable to the Ghanaian society—the only exception being perhaps among the Krobo—and constitutes an infraction of Ghanaian sexual mores. Those who engage in it often conceal their identities by working in suburbs

where they are not likely to be recognized by familiar faces, and some may even change their names altogether.

Ghanaian prostitutes generally operate without pimps. At least two main groups of prostitutes can be identified: home-based prostitutes and hotel-based prostitutes. The former usually work in rented rooms or brothels and are of low class with little or no education. They are usually old, with an average age of around 40 years, divorced, and are heads of households with four or more children to support. They all cite acute financial problems as reasons for prostitution. They charge around \$1 per client per sexual act or "round," and report an average of two or three clients a day.

Hotel-based prostitutes operate from hotels, nightclubs, and discos. They are sophisticated, are of high class, much younger, highly educated, and serve an equally high-class clientele. Their prices, which are generally higher, depend on the class of the hotel where they operate.

Tema is the major port and industrial complex of Ghana, and the visiting seamen, both Ghanaian and foreign, attract many prostitutes. With the scourge of HIV/AIDS infection, intervention programs, with support from Family Health International (FHI) and other international agencies, are being implemented to encourage prostitutes to use condoms, given that in 1986, about 60% of all prostitutes surveyed in Accra had never used condoms before.

## C. Pornography

Nudity is culturally repugnant. It is considered inappropriate for parents to undress in the presence of their children. Societal attitudes to nudity are more severe towards females than males. Women are expected to cover their breasts and thighs in public. In the Muslim areas, the rules are tighter. Even in Ghana's large cities, a lady wearing a pair of shorts in public is considered immoral. Any explicit display of erotic materials is highly unacceptable and magazines on erotica are not available. Television programs never include sexual material likely to be offensive. With the growing number of video rentals and show spots, there is an increasing concern about the sexually offensive nature of some films, although they come nowhere near the soft pornographic materials available in Western countries.

## D. Sexual Taboos

Apart from incest, there are other sexual taboos worth mentioning. These include sexual intercourse while a woman is in her menstrual period, with a widow less than a year after her husband's death, and sexual intercourse with a woman in the bush. The latter is called by the Akan *ahahantwe* (sexual intercourse in the leaves), and is considered antisocial because it threatens the life of the society. By being performed in the bush, sexual intercourse, upon which society depends for its perpetuation and, hence, is regarded as sacred, is reduced to the level of an act that is performed without regard to the environment. If it was done without the connivance of the woman, it could lead to death in the olden days. Today, however, if reported, it is treated as rape. But whether there is consent or connivance on the woman's part, the man is asked to provide a live sheep, which is sacrificed upon the spot where the adulterous act had taken place. This is currently practiced in most rural settings among the Akan.

## 9. Contraception, Abortion, and Population Planning

### A. Contraception

The present high level of Ghana's population is the result of persistent high birthrates and declining mortality

rates over the years, leading to a high rate of natural increase. For a variety of social, economic, and cultural reasons, large families are attractive to many Ghanaians. The average Ghanaian woman in the 1990s is expected to have 6.4 children in her lifetime. Knowledge about contraception is high. According to the Ghana Demographic and Health Survey in 1988, 79% of currently married men and women had heard about contraception, but only 13% of the women were using any method of contraception (5% if restricted to modern methods). The pill and postpartum abstinence are the most popular modern and traditional contraceptive methods, respectively. For adolescents and young adults, however, the condom is the most popular.

There are some differentials in contraceptive knowledge and use by educational level, type of residence, age, and reproductive intentions. Modern contraceptives are available at several service delivery points owned by the Ministry of Health, the Planned Parenthood Association of Ghana (PPAG; an affiliate of International Planned Parenthood Federation), the Christian Council of Ghana, private maternity homes, contraceptive social marketing outlets, and pharmacies. However, about one in every five users obtained their supplies from friends or relatives. With the scourge of HIV/AIDS infection, condom promotion has been intensified through social marketing and community-based distribution.

### B. Teenage Unmarried Pregnancies

Births to adolescents accounted for 11% of Ghana's births in 1978-1980. Teenage premarital pregnancy is becoming an increasing social and health problem. One reason for low teenage (unmarried) pregnancies in the traditional societies was the observance of puberty rites, after which marriage followed almost immediately. Increased education and other forces of social change have eroded the traditional constraints. Unfortunately, no replacement has been found for these rites and the sex education it provided. Modern counseling is inadequate for teenagers, and access to family planning is limited.

When sexual relations between teenagers result in pregnancy, the boy's parents are informed. Pressure is exerted on the man to marry her, unless the girl's lineage does not want him as an in-law. In a few instances, a pregnancy can be used to persuade the elders of a lineage to approve of a relationship to which they would not have normally consented.

### C. Abortion

Abortion is illegal except for medical reasons, and very few Ghanaians would want this changed. Yet many pregnant student girls procure abortions in order to complete school or because their partners are not yet ready to father a child. While these are the official reasons women give, it appears that it is the fear of shame that is the dominant factor. Statistics of induced abortion are hard to come by and, even where they exist, are grossly defective. In a 1990-1991 study among secondary school students, 10% of male students who have had intercourse admitted having impregnated a girl, and for 61% of these, the girl concerned resorted to abortion. Induced abortion is reprehensible and always remains hidden. Although the official rules for procuring an abortion are not liberal, it is well known that, provided the client is able to pay, most hospitals will undertake it.

Many abortions, however, are performed outside of hospital premises by unqualified back-street abortionists, quack doctors, and self-induced or friends. In the last category, herbs and other incredible combinations of concoctions form the largest method. The knowledge of alleged abortifacients among young men and women is amazing. Bleek, in his study among the Kwahu in the 1970s, listed at

least 53 different methods for procuring self-induced abortion, which included "modern" methods involving the use of assorted pills and herbs, such as the insertion of the twig of *nkrangyedua* (*Jathropa curcas*) or *menyenemenyeme* (*Thevetia peruviana*) into the uterus. Many of these amazing methods are still in use. In a study in 1990-1991 among secondary school students, respondents' lists of abortifacients included: a mixture of sugar and lemon, *akpeteshie* (a very strong local gin), and Guinness ale.

The life-threatening risk arising from induced abortions is all too obvious. In 1973, for example, between 60% and 80% of all minor operations at Korle Bu Teaching Hospital, Ghana's largest hospital, involved abortion-related complications.

### D. Population Control Efforts

Currently, Ghana's population growth rate is 3.0% per annum, with 45% of the population below 15 years of age, thus epitomizing a high dependency burden. In 1969, Ghana was among the first countries in Africa to declare an explicit population policy. The Ghana National Family Planning Programme was established in 1970 to offer individual citizens the freedom to choose family planning and eventually slow down the rapid population growth. Not very much has been achieved, partly because of inadequate support from subsequent governments. Since the mid-1980s, however, Rawlings' government has reinforced Ghana's commitment to its population policy through the collaborative participation of international donor agencies. A National Population Council has been established, and it is likely that some decline in the fertility measures will be observed in the near future.

## 10. Sexually Transmitted Diseases and HIV/AIDS

### A. Sexually Transmitted Diseases

Very little is known about STDs in Ghana, but given that it is considered a cofactor of HIV infection, considerable attention is now being focused on its prevalence, prevention, and treatment. Although no reliable data are available, there is the consensus among experts that STDs are fairly common in Ghana, the most common being gonorrhea. There is a greater incidence of STDs among the 15- to 19-year-olds than among other age groups. This may be partly explained by the fact that STDs are considered as part of normal growing up when one begins sexual exploits.

Antibiotic treatment is available in hospitals and health centers, and there are also a few STD clinics, such as the Adabraka STD clinic. Still-infected persons, especially adolescents, are particularly slow to seek medical attention. Many tend to resort to traditional medicine or self-medication.

The government through the National AIDS Control Programme (NACP) has intensified efforts in STD control as part of the national HIV/AIDS control program. The European Economic Community (EEC) Task Force on AIDS is supporting the procurement of material, equipment, and reagents for a project on STD control.

### B. HIV/AIDS

Until recently, it was widely assumed that West Africa has been spared the social, economic, and health burdens of AIDS. Sadly, this optimistic view can no longer be justified. The first reported case of AIDS in Ghana was in 1986. At the beginning of 1995, there were some 12,500 reported AIDS cases. This is likely to be an underestimation since many cases are unreported. Over 80% of all cases of HIV infection involve persons infected through heterosexual in-

tercourse. No other particular sexual practice has been implicated in the sexual transmission. As noted earlier in the chapter, homosexual practice and anal sex are unacceptable and extremely rare. The early phase of HIV transmission was among prostitutes with a history of outside travel. As in many other countries, this led to finger pointing at other countries. The current trend indicates that the diffusion has gone beyond the so-called risk group. There has been almost a fourfold increase between 1986 and 1990 in the number of AIDS patients without any history of foreign travel. It can be stated that the future spread of HIV in Ghana may largely depend not on formal prostitution, but on the socially acceptable and pervasive phenomenon of sexual exchange in which women constantly switch sexual partners in order to maximize material gains accruing from sexual relationships.

In Ghana, as elsewhere, AIDS is primarily a disease that affects the economically active group. For both sexes, adults in the age group 20 to 29 account for 70% of the cases. The pattern, however, shows female preponderance over males. At the early stage of the epidemic in Ghana, there was one male to every eight females, although this has narrowed down to a current level of 1:2. Ghanaian epidemiologists agree that the sex ratio is changing to the direction of 1:1, which is consistent with heterosexual transmission in most countries.

Another pattern of HIV/AIDS infection in Ghana is that the majority of cases were initially not reported from major cities. Recent data on seropositives, however, show a tremendous increase in the number of cases in Ghana's main cities of Accra and Kumasi, thus supporting the generalization that, in Africa, AIDS is primarily an urban disease. Three regions out of ten, Ashanti, Eastern, and Greater Accra, account for over 70% of all reported HIV cases. It is not clear, however, whether the regional variation results from the level of reporting, although the general impression is that certain sociosexual practices in these regions may facilitate HIV transmission.

No nationwide HIV seropositive studies have been conducted yet, apart from a few using convenience samples. However, a study conducted in 1989-90 among patients of Ghana's second-largest hospital, the Okomfo Anokye Hospital in Kumasi, found a prevalence rate of 12.6%. Although this apparently high figure should not be extrapolated to the rest of the country, it definitely indicates a serious problem for the immediate future. Up to June 1991, only 25 out of 2,474 reported AIDS cases were under 5 years. Given that a substantial and fast-growing number of women of childbearing ages may be infected, perinatal transmission will soon become an issue of grave concern in Ghana.

There is a National AIDS Control Program (NACP) within the Ministry of Health. NACP, through information and education campaigns, is attempting to reinforce HIV risk-reduction sexual behaviors by discouraging casual sexual relationships or having multiple partners, and encouraging relationships with one faithful partner (or partners in polygynous homes). Condom promotion has also been intensified through social marketing and community-based distribution. The care of AIDS patients is generally home-based, given the lack of trained counselors, a task now being addressed by the Counseling Unit of the NACP. The best-organized counseling program has been developed at St. Martin's Hospital in Agomanya by the Catholic Mission. Other international nongovernmental organizations, such as the World Vision, are also involved in providing physical and economic support for AIDS patients. [Update 2003: In November 2001, the Ghana Ministry of Education included HIV/AIDS education in the school curriculum as a move to curb the

spread of HIV among the youth. (End of update by B. Opiyo-Omolo)]

[Update 2002: UNAIDS Epidemiological Assessment: HIV surveillance information on antenatal clinic women is available since 1990. Information is available only from Accra in 1990, but by 1994, 20 sentinel surveillance sites were reporting HIV seroprevalence. Overall median HIV prevalence among antenatal clinic attendees was 2.4% in 1994, 3.4% in 1998, and 2.2% in 2000. There are three sites that are included as the major urban areas: Accra (2 reporting sites in 1997, 3 in 2000), Kumasi, and Tamale. In Accra, HIV prevalence increased from 0.7% in 1992 to 3.1% in 2000, while in Kumasi, HIV prevalence has been fluctuating and was 3.8% in 2000. In Tamale, HIV has slowly increased from 1.0% in 1994 to 1.3% in 2000. Outside of the major urban areas, HIV prevalence increased, from 1% in 1991 to 3% in 1998. In 1998, HIV prevalence among the 14 sites ranged from 2% to 12%. In 2000, prevalence at 18 sites ranged from 1% to 7.8%. Both HIV-1 and HIV-2 exist in Ghana with HIV-1 being the predominant type; information on HIV prevalence by type is not available. Implementation of the 2001-2002 antenatal clinic sentinel surveillance survey was underway at the time of this writing.

[HIV seroprevalence rates among sex workers increased from 2% in 1986 to nearly 40% in 1991. By 1997-1998, HIV prevalence in Accra and Tema had reached 74.2% among "seater" sex workers and 27.2% among the "roamer" sex workers. A repeat study in Accra and Tema in 1999 found "seaters" with a rate of 75.8% and "roamers" with a rate of 23.1%. In 1999, sex workers in Kumasi had an HIV-infection rate of 82%. HIV prevalence among STD clinic patients in Accra increased from 2% in 1988 to nearly 9% in 1991. In 1998, HIV infection among female STD patients tested in Adabraka, Greater Accra region, had reached 27%; in 1999, prevalence was 39%.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	30,000	(rate: 3.0%)
Women ages 15-49:	170,000	
Children ages 0-15:	34,000	

[An estimated 28,000 adults and children died of AIDS during 2001.

[At the end of 2001, an estimated 200,000 Ghanaian children under age 15 were living without one or both parents who had died of AIDS. (End of update by the Editors)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

The most obvious sexual disorder is sterility. A barren woman is always in despair. The desire for children makes impotence in men even more disgraceful and pitiful. A childless couple is scorned and despised. Among the Akan, the man's penis is ridiculed as being flabby, and is nicknamed *kote kra* (wax penis). In the olden days, it is reported that an impotent man, after his death, had great thorns driven into his soles, and the corpse addressed: *woanwo ba, mma no saa bio* (you have not borne children; do not return again like that). Although family-planning centers and general hospitals may provide some advice and counseling, professional therapy is almost nonexistent. Given the embarrassment associated with impotence, very few men may accompany their wives to seek treatment from professionals in modern medicine. The source of childlessness is usually attributed to the wife, rather than the husband.

Traditional healers in Ghana, while conceding the superiority of Western biomedical medicine for certain diseases, have insisted that infertility and sexually transmitted dis-

eases are believed to be more effectively treated by traditional medicine than modern medicine. The secret and highly confidential nature of their practice makes traditional medicine men, herbalists, Mallams, fetish priests, and others the main source of treatment. They are visited by people of different educational and economic status. Men who claim to have medicines potent enough to induce pregnancy soon become rich.

## 12. Sex Research and Advanced Professional Education

Studies on sexuality in Ghana are particularly scanty. Until the onset of HIV/AIDS, all that was known was based on anthropological evidence gleaned from discussions on family, initiation rites, and other rites of passage. Although there are no special centers or institutes devoted to sex research, there has been a gradual interest in the subject, and surveys on sex have been undertaken. Specific groups surveyed in addition to the general population include; adolescents, young adults, return migrants, long-distance truck drivers, and secondary school students. The Departments of Sociology and Geography at the University of Cape Coast; the Institute of Statistical, Social, and Economic Research; and the Institute of African Studies, both at the University of Ghana, are all involved in sex research. The Institute of Population Studies, University of Exeter (U.K.), is also engaged in collaborative research, with local investigators on sexual behavior and HIV risk-reduction strategies in Ghana. One key methodological finding on sex research in Ghana is that, on the whole, respondents are more willing to discuss sexual matters and provide frank answers than it was first thought.

There is no professional association, nor are there journals for sexuality. Graduate programs devoted to sexuality are nonexistent. However, there is a Department of Guidance and Counseling at the University of Cape Coast that offers graduate programs. Perhaps the only major book of academic significance that deals exclusively with sexuality in Ghana is Bleek's (1976) *Sexual Relationships and Birth*

*Control in Ghana: A Case Study in a Rural Town*. A well-written book based on participant observation and field survey, the study was done among only one group (the Kwahu), and, therefore, will not satisfy the needs of a student who wants a handbook on Ghanaian sexuality.

## *Demographics and a Brief Historical Perspective*

ROBERT T. FRANCOEUR

### A. Demographics

In southern Europe, the Greek peninsula projects into the Mediterranean Sea from south of the Balkans. The mountainous, mostly non-arable land of the Greek peninsula is deeply indented by long sea inlets and surrounded by over 2,000 islands, of which only 169 are inhabited; these include Myconos, Lesbos, Chios, Samos, Kerkira (Corfu), Crete, and Rhodes. Greece's neighbors in southeastern Europe are Albania, Former Yugoslav Republic of Macedonia, and Bulgaria on the north and Turkey on the east. With an area of 50,942 square miles (131,940 km<sup>2</sup>), Greece is about the size of the state of Alabama.

According to the 2001 Census (May 2001), Greece has a population of 10.939 million, with 5.055 million males and 5.204 million females. (The demographic data below is an integration of the National Statistical Service of Greece 2002, and the CIA *World Factbook* 2002).

**Age Distribution and Sex Ratios:** 0-14 years: 18% with 1.04 male(s) per female (sex ratio); 15-64 years: 67% with 0.99 male(s) per female; 65 years and over: 15% with 0.77 male(s) per female; Total population sex ratio: 1.02 male(s) to 1 female

**Life Expectancy at Birth:** Total Population: 77.92 years; male: 75.39 years; female: 80.59 years

**Urban/Rural Distribution:** 65% to 35%—more than 4 million in the two cities of Athens and Piraeus

**Ethnic Distribution:** Greek: 97%; other: 3% (2002 est.)

**Religious Distribution:** Greek Orthodox: 97%; Muslim: 2%; other: 1% (2002 est.)

**Birth Rate:** 9.55 births per 1,000 population

**Death Rate:** 9.80 per 1,000 population

(CIA 2002)

**Infant Mortality Rate:** 6.15 deaths per 1,000 live births  
**Net Migration Rate:** 5.99 migrant(s) per 1,000 population

**Total Fertility Rate:** 1.29 children born per woman (down from 2.2 in the 1980s)

**Population Growth Rate:** 0.97%

**HIV/AIDS (2001):** Adult prevalence: 0.2%; Persons living with HIV/AIDS: 5,676; Deaths: 1,273 people since the beginning of the epidemic. (For additional details from www.UNAIDS.org, see end of Section 10B.)

**Literacy Rate (defined as those age 15 and over who can read and write):** 95% (male: 98%, female: 93%) (1993 est.); nine years of schooling are compulsory

**Per Capita Gross Domestic Product (purchasing power parity):** \$10,900 (1999); Inflation: 3.8%; Unemployment: 9.6% (National Statistical Service of Greece 2002)

### B. A Brief Historical Perspective

Because sexual identity, attitudes, and behavior are, in a large part, formed in a nation's sociocultural environment, it is important to sketch out the general ethnic, racial, and socioeconomic character of Greece.

In the past century, Greece has been a country searching for its national boundaries and identity, as well as its economic survival. Being a backward agrarian society, its economy has oscillated between self-subsistence and dependency on external markets. Since the advent of the 20th century, constant territorial and, consequently, demographic expansion has provided the foundations for a rapid development. Greece finally embarked on the process of industrialization, though considerably later than the rest of Europe, and under rather violent and short-lived stimuli. However, this rapid development has produced an imbalance between its economic and sociocultural level. This lack of correspondence is a common aspect of societies that are in a stage of development that is neither well articulated nor well defined, and of societies where coexisting economic, social, and cultural structures correspond to different modes of production. Thus, it can be said that Greek economy is characterized by heterogeneity due to the coexistence of "traditional" and "modern" components of technoeconomic activity. The social structure of institutions, groups, and relations is still in a state of inertia imposed by the past. Social groups and/or classes cannot eas-

\*Communications: Dr. Dimosthenis Agrafiotis, National School of Public Health, Sociology Dept., 196, Alexandras Avenue, Athens, 11521, Greece; agrafi@compulink.gr.

ily and creatively articulate their role in the context of prevailing conditions and available opportunities. The cultural environment is under the pressure of imported models, while the traditional characteristics do not show any signs of endurance. There are clear indications that aspects of Greek social life are altering. For example, the Greek family, an institution that remains a core value and practice in Greek society, and gender roles do not share the characteristics of a specific family model, but are gradually altering and follow at a slow pace the Western European model (Maratou-Alibranti 1999). The “modernizing” trend in Greek society concerns the necessity for greater equality and a decline in patriarchy, where structural links increasingly give way to the negotiation of individualized interpersonal relationships. This may also be perceived as part of the individualizing process.

The achievements of ancient Greece in art, architecture, science, mathematics, drama, literature, philosophy, and democracy are acknowledged by all as the foundation of Western Civilization. Classical Greece reached its apex in Athens during the 4th century B.C.E. In 336, the kingdom of Macedonia, which under Philip II dominated the Greek world and Egypt, passed to his son Alexander. Tutored by Aristotle in the Greek ideals, Alexander the Great conquered Egypt, all the Persian domains, and reached India in 13 years. After his death in 323, his empire was divided into three parts: Egypt under the Ptolemaics, Macedon, and the Seleucid Empire. During the ensuing 300 years, the Hellenic Era, a cosmopolitan Greek-oriented culture permeated the ancient world from the borders of India to Western Europe. The sciences thrived, especially in Alexandria, where the pharaohs financed a great library and museum. Major advances were made in the fields of medicine, chemistry, hydraulics, geography, astronomy, and Euclidian and non-Euclidean geometry.

Greece fell under the domination of Roman rule in the 2nd and 1st centuries B.C.E. In the 4th century C.E., Greece became part of the Byzantine Empire, and, after the fall of Constantinople in 1453 to the Turks, a part of the Ottoman Empire. Greece gained its freedom from Turkey between 1821 and 1829, and became a kingdom. A republic was established in 1924, followed by restoration of the monarchy in 1935. In 1940, Greece was occupied by German, Italian, and Bulgarian troops. In the late 1940s, the Communist’s guerrilla warfare ended with restoration of the monarchy; the monarchy was abolished in 1975.

Greece has experienced, although with some chronological differences, about the same population growth as most advanced countries have, despite the mass emigration during the two periods from 1900 to 1922 and from 1951 to 1973. Ever since, emigration has given way to repatriation and the entrance of refugees of Greek origins (*Pontioi*), as well as of foreign refugees and immigrants who came mainly from the former Communist Eastern European countries as well as from Asia and Africa. The massive immigration flow into the country took place in the late 1980s and, especially, after the fall of the Albanian regime in the early 1990s. Most of the immigrants came into the country illegally. Since a legalization process started in 1997, a third of a million migrants have asked for their legalization: 65% are Albanian and the rest come mainly from Eastern European countries.

## 1. Basic Sexological Premises

### A. Character of Gender Roles

In the last 20 years, Greece has been experiencing changes in gender relationships that are altering aspects of family life. Although the institution of the family remains a core value and practice, the foundations are less secure as individualism becomes a stronger force in Greek society.

There is wide agreement that the “traditional” type of patriarchal Greek family has been changing, in line with economic and modernizing forces. Gender relations are at the eye of the storm in these changes. One reason lies in what H. Kataki (1984) discussed two decades ago that is still relevant: the historical coexistence of different types of familial and gender formations and expectations. These, Kataki termed the traditional, the modern, and the post-modern identities of Greek families.

Although Greek society and the state still have patriarchal characteristics, at the family level, even within apparently traditional families, the actual nature of the power relations between men and women is very diverse (Papa-taxiarchis et al. 1992). Equality within the family has always been the outcome of a number of variables, including the ownership of property, social class, the relationship to nondomestic work, education, age, and the personalities involved. Thus, however “traditional” they might be, individual Greek men and women have always been aware of the flexibility and variations possible in gender relationships. Consequently, they often are not experienced with the patriarchal system at the personal level.

There are structured repercussions for gender relations from living in a patriarchal society, e.g., lack of power in political and economic life, but at the family or individual level, gender relations may be played out by the individuals in a far more equitable and nontraditionally gendered manner. Gender relations are constantly mediated through socioeconomic changes, as well as class and educational backgrounds.

### B. Sociolegal Status of Males and Females

From the legal viewpoint, Greek men and women enjoy the same rights as children, adolescents, and adults. Men and women have the same right to vote and equal rights for education and employment.

### C. General Concepts of Sexuality and Love

In Greek society, the expression of sexuality and “romantic” love are interdependent. Many people believe that sexual pleasure is realized only in a relationship governed by love (Apostolodis 1992; Ioannidis et al. 1991; Mandi et al. 1993). The ability to love is regarded as something special, and individuals who are indifferent to or unable to feel it are held in contempt. In a survey on sexual behavior that was conducted in 1998, 33.5% of the respondents reported that it was totally unacceptable to have sex with someone without loving him or her, and 30% said it was rather unacceptable (Ioannidi-Kapolou et al. 2001).

Some believe that although the sexual act is possible with someone else besides the “one and only,” true passion and completeness become real only when there is mutual care and devotion.

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A. Source and Character of Religious Values

In Greece, the majority of the population (97%) are affiliated with the Greek Orthodox religion. There are also some Catholics, a few Jews and Protestants, and a number of Muslims, mainly from Thrace. The Greek Orthodox Church is much more liberal than the Roman Catholic Church in some aspects, allowing divorce (up to three times normally) and remarriage in church. Although archbishops are not allowed to get married, the majority of parish priests are married.

Influenced by the Platonic and Stoic dualism and the Persian Gnostic tradition (Francoeur 1992), Christianity is governed by a dualistic opposition between the soul and the

body, with the soul and mind seeking liberation from the prison of the flesh. Christian faith provides "a special kind of knowledge, gnosis, which the soul can use to transcend this earth and rise to the divine heavenly sphere." Thus, Christianity has awakened in each person the worry of saving one's soul, with this salvation depending on the value of one's personal actions, particularly in the sexual sphere. If the flesh is somehow the source of evil, all sexual practices that are not procreative in character are condemned.

However, there is no correspondence between the official teachings and daily practices, at least in present-day Greece. Greeks regard love and sex as a main part of their existence, as evidenced by the incidence of extramarital relations and abortion, both of which are condemned by the Church. Greece's abortion rate is among the highest in Europe. In reality, Greeks often indicate that they do not consider themselves particularly religious; however, there are the "faithful" who follow the Church's teachings, and the latter does intervene in the sexual life of couples.

### B. Source and Character of Ethnic Values

Until the late 1980s, 98.5% of the population was ethnic Greek. Apart from the Muslims, who comprised about 1% of the population, lived in a particular area, and followed their own religious and cultural patterns, there was ethnic homogeneity. With the massive immigration entering the country, Greece is slowly turning into a multicultural society, at least in the urban centers. At this stage, it is obvious that the country was not prepared to receive and integrate so many different cultures. There were 120 different nationalities registered among those asking for legalization, although 91% came mainly from Albania, Bulgaria, Romania, Pakistan, Ukraine, Poland, Georgia, India, Egypt, and the Philippines).

## 3. Knowledge and Education about Sexuality

### A. Government Policies and Programs

It is not an exaggeration to say that in Greece, sexual education is not the target of any systematic and well-planned governmental program. Even today, sexual education is not included in the school curriculum, although a limited few pilot projects have recently been introduced into a limited number of schools. Sporadic knowledge is given as part of lessons in such subjects as anthropology. However, this knowledge concerns more elements of physiology and anatomy than references to the external genital organs, the sexual relationship, or the search for and existence of pleasure in connection with the body and sexuality.

Currently, there is an effort and movement to include sexual education in the schools, although two Ministries, that of Health and Social Welfare and that of Education, have not made clear which one will be responsible for these matters. In recognizing the need for sex education, the government has taken some steps, starting in the early 1980s, by bringing Family Planning under the auspices of the Ministry of Health and Social Welfare. Prior to this move, contraceptive education was mainly handled by the Family Planning Association, a nongovernmental organization (NGO). The Ministry established 46 Family Planning Centers all over Greece to provide genetic counseling, sexual education, information about AIDS and sexually transmitted and gynecological diseases, contraceptives, and so on.

However, a 1991 evaluation of the efficiency and effectiveness of these centers made by the Family Planning Association has shown that the Family Centers in Greece meet the needs of only a very limited number of people. Their geographic distribution is not sufficient, and there does not

appear to be any strategy for a systematic operation. A large number of the centers have departed from the initial aim of their operation and now focus their interest more on medical matters, such as Pap tests and gynecological pathology, rather than on sexual education.

### B. Informal Sources of Sexual Knowledge

The inadequacy of formal sexual education programs, and the resultant lack of sexual knowledge in the population, have been detected in a small number of studies carried out by the Department of Sociology of the Athens School of Public Health (Pantzou et al. 1991). Four different research projects, focusing on the general population and on pupils (a pilot study) using quantitative and qualitative methods, have indicated that:

- the mass media as a whole, and television in particular, seem to be the main sources of information for both the general population and young people on matters concerning health and AIDS,
- the majority of high school pupils receive no kind of information on sexuality and AIDS at school, and
- there is a need both for intensification of information on sexual contraception, sexually transmitted diseases, and AIDS, and improvement of the quality and specialization of this information.

### 4. Autoerotic Behaviors and Patterns

The data on autoerotic behaviors in Greece are very limited. The only available information is that which is derived from the K.A.B.P. (knowledge, attitudes, beliefs, and practices) study in relation to AIDS in the city of Athens (Agrafiotis et al. 1990). A section of this study was devoted to sexual practices, but only one question, in the section on sexual practices that someone engages in with his or her sexual partner, referred to autoerotic behaviors. According to the results, men reported twice the percentage of self-pleasuring than that of women (10.6% and 5.1%, respectively) when they were with their partner. Otherwise, the frequency and the attitudes towards self-pleasuring, both of children, adolescents, and adults have not been examined.

### 5. Interpersonal Heterosexual Behaviors

#### A. Children

Sexual exploration by children between ages 3 and 5 in nursery school has been observed. The first discoveries are connected with gender and take place mainly among peers. Different kinds of games (playing doctor and nurse, mother and father, or king and queen) imitate adult roles, sometimes producing specific pleasure connected with stimulation of the genitals.

Later on, at the age of 10 or 11 years, children's interest is focused on details and confirmation of earlier knowledge on gender differences. At the prepuberty age, they are usually engaged in self-pleasuring activities that occur either in pairs or in groups of peers of the same and other gender, as well as alone.

#### B. Adolescents

##### *Puberty Rituals and Adolescent Sexual Activities*

In the pubertal period, children are more interested in matters related to emotional/sentimental relations and sexuality. In a survey on "Attitudes of parents on the information of their children on HIV/AIDS and STIs" funded by the Center for the Control of Infectious Diseases (KEEL), 68.6% answered that the mother is the one who talks to children on issues relating to sexual behavior. It is also noticeable that parents avoid discussing with their boys topics

such as masturbation, orgasm, and abortion, while, with the girls, besides masturbation and orgasm, they avoid discussing homosexuality (Ioannidi et al. 1997).

Although there are no particular puberty rituals, the occurrence of the first menstruation and the first nocturnal emission or ejaculation are the signs of sexual maturation. These events, however, are not celebrated in any particular formal way in the family or among relatives.

Premarital sexual activities, especially in large cities, are no longer socially condemned. In a survey of sexual behavior that was conducted on a national general population sample aged 18 to 49, it appears that people start their sexual activity between the ages of 16 and 20. There are differences among men and women, and this gap appears to be closing compared to the past where, in the 1950s, the difference was six years, while at present, it has diminished to two years. Thus, boys start at the age 16 to 18 and girls 18 to 20 (Ioannidi et al. 2000).

Research also showed that the most frequent types of contact are through hugging, deep (open mouth) kissing, petting above and below the waist, sleeping together (without sexual intercourse), and oral and vaginal sex.

In a 2002 survey on virtual sex among students aged 18 to 23 of technological colleges in urban cities, all of the respondents (100%) claimed that virtual sex (TV, Internet, or video) is an important source for sexual information; 95% of males and 89% of females believe that the Internet is the best way to communicate sexual information and to start sexual relations without fear with people of different cultures through the practice of Internet sex (Kampoura et al. 2002).

### C. Adults

#### *Premarital Courtship, Dating, and Relationships*

In a society in which major social and cultural transformations are taking place, it would be misleading to present facts and opinions that seem definite and absolute. However, it does seem obvious and clear that there are great differences concerning premarital relations and courtship among urban and rural settings.

In today's predominantly urban and anonymous setting, young people often have access to automobiles that allow an exceptional degree of privacy in their courting. The practice of dating enables young Greeks to find out about one another, to improve their own interpersonal skills, to experiment sexually if they wish to, and, finally, to select a marriage partner.

In more "closed" rural communities and small villages, premarital relations and courtship are not yet the norm before marriage. Although freer than in the past, young adults, and especially women, do not have the opportunity of dating their future spouse. The idea of arranged marriages and matchmaking (*proksenio*) is still present; the difference is that now women have the right to choose which matchmaking will end in marriage. In some areas, a dowry (*prika*) is still required.

In anthropological literature on family life in Greek villages, reference has frequently been made to the importance of family honor—involving the sexual behavior of women, access in public and social life, and the successful execution of parental and spousal roles (Dubisch 1986). Strikingly, two generations later in a metropolitan center, reference to such values still appear to underlie some attitudes and behavior.

#### *Single Adults*

Up until the last two decades or so of the 20th century, a large proportion of Greek men and women found their primary identification in their family, and moral approval was

given to those who fulfilled traditional expectations of being "good" husbands and "housewives." The proportion of those who remained single was very low and, as a result, data on their sexual behavior and relationships are limited.

However, certain groups, mainly the younger and more educated people, are adopting more-contemporary attitudes towards family and marriage, giving greater priority to their personal rights and self-fulfillment as individuals. Nonetheless, the number of children born to unmarried women is the lowest in Europe. In 1999, the number of children born outside marriage was 3,890, compared to 96,753 who were born to married couples. In 1995, 5% of all the families were single-parent families (Kogidou 1995).

#### *Marriage and the Family*

The Greek family seems to be going through a period of transformation, following the patterns of all other industrial societies. The number of marriages decreased from 7.78 per 1,000 people in 1953 to 6.41 in 1985, 5.77 in 1990, and 5.28 in 1998. On the other hand, the number of divorces is rising.

The typical Greek family unit is monogamous: Greeks may marry only one person at a time. Second, it is increasingly nuclear, although occasionally a grandparent or other relative may live with a family group. Third, it is increasingly egalitarian, with wives becoming much more assertive and husbands more flexible than they were even a decade ago.

#### *Divorce and Remarriage*

The divorce rate, although low compared to other European countries, has been rising steadily in the last decade. Divorces more than doubled between 1979 and 1995—from 4,716 to 10,995, according to the Greek statistical service. The divorce rate has risen from 82.0 per 1,000 marriages in 1982 to 124.2 per 1,000 marriages in 1993.

According to the statistical data on the culpability of a divorce, it is evident that there has been a great change in the mentality and structure of the Greek family. In a total of 5,684 divorces reported in 1980, men were held culpable for the breakdown of 2,162 marriages and women for 1,144. In a total of 6,360 divorces reported in 1989, after amendment of the divorce law, the culpability numbers were 280 and 294, respectively. In addition, the above numbers indicate that "no-fault" divorces are on an upward trend, reaching about 75% of all divorces.

The majority of divorces are obtained after five to ten years of marriage. Also, the majority of divorcing couples have no children or only one child. In 1989, 1,730 divorced couples had no children and 1,520 had only one child. Although both divorced parties may experience difficult times, ex-wives, in particular, may face severe economic problems, especially if they have to raise young children. In the past, when most wives were not expected to work outside the home, courts frequently awarded alimony to divorced women. Now, after adoption of a new Family Law in 1983 that considers women capable of earning their own living, they receive alimony only for a period of three years. After this period, the alimony is automatically interrupted, without considering the possibility that a woman may not find a job. Courts award child custody to mothers rather than to fathers in most cases. However, the courts usually require that the fathers provide child support. A mother cannot retain the children's custody if she is a drug or alcohol addict, mentally or physically disabled, or psychopathic.

The Greek Orthodox Church allows a person to get married up to three times in his or her lifespan. Although there are no statistical data, it is estimated that 90% of those who obtain divorce will marry again—especially now that di-

voices are easier to get and provoke less social disapproval than ever before.

### *Marital and Extramarital Sexual Behaviors*

In a 1998 research study on the sexual behavior of the general population aged 18 to 49 in relation to the risk of HIV infection, respondents were asked if they were involved in a parallel relationship in the last five years. It is interesting that 214 men and only 47 women (in a sample of 2,000 people) admitted that they had a parallel relationship during this period. Among these 261 people who had parallel relationships, 82 described themselves as married (Ioannidi et al. 2000).

According to some opinion polls, however, both men and women, although satisfied with their sexual life, express their desire for even greater sexual activity. In addition, men, in higher percentages than women, report extramarital relationships with at least one partner. In addition, it can be said that there is a kind of tolerance on this matter. For instance, the extramarital relationships of important political persons do not constitute a cause for political disgrace or resignation, as is common in some other European countries.

### *Incidence of Oral and Anal Sex*

The survey conducted by the Department of Sociology of the National School of Public Health (Agrafiotis et al. 1990) has revealed some interesting results in relation to the sexual practices of the general population. The representative sample drawn from the general population of Athens, which really covers one third of the total Greek population, consisted of 1,200 people aged 16 to 65. Generally, for all practices, men reported higher percentages than women. This included vaginal sex (97.3% of men vs. 94.5% of women), oral sex (36.3% vs. 19.3%), and oral sex with body-fluid transmission (8.2% vs. 3.5%). Anal sex was also reported at double the rate of that of women (10.8% vs. 5.1%).

Women were less likely to respond to questions concerning sexual practices, (37% vs. 9%). Age groups also showed a considerable variation in sexual practices, with younger groups mentioning a wider variety of practices and a higher rate of them. Those who were 16 to 22 years old were less likely to practice vaginal sex (92.6% vs. 96%) and more likely to practice anal sex (14.9% vs. 8%). Oral sex was over 40% for the age group 16 to 30, but declined to 5.3% in age group 51 to 64. Of course, whether this difference is related to age, to religious and moral objections, or simply to an unwillingness by the older generation to admit to such practices is open to debate.

The above results were more or less confirmed by Malliori et al. (1991) with a representative sample of 1,980 Athenians of both sexes, 15 to 49 years old. According to these results, 95.5% of the females and 96.5% of the males employ ordinary intercourse, 35.6% of the females and 45.5% of the males use additional fellatio practices, 32% of the females and 40.5% of the males employ cunnilingus, and 10% of the females and 17% of the males use anal intercourse. Greek law contains no legal restrictions on fellatio, cunnilingus, or anal sex.

## *6. Homoerotic, Homosexual, and Bisexual Behaviors*

According to the first scientific research conducted by the Athens Medical School (Hantzakis 1992) in an unrepresentative sample of homosexual men, about half of the sample of 213 men were single without ever being married, and either lived alone or with a parent or relative. The majority of these gay men's sexual activity is taken up in the three behaviors of

self-pleasuring, fellatio, and anal intercourse. In addition, the majority claimed to have heterosexual contacts as well. This can be partly attributed to the fact that, in Greek society, there are different kinds of homosexuals (i.e., gays and bisexuals) and a mixture of tolerance and taboos coexist. As a result, many gay men are forced to get married and pass as heterosexuals, whereas, in reality, they are bisexual or psychologically and emotionally exclusively homosexual, although engaging in some heterosexual relations.

In a survey on gender identity and HIV risk among gay men (Vassilikou et al. 1999), it appeared that, with regard to sexual identity, young gay men frequently pass through an initial identity crisis, which harbors dangers both for their mental and physical health. There was no specific model of a gay man encountered, but rather many and diverse ways of living with being "different." It also emerged that the first disclosure (coming out) in most cases is made to another or other gay men, and their subsequent disclosures are to persons whom they believe will accept them anyway. Disclosure to the family is made either through a third person or through protracted persistent processes or not at all.

The legal age of consent for homosexual men is 17 years. The legislation of 1981 can force STD testing of homosexual men.

## *7. Gender Diversity and Transgender Issues*

Greek society does not provide for any special gender roles, such as the *hijra* of India or the *berdache* among Native Americans. Among the registered prostitutes, 66 are transsexuals who had their surgery abroad, as, in Greece, these operations are not performed.

## *8. Significant Unconventional Sexual Behaviors*

### **A. Coercive Sexual Behaviors**

#### *Child Sexual Abuse and Incest*

The phenomenon of child sexual abuse has only recently been surfacing in Greece as an issue of concern among professionals, researchers, and the public, following a long period of denial that continues to exist in many settings. This change can be partly attributed to the altering of society's general attitudes towards sexuality, as well as to the appearance of AIDS. The term "child sexual abuse" does not exist in Greek criminal law; there are, however, many provisions that specify offenses that infringe upon a child's purity. These offenses are rape, seduction of a minor, indecent assault, incest, and pimping. When the person culpable of such an offense is a parent, a teacher, or a minor's guardian, the punishment is particularly severe. In the seduction of a minor, the younger the child, the harsher is the punishment. If the child is less than 10 years old, the penalty can be at least ten years imprisonment; if the child is between 10 and 13 years, the penalty can be between five to ten years; the penalty is five years imprisonment for children 13 to 15 years of age. For the offenses of rape, incest, and pimping, the prosecution is automatic, *ex officio*, while for the rest of the offenses, the prosecution continues only if the sufferer or his or her legal representative brings a charge against the perpetrator.

In cases of child sexual abuse, it is not possible to ascertain the incidence of pedophilia, because this category is not included as such in the offenses that infringe upon a child's purity. There are no data on incest, and it is very difficult to estimate the extent of the phenomenon, as the cases registered in police records involve rape or pregnancy (Artinoulou 1995).

All types of sexual offenses are socially condemned. Although there is no statistical evidence, a study of child sexual abuse among an unrepresentative sample of Greek college students, conducted by the Department of Family Relations of the Institute of Child Health (Agathonos et al. 1992), has shown that the phenomenon in Greece is unexplored and its magnitude very likely underestimated. Among the 743 respondents, 96 students (13 men and 83 women), or 13%, had experiences of sexual victimization, while 230, or 31%, had sexual experiences that did not contain the element of victimization. In one third of the group with the sexual victimization cases, the abuse had been intrafamilial; in one third of the cases, the perpetrator was known to the child. The remaining perpetrators were strangers. In men, perpetrators were, on average, 12 years older, while offenders were, on average, 22 years older than abused women.

### *Sexual Harassment*

Although Greek legislation does not distinguish this category of behavior, sexual harassment, especially by males in the workplace, is not uncommon.

### *Rape*

Although Greece, according to the statistical data of the United Nation's Report, had the lowest number of rapes per 100,000 women in 1992 (only 2 rapes compared to New Zealand with 254 rapes), scientific studies have shown that only 15% of rapes are reported to the authorities. From police records, the 6% associated with rapes is considered as a relatively low percentage according to an international bibliography (Tsingris 2000). However, it is not indicative of the situation, since many cases are never reported to the police.

According to the legislation, the penalty for rape is between five and 20 years imprisonment. As of early 2003, an ongoing discussion was expected to come to the Parliament for voting a law that includes the punishment of marital rape.

### **B. Prostitution**

Prostitution has, for many years, been a socially accepted practice, especially for young Greek men. Given traditional rules of virginity for women and the expectation of masculine behavior, including sexual prowess, for men, prostitutes were both an outlet and schooling for many men. Nowadays, particularly in the urban centers, young men are more likely to have a girlfriend with whom they have sex.

In Greece, the number of professional prostitutes who are registered is 406. They have a health book and are obliged to report twice a month for health inspection at a special clinic of the Ministry of Health and Welfare. After 1990, with the entrance of illegal migrants into the country, especially from ex-Communist Eastern European countries, the number of unregistered sex workers has risen, and it was estimated that Greece then had as many as 17,000 sex workers. This estimate included Greek women, although the majority here are migrants (Kornarou et al. 2002). According to a survey on condom usage by non-registered prostitutes carried out during the period 1995 to 1997, where 1,805 prostitutes—560 Greeks and 1,245 foreigners—completed a questionnaire, the usage of condoms is low. More specifically, the usage is significantly lower among women of Albanian descent, the prostitutes of older age, and the heroin users (Nestoridou et al. 2002). Alongside the unregistered female prostitutes, there is also an unknown number of male and adolescent prostitutes, mainly in Athens and Thessaloniki.

### **C. Pornography and Erotica**

Despite legislation that prohibits the production and distribution of pornography and erotica, both hard- and soft-core pornography is easily accessible in Greece. In addition,

during the last decade, there have been a few telephone "hotlines," which are extremely expensive. Many kiosks sell pornographic magazines, and pornographic videotapes are unofficially available to anyone over age 18. However, these tapes are not openly displayed, and there is an unwritten code of communications between the customer and the shop owner.

## *9. Contraception, Abortion, and Population Planning*

### **A. Contraception**

Unlike other countries, where a considerable amount of social research has been carried out on attitudes of the population towards contraceptive methods, in Greece until the appearance of AIDS, there were only a few studies on such issues.

There are no official data for the use of contraceptive methods. Research data suggest that condoms and coitus interruptus are the two most familiar methods used (Ioannidi et al. 2000). Estimated data from the Department of Family Planning in the Gynaecological Clinic of Areteio Hospital (Athens) concerning the use of contraceptive methods in the last 5 years in Greece present the following figures: condom 45%, coitus interruptus 20-30%, pill 2%, and IUD 10%.

Indicative of the situation are the findings of research carried out on a national sample of 4,560 women aged 15 to 44, concerning the socioeconomic factors that determine reproduction in Greece: 70% of the women reported withdrawal as the first contraceptive measure, and abortion, which is still considered as a contraceptive method, was reported by 42% of the women (Simeonidou et al. 1997).

In a study carried out by the Institute of Social Preventive Medicine (2001), 50% of the male population used the condom in their sexual relations, and 21.7% used coitus interruptus. Six in ten women admitted that they used the contraceptive method suggested by their partner. One in ten women used a method of their own choice (pill 4.8% and IUD 3.6%).

What is evident in comparison with other European countries is two particularities of the Greek situation in regard to the attitudes towards contraceptive methods. First, Greek society has not fully adopted the use of modern methods of contraception. According to the statistical data provided by the pharmaceutical companies (Margaritidou et al. 1991), such methods are not easily available and their use is relatively low (i.e., IUD sales are 20,000 annually). Thus, the condom, which is available through pharmacies, supermarkets, and kiosks, is still the most widely used method of contraception. Second, there is a tendency for many Greek couples to prove their fertility by not using contraception and resorting to frequent abortion. It is worth noting that while many countries reported that abortion concerns a very small percentage of women and is considered "marginal" behavior from a psychosocial point of view, in Greece repeated abortion and withdrawal are the most widespread methods of birth control (Agrafiotis et al. 1990).

As for education in the contraceptive methods, it can be said that the state or medical practitioners provided little systematic information until the founding of the Family Planning Centers after 1982. Some of these centers provide contraceptive methods free of charge to persons who are not insured, while the National Health Insurance organization does not cover the costs of contraception.

### **B. Teenage Unmarried Pregnancies**

The recent doubling of the teenage pregnancy rate, and its continued increase, can be mainly attributed to several reasons. First is the lack of information on ways to avoid an undesired pregnancy. It has been estimated that in countries

where adolescent sexual education is put into practice, the percentage of undesired pregnancies is kept relatively low. Second, biological maturation of girls now comes earlier than in the past. And third, premarital sexual activities start at a younger age now than they did in the 1940s and 1950s. Many of the expectant teenage mothers, however, decide to terminate their pregnancies, being fearful of both the medical and social consequences. Thus, parallel to the teenage pregnancies, teenage abortions are increasing. This was evident in recent research on European levels, where the U.K. and Ireland, for example, presented as a major problem the high incidence of births in adolescence, while in Greece, the problem focused on the increase of abortions in this age group (Ioannidi et al. 2002).

### C. Abortion

Since 1986, abortion has been legal in Greece, and a great number are conducted in the private sector. There is no official registration of abortions and the data provided by the National Statistical Service of Greece refers to abortions taking place in National Hospitals only, which is not a representative figure. According to the National Report of the General Secretariat of Equality in Greece (2000), the estimated number of abortions is 100,000 to 120,000 cases per year. The fact is that the abortion rates are high, and, according to estimates by gynecologists, the number of abortions equals the number of births (Kintis 1996). Greece possesses the highest percentage of abortions among the European countries.

In research carried out by the National Center for Social Research (E.K.K.E.) in 1988, it was found that the ratio between abortions and live births was nearly one to three. Forty-three percent of all Greek women in the sample reported at least one abortion or miscarriage. In the study conducted by the Family Center in Thessaloniki (Anapliotis 1985), it was found that a large number of women, around 64% aged 16 to 46 (and over), had an abortion, with the ratio between abortion and live births being 1:8 to 1:3 per woman, respectively. Thus, it can be said that repeated abortion is a "norm," a traditional form of birth control, especially for Greek women who have already acquired the desirable number of children.

The above evidence indicates that abortion in Greece is not considered a moral issue of any dimension, and there is a general lack of guilt about the subject. In a recent study (Ioannidi et al. 2001), only 26% of the general population considers abortion a totally unacceptable practice. One explanation provided for this behavior is that the traditional importance of the mother role, and the constraints concerning the expression of female sexuality, come into conflict with the symbolic and real meaning of modern contraceptives (Naziri 1988). Both men and women use the "unwanted" pregnancy that usually ends up in abortion as evidence of their continuing fertility, whereas modern contraception would create doubts about this.

The law allows for abortion until 12 weeks of pregnancy. The National Health System covers the expenses and provides the right of three days full-paid leave. Despite this, only a few women use the National Health System and their insurance fund for abortion, while there is still a substantive use of private gynecologists for unreported abortions. This can be partly attributed to the fact that private abortions are usually performed immediately, in contrast to the state system that requires some bureaucratic procedures and, therefore, involves delays. Finally, it must be stressed that only a vocal minority associated with the Orthodox Church was against the legalization of abortion, though, in general, the Orthodox Church, unlike the Catholic, is not so

absolute in its teachings and is more tolerant in its attitudes towards people's practices such, as birth control, abortion, and so on.

### D. Population Control Efforts

In the last decade, Greece's population growth rate has dropped to 0.97% annually, compared to the rate of 12% to 13% before World War II (National Statistical Service 2000). The government's aim is to promote population growth with financial incentives, such as allowances, houses, and reduced military service. However, the birth-rate still remains very low and is related mainly to socio-cultural and economic aspects.

## 10. Sexually Transmitted Diseases and HIV/AIDS

### A. Sexually Transmitted Diseases

#### *Incidence, Patterns, and Trends*

There are no data available on STD prevalence. The only available data that EKEPAP (Centre for the Surveillance and Intervention of Epidemics 2000) could provide were the total numbers of reported cases in the year 2000 for the following STDs on which they keep a record: chlamydia: 66; gonorrhoea: 103; syphilis: 100; and hepatitis B: 234. For these diseases, however, there are no data concerning the individuals' gender, age, and so on.

Despite the lack of official data, some conclusions can be drawn from a study that attempted to describe the epidemiology of several major sexually transmitted diseases in Greece during a 23-year period (1974 to 1996). The patient population examined included individuals that had visited the outpatient clinic of Andreas Syngros Hospital, which is a national referral center for venereal diseases. The selected STDs studied were syphilis, gonorrhoea, nongonococcal urethritis, genital warts, and HIV/AIDS infection. According to these findings, the incidence rate by sex shows an overall decreasing trend, with slight variations during the study period. In contrast, the incidence of HIV-infected and AIDS patients follows a constant upward trend. The researchers concluded that the incidence of STDs in Greece is characterized by much lower rates than those observed in other countries around the world. These findings may, however, change in the next few years in view of the large number of individuals migrating into the country from Eastern European and other countries (Strategos et al. 2000).

As far as the tracing of STDs and HIV/AIDS, one should take into account the following: There is no compulsory registration of HIV/AIDS in pregnant women. Since 1994, KEEL, in the framework of its surveillance of HIV infection in our country, has suggested to gynecologists to report these cases. There is no compulsory testing for HIV in pregnant women; gynecologists usually suggest it to women and they decide whether they want to take the test or not. Moreover, there is no compulsory tracing to HIV-positive people, but health professionals try to persuade them to keep a contact with their physician. There is also no compulsory registration of STDs, either in pregnant women or the general population, although gynecologists suggest it, as in the case of HIV testing. According to EKEPAP, it is not in the priorities of the Department of Public Health to trace STD cases.

#### *Availability of Treatment and Prevention Efforts.*

In Greece, there are two public dermatological hospitals for the treatment of STDs, with 200 beds in Athens and 60 beds in Salonica.

In Greece, the Ministry of Health is responsible for the design and implementation of public health policy. In the

case of STDs and HIV/AIDS, an independent body has been established, named the Hellenic Center for Infectious Diseases Control (KEEL), which has undertaken the task of implementing preventive policy on a national level. In 1992, KEEL was recognized as a legal entity subject to private law, and it operates in collaboration with other relevant departments of the Ministry of Health and other organizations, both in the public and private spheres. Priority on STDs and HIV/AIDS prevention and/or care policies, is given mainly to women sex workers and mobile populations (gypsies and migrants).

## B. HIV/AIDS

Epidemiological facts on STDs in general, and HIV/AIDS in particular, permit policymakers in Greece not to prioritize these issues as major public health problems. It should be noted here that the spread of infectious diseases in our country follows an epidemiological model that is different from the other Western countries, where a higher number of cases is reported among intravenous drug users along the zone that extends from Spain to the former Yugoslavia. In Greece, the number of homosexuals and heterosexuals infected is higher than the number of drug users. An important number of women have also been infected. A possible explanation for this exception can be attributed to the fact that a development of modern industry has emerged in the above-mentioned areas, which Greece did not follow. Thus, it can be said that "the socio-cultural difference is mirrored in the socio-epidemiological distribution rejecting in this way the myth of cultural homogeneity in the Mediterranean because of the difference among Greece and countries like Italy, Spain, France" (Agrafiotis 1991).

The reporting of AIDS cases in Greece is compulsory (A1/6824/4/7/83). The first surveillance system was initiated in Greece in 1987, four years after the first reported AIDS case in 1983. However, HIV case reporting was implemented in Greece in 1998. It is anonymous, confidential, and mandatory by law (B1/5295/7-8-1998). In KEEL (Center for the Control of Infectious Diseases), there is an office for the epidemiological surveillance of HIV/AIDS infection in our country. In 1998, EKEPAP (Greek Center for Epidemiological Surveillance and Intervention) was also established as a department of KEEL, attempting to keep a record of all STDs reported.

Every six months, an edition of KEEL is published, including the latest epidemiological data, where the following data were reported (June 2001).

The total number of people who live with HIV/AIDS in Greece in the year 2001 (June) is 5,676 persons, 60 of whom are below 15 years of age. The number of women who live with HIV/AIDS in Greece is 883, and most of them are 25 to 39 years old. It should be noted here that these figures might be differentiated slightly, if one takes into account a number of infected people who prefer to go abroad and have an HIV test in order to preserve their anonymity.

The total number of people infected with the HIV virus in the year 2000 was 552, of whom 519 were 15 years of age or older. Among them, 120 women were reported being infected with the HIV virus, all of them above 15 years of age, and the majority being 25 to 39 years old.

There is no official data on the number of people who lived with HIV/AIDS in Greece in the years prior to 2000, because systematic recording of HIV and AIDS cases has only been established from 1999 onwards (KEEL 2001)

The total number of deaths caused by AIDS in the year 2000 was 67 people, 53 men and 14 women, most of whom belonged to the age groups of 30 to 39 and 45 to 54 years. The total number of deaths caused by AIDS since the beginning

of the epidemic is 1,254 people, 1,104 men and 150 women. The majority of these people were 25 to 49 years of age.

As for the prevalence of HIV/AIDS-related routes of transmission, 378 people have declared transmission through heterosexual contact (181 men and 197 women); 19 cases referred to mother-to-child transmission, 1,248 homo-/bisexual male contact, 83 intravenous drug users (61 men and 22 women), and 435 cases (372 men and 63 women) by other routes of transmission.

Overall, sexual transmission accounts for the vast majority of reported HIV adult and adolescent cases. Most of them are men (40%) who have been infected through homosexual intercourse, and approximately 15% are men and women who have been infected through heterosexual transmission. There are signs of increasing trends in both homo- and bisexual men, and heterosexuals. Heterosexual transmission shows, in fact, a faster rate of increase in recent years, while the proportion of heterosexually infected women increases over time (KEEL 2000).

[Update 2002: UNAIDS Epidemiological Assessment: Through December 2001, a cumulative total of 5,859 HIV-seropositive persons, 2,254 AIDS cases, and 1,299 deaths from AIDS have been reported at the national level. Among newly reported HIV cases during the 2000 to 2001 period, 26.94% are men who have sex with other men, 17.78% are heterosexuals, and 2.98% are injecting drug users. The route of transmission is yet to be determined in 51.86% of cases.

[HIV prevalence is low among injecting drug users. During 2000 to 2001, no prostitutes were reported to be HIV-seropositive.

[HIV testing is mandatory and systematic in blood donors and recommended for pregnant women, STD patients, injecting drug users, and persons at high risk for HIV. Case reporting is mandatory and confidential by law for both HIV and AIDS cases at the national level. Infection Disease Units, HIV/AIDS Reference Centers, district, regional, university, and private-sector hospitals and laboratories report cases in real time. Retrospectively updated registries include cases since 1982.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	8,800 (rate: 0.2%)
Women ages 15-49:	1,800
Children ages 0-15:	< 100

[An estimated less than 100 adults and children died of AIDS during 2001.

[No estimate is available for the number of Greek children who had lost one or both parents to AIDS and were under age 15 at the end of 2001. (End of update by the Editors)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

### A/B. Concepts of Sexual Dysfunction and the Availability of Treatment

Even at the end of the 20th century, the sexual act in Greece seems to be shrouded by myths and antiscientific attitudes and approaches that lead to the superficial management of sexual dysfunctions.

It was only at the end of the last decade that some private institutions, both in Athens and Salonica, began to deal with sexual therapy. Having a better mechanism for preserving a patient's privacy, they brought the problem up for open discussion, recognized it, and helped in its demystification. The acceptable methodology for the diagnosis and therapy of sexual dysfunctions is based on the protocol of I.S.I.R. (International Society of Impotence

Research). Impotence is regarded as a symptom of both psychological and organic problems. According to the statistical data of the Andrological Institute, which specializes in male impotence, from a sample of 5,000 patients treated, 25.1% of impotence was because of psychogenic causes, 24.6% by organic causes, and 50.3% resulted from combined causes. The distribution of cases according to age has shown that problems exist in all age groups, with more cases between the ages of 40 and 50. In addition, the analysis of cases according to profession and social class has shown that the problem is present in all social classes with more or less the same frequency. From the same data, it is evident that one in four men in Greece has some kind of sexual dysfunction. (The name "Andrological" reveals the distinction of science into two specialties related to sex. From a sociological and cultural point of view, it is interesting to see how this will operate in Greece.)

## 12. Sex Research and Advanced Professional Education

Agrafiotis pointed out the need for sexual research in Greece in the early 1980s. But it was the advent of AIDS that forced these matters to emerge somewhat into the public consciousness and policy. In Greece, there are no institutions engaged in sexological research on a regular basis. Research on sexual matters is conducted occasionally and by different research teams without any national coordination. Among the teams engaged in various kinds of sexological research are:

University of Athens, Department of Psychiatry. Director: C. Stefanis. Address: 74 Vas. Sophias Avenue, Athens.

National School of Public Health, Department of Sociology. Director: Demosthenis Agrafiotis. Address: 196 Alexandras Avenue, Athens.

National School of Public Health, Department of Epidemiology. Director: A. Roumeliotou. Address: 196 Alexandras Avenue, Athens.

A Syngros Hospital. Address: 6 Dragoumi, Athens.

Family Planning Association (FPA) Address: Evrou & Pontoiraklia 1-3, Athens 115 28.

Athens Medical School, Department of Epidemiology and Hygiene. Director: D. Trixopoulos.

Hellenic Society of Paediatric and Adolescent Gynaecology (HSPAG). Director: C. Kreatsas. Address: 9 Kanarie str, Athens.

The Department of Psychiatry, the FPA, and the HSPAG offer sex education programs for parents.

Undergraduate courses are provided to doctors by the Medical School, but only as part of the general curriculum (knowledge of organic systems), and are not intended to be a study of human sexuality as such. There is no medical specialization in sexology, and the psychiatrists or gynecologists who wish to specialize in this field should go abroad. The question of sexology as a scientific field is not fully recognized, and there is always a controversy on this matter. As a result, psychologists, sexologists, psychiatrists, and psychoanalysts try to determine their domains of competence. On the other hand, the Department of Sociology of the National School of Public Health explores various issues related to sexuality, and, in general, the social sciences include sexuality and sexual issues in their area of research.

There are no Greek journals or periodicals on sexuality.

### A Final Remark

The issue of sexuality in Greece has yet to be adequately studied. Overall, there is an urgent need for a more systematic investigation of the coexistence of traditional and mod-

ern values because of the social particularities of the Greek society and their influence on current sexual attitudes and behaviors. As far as sexual relations are concerned, it appears that couples are well protected from STDs and HIV/AIDS, as the use of condoms is higher than in other European countries. This is explained by the particularities of Greek society, where modern contraceptive methods were never practiced.

Overall, although Greek society and the state still have patriarchal characteristics, there are clear indications that aspects of family life are altering. This is evident in the later age of marriage, increasing rates of divorce, the increase in female participation in the paid labor force, and the very slow increase in single parenthood. The power relations between men and women are very diverse and are played out by the individuals in a far more equitable and nontraditionally gendered manner.

### *Demographics and a Brief Historical Perspective*

ROBERT T. FRANCOEUR

#### A. Demographics

Located at the mouth of the Pearl River about 90 miles (145 km) southeast of Canton (Guangzhou), the former British crown colony of Hong Kong is a very small but important Asian territory and hybrid culture now incorporated as a Special Administrative Region of the People's Republic of China. Hong Kong has 421.6 square miles (1,092 km<sup>2</sup>), including the 32-square-mile (83-km<sup>2</sup>) island of Hong Kong. Most of the island is hilly to mountainous with steep slopes, with lowlands in the north. The climate includes tropical monsoons, and is cool and humid in the winter, hot and rainy from spring through the summer, and warm and sunny in the fall.

In July 2002, Hong Kong had an estimated population of 7.3 million. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 17.5% with 1.13 male(s) per female (sex ratio); 15-64 years: 71.6% with 0.98 male(s) per female; 65 years and over: 10.9% with 0.85 male(s) per female; *Total population sex ratio:* 0.99 male(s) to 1 female

**Life Expectancy at Birth:** *Total Population:* 79.8 years; *male:* 77.1 years; *female:* 82.69 years

**Urban/Rural Distribution:** NA

\**Communications:* Dr. Emil Man-lun Ng, Queen Mary Hospital, University of Hong Kong, Psychiatry Dept., Hong Kong; hrmcml@hkucc.hku.hk, nml@i.am. Joyce L. C. Ma, Ph.D.; joycelai@cuhk.edu.hk. *Note:* The editor gratefully acknowledges the careful review of this chapter and additional comments by M. P. Lau, M.D., a native of Hong Kong and coauthor of the chapter on China in this volume.

*Editors' Note:* Because of space constraints in volume 4 of the *International Encyclopedia of Sexuality* published in 2001, the original chapter on Hong Kong, like Norway, was not included. Instead, the Editors published them as "Supplemental Countries on the World Wide Web" at <http://www.SexQuest.com/IES4/>.

(CIA 2002)

**Ethnic Distribution:** Chinese: 95%; other: 5%

**Religious Distribution:** Buddhist or Taoist affiliation: 90%; Christianity: 7.8%; Hinduism: 1.8%; Muslim: 0.8%; and Jewish: 0.15%

**Birth Rate:** 11.13 births per 1,000 population

**Death Rate:** 6.02 per 1,000 population

**Infant Mortality Rate:** 5.73 deaths per 1,000 live births

**Net Migration Rate:** 7.76 migrant(s) per 1,000 population. Between 1949 and 1962, Hong Kong absorbed more than a million Chinese refugees.

**Total Fertility Rate:** 1.3 children born per woman

**Population Growth Rate:** 1.26%

**HIV/AIDS** (1999 est.): *Adult prevalence:* 0.06%; *Persons living with HIV/AIDS:* 2,500; *Deaths:* < 100. (For additional details from [www.UNAIDS.org](http://www.UNAIDS.org), see end of Section 10B.)

**Literacy Rate** (*defined as those age 15 and over who can read and write*): 92.2% (*male:* 96%, *female:* 88.2%), with over 90% attendance for 9 years of compulsory schooling (1996 est.); *attendance for nine years of compulsory school:* 95% (education is free and compulsory from age 6 to 13)

**Per Capita Gross Domestic Product** (*purchasing power parity*): \$25,000; *Inflation:* -1.6%; *Unemployment:* 5.2%; *Living below the poverty line:* NA (2001 est.)

#### B. A Brief Historical Perspective

In 1841, the 32-square-mile (83-km<sup>2</sup>) island of Hong Kong was ceded by China to Britain. In 1860, Britain annexed Stone Cutters' Island (one-quarter square mile, 0.65 km<sup>2</sup>), 200 other islands, and the 3-square-mile (7.8-km<sup>2</sup>) Kowloon Peninsula. In 1898, Britain leased 355 square miles (919 km<sup>2</sup>) of agricultural land in the New Territories on the adjoining mainland. As a crown colony, Hong Kong was, despite its tiny size, a vibrant capitalist enclave and free port on the edge of China. In 1994, following two years of painstaking negotiation, the British and Chinese governments agreed that Hong Kong would return to Chinese sovereignty on June 30, 1997, when Britain's lease on the New Territories expired. The agreement specified that the territory would retain its social, economic, and legal system as a special administrative region of China under a unique "One Country, Two Systems" arrangement for the next 50 years. The agreement guaranteed freedoms of speech, press, as-

sembly, association, travel, the right to strike, and religious belief. However, the chief executive and some members of the legislature are appointed by Beijing.

### 1. Basic Sexological Premises, and 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

Different sexological premises coexist in Hong Kong, along with a variety and mix of ethnic and religious factors that affect sexual attitudes and behavior in Hong Kong.

#### A. The Original Taoist-Confucian Premise

This most ancient sexological premise of the Hans, the major Chinese tribal group, has a documented history of over 5,000 years. It holds a very natural and utilitarian view of sex. The interaction of two cosmic forces, Yin and Yang, is thought to be universal and essential for the existence, change, and growth of all matters, and sex is just one mode of this interaction in living things. For their well-being and prosperity, human beings are advised to follow this natural interaction to the full, as long as it does not jeopardize social harmony, which is a Yin-Yang interplay of a higher order. Based on this doctrine, both the reproductive and pleasurable aspects of sex were given high consideration. Sex within marriage must serve the purpose of procreation, whereas sex outside marriage is for erotic satisfaction. Within marriage, therefore, contraception is discouraged, and infertility is a good-enough reason for divorce or for the husband to take a second wife or a concubine. Outside marriage, except for incest and rape, a wide range of sexual behavior is acceptable or at least tolerated, including homosexuality, bestiality, prostitution, fetishism, and pedophilia. This explains why, for the Chinese before the second half of the 20th century, prostitution, homosexuality, and pedophilia were openly practiced. Foot fetishism, taking the form of bound feet for females, had even been an open paraphilic custom in China for 1,000 years. From the beginning of the second millennium down to the early decades of the 20th century, some well-bred Chinese women had to undergo extreme pain in childhood to orthopedically deform their feet by means of cloth bindings, splints, and special shoes to a size and shape supposed to be sexually stimulating and fascinating to the men. [*Comment 1997*: While "bound feet" is a most-cruel custom, modern Western women wear high-heeled shoes, pluck their eyebrows, and have their ears pierced, liposuction, facelifts, and breast implants. Male and female ballet dancers wear special shoes and suffer through special exercises to achieve a lilting gait and sprint movements. (*End of comment by M. P. Lau*)]

#### B. The Neo-Confucian Premise

During the Song Dynasty (960-1279 C.E.), a group of scholars started to reinterpret the original Confucian doctrine. The resultant Neo-Confucianism has been very influential on the Chinese concept of sexuality up to the present day. Selected books and passages in the Confucian teaching were given new and strict meanings to denounce sexual intimacy, pleasure, and all types of physical enjoyment. In this premise, the harm of sexual pleasure to bodily health and to spiritual pursuit was very much emphasized. Sexual chastity, especially for the females, had to be guarded at all costs, even at the price of one's life. Premarital sex, extramarital sex, and remarriages were seriously frowned upon. Socially, sex must not be discussed openly, dresses must be all-covering up to the neck, and males and females not belonging to one family must not touch one other under any circumstances. For example, even when a male physician had to ascertain the pulse of a female patient, he should only

do it by feeling the tight extension of a piece of string tied to the patient's wrist.

#### C. The Christian Premise

Christianity came into China as early as the Tang Dynasty (618-907 C.E.), but its influences became significant only after the 18th century when Western civilization, supported by a strong British military superiority, entered China with Western scientific technology and a different lifestyle. The fundamentalist Christian ideas of sex were sown, developed, absorbed, and practiced. They included the denunciation of sexual pleasure, the love-marriage-sex trilogy, and the exclusively monogamous marital system. As a result, at the establishment of modern China in 1949, monogamy replaced polygyny as the only legal marital system of the country. Although Christians represent less than 10% of the Hong Kong population, the influence of the Christian premise on the sexual ethos of the territory must not be underestimated. Up to June 30, 1997, Hong Kong had been under the governance of Great Britain. Hence, Christianity had a great advantage over other religions in promoting their ideology and practices in Hong Kong. For example, up to now, five of the roughly 20 government-designated public holidays have been Christian holidays. None of the government-designated holidays are Buddhist, Taoist, or Confucian holidays. Most of the elite schools in Hong Kong are Christian-affiliated and directed. Instruction in the Christian doctrine is standard and required for all students, whether or not they will ultimately become converted Christians. Many of these elite students become the ruling or influential class in Hong Kong and help to spread the Christian premise consciously or subconsciously.

#### D. The Male Domination Premise

All the above three premises assigned a dominant role for men over women, making Hong Kong still a society tilted in favor of men. Although the participation rate of Hong Kong females in the labor market has increased from 36.8% in 1961 to 49.5% in 1993 and 49.2% in 1996 (Hong Kong Government 1996), their employment is mostly concentrated in traditional service industries (e.g., clerical and secretarial jobs, and manual and menial services with lower job status and lower payment in comparison with their male colleagues). Among all working women, less than 5% are in administrative and managerial jobs (Westwood, Ngo, & Leung 1997). The employment situation of Hong Kong women is more or less similar to that in the cities of mainland China and Taiwan.

The educational statistics also demonstrate this male dominance. According to the mid-census report in 1996 (Census and Statistical Department 1996), in 1986, 66.38% of students in degree courses in tertiary institutions were male and 33.62% were female, whereas in 1996, 57.15% were male and 42.85% were female. Although the gap had decreased, there was still a sizable 15% difference.

The suicide rate among Hong Kong women has increased from 4 to 8 per 100,000 between 1981 and 1994 (Yip 1995), which is lower than in mainland China, where the female suicide rate is 15.9 per 100,000 for urban women and 78.3 per 100,000 for rural Chinese women (Pearson 1998). In a survey of married women's gender views (FPAHK 1993), 22% of the respondents believed that their career achievement should not be higher than that of their husbands, and 17.9% indicated that they would get respect from friends and relatives by giving birth to a son. Because of the disadvantaged position of women in society, it is not surprising to find from a youth sexuality survey (FPAHK 1998) that 8.7% of girls between 18 and 27 wished they were the other gender, com-

pared with 2.7% of boys of the same age range who wished they were female.

### E. The Liberalism Premise

Liberalism is a growing premise in Hong Kong. It could refer to sexual recklessness stemming from a lack of sexual knowledge and ethics, but it is more likely a summation of the confluence of ideas from a wide range of modern philosophies, which call for gender equality, human rights, elimination of sexual discrimination, scientific rationalism, democracy, and freedom. These individual philosophies go hand in hand with the general political change of the territory engineered by the British government before 1997, major examples being the decriminalization of homosexuality in 1991, and the establishment of the Equal Opportunities Commission in 1996. Less apparent changes can also be seen in the growing social tolerance of prostitution and sexually explicit materials. To live by the income of prostitution is illegal in Hong Kong, but patronizing a prostitute is not. Sexually explicit materials are subject to the monitoring and rating by the Obscene and Indecent Articles Tribunal, but only after the materials are published and distributed. Publishers are penalized only if they are found to have produced sexually explicit materials that are obscene or indecent, and distributed this material to readers in the inappropriate age range. It is commonly believed that sexually liberal ideas come from the West. This belief, however, may be too simplistic, at least for Hong Kong, because, as mentioned above, the Chinese culture has a long history of tolerance to varied sexual practices. Hence, modern liberal sexual ideas may be seen as a signal of the swinging back of the pendulum, gradually settling into a new equilibrium.

## 3. Knowledge and Education about Sexuality

### A. Government Policies and Programs

#### *Sexuality Education in Schools*

Hong Kong started public sex education in the 1950s, led by the Family Planning Association of Hong Kong (FPAHK). Various social service and volunteer agencies joined in afterwards (Ng 1988). Late in 1971, the Education Department issued a memorandum to all schools in Hong Kong to include sex education topics in their standard subjects and offered a summary of suggestions on what could be taught. In the subsequent years, efforts were made to include sex education as a part of the social education subject in the junior secondary grades. In 1986, the Department issued its *Guidelines on Sex Education in Secondary Schools* (Education Department 1986). It proposed an interdisciplinary approach to sex education and made further and more-detailed recommendations on resources and references. In the same year, a Sex Education Resource Center was set up by the Department to further assist in-school sex education. Frequent sex education seminars, lectures, and short courses have also been held to train the teachers. These efforts at sex education have received official applause. Some official statistics have also shown that changes do seem to be heading in a satisfactory direction (Pau 1991). A growing number of schools or teachers are reported to show an interest in strengthening sex education and have assigned teachers as coordinators. In 1990, 40% of the schools, which responded to a sex education survey conducted by the Education Department, felt that their sex education plans had been successful.

However, these official figures are far from being firm proof that sex education is making good overall progress. In 1989, the Family Planning Association of Hong Kong did a survey of sex education in schools. They found the topics

taught were mostly the basic biological information like "puberty bodily changes" and menstruation. The teachers were unprepared for topics like contraceptive methods or prostitution, which are also very important (FPAHK 1989). In the in-school portion of the sexuality survey of the Association (FPAHK 1986, 1991a), it was found that the percentage of students who reported having acquired sexual knowledge from their teachers had decreased from 26.4% in 1986 to 21.4% in 1991. The percentage of students who reported they got sexual knowledge from seminars had decreased even further, from 58.4% to 31.6%. Most of them had turned to newspapers and magazines. How this drop has affected the students' sexual knowledge was shown by figures in the same surveys: Except for the question on the safety function of condoms, there was on the average a 12.4% decrease of students who were able to give correct answers to some simple sexual knowledge questions. The disconcerting fact is that, despite a lot of statistics and a lot of work by the educational bodies, they are not meeting the students' educational needs as it has been hoped for.

How this situation has come about cannot be discussed in detail here. The obvious problem is that the "sex education" efforts in Hong Kong so far have only been lip work and service, consisting of empty words much more than effective action or support. Memoranda, guidelines, resources, lectures, and theories abound without paying enough attention to practicality or feasibility. Restricted by the insistence that sex education has to be an interdisciplinary and, therefore, a shared and fragmented subject, sex education teachers in schools lack identity, promotion, and the prospect of any psychological or material reward. Because of the heavy content and examination pressure of other "more important" subjects, it is also impossible for them to squeeze enough sex education materials into the school curriculum to make their sexuality teaching continuous, meaningful, or interesting.

There seems to be little hope for much improvement in the foreseeable future, because the official bodies appear to be sitting tight with their established principles, and are hesitant to move forward. Their work plans are still geared toward setting up more resource centers, publishing more sex education bulletins, and organizing more piecemeal sex education seminars, lectures, and courses. As for the crucial issue of setting up sexuality education as an independent subject and assigning it more time and recognition, nothing substantial is likely to be done if one looks at the second, more recent *Guidelines for Sex Education Guideline* published by the Department of Education in 1997. In these guidelines, all secondary schools are advised to set a minimum amount of teaching time for sex education. The students of Form One to Form Three are to have an annual minimum of 20 hours of Life Education, the contents of which include civics, social ethics, politics, environmental protection, etc., etc., and among all these, also sex education! In view of the special difficulties in sexuality teaching, teachers are likely to continue using most, if not all, the time for the other "more important" content.

#### *Sexuality Information and Knowledge*

Surveys have been directed toward specific groups to evaluate their sex knowledge. In 1994, the Education Department carried out the Study on Knowledge and Attitudes of Secondary School Pupils on Sex and Sex Education with a sample of 4,087 pupils. In this study, a grade of 60 was considered a passing mark, and the average mark the students obtained was 68.4. The subjects showed that they were knowledgeable about AIDS and the risks associated with unprotected sex with an HIV-infected person. However, the students got low marks in two areas, which should be the con-

cern of all secondary school pupils. Only 24.6% of the students stated correctly that the bad effects of masturbation come only from psychological guilt. Only 47.7% stated correctly that the size of the penis does not reflect the sexual ability of a man. For the self-evaluation of sexuality knowledge, only 41% of the pupils claimed to have sufficient knowledge, whereas 45.8% claimed their knowledge was insufficient, and 10.9% claimed it was very insufficient.

In a 1996 study of the sexual knowledge of couples preparing for marriage, Wong had 41 couples with a male age range of 19 to 37 (mean 28.5) and a female age range of 19 to 35 (mean 26.5). They obtained a mean score of 67%. The female respondents got a lower mean score than the males, but the difference was not statistically significant. Knowledge of female sexuality was particularly poor. Approximately half of the sample believed that women must have pain and bleeding at first sexual intercourse. The location of the clitoris was not known to one third of the respondents. Furthermore, the knowledge of those couples who had attended a premarital preparation course (23%) was not necessarily higher. The association between sexual experience and sexual knowledge was tested, but was found not significant, except for the association of experience with knowledge about female sexual arousal. Experienced subjects were more likely to understand that orgasm in women could be produced by various means of foreplay and clitoral stimulation, and not solely by vaginal intercourse. No association was observed between educational background and gender on the overall level of sexual knowledge. One exception was that the higher the level of education, the more correct answers could be obtained regarding the differences in the nature of female and male orgasms. Also, female respondents were generally ignorant about male erectile problems.

Knowledge about HIV/AIDS was studied by Chung and Fung (1999). In testing 1,160 women, ages 20 to 50, the average score of correct answers was seven out of ten. Only 55% of the respondents knew that HIV could be transmitted via breastfeeding. Only 11% of the respondents knew that the incubation period for AIDS was eight to 12 years, not seven years as formerly claimed. See also Section 3B below for data on informal sources of sexuality information.

### *Sexual Attitudes and Values*

The Family Planning Association of Hong Kong (FPAHK) provides the most detailed, reliable, and longitudinal data on sexual knowledge, attitudes, and behaviors in Hong Kong. Since 1981, the Association has been conducting sexuality surveys of secondary school students once every five years (FPAHK 1981, 1986, 1991a, 1991b, 1996). In each of these surveys, to ensure comparability of data from different years, Hong Kong students in Form Three to Form Seven (age range 14 to 19) were sampled by stratified random sampling and given similar questionnaires to answer. Despite problems of non-response and other inevitable technical deficiencies of sexuality surveys, the data represent the most reliable that can be obtained in Hong Kong. Since 1986, the survey has a section added on for the out-of-school youths, graduates, and dropouts, ages 19 to 27, making it possible to trace the direction of change in the sexual knowledge, attitudes, or behaviors of the subjects when they grow older.

According to the FPAHK data, the sexual attitudes of Hong Kong youths are not as open or liberal as many people think. Also, being liberal or not seems to depend on which sexual attitude or value one is looking at. Although an overall picture can be drawn that the Hong Kong youths are increasingly more open and permissive in their sexual attitudes, there are items also showing that in some aspects they are

holding on to sexual repression and conservatism. In the in-school surveys, for example (FPAHK 1986, 1991a), an increasing percentage of males were found to be dissatisfied with their own gender, from 1.4% in 1986 to 2.9% in 1991. In the three out-of-school surveys, which spanned a period of ten years (FPAHK 1986, 1991b, 1996), roughly the same percentage of males could accept single males having sex with prostitutes (36.2% in 1986, 28.4% in 1991, and 30.7% in 1996).

Using and reanalyzing part of the 1986 survey data of the Family Planning Association of Hong Kong, Lui, Cheung, Chan, and Ng (1993) confirmed that different types of traditional sexual values in Hong Kong changed at very different paces. They examined three items in the survey representing three different sets of sexual values: sexual enjoyment, social conformity in sex, and sexual equality. It was found that social conformity in sex was upheld by a strong majority of the subjects (81.7%) and that it was quite resistant to social changes, because covariate analysis demonstrated the small contribution of the subjects' social contextual factors to any of its variation. An even more important finding is that in these subjects, their strong adherence to social conformity went in parallel with their support for the value of sexual enjoyment, which was also quite high (65.9%). The message is that, for whatever reason, even though the Hong Kong youths might increasingly recognize and accept the enjoyable side of sex, the recognition does not necessarily make them less socially responsible in sexual attitudes and behavior. [*Comment 1997*: When confronted with double messages, the youths were able to resolve their conflicts by prioritizing their choices and preferences. (*End of comment by M. P. Lau*)] The moralists could have been misled or misleading when they sounded out alarms simply based on a changing social attitude to the function and value of sex.

It is interesting to find that despite a high acceptance of the value of sexual enjoyment, compared with their counterparts in China, Hong Kong youths show a much more conservative sexual attitude in general. Of the Hong Kong secondary school students in 1991, 80.4% supported the idea of monogamous marriage and said they planned to get married in the future (FPAHK 1991). In the Shanghai secondary school students of 1988, however, only 49.5% had the same idea. As to pornography, only 39.5% of the Hong Kong secondary students of 1991 accepted its existence in the community. This compares with 63.5% of mainland Chinese secondary school students from a large variety of regions, who, in 1989 and 1990, accepted pornography as harmless, and maintained that they should be allowed to read it (Liu et al. 1997). Some scholars (Fan et al. 1995) found evidence that the greater sexual conservatism in the Hong Kong students were because of the greater Christian influences in the territory.

### **B. Informal Sources of Sexual Knowledge**

In the 1994 Study on Knowledge and Attitudes of Secondary School Pupils on Sex and Sex Education carried out by the Education Department with a sample of 4,087 pupils, the main sources of sexuality knowledge for secondary school students were the newspaper (54.1%), television, and biology and science classes at school. As for the sources of sexual knowledge about HIV/AIDS, Chung and Fung (1999) reported that 94% of the 1,160 women respondents, ages 20 to 50, cited television as an information source, 75% cited newspapers and magazines, and 67% cited radio.

### *4. Autoerotic Behaviors and Patterns*

In the Family Planning Association of Hong Kong (FPAHK) 1996 survey of 4,116 students aged 15 to 18, 46% of the boys and 17% of the girls reported experiences of mas-

turbation. Girls had more negative feelings and perceptions about masturbation than boys. About 36% and 51% of boys and girls, respectively, indicated that masturbation was immoral, and about 37% and 43%, respectively, thought it was not good for mental or physical health. Compared with the FPAHK surveys of 1991 and 1986, the percentages of subjects who masturbate have been rising, and those holding negative views about it have kept on decreasing. There are no data on the methods of masturbation. Clinical information suggests that simple manual manipulation is the most common method, followed by squeezing the genital by the thighs or pressing on the bed sheets. Sex aids are rarely used, although they are available openly in "adult shops," which are not very different from the "sex shops" in Western countries.

However, the survey indicated that the more common form of autoeroticism among the youths involved voyeurism and the consumption of sexually explicit materials. About 66% of the boys and 39% of the girls under 18 reported that they had seen pornographic movies, and about 60% and 39%, respectively, had bought pornographic comics. Other channels of consumption included videotapes and discs, the Internet, and sexual telephone services. This finding should be a surprise to some policymakers in Hong Kong, because by law, youngsters below the age of 18 are supposed to be prohibited from access to these materials or services. The degree of sexual explicitness or "obscenity" of all published media in Hong Kong is subject to rating by government officials in consultation with representatives from the public whom the government appoints. The law imposes heavy penalties for anyone who distributes "obscene" materials to anybody, or "indecent" materials to youngsters below the age of 18.

## 5. Interpersonal Heterosexual Behaviors

### A. Youths

By comparing the in-school surveys of the Family Planning Association of Hong Kong (FPAHK) in 1986, 1991, and 1996, a trend of increasing heterosexual activity can be identified among secondary school students. Dating behavior among the boys increased from 42% to 54.2%, and among the girls from 42.5% to 55.0% in five years. In terms of having experience with sexual intercourse, the boys' figure increased from 5.7% to 6.1%, and the girls from 3.5% to 4.3%. The frequencies of other types of physical intimacy increased much more. The out-of-school surveys further confirm the sexually permissive behavior among the youths. A greater number of these youths in 1991 perceived that their friends and relatives were sexually permissive in terms of premarital sex and visits to prostitutes or other "vice" establishments. A greater percentage of the boys, 32.8% in 1986 and 36.7% in 1991, reported having had sexual intercourse. The 1991 survey shows that 16.7% of the males and 15.1% of the females of age 18 to 19 already had sexual intercourse.

However, the out-of-school survey shows that, although the Hong Kong youths of 1991 were becoming more sexually active, they were also more cautious in many respects. For example, much more of those who had sex before marriage did so with their dating partners, 52.2% in 1986 compared with 79.8% in 1991, and much less with prostitutes (28.4% compared with 10.8%). The percentage of males who had ever used prostitutes decreased from 16% in 1986 to 11.7% in 1991. The percentage of males who used condoms in their premarital sexual intercourse increased from 64.5% to 84.2%, and for females from 50.6% to 76.5%, between 1986 and 1991.

With these findings, it would appear that the increase in sexual activities among Hong Kong youths has been moder-

ate. The Hong Kong youngsters are not as promiscuous or reckless with sex as some moralists are trying to portray. The sexual self-control of Hong Kong youths is more obvious if they are compared with their counterparts in China, who are often thought of as very much under the influence of traditional sexual repression and conservatism. If Hong Kong youths are compared with their counterparts from all parts of China, their rates of sexual experience are higher. For example, in 1989, Liu, Ng, Chou, & Haerberle (1997) did a sexuality survey of 6,092 secondary school students in ten cities in China. It was found that only 461 (7.5%) of the Chinese youths had experienced sexual contact (kissing, embracing, petting, and coitus), and of these, 461, only 39 of the males and 95 of the females, reported having experienced sexual intercourse. However, if an equal degree of modernization is taken into account by comparing the Hong Kong youths with the Shanghai youths only, the story is different.

In 1991, the Hong Kong Tertiary Institutions Health Care Working Group did a sexuality survey on all university freshmen of Hong Kong and found 3.5% of the males and 1.4% of the females had experience with sexual intercourse. In the same year, Hong et al. (1994) did a sexuality survey on a random sample of the university freshmen in Shanghai. Their data showed that 6.3% of the males and 2.9% of the females had experienced sexual intercourse. The percentages were nearly double those of Hong Kong. For those who had sexual experience, 19.5% of the Hong Kong male students had sex with more than one partner. For Shanghai, the corresponding figure was 25.0%, also showing that the Shanghai students were more sexually permissive and active.

On the other hand, only 15.0% of the Shanghai males and 20.0% of the Shanghai females had the habit of using condoms, while the corresponding figures in Hong Kong were much higher at 69.5% and 37.5%, respectively. Although there are data to show that Hong Kong subjects are increasingly more open and permissive in their sexual behavior, this openness could just be part of a universal trend in modern cities. The magnitude of change is far below that of many Western societies, and not even up to that of China or Shanghai (Rosenthal 1999). If this change is a necessary adaptation for people in modernizing and developing societies, the slow change of Hong Kong sexuality should be a cause for worry rather than delight, because Hong Kong is supposed to be one of the more modernized of Asian cities.

[*Comment 2001*: History has provided many examples of overseas or expatriate groups clinging to traditional values and identities, while these same values and identities underwent changes in their places of origin. Consider the Romans in their colonies, the Mennonites, the Taiwanese Chinese (who still use the pre-pinyin characters in their alphabet), the Vietnamese Chinese (with their large family sizes), the United Loyalists in Ireland, and the Quebec separatists. Scandinavians in the American Midwest still cling to holiday customs popular with their ancestors when they came to the U.S. as poor immigrants generations ago—customs which their contemporary relatives in Scandinavia gave up long ago. The Marxists in China tried to put loyalty to the state ahead of loyalty to one's family and clan, or material productivity ahead of interpersonal, cultural, and spiritual needs. When loyalty to the central government becomes less intensive, there is a vacuum to be filled, or an anomie that may invite handy substitutes, such as wanton sexual gratification. (*End of comment by M. P. Lau*)]

### B. Adults

The only form of marriage now legal in Hong Kong is the Western Christian form of monogamous marriage. The old Chinese marital system that allowed a man to take an

unlimited number of wives has been illegal since 1971, and arranged marriages are now hardly practiced. For two or more generations, Hong Kong people have subscribed increasingly to romantic love, freedom in dating, courtship, and choice of one's own marital partner. The nuclear family is the rule after marriage, although the older generations are still respected and supported.

The mean age of first marriage in Hong Kong in 1997 was 30 for males and 27 for females. The age has increased by three years in both sexes over that of 1981. The rising marital age is associated with a rise in cohabitation, casual sex, premarital sex, and prostitution, but the exact extent of these is not known.

There are signs that the monogamous marital system is not meeting the needs of those living in the Hong Kong culture. The annual number of divorce cases had doubled from 5,507 cases in 1989 to 10,492 cases in 1997, while the number of marriages in the same period dropped from 43,952 to 37,593 (Hong Kong Special Administrative Government 1998). In recent years, the high number of males who take mistresses in mainland China has caused a number of serious marital tragedies and become a social concern. In 1996, it was estimated that, out of the approximately two million married couples in Hong Kong, about 300,000 husbands had mistresses in China. If unfaithful wives and those husbands who have mistresses in Hong Kong or practice casual sex are included, one may estimate that at least about one third of the married couples are or have been affected by extramarital relationships (Rosenthal 1999).

The Family Service Division of the Hong Kong Council of Social Services Clientele Information Service, a major marital counseling center in Hong Kong, reported that extramarital affairs constituted 26.1% of their cases from 1988 to 1990. The Hong Kong Catholic Advisory Council reported that extramarital affairs occupied about 38% of their caseload in 1993, with husband's affairs accounting for 32% and the wives' for 6%. The Caritas Family Service in the same year reported a similar proportion, and 40% of the extramarital affairs involved a stable partner (Young et al. 1995).

[Update 2002: For thousands of years, Chinese emperors and government officials surrounded themselves with concubines, while traders and businessmen maintained a wife in every port. Under British rule (1841 to 1997), concubines were legal in Hong Kong. In the past generation, enough Hong Kong men had led the double-life to father an estimated 520,000 children. In 1999, a local Hong Kong court exercised its separate legal jurisdiction to grant Hong Kong residency to the half million children born to the second wives of Hong Kong men. That decision would have added significantly to Hong Kong's 6.5 million people packed into a very limited 422 square miles (1,092 km<sup>2</sup>). It also created some serious legal consequences for the "One Country, Two Systems" policy. Not surprisingly, a mainland Chinese court overturned the local decree.

[With Hong Kong and the former Portuguese colony of Macao now under mainland Chinese rule, the borders are increasingly porous, and concentrations of second wives and concubines are expanding in small cities and suburbs within commuting distance of Hong Kong and Macao and along the main rail lines from Hong Kong and Macao to Guangzhou, as well as across southeast China.

[Concerned about the negative effects of the concubine tradition on China's family-planning policies of one child per family in the cities and a tolerated two children in the rural areas, the government is now trying to eliminate or at least reduce concubinage. This will not be easy, for both economic and jurisdictional reasons.

[Mass migration and economic dislocation have made concubines a major problem across the country, wherever rural poverty meets the affluence of the new free market's restrained capitalist economy. For a modest \$200 monthly rent in a village of concubines, a moderately affluent married businessman can enjoy the comfort of an attractive devoted second wife. Second wives are easy to find on farms just outside cities. There is also a flourishing business of go-betweens who recruit young women who are happy to trade the hard life on a poor farm in some distant province for the luxury of a two-bedroom apartment with some modern conveniences in the bustling suburb of a modern city.

[The government tries to combat migration from the farms to the cities by issuing every adult a work permit allowing that person to work legally only within a certain distance of their birthplace. Permits to migrate to a city are strictly limited. In becoming a concubine, a young woman can leave her rural home without a work permit and be supported by a "husband."

[A law introduced in 2000 in Shenzhen, just outside Hong Kong's Kowloon district, provides a prison sentence of 10 months for "factual bigamy"; a single act of adultery is still not a crime. Under a new law in Guangdong province, which includes both Shenzhen and Dongguan, long-term cohabitation by an unmarried couple is now a crime and can bring a two-year sentence at a labor camp. However, the police face a near-insurmountable obstacle proving long-term cohabitation when a monthly lease or no lease enables a man to move his second wife to a new apartment on very short notice.

[The current separate legal jurisdictions of Hong Kong, Macao, and China also make prosecution very difficult. If a Hong Kong woman wants to take her bigamist husband into a Chinese court, she must first make sure that the Chinese police can prove that the husband is living with his mistress somewhere in one of the populous mainland villages of concubines (Landler 2000; Luk 2002). (*End of update by R. T. Francoeur*)

## 6. Homoerotic, Homosexual, and Bisexual Behaviors

Because of the influence of the British laws, up to 1991, male homosexual practices in Hong Kong were illegal. Anal intercourse was punishable up to life imprisonment, while conviction for any act of "gross indecency" could bring up to two years' imprisonment. After 1991, consensual sexual conduct between two males aged 21 or older was decriminalized, following the provision of the Sexual Offenses Act of England (1967). This decriminalization has permitted Hong Kong homosexuals to "come out," the opening of homosexual bars, and the founding of a number of new homosexual societies.

There are now more than ten well-known gay bars in Hong Kong. Together with some special discos and sauna baths, there are places where male homosexuals and bisexuals get together to meet friends and spend their leisure. Lesbians have fewer venues to patronize. These are limited to a few bars, so-called lesbian karaokes, in Causeway Bay, a well-known shopping district in Hong Kong. Some selected public toilets are popular places for male homosexuals to find suitable partners. There are also magazines with personal advertisements that help homosexuals find partners or establish friendships. Homosexual erotica is available in adult shops, as well as on cable or interactive television.

The gay societies in Hong Kong are all voluntary organizations established by homosexuals and bisexuals. They provide mutual support, information, and social activities to

their members. The oldest of these societies is the Ten Percent Club, established around 1984, with an academic flavor. The Horizon, established in 1992, provides professional hotline or face-to-face counseling and produces regular publications for members. After 1997, the Horizon began to receive sponsorship from the Home Affairs Bureau, Government of the Hong Kong Special Administrative Region. The Satanga, established in 1993, gives medical and psychological advice on the health of the homosexuals. Two lesbian groups, the Female Homosexual Club and Homosexual Sisters, were founded in 1996. Around the same time, a Christian homosexual group and a Buddhist homosexual group were also formed. There are no formal governmental agencies that serve specifically the needs of homosexuals. The idea is that it is less discriminative if the life problems of homosexuals are helped through the usual services provided to the general public.

Despite decriminalization, homosexuals still do not enjoy equal rights with heterosexuals in Hong Kong. They cannot be legally married or adopt children, and are barred from certain types of employment. In 1996, the government of Hong Kong started a public consultation to propose legislation to ban some types of discrimination on the ground of sexual orientation. Public opinions received were divided and the matter is still under consideration.

### 7. Gender Diversity and Transgender Issues

Hong Kong had its first sex-change surgery in 1981. In 1986, a special team for the evaluation and assessment of patients requesting sex change was established in Queen Mary Hospital. The team of psychologists, social workers, endocrinologists, lawyers, geneticists, gynecologists, and surgeons is headed by a psychiatrist. They provide the standard assessment and test procedures practiced internationally for gender-conflicted persons (Green & Money 1969). By the end of 1998, a total of 78 gender-conflicted patients had been assessed. Forty-eight had received sex-revision surgery and seven were still under evaluation. The numbers of patients who come to the team have remained rather stable throughout the years and so is the percentage that passed the assessment and was given the surgery. Since there is only one team in Hong Kong doing sex-revision surgery, it might be assumed that the team receives most of the transsexuals in the territory. Based on this assumption, the prevalence of clinically presented transsexualism in Hong Kong is estimated to be about one per 200,000.

With certification by an attending physician, transsexuals can have their names and identity cards changed to agree with their chosen gender, but legally, the law only recognizes and abides by a person's chromosomal sex in case of any judicial disputes. Hence, a male-to-female transsexual cannot be raped according to the legal definition of rape. The law also does not recognize or permit a marriage if one of the partners involved is a transsexual, because the law only recognizes heterosexual monogamy. Because of this legal non-recognition, a transsexual runs the risk of losing many of the social rights enjoyed by ordinary citizens, such as public housing, tax deductions, and children adoption for married couples. Any documents or contracts they sign may become legally invalid if they do not state their chromosomal sex on paper.

The discrimination against transsexuals has caused a lot of suffering to this minority group. In the series of transsexuals who have undergone sex-revision surgery on the recommendation of the Gender Identity Team, none has regretted receiving the surgery and all have found the post-surgi-

cal complications mild and tolerable. It is the social and legal discrimination that has caused in them the greatest tragedies. A female-to-male transsexual was turned down by the Marriage Registry at the last minute, after he had announced his marriage to all relatives and friends. A male-to-female transsexual killed herself after her cohabitation with a male was widely publicized in the tabloids.

Along with the legislative proposal under consideration banning discrimination based on sexual orientation, the Hong Kong government has started public consultation to propose legislation to ban some types of discrimination against transsexuals. However, the proposal focuses on superficial and trivial matters only. It does not say anything about the discrimination created by the legal adherence to chromosomal sex, which is the root of many other discriminations against transsexuals. The Gender Identity Team has recognized its duty to enhance public awareness of the problem of discrimination and the need to correct it. It has also organized self-support groups for pre- and post-surgical transsexuals. But all this work is still at its infancy and far from being successful to a desirable degree.

Cross-dressing is not illegal in Hong Kong and the law does not actively interfere with transsexuals as long as their appearances or behaviors do not upset public peace. However, they are given a strange eye socially, are often the subject of gossip and ridicule, and are disadvantaged at work and in social rights.

### 8. Significant Unconventional Sexual Behaviors

#### A. Coercive Sex

##### *Child Sexual Abuse and Neglect*

Little is known about the type and extent of unconventional sexual behaviors such as child sexual abuse, sex crimes, and spouse sexual violence in Hong Kong. The issue of child abuse did not receive public attention until 1979 when the first comprehensive survey of 22 organizations involved in treating child abuse was conducted, with the aim to understand the prevalence of the problem and to develop better coordinated service for the abused children and their families (Mulvey 1997). In the 1979 survey conducted by the Hong Kong Council of Social Services, a total of 358 cases were identified. Cases of child neglect, that is, the failure to provide the child with adequate supervision, guidance, and care, constituted the largest category, 80.7% of cases reported, while sexual abuse cases accounted for only 4.2% of cases studied. However, the percentage of sexual abuse reported has increased from 4.2% in 1979 to 17.9% in 1995 (Tang & Davis 1996). The increase may probably be the result of increased awareness and reporting.

In a 1992 review of 134 sexual abuse cases by Ho and Mak-Lieh, the typical victims of sexual abuse were females with the mean age of 12.2; 96.3% of the perpetrators were male. These perpetrators are: the victims' friends or members of their household ( $n = 96$ , 64.2%), strangers ( $n = 50$ , 37.3%), father ( $n = 16$ , 11.9%), elder brother ( $n = 4$ , 3.0%), stepfather ( $n = 2$ , 1.5%), parents' cohabiters ( $n = 2$ , 1.5%), and unknown relationship ( $n = 7$ , 5.2%). Vaginal intercourse ( $n = 93$ , 69%) and inappropriate fondling ( $n = 59$ , 44%) were the most frequent types of abuses reported. Although these studies give us some information about the rate, patterns, and characteristics of child sexual abuse in Hong Kong, one has to be cautious of a bias of underreporting in interpreting these data. Chinese families tend to protect the reputation of the family rather than to fight for the welfare of the victim. Hence, Chinese families would be hesitant and reluctant to report any sexual abuse incident to helping professionals or

the police, to avoid the family losing "face" and suffering shame and pain during the investigation.

In recent years, the government and voluntary organizations have invested considerable energy and resources in public education to increase public awareness of the problem of child sexual abuse. This has enabled the social work and legal circles to improve their methods of investigation, identification, and tracking processes for child sexual abuse cases. At the same time, considerations are given to minimize false accusations and psychological trauma to the child during the investigation and trial.

### Sexual Assaults

The rate of sex crimes is a frequently discussed topic, because many local moralists keep trying to use it as a reason for purging commercial sexual institutions, prostitutes, and pornography. The fact, however, is that there are as yet no reliable data to show that the rate of sexual offenses in Hong Kong is on the rise. There are only two sources from which reliable figures of sex crime rates can be obtained in Hong Kong, the annual reports of the Royal Hong Kong Police (on rape and sexual assault cases) and the Family Planning Association of Hong Kong on victims of sexual assault counseled (FPAHK 1988-1992). The police figures (Royal Hong Kong Police 1988 to 1997) show that in the ten years from 1988 to 1997, neither rape nor indecent assault cases, reported or ending in arrest, showed any clear evidence of a rise (see Table 1). From the data on sex criminals below the age of 16, there is no evidence also to support the fear or claim that the age of sex offenders is getting lower.

It might be argued that these official figures could not reflect the actual situation because they depend very much on self-reporting, which could be affected by a lot of social, legal, or psychological factors. However, without more reliable figures or any clear evidence that people are more or less reluctant about reporting sex crimes, one is at least justified stating that there is no proof to show that sex crimes are on the rise in Hong Kong.

### Marital Rape and Spousal Abuse

Domestic sexual violence has been a topic of concern in recent years in Hong Kong. The exact rate of this type of violence before 1980 is unknown, because it had not been surveyed and few people reported it to the police when it happened. In the service statistics of institutions that provide

counseling and asylum to battered wives, such as Harmony House and Wai On House, the average annual number of admissions was around 300 cases for 1986 and 1987 (Yeung 1991; Tang 1994). The official data may not reveal its actual prevalence in society. As estimated by a current survey among 246 female and 136 male undergraduate students at a local university (Tang 1994), 14% of the respondents' parents have made use of physical force against each other; the rate of spouse aggression is comparable to that reported in the United States.

Among the various forms of family violence, there has been an increasing number of spouses who reported having been sexually assaulted by their partners in recent years. In 1998, sexual violence occurred in 6.5% of all the spouse violence cases handled by Harmony House, and the assault was invariably associated with other types of non-sexual bodily or psychological violence. It took the form of forced sexual intercourse, genital injury, or other forced sexual behavior. The victims were predominantly female (96.08%) and mostly between age 30 and 40 (41.7%). Women experiencing spouse abuse ( $n = 21$ ) were the most depressed and anxious, in comparison to those women seeking help from family service for other marital problems ( $n = 20$ ) and the normal group ( $n = 18$ ) (Tang 1997). Local scholars (Tang 1994, 1997) argue that patriarchal beliefs and values from traditional Chinese culture have legitimized and sanctioned men's use of violence toward their wives. However, Hong Kong people are also subjected to the influence of Western values, such as individualism, autonomy, and feminism. Spouse sexual abuse is a complex issue. It is likely to be the result of the interactions among forces at different levels: the individual, family, and society.

### B. Prostitution

Following Chinese tradition, prostitution was initially legal in Hong Kong. It was made a crime only after 1935 when Britain began to ban prostitution. However, the *Crimes (Sexual Offences) Ordinance* (Hong Kong Government 1980) is not exactly aimed at the prostitutes. It only punishes those who run brothels, or live wholly or partly on the earnings of prostitution. That means, if a prostitute appears to be just working on her (or his) own, she or he can still make a living without being prosecuted. Hence, although prostitution is illegal in Hong Kong, with the existence of the black market as well as independent operators, it is not difficult to find prostitutes. And, they do have rather good business. The Family Planning Association of Hong Kong (FPAHK) survey in 1996 showed that 10.2% of males up to the age of 27 got their first sexual experience with prostitutes and 13.9% had had sexual intercourse with at least one prostitute. (See also Sections 1/2A and E, Basic Sexological Premises and Religious, Ethnic, and Gender Factors Affecting Sexuality above.)

Pearson and Yu's study (1995) of eight prostitutes on the streets of a working-class area in Kowloon reveals that these women entered into the trade voluntarily in the face of negative life events, such as sudden widowhood or heavy gambling debts. Working on the street as a commercial sex worker enabled them to earn "quick" money, exert control in the choices of their customers, and, most importantly, to pay off the significant debts. Use of soft drugs or alcohol was common. Perceiving themselves as forever polluted, they hid their professional status from their spouses, children, and parents. Despite of the lack of trust toward their customers, a few of them could develop genuine affection with their customers.

Since the prostitutes have to practice semi-secretly, their business could only have very poor quality control. There is

**Table 1**  
Annual Sex Crime Rates in Hong Kong  
(Police Figures)

Year	Prosecuted Rape	Prosecuted Indecent Assault	Reported Rape	Reported Indecent Assault
1998	81 (4)*	768 (110)*	90	1214
1997	89 (9)	753 (85)	74	1114
1996	67 (6)	776 (98)	86	1214
1995	102 (6)	744 (96)	103	1099
1994	84 (0)	677 (113)	100	1066
1993	97 (5)	607 (76)	103	1030
1992	86 (3)	611 (57)	116	1099
1991	86 (10)	655 (81)	114	1101
1990	109 (10)	659 (80)	111	1078
1989	101 (5)	584 (77)	120	1019
1988	92 (7)	479 (38)	97	922

\*Figures in parentheses are the numbers of offenders below age 16. (Source: Royal Hong Kong Police Annual Reports 1988 to 1998)

no way to obtain a reliable figure on their number in Hong Kong or to monitor their service to ensure their safety or that of their clients. The public generally looks down on the profession. Supported by this attitude, the law enforcers could still have many ways to legally harass the prostitutes, for example, by arresting them for aiding or abetting the commission of other offenses, for indecent behavior or exposure in public, or for "loitering" or soliciting for immoral purposes. In 1995, a well-intentioned social worker organized a small work-union type of association for the prostitutes to help them fight for civil and legal rights. The group is growing and its voices are heard more year after year.

[Update 1997: In 1997, investigative journalist Kate Whitehead and top Asian writer Nury Vittachi published *After Suzie: Sex in South China*, their report of the sex industry in and around Hong Kong. After reviewing the colonial history of prostitution, Whitehead and Vittachi detailed the state of the sex tourism business in the mid-1990s in Wan Chai at Mong Kok, Hong Kong's real sex center, the hostess bars, fishball stalls, and the world of expensive escorts and gigolos after the 1950-to-1970 days of Suzie Wong, Hong Kong's fictional prostitute made famous by Hollywood and Broadway. (End of update by R. T. Francoeur)]

### C. Pornography

Pornography is officially regulated by two government authorities, the Obscene and Indecent Articles Tribunal and the Television and Entertainment Licensing Authority (TELA). These two agencies interpret and apply two ordinances passed in 1995 toward the end of British rule (Hong Kong Government 1995ab).

The Obscene and Indecent Articles Tribunal monitors printed matters, exhibits, and electronic publications (such as videotapes and computer programs). It does not pre-censor materials, but has the authority to grade them to the effect of declaring whether they are suitable, if at all, to be made available to people of a certain age group. There are essentially three grades: the obscene grade that is totally unsuitable for any person, the indecent grade suitable for adults above 18 years of age only, and the all-age grade for people of any age. Any person found by the police, the tribunal staff, or any member of the public to have printed, published, or distributed materials of the obscene grade or of the indecent grade to underage people will be committing an offense punishable by law. Hence, before printing or marketing any sexually explicit materials, a publisher would be wise to apply for an examination and grading from the Tribunal beforehand unless he or she can judge from personal experience and knowledge of the public standard to which grading it is likely to belong. To grade material, the Tribunal calls upon a group of adjudicators consisting of a magistrate and two or more lay adjudicators appointed by the government from a list of volunteers from the general public. The grading takes about two weeks, and can be speeded up if necessary, for which the Tribunal charges a small fee.

The Television and Entertainment Licensing Authority (TELA) monitors movies, radio and television programs, shows, and theatrical and related productions. The grades for these materials are slightly different from those for printed matter. They include: the all-age grade, the parental-guidance grades A and B, and the adults-only grade that must not be shown or distributed to people below 18. Movies have to be censored before public showing. For other materials where pre-censorship is not practical, the principles for printed matters apply. That is, the producer will be punished and the broadcast terminated if found to have gone beyond an adjudicated grade. The TELA adjudicators are also appointed volunteers from the general public, but it

is different from the Tribunal, with their number for each production larger (nine nonofficial members and an ex-officio member, who is a secretary for Information Technology and Broadcasting). A magistrate is not required.

The sentiments of the adjudicators are supposed to represent the standard of the general public, but because each adjudication can be made by a different group of people, the standard cannot be perfectly uniform, and unexpected grading does come up from time to time. A work of art, e.g., a plain photograph of Michelangelo's *David* in a newspaper, was once rated to be indecent. Appeals for an adjudication review is time-consuming, expensive, and rarely successful. There are still frequent public debates on how to make this monitoring system more fair and reliable, with the least interference on the freedom of speech and publication. The authorities are willing to listen and are always finding ways to improve the system according to public needs.

Despite laws to prevent youngsters from having access to pornographic materials, the FPAHK Annual Report (1996) showed that they are not very effective. About 1% of the males surveyed reported that they started viewing pornography as young as 7 years old. The mode was 15 for males and 18 for females. Also, 34% of males and 6% of females had bought pornographic materials when under the age of 18.

## 9. Contraception, Abortion, and Population Planning

### A. Contraception

Contraception is widely practiced by Hong Kong people. This is partly because of the hard and successful publicity work of the Family Planning Association of Hong Kong (FPAHK), and partly because of the reality needs in a crowded city. The accepted motto to follow is, "Two (children) are enough." Couples of higher social status and education tend to want only one child. As a result, Hong Kong has kept its annual natural population growth down below 1% for more than 20 years. The 1995 total fertility rate for Hong Kong was 1.3 children per fertile woman, ranking Hong Kong 220 among 227 nations.

The most popular contraceptive method is the oral contraceptive pill, used by 50.1% of ever-users of contraceptives. The oral contraceptive is available over the counter, without prescription. The male condom is used by 32.4%, the rhythm method or natural family planning, by 5.9%, the intrauterine device by 3.9%, injections or implantables by 3.3%, and female sterilization by 1.6% (FPAHK 1993). Vasectomy is the least popular contraceptive method.

### B. Abortion

In essence, there are three conditions for legal abortion in Hong Kong:

1. approval from two medical doctors to verify that the pregnant woman or the child will be in physical or mental or social danger if the pregnancy continues or is allowed to come to delivery;
2. the pregnant woman is under 16 years old; or
3. there is evidence that the pregnancy is a result of rape or incest.

Most educated women know these conditions. Among those who have been pregnant, 22% have experienced an induced abortion and the rate is increasing. Younger females with lower income tend to have a higher incidence of having an induced abortion (FPAHK 1993). However, only about 45% of abortions that the women received were legal abortions, because illegal abortions are readily available and convenient in secret clinics in Hong Kong (15%) or in

proper hospitals in mainland China (25%). An abortion round trip to China needs only one day. The laws there are much more lenient and the costs lower.

**C. Population Programs**

As noted above, while Hong Kong’s total fertility rate of 1.3 children per fertile woman, well below replacement level, makes it one of the slowest growing countries in the world. In the future, the demographic shift from a youthful population to a graying population is bound to result in major societal disruptions and adjustments.

[Update 2003: While Hong Kong remains one of the most crowded cities on earth, it has become concerned with a steep decline in its birthrate; the current birthrate is 0.9 children per fertile woman, well below the replacement level of 2.1. In February 2003, the government announced a policy to begin accepting immigrants based partly on their wealth and talents. Adjustments in the tax policies were announced to offer the same tax deductions for all children and to end the current policy of offering smaller deductions for third and subsequent children.

[Employers of foreign domestic helpers will now be taxed, and the minimum wage for such helpers reduced by an equal amount. Hong Kong’s population of 7 million includes nearly 240,000 foreign maids, mainly from the Philippines, and they are encountering resentment because of high unemployment among native-born residents.

[Hong Kong’s immigration policies have long been criticized for allowing mainland residents to settle here permanently—150 a day, almost all spouses or children of current Hong Kong residents. Despite this emphasis on the reunification of families, mainland residents can wait up to a decade for permission to move here. There has been heavy intermarriage across the border since Britain handed over Hong Kong to China in 1997. Businesses claim this makes it hard for them to transfer experienced professionals here if they are mainland citizens. The new rules create a new category to permit mainland managers and professionals to move here. Immigrants, other than those from the mainland, will also be allowed to settle here if they invest at least \$833,000. Singapore, Australia, Canada, Britain, and other countries also have special immigration rules for people who invest large sums, and the United States is discussing this approach (Bradsher 2002). (End of update by R. T. Francoeur)]

*10. Sexually Transmitted Diseases and HIV/AIDS*

**A. Sexually Transmitted Diseases**

Government statistics in Table 2 show that traditional types of sexually transmitted diseases are rather well con-

**Table 2**

**Annual Number of New Cases of Gonorrhea and Syphilis Treated in Public Hospitals, Correctional Institutions, and Private Hospitals from 1990 to 1997**

	1990	1991	1992	1993	1994	1995	1996	1997
Syphilis	87	100	78	94	133	147	129	153
Male Deaths	3	1	2	1	4	3	0	0
Female Deaths	1	0	0	0	2	0	0	1
Gonorrhea	22	11	11	8	20	17	12	19

(Hong Kong Government Department of Health statistics 1990-1997)

trolled in Hong Kong. This could be because of the generally effective therapies available and the good public knowledge about precautions. But government statistics are not reliable in this respect, because many people go to the offices of private practitioners for treatment and these cannot be recorded.

**B. HIV/AIDS**

*HIV/AIDS Incidence*

The statistics on HIV/AIDS come from voluntary reporting since 1984. The cumulative number of HIV/AIDS cases as of June 1998, and some analysis, are shown in Table 3. The trend is an increasing number of HIV/AIDS cases reported year after year, with a continued narrowing of the male-to-female ratio of new HIV infections. Mother-to-baby transmissions have been found only in the last five years and number between one to two cases per year. The number of HIV cases in homosexuals and bisexuals has continued to rise, but its ratio with heterosexual cases was inverted after 1989.

*HIV/AIDS Prevention*

There are four basic components in the strategies for AIDS prevention, care, and control in Hong Kong. The first is to prevent its transmission by the providing of transmission information and education to bring about behavioral modification, as well as early detection and treatment of sexually transmitted diseases. Secondly, the AIDS-care programs aim to relieve physical and psychological suffering. A third component focuses on understanding better the dimensions and impact of HIV/AIDS in Hong Kong—epidemiological surveillance studies and monitoring are conducted regularly to obtain useful and accurate information about HIV/AIDS distribution in the community. The fourth component consists of partnerships, with the community and internationally, to bring about a coherent and constantly updated method of prevention and control. These strategies are carried out jointly by governmental and nongovernmental organizations (NGOs). The main governmental organizations come under the Department of Health. They are the AIDS Hotline, for public education, and the AIDS Unit, for

**Table 3**

**Cumulative Reported HIV/AIDS Statistics from 1984 to June 1998**

	HIV+	AIDS
Sex

Undetermined	100	20
Total	1,066	349

(Department of Health 1998)

the screening and treatment of AIDS patients. On the non-governmental side, there are the Hong Kong AIDS Foundation, which centralizes and distributes public donations for running AIDS education, counseling, or research programs, AIDS Concern, to give assistance to AIDS patients and their relatives, and TeenAIDS, which runs AIDS educational programs for the youngsters. The government Secretariat has an Advisory Council, comprising AIDS experts from various fields, to advise on the implementation and coordination of all these organizations and strategies.

[Update 2002: UNAIDS Epidemiological Assessment: Since the first HIV/AIDS cases were reported in 1984, there has been a slow increase in reported cases in Hong Kong, China. At the end of June 2001, 1,636 cases (including 524 AIDS cases) had been reported. The best estimate of HIV prevalence as of 2000 was about 2,500. Although there is a steady increase in the number of HIV cases, the prevalence rate is estimated to be less than 0.1% in the adult population. The majority of reported cases occurred among men (82%). Mode of transmission was largely through either heterosexual contact (57%) or homo-/bisexual contact (24%).

[STDs are reported only from social hygiene clinics (SHC), with data showing an increase in reported STDs over time. Periodic surveys of private medical practitioners are conducted to complement passive STD surveillance. However, it appears that only about 20% of all STDs are taken care of by public doctors. Gonococcal antimicrobial resistance has increased. Data on HIV/STD risk behavior are available through monitoring of STD patients, methadone clinic attendees, and prison inmates.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	2,600 (rate: 0.1%)
Women ages 15-49:	660
Children ages 0-15:	< 100

[An estimated less than 100 adults and children died of AIDS during 2001.

[No estimate is available for the number of children who had lost one or both parents to AIDS and were under age 15 at the end of 2001. (*End of update by the Editors*)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

Before the advent of the modern sex therapies in the 1970s, the treatment and counseling of people with sexual dysfunctions relied mainly on folk medicine or traditional Chinese medicine. These treatment methods included the use of herbs, health tonics, physical exercise (e.g., Kung-Fu) or breathing exercises (e.g., Chi-Kung), acupuncture, acupressure, and sex aids. There is some evidence that some of these modalities are effective (Ng 1988), and they are still used by many in Hong Kong (Liu & Ng 1995; Rosenthal 1999). Supportive psychotherapy and anxiolytic drugs are also used.

The first sex clinic to offer the Western type of sex therapy in Hong Kong was established about 1979 as a part of the general psychiatric clinic in the Department of Psychiatry at Queen Mary Hospital. The clinic receives referrals from all other clinics for cases of sexual dysfunction, paraphilia, and miscellaneous sexual problems. Referrals in the early years were few, but they have increased steadily. The male-to-female ratio of initial presenters has also changed from 5:1 in 1977 to around 2:1 in 1997, showing a rising awareness and initiative among females in understanding and meeting their sexual needs and rights. There has been a gradual change in the types of cases attending the sex clinic too. For males, the most common cases have

changed from retarded or inhibited ejaculation to erectile dysfunction. For females, the shift has been from vaginismus to general sexual dissatisfaction. These changes are found to be associated with a diversification of referral sources, which indicates a general awareness by the medical profession and general public of the effectiveness of the Western type of sex therapy in dealing with a variety of sexual problems (Ng 1990b).

Despite this increasing demand, only one other formal sex clinic has been established. This clinic, established in 1997, will be discussed in the next section. Other less specialized or comprehensive sex therapy or counseling is offered by social workers or psychologists in private practice or in non-profit organizations, such as the Family Planning Association of Hong Kong, the Social Welfare Department, and agencies for the mentally or physically handicapped. Some psychiatrists, gynecologists, and family physicians have also gained a reputation for being able to provide sexual counseling. Urologists, of course, have always helped to manage a large share of erectile dysfunction cases that are principally of organic origin.

All types of medication found to be useful for erectile dysfunction are used in Hong Kong, including intracavernosal injection or urethral insertion of prostaglandin E1. Most recently, in February 1999, Sildenafil (Viagra) was approved and, as in many other places, the drug has caused sensational public reaction even before its approval, leading to abuses and illicit sales. However, there have not been any reported cases of death or severe complications because of the drug up to the time of writing (April 1999). The government has imposed strict regulations on the prescription and dispensing of Viagra to prevent abuses.

## 12. Sex Research and Advanced Professional Education

### A. Advanced Sexuality Education

There is no sex education on the advanced level. Different faculties in different universities run their own sex courses to meet the specialized needs of their students. The advanced sex education course with the longest history at a tertiary institution is the Human Sexuality Course in the Medical Faculty of the University of Hong Kong. It was started in 1981 by the Department of Obstetrics and Gynecology and was taken over by the Department of Psychiatry in 1990. Its aim is to provide the medical students with a basic understanding of the interdisciplinary nature of the study of human sexuality and its relation to the practice of medicine. The course is run at the end of the third year of the medical curriculum and lasts for five half-days (about 20 hours). The topics include introduction to medical sexology, Chinese sexual attitudes and practices, sexual philosophy, social construction of sexuality, psychosexual development and sex education, sexual variations, forensic sexology, sexual attitude reappraisal, sexual problems in medical practice, clinical sexual interview, introduction to sex therapy, sexology, and AIDS. The teaching format consists of lectures, video demonstrations, intranet computer-interactive teaching, group discussion, opinion polling, and role-plays. Besides medical practitioners, non-medical specialists, including a social worker, a philosopher, educators, and psychologists participate in the teaching significantly. Prominent sexologists from different parts of the world have been invited regularly to take part and to advise on the teaching as well. This has helped to ensure the quality of the course and to regularly update its contents. From the post-course feedback, it has been found to be one of the favorite courses for the students.

There are other sexuality courses in other departments or universities, but they are of shorter history and less systematic, usually focusing on areas of direct interest to the discipline concerned. For instance, in 1993-1994, a general education course known as Sexuality and Culture was started at the Chinese University of Hong Kong, with the aim to equip the undergraduate students with a cultural perspective on human sexuality. This course was stopped in 1995 and was reintroduced in 1998 upon the request of the students. The popularity of this course can be reflected by the fact that over 100 students attended.

Even less systematic are those short or part-time courses organized ad hoc by health or family planning agencies. These courses do not have set structures, formats, or content, but are run to meet immediate social or professional needs only.

Generally, although advanced sexuality courses in Hong Kong are improving both in quantity and quality, sexology in Hong Kong has not been recognized for its value and deserved status. There is no advanced sexuality program that can lead to a separately recognized degree in sexology or sex education, although a postgraduate student can take up a sexuality subject as a research project for a master's or doctoral thesis.

## B. Sexual Medicine and Research

Hong Kong has been proud of its medical services. It is the first Chinese community in the world to provide valuable and verifiable organized service for sexual problems. The excellence of this service has been well supported for a long time by statistics on obstetric care, infant mortality, neonatal care, population control, and the treatment and prevention of sexually transmitted diseases (Ng 1990a). The sex clinic in Hong Kong, set up in 1979, was the first in Chinese communities. It was also in Hong Kong that the first Chinese sexology association, the Hong Kong Sex Education Association, was set up in 1985. The Association was instrumental in the formation of the Asian Federation for Sexology in 1992. Despite an early start, the subsequent growth of sexual medicine in the territory has been slow. Besides the clinics run by traditional healers, there is only one sex clinic in the public hospitals in Hong Kong, established in 1997. Aside from the gynecologists and urologists with partial interests in sexual problems, only one new medical doctor has specialized in the field of medical sexology and sex therapy. A sex clinic needs not just a doctor and a consultation room, but also nurses, social workers, psychologists, technicians, and many other auxiliary personnel, as well as laboratories, drugs, reading materials, instructions, and treatment devices that can be easily accessed by the public. Patients also have to know where and when to come, and they need to not be too shy to come. All these require a sexually enlightened and open atmosphere.

[Update 1997: In understanding the uniqueness of sexology in Hong Kong and the conflicting currents that have inevitably had an impact on Hong Kong culture as its people moved from being a British colony into the People's Republic of China, it is important to remember that in democratic societies, the majority decides how the public should be governed, and the lay and nonprofessional perspectives prevail, as a safeguard against the pitfalls of professionalism and authoritarian government. Although the experts have the cutting-edge knowledge and skill, they need to be sensitive to the historical, political, and emotional elements involved in making public decisions.

[Frustrated as professionals may be at times by the obstacles and the resulting inclination to ventilate, influencing public health policy decisions requires another set of per-

spectives and skills. These include an understanding of the dynamics and processes involved in dealing with controversial and polemical political issues and in testing the applicability of new ideas in certain frameworks. More time, effort, and patience are required for more progress—as well as more communication, lobbying, the alignment of support groups, and the creation of new coalitions. Cooperative alliances are particularly effective, especially when they bring together the collaborative skills of professionals and laypersons and facilitate the exchange of ideas. (End of update by M. P. Lau)]

Like all other societies making a start on sex research, Hong Kong spends quite a lot of effort on sexuality surveys to understand the basic sexual characteristics of its people. These surveys have ranged from the broad knowledge, attitudes, beliefs, and practices surveys to specific ones focusing on the consumption of pornography, experience, and attitudes toward rape (Cheng, Ip, & Cheung 1984; Cheung, Audry, & Tam 1990), sexual harassment (Tang, Yik, Cheung, Choi, & Au 1995), child sexual abuses (Tang & Davis 1996), homosexuality, gender inequality (Westwood, Ngo, & Leung 1997), and sex among the disabled and the mentally handicapped. Some of these surveys are commissioned by the government to guide its social or health policies, some by voluntary agencies to evaluate their work, some by religious or political groups to support their views and affirmations, and some are sponsored by academics with theoretical interests. The quality of these surveys is very variable. The religious and political surveys are well known to be very unscientific. They use vague and broad definitions and unrepresentative samples. Good surveys should satisfy international standards and their data should be suitable for cross-cultural comparisons.

Clinical sexuality research has focused on the development and application of sex therapy, family therapy, and psychotherapy, drugs and devices in the treatment of sexual dysfunction, and transgender problems. There is also sexuality research into the biomedical aspects of sexuality, such as research on sexually transmissible infections, contraception, assisted reproduction, prostate and penile surgery, sex hormones, and women's health. As in most other countries, it is difficult to obtain funding for sexuality research in Hong Kong. Research studies on sexual behavior, psychology, and sexual minorities are often thought to be unimportant and unscientific, and attract little financial support unless they are done for specific political or ideological causes. This is a principal reason for the highly uneven quality of sexuality research in Hong Kong.

## Conclusion

Hong Kong is a very special place as far as the evolution of understanding sexuality is concerned. One finds Hong Kong very sexually open if one reads the newspapers, watches the "illegal" videotapes or disks that are easily available in street shops, listens to sexual discussions on the radio and television, experiences how easy it is to find casual or commercial sex, and follows the lifestyles of some of the movie stars and socialites. On the other hand, the laws are strict, voices for sexual conservatism are loud, and sex education activities or serious discussion of sexual matters are difficult to find. Such a sexuality split is found probably in many other communities around the world, but it is certainly very strong in Hong Kong. This could be because of the strong influences of both the Chinese and Western civilizations, which often clash vigorously with each other, creating difficult choices for the common people. Luckily, and probably because of the high level of mutual tolerance in the Chinese, open physical violence between antagonistic

camps has rarely, if ever, occurred. This type of sexuality environment should make Hong Kong a particularly interesting place for sexologists to study, to see how sexual diversities can coexist peacefully and be properly managed and promote growth.

[*Comment 1997*: In commenting on this summary of sexuality in Hong Kong, M. P. Lau, coauthor of the China chapter and a native of Hong Kong, emphasized that “in spite of on-going conflicts and some set-backs, amazing progress has been made in Hong Kong so that there are many reasons to be optimistic and upbeat. Admittedly, the people of Hong Kong, and pioneers in sexology like Emil Man-lun Ng and Joyce L. C. Ma, have found themselves confronted with double messages, conflicting views, inconsistent commandments, and ambiguous role models, out of which they have struggled to emerge with decisions for action. Both professionals and laypeople in Hong Kong have witnessed the struggle and the dissonance, the casualties and sufferings, the resolution and reintegration, however idiosyncratic these may be. The crises and opportunities in Hong Kong, a crucible of diverse worldviews and ideologies, some very fascinating, invite further scrutiny and empirical endeavors.” (*End of comment by R. T. Francoeur*)]

## Demographics and a Brief Historical Perspective

SÓLEY S. BENDER

### A. Demographics

Iceland is an island nation located just south of the Arctic Circle in the North Atlantic Ocean. Geographically isolated until 870 when the first settlers arrived, Iceland's nearest neighbors are Greenland about 190 miles (305 km) to the northwest, Norway about 620 miles (1,000 km) to the east, and the United Kingdom 500 miles (800 km) to the south. Iceland's total land area is just under 40,000 square miles (103,000 km<sup>2</sup>), with a coastline of 3,100 miles (4,990 km), making it slightly smaller than the state of Kentucky. About 65% of the country is mountainous, with glacial rivers coursing through sandy deserts and lava fields. About 11% of Iceland is covered with glaciers (Hagstofa Íslands 1998).

There are innumerable hot springs both in the lowlands and in the mountains. Natural hot water is used to heat houses. There are many geysers in Iceland, the most famous being the Great Geyser in Haukadalur, which gives its name to geysers all over the world. The Gulf Stream makes Iceland's climate much warmer than the name suggests. Icelanders import grain and vegetables, but are self-sufficient in meat and dairy products.

In July 2002, Iceland had an estimated population of 279,384. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 23% with 1.07 male(s) per female (sex ratio); 15-64 years: 65.1% with 1.02 male(s) per female; 65 years and over:

(CIA 2002)

11.9% with 0.81 male(s) per female; *Total population sex ratio:* 1 male(s) to 1 female

**Life Expectancy at Birth:** *Total Population:* 79.52 years; *male:* 77.31 years; *female:* 81.92 years

**Urban/Rural Distribution:** 92% to 8%. In 1999, 61.5% of Icelanders lived in the Reykjavík metropolitan area.

**Ethnic Distribution:** a homogeneous mixture of descendants of Norwegian (Norse) and Celtic settlers who arrived over 1,300 years ago

**Religious Distribution:** Evangelical Lutherans: > 90%; other Protestant and Roman Catholic: 3%; no affiliation: 1%

**Birth Rate:** 14.37 births per 1,000 population

**Death Rate:** 6.93 per 1,000 population

**Infant Mortality Rate:** 3.53 deaths per 1,000 live births

**Net Migration Rate:** -2.27 migrant(s) per 1,000 population

**Total Fertility Rate:** 1.99 children born per woman; in 1997, Icelandic women had a TFR of 1.8 children. The mean age of having the first child in 1998 was 25.1 years and the mean age of women in general to have a child was 28.8 (Hagstofa Íslands 1999b).

**Population Growth Rate:** 0.52%

**HIV/AIDS** (1999 est.): *Adult prevalence:* 0.14%; *Persons living with HIV/AIDS:* 200; *Deaths:* < 100. (For additional details from [www.UNAIDS.org](http://www.UNAIDS.org), see end of Section 10B.)

**Literacy Rate** (*defined as those age 15 and over who can read and write*): 99.9% (1997 estimate); schooling is compulsory from age 6 to 16. The language is Icelandic, which is actually similar to the language spoken by the Vikings who settled in Iceland in the early days. Most education is free. The number of women graduating from universities is rising, with 59% of the 1995-1996 graduates being women and 41% male, compared with a 93:7 ratio in the early 1950s (Hagstofa Íslands 1997).

**Per Capita Gross Domestic Product** (*purchasing power parity*): \$24,800 (2000 est.); *Inflation:* 3.5%; *Unemployment:* 1% (April 2001 est.). Iceland's unemployment rate in 1998 was 2.7%, 3.3% for females and 2.3% for males (Hagstofa Íslands 1999b). The majority of Icelandic women, 83%, participate in the labor force, which is higher than in the other Nordic countries (Nordic Council of Ministers, 1999). *Living below the poverty line:* NA

\**Communications:* Sóley S. Bender, R.N., M.S., Department of Nursing, University of Iceland, Eirberg, Eiríksgotu 34, 101 Reykjavík, Iceland; [ssb@rhi.hi.is](mailto:ssb@rhi.hi.is). ## B. A Brief Historical Perspective

The first settlers of the volcanic island of Iceland were Vikings who arrived from Norway in 874 C.E. accompanied by a number of Scots and Irish. The Icelandic people are therefore mainly Scandinavian, genetically very homogeneous because of their longstanding geographic isolation. In 930, the Vikings established their legislative assembly, the Althing at Thingvellir, the world's oldest parliament. Christianity arrived in Iceland around the year 1000. In the year 1262, Iceland came under Norwegian rule. In 1380, it came under the rule of Denmark when the Danes gained control of all of Scandinavia. In 1918, Iceland became an independent sovereign state in union with Denmark through a common king. In 1944, with the Nazis occupying Denmark, Iceland deposed its king and declared itself a republic. The republic developed a Scandinavian-style welfare state, with comprehensive social benefits, that have produced one of the healthiest and best-educated populations (Olafsson 1989, 1990, 1999). Since 1944, Iceland has been an independent republic with the president chosen by a general election every four years.

### 1. Basic Sexological Premises

SIGRÚN JÚLIUSDÓTTIR

The character of gender roles, the sociolegal status of males and females, and general concepts of sexuality in Iceland are dealt with here as the product of the interaction between macroconditions and cultural values on the macro level, and lifestyle and adjustment on the meso or family level within Icelandic culture. These three basic sexological premises are discussed on the basis of statistics and research, as well as on clinical experience.

### A. Character of Gender Roles

The rather young and small Icelandic society is known for its ancient literature, the *Sagas*, from which some basic cultural values derive. From the 1,000-year-old Saga period, we have colorful and influential descriptions of powerful gender characteristics of men and women and their equally esteemed gender roles as Vikings and Valkyries.

The written sagas and their narratives reflect cultural-ethical values and social norms, which have been transmitted through the generations in written texts, oral history, and developing myths. They have brought with them strong ideas, or even ideals, for modern men and women, for good and for bad. Also, some of the old values linked to survival and social adjustment in a tough natural environment under poor socioeconomic conditions in earlier times are still today reflected in men's and women's tough attitudes to work, love, and children (Juliusdottir & Asmundsson 1987). Accordingly, the modern woman sees herself as strong and independent, but simultaneously, she still assumes almost single-handedly the responsibility for the internal life of the family, reproduction, emotional care, and survival. Modern young men still see themselves as socially and economically responsible for the family's external, reproductive, and economic survival.

A family study on coping strategies in Icelandic families with children includes an analysis of the interaction of old cultural values and modern lifestyle. The results show how the ties to earlier times shape a set of gender-based complementarity of responsibilities enchainning both sexes to old hidden loyalties, which often seem to be a stumbling stone to individual freedom and career goals (Juliusdottir 1993).

Strivings for equality in Iceland started more than a century ago with women's movements and activity in different social organizations. Several factors, such as different formal human rights early in the 20th century, have contrib-

uted to the development of a myth about the strong Icelandic woman. Icelandic women gained eligibility and the right to vote in 1915, and the first woman was elected to the Parliament in 1922 (Erlendsdottir 1993; Kristmundsdottir 1997). Other historical events are often referred to as verifying instances of gender equality and the somewhat special position of Icelandic women. These are the strong Redstocking Movement (for sexual equality) around 1970, the celebrated "Day of Women's Strengths and Solidarity" (*Kvennafridagur*) on October 24, 1975, the Women's Slate Movement and the subsequent Women's Party from 1982 onwards, and the election of Vigdis Finnbogadóttir in 1980 as the first woman president of a nation in the world. Also cited are the establishment of the Society for Sheltering Battered Women in 1979, followed by the first study of violence against women (Olafsdottir et al. 1982; Juliusdottir 1982), and the Women's Counselling Service in 1984. All these are evidence of the progress modern Icelandic women have made in their endeavors for solidarity with victims of violence and injustice.

Being strong, however, is not the same as being free and independent, a distinction that may apply to both men and women. In spite of the positive image of the strong Icelandic women, statistics give another picture. Figures on the low wages and occupational status of Icelandic women, and their poor participation and lack of recognition in the public sphere, in politics and the economy, show the opposite, i.e., a much lower status of women than men (Hagstofa Íslands 1999b, 67, 184).

The increasing pressures of globalization have reduced the historic isolating effects of Iceland's geographical distance from other countries. Modern electronic and computer/Internet media rapidly import new scientific knowledge and convey the latest ideas from abroad about gender equality and behavior patterns. Ideas about the personal freedom to choose and plan one's educational path, occupational career, children, and family obligations thus often collide with the persistent old values related to the virtue of personal sacrifice, hard work, and social adjustment in Iceland.

The labor force is in short supply and both professionals and qualified and unqualified workers are badly needed. Thus, the relatively few inhabitants are not only expected to contribute with long working hours, but also are simultaneously expected to find for themselves effective solutions for family matters, such as childcare and care for the elderly. A strong informal family network often comes into play when public services and support are lacking for dual-career couples. Another example of how social concerns are dealt with in the private sphere is the expectation that married couples will successfully negotiate their own marital/familial roles and responsibilities (Rafnsdottir 1994; Olafsson 1990).

There is strong social pressure to reach the goal of a first-class housing standard, high educational level, and modern material consumption pattern for all Icelanders. Simultaneously, the old values of still having many children, taking care of one's own parents, and other "old fashioned" family obligations often put young parents in a situation of heavy conflicts in their daily lives.

### B. Sociolegal Status of Males and Females

The small, traditionally rural Icelandic society changed rapidly after World War II. The process of urbanization with a civil environment and modern lifestyle did not appear until the 1950s. Iceland is supposed to share the welfare-state ideology of the Nordic countries. The implementation of constitutional and juridical issues is, however, somewhat different (Olafsson 1999, 1989). Iceland's healthcare expenditure is in

line with the other Nordic countries and even higher in some cases. In Iceland, consumers of health services, however, pay a larger part of the medical costs themselves. The high-quality health-service results include the lowest infant mortality rate and the highest life expectancy in the Nordic countries (NOMESCO 1998, 67-69, 161, 164).

On the other hand, the government's economic contribution to social and family matters is much lower than it is for the health services. Thus, daycare centers and services for the elderly are insufficient to meet the needs of the people (NOSOSCO 1996). The difference is striking, when long working hours, the number of children, and the considerable number of three-generation households are taken into account. In spite of the high divorce rate, approximately 40% of the weddings, the strong and still increasing familialism with its emphasis on building families early and having many children, makes the percentage of intact families (married or cohabiting with their own children) up to 50% plus. At the same time, the number of single-parent households is 8.5% and 7.3% for stepfamilies (Hagstofa Íslands 1999b, 33, 60, 65; Juliusdottir et al. 1995, 40-41).

Statistics show that, on average, men between the ages of 25 and 54 have a workweek of 54-plus hours and women 45 hours (Hagstofa Íslands 1999b, 88). Ninety-six percent of the men and 85% of the women between ages 25 and 54 are actively employed (Hagstofa Íslands 1999b, 79). The choice of fields in this labor market is highly segregated by gender. The proportion of women is highest in public services, healthcare, and education, whereas that of men is highest in administration, special techniques, fishing, and agriculture (Hagstofa Íslands 1999b, 86). The wages of women are only 52% of those of the men, and that has not changed in recent years (*Heilsufar Kvenna* 2000).

Icelandic women have reached a high level of education. Among the 20-year-olds, 42.3% of the women and 28.5% of the men pass the matriculation examination. Also, proportionally more women than men are admitted to universities, and they graduate more frequently than men, both with undergraduate and graduate-level degrees (Hagstofa Íslands 1999b, 269). Women do not seem, however, to realize their potential in a vocational career to the same extent Icelandic men do, as already pointed out above.

After World War II, the work of Icelandic women outside the home increased and their educational level improved considerably. There has, however, been a significant difference between single and married women. The latter continued to give birth to many children and take care of their parents, although the daycare system and services for the elderly did not expand in proportion to the demand. As elsewhere, the social care services have developed as a gender issue, both regarding the employed and the families as consumers (Rauhala et al. 1997).

During the last decade, several improvements of crucial importance for equality have been legislated. One sign of progress for equality of the sexes was new legislation on parental leave of nine months at childbirth, which is to be implemented in steps in the next few years. It allows three months leave for the mother, three months for the father, and three months to be divided as the parents choose.

In 1992, Iceland was late in introducing legislation on joint custody for children of divorced parents. A new study on the experience of this alternative shows that parents who choose joint custody adjust in several ways better and more equally to their new life circumstances. Both parents and children report better health on average, and the frequency of depression and social isolation is less than among parents with divided custody. They use alcohol less often and the contact with families of origin is more frequent, especially

for the fathers. The parental responsibilities also came out more equal for both sexes than when custody was divided (Juliusdottir & Sigurdardottir 2000).

A recently established public Family Council, followed by the Year of the Family in 1994, has played a role in preparing an integrated and comprehensive family policy, recommending political initiatives, and facilitating actions in family matters, such as family planning and family life education. The Family Council is also supposed to serve as a consulting organ for the government.

The rapid socioeconomic evolution has caused a cultural lag, where families and couples are struggling with adapting to the new society's demand for consumption and self-realization, but at the same time taking on family obligations in the spirit of the still-alive old values and images.

Sometimes the loyalty to old values is beneficial and sometimes it restricts the changing character of Icelandic gender roles. The influences of the macro- and mesofactors mentioned above often appear strikingly in parental roles and in couples' intimate relationships affecting their emotional and sexual lives. A comparison between two Icelandic and Swedish counseling services shows that the reasons for seeking professional help are different. The Swedish clinical population in marital and family therapy seems more prone to seek help to improve couples' emotional relationships and communication when dealing with personal and interactional conflicts. This may, unlike the case in Iceland, have to do with the fact that Swedish parents are not so busy struggling with practical (e.g., financial, housing, working, and daycare) problems of daily life as Icelandic parents are. Such practical needs and the problems related to them are not so prominent in Sweden. They are, to a greater extent, taken care of through effective family policy with sufficient official family support (Juliusdottir 1993).

In modern European societies, where the public is generally well educated and conscious about qualities of life, there is also increasing emphasis on harmonious proportioning of work, private life, leisure, sex, and pleasure. In Iceland, some similar changes in cognitive attitudes are appearing. In a comparative European study, 66% of Icelanders agreed with the statement, "The government must offer extensive social services, even if it requires higher expenditures and increased taxes." This percentage of agreement was similar to that in other European countries. On the other hand, 79% in the Icelandic sample were strongly against the statement, "Social service is too expensive and must be cut down" (Olafsson 1999; Olafsson et al. 1998).

### C. General Concepts of Sexuality and Love

Icelandic constructs of sexuality related to family building, health, work, values, and moral attitudes provide a third domain of basic sexological premises.

The Icelandic population, in general, holds rather permissive attitudes regarding sexual relations and other related social-moral issues. Although the age of majority for males and females is 18 years, young people start working already at an earlier age and consequently identify with adult behavior in many regards. Icelandic adolescents, boys earlier than girls, start petting early in comparison to other countries, often before age 16, and have their first sexual intercourse, on average, at age 15 (Jonsdottir & Haraldsdottir 1998). Approximately 55% of 14-year-olds, girls more often than boys, have started smoking. A somewhat higher proportion at this age has started drinking. There is no difference between the sexes until the age of 17, when the proportion is significantly higher for the girls (Adalbjarnardottir et al. 1997). Another Icelandic study confirms these results, but also shows that young Icelandic adolescents in general use alcohol and drugs

to a somewhat lesser extent than those in the other European countries (Thorlindsson et al. 1998).

Young people, on average, leave home at the age of 20-plus and start cohabitation or marriage, on average, about the age of 21. It is most common to start "going steady" at about the age of 18 and to have experienced two longer relationships before cohabitation. At least 40% start cohabiting in the housing of their parents or parents-in-law (Juliusdottir et al. 1995, 52).

The generally liberal attitudes of Icelanders are reflected in the Icelandic part of an international opinion study of a nationwide representative sample (Jonsson & Olafsson 1991). In some moral attitudes and values concerning sexuality and family life, Icelanders do not differ from the average on most items. Approximately 24% agree on a requirement of "totally free and unregulated sexual behavior," whereas the other Nordic countries are harder on that issue. Icelanders differ from other Scandinavians, on average, in holding more-positive attitudes towards divorce, abortion, and homosexuality. On the other hand, Icelanders are, on average, more negative than other Scandinavians when it comes to marital infidelity.

In the 1991 family study just cited, approximately 80% of responding husbands and wives said that it never occurred in their relationship. The respondents, however, reported that they would discuss it rather than see it as a reason for divorce. Asked about their attitudes to their own sexual life, they commonly reported that they have intercourse six to ten times per month (45% of the men; 49% of the women). They emphasized caring more than intercourse (45% men; 70% women), and preferred showing physical closeness and warmth (30% men; 21% women) (Juliusdottir 1993, 186, 190).

In an international study of 60 countries (Gallup 1999) with a representative sample of Icelanders, the respondents evaluated similar factors as the other Nordic countries as most important in life, specifically, good health and happy family life. A recent nationwide Icelandic opinion study on moral values and virtues showed similar results (Proppé 2000). What Icelanders saw as more important to care about and to pursue were family and friendship (50%) rather than education and vocational career (11%). This was especially true among younger people.

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

SÓLEY S. BENDER

### A/B. Source and Character of Religious and Ethnic Values

In Iceland, about 89% of the population are registered members of the state Lutheran Church, 3.6% belong to the Lutheran free churches, 3.3% belong to other religious organizations, and of those, there are 1.4% Catholic (Hagstofa Íslands 1999b). There is not a strong religious influence on sexual life. According to the Lutheran religion, people should only have sex within marriage. In the earlier days, marriage was arranged between two clans. Both the bride and the bridegroom had to have enough money to be able to get married (Gudmundsson 1990).

In Thorvardarson's 1978 study, students in the age group 16 to 18 were asked about the importance of teaching about Christian values, especially regarding sexuality and marriage. Only 10% considered it very important to teach religious values in sex education. This issue had the lowest value when compared to other topics in sex education, such as sexually transmitted diseases (97%), contraceptive methods (92%), where to get information (86%), and sexual problems (61%).

Nowadays, marriage is not a prerequisite for living a sexual life. Cohabitation is common and some people never get married, although they may have several children. Icelanders widely accept single persons having a sexual life.

## 3. Knowledge and Education about Sexuality

SÓLEY S. BENDER

### A. Government Policies and Programs

In the 1950s, sex education in Iceland's schools was limited. For the most part, it consisted of two pages in the human health book. In many schools, the teachers skipped these two pages. In 1948, *Sexuality* by Fritz Kahn, M.D., was published in Iceland. It was a popular possession of many families at that time. Through the years, several books about sexuality have been translated into Icelandic. Some of these books have been used in teaching sex education. In 1976, *The Man, Birth, Childhood and Adolescence* was written by Icelanders to be used for sex education (Eiriksdottir et al. 1976). It has since been widely used for 5th and 6th graders (10- and 11-year-olds). *Human Reproduction*, published in 1983 (Kjartansson & Brynjólfsson), was another Icelandic addition to textbooks for sex education in the schools. It has been widely used in the schools for 13- to 16-year-old students.

The 1985 diagnosis of the first person in Iceland with AIDS raised the importance of preventive work in the schools. This meant increased emphasis on sexually transmitted diseases and the importance of condom use. Because of AIDS, new Icelandic educational material about sexually transmitted diseases was published in 1988 by the Ministries of Education and Health for use by teachers and others in sex education. In 1989, the Ministry of Education issued a curriculum plan for grades 1 through 9. In this plan, sex education was emphasized as a part of many subjects in the schools, like Christianity, sociology, and biology. Teachers in the schools and health professionals from the local community health center were encouraged to work together on sex education. In the fall of 1999, a new curriculum plan was released by the Ministry of Education for grades 1 through 10 and beyond. Presently, teachers in every school make their own teaching plan, and the number of hours devoted to sex education can vary considerably. Sex education is, therefore, in the hands of individual teachers and schools. Some schools have very good sex education, whereas others are very limited.

A standard curriculum for sex education was lacking for many years. It was not until 1991 that a holistic curriculum for sex education for the 8th through the 10th grades was introduced in the schools. This program, *Human Sexuality, Values and Choices*, was an American sex education curriculum from Minnesota. It was translated, adapted to Icelandic culture, and pilot-tested in seven schools in 1990 (Axelsdottir et al. 1990). The pilot test was based on an experimental design. It showed that there was a significant increase in knowledge among those in the experimental group compared to those in the control group, but it showed very limited changes of attitudes. This sex education curriculum is based on 15 lessons, with lessons about the biological facts of human sexuality, but also about feelings and intrapersonal relations. It does stress identity, feelings, how to make decisions, and knowing what to do when it comes to making decisions about sexuality. It has a comprehensive handbook for teachers, with objectives and the contents of the lessons, as well as projects for the students. It also has a video of 120 minutes that has short episodes of certain sex education sessions meant to facilitate group discussion. There is an additional handbook for parents.

The teachers are supposed to have three meetings with the parents about the curriculum. Many projects are intended to be completed by the students in cooperation with their parents or other adults. This program is now in use in many schools and it has made a considerable difference for sex education. A 1993 study showed that this curriculum was used by 63.6% of the 60 schools participating in that study (grades 8 through 10) (Palsdottir & Hardardottir 1993).

No comprehensive curriculum has been developed for students younger than 13 years old or for those older than 16 years old. There is no sex education in the junior colleges except when students arrange it themselves. Representatives from the Icelandic Association for Sexual and Reproductive Health have been asked to go to several schools to give sex education. Also lacking are regular training courses about sex education for teachers and school health nurses. The last time such a training course was offered was in 1992.

A regulation about health promotion in schools from 1958 is probably one of the oldest legal documents that deal with sex education. In addition, sex education is based on 1975 laws about information and counseling regarding sexuality and responsible parenthood, abortion, and sterilization, 1976 laws about gender equality, and 1978 laws about sexually transmitted diseases. A 1975 law stated: "Educational authorities should in cooperation with the chief school health physician give information about sexuality and moral issues regarding sexuality in the compulsory school system. Additionally information should be given in other educational programs."

In Thorvardarson's 1978 study, 6.4% of boys and 13.7% of girls in the 6th grade said that they received good enough sex education. In the 8th grade, the percentages were 2.9% for boys and 3.7% for girls. In the same study, 79% of the 6th graders and 96% of the 8th graders wanted the school to provide sex education. A nationwide study of sex education, based on a sample of 60 teachers in 60 schools, showed that the mean hours of sex education for the 9th grade was 19.7 hours, and for the 10th grade, it was 15.6 hours (Palsdottir & Hardardottir 1993). In this same study, participants were asked how they taught each issue. More teachers reported that they taught the contraceptive methods (condom, pill, diaphragm, IUD, etc.) well, than reported that they taught the STDs (gonorrhea, chlamydia, herpes, etc.) well (91% to 84% for contraception versus 62% to 81% for STDs). Eighty-eight percent thought they taught about puberty and human reproduction very well, and 81.8% felt they did well teaching respect for the decisions of others (Palsdottir & Hardardottir 1993).

Although the 1993 study showed that there were several issues considered by the teachers to be taught well, the survey results can give us only limited information about the actual sexual education on these topics. The study had a response rate of 60%, and it is a question whether the 40% who did not answer did not respond because they were not motivated to teach the subject or because of some other reasons. These study results do not agree with the results of three interviews with student focus groups, who frequently stated that they got very limited sex education in grades 8 through 10 (Johannsdottir 2000).

What needs to be done in the future is to have sex education as a compulsory subject in the school system, to have training courses on a regular basis, and to develop a curriculum for junior college (age groups 16 to 20).

## B. Informal Sources of Sexual Knowledge

People have had access to sexual information from books, magazines, films, and the media. There has been a considerable increase in the publication of educational ma-

terial about sexual and reproductive health from the Director of Public Health, from the Icelandic Association for Sexual and Reproductive Health, and from the Icelandic Incest Center (Stigamot). In 1990, Ottar Gudmundsson wrote *Íslenska Kynlífsbókin* (*The Icelandic Sexuality Book*), the first comprehensive Icelandic book about sexuality. Before that time, the books that were available were translated from other languages and cultures. Over the last few years, especially after AIDS got into the picture, sexuality has been discussed more openly on television and on the radio.

## 4. Autoerotic Behaviors and Patterns

SÓLEY S. BENDER

There are many negative terms in the Icelandic language for masturbation, starting with *self-pollution* (*sjálfsflekkun*). In *Sexuality* by Fritz Kahn, which was translated and published in Iceland in 1948, masturbation was explained in a detailed manner for both genders. It was stressed that masturbation was not bad for the health and that this behavior was not related to diseases. Kahn mentioned that Simon André Tissot, who published a treatise on the vice of "onanism" in 1760, had a considerable negative influence on attitudes toward masturbation. Tissot described the terrible effects of masturbation, ranging from nervousness to insanity.

There is no Icelandic study that provides any information about masturbation. Today, it is stressed that masturbation is a good way to get to know oneself. It is considered important to know one's own body sensations before sharing it with someone else.

## 5. Interpersonal Heterosexual Behaviors

SÓLEY S. BENDER

### A. Children

No Icelandic studies have been done about the sexual explorations of young children.

### B. Adolescents

A 1977 study by Sigurgestsson showed that among 14-year-olds, 23.2% of the boys and 21.2% of the girls said they had had sexual intercourse. This was considerably higher than in countries like Denmark, and the difference between genders was less in Iceland compared to other countries like Norway. A 1990 study showed results similar to those reported by Sigurgestsson: 25.6% of 14-year-old boys and 22.5% of the girls said they had had sexual intercourse (Axelsdottir et al. 1990).

A study by Jonsdottir (1994) showed that the mean age at first sexual intercourse was higher among the older age group than the younger, suggesting that the age of first sexual intercourse has been going down. For 50- to 60-year-olds, the mean age at first sexual intercourse was 17.6 for males and 18.6 for females. For 16- to 19-year-olds, the mean age at first sexual intercourse was 15.1 for males and 15.4 for females. Among the 50- to 60-year-olds, 4.1% had never had sexual intercourse, 48.7% were 16 or younger when they had their first sexual intercourse, and 47.2% were 17 or older. Among the 16- to 19-year-olds, 25% had never had sexual intercourse, 64.3% were 16 or younger when they had their first sexual intercourse, and 10.7% were 17 or older. This is a considerable difference for the age group 50 to 60, where 3.3% had never had sexual intercourse, 32.9% had sexual intercourse at age 16 or younger, and 65.8% were 17 or older.

A 1996 study showed that the mean age of sexual conduct was 15.4 years for both genders. The main author of this chapter conducted this national study based on a random sample of 1,703 people in the age group 17 to 20 years

old (Bender 1999a). Table 1 shows the age distribution for first sexual intercourse.

### C. Adults

#### Marital Data

Between 1961 and 1965, the rate of marriage per 1,000 population was 7.9; in 1995, this was 4.6 (Hagstofa Íslands 1997). In 1998, 34.5% were married or cohabiting, 56% were not married, and 9.3% had been previously married and divorced (Hagstofa Íslands 1999b). The divorce rate has been increasing, doubling from 0.9 in 1961 to 1.8 in 1995 (Hagstofa Íslands 1997). The mean age of people who get married has also been going up. In 1961 to 1965, the mean age was 24.4 for brides and 27.4 for bridegrooms. Thirty years later, it was 29.9 for brides and 32.4 for bridegrooms. The attitudes of people to having a child out of wedlock are quite relaxed. A Gallup study (1997) showed that 95% did not think this was wrong.

#### Heterosexual Behaviors

A study conducted in 1992 by Jonsdottir and Haraldsdottir (1998) about sexual behavior and knowledge of AIDS showed that the average number of sexual partners is nine over the life span. Men have more sexual partners than women (12 versus 6). There is an identical ratio of men compared to women who have had anal sex (16.2% and 16.3%). The majority of men, 62.7% of those between ages 16 and 60, had experience with cunnilingus.

Those who have had two or more sexually transmitted diseases have had much higher numbers of sexual partners (26.4%) than those who were infected by one STD (11.9%) or none (6.2%). Casual sex is most frequent among those who are 16 to 25 years old.

This same study asked if participants had or knew about someone close to them who had had an affair while married or cohabiting. The results showed that 71.8% answered yes to this question (Jonsdottir & Haraldsdottir 1998). This may not be very reliable or accurate information, but it is the only available information about extramarital affairs.

## 6. Homoerotic, Homosexual, and Bisexual Behaviors

THORVALDUR KRISTINSSON

As of late 2000, no study provided reliable information about the frequency of homosexuality in Iceland. A study conducted in 1992 came closest to this by asking the participants about the sex of their partners. This national study of sexual behavior and knowledge about HIV had a sample of 971 people 16 to 60 years old. The response rate was 65%,

with 53% of the respondents being women and 47% men. The percentage of people who reported having had sex with a person of the same sex ranged from zero to 1.8% for different age groups, with an overall average of 0.7%. In the age group 16 to 19, 1.8% reported a same-sex partner. Among 30- to 34-year-old respondents, only 0.6% reported a same-sex partner. Of those who had had homosexual experience, 0.3% were married, 2.2% single, and 5.6% divorced (Jonsdottir 1994; Jonsdottir & Haraldsdottir 1998).

Until the 1970s, lesbians and gay men were practically invisible in Icelandic society, which surrounded them with contempt and a massive silence. Their reaction was either to hide their sexual orientation completely, finding an occasional escape from the oppression while touring abroad, or to move to the metropolitan cities of continental Europe and North America. Many of those people never returned, being later referred to as sexual political refugees. The silence was first broken in 1975 when the first gay Icelandic man, influenced by the international liberation movement, revealed his sexual identity publicly in the media. Three years later, Samtökin 78, the organization of lesbians and gay men in Iceland, was founded by some 20 people. After 20 years, it has become the most powerful force in the gay liberation movement of Iceland with a little less than 400 members. Typical of the prejudice and hostility that met this small group on its way to visibility in its early years, was the case of a discotheque in Reykjavik, which in 1983 advertised in newspapers: "Everyone is welcome—except gays and lesbians." Another example from the same year took place in the Nursing School of Iceland, which forbade its students from meeting with the educational group of Samtökin 78, a meeting which the students themselves had organized after a gay student found himself forced to leave the school because of group harassment and hazing.

Nevertheless, the few who had the courage to speak up for homosexuals saw remarkable progress in the 1980s. They rejected, for instance, the commonly used derogatory Icelandic terms, such as *kynvilla* (sexual aberration) for homosexuality, a term analogous to the older word *truvilla* (religious aberration) for heresy. For a decade, they fought with the Icelandic State Radio against being labeled in such a derogatory manner, and suggested their own popular words, *lesbia* and *hommi* for themselves, and *samkynhneig*, a compound of same-sex and orientation, for homosexuality. Finally, they won.

Since then, gay activism in Iceland has been characterized by educational and legislative work with positive results. Several other gay associations have recently appeared, including an association of gay, lesbian, and bisexual students at the University of Iceland, and an association of gay junior college students (Stonewall), both founded in 1999. In 1983, a new political party, the Socialdemocratic Alliance, was the first one to place gay human rights on its agenda, and two years later, a recommendation was presented in the Parliament by four political parties demanding action to abolish discrimination against lesbians and gay men. It never passed, and it was not until 1992 that a similar recommendation passed Parliament, after the original recommendation had been reworked by five political parties. As a result of the research work ordered by this recommendation, a law on registered partnerships for same-sex couples passed the Parliament in 1996, although it denied same-sex couples any right to adopt children or to seek insemination in an official clinic. With this law, Iceland became the first country in the world to legalize common custody of children brought into a same-sex partnership from previous marriages. At the same time, the Protestant Lutheran state church did not approve of a formal church wedding, causing friction and open fights with the church authorities, which are still unresolved. In the year

**Table 1**

**Age at First Sexual Intercourse**

Age	Percent	Cumulative Percent
12 or younger	1.2	1.2
13	6.4	7.6
14	17.9	25.5
15	27.2	52.7
16	24.8	77.5
17	15.5	93.0
18	5.7	98.7
19	1.2	99.9
20	0.1	100

(Source: Bender 1999b)

2000, the Parliament passed a new law on registered partnerships giving same-sex couples the right to adopt stepchildren who are brought into the partnership. An antidiscrimination law passed the Parliament in 1996. It is worth noting that the parliamentary opposition in the debate preceding these legislative improvements was minimal, compared to the parliamentary opposition in other Nordic countries. To find an example of organized opposition, one has to go to the very small Christian fundamentalist congregations functioning outside the state church of Iceland.

Opinion polls nowadays show a surprising change of values in the society, and they express, in fact, more respect and tolerance towards gay men and lesbians than in other Western societies. When asked by an international opinion survey in 1990 about to what extent certain acts were justifiable on a one-to-ten scale, Icelanders expressed more tolerance than people in other nations regarding homosexuality, showing an average of 5.5. Other nations placed around 4.7 on the average, with the United States at a low 3.0. An international opinion survey of the same kind from 1984 gave the Icelanders an average rate of 3.3. This positive change is generally confirmed by what lesbians and gay men experience in their everyday life (Olafsson 1991). In a surprisingly short period of time, Icelandic society has left its homophobic attitude of the past and opened up for new visions and ideas.

### 7. Gender Diversity and Transgender Issues

SÓLEY S. BENDER

There is no study that provides information about Icelandic persons with gender conflicts or confusion. Given the clinical experience and incidence figures for gender-conflicted persons in nearby culturally similar countries, it seems reasonable to assume that a few hundred or more of the 280,000 modern Icelanders experience various forms of transsexualism, transvestism, hermaphroditism, pseudohermaphroditism, and intersexualism. Given the presence of support groups for gender-conflicted persons on the Internet and World Wide Web, one can reasonably assume that some gender-conflicted Icelanders may find local counselors and psychologists sensitive to their needs and explore possible medical help on the island and abroad.

### 8. Significant Unconventional Sexual Behaviors

SÓLEY S. BENDER and GUDRÚN JÓNSDÓTTIR

#### A. Coercive Sex

##### *Sexual Harassment*

No prevalence studies have been done regarding the frequency of sexual harassment, but the Icelandic Office for Gender Equality has made some small surveys in a limited number of workplaces. They show that between 12% and 16% of the female workers have been subjected to sexual harassment in their workplace. In the last few years, employees have been better informed than before about their rights if they are victims of sexual harassment. However, many myths still exist regarding this issue.

##### *Sexual Abuse and Incest*

No prevalence studies have been conducted regarding sexual abuse and incest in Iceland. Even so, it was clear to a group of women who had been working as volunteers in different services for women that incest and sexual abuse of women and children is not unknown in Iceland. In 1986, these women formed a group whose purpose was to develop services for survivors of sexual violence. The group was named the Working Group Against Incest. In 1987, when an

office was opened half a day, the demand for the service increased steadily. The Stigamot (The Icelandic Incest Center), which opened in 1990, is the product of this movement. Stigamot is an information and counseling center for women and children who have experienced sexual violation. In its first decade, Stigamot helped a total of 2,811 persons, with 213 new individuals seeking help in 1999. The two main reasons women and children have come to Stigamot are incest (about 60%) and rape (about 30%). Those who use the service are mainly 19 to 49 years old (80.2%); the majority have limited education (Jonsdottir & Sigurdardottir 2000).

The Government Agency for Child Protection does coordinate and strengthen child protection in Iceland. In 1997, this agency recommended to the Minister of Social Affairs that a special Children's House (Center for Child Sexual Abuse) should be developed to coordinate the work of child protection authorities, social service, police, the state prosecution, doctors, and others when investigating sexual abuse, to improve the quality of the service for children, and to protect the child from having to go through many traumatic forensic interviews and possibly relieve the difficult experience. In November 1998, this Children's House started as a two-year experimental project. In 1998, there were 21 children referred to this center and in 1999, there were 119. In 1999, laws were passed about new procedures for court cases, which gives the responsibility of the forensic interview to the judge (Gudbrandsson 1999). The experience has been that not more than 10% of cases go to court. The center also offers treatment services. On average, each child has about 14 interviews during the treatment process. This center serves the whole country. In late 2000, the future of the center was uncertain.

The criminal law about incest (1940) states that a parent who has sexual intercourse, vaginally or by other means with his child, shall get up to six to ten years in prison. Conviction for other types of sexual harassment by a parent towards a child can bring a prison sentence of up to two years and four years if the child is younger than 16 years old. Whoever has sex with a child younger than 14 years old can get imprisonment up to 12 years. Other types of sexual harassment and assault can lead to imprisonment up to four years.

In 1998, 58 legal charges of sexual abuse were brought in all of Iceland (Ministry of Law and Justice, personal communication, 4 July, 2000). Since 1981, the number of prison sentences stemming from sexual crimes has been rising. Between 1981 and 1985, there were 11 prison sentences and in 1998, there were 28. The mean number between 1985 and 1998 was 19.1 annually (Hagstofa Íslands 1999b).

##### *Rape*

In 1984, a group of women formed a group of counselors for survivors of rape. In the City Hospital in Reykjavik, a rape trauma center was established in 1993. As of mid-2000, 640 individuals had been attended to by the service. Seven were mentally retarded. In 1999, 103 individuals, 97 women and 6 men, used the service (Arsskrysla Sjúkrahuss Reykjavíkur 2000). The majority of clients are females, but annually three to four men seek help. The clients range in age from 12 to 78 years, with 65% to 70% 25 years old or younger. The service is free of charge (Jonsdottir 2000). Rape is punishable under a 1940 law with imprisonment of between one and 16 years.

#### B. Prostitution

Prostitution has probably been organized in Reykjavik, but valid information is hard to obtain. In recent years, several nightclubs offering nude dancing have opened both in Reykjavik and other cities. The women there have mostly

come from abroad, particularly from Eastern European countries, to work as "dancers." This is probably hidden prostitution.

Sexual telephone service has become more and more obvious and is advertised in one of the main newspapers. This service was temporarily advertised with porno pictures. This was recently changed and now there is only text in the advertisements. These advertisements for sexual telephone services are also probably hidden prostitution services.

The 1992 study of sexual behavior and knowledge of AIDS showed that there were 71 individuals who had had sexual experience with a prostitute. Most of them were men and two were women. The majority were in the age group 25 to 39. The greater majority, 91%, had this sexual experience abroad (Jonsdottir & Haraldsdottir 1998). A person convicted of making a living by being a prostitute can get a prison sentence of two years. A person who gains a living from organizing the prostitution of others can get four years imprisonment. A person who encourages someone who is younger than 18 years old to work as a prostitute can get up to a four-year sentence in prison.

#### D. Pornography and Erotica

Pornography and opposition to it have existed in Iceland for centuries (Gudmundsson 1990). In the 20th century, there has been some control over pornography in books and movies. Today, there seems to be very limited control. Books, magazines, movies, and videos showing pornography are easily available.

According to the 1940 criminal law, it is illegal to make, import, sell, and/or distribute pornographic material. It is also criminal to give pornographic material to a person younger than 18 years old. It is also not allowed to store pornographic material of children. These offenses can lead to a fine and/or up to six months in prison.

### 9. Contraception, Abortion, and Population Planning

SÓLEY S. BENDER

#### A. Contraception

Contraception is available through Iceland's community health centers, gynecologists, and some hospitals. Around 1994, the only specialized family planning clinic, which served mostly young people, closed. In 1995, the Icelandic Association for Sexual and Reproductive Health started an information and counseling service for young people on sexuality, STDs, and contraceptives. As with the early clinic, mostly young women have used this service.

Few studies have been conducted about the use of contraceptives of women in their reproductive years. In the 1977 Sigurðsson study, young people 14 years old gave information about their use of contraceptive methods at their first sexual intercourse. Overall, 40.6% of the respondents, 43.7% of the boys and 36.7% of the girls, said they had used contraception for their first full sexual intercourse. A 1990 study showed that the most frequent reasons for not using contraception were: not having thought about it, 61.7%; not daring to go to the community health center, 61.1%; being too shy to discuss this with their partner, 51%; and believing coitus interruptus was sufficient contraceptive protection, 49.2% (Axelsdottir et al. 1990). A 1996 study of 1,703 individuals ages 17 to 20 showed that 59% used contraception at first coitus. The methods most used were the contraceptive pill, 7.6%; condom, 61.7%; diaphragm, 0.58%; and other, 1.0%. After first coitus, the pill, the condom, and coitus interruptus were in that order the most frequently used methods (Bender 1999). There are no national studies of contraceptive use among the over-20 population.

Some data from the Cancer Society have been analyzed. This data shows that the most frequently used contraceptive method for younger women is the contraceptive pill and for older women the intrauterine device. In the 20-to-44 age group, 35% of contracepting Icelanders used the IUD and 18% the contraceptive pill (Geirsson & Gudmundsson 1988, 1987). In 1997, sterilization was used as a permanent method by 640 (83%) of contracepting women and by 130 (17%) of contracepting men. In 1983, this gender ratio was 95% for contracepting women and 5% for men.

A 1988 survey exploring information and counseling about sexual and reproductive health in Icelandic community health centers showed that the more-common subjects for counseling and information were: contraceptive methods, 84.4%; menopause, 72.8%; STDs, 72%; pregnancy tests, 67.1%; and premenstrual syndrome (PMS), 65%. Less frequently provided information dealt with: abortion, 23.4%; sexual problems, 29.8%; and sexual health, 30.2%. Most of these services were provided by family practitioners (Bender 1990).

The present legislation about contraception, abortion, and sterilization took effect in 1975. This 25-year-old law suggests that people should get subsidized contraceptive methods, but this has not been acted on.

#### B. Teenage (Unmarried) Pregnancies

The incidence of teenage pregnancies is considerably higher in Iceland than it is in other Nordic countries. Table 2 compares the rate of teenage pregnancies in these countries. Table 3 compares the birthrates. Although the birthrate among young women in Iceland has been dropping significantly, from 73.7 per 1,000 in 1970 to 24.9 in 1998, it is still much higher than in the other Nordic countries.

The percentage of live births by mothers under age 20 as a percentage of all live births in Iceland declined from 15.3% in 1977 to 6.3% in 1998 (Hagstofa Íslands 1999b). Table 4 shows comparable Scandinavian percentages for 1998.

A recent study showed that the birthrate among young women in Iceland is considerably less in the capital area compared to other places in Iceland, but the abortion rate is

**Table 2**

**The Rate of Teenage Pregnancies per 1,000 Pregnancies in 1997**

Country	Rate per 1,000
Iceland	46.2 (1997)
Norway	31.7 (1997)
Sweden	25 (1997)
Finland	19.2 (1997)
Denmark	23.5 (1996)

(Source: NOMESCO 1999)

**Table 3**

**The Birthrate among Young Women per 1,000 Pregnancies in 1998**

Country	Rate per 1,000
Iceland	24.9 (1998)
Norway	12.7 (1997)
Finland	9.0 (1998)
Denmark	8.4 (1998)
Sweden	7.2 (1998)

(Source: NOMESCO 1999)

also higher (Adalsteinsdottir 2000). At the same time, as the birthrate among teenagers (15 to 19 years old) there has been declining, the abortion rate has been rising (5.8 per 1,000 in 1976 and 21.7 in 1997). Now, close to 50% of pregnancies end in abortion and 50% in childbirth. A descriptive study of the health of teenage mothers (15 to 19 years old) during pregnancy and the health of their newborns, compared to older mothers (25 to 29 years old) and their newborns, based on a sample of 50 mothers in each group and 50 newborns of both groups, showed that the mean numbers of prenatal visits were identical in both groups. Teenage mothers attended 11.0 times and the older mothers 12.0 times. The younger mothers did not start to attend the prenatal visits later than the older mothers did. Health problems, such as pre-eclampsia and anemia, were more common in the older age group. There were fewer medical and surgical interventions during the delivery for the younger mothers. The percentage of low birthweight was identical for both groups (6% in each). The younger mothers, on the other hand, smoked more than the older mothers (25.5% versus 18%) and had higher frequency of delivering before the 37th week of gestation (6.3% versus 2.1%). The easy access to and no cost of prenatal service seem to contribute to fewer health risks among young mothers (Lorensdottir et al. 1994).

Young people do encounter some hindrances in obtaining contraceptive methods based on their insecurity, shyness, and the cost of the product. They also consider the health service at the community health centers to be too expensive and difficult to obtain, in contrast with the no-cost and easy availability of prenatal care (Johannsdottir et al. 2000). Young Icelanders want sexual and reproductive health services that are organized according to their needs. They have special needs regarding open hours and are sensitive to the environment and the interactions with the healthcare providers (Bender 1999a). This was further verified in a recent focus group study. This focus group study was based on three interviews of young people 16 to 19 years old, and showed that their special needs were better service hours in the afternoons or evenings, healthcare providers who show respect to young people, and a friendly staff attitude and friendly environment. They want to have music channels on the television in the waiting room, but not educational movies about STDs (Johannsdottir et al. 2000).

Most young mothers are probably single. Often they get good support from their families. A study based on two focus group interviews with young mothers showed that it was their mother who mostly helped them. They sensed the great responsibility of being a mother. Their inexperience, however, was demonstrated in being intolerant to breastfeeding and not knowing what to do when caring for the child. In spite of that, they felt good about being alone with the child, but often sensed insecurity when they were with others. Oftentimes, they felt that adults were interfering with their

childrearing practices. They sensed that they had little time for themselves, had less freedom, and often felt isolated from their friends. All of the participants had some future vision. Most of them wanted to go to school or to finish the school they were attending (Sveinsdottir & Gudmundsdottir 2000). These results show the need of young mothers for support and guidance about childrearing practices.

Based on the high teenage pregnancy rate, more preventive efforts need to be made. Sexuality education needs to be improved, and specialized sexual and reproductive health services for young people need to be developed.

### C. Abortion

The present law legalizing abortion took effect in 1975. Anyone can apply for an abortion for medical or social reasons or following a rape. Abortions can only be done within a hospital setting. According to the legislation, permission is required for the intervention to be performed. The application form needs to be signed either by a social worker and medical doctor or two medical doctors depending on the reason. Women who apply for an abortion report low use of contraceptives. In 1977 to 1980, about 30% of women seeking an abortion had used some type of contraception at the time of conception; in 1981 to 1984, contraceptive use rose to 37% (Oskarsson & Geirsson 1987). Because of the rising number of abortions, a contraceptive counseling service has been developed within the National Hospital for women before and after an abortion.

Abortion is free of charge, but there is small outpatient fee for the laboratory tests and physical examination before the operation. The majority of abortions are done for social reasons. The rate of abortions for all age groups has been rising over the last 24 years and is now identical to those in other Nordic countries; but their abortion rates have been going down over the years (Bender 2000). Between 1976 and 1980, 472 abortions were performed; in 1998, the number was 901. Table 5 shows the abortion rate by age group in 1998. Between 1976 and 1980, the abortion rate for the age group 15 to 19 was 9.4 per 1,000. In 1996, the abortion rate among 15- to 19-year-old Icelandic women was the highest among the Nordic countries.

There has been a group opposed to abortion in Iceland, but it has never been very active.

### D. Population Programs

Iceland is a pronatalistic country, as demonstrated by the positive attitude to having many children. In 1997, a Gallup study showed that about 70% of Icelanders wanted to have three or more children. Eighty-five percent of those surveyed considered it necessary to have a child to feel fulfilled. This pronatalism is also evident in the fact that there are no government-run teenage clinics. Teenage pregnancy is high and seems to be generally accepted. There is a trend of population movement from the rural to the urban areas.

**Table 4**

**Live Births by Mothers Under Age 20  
per 1,000 Live Births in 1998**

Country	Rate per 1,000
Iceland	6.3
Norway	2.7
Finland	2.6
Denmark	1.7
Sweden	1.3

(Source: Haagensen 1999)

**Table 5**

**Abortions in Iceland in 1998**

Age Group	Abortions per 1,000 women
15 to 19 years	24.1
20 to 24	23.2
25 to 29	16.2
30 to 34	11.0
35 to 39	9.1
40 to 44	3.8
45 and older	0.2

In some rural areas, there are recent efforts to increase the local population by using some financial incentives for young people to have children.

The discussion about the need for better contraceptive counseling services for people at reproductive age is new. The Icelandic Family Planning Association (The Icelandic Association for Sexual and Reproductive Health, or IcASRH) was established in 1992. This Association has been giving information to professionals and the public about these issues. One of these issues has been about emergency contraception. IcASRH published a special pamphlet about emergency contraception in 1996 and this has been widely distributed. The 1996 study about the attitude of young people to sexual and reproductive health services showed that only 35% of the 17- to 20-year-old participants knew what emergency contraception was.

In 1991, an infertility program was established at the National Hospital in Reykjavik. Before that time, people had to go abroad to have infertility treatment. The success rate of the Icelandic in-vitro fertilization (IVF) program has been high.

## 10. Sexually Transmitted Diseases and HIV/AIDS

SÓLEY S. BENDER

### A. Sexually Transmitted Diseases

#### *Incidence and Trends*

Iceland's national registration of sexually transmitted diseases does not provide accurate information about the prevalence of those diseases. The most accurate information about the rate of STDs is based on data from the Department of Infectious Diseases at the National Hospital in Reykjavik. Based on their information, there were 9,415 chlamydia cases between 1981 and 1990, about 941 annually. The number of positive tests for chlamydia has been dropping from 26% in 1981 to 11% in 1990 (Steingrímsson et al. 1991). From 1991 to 1997, the incidence of positive tests was 11 to 13%.

*Chlamydia trachomatis* has been the most frequent sexually transmitted disease in Iceland for several years. The number of gonorrhea cases has been dropping over the years, but herpes and condyloma have increased. The 1992 sexual behavior study showed that there were 9.3% who had gotten *Pediculus pubis* (pubic lice), 8.4% chlamydia, 8.0% scabies, 5.6% condyloma, 4.5% gonorrhea, and 2.5% herpes (Jonsdóttir 1994). In the same study, 20% of the participants said they had had one STD, while 6.8% reported two or more infections, with men having a higher frequency at 9.3% compared with 4.7% for women (see Table 6).

#### *Treatment and Prevention Efforts*

There is one STD clinic in Reykjavik offering diagnosis and treatment. People can also visit their family practitioner at community health centers all over Iceland. The diagnosis and treatment is free for the client.

**Table 6**  
Percentage Infected with STD

	All (n = 966)	Men (n = 450)	Women (n = 516)
Never infected	73.1%	70.2%	75.6%
Once infected	20.1	20.4	19.8
Infected by two or more STDs	6.8	9.3	4.7

(Source: Jonsdóttir & Haraldsdóttir 1998)

There are many aspects that need to be considered regarding prevention and risk-reduction efforts regarding STDs in Iceland. The 1992 study showed that about 8% of those surveyed had had casual sex once or more often in the last three months before the study was conducted. Casual sex was most frequent in the age group 16 to 24. About 10% of those who had casual sex were always or most often under the influence of alcohol or drugs during sexual intercourse (Jonsdóttir & Haraldsdóttir 1998).

In the same study, 9% of men 16 to 24 said it was difficult to talk to their partner about the use of condoms; 5% of the women in the same age group shared this difficulty. Fifty-two percent of the men and 44% of women felt that the condom spoiled sexual pleasure. In the 16-to-19 age group, 23.1% of participants who had had casual sex in the last 12 months before the study never used a condom during that time. The average non-use of condoms for all other age groups was 14.9% (Jonsdóttir & Haraldsdóttir 1998).

STD preventive efforts in Iceland have been focused on the importance of increasing knowledge about STDs and influencing attitudes. There are several hindrances that make this preventive work not as effective as it could be. In Icelandic society, as in many other countries, there are not many healthy role models for young people regarding the use of condoms. Most movies show sexual intercourse without anyone mentioning the need for protection against STDs or pregnancy.

### B. HIV/AIDS

#### *Incidence and Trends*

As of January 2000, Iceland had 140 individuals diagnosed with HIV. The annual number of individuals diagnosed with HIV has ranged from zero to a high of 16. Most of those who became infected were homosexuals, but the number of infected heterosexuals is growing. Men have a higher frequency of HIV infection than women, as shown in Table 7. As of the end of 1999, a total of 50 cases of AIDS had been diagnosed and reported to the authorities; 33 Icelanders have died of AIDS.

#### *Treatment, Prevention Programs, and Government Policies*

In 1988, a national AIDS committee was formed by the Ministry of Health. The role of this committee included creation of guidelines regarding prevention of HIV. This committee decided to conduct a study about the sexual behavior of Icelanders and their knowledge about HIV/AIDS (Jonsdóttir 1994; Jonsdóttir & Haraldsdóttir 1998). This study showed that Icelanders were interested in three ways to promote safer sex behaviors in order to reduce the risk of HIV infection: increasing the use of condoms, having fewer

**Table 7**  
Incidence of HIV from 1985 to 1996  
per 100,000 Population

	Total	Women	Men
1985	7.5	1.7	13.2
1990	2.0	—	3.9
1991	3.9	1.6	6.2
1992	4.2	0.8	7.6
1993	1.1	0.8	1.5
1994	3.0	1.5	4.5
1995	1.9	1.5	2.2
1996	1.9	1.5	2.2

(Source: Hagstofa Íslands 1997)

casual sexual partners, and being more careful with the use of alcohol and drugs.

[Update 2002: UNAIDS Epidemiological Assessment: The HIV epidemic remains at a low level in Iceland. By mid 2001, a cumulative total of 148 cases of HIV infection had been reported. Testing is mandatory in blood donations; the first HIV-positive case was detected in 1995. Among 400 persons attending the HIV-testing site in the capital city between 1987 and 1992, 2 (0.5%) were detected positive. Diagnosed HIV cases are reported at the national level.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	220 (rate: 0.2%)
Women ages 15-49:	< 100
Children ages 0-15:	< 100

[An estimated less than 100 adults and children died of AIDS during 2001.

[No estimate is available for the number of Icelandic children who had lost one or both parents to AIDS and were under age 15 at the end of 2001. (End of update by the Editors)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

SÓLEY S. BENDER

### A. Sexual Dysfunctions and Availability of Therapy

Since only very limited studies about sexual dysfunctions have been done in Iceland, very little is known on a national level about the prevalence of these problems. Sexual dysfunctions have been reported postpartum in relation to postpartum depression. Sexual dysfunctions are mostly presented in connection with other problems that people have when they visit their family practitioner. It therefore depends on the sensitivity of the attending physician to discover the oftentimes hidden problem. In general, people seem inhibited about discussing sexuality in general and sexual problems in particular. This reluctance often seems to apply to medical practitioners as well. The 1992 study about sexual behavior showed that 28.2% of the respondents had had some discussion with a family practitioner or a nurse at the community health center, and 16.8% had discussed sexuality with a healthcare professional in a hospital (Jonsdottir 1994). From the healthcare providers' perspective, 29.8% said they often and rather often provide information and counseling in the community health centers about sexual problems (Bender 1990). Psychiatrists, psychologists, social workers, urologists, and gynecologists are the practitioners most likely to be consulted or involved in diagnosing sexual problems. Some people turn to the IcASRH for advice about their sexual problems.

There is no one certified as a sexual therapist by the Ministry of Health or a professional association in Iceland, and no sexual treatment center run by the government of Iceland. In 1975, a treatment center was launched and functioned for about ten years. Information and counseling services about sexuality and its relation to diseases are lacking within the hospital setting. There is no therapist practicing in Iceland who has a master's or doctoral degree in sexology.

## 12. Sex Research and Advanced Professional Education

SÓLEY S. BENDER

### A. Graduate Programs and Sexological Research

No undergraduate or graduate sexology programs are offered at the University of Iceland or in other universities in the country.

Very few Icelandic studies have been done about human sexuality. Before the 1975 abortion law took effect, there had been considerable discussion about the issue, and members of Parliament were stressing the need for preventive work. Following this, Sigurgestsson completed a psychology dissertation in 1977 based on a sample of 1,420 young people and conducted among all 14-year-old students in the Reykjavik area. The response rate was 92%. This study was the first of its kind to explore sexuality among this age group. The focus of this study was on puberty, sexual activity, and sex education. A year later, in 1978, Thorvardarson conducted a study of sex education as part of a Bachelor in Education program. This study was based on a sample of young people in the 6th grade ( $n = 460$ ), 8th grade ( $n = 480$ ), and among 16- to 18-year-olds ( $n = 345$ ).

Following the first cases of HIV/AIDS, the first national study about sexual behavior and knowledge of HIV/AIDS was sponsored in 1992 by the Directorate of Public Health (Jonsdottir 1994; Jonsdottir & Haraldsdottir 1998). The purpose of this study was to get information for the direction of preventive strategies regarding HIV and AIDS. This study was a cross-sectional postal survey based on a national sample of 971 individuals in the age group 16 to 59. As noted in Section 6, Homoerotic, Homosexual, and Bisexual Behaviors, the response rate was 65%; 47% of those responding were males and 53% females.

Another national cross-sectional study was done in 1996 based on a stratified random sample of 2,500 young people 17 to 20 years old, 20% being teenage boys and 80% being teenage girls. The crude response rate was 68%. This study explored the attitudes of young people to sexual and reproductive health services, sexuality and the use of contraceptives, and the use of contraceptive services (Bender 1999).

### B. Sexological Organization and Publications

The Icelandic Sexology Association was established in 1985 and was active for the first ten years. Its goal was to promote sexology and the cooperation of people working as teachers, therapists, and researchers in the field of sexology. It was a member of the Nordic Association for Clinical Sexology (*Nordisk Forening for Klinisk Sexologi, NACS*).

The Icelandic Family Planning Association (The Icelandic Association for Sexual and Reproductive Health, IcASRH) was established in 1992. The Association has been focusing on teenage sexuality and the special needs of young people. It has published several pamphlets, postcards, and a semiannual newsletter. It is a member of International Planned Parenthood Federation (IPPF) and belongs to the European Network of IPPF. The address of the Association is: P.O. Box 7226, 127 Reykjavik, Iceland; email: fkb@mmedia.is; www.mmedia.is/fkb.

Stigamot (The Icelandic Incest Center), discussed in Section 8A under Sexual Abuse and Incest, has a website at www.stigamot.is.

There is no Icelandic sexological journal or periodical published exclusively about sexology. There have been some articles published in the Icelandic medical and nursing journals about sexuality. The Icelandic Sexology Association published a few issues of a newsletter, and the Icelandic Association for Sexual and Reproductive Health currently publishes a newsletter two times a year.

## Demographics and a Brief Historical Perspective

ROBERT T. FRANCOEUR

### A. Demographics

India, with an area of 1.27 million square miles (3.29 million km<sup>2</sup>), is the largest democratic country in the world. India is one-third the size of the United States and occupies most of the Indian subcontinent in south Asia. In southern Asia, India's southern neighbor is the island nation of Sri Lanka. India borders on the Arabian Sea and Pakistan in the west and the Bay of Bengal, Bangladesh, and Myanmar in the east. China, Bhutan, and Nepal are on India's northern border.

The terrain is upland plains, the Deccan Plateau, in the south, flat to rolling plains along the Ganges River, deserts in the west, and the Himalayan Mountains in the north. Below the Indo-Ganges plain, which extends from the Bay of Bengal on the east to the Afghan frontier and Arabian Sea on the west, the land is fertile and one of the most densely populated regions of the world. The three great rivers, the Ganges, Indus, and Brahmaputra, have their origins in the Himalayas. With one quarter of the land forested, the climate varies from tropical monsoon in the south to near-Arctic in the north. The Rajasthan Desert is in the northwest; in the northeast, the Assam Hills receive 400 inches (1,000+ cm) of rain a year.

In July 2002, India had an estimated population of 1.045 billion people, giving it about 16% of the world's total population living on 2.4% of the earth's land area. Next to China, India is the most populous country in the world. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 32.7% with 1.06 male(s) per female (sex ratio); 15-64 years: 62.6%

(CIA 2002)

with 1.07 male(s) per female; 65 years and over: 4.7% with 1.03 male(s) per female; Total population sex ratio: 1.07 male(s) to 1 female

**Life Expectancy at Birth:** Total Population: 63.23 years; male: 62.55 years; female: 63.93 years

**Urban/Rural Distribution:** 28% to 72%. In 1991, one third of the 12.6 million inhabitants of Bombay were homeless, living on the streets or in squatters' camps built on putrid landfills. Bombay, India's most populous city, has 100,000 people per square kilometer (0.39 mi<sup>2</sup>).

**Ethnic Distribution:** Indo-Aryan: 72%; Dravidian: 25%; Mongoloid and other: 3% (2000 est.)

**Religious Distribution:** Hindu: 81.3%; Muslim: 12%; Christian: 2.3%; Sikh: 1.9%; other groups, including Buddhist, Jain, and Parsi: 2.5%

**Birth Rate:** 23.79 births per 1,000 population

**Death Rate:** 8.62 per 1,000 population

**Infant Mortality Rate:** 63.19 deaths per 1,000 live births

**Net Migration Rate:** -0.07 migrant(s) per 1,000 population

**Total Fertility Rate:** 2.98 children born per woman

**Population Growth Rate:** 1.51%

**HIV/AIDS** (1999 est.): Adult prevalence: 0.7%; Persons living with HIV/AIDS: 3.7 million; Deaths: 310,000. (For additional details from www.UNAIDS.org, see end of Section 10B.)

**Literacy Rate** (defined as those age 15 and over who can read and write): 52% (1995 est.) with schooling compulsory to age 14. The literacy rate is significantly lower for females than for males, 37.7% versus 65.5%.

**Per Capita Gross Domestic Product** (purchasing power parity): \$2,500 (2000 est.); Inflation: 3.5% (2000 est.); Unemployment: 4.4% (1999 est.); Living below the poverty line: 25%; more than a third of the population cannot afford an adequate diet.

### B. A Brief Historical Perspective

Modern India is one of the oldest civilizations in the world. Excavations in the Indus valley trace civilization there back for at least 5,000 years. India's cultural history includes prehistoric mountain cave paintings in Ajanta, the exquisite beauty of the Taj Mahal in Agra, the rare sensitivity and warm emotions of the erotic Hindu temple sculp-

\*Communications: Jayaji Krishna Nath, M.D., National Institute for Research in Sex Education Counseling and Therapy (NIRSECT), 'SAIPRASAD' C5/11/0.2 Sector-4 (C.B.D.) Vivekanand Nagar, New Bombay 400615 India. Karen Pechilis-Prentiss, Ph.D., Drew University, Department of Religion, Madison, NJ 07940 USA; kpechili@drew.edu.

tures of the 9th-century Chandella rulers, and the Kutab Minar in Delhi.

Around 1500 B.C.E., Sanskrit-speaking Aryan tribes invaded the Indus valley from the northwest and blended with the earlier inhabitants to create the classical Indian civilization. Asoka ruled most of the Indian subcontinent in the 3rd century B.C.E. and established Buddhism; but, Hinduism experienced a revival and became the dominant religious tradition. The Gupta kingdom, in the 4th to 6th centuries of the Common Era, enjoyed a golden age of science, literature, and the arts. In the 8th century, Arab invaders brought the Muslim faith to the west, and Turkish Muslims gained control of north India by 1200. Vasco da Gama established Portuguese trading posts in 1503, and the Dutch followed soon after. Between 1526 and 1857, India was ruled by the Mongul emperors. In 1609, the British East India Company sought concessions for spices and textiles from the Mongul emperor, and subsequently gained control of most of India. The British curbed the rule of the *rajahs* around 1830 and supported the native rulers in the mutiny of the Sepoy troops in 1857-1858.

After World War II, the Indian National Congress joined with the Muslim League. Mohandas K. Gandhi, who had launched opposition to the British in 1930, emerged as the leader of the independence movement. In 1935, the British partitioned British India, giving India its own constitution and bicameral federal congress and establishing India as a self-governing member of the British Commonwealth. The partition created an independent Pakistan, triggering a mass migration of more than 12 million Hindu and Muslim refugees that was often violent and set the stage for a war in 1971-1973. This time, the massive migration involved some ten million refugees. Kashmir, a predominately Muslim region in the northwest, which has been in dispute with Pakistan and India since 1947, was divided in 1949, with Pakistan incorporating one third of Kashmir and India two thirds. India's new territory became the states of Jammu and Kashmir with internal autonomy. In 1952-1954, France peacefully yielded to India the five colonies of former French India, Pondicherry, Karikal, Mahe, Yanaon, and Chandernagor.

Ethnic violence accompanied several Sikh uprisings in the 1980s—the former British protectorate of Sikkim had become a protectorate of India in 1950 and was absorbed into India in 1974. Violence also broke out in the Pungab in 1988 and Assam in 1993. Also in 1993, the largest wave of criminal violence in Indian history jolted Bombay and Calcutta with devastating bombings.

## 1. Basic Sexological Premises

### A. Gender Roles

The family in Indian society provides for the satisfaction of the fundamental biopsychic drives of hunger and sex, and makes it possible to perpetuate the species through reproduction and the social heritage through the handing down of traditions from generation to generation. The function of preserving language, customs, and traditions is normally performed in collaboration with other social groups. Husband and wife, though, contribute to the maintenance of the family. There is a clear division of labor based on sex. The sex roles of a person consist of the behavior that is socially defined and expected of that person because of his or her role as a male or female. Rigid, mutually exclusive, conceptualizations of appropriate abilities or activities, tasks, characteristics, and attitudes are assigned differently to men and women in all Indian cultures. Because of rapid social and technological changes, it is observed that in the recent period, traditional gender-role differentiation is breaking down, espe-

cially in the fields of education and work. The historical analysis of the status of women shows that in Vedic India, as revealed by its literature, women were treated with grace and consideration. However, in the post-Vedic age, there was a slow but steady decline of their importance in the home and society. A decline, indeed a distinct degeneration in their status, is visible in medieval India. The *pardah* system of female seclusion, the *sati* tradition of immolating the widow on the husband's pyre (Weinberger-Thomas 1999), the dowry, and child marriages were obvious in the preindependence period. Following independence from England, however, there was a distinct, if uneven, and gradual liberal change in the attitude toward and status of women.

[In India's] male-dominated tradition, and everywhere in Vedic, classical, medieval, and modern Hinduism, the paradigms in myths, rituals, doctrines, and symbols are masculine. But just as goddess traditions encroached successfully on the territory of masculine deities, so too has the impact of women's religious activity, the ritual life in particular, been of increasing significance in the overall scale of Hindu tradition. To put this another way, in traditional life the unlettered folk have always shaped Hinduism, and half of them have been women. It is not feminine roles in Hinduism that have been lacking but rather the acknowledgment of such in literature, the arts, and institutions such as the priesthood and temple and monastic administrations. Only now, in a world rapidly changing because of education opportunities, are such institutions and media beginning to reflect accurately the total picture of Hindu class, caste, gender, and regional life. (Knipe 1991, 10-11)

The urban/suburban environment has given birth to a fascinating mix of traditional and new male/female roles and role models among the affluent middle class. Bombay films are much more influential in creating new role models than the Hollywood films were in their early days in the United States. While the United States had one example of a film star succeeding in presidential politics, India has seen many famous film stars, both male and female, achieve political prominence. In 1966, Indira Gandhi became prime minister of India, at a time when few Western nations would have accepted a woman head of state. And yet, India remains a very male-dominated society.

Despite new currents, very often in Indian culture a woman's body is not seen as an object of pride or pleasure, but as something that is made impure every day, an abode of sinfulness. Thus, a muted yet extremely powerful theme can be found in Hindu marriages: "the cultural unease, indeed, the fear of woman as woman." Women, as reflected in popular novels and clinical practice, frequently view their sexuality as a capacity to redress a lopsided distribution of power between the sexes (Kakar 1989, 13). The age-old, yet still persisting, cultural splitting of the wife into a mother and a whore, which underlies the husband-wife relationship and which explains the often-contradictory Hindu views of the woman, is hardly unique to Indian culture, though it may be more pervasive here than in other cultures (Kakar 1989, 17).

The social context determines whether the woman is viewed as divine, good, or bad—as partner in ritual, as mother, or as whore. In the context of ritual, women are honored and respected. In her maternal aspect, actual or potential, woman is again a person deserving all reverence. "It is only just as a woman, as a female sexual being, that the patriarchal culture's horror and scorn are heaped upon the hapless wife" (Kakar 1989, 17).

[Update 2001: In the complex of conservative and patriarchal Indian society, contemporary roles for and attitudes

toward women are informed by traditional images of women from each of India's many religions. Across all of these traditions, women are expected to marry, to bear children, especially sons, and to be devoted to their husbands. This image of women's role and duty remains a tenacious traditional ideal in Indian society. What many people may not be aware of, especially in the West where journalistic reports detail the problems of Indian women seemingly without ever presenting the efforts to find solutions, is that contemporaneous with this traditional ideal are ongoing public discussions and activist mobilizations in contemporary Indian society on the issue of women's rights. Women's rights, especially women's equality, is an ideal espoused among educated middle-class Indians and the politicians they elect, but it is also growing in influence, especially at the grassroots level. In this discourse, the sexual oppression of women is openly discussed and opposed. What remains largely implicit in this discourse is the pleasurable side of women's sexuality: that women not only have the right not to be abused sexually, but that they have the right to enjoy themselves sexually. This reticence is certainly related to the slowly changing traditional attitude that sexual fulfillment is not a proper subject for public discussion or experience (for women). This aspect of sexuality may yet find a place in the ongoing organized attempts to change ingrained patterns of defining and relating to women. Many of these attempts cut across boundaries of religion and regional tradition. (End of update by K. Pechilis-Prentiss)]

#### [Contemporary Use of Traditional Female Images

[Update 2002: From the cries of "Mother India" during Independence to the comparisons of Prime Minister Indira Gandhi and the contemporary policewoman, Kiran Bedi, to the Hindu Goddess Durga, classical feminine images have had a prominent place in contemporary expressions of national aspirations and role models (Robinson 1999). In a recent article, scholar Lina Gupta has deconstructed the patriarchal image of the Hindu Goddess Kali, in order to assert that Kali is actually an emblem of women's intellectual, emotional, and sexual power: "The dark goddess is perpetually present in the inner and outer struggles faced by women at all times. Her darkness represents those rejected and suppressed parts of female creativity, energy and power that have not been given a chance to be actualized" (Gupta 1991, 37). With respect to its long and distinguished cultural history, as well as its contemporary multiculturalism, Indian society today actively engages tradition with modernity. (End of update by K. Pechilis-Prentiss)]

### B. Sociological Status of Males and Females

While it is mostly the husbands who are breadwinners, the women generally take care of the household activities, besides bearing and rearing children. However, because of widespread educational programs and improvement of educational facilities for girls, women nowadays are accepting jobs outside the home, and thus contributing financially to the family budget. Also, because of constant efforts in making women aware of their rights and the importance of their involvement in day-to-day family matters, the status of women has increased significantly. Because of all these measures, women nowadays actively participate not only in their family affairs, but also in social and political activities in the communities.

The occupations that were earlier monopolized by men are gradually being shared by women. Similarly, various professional courses, like engineering, architecture, and allied disciplines, are also studied by women. In spite of these changes initiated for the benefit of women in India, the people's attitude to equal status for women has not changed sig-

nificantly in actual practice, and in this regard, various educational programs for men are still in great need of changing their outlook. For instance, although the legal age of marriage for girls is set by the government at 18 years, people, especially in rural and tribal India, encourage early marriage for girls, mostly within a short time of their attaining puberty. Similarly, in the educational development, the dropout rate among females is very high.

### C. General Concepts of Sexuality and Love

Adult marriage is generally the rule in India. Usually, it is expected that a husband must be in a position to earn a living and his wife must be able to run the home, which they set up after marriage. The influence of the Hindu religion has resulted in some prepuberty marriages. The vast majority of irregular marriages are still parent-made, arranged marriages. Irregular marriages do occur with the increasing influence of Western concepts of romantic love in the mass media of magazines and movies. In one form of irregular marriage, the two lovers run away and stay away until they are accepted by their families, which is done as a matter of course. In a second form, known as "intrusion," a girl confronts her chosen husband and his parents and presses their acceptance of her by living in the house. A third form involves "forcible application of vermilion," when a young man takes the opportunity at some fair or festival to place a vermilion scarf on his chosen girl's head. Sometimes, a betrothal ceremony takes place before the marriage proper is solemnized. Legally, marriage takes place only between those who have passed the puberty stage. At the marriage ceremony, the local priest is required to officiate and prayers and offerings are made to the gods.

Because of modernization and the influence of Western culture, arranged marriages are becoming less popular and common, especially in metropolitan cities. In its place, marriages based on the couple's choice, often crossing caste and/or religious boundaries, are becoming more common.

While sexual urges had to be subordinated to social norms in the joint-family system, except for rare rebellious behavior or outbursts, the present newly found freedom has instigated more openness and casualness in matters of sexual behavior. Expressions and feelings that would have been termed scandalous and in need of being tamed to adhere to socially accepted rules, values, and practices, are now accepted as natural.

Individualism, in its Western Euroamerican consciousness, is foreign to the traditional Indian social consciousness and experience. However, this is changing. Sudhir Kakar, a distinguished psychoanalyst who has taught at the Universities of Harvard, Chicago, and Vienna, and has written extensively on Indian sexuality, notes that "individualism even now stirs but faintly" in India (Kakar 1989, 4).

Traditional Indian folklore and stories, as well as modern novels, provide an important theme—the perennial, cosmic-based conflict between man and woman—that flows through much of male-female relationships in Indian culture and domestic life. Margaret Egnor sums this theme up in her study of *The Ideology of Love in a Tamil Family*. Based on her research in Tamil Nadu, Egnor observed that:

Within the household, as well as in the domain of paid labor, there was a strong spirit of rivalry between many women and their husbands. Wives would not automatically accept submission. Neither would their husbands. Consequently, their relationship was often, from what I was able to observe, disputatious. . . . The eternal conflict between spouses is abundantly reflected in Indian mythology, especially Tamil which debates the issues of male vs female superiority back and forth endlessly on a cosmic

level in the form of battles and contests between deities or demons and their real or would-be mates. (Egnor 1986).

In Indian folklore, Shiva and Parvati argue interminably about who is the better dancer, while Vishnu and Lakshmi are constantly debating which is the greater divinity.

In most regions of the country, male folk wisdom traces the reasons for man's perennial war with woman to the belief that the female sex lacks both sexual morality and intelligence. The Punjabis and Gujaratis agree that "The intelligence of a woman is in her heels." Tamils maintain that "No matter how educated a woman is, her intelligence is always of the lowest order." The Malayalis warn that "One who heeds the advice of a woman will be reduced to beggary."

Men in southern India seem more resigned and willing to acknowledge their helplessness in the face of "general female cussedness and constant provocation." Kannada and Telugu men admit that "Wind can be held in a bag, but not the tongue of a shrew," while Telugu males confess that "Neither the husband nor the brother-in-law can control a pugnacious woman." By contrast, in the northern regions of India, folk sayings place "singularly greater emphasis on the employment of force and physical chastisement to correct perceived female shortcomings." "The place of a horse and a woman is under the thighs." Two proverbs from Gujarati echo this view: "Barley and millet improve by addition of salt; women through a beating by a pestle," and "Better to keep the race of women under the heel of a shoe" (Kakar 1989, 6).

Faced with this perennial conflict between husband and wife, the object of the wife's affectional and sensual currents traditionally has been the husband's younger brother in the joint or extended Indian family.

For a time in Indian social history, the custom of *nigora* officially recognized the erotic importance of the brother-in-law—in the sense that he would or could have sexual relations with his elder's brother's widow. The *nigora* custom has been traced back to the times of the Rig-veda, where a man, identified by the commentators as the brother-in-law, is described as extending his hand in promised marriage to a widow inclined to share her husband's funeral pyre.

Although the custom gradually fell into disuse, especially with the prohibition of widow remarriage, the psychological core of *niyoga*, namely the mutual awareness of a married woman and her younger brother-in-law as potential or actual sexual partners, remains very much an actuality even today (Kakar 1989, 13).

Kakar has added a perspective from clinical practice, noting that women who are on terms of sexual intimacy with a brother-in-law rarely express any feelings of guilt. Their anxiety is occasioned more by his leaving home or his impending marriage, which the woman perceives as an end to her sensual and emotional life (Kakar 1989, 13-14).

The fate of sexuality within marriage is likely to come under an evil constellation of stars. Physical love will tend to be a shame-ridden affair, a sharp stabbing of lust with little love and even less passion. Indeed, the code of sexual conduct for the householder-husband fully endorses this expectation. Stated concisely in the *smritis* (the Law codes), elaborated in the *puranas*, which are not only collections of myths, but also contain chapters on the correct conduct of daily life), modified for local usage by the various kinds of religions, the thrust of the message seems to be "No sex in marriage, we're Indian" (Kakar 1989, 19).

According to Hindu tradition, a husband should only approach his wife sexually during her *ritu* (season), a period of 16 days within the menstrual cycle. But intercourse is forbidden on six of these 16 days, the first four days, and the

11th and 13th. This leaves only ten days for conjugal relations, but since the all-important sons are conceived only on even nights and daughters on uneven nights, the days for conjugal relations shrink to five. Then there are the *parvas*, the moonless nights and those of the full moon when sexual relations lead either to the birth of atheist sons (*Brahma Purana*) or the "hell of feces and urine" (*Vishnu Purana*). Add to these taboos the many festival days for gods and ancestors, when erotic pleasures are forbidden. Sex is also beyond the pale during the day.

There is a general disapproval of the erotic aspect of married life, a disapproval that cannot be disregarded as a mere medieval relic; this general disapproval of the erotic, even in marriage, continues to inform contemporary attitudes. This is quite understandable, since changes in sexuality occur at a more gradual pace than transformations in the political and social sphere; sexual time, as Kakar suggests, beats at a considerably slower pace than its chronological counterpart. Sexual taboos are still so strong in some Hindu communities that many women, especially those in the higher castes, do not have a name for their genitals (Kakar 1989, 20).

Cultural taboos may not, despite their pervasive presence in Indian society, affect the sexual expressions of men and women across the economic and caste spectra of India. But they can, and apparently do, increase the conflicts around sexuality, sour it for many, and generally contribute to its impoverishment. This can effectively block many men and women from a deep, fulfilling experience of sexual love. Accordingly, the considerable sexual misery one can deduce as being reflected in the Indian marriage and family, from cultural ideals, prohibitions, and modern fiction, are the sexual woes expressed by middle- and upper-class women who seek relief in psychotherapy, and is also evidenced in the interviews Sudhir Kakar and others have conducted with low-caste, "untouchable" women in the poorest areas of Delhi.

Most of these women portrayed their experiences with sexual intercourse as a furtive act in a cramped and crowded room, lasting barely a few minutes and with a marked absence of physical or emotional caressing. It was a duty, an experience to be submitted to, often from a fear of beating. None of the women removed their clothes during intercourse, since it is considered shameful to do so (Kakar 1989, 21).

Despite these pervasive negative images of the conflict between the sexes in marriage, and the negative view of women and sexuality, it must be pointed out that Indian sexual relations are not devoid of regular pauses in the conflict between man and woman. Tenderness, whether this be an affair with the soul of a Mukesh song, that is much quieter than a plunge into the depths of erotic passion known in Western culture, or sexual ecstasy of a husband and wife who have found their way through the forest of sexual taboos, does exist in India (Kakar 1989, 22-23).

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A. Source and Character of Religious Values

India is a multiethnic and multilingual society with wide variations in demographic situations and socioeconomic conditions. People in India practice different religions, and there are numerous cultural identities. The religious composition of India shows that a majority, 82%, are Hindu. The other religious groups are Muslim, 11.7%; Christians, 2.4%; Sikhs, 1.9%; and other religious groups, 2%.

In a nation as religiously and ethnically diverse as India—the nation is commonly described as "a jumble of

possibilities”—the people follow a wide variety of customs and have varied beliefs that ultimately mold their lifestyles. In the life of a Hindu male, for instance, marriage is regarded as necessary, because without a wife he cannot enter the *Grihasthasrama* (the life stage of a householder). In addition, without marriage there can be no offspring, and without a son no release from the chain of reincarnation in birth-death-rebirth. According to Hindu custom, which still prevails in most families, marriage must take place within one's caste or *Varna*, although marriages between members of different castes and communities are gaining acceptance. Hindu marriage, being a religious sacrament, is indissoluble.

The *purdah* system still prevails in the Muslim northern region of the country, where a female has to cover her face in front of other males and elders, but this custom is also slowly fading out. The Muslim male, who is allowed to have four wives, subject to specified conditions, is also realizing the wisdom in small families and monogamy (more so the educated, urban Muslim male). Marriage is solemnized by signing a legal document and can be dissolved. Divorce is almost exclusively the husband's privilege, although a divorcing husband has to pay the “Dower,” a settlement made to the wife out of her husband's property to compensate her in the event of death and divorce.

Indian Christians are also influenced by the social practices of the region, but they tend to follow the pattern of a family as an independent unit, in which their lifestyles and interactions revolve around the community and the local church. They have more freedom in their general outlook and easily adapt to local conditions and trends.

The tribal people of India have varied religious and social practices, often with a more natural approach to sexuality and age-old practices of premarital sex and premarital experimental cohabitation.

Although there is a decreasing acceptance of orthodox beliefs and religious practices among India's younger generation, each of India's religious traditions maintains its own forms of observations of various practices, starting with birth and regulating life through marriage to the death ceremonies. The lifestyles of the people, including their sexual behavior, are generally governed by these prescribed practices.

### B. Source and Character of Ethnic Values

India's dominant ethnic element is the Indo-Aryan peoples with 72% of the population. The Aryans invaded India from the northwest between 2400 and 1500 B.C.E. and intermingled with already well-civilized native people. The Australoid Dravidans, including the Tamils, constitute 25% of the total population and dominate in southern India. Arab invaders established a Muslim foothold in the western part of the country in the 8th century, and Turkish Muslims gained control of northern India by 1200. These Muslims were in part responsible for the decline of the Chandella culture that dominated in northern India from c. 200 B.C.E. to C.E. 1200. The great “love temples” of northern India, including Khajuraho, were built in the 11th century and were in part destroyed by the invading Muslims (Deva 1986). In 1526, Muslim invaders founded the great Mongul empire centered in Delhi. This empire lasted, at least in name, until 1857. Today, 3% of Indians are of Mongoloid ancestry.

The Portuguese influence in Bombay and the Indian subcontinent dominated trade with Europe in the 1500s. In 1612, the English influence began to spread with the founding of the East India Trade Company. In 1687, the English took over Bombay, setting the stage for their defeat of the French and Islamic armies, and laying the foundation for

the incorporation of India into the British Empire in 1858. English Victorian views of sexuality remain a strong influence in urban India.

In 1947, the Indian Independence Act was passed, and a new constitution establishing India as an independent democratic country was adopted in 1949. In the 1970s, a war in the north between East and West Pakistan ended with Indian intervention and establishment of East Pakistan as the new nation of Bangladesh.

## 3. Knowledge and Education about Sexuality

### A. Government Policies and Programs for Sex Education

Present-day children in India are more exposed to new areas of knowledge than their parents were. As a matter of fact, young people are simply deluged these days with movies, magazines, and books—all prime sources of sexual information and stimulation. Young people nowadays want to know more about the pros and cons of marriage, premarital and extramarital sexual relationships, venereal diseases, and so on. In a survey of college students conducted by the All India Educational and Vocational Guidance Association, it was reported that 54% of male students and 42% of female students stated that they did not have adequate knowledge regarding matters of sex. Though parents have the primary responsibility of imparting sex education to their children, it has been found that a majority of young people in India derive their information about sex and sex behavior largely from companions, street-corner conversation, movies, and magazines. The government is seriously contemplating introducing sex education as a part of the curriculum from the secondary school level onwards. One important reason for giving the school responsibility for sex education is that many parents feel unable to handle this task themselves. Many have inhibitions about discussing sex with their children; others admit that they do not have the technical knowledge to answer all the questions their children ask. In this situation, the teacher is a major factor in determining the success of any sex-education program. Serious efforts are under way in specifying the contents and components of sex education and the level at which this has to be taught. No information is available on the provision of sex education in special schools, such as those for mentally handicapped persons.

### B. Informal Sources of Sexual Knowledge

Parents give their young children sex education many years before they can begin to convey sex information verbally. The mother's behavior, attitudes, and roles are a clear model for the growing girl. Similarly, the father provides a role model for a son. The relationship, warmth, and responsiveness between parents provides for all children a model for their later marriage. By observing their parents, children see the basic qualities that make men and women different. Similarly, when the child is in the company of his friends, he or she learns through them the various facets of their life. The other important informal sources of sexual information for the child are peer-group influence, teachers, books, movies, magazines, and siblings.

Fifteen million Indians attend the cinema every day. Hindi cinema, perhaps more than the cinema of many other countries, provides fantasy, the stuff that dreams are made of. The cinema is the major shaper of an emerging, pan-Indian popular culture. As such, the mix of fantasy and reality, dreams and hopes, that permeates Hindi cinema is already a major factor in the remolding of Indian sexual values, ex-

pectations, and attitudes, as well as gender relations, marriage, and the family (Kakar 1989, 25-41).

#### 4. Autoerotic Behaviors and Patterns

Masturbation is generally unacceptable among girls. For boys, however, it is considered a preparation for mature sex life. Though boys at the younger ages may masturbate together without shame, at little more-mature ages, they all give it up. This seems to be particularly so in the case of married men. In recent years, the availability of sexually explicit books, magazines, and videos has also acted as a major contributory factor for male autoerotic activities.

#### 5. Interpersonal Heterosexual Behaviors

##### A. Children

Indian children are pampered as much as possible, often until age 6 or 7. Before puberty, a natural approach to sexuality and nudity prevails, especially in rural areas. Daughters and sons are carefully prepared for their future domestic roles as mothers and fathers. Women are considered to be much more skilled than males in love and sexual pleasures. At puberty, most boys and girls are segregated. In some regions of India, pubescent girls are not even allowed to enter a house where a single young man is present.

Sexual views and behavior are somewhat more natural and less inhibited in India's rural villages, according to Dr. Promilla Kapur, a research psychologist and sociologist at New Delhi's India International Center. Some tribal groups practice totally free sex among adolescents.

Nowadays, with the advent of various satellite television programs, children are exposed at their early ages to various programs, including considerable sexually related material. This exposure often results in conflicting responses for girls raised in a society that represses or ignores female sexuality. In rural areas, adults sometimes talk loudly about their sexual experiences in the presence of children, and this provides opportunities for the young men to think more about sex. In urban areas, especially cities where housing shortage is very acute, adults in public places, like parks and cinema theaters, generally satisfy their sexual feelings through hugging or other noncoital sexual practices. These acts also provide learning opportunities for the younger ones. Sexual play, such as looking at another child's buttocks or genitals, genital touching games, sharing a bed with a child of the opposite sex, and so on, likewise provides children with opportunities for sexual exploration; the parents would not necessarily be aware of these acts of their children.

##### B. Adolescents

Adolescents in India today face a number of problems related to changing value systems and social expectations. The sexual world of adolescents is becoming increasingly complex. In traditional Indian society, adolescents were initiated into their sexual roles, more or less, in a clearly defined period and by a series of ceremonies and rites. As in some other cultures, these included instruction on their sex roles, marriage customs, sexual morality, and acceptable sexual behavior. But with the influence of Western culture, the present generation of youth is facing a number of problems that are ultimately forcing them to violate the traditional norms as laid down by the society.

When Kakar and Chowdhary (1970) examined some aspects of sexual behavior among young men prior to marriage, they found that a lack of adequate information and opportunities prompted these young people to turn to literature (often pornographic), to experimentation with prostitutes, friends, or relatives of the opposite or same sex, to co-

vert observation of the sexual activities of others, and to masturbation. Reddy and his colleagues, in a 1983 study of young people, found that the sample youth had their first sexual experience between the ages of 15 and 24 years. Homosexual activities were also reported in this study: 38% of women in the sample reported that their first sexual activity had been with a partner of the same sex. The Family Planning Foundation of India undertook a study in 1990 among teenagers (between 14 and 17 years) and found that about one fourth of them expressed their acceptance of premarital sexual contact, "if the boy and the girl were actually in love." While a good number of respondents were aware of at least one contraceptive method, they had very little precise knowledge. Men were found to be more liberal in their views than women.

Mane and Maitra (1992) have rightly inferred that "relatively little is known about the sexual behavior and attitudes towards different aspects and forms of sexual activity in India." With changing conditions in India, the opportunities for risk-taking behavior among adolescents seem to be increasing. Coping with sex is a growing problem for young people. Today's teenagers are faced with an ever-widening gap between the age at which they are physically ready to have sexual intercourse and the age at which it is culturally acceptable for them to do so. Youngsters are, in fact, often sandwiched between a near-obsessive preoccupation with sex in the media and a veritable wall of silence from other sources of information on the subject. Sex education, including family planning and reproductive health management, has to be the cornerstone of any youth program that is attempted. The social, psychological, and emotional consequences to early sexual involvement also need to be carefully explained.

##### C. Adults

###### *Premarital Courtship, Dating, and Relationships*

The marital bond involves a social sanction generally in the form of a civil or/and religious ceremony authorizing two persons of the opposite sex to engage in sexual relations and assume the consequent and correlated socioeconomic relationships and responsibilities society maintains for a married couple. Under the kind of social structure that caste has given rise to in India, there are certain restrictions in the limits beyond which the parents, in the case of an arranged marriage, and a man and a woman, in the case of a love marriage, cannot go in choosing a spouse; he or she must invariably marry outside his or her own *gotra*. (*Gotra* is the name of the ancestral head or father of the family.) A decision to marry is usually marked by an "engagement," where the elders of both the parties announce their intention to conduct the marriage to their family and friends.

Traditionally, premarital sex activity was controlled in India. As the marriages were mostly arranged by elders, premarital sex was not the accepted practice. Although premarital sex among the tribal societies of India has been widely reported, there is very little, if any, reliable data on this topic in either the rural or urban areas.

A recent study by Savara and Sridhar in 1992 showed that 30% of the respondents had experienced premarital sex, while 41% of unmarried men and 33% of married men had their first intercourse before attaining 20 years. In another study, they found that about one quarter of married women had sex with their husbands before marriage. Other premarital sexual partners for women were mostly friends, relatives, and work acquaintances. A majority of the respondents—43%—agreed that casual sex is all right, and it is acceptable to sleep with someone you have no plan to marry. It is clear that, although premarital sexual relationships are considered

generally as immoral in contemporary India, the majority of the young generation do not find it objectionable. A gradual increasing openness about sex in films, video music, television, magazines, and so on, is clearly influencing the young in India to be more adventurous about premarital sex than their parents and elders were.

### Single Adults

Since marriage is strongly endorsed for all adults in India, the number of men and women remaining unmarried is very negligible. With the rapid increase in urbanization and industrialization, more and more young people are moving out of the rural areas into the urban areas, mainly in search of a livelihood. Mostly they move to urban areas by leaving their families, sometimes including a spouse, in their place of origin, because of the lack of proper housing facilities and the high cost of living in their new home. In the absence of their spouses, many married men turn to the brothel houses for satisfying their sexual urges. In so doing, they face many health problems, like STD and HIV.

### The Dowry Conflict

The centuries-old marital tradition of the dowry has recently become troublesome among some young married couples. Since females historically could not inherit property, parents would give their daughters money and property—a dowry—when they married. Young men came to depend on a good-sized dowry to start them off in a comfortable middle-class life. Although dowries were outlawed in the 1947 Constitution and in subsequent laws passed by the Indian Parliament in the 1970s, the new law has created serious problems for brides whose parents refuse to give a sizable gift—the equivalent of the traditional dowry—to the groom. In such cases, some new husbands and their families conspire to drive the young bride to suicide, or if this fails, even murder her (see Section 8A, Significant Unconventional Sexual Behaviors, Coercive Sex, on domestic violence and dowry deaths). In this way, a young man might marry several times and eventually accumulate enough in illegal dowries to live comfortably. But dowries remain important for Indian women today. Even though they can inherit and no longer depend on the dowry for financial security, Indian women still consider the dowry their right. In the mobile social strata of the cities, the size of a woman's dowry definitely affects her social status. In West Bengal, the groom and his family may demand dowry payments of as much as 60,000 rupees, or nearly \$2,000, more than ten times the annual income of many rural families.

Effective enforcement of the antidowry law and protection of brides from abuse is difficult, despite the efforts of women's rights groups and special courts set up by the government. Many believe the only hope for permanent improvement lies in changing social attitudes, including the promotion of marriages based on love instead of arranged marriages.

[Update 2003: In May 2003, 2,000 guests gathered to celebrate the wedding of Nisha Sharma, a 21-year old computer student, and Munish Dalai, 25, in Noida, an eastern suburb of Delhi. According to later reports in major newspapers around the world, the father of the bride had already provided two Sony television sets, two home theaters, two air conditioners, and two sets of electrical appliances for the kitchen—one of each for the couple and the other for the groom's older brother, who had headed the household after the death of their father. A car for the older brother was also included in the unofficial dowry. All went smoothly at the wedding until, at the very last minute, the groom's older brother demanded 25,000 rupees in cash for their mother.

[As the media was quick to report, the free-for-all that erupted between the two families ended when “the bartered bride put her hennaed foot down, reached for her royal blue cellphone and dialed 100.” When the police arrived, they spent an hour calming down the families and guests, which allowed the groom and his family plenty of time to escape. Three hours later, Ms. Sharma accompanied the police to the station and filed an official complaint against the groom and his family for demanding an illegal dowry. By chance, a television crew from *Aaj Tak* news channel happened to be in the station. As the bride's father later described what happened, “With the pressure of the media people, the police went to the boy's house and arrested him.” The groom would be in jail until he could be arraigned and officially charged with violating the antidowry law.

[India's new 24-hour news stations then propelled Nisha to “Hindi stardom” and a media blitz was on. The *Times of India* headline admitted, “It Takes Guts to Send Your Groom Packing.” *Rashtriya Sahara*, a major Hindi daily, wrote, “Bravo, Nisha, We're Proud of You.” *Asian Age* hailed her “as a New Age woman and . . . a role model to many.” Major newspapers and television news programs around the world picked up the story of the bride who refused to be bartered. In the next few days, Ms. Sharma was unfazed by the loss of her fiancé, as 1,500 supportive emails poured into a special number set up by the 24-hour news stations. She also received two-dozen marriage proposals by cellphone, email, and letter (Brooke 2003). (End of update by A. Kadari)]

### Marriage and Divorce

Despite an increasing modernization and shift to love-based marriages, most marriages in India are still arranged by parents. Family concerns take precedence over the interests of young couples, because Indian parents strongly believe that a marriage will be good only if the bride and groom come from similar backgrounds. The impetus for arranged marriages is respect for the wisdom of one's elders. To assure that their offspring marry within their own community or caste, many Indian parents use the classified advertisement sections of newspapers to make contact and arrange marriages for their children. In the villages and rural areas, distinctions in the caste system are much stronger and sharper than they are in the cities.

Although the tradition of arranged marriages has a practical value in preserving family traditions and values, it encounters some opposition as young Indian men and women learn of the Western tradition of romance and love. Urban middle-class Indians are most affected. Most Indian men and women attending college outside India are careful not to compromise their prospects back home by letting their family or parents know they have dated a foreigner.

While marriage is a sacred arrangement made in the presence of elders, divorce is legally possible. The incidence of divorce was very negligible in the past, mainly because of the low status of women in the society and the very low level of educational background of females, which left divorced women incapable of supporting themselves. Current trends show that the divorce rate is increasing in the recent past, especially in urban areas. This clearly indicates that women are becoming more aware of their rights, and more assertive in maintaining their individual identity in their employment and personal earnings without being submissive to men.

The joint or extended Hindu family, which dominated in the past, is gradually disintegrating. In the traditional Hindu extended family, the eldest male governed the entire family; the daily life of its members revolved around this huge family. The family head, in consultation with other elder males,

arranged marriages in which the youngsters had little say. The females lived behind closed doors—"within the four walls" environs. Festive occasions were the only times when they had the opportunity to interact with others in the neighborhood or relatives. With the disintegration of this family unit into individual families, the problems of insecurity and social influences of the neighborhood have become common. This is indeed leading to the assertion of individual freedom in the choice of marital partners and lifestyles.

[Update 2003: Srinath Krishnan (2003) echoes the opinion of most South Asian Indians that arranged marriages "have been around in India as long as probably the institution of marriage itself." Indian marriages were and still are a family matter, with romantic love and the input of the young woman and man traditionally of minor concern. Older, and wiser, women in the family, known as "Aunt Bijis" in the Muslim community and "Aunties" among the Hindi, still bear the responsibility of investigating the family background and history of the potential bride and groom, his education, caste, religious persuasion, economic status, and career potential to find the most compatible young man for their daughter/niece. Once the Aunties select the groom, the daughter's mother usually shows her a picture of the young man, and then arranges for a brief formal meeting with the prospect and his family, followed by a brief engagement and the marriage, with the bride and groom having little opportunity to become acquainted along the way. Today, in some families, after the engagement the couple might have a few formal meetings or dates chaperoned by a family member. But the engagement is binding and seldom broken. A more formal meeting might also be arranged, in which the young man, his mother, and several other relatives visit the young woman and her family. "These formal meetings could be awkward, drawn-out affairs for which the young woman wore her best Indian outfit, a sari or elegant Indian pants and top. She sat quietly, which is almost impossible to fathom, considering her chattiness. When called upon, she poured tea, and then talked briefly to her potential mate in a side room" (Alvarez 2003).

[Over the centuries, the customs of arranged marriages have gradually evolved as social circumstances changed. This adaptation and change is accelerating in the diverse urban and rural communities of the Indian subcontinent, but they are more obvious in the tight-knit Indian communities in Britain, where second- and third-generation children of Indian expatriates are exposed to a very different culture. In the 1960s, after Aunties arranged for a young couple and their extended families to meet, the couple might meet alone several times, either with family members in another room or at a restaurant, before the couple decided to marry. Even then, the decision was heavily influenced by family responsibilities. Today, these pre-engagement meetings take place in public venues with the family encounter coming later. In recent years, the traditional role of the family and Aunties has been reduced, as young Indians take advantage of a boom in Asian marriage Web sites, Internet chat rooms, and personal advertisements. "Speed dating" for Muslims on one night at a local restaurant or bar, and Hindi on another night, are also becoming a popular way for young Indians to meet each other for just three minutes before moving on to the next potential mate. If a woman meets a suitable, interesting candidate, she can inform the matriarchs in her family, her mother and Auntie, and let them make further arrangements. An "assisted arranged marriage" is the new term for this changing pattern of courtship and marriage (Alvarez 2003).

[The advantages of an arranged marriage are still evident, since the matriarchs base their advice and recommendation not on passionate, romantic, lusty love, which can

"fizzle out," but on longer-lasting considerations of family and mutual compatibility. Not all Indian parents are comfortable or accepting of these changes, but parents and elders, eager to avoid alienating their children, making them miserable or seeing them go unmarried, are showing considerable flexibility, especially in middle-class and urban Indian communities. South Asian expatriate parents and elders in Britain and Europe have had to adapt, in large part because the number of potential partners is much smaller there than in their home countries. Rather than see an educated daughter go unwed, parents and elders have accepted these more modern approaches. But there is also a cultural exchange with changes in the courtship and marriage customs outside India gaining root in the urban middle class on the Asian subcontinent. (End of update by A. Kadari and R. T. Francoeur)]

### Family Size

In India, the demographic transition is at the middle stage where both birth and death rates are showing a declining trend, but the death rate is declining at a faster rate, while the fertility rate is not declining as fast as expected. As marriage is almost universal, in almost all religious groups the age at marriage—especially of females—is very low. For instance, the average age for females at marriage is 18.3 years; for males, it is 23.3 years. Because women have a long reproductive span, Indian couples tend to have large families. The total fertility rate in India is 4.5 and the total marital fertility rate is 5.4. Various factors, such as a strong preference for a son, the low status of women, a high infant mortality, a high illiteracy level, inadequate healthcare facilities, and irregular follow-up services provided by the health staff play a major role in keeping couples from accepting contraception.

More than 80% of deliveries in India, especially in rural and tribal areas, are conducted by the traditional birth attendants, locally called "Dais." In the absence of a formal healthcare system within their reach in times of need, people in general depend on these indigenous people for their deliveries. These older women generally have very high credibility and act as good change agents in the community. Though in traditional societies, a joint family system is more commonly observed, nuclear families have become more common in the recent decades, mainly because of changes in the occupational structure and dispersal of family members in search of livelihood, and their movements into urban areas.

### [Sexual Abstinence

[Update 2002: Abstinence from sex is a strategy within marriage adopted by some wives in order to assert their own control over domestic space and family life. Women's rights author and activist Madhu Kishwar (1997) profiles contemporary women from several different walks of life who self-consciously pursue this strategy. For some Hindu women, this abstinence is related to their role as a medium for the Goddess: They are both vehicles for the Goddess and thus subject to Her command, yet they enjoy status, influence, and control with respect to their families and to the devotees who solicit the Goddess' favor through them (Hancock 1999, 141-173).

[Abstinence can also indicate that a woman has chosen a life path distinct from marriage and childbearing; religion is one of the few established institutional avenues in India through which a woman may make such a choice. Jains in India possess a very well established and living tradition of nuns, who renounce all ties to their families in order to practice intense spiritual discipline. In Hinduism, there are

many contemporary female gurus who are celibate; some are married, but are understood not to have consummated their marriages. The internationally famous female guru Anandamayi Ma (1896-1982) established an ashram exclusively for women to practice spiritual discipline, as well as a Sanskrit school for young girls, which “provide protection for girls who [do] not desire marriage and education for those who do” (Hallstrom 2000, 206). (End of update by K. Pechilis-Prentiss)]

### *Sexuality and the Physically Disabled and Elderly*

There are no organized attempts made so far to assess Indian attitudes about the sexuality of physically and mentally handicapped persons and elderly. Very little attention has been paid so far in sexuality training for the teachers and health personnel who work with these disadvantaged groups. Furthermore, there is no effort made by the institutions that serve these people to deal with the sexual needs of their residents.

### *Incidence of Oral and Anal Sex*

Vaginal intercourse is the norm for marital sexual activity. The incidence of fellatio and cunnilingus is not known in the Indian context. However, oral sex appears to be relatively uncommon.

## *6. Homoerotic, Homosexual, and Bisexual Behaviors*

Heterosexual acts, the only socially acceptable sexual expression, is based primarily on the much wider contact and more common relationships between males and females in society. The family is promoted as the early valid social unit. Although homosexuals existed even in ancient India, they never attained social approval in any section of the Indian population. There was a reference to such practices in the *Kamasutra*, written by Vatsyayana more than 1,500 years ago and long admired as an extraordinary analytic treatise on sex and love.

Very little is known about the current practice of male or female homosexuality in India. Homosexuality is slowly gaining acceptance, in part because of the efforts of one or two organized groups in metro cities that are affiliated with a couple of activist homosexual groups connected to international bodies of gays. A regular voice of one organization, and of its homosexual members, is published in Bombay, titled *Bombay Dost*, or “Bombay Friend.”

Savara and Shridhar (1992) reported that 12% of unmarried men and 8% of married men reported that their first sexual experience was with another man, and most of them had it before they were 20 years of age. About two fifths of them had a homosexual experience with one or two persons, while over a fifth had such experiences with more than ten persons. In their homosexual acts, only 21% of them had used condoms. Ahmed (1992), in his study of truck drivers, found that 15% of them admitted previous homosexual experience. Parasuraman et al. (1992), from a study in Madras, found that 3% of the homosexuals earned their livings as dancers and/or sex workers. It is further reported in this study that most of the men were between the ages of 21 and 30, and took both active and passive roles in unprotected anal and oral intercourse.

### *[Lesbianism]*

[Update 2001: The issue of women’s sexual fulfillment was dramatized in Deepa Mehta’s controversial film of 1996, *Fire*, in which a young urban middle-class woman marries, is neglected by her husband, and begins a lesbian relationship with an older married woman in the family whose husband

also neglects her. While many felt the film was rather crude in its presentation of Hindu Indian tradition as a foil for the “modern” approach of lesbianism, in the process relegating lesbianism to a response to selfish men (Kishwar 1998), the film takes a very public stand that women have the need and the right to be fulfilled sexually. Currently, lesbian groups in India are campaigning to decriminalize homosexuality. In 1999, the Campaign for Lesbian Rights in Delhi issued a report describing the intimidation and difficulties of lesbians in India. (<http://www.umiacs.umd.edu/users/sawweb/sawnet/news/news337.txt>) (End of update by K. Pechilis-Prentiss)]

[Update 1999: As in other parts of the world, India has seen a growing lesbian and gay movement, one which has also received its share of media attention. In early 1998, when two policewomen in Madhya Pradesh decided to get married, the news was picked up by the press. This was perhaps the first occasion when lesbianism became a matter of widespread public debate. The furor created by this debate made it difficult to dismiss the issue as yet another Western aberration. As a political event, however, it also raised troubling questions for the women’s movement and for the fledgling gay and lesbian politics, whose relationship to each other was far from clear. An important article highlighted the “elaborate apparatus of explication” evident in most reports of the marriage, which explained away the decision of the two women in terms of their suffering and victimhood at the hands of a patriarchal society, never allowing for the possibility of an affirmative, let alone sexual relationship.

[Over the last decade, the gay and lesbian movement has grown in visibility, with a mushrooming of groups and publications in India, and among South Asians in the West. Legal activism has extended from ongoing efforts to change the discriminatory legislation embodied in the antisodomy laws, to proposals to amend the Special Marriages Act to permit same-sex marriages. In a recent overview, Sherry Joseph has tried to plot the emergence of the identity politics of the gay and lesbian movement in its relations with similar movements in the West, as well as the specific dilemmas faced by lesbians within a movement that is male-dominated (John & Nair 1999). (End of update by K. Pechilis-Prentiss)]

## *7. Gender Diversity and Transgender Issues*

Gender-conflicted persons are generally regarded as homosexuals. Traditional Indian society did not provide for special gender roles. In the case of transsexuals, it is not possible to alter one’s birth certificate to change the sex designated at birth.

The *hijra*—an Urdu word for eunuchs—are the most notable example of gender variance in India (Jaffrey 1996; Nanda 1990, 1994, 1999, 2000). *Hijra*, who live predominantly in the larger cities, belong to a Hindu caste of males who dress as females. Their religious role is to perform as mediums for female goddesses, hence their role at weddings. Usually, they leave their families in their teen years to join adult *hijra* in a large city. Some may finalize their gender status by castration. Their societal role, and means of making a livelihood, involves providing entertainment at weddings and other festivals, sometimes uninvited but always expecting to be paid. They may also engage in sexual activity with men for money or to satisfy their own sexual desires. The most commonly used technique of the *hijra* is the anal-intercourse passive role without the use of condoms. Characteristically, according to Walter Williams (1986, 258-259), *hijra* are bitchy like American gay drag-

queens—heterosexual transvestites are rarely or never bitchy. Insistent and bad-tempered, they wear no underwear and lift their skirts to expose themselves to the embarrassed guests if not paid. They tend to complain and frequently make demands on others in public, such as demanding (rather than politely asking) rich women for their clothes on the street (Weinrich 1987, 96).

[Update 2002-2003: India's third-sex caste, the *hijra*, who are neither male nor female, include males born with deformed genitals, hermaphrodites, self-castrated eunuchs, and gay cross-dressers. Early Hindu texts, like the *Kamasutra*, tell of these third-sexed persons who danced at weddings, cast spells, guarded harems, and entertained guests in the royal courts. In more recent times, India's estimated half a million to two million *hijra* have existed on the fringes of Indian society. That may be changing, in part because a Constitutional amendment in 1993 reserved a quota of seats in city and village councils for women and oppressed castes. In 2000, a dozen *hijra* were elected to city and provincial offices, including Asha Devi, mayor of Gorakhpur in northern India, Kamla Jaan, mayor of Katni, and Heera Bai, city councilwoman in Jabalpur, a city of 1.4 million. Formation of a national political party of eunuchs was announced early in 2001 as a voters' alternative to the major political parties (Bearak 2001).

[In February 2003, the High Court of Madhya Pradesh state upheld a lower court ruling that eunuchs are still male and cannot seek election to offices reserved for women. At issue was the election of Kamla Jaan, a *hijra*, as mayor of Katnia. The court noted that this mayoral office was set aside for women to encourage their participation in politics. Kamla Jaan announced plans to appeal to India's Supreme Court (Associated Press). (End of update by R. T. Francoeur)]

## 8. Significant Unconventional Sexual Behaviors

### A. Coercive Sex

#### Sexual abuse

Because of the pressures of social change and the loss of the holding power of traditional taboos, child sexual abuse seems to be increasing in India. However, there is a growing awareness about child sexual abuse in the society. Girls who are near to attaining their puberty, or have just attained it, are often objects of older men's attention.

Although it is socially disapproved, some instances have been reported where parents, because of their poverty, accept a brideprice for the marriage of a very young daughter to an older man seeking a young girl as a second wife. In spite of rigorous efforts by the government in educating the people, it is still an accepted practice, especially in rural areas, to arrange marriages of young girls.

#### Incest

Repressed sexuality has also been a factor in what in the West might be considered widespread incest. In India's extended family system, sex between brothers-in-law and sisters-in-law, for example, or between cousins, or uncles and nieces, or aunts and nephews is common, although hard statistics are not available. See Section 1C, Basic Sexological Premises, General Concepts of Sexuality and Love, for the tradition of *niyoga*, describing the relationship between a wife and the younger brother of her husband.

#### Sexual Harassment

Poverty forces many rural girls around 10 years of age to be employed as housemaids in rich and middle-class homes. In addition to the economic exploitation, some of these girls

also face sexual harassment by males in these households. Since these girls are in no position to resist sexual advances, most sexual harassment acts are not reported or complained about to the police. College girls and young working girls face the problems of harassment. The problem of "Eve-teasing"—old-fashioned pinching, fondling, and other sexual harassment of women on the street—has become so serious in recent years that the government has had to promulgate a law prohibiting this behavior.

One small but significant incident that may signal a change in the pervasive acceptance of sexual harassment in Indian culture occurred in mid-1996, when a 61-year-old Punjab state official was convicted of "outraging the modesty" of a woman in public by slapping the backside of another senior Punjab official at a public event in 1988. After eight years of delays and alleged government coverups for the defendant, the court unexpectedly convicted the defendant, the former general of police for the Punjab district and a national hero for his suppression of the Sikh rebellion. While the sentence appeared insignificant, a mere three months in jail and a \$20 fine, the court did stipulate that the defendant be subjected to what is known in India as "rigorous imprisonment," a harsh regimen generally reserved for serious criminals and hardly befitting a national hero. While recognizing this verdict as a small measure of justice, women's groups in India hailed it as a landmark because of the prominence of those involved, and the fact that appeals will keep this harassment case in the public view for some years to come.

#### Rape

Sexual exploitation of girls is another problem faced by females in India. Data on the crime of rape shows that a total of 4,919 rape cases were registered in the country in 1981, with an increase of 12.8% from 1980.

Few cases of rape are actually reported to the police because of the negative consequences to the future life of rape victims. Young Indian women who are known to be victims of rape are viewed as outcasts, and their families disgraced, even though they were not in any way responsible for the attack. The spread of Western culture, the disruption of urbanization, exposure to films with lots of sex scenes, and pornographic materials are all blamed for the increasing number of rape cases in India.

[Update 2001: Indian dimensions on rape include the serious reluctance of women to rely on the law for recourse, not only because of the publicity it would engender, thus ruining a woman's chances for marriage, but also because some of the most infamous cases have been perpetrated by police officials. In addition, rape is a frequent aspect of conflict between castes and between caste groups and tribals. In part because of these factors, women's groups have sought to address incidents of rape at the local level. For example, the Rural Women's Liberation Movement in Tamilnadu, south India, has brought cases before village councils, and received monetary compensation for victims of rape from their attackers (Kumar 1997, 136). (End of update by K. Pechilis-Prentiss)]

#### Dowry Deaths

[Update 2002: Some claim that the "dowry deaths" in India widely reported in the international news media maim or kill some 25,000 women a year, but most incidents of dowry-related bride-burning are concentrated in the city of Delhi and in the north Indian states (Menski 1998, xiv). Government statistics are much more conservative, claiming that husbands and in-laws angry over small dowry payments killed nearly 7,000 women in 2001 (Brooke 2003). Although the absence of accurate figures do not allow a

comparison of dowry deaths in India with domestic violence in Western developed nations, feminist scholar Uma Narayan suggests that dowry murder rates in India are “roughly similar” to rates for domestic violence murders in the U.S. (Narayan 1997, 99). This means that the shocking and horrific incidents of murder over dowry, which attract the news media, must be seen in the context of patterns of domestic abuse of women in patriarchal societies. The dowry is very much a canvas on which male power and status are portrayed. The dowry enables the bride’s father to publicly demonstrate his wealth and the groom publicly to confirm his own worth. These factors are the cultural context that drives the practice of dowry, even among wealthy Indian families who live outside of “traditional” India (Menski 1998, 163-174).

[Dowry murders are but one example of domestic violence; the more commonly occurring example would be wife beating: “Indeed, the term dowry has become a euphemism for wife-battering, a practice so familiar that such violence has become a key issue in practically all movements in which women have been active” (Kumar 1997, 116). The widespread occurrence of wife beating suggests that its dynamics of intimidation and submission are accepted as emblematic of husband-and-wife relations across much of the populace. Emergency measures, such as Western-style battered women’s shelters, have been proposed, but their usefulness has been questioned, because of the pervasive attitude in Indian society that an unmarried woman is an object of shame. However, there are counseling and service centers for abused women in the major cities of India, including Delhi, Mumbai (Bombay), Chennai (Madras), Bangalore, and Calcutta. Since the mid-1970s, women’s groups have held demonstrations, rallies, public denunciations of suspect families, and street plays to combat accepting attitudes toward domestic violence. One of the most active has been the Stri Sangharsh in Delhi, “whose campaign made dowry murder a household term” (Kumar 1997, 118). (*End of update by K. Pechilis-Prentiss*)]

[*Update 2000*: R. B. Ahuja, a surgeon and secretary of the National Academy of Burn Doctors in India, estimates that three-quarters of the injuries he sees are the result of deliberate wife-burning associated with dowry and the pervasive acceptance of wife-beating. Perhaps a quarter of the injuries he sees are the result of true accidents caused by the cheap pump-action kerosene stoves used mainly by the urban poor. Although all admit that the official statistics on burn “accidents” are hardly reliable, the fact that 1,280 men died of kitchen accidents, out of an official total of 7,165 kitchen deaths in 1988, would seem to lend credence to a role for the common, explosively dangerous but affordable pump-action kerosene stoves. While recognizing the problems of domestic violence and dowry-burnings, some activists are also calling for immediate government action to improve the safety standards for manufacture of these stoves (Diwan 2002; Dugger 2000; Grover 1990; Mukherjee 1999; Oldenburg 2002; Sen 2002; Weinberger-Thomas 1999). (*End of update by R. T. Francoeur*)] (See also Sections 1C, Basic Sexological Premises, General Concepts of Sexuality and Love, and 2A, Religious, Ethnic, and Gender Factors Affecting Sexuality, Source and Character of Religious Values.)

## B. Prostitution

Prostitution, the indulgence in promiscuous sexual relations for money or other favors, is an age-old institution in India. Purchasing young girls and dedicating them to temples, the Devadasi system, was an established custom in India by 300 C.E. These girls often served as objects of sexual pleasure for temple priests and pilgrims. The current knowledge

about female sex workers is mostly gained from studies done in the red-light districts of metropolitan cities. Generally, prostitutes tend to come from the less-educated class of women, including single abandoned girls, and economically distressed women. Some of the studies on prostitutes in India revealed that a majority of them had STDs, tuberculosis, chronic infections, anemia, scabies, and parasite infestation. Most of them were treated by the local medical practitioners, who are quacks in their profession. Most of these women were either forced by gang members and others to take up this profession or were betrayed with false promises of a job. Both the central government and the state governments have enacted statutes to repress and abolish prostitution. The central act, the Suppression of Immoral Traffic in Women and Girls Act (SITA), 1956, has been amended as the Immoral Traffic (Prevention) Act (ITPA), 1956. However, these statutes have made little impact on the increasing traffic in persons and sexual exploitation and abuse (Pawar 1991).

[*Update 1997*: According to investigative reporter Robert I. Friedman (1996), there are more than 100,000 female commercial sex workers in Bombay, which he describes as “Asia’s largest sex bazaar.” In all of India, there are as many as 10 million commercial sex workers. According to human rights groups, about 90% of the Bombay prostitutes are indentured servants, with close to half trafficked from Nepal. One in five of Bombay’s sex workers are under age 18—the government is aware of child prostitution, but generally ignores the problem. Child sex workers as young as 9 are sold at auctions, where wealthy Arabs from the Persian Gulf compete with wealthy Indian males who believe that having sexual intercourse with a virgin cures syphilis and gonorrhea. A major motivation in the bidding for and slavery of child virgins is the fear of AIDS. In this context, child virgins often bring up to 60,000 rupees, the equivalent of US\$2,000. (See also HIV/AIDS discussion in Section 10).

[The commercial sex district of Bombay is actually two interconnected neighborhoods in the south-central part of the city, approximately three square kilometers (about 1+ mi<sup>2</sup>) sandwiched between immense Muslim and Hindu slums. It is also the home of the largest organized crime family in Asia. This red-light district is well served by two major railway stations just a half-kilometer away, and 25 bus routes. The district is laid out with 24 lanes of wooden-frame brothels with gilded balconies interspersed with car repair shops, small restaurants, liquor stores, 200 bars, numerous flophouses, massive tenements, three police stations, and a municipal school from which only 5% of the students graduate.

[Two thousand *hijra* work on Eunuch Lane. Dressed in short black leather skirts or saris, they are virtually indistinguishable from the female prostitutes, except many are extremely beautiful. Shilpa, a 30-year-old social worker with five years experience working in the red-light district, provides a fair description of this aspect of Bombay’s sex workers:

[The eunuchs, or hijras, have deep roots in Hinduism. As young boys they were abandoned or sold by their families to a sex cult; the boys are taken into the jungle, where a priest cuts off their genitals in a ceremony called *nirvana*. The priest then folds back a strip of flesh to create an artificial vagina. Eunuchs are generally more ready to perform high-risk sex than female prostitutes, and some Indian men believe they can’t contract HIV from them (quoted by Friedman 1996, 14).

[Female sex workers are often harassed by the police, although their madams pay the police weekly bribes to look the other way. To protect themselves, each girl services several police for free.

[Though on average the girls see six customers a day, who pay between \$1.10 and \$2 per sex act, the madam gets the money up front. By the time the madam deducts for food, electricity, and rent, as well as payment—with interest—on her purchase price, there is almost nothing left. So to pay for movies, clothes, makeup, and extra food to supplement a bland diet of rice and dal, the girls have to borrow from moneylenders at an interest rate of up to 500%. They are perpetually in hock (Friedman 1996, 16).

[Bombay's flesh trade is an efficient business, controlled by four separate, harmonious crime groups. One group controls police payoffs, a second controls money-lending, and the third maintains the district's internal law and order. The fourth group, the most powerful, manages the procurement of women in a vast network that stretches from South India to the Himalayas (Friedman 1996, 18). (End of update by R. T. Francoeur)]

### C. Pornography

All forms of sexually oriented publications are illegal in India. The government-appointed Central Board has the power to make cuts or ban the indecent or obscene scenes in films. Although pornographic books, magazines, and videos are illegal, their display and sales are casually noticed in urban areas, especially in the major cities.

## 9. Contraception, Abortion, and Population Planning

### A. Contraception

#### *Contraception and Population Control*

As wide differences exist among different regions of the country, the population distribution is also not uniform among these regions. Despite the wide variations of existing customs, beliefs, and socioeconomic development among India's 866 million, the people generally favor a large family size and therefore are not in favor of adopting modern methods of contraception. India is the first country in the world to realize the importance of controlling the population growth and therefore initiated the Family Planning Program as far back as 1952.

There are nearly 145 million married couples with wives in the reproductive age group of 15 to 44 years. Assessment of the Family Planning Program performance reveals that nearly 40% of the eligible couples were effectively protected by one of the contraceptive methods. The Family Planning Program in India is being promoted on a voluntary basis as a people's movement in keeping with the democratic tradition of the country. The services of the program are offered through Health Care Delivery System. The program makes extensive use of various mass-media sources including television, radio, newspapers, posters, and pamphlets, besides interpersonal communication, in its strategies for explaining the various methods of contraception and removing the sociocultural barriers that work against the program.

Since the majority of the population lives in rural areas, which lack a good infrastructure of healthcare facilities and an adequate Social Security System, these people almost universally perceive children and large families as an asset. Added to this is a strong preference for a son that acts as a barrier in limiting the family size. In spite of the availability of various contraceptive methods like sterilization, IUD, condoms, hormonal pills, and other temporary methods, the adopters of the program mostly opt for sterilization, more often tubal ligation or tubectomy.

Because of widely varying customs, beliefs, and the very low level of involvement of the wife in the decision-

making process, it is the women who ultimately are adopting the method of contraception. It is not surprising to know in a male-dominated society, especially in rural areas, that people generally perceive that the program is mostly meant for the womenfolk, as they are bearers of the children. Some common beliefs, like "using a contraception reduces a man's masculinity" and "contraception impairs the health of working men," also acts as a barrier for the adoption of the program by men. Methodwise data of adopters generally reveals that the temporary methods are mostly utilized by people with relatively high educational backgrounds and those living in urban areas. The condom, a simple reversible and nonchemical method of contraception, is widely accepted by couples in the younger age group, mostly for spacing pregnancies.

The government has adopted a primary healthcare approach that uses various indigenous and local medical practitioners, traditional birth attendants, and religious and community leaders as change-agents in convincing the eligible couples to adopt family planning. The medical termination of pregnancy, which is legalized in the country, is also considered as one of the methods of family planning. In spite of vast investments in a supportive infrastructure and manpower, the achievements of the Family Planning Program have fallen short of its targets. Rigorous efforts are needed to implement the program more effectively.

#### *Selective Female Abortion and Infanticide; Unbalanced Sex Ratios*

Census counts in India have shown a disturbing pattern, moving from 972 females for every 1,000 males in 1901, to 934 in 1981 and 927 in 1991. In Haryana, a populous northern state surrounding Delhi, there were only 874 females for every 1,000 men, an unprecedented disproportion.

A law passed in 1994 by the Indian Parliament provides penalties of three years in prison and a fine of about \$320 for those found guilty of administering or taking prenatal tests—mainly ultrasound scans and amniocentesis, solely to ascertain the sex of the fetus. The new law focuses on hospitals and clinics, but leaves the operators of mobile van clinics outside the law's purview. Charges for fetal screening tests can run as low as 150 rupees, about \$5, in poor rural areas ten times as much or more in more-affluent urban areas. Under Indian law, ending a pregnancy only because the fetus is female was illegal even before the 1994 law was enacted, even though the practice remains common. No reliable figures are available on the number of abortions performed every year solely to prevent the birth of girls. But, with some clinics in major cities like Delhi and Bombay admitting to conducting as many as 60,000 sex-determination tests a year, child welfare organizations estimate the nationwide figure at tens of thousands every year, possibly higher (Burns 1994).

Another concern among women's groups has been the fear that curbing sex-determination tests will drive many families back to the centuries-old practice of killing baby girls soon after birth, or so favoring boys with scarce supplies of food that girls die young. In a 1993 survey conducted by the National Foundation of India, a private group working on child welfare issues, it was estimated that 300,000 newborn girls die annually from what it called "gender discrimination" (Burns 1994).

[Update 2000: A United Nations survey of six nations bordering India, namely Pakistan, Bangladesh, Nepal, Sri Lanka, Bhutan, and the Maldives, published in 2000, revealed some 79 million women were "missing" in South Asia, because parents practiced female infanticide or used ultrasound scans and amniocentesis to selectively abort female fetuses. Most likely, India has a shortage of females

similar to that reported in its six neighbors and the 40 million shortfall recently acknowledged in China. (*End of up-date by R. T. Francoeur*)]

## B. Teenage Pregnancies

Sexual activity at an early age but within marriage is common in India. The most obvious health risk of teenage sex among the young is pregnancy for girls who are not yet physically matured. Further, if the pregnancy is unwanted or illegitimate, the health hazards are likely to be compounded by the social, psychological, and economic consequences. In their study of infant and childhood mortality, K. Mahadevan et al. (1985) found that the mean age of women at first conception was only 16 years; further, they found that infant mortality was very high for the first, followed by the second birth order, and then tapered down subsequently. The findings reveal that the high incidence of infant mortality among the first two birth orders may be mainly because of teenage pregnancy and childbirth. In traditional societies where mothers marry young, there is family support for the young parents, although medical risks remain high. But in today's transitional society, the family support is gone, and many times, the teenage pregnancies lead to abortion and thus have dangerous consequences.

## C. Abortion

Abortion is not considered a method of contraception in the strict sense, although it is treated as one of the methods of family planning because of its dramatic impact on birthrates. The Medical Termination of Pregnancy Act (1971) has great importance. Attempts are continuously made to induce all women seeking abortion to accept a suitable method of family planning, although abortion is mostly advocated on health grounds. The main health reasons for recommending an abortion are: (1) when continuance of the pregnancy would involve a risk to the life of the pregnant woman or of grave injury to her physical or mental health; and (2) when there is a substantial risk that the child, if born, would suffer from such physical or mental abnormalities as to be seriously handicapped. Since the inception of the 1971 Act, the annual number of abortions is around 7.6 million. Despite the legalization of abortion, the lack of trained health personnel and termination by local *Dais* who abort by using unscientific instruments, the death rates for women who have undergone termination of their pregnancies are also high, especially in the remote rural and tribal areas. It is also observed that young unmarried girls who experience a premarital pregnancy and approach unqualified charlatans seeking an abortion also experience similar high risks of mortality and morbidity. Though official statistics on these situations are not available, these situations are common, and their incidence may well be in an upward trend because of modernization and Westernization.

## D. Population Control Efforts

See the discussion above in Section 9A, Contraception.

### 10. Sexually Transmitted Diseases and HIV/AIDS

#### A. Sexually Transmitted Diseases

The spread of sexually transmitted diseases is affected by sexual promiscuity resulting from marital maladjustment, and in some distinct inadequacies in the social and economic life of India and its healthcare system. Gonorrhea, syphilis, and other sexually transmitted infections are major problems for young people, especially in urban India, where social change is rapid, marriage tends to be delayed, and traditional restraints on premarital intercourse are reduced. Many cases

of STD infections remain untreated, especially in the large urban areas, mainly because the sufferers do not know that they are affected, and also because they fear revealing their problem. The lack of scientific knowledge about the diseases among the infected also adds to the misery of the victims. In some communities, parents act as a major source of information on sex for their sons and daughters, but for most of the communities in India, sex is a taboo topic, and parents generally avoid communicating it to their offspring. Among most of the young people in India, even in urban areas, ignorance of the most basic facts about sexuality, conception, and contraception still continues to be the norm. The combination of the rapid social change in India and the ignorance on the basic information about sexuality are creating major and widespread health problems for the young generation.

#### B. HIV/AIDS

The first confirmed evidence of AIDS infection in India came in April 1986, when six prostitutes from Tamil Nadu tested positive for HIV antibodies. Subsequent findings indicate that between October 1, 1985, and September 30, 1993, a total of 459 AIDS cases have been detected in India, of which 444 are Indians and 15 are foreigners. Data available in early 1995 indicate that, thus far, 1,898,670 persons have been screened for the HIV virus, and 13,254 were found positive to HIV by the Western-Blot test. The seropositive rate is 6.98 per 1,000.

An indication of the population at risk for HIV infection can be found in the millions of STD cases occurring in the country. In addition to being a marker for behavioral vulnerability to HIV infection, untreated STD cases facilitate HIV transmission. In Pune, the HIV infection rate among people seeking treatment for STD has increased from about 9% in 1991 to 17% in 1992. An infection rate of up to 25% was reported in 1992 from surveys among prostitutes in Bombay. Meanwhile, there is little public support for or interest in promoting safer sex practices and condom use among the prostitutes, who are generally viewed as outcasts in India's caste-bound society and deserving of any ills that befall them. Among Bombay's estimated 100,000 prostitutes, the HIV rates shot up to 52% in 1994, from 2% in 1988. The sale of young girls into sexual slavery in the Persian Gulf complicates the situation (Burns 1996).

The prevalence of HIV infection among the 5 million long-route truck drivers is also very high. Health officials believe that the drivers are at the center of an imminent explosion of AIDS among India's 970 million people. The problem is evident at Petrapole, 75 miles (120 km) from Calcutta, on the main road between India and Bangladesh. While grimy trucks line up fender to fender for miles, often waiting a week or more to cross the Broken Boat River, thousands of drivers, helpers, and hawkers mix with local women and teenage girls willing to engage in sex for as little as 10 rupees, about 28 cents. It is common for these men to buy sex every day, and sometimes several times a day, while they wait. Researchers estimate that the truck drivers average 150 to 200 sexual encounters with sex workers a year. A single sex encounter can earn a woman enough to feed her family for a day. They seldom use condoms. In late 1996, experts estimated 30% of India's long-distance truck drivers were HIV-positive. The impact on the family is already evident. In a 1994 study by the National AIDS Research Institute in Pune, 100 miles (160 km) southeast of Bombay, 14% of the married women who reported no sexual contact with anyone other than their husband tested HIV-positive (Burns 1996).

The United Nations estimated that by the end of the 20th century, over a million Indians will be sick with full-blown

AIDS, and 10 million will be HIV infected. A quarter of the world's projected infected will be in India. Some Indian experts paint a still grimmer picture, estimating that between 20 and 50 million Indians will be infected by HIV by the year 2000. In this event, there will be more AIDS patients in India than there are hospital beds (Burns 1996).

While the principle mode for transmission of HIV infection in India is by heterosexual promiscuity, the prevalence of the disease is also high in intravenous drug users, who share syringes and needles, in Manipur state, in India's far northeast, bordering with Burma (Myanmar), Laos, and Thailand, where studies have been conducted by the field-practice unit at the surveillance center for HIV infection in Imphal. The results show that the situation in this area is different from the rest of the country, primarily because injectable heroin is easily available here. After the first seropositive case in Manipur appeared in 1989, HIV infections soared among drug users to 54% within six months. By the beginning of 1992, 1,600 HIV-positive cases had been detected, most of them being intravenous drug users.

Apart from unprotected sexual intercourse and intravenous drug injections, contaminated blood transfusion is one of the main sources of infection. In India, the sale of blood for transfusion and for preparation of blood products is a big business and subject to very little control. Estimates of the incidence of HIV-infected mothers transmitting the virus to their children during pregnancy and delivery show that every year, 20,000 out of 24 million deliveries in India are likely to occur in HIV-positive women (Ramachandran 1992).

More than half of Bombay's sex workers are HIV-positive, according to Dr. Subhash Hira, an Indian-American, who runs an AIDS clinic in Bombay. Currently an estimated 5 million people in India are HIV-positive. Hira predicts that by the year 2000, as many as 20 million Indians will be HIV-positive. However, with the incidence of the virus currently doubling every year, it is more likely that the figure for HIV-infected people in India will be about 15%, or 160 million. This, according to Dr. I. S. Gilada, a leading Indian expert on AIDS, could bring a collapse in India's economy, set the country back at least 50 years, and pull it "into a black hole of despair unlike anything seen in this century" (quoted by Friedman 1996, 12). India's national politicians and public health officials refuse to recognize or discuss this crisis, often considering sex workers as an expendable commodity.

The government has proposed to set up a resort for AIDS Rehabilitation and Control as a preparatory measure to cope with the AIDS threat looming large over the Indian horizon. However, the nation's annual AIDS budget is only about \$20 million, or slightly more than two cents a person. Despite an \$85 million World Bank loan to set up a national AIDS control organization, India's expenditures for the control of AIDS is woefully inadequate. In late 1996, with only a year of the program left to run, only \$35 million of the \$85 had been spent (Burns 1996).

Opponents of spending money on AIDS prevention, including many politicians and other opinion makers, argue that the government should give top priority to controlling diseases like malaria and tuberculosis, which kill tens of thousands of Indians every year. In a nation which spends six tenths of 1% of its \$50 billion annual budget on all healthcare, there is little money for educational publicity and free condoms. Some programs have been able to distribute packets of four condoms at two rupees (three cents), about half the usual cost. There is no money for AZT and other drugs (Burns 1996).

Although the HIV virus apparently did not begin to circulate in the Indian subcontinent until about a decade after it

arrived in the United States, where the disease was first recognized in 1981, the virus has spread much more rapidly in India than elsewhere. According to a July 1996 report at the 11th international meeting on AIDS, well over three million Indians were HIV-positive. This number easily surpassed South Africa with 1.8 million cases, Uganda with 1.4 million, Nigeria with 1.2 million, and Kenya with 1.1 million.

[Update 2001-2003: According to an October 2000 report from the United Nations, India had 3.7 million persons with AIDS and 34 million HIV-infected persons. Fourteen million had already died of AIDS. Assuming that treating an AIDS patient will cost 18,000 rupees or US\$386 per month, Prakash Kothari, a prominent Indian doctor, has argued that even the most innovative budget planning could soon be useless unless India's government begins to take the AIDS crisis as serious as it takes its arch-enemy Pakistan: "There will simply be no resources available to finance anything else in this country of ours." Part of the solution, Kothari argues, could be to create a "Ministry of Sex" that would put dealing with the AIDS crisis on a par with national defense. Meanwhile, officials in the Indian state of Patna, on the border of Nepal, are so concerned about the rise of HIV/AIDS that they distribute free condoms at all transit points to Nepal and at truck stops along the National Highways and Grand Trunk Road. Health officials adopted the plan because truck drivers coming from the northeastern states are reported to indulge in multipartner sex without using condoms.

[Also, in late 2002, a special National Intelligence Council meeting convened by the independent Center for Strategic and International Studies identified India, Nigeria, Ethiopia, China, and Russia as countries facing devastation by a second wave of HIV/AIDS infections in the next decade (see Table 1). Analysts at the meeting predicted famines, civil war, economic reversals, and a collapse of social and political institutions in these countries by 2010 (Garrett 2002).

[The head of India's national AIDS program, Meenakshi Datta Ghosh, denounced the intelligence report as "alarmist," but admitted that at least four densely populated states already had infection rates above 1% of all pregnant women. India has set ambitious goals for its AIDS programs, but the country lacks a coherent infrastructure for implementing prevention and treatment efforts. At least two AIDS epidemics are raging in the world's second most populous nation. The first, centered in the south and west, is heterosexual, fueled by India's large prostitution industry, while the second, focused in the far eastern provinces, is an intravenous drug use-driven epidemic. If India's programs can be solidified, Ghosh projected that by 2006, the country will have 9 million people living with HIV. If those programs remain fragmented, the number could reach 14 million, with 1.9 million deaths annually by 2002 and 20 million to 25 million

**Table 1**

**Leaders in an Expanding Pandemic: Current and Projected HIV/AIDS-Infected Adults**

	Current Number Infected		2010
	Government Data (millions)	Expert Estimates (millions)	Expert Estimates (millions)
India	4.0	5 to 8	20 to 25
Nigeria	3.5	4 to 6	10 to 15
Ethiopia	2.7	3 to 5	7 to 10
China	0.80	1 to 2	10 to 15
Russia	0.18	1 to 2	5 to 8

HIV-positive Indians by 2010, or 4% of the nation's adults (Garrett 2002). (*End of update by R. T. Francoeur*)

[*Update 2003*: When the first case of HIV was discovered in Chennai in 1986, the Indian Government responded to it immediately. Under the Ministry of Health and Welfare, the Indian government constituted a committee in 1987. The land of *Kamasutra* was suddenly under the surveillance. HIV levels were high amongst sex workers and STD clinic attendees. The spread of HIV within India is as diverse as the societal patterns between its different regions, states, and metropolitan areas. India's socioeconomic status, traditional social ills, cultural myths on sex and sexuality, and a huge population of marginalized people make it extremely vulnerable to the HIV/AIDS epidemic. In fact, it has become the most serious public health problem faced by the country since the Independence.

[HIV infection in India is currently concentrated among poor, marginalized groups, including commercial sex workers, truck drivers and migrant laborers, men who have sex with men, and injecting drug users. Transmission of HIV within and from these groups drives the epidemic, but the infection is spreading rapidly to the general community. The epidemic continues to shift towards women and young people, with about 25% of all HIV infections occurring in women. This also increases mother-to-child HIV transmission and pediatric HIV.

[In India, as elsewhere, AIDS is perceived as a disease of "others"—of people living on the margins of society, whose lifestyles are considered "perverted" and "sinful." Discrimination, stigmatization, and denial are the expected outcomes of such values, affecting life in families, communities, workplaces, schools, and healthcare settings. Because of HIV/AIDS, appropriate policies and models of effective prevention remain underdeveloped. People living with HIV and AIDS continue to be burdened by poor care and inadequate services, while those with the power to help do little to make the situation better.

[India is in some respects a *gendered phenomenon*. Women are often blamed by their parents and in-laws for infecting their husbands, or for not controlling their partner's urges to have sex with other women. Children of HIV-positive parents, whether positive or negative themselves, are often denied the right to go to school or are separated from other children. People in marginalized groups (female sex workers, *hijra* [transgenders], and gay men) are often stigmatized in India on the grounds of not only HIV status, but also for being members of socially excluded groups. (*End of update by A. Kadari*)

[*Update 2002*: UNAIDS Epidemiological Assessment: The first case of AIDS in India was detected in 1986. Since then, HIV infections have been reported in all States and Union Territories. With a population of one billion—about half in the 15- to 49-year-old population—HIV epidemics in India will have a major impact on the overall spread of HIV in Asia and the Pacific, as well as globally.

[The spread of HIV within India is as diverse as the societal patterns between its different regions, states, and metropolitan areas. The epidemics are focused very sharply in a few southern States, with most of India having extremely low rates of infection. An overwhelming majority of the total reported national AIDS cases—96%—were reported by only 10 of the 31 states. The major impact is being felt in Maharashtra in the west, Tamil Nadu in the south with adjacent Pondicherry, and Manipur in the northeast. The epidemics vary between states with heterosexually transmitted infections predominating in Maharashtra and Tamil Nadu, while infections concentrated among injecting drug users and their partners predominate in Manipur. With a high

prevalence of tuberculosis infection in India, the problem of tuberculosis related to HIV infection also poses a major public health challenge.

[Between 1994 and 1997, HIV prevalence among STD clinic attendees in Maharashtra state increased from 6% to 36%, and prevalence among injecting drug users in Manipur increased from 25% to 61%. However, there were insufficient numbers of sentinel surveillance sites to get an adequate picture of the overall HIV situation. In 1998, the number of HIV Sentinel Surveillance sites increased from 55 to 180: 83 for STD, 89 for antenatal clinics, and 8 for injecting drug users. HIV prevalence data were collected twice in 1998, February to March and August to October. The 1998 HIV sentinel surveillance data from antenatal clinics in seven metropolitan cities showed HIV prevalence to be over 2% in Mumbai, more than 1% in Hyderabad and Bangalore, and below 1% in Calcutta, Ahmedabad, and Delhi. HIV-prevalence levels outside these major urban agglomerations were in general lower, and no infection was found in a number of rural HIV Sentinel Surveillance sites.

[In late 1998, NACO convened a group of national and international experts to review the results of the first round of the expanded HIV Sentinel Surveillance to produce state-specific and national estimates on HIV/AIDS. The new calculations provide greater consistency in making a national estimate of HIV prevalence in India. The national prevalence estimate was increased for 2001 to 3.97 million.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	3,970,000 (rate: 0.8%)
Women ages 15-49:	1,500,000
Children ages 0-15:	170,000

[No estimate is available for the number of adults and children who died of AIDS during 2001.

[No estimate is available for the number of Indian children who had lost one or both parents to AIDS and were under age 15 at the end of 2001. (*End of update by the Editors*)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

### A. Concepts of Sexual Dysfunction

The concept of sexual dysfunction in the Indian context is defined differently with reference to the person's socioeconomic and demographic background. Generally, it is differentiated for men and women, young and old, rich and poor, and able-bodied and disabled persons.

### B. Availability of Counseling, Diagnosis, and Treatment

There are no legal or other restrictions on who may practice as a psychosocial or sexual therapist in India. Most of the persons with sexual problems who feel that they need some treatment, seek help related to their symptoms. What sexual therapy there is available deals with symptom relief and is generally regarded as successful if this is the outcome. Though there is no clear-cut, government-funded, psychosexual therapy services available in India, most of the health and family planning clinics provide one or more of these services to their clients. Counseling by some of the marriage counseling services, especially in cities, are also widely reported in the society. Quacks who pose as very knowledgeable in sexual therapy, and widely advertise about the effectiveness of their treatment, are commonly seen, especially in rural areas and small towns. Because many people do not understand the need for qualified training of sexual therapists, these fraudulent therapists and their

clinics attract many of those who need proper counseling, and cash in on their weaknesses.

A prevailing Victorian sexual repression, left over from colonial times, still makes it impossible for many married couples to function well sexually, or even to function at all. Sex clinics around New Delhi and other large cities typically cater mostly to men, and offer advice, hormone injections, and herbal remedies at a cost of up to about \$500 for a full course of treatment.

There is no organized data available on such incidences, nor on the effectiveness of their treatments. Moreover, with the topic of sex being a taboo in Indian society, people generally do not discuss their problems openly with others. In the process, they easily become victims of such quacks in their communities.

## 12. Sex Research and Advanced Professional Education

There is very little sexological research being carried out in India thus far. Very few institutions have concentrated any effort in this area of research or undertaken any formal program on this important topic. Although there is no graduate or postgraduate program on sexuality in any of the educational institutions, because of the recent widespread discussions of HIV/AIDS, sexually transmitted diseases, and a host of other problems like bride-burning and marital violence, there is a growing inclination to undertake research in the area of sexuality, and to impart proper sex education for the people in the society.

The National Institute for Research in Sex Education, Counseling and Therapy (NIRSECT) is the only official professional organization devoted to sexual research in India. Its address is: Saiprasad-C5/11/02, Sector-4, C.B.D. New Bombay, 4990615, India. The director is Dr. J. K. Nath, first author of this chapter.

Other important sexological organizations are:

Sex Education, Counseling, Research Training Centre (SECRT). Family Planning Association of India (FPAI). Fifth Floor, Cecil Court, Mahakavi Bhushan Marg, Bombay 400 039, India (Phone: 91-22/287-4689).

Indian Association of Sex Educators, Counselors, and Therapists (IASECT) 203 Sukhsagar, N.S. Patkar Marg., Bombay 400 007, India (Phone: 91-22/361-2027; Fax: 91-22/204-8488).

Parivar Seva Sanstha. 28 Defence Colony Market, New Delhi 110-024. (Phone: 91-11/461-7712; Fax: 91-11/462-0785).

## PART 1:

### NATIONAL AND URBAN PERSPECTIVES

WIMPIE I. PANGKAHILA and  
 J. ALEX PANGKAHILA

#### *Demographics and a Brief Historical Perspective*

ROBERT T. FRANCOEUR

#### A. Demographics

Located in the archipelago southeast of Asia along the equator, Indonesia comprises some 13,700 to 17,000 islands (depending on who does the counting). While only about 6,000 are inhabited, the island of Java is one of the most densely populated areas of the world. Besides Java, Indonesia includes four other major islands: Sumatra, the largest and most western of the Indonesian islands, Kalimantan (most of Borneo), Sulawesi (formerly Celebes), and the "Paradise Island" of Bali, as well as the western half of the island of New Guinea, formerly known as Irian Jaya. Indonesia's total area covers 741,100 square miles (1,919,440 km<sup>2</sup>) and is roughly three times the size of the state of Texas.

The mountains and plateaus on the major islands have a cooler climate than the tropical lowlands. In the eastern island of New Guinea, the mountain peaks may be snow-covered. The Indonesian archipelago lies southeast of the Asian mainland. Straddling the equator, Indonesia's neighbors are Malaysia to the north, Papua New Guinea to the

\**Communications:* Wimpie I. Pangkahila, M.D., Ph.D., The Master Program in Reproductive Medicine, Udayana University Medical School, Jl. Panglima Sudirman, Denpasar, Bali, Indonesia; wim@denpasar.wasantara.net.id. Ramsey Elkholy, Ph.D. (cand.), 105 Fifth Avenue, Apt. #6E, New York, NY, USA 10003; relkholy@hotmail.com.

\*\**Editor's Note:* The cultures of the eastern half of the island of New Guinea, the nation of Papua New Guinea, are covered under that nation by Shirley Oliver-Miller. In Part 1 of this present chapter, Wimpie L. Pangkahila and J. Alex Pangkahila provide insights into the national and urban perspectives of sexuality in Indonesia. In Part 2, Ramsey Elkholy reports on the Indonesian Orang Rimba minority group. Elkholy's report on Indonesian New Guinea and Oliver-Miller's discussion of the many indigenous groups of Papua New Guinea offer some interesting complementary insights.

east, Australia to the south of its western islands, and the Indian Ocean to the west. Situated in a part of the "ring of fire," Indonesia has the largest number of active volcanoes in the world. Earthquakes are frequent. The "Wallace line," a zoological demarcation, divides Indonesia, marking the separation of Asian and Australian flora and fauna.

In July 2002, Indonesia had an estimated population of 231.32 million. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 30.26% with 1.05 male(s) per female (sex ratio); 15-64 years: 65.11% with 1 male(s) per female; 65 years and over: 4.63% with 0.78 male(s) per female (2000 est., *The World Almanac and Book of Facts* 2000)

**Life Expectancy at Birth:** Total Population: 68.63 years; male: 66.24 years; female: 71.13 years

**Urban/Rural Distribution:** 36% to 64%

**Ethnic Distribution:** Javanese: 45%; Sundaese: 14%; Madurese: 7.5%; coastal Malays: 7.5%; Minahasans, Balinese, Bataks, Dayaks, Timorese, Papuans, Chinese, Arabs, Indians, Europeans, and other: 26%. Indonesia has more than 300 ethnic groups, most of which are very small minorities. Some very small ethnic groups still live in the jungles where they maintain their traditional cultures. Part 2 of this chapter examines the sexual culture of the indigenous hill tribe of the Orang Rimba. Each ethnic group has its own culture and language. Fortunately, there is one Indonesian language as a national language, so that people of the different ethnic groups, with the exception of small geographically isolated peoples, can usually communicate with each other.

**Religious Distribution:** Muslim: 88%; Protestant: 5%; Roman Catholic: 3%; Hindu: 2%; Buddhist: 1%; other: 1% (1998 est.)

**Birth Rate:** 21.87 births per 1,000 population

**Death Rate:** 6.28 per 1,000 population

**Infant Mortality Rate:** 39.4 deaths per 1,000 live births

**Net Migration Rate:** -0.21 migrant(s) per 1,000 population

**Total Fertility Rate:** 2.54 children born per woman

**Population Growth Rate:** 1.54%

**HIV/AIDS** (1999 est.): Adult prevalence: 0.05%; Persons living with HIV/AIDS: 52,000; Deaths: < 3,100. (For additional details from www.UNAIDS.org, see end of Section 10B.)

**Literacy Rate** (defined as those age 15 and over who can read and write): 83.8%; (male: 89.6%, female: 78%) (1995 est.); attendance for nine years of compulsory school: 95% (education is free and compulsory from age 6 to 15)

**Per Capita Gross Domestic Product** (purchasing power parity): \$3,000 (2001 est.); Inflation: 9%; Unemployment: 15% to 20%; Living below the poverty line: 27% (1999 est.)

Indonesia is a developing country with major problems in the social, political, and economic areas. Most people still have a low-subsistence standard of living. However, the small middle- and upper-class populations have a very good standard of life. Some Indonesian businessmen even have their companies in some other countries. This means that there is a wide gap between the poor, as the majority, and the rich, as a very small part of the population. It is estimated that the country will join the developed countries in the near future.

## B. A Brief Historical Perspective

It is generally believed that the earliest inhabitants of the Indonesian archipelago came from India or Burma (Myanmar). Later immigrants, known as Malays, came from

southern China and Indochina. This later group is believed to have populated the archipelago gradually over several thousand years. Hindu and Buddhist civilizations reached Indonesia about 2,000 years ago, taking root mainly on the island of Java. In the 15th century, Islam was spread by Arab traders along the maritime trade routes and became dominant in the 16th century.

In the 17th century, the Dutch replaced the Portuguese as the dominant European power in the area. The Dutch gained control over Java by the mid-1700s, but the outer islands were not subdued until the early 1900s, when most of the current territory of Indonesia came under Dutch rule. On the other side, the Dutch and the Portuguese also brought Christianity to the Indonesian people.

After the Japanese occupation of 1942-1945, nationalists fought four years until the Dutch granted Indonesia its independence. Indonesia declared itself a republic in 1945. In 1957, Indonesia invaded Dutch-controlled West Irian (the western half of New Guinea); in 1969, tribal leaders voted to become part of Indonesia, a move sanctioned by the United Nations.

Indonesia also invaded and annexed East Timor in 1975-1976, as Portuguese rule collapsed. However, this annexation brought many internal social, economic, political, and security problems and tensions in Indonesia's international relations. After the fall of President General Soeharto in 1998, the transitional president, B. J. Habibie, proposed East Timorese vote on two options: independence or integration as a part of Indonesia. Through a self-determination vote under United Nations supervision in 1999, the East Timorese decided to be independent from Indonesia. The level of unrest and violence remains high in East Timor.

In the same year, the Indonesian people held the most democratic general election to that time to choose the people's representatives in the Parliament and Assembly. Through the Assembly, Indonesian people now have a legitimate president, K. H. Abdurrahman Wahid, and vice president, Megawati Soekarnoputri, for the period 1999 to 2004. This, however, does not mean that the country has already been freed from its major problems. These economic, political, and security problems are the major problems faced by Indonesians under the new legitimated government.

## 1. Basic Sexological Premises

### A. Character of Gender Roles

In traditional Indonesian society, women clearly occupy a lower social status than men. This is still the dominant value in Indonesian culture. The idea that a female's place is in the kitchen is still easy to find, especially in the villages. The husband-wife relationship is a chief-assistant relationship rather than a partnership.

Nevertheless, the role of women is improving in modern Indonesian society. Many women work outside the home, particularly in restaurants and in garment and cigarette factories, even though their wages are lower than those of males. Many female physicians, notaries, and lawyers are found in modern Indonesian cities. A few women have achieved high political positions as Cabinet and Parliament members. Vice President Megawati Soekarnoputri, elected in 1999 by the people's representatives in the most democratic general election, is a female.

In modern Indonesian society, the husband-wife relationship is also improving, with a gradual shift to a partnership. Husbands increasingly treat their wife as a partner rather than as an assistant. It is no longer strange to see a husband taking care of his baby while his wife is working outside the home. Unfortunately, this improvement mostly

occurs in well-educated couples, which are only a small part of the population. Furthermore, sometimes the change of the husband-wife relationship results in the disharmony of the relationship, mostly because of the negative response of the husband. For example, the husband will feel unhappy if his working wife's salary is more than his, or he will get angry if his working wife does not prepare dinner for him (Blackburn 2000; Hancock 2000; Robinson 2000).

## B. Sociological Status of Males and Females

From the standpoint of national law, males and females enjoy the same rights in schooling and careers. However, in some areas, traditional and cultural laws discriminate against females. Only males, for instance, have a right to receive a legacy from their parents. This contributes to a higher status for males.

Another consequence of traditional values is that parents insist on having a son, even though the government has proclaimed a limit of only two children per family, regardless of sex. Many women come to clinics seeking male-sex preselection, even though there is no method that can give a 100% guarantee of having a male child.

In many families, parents give special treatment to the son over the daughter. For example, parents are more likely to support higher education for a son than they would for a daughter. This is based on the stereotype that females will ultimately end up working in the kitchen, while males, as the chief of the family, will work hard to gain money.

Another more serious consequence of the traditional law is that males feel they have a higher social status, and therefore feel more powerful than females. This effect appears in the relationship between a husband and wife where the husband feels he has power over the wife and acts as a chief in the family. Husbands also feel free to do what they want, including having sexual intercourse with other women.

However, among the Miharg Kabou of West Sumatra, females have a higher status than males. Unlike other regions of Indonesia where the male courts the female, Miharg women court the men (Blackburn 2000; Hancock 2000; Machali 2000; Robinson 2000).

## C. General Concepts of Sexuality and Love

Traditionally, Indonesian women connected sexuality with love and engaged in sexual activities only with the males they loved, specifically their husbands. A woman, it was believed, was not able to have sex with a male unless she loved him. In contrast, the traditional view fully accepted males as having sex with any female they liked. In essence, females were only sexual objects, designed for male pleasure.

This traditional view is changing in modern Indonesia. For many, sex and love are easy to separate and are frequently viewed as two different things. Many females, especially among the young, want to engage in sexual intercourse with anybody they like without the necessity of loving that person or without any interest in marriage. This concept, of course, is not well received by the older generation.

This concept change does not seem to occur only in the large cities, but also increasingly in the villages. Some studies performed of the young of the villages showed that there is no significant difference in sexual behavior between the young in the village and in the city. The difference is only in the physical environment and other circumstances that facilitate or permit sexual intercourse. Whether in the city or in the village, the young have the same perceptions about pregnancy, abortion, and family planning. The sexual knowledge and behavior of the young seem to be a new dimension, which is separated from the settings and culture of traditional social organization, family, and religion. The opinion

that the village is a traditional and homogeneous community, which holds strongly the cultural and religious norms and is not easy to change, is no longer a reality.

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A. Source and Character of Religious Values

During the first few centuries of the Christian era, most of the islands came under the influence of Hindu priests and traders, who spread their religion and culture. Muslim invasions began in the 13th century, and most of the area was Islamicized by the 15th century. Today, 88% of Indonesians are Muslim, with Hindu, Buddhist, and both Protestant and Catholic Christian minorities. There is a commendable degree of religious tolerance among the people.

Evidence of the Hindu influence can be found in some large ancient temples, like Borobudur, Prambanan, Mendut, and Kali Telon in Middle Java, and Jago temple in East Java. The temple in Borobudur is ranked by many as one of the seven miracles in the world. Many reliefs in the walls of these temples portray erotic themes. In the wall of the Kali Telon temple, for example, there are relief figures of males and females having sexual intercourse. In the Mendut temple, people can see in relief figures a scene of a male and female petting.

Christian Portuguese traders arrived early in the 16th century, but were ousted by the Dutch around 1595. In the early 1800s, the British seized the islands, but returned them to the Dutch in 1816. After the end of the Japanese occupation and World War II, Indonesia declared its independence from the Dutch.

In the past, conservative religious and cultural values had a strong influence on sexual attitudes and behaviors. For instance, it was taboo for male and female adolescents to walk together in public. A daughter who became pregnant before marriage created disastrous consequences for her whole family.

However, the influence of religious and traditional cultural values has decreased in recent decades, most noticeably since 1980. This decrease can be seen in the fantastic changes in the sexual attitudes and behaviors of the people, especially among the young. The widespread distribution of contraceptives, which the government initiated as a national program in 1970, brought many changes in the sexual attitudes and behaviors of the people.

The incidence of abortion among the young, which is estimated at around one million per year in the whole country, shows that the strength of religious values has decreased in today's Indonesian society. On the other hand, attendance for all the different religious services is very high.

### B. Character of Ethnic Values

Each ethnic group has its own culture and sexual values. The Javanese, Sundanese, Minahasans, and Balinese, for instance, are more "modern" than the Dayaks and Papuans. In general, however, sex is considered something private and even secret. Sex is appropriate only between husband and wife. Women are like maids; they are only for their husbands' benefit. Wives are subservient to their husbands in everything, including sexual contact.

In a certain Javanese art community of East Java, known as the Reog Ponorogo, some men engage regularly in homosexual behavior, because they believe that they have supernatural powers that will disappear if they have sexual contact with women. These men, known as *waroks*, take care of young males called *gemblaks* who are treated as females. *Waroks* engage in homosexual intercourse with *gemblaks* instead of with females.

In relation to supernatural belief or culture, in a certain community sexual intercourse is practiced as a part of ritual. Many people, hoping to receive a blessing, visit a cemetery on Mount Kemukus in Central Java. However, to receive the blessing the visitors must fulfill one erotic condition. The condition is that the visiting petitioners have to engage in sexual intercourse with each other. They are forbidden to have sex with their own partners during the visit to the sacred cemetery. The other condition is that the sexual intercourse must be done in seven visits with the same partner. It is hard to imagine hundreds of couples having intercourse in the open air under the trees covered with clothes. This cemetery is still visited today by many people from different places, and the free sex among the sacred cemetery visitors continues to the present.

In certain isolated ethnic groups living in remote areas, there is a custom whereby a man may borrow another's wife. This custom is based on the fact that the number of females in the group is very limited and out of balance with the number of adult males. This custom allows a man to enjoy the other man's wife for a few days, but after that, he has to bring her back to her husband.

In today's globalization trends, sexual attitudes and behaviors are changing rapidly in all the cultures of Indonesia. Premarital sex, for example, is now common among adolescents. Even premarital pregnancy is easy to find and, for many parents, it no longer has the disastrous consequences it did only a generation or two ago.

There is a homogenous tendency in sexual perception, knowledge, and behavior, especially among the young, which crosses the ethnic and religious boundaries.

### 3. Knowledge and Education about Sexuality

#### A. Government Policies and Programs

Sex education is not a priority in the government's program. Until the year 1999, school curricula did not offer students any education on sexual topics or issues. However, the Department of Education and Culture has recommended a book, *About the Sexual Problems in the Family*, by Wimpie Pangkahila, as a source of sexual information for high school students. This 152-page text, published in 1988, discusses many sexual problems that occur in Indonesian families as a result of misinformation, misunderstanding, and myths, such as the belief in the harmful consequences of self-pleasuring or the impossibility of pregnancy if sexual intercourse occurs only once a month.

The Indonesian Health Department and the National Coordinating Board of Family Planning have a program for Reproductive Health Education. This program, designed for young people, provides seminars on topics of reproductive and sexual health.

In recent years, some secondary high schools have introduced a small segment of sex education as part of their extracurricular offerings. Outside experts are invited to talk about sexuality in these seminars. The era of reformation in Indonesia has also changed the policy of the government on sex education. The new government, through the Department of Education and Culture, has legalized sex education for students under the title of "healthy reproductive education." Now sex education is formally a part of school curricula.

#### B. Informal Sources of Sexual Knowledge

Despite public reticence about sexuality, the Indonesian people are eager for and need more information about the subject—hence, the popularity of public and semi-private seminars on sexual topics. Many social organizations for young people and women sponsor seminars for their mem-

bers, with outside experts invited to speak about sexuality. The seminars are not only held in the big cities, but also in the small cities and suburbs.

Some magazines, newspapers, radio broadcasts, and TV stations also have columns or programs in which sexuality and sexual problems are discussed. Readers, listeners, and viewers write or call in asking about some sexual issue or problem they are facing or they want to know about. Television viewers can watch advertisements for condoms every day in the context of HIV/AIDS prevention.

With the advent of cyberspace, some Indonesian Web sites now offer popular sites for dialog about sexuality. The popularity of these sites among Indonesians makes it hard to believe the view of some people that sex is still a taboo topic among the Indonesian people.

## 4. Autoerotic Behaviors and Patterns

### A. Children and Adolescents

Autoeroticism is common among children in the phallic stage of their psychosexual development. Although some parents report that they watch their children pleasuring themselves to orgasm, many parents are afraid when they discover their children self-pleasuring because they believe this to be an abnormal act.

Autoeroticism is also common among adolescents as a way of tension release. One unpublished study by Wimpie Pangkahila found that 81% of male adolescents and 18% of female adolescents aged 15 to 20 years old engaged in self-pleasuring. Most reported using their fingers, sometimes lubricated with a liquid. Some rubbed against a pillow or mattress. Only a few females reported using a vibrator.

However, there is still considerable misinformation and misunderstanding about autoeroticism. Many adolescents still believe that autoeroticism or masturbation may result in various health problems, like decreased memory, erectile dysfunction, infertility, and decreased bone marrow.

On the moral side, many adolescents feel that autoeroticism is sinful. But they continue to practice this sexual activity. Questions about autoeroticism appear very often in many informal sources of information about sexuality, such as seminars, interactive Internet chat groups, newspapers, and radio programs. The questions are usually related to the consequences of autoeroticism for the practitioner's health.

### B. Adults

Autoeroticism is very common among adults, especially single adults. The pattern is the same as among adolescents. The use of sexual accessories, like various kinds of vibrators and doll partners, are becoming common even though these materials are still illegal. No legal sex shop can be found anywhere in the country, even in the larger cities. One sex shop did open early in 2000 in Surabaya (East Java), Indonesia's second largest city, but the police quickly closed it on the grounds that the sex shop did not have a license from the government and that such shops are contrary to Indonesian culture and morality. It is really difficult to understand such reasoning, especially when this episode triggered a flood of questions in various media—questions, such as "Why close a sex shop? Why don't the police shut down the prostitution?" However, some drug shops still sell those sex accessories illegally, and people can buy from them.

Masturbation among married men or women is practiced in certain situations, like when they stay apart from their partners, if they cannot reach orgasm by sexual intercourse, or if the partner is not able to engage in sexual intercourse for some legitimate reason. Some wives practice masturbation directly in front of their husbands after they have had sexual intercourse without reaching orgasm. A

few of them use vibrators or other sexual accessories, whereas others do not want to do it in front of their husbands. The result is that the husbands often do not know that their wives are not reaching orgasm by intercourse and are relying on masturbation for this.

Even though autoeroticism is very commonly practiced among both adolescents and adults, many people still believe that autoeroticism is morally wrong and will result in harmful physical and mental consequences.

## 5. Interpersonal Heterosexual Behaviors

### A. Children

Sexual exploration and sex rehearsal play are common among children as a natural part of their psychosexual development. However, many parents are afraid of such behaviors, believing that the child is suffering from some sexual abnormality or that this behavior will result later in life in some sexual abnormality. Some parents bring their children to psychologists to find out whether their child has had actual sexual intercourse.

Many adolescents are afraid of not being virgins because they had sex rehearsal play a long time ago during their childhood. Some of them even come to the clinic to make sure that they are still virgins. Others seek answers to their questions about childhood sexual rehearsal play and virginity from the dialog columns on sexuality in the newspapers.

### B. Adolescents

#### *Puberty Rituals*

Some ethnic groups, especially in the remote areas and among tribal people, have ritual ceremonies for adolescents. These ceremonies differ greatly from one ethnic culture to another.

In certain areas, there is a ritual ceremony for the female on the occasion of her first menstruation. This ceremony is actually a way to inform the community that this young female now has become an adolescent and is ready to marry. In one area in East Nusa Tenggara province, male adolescents have to practice sexual intercourse after they are traditionally circumcised. For practical reasons, these male adolescents tend to practice with sex workers. With the unhealed penile cut, this practice, of course, can result in transmission of STDs. This practice also poses a high risk factor for the transmission of HIV/AIDS. However, these ceremonies are no longer practiced in most modern areas of Indonesian society.

#### *Premarital Sexual Activities and Relationships*

Premarital sexual activities are still generally considered taboo. In general, older persons and parents oppose all sexual activities engaged in before marriage. However, during the past decade, there has been a change in sexual attitudes and behaviors among adolescents. Some small studies in a few Indonesian cities reveal a growing trend among adolescents to engage in premarital sexual activities, such as necking, petting, and even intercourse.

These sexual activities are also becoming common among adolescents in the villages and suburbs. Today, there is no significant difference in sexual perception and behavior between the young in the big cities and the villages.

However, knowing that parents and the older generation oppose premarital sexual activities, young people hide their activities from them. On the other hand, parents frequently give their children more opportunities to be alone with their boy- or girlfriends, and many adolescents take advantage of these opportunities for sexual activities.

In their sexual activities, oral sex is becoming popular among adolescents. There are at least two reasons why ado-

lescents prefer oral sex. First, with oral sex they can avoid the risk of premarital pregnancy. Second, the female feels secure, because oral sex leaves her hymen, a mark of her virginity, intact. A few adolescents engage in anal sex for the same reasons.

Unfortunately, the changes in sexual behavior, which tend to be freer today than in the past, are not accompanied by any increase in sexual knowledge. Most adolescents have many questions about their sexual lives and experiences, which, if expressed, bring negative responses from the older generation, who still believe that such questions are not appropriate for adolescents to inquire about. However, it seems that the general public tends to be more permissive of these changes. Of course, the lack of sexual knowledge results in some negative personal consequences for adolescent life: feelings of guilt and anxiety, unwanted pregnancy, abortion, and STD transmission.

[*Update 2003*: Alarmed by increasing teenage pregnancies in the 1990s, the Indonesian government started planning to incorporate sexuality education into courses such as biology. Similar concerns prompted NGOs, supported by the United Nations Population Fund (UNFPA), to train peers to provide reproductive health information and services to reduce the rate of unwanted teen pregnancies. UNFPA expanded its information and education materials to reach parents, policymakers, and community leaders, as well as teenagers. Under the theme "Having sex before marriage is not appropriate among youth," specific messages stress such issues as: "Responsible relationships between boys and girls," "The world of youth is free, but there are limitations," and "Youth must get correct and clear information about sexuality." The UNFPA and its cosponsors program use regional newspaper columns, a question-and-answer book on the 100 most-asked questions about adolescent reproductive health, leaflets, posters, stickers, calendars, and T-shirts, as well as radio and television talks for youth (UNFPA 2000). (*End of update by R. T. Francoeur*)]

### C. Adults

#### *Premarital Courtship, Dating, and Relationships*

Dating and premarital sexual relations among adults are very common in modern Indonesian society. The culture requires a particular kind of courtship when a couple wants to marry. In this courtship, the parents and family of the male approach the parents of the female to make the arrangements.

In some ethnic groups, a courtship document is signed when presents, such as cows, buffaloes, gold, and jewelry, are given. For many people in these groups, this custom is very expensive, because they need to save enough money to buy the presents for courtship. Presently, this custom is still practiced among certain ethnic groups, particularly those who live in the areas where they have little contact with outsiders. This custom actually implies that the male has bought and now owns the female.

However, traditional courtship customs are no longer practiced by people who live a modern lifestyle, especially those who live in big cities far from their original area. It is much more practical for them to abandon the traditional customs of courtship, which are both expensive and impractical. The simpler courtship custom of modern Indonesians calls for the parents of the young man to visit the parents of the young woman and agree to their children courting, but without expensive presents.

#### *Sexual Behavior and Relationships of Single Adults*

Self-pleasuring is a common sexual behavior among single adults, even though it is not allowed by religious and

moral values. Sexual relationships among male and female single adults are also taboo. However, some data show that many couples engage in sexual relations before they marry. A 1991 study by Wimpie Pangkahila suggested a rate of 53% for urban couples. Another unpublished study of rural, pregnant women found a premarital intercourse incidence of 27%.

This incidence is now believed to be much higher because of more-liberal relationships, between single adults and adolescents as well. The term “the other man or woman” has become very popular in the last few years. It is no longer a surprise if somebody is said to have a relationship with an extramarital partner.

Many single adult males have sexual contact with prostitutes. Prostitution exists in many places in Indonesia, whether it is legal or illegal. The range of services comes in various classes from low/cheap to high/expensive (see Section 8B, Unconventional Sexual Behaviors, Prostitution, below).

### *Marriage and Family*

Indonesia has had a marital code to regulate marriages since 1974. The law requires that a marriage be performed in a religious ceremony and then be registered in the civil act office for Christians, Buddhists, and Hindus. The marriages of Muslims are registered in the Muslim Religion Affairs Office.

Generally, marriage in Indonesia involves the families of both partners. It is uncommon for a marriage to be conducted without involvement of the families of both spouses. In case the families cannot agree for whatever reason, there are two choices for the couple. Adult couples who insist on marrying can arrange their own marriage. The other choice is to delay or cancel the wedding. Couples who insist on marrying, even though their families do not agree, usually attempt to repair their relationships with their families.

Divorce is prohibited in Christianity. However, Christian couples who want a divorce may apply to a state court for a civil divorce. In Islam, Hinduism, and Buddhism, divorce is allowed for certain reasons, mainly infertility and adultery on the part of the wife.

In some areas, the incidence of divorce is very high because of financial problems, family conflict, and infidelity. For example, in Lombok Island (West Nusa Tenggara Province) there are many young widows with or without children. Of course, this becomes a serious social problem in the society.

Extramarital intercourse is common, especially among males. Many married men seek prostitutes or have sexual relations with single or married women. Extramarital intercourse is also found among married women, but at a lower incidence than among husbands. Although married women do have sexual relations with single and married men, most people consider this as very bad and unacceptable behavior. In a typical, double moral standard, extramarital sex by males is considered something usual, even though it is forbidden by religion, local morality, and law.

### *Sexuality and the Physically Disabled and Aged*

Most Indonesians believe that sex is only for physically normal and young people. Most feel uncomfortable when a disabled or aged person still thinks about or expresses an interest in sexual activities. A disabled young woman wrote her complaint and protest in a newspaper because she was discriminated against by a dating and marriage service. The manager of the organization had refused her membership because she was a disabled person. The male manager mentioned that nobody would be attracted to a disabled female.

Even though there is discrimination against disabled persons, marriages do occur between disabled persons, or

between disabled and able-bodied persons. Some disabled and many aged people do come to sexual clinics with their sexual problems for counseling and treatment.

The misinformation that sexual intercourse should not be performed after menopause may lead a male with a postmenopausal wife to seek sex with another woman—prostitutes included. Erectile dysfunction is the most common sexual complaint of older males. On the other hand, pain during sexual intercourse is the most common sexual complaint of older females.

### *Incidence of Oral and Anal Sex*

Generally, Indonesians do not accept fellatio, cunnilingus, and anal sex as foreplay or sexual outlets. Most people consider these behaviors as abnormal or sinful. On the other hand, many people do engage in fellatio and cunnilingus, but not with their own spouses.

Many men seek out prostitutes only for fellatio, because their wives refuse to engage in it. Some women do like to have cunnilingus, but refuse to perform fellatio for their husbands. Still, many couples enjoy both fellatio and cunnilingus as a part of their normal sexual activities.

Fellatio and cunnilingus are becoming popular among the new generation as a sexual alternative to vaginal intercourse, and as foreplay as well. Generally, they decide to practice fellatio and cunnilingus after watching this behavior on pornographic cable television or on videocassettes. Very few couples engage in anal sex.

## *6. Homoerotic, Homosexual, and Bisexual Behaviors*

### **A. Children and Adolescents**

Homoerotic and homosexual activities are not common among Indonesian children, although some sexual exploration involving exhibiting the genitals is known to occur. Some children who experience homosexual experience with adults may be drawn into long-term homosexual behavior, but no data are available on the various outcomes of child-adult same-sex experiences.

Some adolescents engage in homosexual activities as a sexual outlet, while others engage in this activity for material gain as homosexual male prostitutes. In one Javanese society of traditional artists, known as Reog Ponorogo, some adolescents engage in homosexual activities to serve adult males who are believed to have supernatural powers (see Section 2B, Character of Ethnic Values).

### **B. Adults**

In general, Indonesians consider homosexuality and bisexuality as abnormal acts forbidden by morality and religion. Despite this taboo, thousands of adults engage in homosexual and bisexual relationships. An organization called the Functional Group for Gays and Lesbians exists, with branches in some of the larger cities. This organization also publishes a newsletter/bulletin to help homosexual persons keep in touch and build support.

Most gays and lesbians, however, hide their orientation and activities, because they know that most people oppose homosexual behavior. Only very few male homosexuals want to be open and frank about their sexual behavior. Some homosexual males hide their sexual orientation by marrying a woman for social status and conformity. Their wives only learn that their husbands are homosexual after the marriage occurs. Some of these marriages end in divorce, but some others remain intact for social or religious reasons.

Some men gradually discover their homosexual orientation during adolescence or early adulthood. Others may be

drawn into a homosexual lifestyle, because they had homosexual experience during their childhood. Some engage in homosexual behavior strictly for profit as male prostitutes, and then discover that they have a homosexual orientation.

Since same-sex marriage is illegal, homosexual persons are limited to living-together arrangements and cohabitation without legal sanction. In terms of socializing, some of the larger cities offer places where homosexual persons can gather and meet each other. Sexual outlets among homosexual, lesbian, and bisexual-oriented adults include oral sex, anal sex, and mutual self-pleasuring. Some lesbians use vibrators or other sexual accessories. But, unlike male homosexuals, lesbians are much less obvious in this society.

## 7. Gender Diversity and Transgender Issues

There are no precise statistics on the incidence or sexual lives of gender-conflicted persons. It is commonly assumed by professionals in the field that there are thousands of male transsexuals in Indonesia. *Banci*, a slang term, and *waria*, an abbreviated combination of *wanita* (female) and *pria* (male), are popular terms for gender-conflicted persons in Indonesia. In Surabaya, the capital city of East Java, Perkumpulan Waria Kotamadya Surabaya, the Association of Waria in Surabaya, provides members with support, education, and career training as beauticians, artists, or dancers. These skills, they hope, will allow *waria* to support themselves and avoid a life of prostitution. Support groups also provide information about HIV/AIDS prevention.

In modern-day Indonesia, people can see many transsexuals working as beauticians, dancers, or entertainers. However, on the other hand, many of them also work as low-class prostitutes. This gives all transsexuals a negative image in the eyes of the wider Indonesian society.

Only a few male transsexuals, usually well-known artists, can afford to have surgery to change their sexual anatomy. The average cost for such surgery is the equivalent of 30 to 40 times a lower-class worker's monthly income, about US\$2,000 to US\$3,000.

## 8. Significant Unconventional Sexual Behaviors

### A. Coercive Sex

#### *Child Sexual Abuse, Incest, and Pedophilia*

There is no research on child sexual abuse, incest, or pedophilia in Indonesia. What is known about these issues comes from reports in the newspapers detailing some incidents of coercive sex involving children. Legal penalties exist for persons convicted of child sexual abuse, incest, and pedophilia. The social response to these acts is very negative, and the perpetrators are viewed as criminals.

Many street children, whether female or male, experience child sexual abuse. Many male street children are sexually abused by female lower-class prostitutes, who believe the myth that anyone who has sexual intercourse with children or adolescents will remain young.

Incest usually occurs among poor and uneducated families, although this may be a myth. The housing situation of poor families with a single bedroom facilitates the occurrence of incest. Some cases of incest come to public attention when the victims become pregnant and the perpetrators cannot hide the incident. Neighbors and family normally become angry and physically abuse the perpetrator when they learn of such incest.

In the last few years, as the terms pedophilia and sex tourism have become common in Indonesia, knowledge of the incidence of sex with children is increasing. The victims

are children of poor families in the villages, while the perpetrators are foreign tourists from other countries. Parents of the children do not object to the foreign tourists who visit their family and offer to help their children. Frequently, the parents agree when the tourists want to bring the children to the city.

It is reported that the organizers are members of an international syndicate of promoters of pedophilia. A video of pedophilia involving Indonesian children is reported to be widely available in many countries.

However, it is necessary to study whether the tragedy inflicted on the children of poverty-stricken families is really the result of paraphilic pedophilia or whether it occurs more because of the belief that sexual intercourse is safer with children who are assumed to be "clean," free from STDs including HIV/AIDS.

### *Sexual Harassment*

Even though there are no significant data about sexual harassment, it is believed that it is a common occurrence in Indonesia. Many women who work in factories or offices, or walk along the street, suffer from a variety of sexual harassments, although few women realize they are victims of sexual harassment. Conviction on a charge of sexual harassment may result in three to six months in prison.

Fortunately, in recent years, some women leaders have been trying to educate women, teaching them that sexual harassment is illegal and that women have the right to prosecute those who engage in it.

### *Rape*

As with other forms of sexual coercion, there are no significant data on the incidence of rape in Indonesia. Rape incidents perpetrated by an acquaintance, boyfriend, or stranger, and rapes that end in murder are sometimes reported. However, most rapes reported to the police do not end up in a court trial. One of the reasons for this is to protect the victim from public embarrassment in the mass media. Another reason is that the punishment for rapists is considered to be very light.

Marital rape is not reported in the news media, although some wives in counseling or therapy do report being raped by their husbands when they refuse to have sexual intercourse. However, none of the wives want to report this to the police, because they never realize that it is a rape if done by a husband to his own wife. Some wives, however, resist their husbands and threaten to divorce them when forced to have sex against their will. [*Update 2003: Indonesia has no law on marital rape, despite considerable debate between religious and legal experts on the subject (Idrus 2000). (End of update by R. T. Francoeur)*]

Some taxi passengers are raped by the drivers, and have ended up being murdered. According to the confessions of the taxi drivers, at the beginning they only wanted to rob the passengers, but this in the end resulted in sexual arousal, assault, and murder. Some wives and their daughters become the victims of gang rapes perpetrated by robbers when they are discovered at home during a robbery.

### B. Prostitution

Prostitution is widespread and occurs in many locations from small to large cities, even though it is often illegal. In some jurisdictions and cities, where prostitution is illegal, the law may prosecute either the prostitutes or those who manage the business of prostitution.

In a few large cities, prostitution is legal. Many prostitutes ("sex workers") of different ages, from adolescence to middle-aged, can be seen. The sex workers are not only local or Indonesian females. There are also some foreigners

working as prostitutes. They are divided into different groups based on their appearance, with low-, middle-, and high-class categories. The price of sexual services offered by the sex workers varies, depending on the class determined by their managers. It varies from only 25,000 Rupia (Rp.) (US\$3) to Rp. 3,000,000 (US\$400) for a short time and one coitus.

Beside legal and illegal prostitution, there is also a hidden prostitution. This is a form of prostitution concealed in another business, such as a massage parlor, beauty parlor, or karaoke place. In terms of STD transmission, this sort of prostitution is worse because the masseuses, the beauticians, or the karaoke escorts do not feel that they are prostitutes; on the other hand, the male customers do not feel that they have had sexual intercourse with sex workers. As a result, many males are unknowingly infected with STDs after they have intercourse with masseuses, beauticians, or karaoke escorts.

Childhood prostitution is often supported by wealthy tourists from the Middle East, Europe, Japan, and other countries, but it is not the extensive problem it is in neighboring nations, like Thailand, Cambodia, Myanmar, and Vietnam. The increase of childhood prostitution is related to the myth that children are "clean" and free from STD infections.

In a few large cities, male sex workers also operate. Their customers are widows, women of middle age or older, and female visitors from foreign countries. Some of them operate quietly as masseurs providing special services for women.

In certain tourist areas, such as Bali, some foreign tourists end up marrying a sex worker whose services they originally sought for pay.

### C. Pornography and Erotica

In keeping with our conservative Indonesian tradition, pornography is illegal throughout Indonesia. However, it is not difficult to find "blue" or hardcore video material. Some people sell pornographic books, magazines, and pictures, despite their being illegal. People, including adolescents, can easily rent pornographic videos and videodisks in many rental places for a low price because so many of them are illegal copies.

Police have caught some criminals who illegally produce or import copies of pornographic video material. However, the illegal business never stops, and people can always rent or buy such hardcore video materials. There is no protection for adolescents from pornographic materials, so they can rent or buy it easily. The video renters/sellers do not feel a moral responsibility to protect adolescents from the effects of the hardcore materials they sell.

In the era of cyberspace, it is much more difficult to protect adolescents from pornography, because it is very easy to access pornographic Web sites. In big cities, there are many places where people can gain access to the Internet and no one can control this access to pornographic Web sites on the Internet.

## 9. Contraception, Abortion, and Population Planning

### A. Contraception

Indonesia has a national program promoting contraception to help married couples plan their families. This program addresses only married people, and not adolescents or unmarried adults. Information on contraception is provided through women's social organizations, newspapers, and radio and television broadcasts.

In 1970, the government began providing free contraceptives at public health centers. In 1988, with an improv-

ing economic situation and people recognizing the need for family planning, the government gradually began reducing its support, encouraging people who could afford them to obtain contraceptives from physicians in private practice or midwives with reasonable fees. The poor can still obtain free contraceptive services at public health centers where the only charge is for an inexpensive admission ticket.

The most popular contraceptives are the oral hormonal pill, hormonal injections, and IUDs. Women have to be examined by a physician before they can obtain a prescription for oral hormonal pills, but renewal of such prescriptions is not limited. Hormonal injections and IUDs are administered by doctors or by midwives. The other contraceptives are hormonal implants and tubectomy. As for males, acceptance of contraception is very limited. There are at least two reasons for this resistance. First, perceived male social superiority results in males not accepting their responsibility for contraceptive decisions and use. Second, there are only two alternatives in choosing male contraceptives, condoms or vasectomy. Condom users account for only about 5% of the total number of contracepting men and women.

Despite the limiting of contraceptive information to married women, some adolescents and unmarried women also use contraceptives. They are available in pharmacies (apothecaries or chemists), and include the condom and vaginal film (tissue). Often the hormonal pill can be obtained without a physician's prescription.

In general, the people do not agree that unmarried people should have access to and use contraceptives. Thus, there is no formal education in the schools about contraceptives for adolescents. Sexually active adolescents and single adults have only informal sources of information about contraceptives: newspapers, television, radio programs, and seminars sponsored by interested social groups. As a result, not many adolescents understand how to prevent unwanted pregnancies. They do not even understand how to estimate their fertile period. However, with the government agreement on sexual education as a part of the curriculum in the schools, adolescents will have access to complete information about sexuality, including contraceptives.

### B. Teenage (Unmarried) Pregnancies

Unmarried pregnancies are not uncommon, but data are nonexistent. What little information is available from routine clinical statistics simply documents the number of unmarried pregnancies in different years. Unpublished data from one urban clinic, for instance, reported 473 unmarried pregnant women seeking aid in 1985-1986, a second clinic served 418 pregnant unmarried women in 1983-1986, and a third clinic reported 693 unmarried pregnancies in 1984-1990.

These reports provide only raw data with no perspective, and the frequency and incidence of unmarried pregnancies are much higher than these few studies indicate. Likewise, there are no data that would allow one to compare the incidence of unmarried pregnancies in the cities and rural areas. However, the incidence of abortions performed illegally by medical doctors or traditional healers suggests that unwanted pregnancies are not uncommon, either in the cities or in the rural areas.

Of course, not all unwanted pregnancies result in abortion. Some pregnant adolescents are forced to marry even though they do not want to. The unwanted babies born by unmarried adolescents or young adults that are taken care of in orphanages also indicate that unmarried pregnancies are not uncommon. Some unwanted babies are left by their mothers in the clinic after delivery. Others are simply left in front of somebody's house to be rescued.

Based on an estimated one million teenage abortions a year, and the fact that not all unmarried pregnancies result in abortion, it is believed that the actual number of teenage unmarried pregnancies is well over a million a year.

### C. Abortion

Abortion is illegal throughout Indonesia, except in rare medical cases to save a mother's life. It is impossible to obtain any realistic number of abortions performed in Indonesia, simply because it is illegal. However, many abortions are performed. In addition to abortions performed illegally by medical doctors, abortions are also performed by native or traditional healers, who use traditional methods that are often unsafe and result in complications. One such method uses the stem of a coconut tree leaf, which is inserted into the uterus through the vagina and cervix. This method, of course, is very risky, because it is not sterile and the healers do not understand the sexual anatomy. Some deaths are reported after abortions by native healers because of uterine rupture, bleeding, or infection.

Some doctors are caught by the police because they perform abortions in their clinics. A few of these cases were reported in the news media when police found many dead fetuses buried in the yard of a clinic or in plastic bags thrown into the garbage bins or dumps.

It is estimated that around 2.5 million abortions are performed each year throughout Indonesia, for both married and unmarried women. Of these, around one million are abortions performed on teenagers.

### D. Population Programs

The success of Indonesia's national program of family planning was recognized in 1989 when the United Nations gave its Population Award to the president of Indonesia. Efforts are being made to achieve zero population growth in the near future.

These efforts are particularly important considering that the island of Java is one of the most densely populated areas of the world with 2,100 persons per square mile (2.6 km<sup>2</sup>) and over 100 million people on the island of 51,023 square miles (132,149 km<sup>2</sup>). By comparison, the states of New York, North Carolina, and Mississippi are each roughly the same size as Java, but have only 18, 6.6, and 2.5 million people, respectively.

One important effort is to increase the participation of males in family planning. Up to now, their participation is very low. The involvement of males in family planning is only 6% of the contraceptors because of various factors. The male superiority is one of important factors that inhibit males accepting responsibility in family planning. Most males are not interested in using either condoms or vasectomy.

## 10. Sexually Transmitted Diseases and HIV/AIDS

### A. Sexually Transmitted Diseases

Although no survey and reliable clinical reports are available, it is the clinical experience of the authors and their colleagues that sexually transmitted diseases are common among Indonesian adolescents and young adults, indicating that the taboos against premarital sex are not observed. The incidence is highest among those between ages 20 to 24, and lower among the 25- to 29-year-olds and 15- to 19-year olds. As would be expected given the social customs, the incidence among males is higher than it is among females. The most commonly reported STDs are nonspecific urethritis, gonorrhea, ulcus molle, and genital herpes. Syphilis is no longer common, although it appears to be increasing in recent years.

Transmission of STDs is caused by unsafe and high-risk sexual behavior, including intercourse with sex workers. The use of condoms is not popular among males who are involved in high-risk sexual behavior.

Treatment for STDs is available at all health clinics throughout the country. Some years ago, the government sponsored a program to reduce the spread of STDs by providing prostitutes with penicillin injections. Unfortunately, the program is no longer available.

Currently, sex workers have taken the initiative in preventing STD transmission. However, their effort is often medically unsound because it is only based on misinformation from friends or other lay people. The most popular method employed by sex workers is consuming an oral antibiotic after sexual activity. The other is irrigating the vagina with antiseptic. These methods, they believe, can prevent STD transmission, including HIV/AIDS. On the other hand, the customers also believe that if the sex workers do not have any visible signs of an STD, they are not at risk of being infected even though they do not use a condom.

The prevention efforts by the government and non-governmental organizations (NGOs) focus on providing information in seminars and the mass media, including the newspaper, radio, and television.

Some informal studies of STD prevention have found that most Indonesians do not understand well the nature and character of STDs. The obvious question, then, is whether the strategy and/or technique of prevention efforts have to be reevaluated, and probably even changed.

### B. HIV/AIDS

The first case of AIDS found in 1987 in Denpasar (in Bali) was a Dutch visitor. This incident scared many people, including the hotel staff where he stayed and the hospital staff where he was treated a few days before he died. Fortunately, in revealing that HIV/AIDS was indeed present and active in Indonesia, this incident raised the awareness of many Indonesians, including doctors and government officials.

Until the end of 1987, there were only 6 cases of HIV/AIDS reported in Indonesia. Thereafter, this incidence has increased rapidly as reported by the Indonesian Department of Health (see Table 1). In the first two months of the year 2000, 103 new cases were reported, suggesting the start of an exponential increase, with perhaps a tripling of cases to about 600 for 2000. The cumulative number of HIV/AIDS cases until February 2000 was 1,146, consisting of 853 cases of HIV positives and 293 cases of AIDS. However, it is believed that the real number of HIV/AIDS cases is much higher than the reported number. The real number of HIV/AIDS cases is estimated around 100 to 200 times greater than the reported number (Indonesian Department of Health 2000).

The 1,146 cases of HIV/AIDS reported as of February 2000 are spread throughout Indonesia's 23 provinces. These involve 679 males and 412 females, with the sex of 55 patients unidentified. Most of the HIV/AIDS cases in Indonesia resulted from heterosexual contact. Most of those infected

**Table 1**

**Incidence of AIDS in Indonesia, 1988-1999**

Year	Cases	Year	Cases	Year	Cases
1988	7	1992	28	1996	137
1989	7	1993	113	1997	118
1990	9	1994	87	1998	200
1991	18	1995	89	1999	225

are between 15 and 39 years of age (Indonesian Department of Health).

Sex workers are believed to be one source of infection transmission, but the freer sexual behavior among today's people has also become a prominent factor. In the early years of HIV/AIDS transmission in Indonesia, it is estimated that some HIV-positive foreign tourists who came to popular tourist centers like Bali introduced the virus through sexual contact with sex workers or local people.

Prevention efforts have been provided for some groups of people, such as sex workers, both female and male, people who work in the tourism industry, university and high school students, long-distance truck and bus drivers, women leaders, and religious leaders. These efforts involve providing information, education, and training on how to reduce the spread of AIDS, and include blood tests for HIV infection. Campaigns to popularize the use of condoms are now conducted through the mass media, including newspaper, radio, and television. However, it is not easy to make people aware and encourage condom use if they engage in high-risk sexual intercourse.

The classical belief that using condoms inhibits the joy of sex is still fixed in the mind of almost all Indonesian males, as well as females. The simple distribution of condoms to sex workers does not solve the problem. Most males seeking sex workers do not want to use condoms because of the classic myth of inhibiting pleasure. Sex workers are in a very weak bargaining position, so they do not have enough power to refuse the customers who do not want to use condoms. If they insist and refuse the customer who does not want to use a condom, they will have to answer to their manager, and this could lead to further difficulties. No one seems to know what policy could best convince those who have sex with sex workers that condoms are a must in today's world. Indonesia very much needs a national policy to encourage men frequenting sex workers to use condoms, or to press sex workers not to do their job if the customer does not want to use a condom. If such a policy is not found and implemented effectively, Indonesia faces the distinct likelihood of an explosion of cases of HIV/AIDS in the near future.

[*Update 2003*: Indonesia faces a national health disaster, which belies its reputation as the world's largest, and quite conservative, Muslim community—an epidemic of IV-drug use that suggests needle sharing will soon surpass unsafe sex as the most common method of contracting HIV (*The Age* 2003).

[According to Henry Yosodiningrat, a Jakarta lawyer and member of the government's National Narcotics Agency, "This is an extremely serious issue for us. It's a threat that could kill an entire generation. There's not a school or district anywhere across the country where drugs are not used." In January 2003, Broto Wasisto, head of the Health Ministry's committee on drug control, and a member of the national HIV/AIDS control board, agreed that IV-drug use "is a national emergency as far as controlling the spread of HIV/AIDS is concerned." In February 2002, a report by Melbourne's Macfarlane Burnet Institute for Medical Research and Public Health estimated that there were between 1.3 million and two million IV-drug users in Indonesia, with up to one million of these injecting. Some local estimates put the number of users at four million—about one in every 50 Indonesians.

[In 1996, Jakarta's RSKO hospital, which specializes in treating drug addicts, dealt with 2,000 patients; three years later, the number had risen to 9,000. In the process, users are getting younger, with most now between the ages of 16 to 25. The full range of drugs available in the West, and more, is used here. Premium-quality marijuana from Sumatra, ec-

stasy, heroin, and methamphetamines are offered for sale. Shabu-shabu, a potent new form of methamphetamine that is injected, inhaled, or taken orally, increases the duration and intensity of sex and reduces inhibitions, making users fearless and prone to risk-taking. It is popular among prostitutes and their clients in Indonesia's massive sex industry and is cheaply produced in backyard factories. There is a caste system among Indonesian drug users. The middle class use ecstasy; poorer people use shabu.

[Despite the growing awareness of the problem, Indonesia faces unique obstacles and some reluctance in dealing with it. "Although the use of illicit drugs is increasing, political conflict, power struggles, and widespread corruption are influencing how the drug-related HIV/AIDS crisis should be tackled," the Macfarlane Burnet report concluded. A major obstacle in the anti-drug war is a mind-boggling array of other social, economic, and security crises competing for the government's attention. Then there are too many other pressing health problems: high maternal and infant-mortality rates, malaria, tuberculosis, and a multitude of diseases because of the lack of clean drinking water. All these obstacles are complicated by the free flow of money from the drug syndicates to buy officials, police, and the army. There is also evidence that elements of the underfunded police and military are themselves involved in the drug trade and are willing to fight public turf wars for their share of it. In October 2002, at Binjai in north Sumatra, soldiers in an army airborne unit tied up their officers and attacked police stations using rocket-propelled grenades, mortars, and automatic weapons, killing eight police and civilians. The soldiers were upset after the police arrested a drug dealer and seized 1.5 tons of cannabis.

[Meanwhile, the East Timor government and the UN have launched an AIDS-awareness campaign on television, radio, and print media, hoping the country can avoid the explosion in HIV/AIDS seen elsewhere in the region. East Timor, newly independent from Indonesia on May 20, 2002, has so far avoided an HIV/AIDS epidemic, but social dislocation, cross-border migration, high unemployment, illiteracy among the rural population, and low awareness about HIV indicate a significant risk. In 2002, preliminary estimates from the Ministry for Health showed the rate of HIV infection at 0.64% of people of reproductive age. Cambodia, Thailand, and Myanmar have HIV rates of more than 1%, according to UNAIDS (Reuters Health, 2002). (*End of update by R. T. Francoeur*)]

[*Update 2002*: UNAIDS Epidemiological Assessment: Until the end of 1998, all HIV/AIDS data collected in Indonesia from all sources indicated that HIV-seroprevalence rates were very low (below 0.1%), even in the highest heterosexual risk groups, such as female sex workers. The exception to this very low HIV prevalence was in Merauke (in West Irian) where relatively high HIV-prevalence rates were reported among female sex workers several years ago.

[Starting in 1999 and continuing in 2000, several HIV Sentinel Surveillance sites for female sex workers began to detect increasing numbers of HIV infections, and prevalence rates from 1% to 5% were found in several areas. Although injecting-drug-user populations were not included as a routine sentinel surveillance group, several ad hoc serosurveys throughout Indonesia, especially in Jakarta, detected sharply increasing HIV prevalence (up to over 35% in Jakarta) among injecting drug users in late 2000. This increasing trend of HIV prevalence can be seen in blood-donor data from the Indonesian Red Cross from 1992 to 2000. In recent years, approximately 750,000 to 1,000,000 blood donors have been screened annually for HIV; a marked increase was seen in 1999 and 2000, probably reflecting the

large increase among injecting-drug-user populations noted during the same time period.

[Indonesia is classified as a country with a concentrated HIV epidemic, primarily among its injecting-drug-user population. At the end of 2001, an estimated 120,000 people were living with HIV/AIDS. The estimated number of AIDS deaths for the year 2001 is about 4,600. Most of these AIDS deaths occurred in or around Jakarta, where the majority of the HIV-infected injecting-drug-user populations live.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	120,000 (rate: 0.1%)
Women ages 15-49:	27,000
Children ages 0-15:	1,300

[An estimated 4,600 adults and children died of AIDS during 2001.

[At the end of 2001, an estimated 18,000 Indonesian children under age 15 were living without one or both parents who had died of AIDS. (*End of update by the Editors*)]

### 11. Sexual Dysfunctions, Counseling, and Therapies

The diagnostic paradigm used by Indonesian sexologists is basically that of William Masters and Virginia Johnson, with presenting cases of inhibited penile erection (erectile dysfunction), early (premature) ejaculation, inhibited (retarded) ejaculation, male and female dyspareunia, inhibited female orgasm, and vaginal spasms (vaginismus).

However, the development in diagnostic tools has changed both the results of the diagnosis and the strategy of case management. With some diagnostic tools, like the erectionmeter, Doppler pen, and Rigiscan, a more accurate diagnosis can be achieved. For example, before the new diagnostic tools were developed, most erectile dysfunction was considered to be psychological in origin. But after the development of new diagnostic tools, it is found that most erectile dysfunctions are organic. This finding, supported by the new medicines like sildenafil, has changed the strategy in the management of erectile dysfunction. Now the treatment of erectile dysfunction is divided into three steps: first-, second-, and third-line therapies. First-line therapy consists of sexual or psychosexual therapy, oral erectogenic agents (primarily Viagra), and a vacuum constriction device. Second-line therapy includes intracavernosal injection and intraurethral application. Third-line therapy is the surgical procedure of penile implant. These advanced treatments are available only to a small minority of Indonesians living in urban centers who can afford them.

A common psychological sequel for males with a sexual dysfunction is a feeling of inferiority with regard to their partner. This feeling is often what brings the male to seek treatment.

Many women, on the other hand, tend to hide their sexual problems and feel shy about seeking treatment. Many married women never have orgasm and never tell their husbands. At the same time, many husbands are unaware or do not even suspect that their wives never have orgasms. Many of them are simply unaware of their wife's sexual dysfunction even after the wife complains to a sexologist.

Out of 4,135 women who came for consultation at the authors' clinics for their own or their husband's sexual problem, 2,302, or 55.7%, have never had an orgasm, and 527, or one in six (12.7%), have experienced orgasm only rarely. Among those who never reached orgasm, 60 (2.6%) experienced dyspareunia, 67 (2.9%) experienced hypoactive sexual desire, and 27 (1.2%) suffered from vaginismus.

The high incidence of sexual dysfunction among Indonesian females is caused by poor communication between husbands and wives, poor sexual knowledge, and male sexual dysfunction. However, good diagnosis and treatment for sexual dysfunctions are available in only a few urban clinics, and are available only to those who can afford it.

### 12. Sex Research and Advanced Professional Education

A few Indonesian sexologists have finished their education and training in the United States, Belgium, and Australia. Some informal unpublished clinical studies of sexuality in Indonesia have focused on sildenafil and alprostadil for the treatment of erectile dysfunction, on sexual perception and behavior among the youth in cities and villages, and sexual knowledge, perception, and behavior of STD patients. Some studies are currently in progress, including management of erectile dysfunction using the new medications, and high-risk sexual behavior in relation to HIV/AIDS transmission.

Advanced education on sexuality is available only in the Master Program in Reproductive Medicine at Udayana University in Denpasar, Bali. This program offers sexology lectures and study as a part of the curriculum. As a postgraduate program, it requires a two-year study course in sexology, spermatology, experimental reproductive biology, reproductive endocrinology, embryology, family planning, and infertility management. Instruction in sexology includes perspectives on sexuality, gender and sexual behavior, childhood, adolescence, and adulthood sexuality, sexual fantasy, sexual variation, sexual dysfunction, sexual deviation, and premarital and marital counseling.

The mailing address of this center is: The Master Program in Reproductive Medicine, Udayana University Medical School, Attention: Prof. Wimpie I. Pangkahila, M.D., Ph.D., Jl. Panglima Sudirman, Denpasar, Bali, Indonesia.

PART 2:  
THE INDIGENOUS ORANG RIMBA  
FOREST PEOPLE

RAMSEY ELKHOLY

*Demographics and a Brief  
Historical Perspective\**

**A. Demographics**

The Orang Rimba are an indigenous minority population inhabiting the primary and secondary lowland forests of south-central Sumatra, the largest and most western of the Indonesian islands just south of Malasia. *Kubu* is the most commonly used exonym by local villagers and the general Indonesian populace, and it is the most common referent found in the anthropological literature (see Van Dongen 1906; Loeb 1942; LeBar 1972; Sandbukt 1984, 1988ab; Persoon 1989; Suetomo 1992). However, it is a title they resent being designated by, as it is a pejorative term connoting “savage” or “primitive.”

They practice a nomadic or semi-nomadic form of hunting and gathering economy, occasionally supplemented with basic slash and burn (swidden) agriculture. Precise population figures are difficult to obtain, but 2,600 to 3,000 are realistic estimates, with the large majority living in Jambi Province, and nearly one third of the total population concentrated in the Tembesi-Tabir interfluvium, where slash and burn agriculture has intensified in recent decades, thus leading to higher birthrates. Significant numbers are also found in South Sumatra Province, while remnant populations and new migrants can also be found in West Sumatra and the Riau Provinces.

Group sizes range from small nuclear domestic units to larger swiddening (slash and burn) camps, which can reach 100 or more persons (Sandbukt 1988a). In cases where residential groups consist of nuclear family dwellings, it is common for two or more kin-related families to consolidate their efforts by sharing game and other wild foods to compensate for their small group sizes. In recent decades, some groups have adopted a more sedentary life, shifting their economic orientation towards subsistence horticulture and rubber tree cultivation and tapping. This has led to higher birthrates among women, but infant mortality remains high, particularly in areas where deforestation has occurred, where they are coping with the transition to sedentism without proper healthcare and hygienic education.

**B. A Brief Historical Perspective**

For centuries, the Orang Rimba have avoided sustained contact with neighboring agricultural peasantries, preferring to trade only with a select few trusted villagers. Various historical accounts report that in certain areas they had practiced a form of “silent trade,” whereby forest products were placed on the fringes of the forest to be collected by villagers, who would exchange these products with needed goods, such as

salt and metal for spear heads and machetes, by placing them in the same spot—both sides never meeting face to face (Boers 1838; Forbes 1885). This form of barter may have been replaced, in some cases, with face-to-face encounters with a Malay intermediary known as *jenang* or *bapak semang*. He was seen as a guarantor of their autonomy, and the forest products they forfeited to him (e.g., rattan, damar, “dragon’s blood,” and honey) were often of much greater value than the goods received (e.g., salt, tobacco, metal tools, and clothing), which were to be seen as gifts rather than direct equivalents of the goods offered (Sandbukt 1988b, 112-13). This system lasted until recent years and still persists in some areas, but in a less paternalistic and strictly economic form.

Such extreme xenophobia may have been a response to the fears of slave raiding in past times. According to Sandbukt (1988a, 111) and Marsden (1811, 41), slave raiding on the inter-local level was a real and serious threat to the Orang Rimba until only a few generations ago. Such dangers may have increased with the spread of Islam from the 14th century onwards. In the Islamic faith, it is forbidden to enslave other Muslims. The non-Muslim indigenous populations of the interior, such as the Orang Rimba, were, therefore, obvious targets for slave raids and other forms of persecution (cf. Denatan et al. 1997).

Their long history of avoidance of the outside world is deeply rooted in an ideology, passed down from their ancestors, that envisages the bifurcation of humanity into two types: Malays—who live in permanent villages and follow the dictates of Islam; and the Orang Rimba—who live in the forest and follow the traditions and customs of their ancestors (see Sandbukt 1984). This distinction is the inspiration and guiding principle of their lives, and any crossing or confusing of these two domains would be seen as a breach of the sacred mode of life passed down from their ancestors. The Orang Rimba identify all that is sacred with the forest and, concomitantly, view many of the Islamic customs practiced by their sedentary village-dwelling neighbors as somehow impure and, therefore, taboo. The coexistence of these two groups, the Orang Rimba and Muslim villagers, is an excellent example of what anthropologists call a “commensal relationship,” two groups who can reside in the same area without competing, because they have independent or different values and customs. Commensality practices perfectly illustrate this. The foods commonly eaten by Muslim villagers, such as goats, cows, buffaloes, and chickens, are foods that are forbidden to the Orang Rimba, whereas certain forest game, such as wild boar, turtle, and snake, foods quite common to the Orang Rimba, are taboo to the Muslim villagers.

The Orang Rimba integrate and associate religion, the supernatural, notions of well-being, subsistence practice, and survival in general with their forest environment. Richly imbued with nurturing and life-giving qualities, their forest world is viewed as a pantheistic totality where a wide variety of deities reside under the auspices of a benevolent and omnipotent Godhead (*Behelo*). Forest deities are contacted regularly by experienced shamans who, while in trance, are endowed with the special ability to see and communicate with these otherwise invisible beings. Such sacred communication insures protection from physical and supernatural dangers and promotes success in hunting and the general well-being of the group. It also serves to maintain and regenerate the delicate dialectical balance between themselves and the forest, and the sacred mode of life practiced therein.

Despite their rich and complex system of beliefs, they are, nonetheless, considered pagan savages or “infidels” by their Muslim agriculturalist neighbors. Moreover, these encompassing agricultural peasantries, along with a continual

\**Editor’s Note:* Because there are over 300 distinct indigenous ethnic groups in Indonesia, the authors of Part 1 of this chapter focus mainly on urban and village Indonesians, for whom some data are available. Here, in Part 2, Ramsey Elkholy, a sociocultural anthropologist, expands on this picture of sexuality among modern urban and village Indonesians with insights from his fieldwork with the indigenous Orang Rimba hunter-gatherer forest people of Sumatra, Indonesia. For additional insights into the sexual attitudes and behavior among other indigenous peoples, the reader is referred to the sections on the aboriginal people of Australia and Brazil, Canada’s First Nation People, and the indigenous people of French Polynesia and Papua New Guinea in this volume.

influx of transmigrants from Java, continue to clear Orang Rimban forestland for their slash and burn fields. More threatening still to Orang Rimban environments are the large-scale logging operations that continue in both South Sumatra and Jambi Provinces. These days, many groups camp on the side of logging roads in order to gain easier access to outer-market goods and services. Exchange contacts have also increased and diversified as a consequence of their broadening knowledge of the outside mercantile economy, and they no longer accept the paternalistic relationships with Malay intermediaries whereby “gifts” are received for their labor and forests products. Although they are enjoying greater access to the wider market economy, which has provided them with unprecedented opportunities to amass personal wealth (usually measured in sheets of cloth, gold, currency, and outer-market goods), there are few, if any, Orang Rimba environments that are not somehow threatened by the forces of encroaching development.

Aside from the destruction of their forests, the Orang Rimba have been under increasing pressures from central and local governments to assimilate. In the 1960s, the Department of Social Affairs (Depsos) initiated an assimilation campaign in an attempt to settle the Orang Rimba permanently in Malay-style villages and encourage them to practice subsistence agriculture. In coordination with Indonesia’s Department of Religion (Dinas Agama), and occasionally through missionaries—sometimes foreign—attempts have been undertaken with varying degrees of success to convert them to Islam, the nation’s predominant religion. Christian missionaries have also played an active role in persuading the Orang Rimba to abandon their traditional mode of life in the forest and assimilate to Malay ways, which involves taking up permanent residence in or near one of the nearby villages. Since Indonesia’s independence in 1945, most villages have established Government-sponsored primary schools, where Pancasila national philosophy and modern Indonesian is taught. This has promoted a sense of nationalism and broader regional awareness that is largely absent among the Orang Rimba, who by and large still remain separate geographically and culturally, and continue to see the world from a purely provincial or local perspective.

While the pressures of deforestation and development are causing rapid social changes and challenging the resiliency of their traditional way of life, domestic practices, including gender roles and relations, have remained relatively unaffected, aside from higher incidence of male defection to local villages where intermarriage is sought. No known precedence has been set for villager males marrying into forest-dwelling Orang Rimban camps. As such, these groups remain ideal contexts for studying traditional internal social dynamics. However, the Orang Rimba’s well-established history of avoidance behavior had, in the past, undermined many attempts at conducting in-depth anthropological investigation, particularly regarding sensitive matters such as gender and sexuality, which require intimate contact on the domestic level and access to women by researchers. The information reported here is based on a field study of close to two years, when the author lived among the Orang Rimba on the domestic level. The demands of local customs necessarily restricted the author’s access to Orang Rimban women.

## 1. Basic Sexological Premises

### A. Character of Gender Roles

The Orang Rimba use kinship categories as the basic societal building blocks of their social organization. Kinship ties determine residential arrangements, distribution of resources, and key social alignments, in effect producing and

reproducing their ideational ties and wider social order. Populations who may be separated by hundreds of kilometers will maintain contacts with their near and distant kin, either directly or through intermediaries. Through these “kinship networks,” one enduring cultural type—however dispersed—may be said to exist. Gender relations are equally conditioned and affected by kinship relations and, therefore, kinship affiliation plays a fundamental role in shaping Orang Rimban social values and general modes of behavior.

Postmarital residence is uxori-local. A male will marry-in to his spouse’s group and, after an unspecified period of bride-service to his father-in-law, he will remain under his authority and be expected to provide his labor power and moral support indefinitely. He will eventually replace his father-in-law’s position, either by usurping his power when he is physically unfit or too old to make important decisions (e.g., resolving disputes, representing the group and their needs to outsiders, etc.), or when he finally dies. Marriage is normally a strenuous affair for in-marrying males as well as for both families involved. Most family members, fathers and brothers in particular, will fiercely resist any attempts by an outsider male to marry into the family. The outsider male must first gain the family’s trust, and the suitor’s bride-service is aimed at achieving this end. Cross-cousin marriage is preferred over unions with non- or distant kin, as trust has already been established through previous consanguinal relations between siblings.

An Orang Rimban man will commonly exhibit “macho”-like characteristics, asserting a “don’t fool with me” status to other men. Such a disposition is largely because of the ever-present need to claim one’s rights to women, particularly spouses, but also female children of marriageable age who are increasingly coming under the eyes of amorous young bachelors. While a male’s masculinity is often exaggerated in manner, he may be openly affectionate and nurturing towards his young children, particularly infants. Men will also display affection openly by embracing and weeping upon uniting with long-separated male relatives. Group weeping (*bubughatongpon*) in cases where long-separated parties unite is also common, as well as in the event of death, in which case weeping may continue sporadically for weeks on end. Embracing, however, is restricted to the same sex, and it is more common that a woman will bow her head and sniff the hand of a male relative, which signifies respect during such greetings and farewells.

Traditionally, the role of an Orang Rimban man is that of “the hunter,” the provider of meat, and the protector of women and children. A woman’s role is twofold, that of “the gatherer” of wild food, which includes digging edible tubers, and that of “the nurturer” of the young. While Orang Rimban society appears to be male-dominated in most respects, women often enjoy considerable autonomy and hold considerable political sway over their spouses, particularly when their fathers and male siblings are nearby, where they can voice their complaints and thereby summon their support (see Sandbukt 1988a).

Domestic space is delineated by the male and female domains in their split-level shelters. The upper level is the male domain, where visiting men are welcome to sit, smoke tobacco, and pass the time of day; the lower level is strictly for women and children. The lower level physically marks off a boundary from the rest of the shelter and is strictly off limits to all adult males except for a woman’s spouse.

These days, collecting forest products for external exchange is increasing, as the Orang Rimba’s ever-growing dependency on outer-market goods, such as cigarettes, coffee, sugar, and rice increases. It is now more common for women to frequent village shops to buy supplies and to sell

their forest products. In some areas, however, women are still fiercely protected from the perceived dangers of the outer world and are forbidden to enter the village without male accompaniment. In more-rare cases, where traditions still strongly prohibits contact with outsiders, women are forbidden from entering the village altogether.

Labor power is a central concern in Orang Rimban society, and every member, if able, is expected to contribute to the well-being of the group. Even child labor is utilized to its fullest extent. As soon as children can walk, they learn, mostly through imitation, the tasks appropriate to their gender. Girls will look after their younger siblings, fetch water, cook, weave sleeping mats, collect firewood, help clear swiddens, and other household chores. Boys will also help clear swiddens and follow older boys and adult males on fishing and hunting excursions.

Young girls will be expected to take care of and nurture younger siblings, and it is not uncommon for a 7-year-old to spend an entire afternoon looking after younger siblings while her mother is out collecting forest products. On other occasions, they may accompany her on short excursions to dig for edible tubers. At this age, a girl will mix freely with boys, but as she approaches menarche her domestic responsibilities will increase along with her increasing awareness of her sexuality. She will already understand and adhere to the social sanctions regarding excessive contact with males. When she reaches her menarche, and for the remainder of her pre-marriage years, the only men she will interact with will be her male siblings and father. It is not uncommon, however, for an adolescent or young-adult girl to eschew intimate contact even with her male family members, who, following the same code of conduct, may speak to her only when necessary.

Female children are particularly coveted and prized. Aside from helping with household chores, such as cooking, collecting firewood and water, nurturing younger siblings, and various other domestic tasks, they will someday fetch a brideprice or fine, often paid in sheets of cloth. In more recent times, gold and currency have also been used. Female children are also valued for the subsequent labor power of an in-marrying male they will bring. More pressure to be self-sufficient is brought to bear on boys, and they will be encouraged to collect forest products or go fishing at the early age of 7 or 8. As they approach their adolescent years, they will accompany men on hunting excursions and increase their proficiency in forest-product collecting. They will commonly give their earnings to their mother for safekeeping or for the group's immediate needs. The logic behind expecting young boys to produce and contribute to the camp's subsistence base lies not only in their inherent abilities, but also in the recognition that they will provide their labor power during their growing years, but eventually will leave the camp to marry-in to another group. Moreover, they will need such survival skills in order to seek a wife and support a family someday.

Obedience to adults, particularly fathers, is an enduring characteristic of Orang Rimban family life. Unlike most of the world's egalitarian hunting and gathering societies, where children enjoy great personal autonomy and are expected to respect, but not necessarily obey their parents (Denatan et al. 1997), Orang Rimban children are highly disciplined and are expected to both respect and obey their elders. A child that does not obey a parent is referred to as "evil" (*jahat*) and, in extreme circumstances, may be subject to physical punishment. This is more common among same-sex parent-child relations. For example, a father will not beat his daughter, and a mother will rarely, if ever, beat her son. More commonly, however, children are scolded

verbally to invoke a sense of shame that is especially felt when their behavior is called into question publicly before the scrutiny of the camp.

## B. Sociolegal Status of Males and Females

### *The Adult World*

As mentioned above, most of the world's hunting and gathering peoples are egalitarian in their social organization. The Orang Rimba are an exception in this regard, in that competition between men based on unequal access to women creates distinct inequalities between men. As a result, disputes commonly arise between men over their "rights" to women. Out of the need to protect one's claims to women, fathers over daughters and husbands over wives, the Orang Rimba have developed strong notions of law and social order. A male's voice is often oratorical and loud, and their strong sense of law and moral propriety is revealed in the content and character of their speech. In some areas, they have assimilated to an archaic Malay hierarchy, one which the Malays themselves no longer ascribe to, where various ranks preside under the authority of a high-ranking headman (*tumenggung*). These hierarchies most likely served as a mechanism through which they could be governed, however loosely, by the wider rural society, and to extract valuable forest products for external exchange. But they also serve as a legal mechanism through which serious disputes can be resolved. Incumbents are elected to office by their own kinsmen after demonstrating their mastery of formal *adat* customary law, which is exhibited through a public recital of its precepts. In areas where the Orang Rimba have not assimilated to this hierarchy, marked inequalities between men still persist, mainly as a consequence of uxorilocal postmarital residence and the requisite subordination of in-marrying male's to their father-in-laws.

A deep mistrust between distant or non-kin males regarding access to women is a pervasive characteristic of Orang Rimban social relations. Women are fiercely protected from outsiders, and restrictive taboos on interaction with women by non-kin males are strictly adhered to by all but the southernmost groups. Local residential camps, therefore, are usually comprised of only close kin. Groups with distant or no kinship ties, although cooperating occasionally, perhaps by sharing game or storing foodstuffs for one another, will occasionally suspect each other of wrong doings. The nuclear or extended family, therefore, is the core and basic building block of Orang Rimban social life. Constituting their domestic sphere, it is the fulcrum from which all notions of self and collectivity, as well as relations with others, emanate.

Women are normally regarded as legal minors (Sandbukt 1988ab); but while women are normally subordinate to either their spouse or male relatives, they do often enjoy considerable autonomy within the domestic context, holding considerable influence in private family matters and in the unconditional loyalty they receive from their children. In legal matters, however, in cases of dispute or whenever personal rights are called into question, women are always subordinate either to their male consanguines or affines. Adultery, "wife stealing," and excessive intimacy with an unwed girl (*gadis*) are the most serious breaches of Orang Rimban customary law, and severe punishments may be administered by a headman when such transgressions occur. In cases when a headman is not present, a male litigant, perhaps a father or male spouse, will demand payment of a fine outright, as compensation from the accused male. Such fines are commonly paid in cloth, gold, and cash currency. When disputes cannot be effectively resolved by the two parties concerned, a headman or local villager, perhaps a village headman, will

be summoned to mediate. In most cases, the woman involved will not be held accountable. Her actions are more often viewed as a subconscious response to the male offender's sorcery or "love magic." Full responsibility, therefore, is brought to bear on the actions of men, while strict behavioral constraints are adhered to by both sexes in order to temper suspicions and prevent such transgressions from occurring.

### *The World of Children*

The legal status of children is called into question when a parent dies. For example, in instances when a mother has died, her brother, rather than her spouse, will claim legal custody of the children, as is prescribed by traditional *adat* law. This often leads to a dire situation for fathers, who are pressed to either run off with their children or mount a defense against their brother(s)-in-law for custody. Life-long discord between men often results out of such situations, leading to disputes that may never be effectively resolved. "Legally," however, a widowed male will be required to join the group of a brother-in-law and remain subordinate to him. A man who loses a spouse, therefore, also loses a degree of autonomy over his children and himself if he wishes to remain with his children without fleeing the area.

In cases when a father dies, men, particularly those wishing to acquire a second wife, will often assert their claim to the widowed woman. In such instances, a woman can be taken against her will if her male relatives are unable to ward off such men. This happens when the male siblings are too young or simply unable to effectively assert themselves. Having a second wife increases a man's prestige and contributes greatly to the labor force, particularly because child-labor is also utilized. Moreover, female children will one day fetch bride-service and the requisite subordination of any in-marriage male. Orang Rimban life, therefore, is highly political, and power relations between men very much hinge on their ability, or inability, to claim and maintain their "rights" over women and children.

In many cases, women are enjoying greater autonomy these days as contact with neighboring village populations increases. They often travel to village markets to buy supplies unaccompanied by men. This would have been unheard of only a decade ago when women were still fiercely protected against the dangers of the outside world. In some areas, the Orang Rimba still maintain such taboos regarding excessive contact with outsiders. In all cases, however, a woman will not travel to the village unless accompanied by another woman or by children. Unwed and newly wed women are particularly restricted from excessive contact with outsiders, and they often do not leave the general vicinity of the camp unless they are deep in the forest. Boys, however, are free to travel as they desire, shifting their residence as personal whim dictates, often without announcement. Only when a male marries will he be obligated to other persons.

### **C. General Concepts of Sexuality and Love**

There is only one word in the Orang Rimba's lexicon that corresponds to the Western notion of "love" (*sayang*). While translating literally into the English notion of "pity," it more accurately connotes empathy and endearment. Often asexual in its usage, it is most commonly used to describe feelings toward children and long-acquainted spouses, particularly where bonds have grown and strengthened throughout the years. Romantic love is a much less articulated notion, most probably because it commonly occurs among young persons and leads to tensions between the two families involved, who must negotiate a solution, such as marriage or payment of fines to the

girl's family in cases where excessive intimacy, which can consist of mere flirting, has occurred. Where marriage is consummated between first cousins, strong bonds may quickly develop through the pre-existing stable relationship between families, particularly in cases where the spouses have been acquainted since childhood.

While the complexion of any relationship is highly contingent on the individual personalities involved, the ability to bear children and perform adequately in household and subsistence-related activities is a necessary prerequisite for both sexes in order to allow a stable union to develop. Both sexes will seek an industrious mate, but in many cases their families will assist, or even determine, their children's spouse, particularly in the case of females. In the female context, bearing and nurturing children, forest-product and tuber collecting, and general domestic efficiency are highly valued attributes. A barren woman is either divorced or relegated to the subordinate status of second wife. In the male context, good hunters and natural leaders who are brave in articulating the group's needs to outsiders, thereby politicking effectively, are sought out, and in some cases, are able to marry more than one wife.

Lust is considered a natural inclination among men, but is downplayed in women. Far from embracing a woman's natural sexual desires, the Orang Rimba see women as innately vulnerable and, therefore, in need of protection against the predation and charms of men. Strict rules prohibiting male-female contact outside of marriage serve to combat or remedy a male's natural proclivity to seek a female. Although sex is accepted as a human urge, its referent, *mengawan*, is rarely spoken in the presence of women. Sometimes, a young man's desire for a woman will prompt him to run off with a girl without the consent of her father, particularly in cases where he either does not wish to perform bride-service, does not have the resources to pay a brideprice, or is simply unable to gain the trust and acceptance of the girl's family (see Section 5B, Interpersonal Heterosexual Behaviors, Adults, on Courtship and Marriage). Whatever the method of consummation, strong emotional dependencies will develop through the course of a lifetime, and the losing of a spouse is met with uncontrollable weeping that can last for weeks on end. (Keep in mind the hardships and loss of status experienced by widowed men and women discussed above.)

## **2. Religious, Ethnic, and Gender Factors Affecting Sexuality**

Among males, loincloths are worn that cover the genitalia while exposing the buttocks. Women wear wraparound skirts known as sarongs and often go bare-breasted, particularly if they are nurturing young children. No sense of embarrassment is felt by such bodily exposure, because domestic units are comprised of only close kin. However, while in the village to trade, Orang Rimba now adhere to village etiquette and wear Western-style trousers, Indonesian sarongs for women, and shirts. Back in their forest camps, however, they revert back to their traditional attire. Men these days, however, are increasingly wearing short pants, even while in their forest camps.

Since their introduction in recent decades, brassieres have been commonly worn by women, often with no shirt. In the past, women wore brassieres outside their shirts as decorative attire, ceasing only when local villagers explained the proper manner in which they are to be worn. Orang Rimban women, nonetheless, continue to wear only brassieres without shirts while in their forest camps to provide easy access for breastfeeding an infant.

Children will remain naked until they reach the age of 3 or 4. During these years, they will mix freely with few, if any, behavioral constraints relating to gender. At this early stage in a child's development, however, a boy's sexuality will be exalted. This is best exemplified by the playful attention a boy's genitalia receive from camp members. The foreskin of the penis is often squeezed and the residual odor on the fingertips is smelled with much fervor and delight by all, who will claim it smells "sweet." A female's genitalia, however, do not receive such attention; on the contrary, they are rarely, if ever, referred to. A male infant will also receive a kind of "erotic" nurturing from his mother, who will adore and kiss him by smelling or sniffing while breastfeeding, or massage his penis and anus with no inhibitions. Female children, however, do not receive such attention from either parent.

As children grow, maternal bonds weaken and they are encouraged to be independent, both economically and emotionally. They will increasingly seek the company of their age-mates, with whom they will play and venture into the forest to search for food and forest products. They will no longer be permitted to sleep with their mothers, not only in order to encourage independence, but also to discourage incestuous desires in the boys. By the time adolescence is reached, both sexes will be well versed in the particular modes of conduct appropriate to their gender. Boys avoid all contact with young unwed females, while the latter eschew contact with all men.

A girl will cover her breasts during her adolescent years, exposing them once again only after marriage, when she will need to nurture her young. Expressions of female sexuality and displays of femininity are, therefore, systematically discouraged; and whereas only men are held "legally" responsible for their actions, heavy responsibility also rests on women to uphold ideals of purity and chastity, a task which often proves to be increasingly difficult as they come of age and become the temptation to acquisitive young bachelors or older males wishing to acquire a second wife. Should a woman fail in upholding these ideals, a sense of shame and embarrassment will be brought to bear on herself and her family.

### 3. Knowledge and Education about Sexuality

#### A. Government Policies and Programs

The vast majority of Orang Rimba live in geographically isolated areas outside the main network of roads that connect most larger rural villages and towns and, therefore, have little or no access to formal schooling. Only those settled groups that are near roads have access to the primary schools found in nearby villages. Even in these cases, however, attendance is sporadic, as children are often required to help their families with subsistence-related work and/or parents may be unwilling to permit children to attend for fear of enculturation into the "village-world," where Malay customs and Pancasila national philosophy are taught. (Recall the Orang Rimba's staunch opposition to village ways described in the opening section on Demographics.)

In some cases, however, the Indonesian Department of Health (Dinas Kesehatan) has sent healthcare workers to those Orang Rimban settlements that are accessible by road to hand out hygienic supplies and offer advice on contraception and family planning (see Section 9, Contraception, Abortion, and Population Planning).

#### B. Informal Sources of Sexual Knowledge

As camp life is normally public and informal in nature, unmediated by walls or strong notions of privacy, children are free to overhear whatever they may take an interest in.

Young children may overhear or see the silhouettes of their parents making love in the same shelter should they awaken in the middle of the night. As married men will always be on alert for any undue attention or sexual overture towards their spouses, they will rarely discuss matters that are sexual in nature with other married men so as to avoid attracting such attention to her. However, boys and young men may discuss sex among themselves, outside the company of women. While uttering the word *mengawan* (sex) in the company of females is forbidden, young boys commonly discuss young girls, as well as their own sexuality, among their close age-mates. Masturbation and female anatomy may also be discussed, often playfully, by young males. Girls may have similar discussions, albeit in a less explicit manner.

Almost all sexual knowledge, therefore, is gained in the informal context of the camp, either through overhearing adults or through rehearsal with their same-sex age mates. Such rehearsal or "play" may occasionally lead to homosexual behavior among boys (see Section 6, Homoerotic, Homosexual, and Ambisexual Behaviors). While girls may overhear the discussions of older women and are well aware of the process of conception, they are generally less experienced in terms of premarital sexual exploration, because of the considerable pressures they are under to uphold ideals of chastity. It is therefore most probably the case that women learn the techniques of sexual intercourse only after marriage, following the lead of their spouse. This may simply involve assuming the bottom position, as the act of coitus is always performed in the "missionary" position.

### 4. Autoerotic Behaviors and Patterns

As mentioned above, the genitalia of male infants and children are the object of much playful affection. As male children reach adolescence, and often in their prepubescent stage, they will begin to explore their own bodies and perhaps even the bodies of their male age-mates. Young boys who have developed intimate relations with one another are extremely uninhibited with their bodies in each other's presence, and it is not uncommon for young boys to touch and comment on the dimensions, size, and general qualities of an age-mate's penis. At the site where this author collected data for this report, preadolescent and adolescent boys were well aware of which boys could and could not ejaculate through masturbation. And while this was most commonly performed in private, they did not feel any sense of shame or embarrassment when detected by the author of this chapter or their peers.

Among adults, masturbation is looked upon as something natural to the male gender. Women, on the other hand, are expected to live up to the ideals of purity and loyalty to men, and are thus discouraged from showing any expression of sexual enjoyment outside of marriage. It is therefore unlikely that masturbation would occur with anything near the same frequency as found among males because of the behavioral restraints imposed upon them.

### 5. Interpersonal Heterosexual Behaviors

#### A. Children and Adolescents

##### *Puberty Rituals, and Premarital Sexual Activities and Relationships*

Orang Rimba do not practice any formal puberty rituals or rites of passage. However, when both genders have demonstrated a degree of self-reliance, which for boys includes proficiency in hunting and forest-product collecting—the former a skill required to perform adequate bride-service and eventually feed a family, and the latter as a means of cash income—they will be accorded relative degrees of re-

spect by their elders. An indication that a child or adolescent has reached a level of self-sufficiency may be when she or he has a personal debt recorded in a villager's debit book. This implies that debts will be paid for products credited (e.g., rice, cigarettes, sugar, coffee, flashlight batteries, etc.) without the help of the young person's parents. In some rare cases, parents will wait until the child reaches this degree of sufficiency before giving a name.

Other indications that a child has "come of age" might be smoking cigarettes bought with their own earnings with other males, and for girls, covering the breasts with a sarong. This may occur well before menarche is reached, as the girls become increasingly aware of their sexuality and the appropriate modes of conduct incumbent on them. Marriage, however, is the decisive indication of adulthood, perhaps more so for men than women. A woman achieves the full respect accorded to womanhood when her first child is born.

As noted earlier, adolescents and pre-adults are required to adhere to strict taboos on touching or flirting with the opposite gender, and any act perceived as constituting excessive intimacy is grounds for adults to convene in order to discuss the matter and administer a fine to the accused. Because of such fear of punishment, premarital affairs of any sort are uncommon and always secretive. In almost all cases, the male will be blamed for "corrupting" the girl and he will be required to pay a fine (*dendo*), most commonly in cloth, currency, and occasionally gold. In cases where sex has occurred between the couple, they will be required to marry, but only after the male endures a frenzied beating by the girl's younger siblings for the shame he has caused her family.

Any sort of premarital sexual activity, therefore, is very rare, as it is considered among the most serious of crimes in Orang Rimban society, and is punished accordingly. In most cases, men also have no sexual experience with a woman prior to marriage. These days, however, pre-adult males are in increasing contact with local villagers and, in one case that was reported to the author, young Orang Rimba men were beginning to seek the services of prostitutes for "unattached" sexual enjoyment.

## B. Adults

### *Courtship and Marriage*

Marriage is rarely consummated as a result of a woman's personal preference. She may, however, be able to refuse a male suitor, depending on the nature of her relationship with her family and their own position on the matter. In most cases, however, daughters will acquiesce to the wishes of parents, their fathers in particular, as after many years of segregation from males outside the immediate family, they have developed no other ties with men, romantic or otherwise, and, therefore, may see marriage as an opportunity to progress to the next stage in their development. They would rather enjoy the accorded prestige and status of marriage, rather than remain a subordinate member in their cognatic family. In other cases, however, girls may be afraid and apprehensive of leaving the security of their parents' guardianship to enter into a new and unfamiliar living arrangement with a man. This may be particularly true when girls are betrothed at an early age to a male that they are relatively unfamiliar with or do not have feelings for.

In many cases, marital unions will occur between first or second cousins, most preferably where their parents are siblings of opposite gender. It is considered a mild form of incest (*sumbang*) when persons descending from same-sex siblings marry. In such cases, the male suitor must pay a fine to the family of his bride. In cases where a woman's family approves of the union, the father will fix a brideprice, which

will be paid to the father and, in some cases, be distributed to the bride's male siblings as well.

Loyalty is the most important quality sought in a son-in-law, and the latter's bride-service is aimed at gaining the trust of the bride's family. During this period, which can last months or years, the male suitor is scrupulously tested for his honesty and generosity, which he demonstrates by sharing the spoils of his hunting and whatever other resources he acquires, such as coffee, cigarettes, and other products bought with his earnings from forest-product sales. He is also expected not to be "proud" (*banga*), which might be revealed through not showing proper respect to the bride-to-be's family or "saying one thing and doing another." If he is unable to demonstrate proficiency in subsistence-related skills, including collecting forest products, the male suitor will be thought to be either insincere in his intentions of marriage or simply incompetent in his ability to support a family and, consequently, he will be deemed an unworthy candidate for marriage into the girl's family.

In many cases, after being refused marriage by a woman's father, and finding no other welcoming host families, a suitor is pressed to either run off with the girl or express his intentions of marriage to her in private, in an attempt to circumvent the authority of her disapproving family. In such cases, the union may take place, but only after he pays a fine and possibly endures a beating by the bride's female family members and younger siblings for his unduly intimacy with the girl (Sandbukt 1988b, 114-115). The bride may also be severely beaten by her mother for her defiance and the consequent shame she has brought upon her family.

Payment of a fine is preferred by the host family, as it does not carry implications of bride ownership as does the outright payment of a brideprice. This type of union, *kawin lari* (literally, "marrying on the run"), often brings a sense of embarrassment and shame to the family of the groom, but nonetheless occurs with at least the same frequency as arranged marriages. Elopement of this sort may also occur between first cousins where the bride's family does not approve of the union. In one recorded case, a young man threatened to defect to a nearby village and "enter Islam" if his male cousin, whose father was deceased thereby entrusting him by default with the authority to betroth his sister, refused to give her in marriage. This young man was competing with another cousin and with his own father, who wanted to take the girl as a second wife.

In extremely rare cases where marriage occurs between male villagers and Orang Rimban women, the couple will always take up residence in the village. As such, this sort of marital arrangement is deeply resented by the Orang Rimba, in terms of the loss of a female family member, the lost labor power of an in-marrying male, and perhaps most significantly, in the act of making the prohibited cultural crossing of forest and village domains. Consequently, the family will often break ties with the female defector.

In cases where a woman's father is deceased and her siblings are either too young or unable to assert themselves with an older, more dominant male, the latter may bring enough pressure to bear on the situation, that the girl will be taken by coercion, and he may simply pay a compensatory fine to her male siblings. Having no father-in-law to provide bride-service for or be subordinate to in an uxoriocal residential arrangement, he may simply adopt the new wife to live in his own group. As such, this sort of marital arrangement is highly undesirable to the family of the bride and, concomitantly, is much sought after by Orang Rimban men, as it provides them with a high degree of personal autonomy that would not otherwise be achieved until the death of a father-in-law.

In another instance, an adult male of approximately 24 years of age (Orang Rimba do not keep track of age or birth dates) violated the above courting and marriage customs on two separate occasions by expressing his intentions of marriage directly to the girl and, later, by approaching another girl's father and not adequately performing the incumbent bride-service duties or producing the specified brideprice at a later date. In the former case, he was fined five grams of gold, whereas in the latter, he was required to pay 60 sheets of cloth to the offended father. This young adult male, having exhausted all internal options for marriage, eventually defected to a nearby village and adopted Islam, albeit superficially, in order to increase his mating selectivity in a new social environment. In such cases of defection to local villages, Orang Rimba are considered only marginal members of the wider rural society and are treated accordingly. During the time of this writing, the aforementioned male had yet to find a spouse, because of what local villagers claimed was the typical Muslim man's unwillingness to betroth a daughter to an Orang Rimban male for fear of causing shame to the family, or producing "stupid" offspring. This reasoning is based on the assumption that intelligence, or lack thereof, is hereditary, and the Orang Rimba are inherently inferior with limited intellectual capacities.

Among some groups, particularly in the southern areas, newlyweds will leave the group to camp alone for several days. In some cases, a week of prohibition on sexual intercourse is observed (*pantangan*), during which time parents of the bride will bring food to the couple, who are also not permitted to leave their shelter to engage in subsistence-related activities. In all cases, newlyweds will construct a shelter in which they will cohabit, signifying the commencement of their new marital arrangement. Consisting of tree stalks for scaffolding and tied with vine with logs sometimes overlain with bark for flooring, these temporary shelters are not built with walls and are customarily constructed by women. The birth of the first child symbolizes a stable union, while inability to produce a child is commonly seen as infecundity on the part of the woman and may be grounds for divorce.

A married male will be required to remain subordinate to his in-laws, continually sharing resources and providing moral support while residing in the same camp. Occasionally, the couple will reside in another camp should resource distributions necessitate, but are nonetheless always required to share any captured game and other resources. They are expected to return eventually to the camp of the bride's family. This ensures the bride will have sufficient moral support while her family will reap the benefits of her spouse's labor.

In time, a wife's loyalty will grow toward her husband, but she will also be expected to devote her loyalties to her blood relatives. Occasionally, tensions arise when nuptial and consanguinity obligations conflict, such as in cases where a woman complains to her father or brothers of maltreatment or insufficient food provided by her husband. In such cases, a husband will feel betrayed and may threaten to kill his wife. It should be noted, however, that homicide among the Orang Rimba is virtually unheard of, and such displays of anger more commonly serve as mere outlets for one's frustration and/or a strategy for dissuading a wife from further pursuing the matter.

Polygamy is a common conjugal arrangement and second wives are most commonly divorcees, orphans, or lack a father and/or other male consanguines. In the latter cases, a woman's matrimonial value is decreased and she is also rendered a more vulnerable target because male support is lacking—a situation that males will capitalize on without

exception. An upper limit of seven wives has been reported, while at one field site in this author's study, a man was cohabiting with five wives, the fifth wife being an adopted daughter. In most cases, however, monogamy is the most common arrangement.

When a second wife is taken, she must first endure a ritual beating by the first wife for the shame that has been caused to her that her husband would seek another spouse, and to assert her seniority in their new residential arrangement. The new wife is not permitted to strike back or retaliate at any time and she is expected to remain subordinate to the former indefinitely. Their shelters may stand as little as three feet from one another, and the husband normally alternates residence with no fixed pattern; his original wife, however, may be given preference. Should a first wife discover her spouse in the act of coitus or other intimate activity with a second wife, the latter may once again undergo a severe beating for arousing jealousies and her perceived insolence in displaying her affection.

Divorce is not uncommon but becomes increasingly rare after the first child is born. Divorce may be initiated by the family of the bride, often when a husband does not adequately provide for his wife and children, or does not share with or show the proper respect to his spouse's consanguines, particularly her father, but also her mother and brothers.

If a woman wishes to remarry, she will be expected to wait at least two to three years in order to avoid being perceived as overly eager in her desire to form a union with another man. If she has been proven guilty of adultery in the past, she may be forever stigmatized and forbidden to remarry, in theory at least. If a woman remarries shortly following her divorce, she will be fined 500 sheets of cloth by her ex-husband and may lose custody of her children. A man is expected to abstain from marriage for at least six months, and a lesser fine, perhaps 20 sheets of cloth, must be paid to the family of his first spouse in the event that he remarries too soon.

Wife stealing is a reported occurrence, and in such cases the woman in question may not be held liable (see Section 1B, Sociolegal Status of Males and Females). The "stolen" wife's family and spouse may prefer rather to accuse the male culprit of enticing or alluring the woman with sorcery or "love magic." In one instance, a male was known to have "stolen" four wives, all on separate occasions. The putative punishment would have been severe fines or death by the spear of the woman's male siblings or husband. In this case, purportedly, no male siblings or husbands were courageous enough to seek retribution, and the fearless offender, aside from being banished from the area, was said to only have endured a physical thrashing by the women's younger siblings. However, if it were perceived that the woman fled intentionally and was willingly cohabiting with another male, she would also be the subject of death threats made by her male siblings, father, and/or husband for her immoral conduct.

### *Sexual Behavior*

Immediately after marriage, a couple will take up residence in the same shelter, but in many cases, sexual activity will not commence until a much later date, when the girl overcomes her initial fear of sex with her new spouse and gradually adjusts to her new residential arrangement. Such a disposition is created by years of avoidance of males, which in many cases has instilled a deeply inculcated sense of embarrassment towards men as well as her own sexuality. This may be particularly true in cases where girls marry at an early age. A newly wed wife, therefore, may require up

to two to three years before she is comfortable with engaging in sexual intercourse.

Occasionally, couples will reside a short distance apart from the rest of the group for the sole purpose of conception. This is particularly so in polygamous marital arrangements, in order to remain out of the purview of other spouses so as not to arouse jealousies. In most cases, because their simple temporary shelters do not contain walls, the couple will engage in sexual activity discretely during the night while others are sleeping or camped a safe distance away. Once children are born, the couple must engage in sexual activity only when children are sleeping, or during their infancy years when they are too young to be aware of their parents' behavior. Recall the rule prohibiting children, once they reach the age of 5 or 6 from sleeping with their mothers. This also insures that a couple will have sufficient privacy to engage in sexual intercourse in the confines of the small family shelter.

In most cases, the male initiates sexual activity. His spouse will normally not refuse him, particularly in polygamous arrangements where time may be divided between wives. In cases where a male has been effectively subordinated to his in-laws, a woman may exercise her power to refuse him or voice her opinion regarding the matter. Also, where couples are first cousins, a considerable rapport may develop, thus creating an arrangement through which mutual compliance dictates their course of action regarding such matters.

Acts of fellatio and cunnilingus are unheard of within traditional modes of sexual intercourse. Coitus is always performed with the man on top and woman on bottom in the "missionary" position. As is the custom in most areas of the Indonesian archipelago, kissing is not performed with the lips but, rather, involves the smelling or sniffing of the nose and facial area. Incidentally, mothers and fathers also practice this behavior in their nurturing of infants and young children.

### 6. Homoerotic, Homosexual, and Bisexual Behaviors

Male homosexual behavior has been reported in rare instances among adolescent boys and young adult males, whereas it is practically unheard of among married men. The actual form and nature such relationships take is unclear, and in most cases may amount to mere sex rehearsal or exploration. One case, however, has been reported first hand to the author by two married men of their engagement in anal intercourse during their adolescent years. After being detected by an adult, they were each fined 20 sheets of cloth and stigmatized for a brief period. As married adults with children, both men recounted the episode with humor and expressed no shame or embarrassment. While no cases are known of married men engaging in homosexual activity, informants claim that this may have occurred in previous generations. They could not recall actual incidents, but claimed that the men involved must have been punished severely, perhaps even killed by the male members of the wives' families. (Recall that homicide is more commonly threatened and rarely actually occurs.)

Despite the lack of information regarding incidence of female homosexuality, the sense of shame and ideals of purity regarding the female body and sexuality that are so deeply inculcated in a girl during her years of development and throughout her entire life may inhibit any actual lesbian activity from occurring, even if such desires should arise. However, while questioning men regarding the issue, they claimed that such conduct would not be seen as a serious of-

fense, most probably because it does not threaten the delicate balance of power relations between men as do other forms of sexual misconduct, such as adultery.

### 7. Gender Diversity and Transgender Issues

In the small Orang Rimbal population of less than 4,000 persons, incidence of gender-conflicted persons is statistically rare. No cases have been reported of transvestite, transgenderist, or transsexual individuals. Even if such tendencies are harbored in individuals, they may never be realized because of the ever-present pressures to assimilate. Cases of specially gendered persons, such as hermaphrodite, *hijra*, *berdache*, *xanith*, or intersexual, are also unreported.

### 8. Significant Unconventional Sexual Behaviors

#### A. Coercive Sex

##### *Child Sexual Abuse, Incest, and Pedophilia*

Child sex abuse has not been reported, but informants claim that such occurrences may occur between men and adopted daughters, but never between men and their natural-born children. Purportedly, an offender would be speared or liable to pay severe fines if detected. Pedophilia involving two males, although virtually unheard of, is not considered a serious offense, mainly because the male body is not seen as an object of purity to be coveted. Death, however, is the stated punishment if such an occurrence involved a young girl. Again, it should be emphasized that actual cases of homicide are extremely rare, and it is more commonly the case that only death threats are made, but never actualized in violent action.

Incest taboos are strictly adhered to, and there are no known cases of sibling or parent-child unions or sexual relations. Indirect forms may occur, but are subject to varying interpretations as to whether they constitute actual incest. For example, the above-mentioned instance where a male married an adopted daughter was not seen as constituting incest by the former; but his sons, who were raised with the girl and considered her a natural sister in every way, strongly disagreed. Despite their attempts to prevent the union from taking place, which included a report to the chief of a nearby Malay village, their father insisted he was not committing incest, as the girl was not related to him by blood.

##### *Sexual Harassment and Rape*

Incidence of sexual harassment and rape is rare and always subject to interpretation by the parties involved. For example, in the above-mentioned cases where men elope with women in an attempt to bypass the authority of the latter's disapproving family, the family of the girl may claim that she was carried off against her wishes or while under duress. If the daughter agrees that this was the case—which may be in her best interest in instances where she fears punishment—her family may claim abduction, or even rape, if it can be established that sexual intercourse had occurred. In such instances, the male would be required to marry the girl and pay severe fines, as well as endure a beating by the girl's younger siblings.

Other sorts of harassment initiated by men towards women will, almost without exception, be interpreted as sexual in nature. In one case observed by the author, an adolescent male was accused of following a girl in the forest while collecting forest products. During a series of meetings between both fathers, which lasted three days, the accused male claimed to have been coincidentally working in

the same area of forest, while his father, knowing well that his son was attracted to the girl and was indeed following her, tried to “settle amicably” by suggesting the two marry. The father of the girl refused vehemently in typical Orang Rimban fashion, and the young male was fined 20 sheets of cloth for a kind of “sexual harassment,” even though physical contact, or even verbal communication between the two, did not occur.

### 9. Contraception, Abortion, and Population Planning

Plant contraceptives and abortifacients are not used and infanticide is unheard of. A postpartum taboo on sexual intercourse is adhered to for several years after a child is born, in order to allow for a sufficient weaning period. During a swiddening cycle, taboos are more lax; hence, when groups revert back to nomadic foraging, a woman may have more children to feed than she can comfortably manage. “Blood money” (*bangun*) is paid to a woman’s parents if a child is thought to have died of milk deprivation caused by closely spaced pregnancies, which are thought to disrupt an infant’s weaning cycle (Sandbukt 1988ab).

Most groups are inaccessible to the Indonesian Department of Health’s regional and local offices, which deal primarily with neighboring rural village populations. Groups of Orang Rimba living in government-sponsored settlements, or who have settled on their own accord, may be visited by Department of Health nurses, workers, and, occasionally, government bureaucrats. Advice on infant care and family planning is given, and most recently, contraceptive injections have been offered, but widely refused, mainly because of mistrust and disapproval on the part of their spouses, who would prefer that the government not get involved in private family matters. Their visits are seen as mere formalities with distracted objectives. Such meetings involve little or no evaluation and are sporadic with no routine follow-up visits. During these “courtesy calls,” soap, combs, and other toiletries are handed out, which the Orang Rimba find insulting, along with biscuits and cigarettes! For this reason, the Orang Rimba, males in particular, may resent the efforts of representatives of the Department of Health, which they perceive as being insensitive to their true needs.

### 10. Sexually Transmitted Diseases and HIV/AIDS

#### A. Sexually Transmitted Diseases

Not much is known about the incidence and types of sexually transmitted diseases among the Orang Rimba. Male informants can name at least three different classes of sickness attributed to sexual contact:

- *Koreng*, literally “scabies”: symptoms include itching and skin irritation in or near the genitalia. Instances are said to occasionally lead to divorce in cases where symptoms have not dissipated.
- *Sakit bini/sakit laki* or *sakit kocing*, literally “wife/husband sickness” or “urinating sickness”: symptoms include urinary tract infection characterized by a burning sensation during urination.
- *Buntal*, or “swelling,” which is said to feel like biting crabs. Buntal can infect the urinary tract and eventually lead to erosion, with death in rare cases. A tale was recounted (whether symbolic or literal is unknown) of a man’s father spearing to death his daughter-in-law for allegedly afflicting and eventually killing his son with this disease.

The Orang Rimba employ a limited range of plant remedies, mainly derived from bark, leaf, and root extracts. For venereal disease, however, only bamboo water is used. Normally for the treatment of *koreng*, pulp water is drunk directly from the fillings of a species of bamboo shoot (*ae kurung bamboo*).

#### B. HIV/AIDS

Intermarriage with local village populations is rare, and in cases where intermarriages do occur, Orang Rimba will marry into the village rather than vice-versa. Their forest-dwelling populations, therefore, are somewhat pristine, from a genetic point of view. This, coupled with the very low incidence of sex outside of marriage, has rendered their populations relatively safe from the wide range of sexually transmittable diseases that may occur among the surrounding Indonesian populace. There are no reported cases of HIV or AIDS among forest- or village-dwelling Orang Rimba.

### 11. Sexual Dysfunctions, Counseling, and Therapies

Male impotency is a sexual dysfunction that is rarely reported; but inability to conceive when males do not suffer from impotence may also be considered a form of sexual dysfunction, for which a female spouse will most commonly be blamed. In cases where the woman is known to be fertile, as in second marriages where she has produced offspring during her first marriage, she may seek a divorce on the grounds of her spouse’s infertility. In cases of male impotency, an aphrodisiac is used to induce penis erection. This remedy is a root extract from a species of plant locally referred to as *penyega*, and can be boiled and drunk with water, or eaten directly.

#### [A Postscript on the Dugum Dani]

ROBERT T. FRANCOEUR [Update 2003]

[In 1938, the Dutch government discovered the people of Dugum Dani living in a fertile valley of the New Guinea mountains. Aside from one basic sexual taboo, the Dani live a free, unpressured sexual lifestyle with a positive view of sex and intercourse. They have only one restriction—that a member of the Wida Dani should never have sex or marry a member of the Waija, although the two clans are friendly. Yet there is little sexual activity among either clan of the Dani at any age.

[Couples seldom engage in premarital intercourse, not because of any taboo, but because they really are not interested in sexual intercourse. Whatever premarital sex occurs is always between seriously courting couples. When the Dani do marry, they usually delay having intercourse for at least two years until they have established a new residence. (Within the village compound, Dani men and women continue to sleep apart, the men in one hut and the women and children in another. After a child is born, the couple may remain celibate for five or six years before having intercourse again, allowing the mother to concentrate her efforts on raising the child. Others breastfeed their children for several years, and some Dani women still breastfeed hungry piglets if the sow is nowhere to be found, although this is not as common now as when they were discovered 70 years ago. After the death of a spouse or a divorce, a person may wait months or years before engaging in sexual intercourse. There are no taboos against male or female masturbation, but the Dani seldom do it at any age. In all these situations, the society places very few if any restrictions or negative messages on any sexual expression as long as it occurs between two persons in the same clan.

[Generally, Dani women see no advantage in having a lot of children, because their only social function is to care for the pigs, and one or two children per family can easily do that. Often the women will end an unwanted pregnancy by having a skilled friend massage and pummel the uterus, even though inducing an abortion is frowned upon.

[The Dani's low interest in sexual activity does not relate to prohibitions, repression, or a negative attitude toward sex. They live in a "perfect" climate, have a good diet, and no endemic diseases. Their hormonal balance has been found to be normal, as is their fertility rate, considering how infrequently they engage in intercourse. It is also interesting to note that the neighboring tribes do not share the Dani's lack of interest in sex. Therefore, it can be assumed that this is not a type of behavior learned from other cultures.

[Their low sexual activity seems to be a reflection of a generally low-keyed life. They are not an emotional society. They rarely show overt anger or fight. Occasionally, they have ritual battles with other tribes, but the battles, while bravely fought, are usually short, lacking in intensity and excitement. One can conclude that this society invests little psychological or emotional energy in anything they do, a characteristic reflected in their sexual relationships (Gardner & Heider 1974; Lindholm & Lindholm 1981; Sims 2001). (End of update by R. T. Francoeur)]

## Demographics and a Brief Historical Perspective

ROBERT T. FRANCOEUR

### A. Demographics

In the Middle East, the Islamic Republic of Iran occupies 636,363 square miles (1,648,173 km<sup>2</sup>) of mainly salt desert area, with many oases and forest areas, surrounded by high mountains. Iran is bordered by the former Soviet republics of Azerbaijan, Turkmenistan, and Uzbekistan in the north, by Turkey and Iraq in the west, Afghanistan and Pakistan to the east, and the Persian Gulf on the south. It is slightly larger than the state of Alaska. The climate is mostly arid or semiarid, with subtropical along the Caspian coastline.

\**Communications:* Paula E. Drew, Ph.D., 122 High St., Randolph, NJ, USA 07869; spid@nac.net.

\*\**Editors' Note:* Of all the countries examined in this *Encyclopedia*, Iran is among the most controversial. Major factors in Western/Iranian misunderstandings include the history of British imperial expansionism into Iran, influence struggles between the Soviet Union and the West over oil-rich territories, post-World War II efforts of Iran to nationalize its oil production, and several decades of armed and unarmed conflict between Iran and the United States. Another factor in Iran's negative image in the West has been the Salman Rushdie affair. These circumstances conspire to make an objective and scholarly study of sexuality in Iran very difficult.

Fluent in Farsi, Dr. Paula Drew is a British-born-and-educated cultural anthropologist. While married to an Iranian, she held consecutive tenured positions at the University of Tabriz in northern Iran and the National University of Teheran between 1964 and the fall of the Shah in 1978. In these universities, she taught Iranian women French, German, English, and psychology. For three years, she served as academic and personal advisor to female students in the humanities. She also ran a clinic for mothers and babies in an Iranian oasis community for almost ten years. Her field-note observations formed the basis for her doctoral thesis in anthropology on arranging marriages in Iran. Dr. Drew presents her view of a society torn by

(CIA 2002)

In July 2002, Iran had an estimated population of 66.62 million. (All data are from *The World Factbook 2002* (CIA 2002) unless otherwise stated.)

**Age Distribution and Sex Ratios:** 0-14 years: 31.6% with 1.05 male(s) per female (sex ratio); 15-64 years: 63.7% with 1.01 male(s) per female; 65 years and over: 4.7% with 1.1 male(s) per female; Total population sex ratio: 1.03 male(s) to 1 female

**Life Expectancy at Birth:** Total Population: 70.25 years; male: 68.87 years; female: 71.69 years

**Urban/Rural Distribution:** 40% to 60%; an estimated 4 to 6 million Iranians reside outside the country, the majority of these in the United States

**Ethnic Distribution:** Persian: 51%; Azeri: 24%; Gilaki and Mazandarani: 8%; Kurd: 7%; Arab: 3%; Lur, Baloch, and Turkman: 2% each; other: 1%

**Religious Distribution:** Shi'a Muslim: 89%; Sunni Muslim: 10%; Zoroastrian, Jewish, Christian, and Baha'i: 1%

**Birth Rate:** 17.54 births per 1,000 population

**Death Rate:** 5.39 per 1,000 population

modernization, yearnings for traditionalism, undertows of ancient customs, conflicts between urban and rural segments, tensions between newly affluent classes and the historically poor, and the influx of petro dollars, all of these surmounted by intensely complex religiopolitical conflict and warfare. Since Dr. Drew left Iran in the late 1970s, Iran has seen a revolution, a major war with Iraq, and an upsurge in Islamic activism.

Several Iranian commentators, all men, reacted strongly to Dr. Drew's depiction of sexuality and gender in Iran. They provided important clarifications and alternative viewpoints. As Dr. Drew's essay makes clear, sexuality and gender have been crucially affected by large-scale changes in Iran's modern history. In a world torn as painfully as Iran, it is probably impossible to attain consensus about the recent tidal changes in sexuality, women's roles, and gender in Iran. In the editors' view, these disagreements exist in a matrix of conflicts between West/Middle East, developed/developing economies, native/foreign, Judeo-Christian/Islamic, and male/female perspectives. There is also a strong overtone of national pride in Iran and its achievements, both under the Shah and the Ayatollah.

This chapter represents a starting point for disentangling the web of changes that have affected sexuality, gender, women, and reproduction in Iran.

\*\*\*Pseudonym for an Iranian historian and social researcher.

**Infant Mortality Rate:** 28.07 deaths per 1,000 live births

**Net Migration Rate:** -4.46 migrant(s) per 1,000 population

**Total Fertility Rate:** 2.01 children born per woman

**Population Growth Rate:** 0.77%

**HIV/AIDS** (1999 est.): *Adult prevalence:* < 0.01%; *Persons living with HIV/AIDS:* 3,473 reported through January 2002 (however, the U.S. Centers for Disease Control (CDC) estimated the more realistic figure was 19,000); *Deaths:* 350. (For additional details from www.UNAIDS.org, see end of Section 10B.)

**Literacy Rate** (*defined as those age 15 and over who can read and write*): 72.1% (1997 est.: 79%); (*male:* 78.4%, *female:* 65.8%) (1994 est.); education is free and compulsory from age 6 to 10

**Per Capita Gross Domestic Product** (*purchasing power parity*): \$6,400 (2001 est.); *Inflation:* 13% (2001 est.); *Unemployment:* 14% (1999 est.); *Living below the poverty line:* 53% (1996 est.)

## B. A Brief Historical Perspective

Iran, once known as Persia, emerged in the second millennium B.C.E., when an Indo-European group supplanted an earlier agricultural civilization in the Fertile Crescent of the Tires and Euphrates Rivers. In 549 B.C.E., Cyrus the Great united the Medes and Persians in the Persian Empire. Alexander the Great conquered Persia in 333 B.C.E., but the Persians regained their independence in the next century.

When Muhammad died suddenly in 632, he had designated no successor (*caliph*). Despite the ensuing struggle over religious leadership, the second *caliph*, Umar (in office 634-644), captured the ancient city of Damascus, defeated the Byzantine Emperor Heraclitus, and annexed all of Syria. Jerusalem and all of Palestine fell to the Muslims in 638; Egypt in 639-641. Islam arrived in Iraq in 637, and in Iran between 640 and 649, replacing the indigenous Zoroastrian faith. After Persian cultural and political autonomy was restored in the 9th century, the arts and sciences flourished for several centuries while Europe was in the Dark Ages. The Caliphs of the Umayyad dynasty (661-750), who ruled from their capital in Damascus, masterminded and extended the great Arab-Islamic conquests of Palestine, Syria, Iraq, and Egypt, across North Africa, through Spain, and into France in the west. In south and central Asia, the Caliphs extended their rule to the Indus and as far north as the Jaxartes River. Turks and Mongols ruled Persia, in turn, from the 11th century until 1502 when a native dynasty reasserted itself. In the 19th century, the Russian and British empires vied for influence; Britain separated Afghanistan from Persia in 1857 (Denny 1987, 32-39; Noss & Noss 1990, 552-556).

When Reza Khan abdicated as Shah in 1941, his son, Mohammed Reza Pahlavi succeeded him. Under the Pahlavis' rule (1921-1979), Iran underwent major economic and social change, strongly influenced by Western culture. Despite the repression of political opposition, conservative Muslim protests led to violence in 1978. The Shah left Iran January 16, 1979, and was replaced two weeks later by Ayatollah Ruhollah Khomeini, an exiled conservative religious leader. An Islamic Constitution was adopted, setting up a theocracy with the Ayatollah Khomeini as the final authority, the sole contemporary representative of the last divinely guided Imam. The complete takeover by very conservative Islamic clerics brought revolts among the ethnic minorities, a halt to Western influences in society, and a tension between the clerics and Westernized intellectuals and liberals that continues to the present. The new regime quickly revoked the Family Protection Act, which, under the Shah, allowed mothers some custody rights of their children in

cases of divorce, and restored the *Shar'ia* provisions giving child custody to the father. The war with Iraq (1980-1988) was particularly devastating to Iran. In addition to the death of thousands of young males, Iran's economy suffered severely following the 1979-1981 seizure of the American embassy and the break in international diplomatic relations.

Following the Persian Gulf War in 1991, some one million Kurds fled across Iran's northern border into Turkey to escape persecution. Following the 1989 death of the Ayatollah Khomeini, the Islamic authorities were faced with pressure from the business community and middle class to moderate somewhat their opposition to Western influences. In the 1992 Parliamentary elections, President Rafsanjani and his supporters easily won control of the government against the anti-Western opposition.

[*Update 1997:* In 1997, reform-minded Mohammed Khatami was elected president; he was easily reelected in 2001. The new President's powers, however, were severely limited, as hard-liners retained control of the judiciary, security forces, army, large economic centers, the press, and the government-run television. One of the most substantial obstacles to change has been the religious panel called the Guardian Council. Members of the panel are appointed by the supreme religious leader, Ayatollah Ali Khamenei, and are authorized to reject any legislation they consider counter to the Constitution or Islamic law. By mid 2002, with the Guardian Council frustrating Khatami's every effort at reform, the President openly challenged the Council and moved to regain powers assigned his office by the Constitution. In late 2002, the outcome of this challenge, and efforts to improve the status and freedom of women, was still uncertain (Fathi 2002c). (*End of update by R. T. Francoeur*)]

## 1. Basic Sexological Premises

### A. Character of Gender Roles

Gender roles in Iran must be discussed in terms of different stages of the lifecycle and in terms of different kin roles: mother, father, aunt, son-in-law, daughter-in-law, and so on. Iran is a dependency culture.

### B. Sociological Status of Males and Females

Children are raised to be dependent on other family members and to remain so throughout their lives. Children are taught to contribute their labor to the family as part of their duty, with no expectation of financial reward or praise. Teenage boys help their father, uncles, or grandfathers in their business. Girls help in the home and with the care of younger siblings. They make few choices with regard to their clothing or the way they spend their time, and have little or no access to money. Working outside the family is frowned upon.

At a suitable age, determined by the parents and other older kin, a husband or wife will be selected for a daughter or son by the mother. She will investigate the health, wealth, and character of the proposed spouse and bring about the agreement of the person's parents that the marriage will take place. She will also ensure the compliance of her son or daughter. The father will negotiate with the proposed spouse's male kin with regard to all financial aspects of the marriage.

Since loss of virginity invalidates these financial agreements, female offspring are physically supervised by older relatives from cradle until the post-nuptial proof of a hitherto-intact hymen. It is thus part of the female role, in the capacity of mother, aunt, or grandmother, to participate in the continual supervision of younger females, leaving no opportunity for behavior that might jeopardize nuptial agreements. Once the marriage occurs, the mother-in-law takes

over from the bride's mother the responsibilities of supervising her new daughter-in-law, ensuring her fidelity as a wife. The importance of this particular role depends both on the education level of the groom son and the residential situation, i.e., whether patrilocal or neolocal. As a wife, a woman is subordinate to her husband and his older kin, particularly his parents and older sisters. Regardless of her age, a woman's friendships with males are confined to those with her father, brothers, and sons. This is particularly true for upper-class women; the greater her family's wealth, the more likely the female is to be controlled and supervised. At the same time, there is a strong emotional component in father-daughter and brother-sister relationships, including familiar touches Westerners would likely consider somewhat erotic, if not lightly sexual.

Like the female, the male has a set of gender-defined kin roles. He remains subordinate to his father, uncles, and grandfathers until the age when his own children are marriageable. As he ages, he acquires more say in the financial affairs of the family. His major arena of power until well into middle age is the control of his wife. His mother, maternal aunts, and older sisters act as allies in enforcing his rules when he is away from home. This makes opportunities for shirking household duties, unmonitored phone calls, or unaccompanied shopping expeditions highly unlikely—let alone opportunities for infidelity. In the 1970s, wives in college and the workforce were more often than not accompanied to and from their places of study or business by an older relative or the husband. At the National University of Iran, the guard at the gate would not allow a father or brother to escort a daughter or sister to class within the enclosed campus.

As a father, uncle, and father-in-law, a man's power of veto in family decisions increases with age. He is likely to exercise strong veto over the education of his daughters and the way they dress. In this respect, he sets the rules, and his wife carries out the necessary supervision. The gender roles are thus closely tied to maintaining the rules and upholding the honor of the extended-family unit.

When the Shah of Iran was ousted in February 1979, the country reverted from a legal system, based on that of Switzerland, to the *Shar'ia* or Islamic law, under which females are not considered legally or mentally the equal of males. A woman must be represented in all legal transactions by a man, by her father or brother if she is unmarried, or by her husband if she is married.

At any time, a woman is at risk of repudiation. Divorce—male-initiated, incontestable, and brought about in a matter of days—can bring the immediate loss of her children to the husband's family. Children under Islamic law are perceived as the "substance of the male," merely incubated by the female body without any biological or genetic contribution. Children thus belong to the male, and Islamic law reflects this by allocating custody of children to the father. It is thus part of a woman's concept of her own sexuality that it is inextricably linked with the production of children; she will love them but forever risk losing them through repudiation. To keep her children, she must not risk repudiation by her husband. In a culture that has not encouraged romantic attachments leading to marriage, and discourages affection and companionship between spouses, the fear of losing her children often sustains the woman's efforts—culinary, domestic, and sexual—to please the husband, at least until the children are into their 20s. This fear of repudiation is stronger today, because of the 1979 restoration of the father's rights to child custody.

This fear of repudiation is further exacerbated by the lack of acceptable societal slots for divorced women. In a country where houses are not rented to single people, espe-

cially female, a repudiated woman must inevitably return to the home and control of her parents. Remarriage usually means becoming the wife of a man with custody of children from a previous marriage, who will often address her and refer to her by the title *zan baba*, "Daddy's woman/wife." If the children by an earlier marriage are on friendly terms with the new wife, they may refer to her by her first name or a more appropriate title.

Legal adulthood has little practical meaning, because children are always the responsibility of the father, regardless of their age. The war with Iraq (1980-1988) saw compulsory conscription to active combat of all males over the age of 12, other than only sons of widows. If a man dies, his brother automatically takes on the financial burden and social responsibilities of the widow and children. In this dependency culture, custom, not law, compels him in this.

If children do not like the arrangements made for them, it is not their place to comment, nor are there social agencies to which they could appeal. Kinship binds more strongly than law. There is also little infrastructure concerned with legalities other than blatant criminality or property disputes.

It is apparent to the careful observer that the legal and social status and rights of Iranian women are very much in transition, creating an unexpected blend of "traditional Islamic" and modern Western values. While the government still warns against a return to the near-Western freedoms that women experienced in Iran under the Shah, the strict fundamentalist practices introduced by the 1979 Islamic Revolution have undergone a major shift. Iranian women are still subject to fines, and sometimes flogging, for not wearing the *chador* (veil); they also suffer from the persistent denial of gender equality in Islamic law. Still, many Iranian women maintain that wearing the *chador* is not repressive, but in fact protects them from sexual harassment when they go out in public.

[Update 1997: In November 1994, thousands of Iranian women marched in a Teheran stadium to celebrate Women's Week and show their support for women's rights and a shift in government policy which started in 1991. The celebrations for the 1994 Women's Week included exhibitions by female artists, award ceremonies for female factory workers, and amnesty for 190 women prisoners. In recent years, a dormant family-planning program has been restarted. State-approved prenuptial contracts allow women the right to initiate divorce proceedings. Restrictions banning women from higher education to become engineers and assistants to judges have been lifted. As a result of these and other developments, the number of women in the workplace and in institutions of higher education have increased. In 1994, 30% of government employees were women as were 40% of university students, up from about 12% in 1978.

[Faezeh Hashemi, the Iranian President's oldest daughter, has become the chief spokeswoman for the emerging women's movement. In 1993, the 31-year-old former volleyball coach organized the first Islamic Women's Olympics in Teheran in 1993. "Our goal was to give women a sense of self-confidence," Ms. Hashemi announced. "In most of the Islamic world, women have cultural problems. They are regarded as a commodity. For Iranian women, the values have changed." She does not see restrictions, such as wearing the *chador*, as necessarily impeding a woman's career.

[Iranian secularists are not satisfied by this slow return to women's freedoms. They compare an event like the Women's Olympics, which attracted 700 athletes from 11 countries, but was closed to men and photographers, as a continuation of harem seclusion. Meanwhile, fundamentalists are equally unhappy, warning against the subversion of traditional Islamic values by "obscene Western values."

[The younger generation among Iranian government officials and administrators, who are more open to the West, are working to create their own complete and comprehensive version of Islamic fundamentalism that will rival Western liberalism and be viewed as better than it and other alternatives (*The New York Times* 1994). (*End of update by R. T. Francoeur*)]

### C. General Concepts of Sexuality and Love

Iranian culture is quite comfortable with speaking openly about all the physical aspects of sexuality and sexual responses. This includes open teasing about the physical side of sexuality. There is, however, a strong taboo when it comes to mentioning or discussing the emotional aspects of relationships.

The onset of attraction to the opposite sex is generally spoken of in physical terms. Teenage boys are openly subjected by older kin to routine inquiries as to their health and capacity for erections as soon as hair appears on the upper lip. "Your mustache is beginning to sprout. Do you need a wife yet?" is a more coy version of the same inquiry. The physical maturation status for young girls is measured by the onset of menarche.

Among young people, feelings of love for a person of the opposite sex are, if suspected by older kin, thought of as something to be ignored or ridiculed away rather than respected and indulged. Such feelings are only considered if they are directed towards a person found suitable for marriage after investigation by the older kin. Love is not considered a basis or prerequisite for marriage, which in turn is the only acceptable social matrix for sex.

Popular Iranian songs speak of love. Soap operas on Teheran television make much of love matches thwarted by economically more viable arrangements made by parents. Both songs and soap operas reflect the social reality. Young people see and are attracted by the face and form of members of the opposite sex, but such feelings cannot be nurtured and encouraged by dating into a situation where emotional and physical inclinations coalesce, unless there is social and financial eligibility for an imminent marriage approved by the older kin on both sides.

Even where a boy and girl meet these requirements, they will be most carefully watched to make sure they do not anticipate financial settlements. A girl who loses her virginity before such financial matters are agreed upon is not considered as having behaved immorally, but as having given the other side an advantage in negotiations, in that the girl's parents cannot now threaten to withdraw from the match, however poor the terms offered. Emotional attachment in marriage is considered desirable on the part of the wife towards the husband, but not vice versa. The male's power and control over his wife is considered in jeopardy if he is overly fond of his wife. In the early months of marriage, the husband's father and older brothers will often set up competing demands on the young man's time should they become privy to any prior arrangements he has made with his new wife. A husband will be ridiculed if he shows the weakness of acceding to his wife's wishes. A man's mother and older sisters will also often erect barriers in the way of companionship and intimacy between spouses by their continual presence and superior claims on the husband's time.

## 2. Religious, Ethnic, and Gender Factors Affecting Sexuality

### A. Religious Factors

[*Update 1997*: Islam, the dominant faith of Iranians, has two traditions or divisions: Sunni and Shi'ite. The Shi'ites, who account for 93% of Iranians, regard 'Ali, the son-in-law

of Muhammad, as the founder's proper successor, while Sunni Muslims follow the three caliphs who actually succeeded Muhammad. Shi'ite Muslims believe that God guides them through the divine light descending through 'Ali and several Imams, or divinely guided "leaders" of Shi'ism. Shi'ites have never ceased to exercise *ijtihad*, the intellectual "effort" of Muslim jurists to reach independent religiolegal decisions. Shi'ite Muslims are generally considerably more flexible and adaptive than the Sunni Muslims. However, both Shi'ite and Sunni Muslims consider each other to be members of the same tradition of faith, order, and community. To understand the connection between Islam and sexual attitudes and behavior, it is important to keep in mind that the worldwide Muslim community or *Umma* can be compared with a triangle whose sides represent history, the religious doctrine/ritual, and culture. In different historical eras in Iran's long history, as well as in other Muslim countries and communities, the balance between these three elements varies. At times, doctrine and ritual are emphasized over culture and history. At other times, cultural and ethnic identity within particular regions have been emphasized. At still other times, Muslims have emphasized the ideal of certain historical eras of Islam. Still, all three dimensions are essential to the *Umma*. (Denny 1987, 5-12, 32-71; Noss & Noss 1990).

[While the number of Sunni Muslims in Iran is much smaller than that of the Shi'ites, they and other minorities of Christians, Jews, B'hai, Zoroastrians, Ismailies, Sikhs, and Buddhists quietly reside in isolated communities. There are also seven to eight million ethnic Kurds and Belouch, the majority of whom are Sunni Muslim (Denny 1987; Noss & Noss 1990). (*End of update by R. T. Francoeur*)]

Islam, like other monotheistic religions, prohibits pre- and extramarital sex. Sex between two adults married to others is condemned as the most serious of sins (*zina*)—under Islamic law, adultery and fornication incurs the penalty of stoning to death. Some Islamic countries have at different points in time lifted the death penalty for adulterous males, while retaining it for females. In Iran and probably most Islamic countries, adultery is rare, not because of Islamic prohibitions, but because of social mores that segregate the sexes and allow no privacy. [*Comment 1997*: In the upper classes, it is rampant, for both men and women! (*End of comment by F. A. Sadeghpour*)] The Islamic sense of pollution, which prohibits all acts of worship under certain conditions of spiritual and physical uncleanness, makes public—and therefore amenable to control—otherwise private, biological events, such as menarche, menstruation, sexual contact, and ejaculation.

Males who have ejaculated, females whose external or internal organs have had contact with seminal fluid, and females who are menstruating may not pray or touch a copy of the Qur'an without first performing ablutions. Since these ablutions were not possible in the majority of Iranian houses in the 1970s, these necessary ablutions had to be performed at public facilities and were, therefore, open to public scrutiny. Prayers were said individually within the home, but audibly and in full view of others at the prescribed times of the day. Thus anyone who, through fear of committing sacrilege, had to abstain from ritual recitation of prayers or from the obligatory periods of fasting set down by the Islamic calendar, would be subject to scrutiny and interrogation by older family members about the reason for such abstention.

Most Iranian housing consists of a one-story, single large room, or two-story, two-room, with-curtain-hung alcoves, a private courtyard enclosed by a high wall, and a toilet/bath in one corner of the courtyard. The wealthy can afford to live in moderate high-rise apartments, but these are

limited because of the danger of earthquakes. This architecture and the desert environment makes privacy a premium.

Menarche announces itself to the entire household when a young girl is unable to recite her prayers. This is often the signal for parents to conclude marriage arrangements, so that the girl can be wed before her second menstruation. Intercourse between married members of the household is similarly monitored. Conception or failure to conceive is similarly apparent to all. The approximate time of any woman's ovulation can be informally calculated by interested parties. Wet dreams and visits to houses of prostitution can be surmised by the family in the same way, by watching who does and does not pray and when. Wash basins or pools for routine washing of the face, hands, and feet are set in full view of all household members in the hallway or yard. Bathing the body under a shower takes place at the neighborhood bathhouse where abundant hot water is available for a modest sum. Taking a shower, for the most part, is seen not so much as a hygienic measure, but as a way of ridding the body of anything that makes it spiritually unclean and the person unfit to participate in religious activities. The body parts are washed in ritualized sequence with prescribed prayers. The bathing practices of family members reveal a great deal of otherwise private information to those interested in monitoring them. The rituals of Islam thus abet the older members of the family in their task of controlling the sexual behavior of all those potentially reproductive or sexually active within the household.

There is a strong resistance among older women to the growing practice of installing hot water systems in the home. Although simplifying their dishwashing and laundry tasks, an automatic hot water system interferes with their ability to supervise the bathing practices of their husbands, offspring, and daughters-in-law, and thereby keeping tabs on their sexual behavior. Even in houses with a shower, the matriarch of the household often controls the means of igniting the hot water system. Similarly, she controls the supply of laundered undergarments and towels, keeping them tied up in bundles so that nobody can retrieve these essentials without her help.

Although the Qur'an does not prescribe the covering of the head for women nor the separation of men and women in public places, Iranians follow a style of dress and segregation of the sexes characteristic of Islamic societies of the Middle East. In Iran, some cities have always been more conservative than others in this regard, but the Ayatollah Khomeini did much to bring about conformity to the strictest code by making violations subject to immediate physical punishment at the hands of the young revolutionary guards, the Pastoran. [*Comment 1997*: Commentators strongly agree with this observation. (*End of comment by R. T. Francoeur*)] The traditional veil or *chador*, which in many villages and towns often concealed only the back of the head and the general outline below the waist, is now supplemented with bandannas pulled low over the forehead, and thick stockings to conceal lower limbs not completely covered by loose pants. The outline of the ankle has to be obscured because its dimension is thought to be related to that of the vagina. The veil itself is pulled firmly across the face and chest, as was always the custom in Qum, Mashad, and most of Tabriz. Now "modesty" is a requirement for all girls over the age of 9. No hair must show around the face.

By custom, certain times of the day are "women's hours" on the streets and few men are about. At other times, only men through the streets, so a woman would be conspicuous and likely to be harassed. Many stores have sex-segregated service lines, often with a curtain separating the two.

Public baths have days for women and days for men, identified by the color of the flag hoisted above the establishment. Schools, too, are segregated to the point that girls' schools employ only female personnel at any level. Places of worship are divided into men's and women's quarters with separate entrances. Informal prayer meetings are only for one sex or the other. Many celebrations and funerals in private houses send males and females into separate rooms. Women are barred from many places, such as some cinemas, restaurants, and teahouses. Other places, such as swimming pools and ski areas, allow families to enter but not young men or women, either singly or in same-sex groups. Young multiage groups of cousins might be allowed into a cinema, if several of the older males are obviously in charge.

The Iranian culture, especially now with its conservatism bolstered by the Islamic regime, is not one in which people of the opposite sex can meet casually. Clandestine meetings, for which there are few arenas, are made dangerous by the pervasive armed guardians of Islamic law, the Pastoran, who demand to see marriage certificates of couples on the street, at beaches, and parks.

## B. Ethnic Factors

Just over half of all Iranians are Persian, 25% Azerbaijani, and 9% Kurd. Although the vast majority of Iranians are Muslim, each has its own distinctive character with regard to the extent to which Islamic dress codes for women, and sexual segregation in streets and public buildings are enforced. [*Comment 1997*: For instance, the Bakhtiari, Quashquai, and Lore tribes, who live in the Zagros Mountains in the west, do not follow the Islamic dress codes or the practice of female segregation in public places. Although these tribes are Muslim, they do not comply with the Islamic regime's heavy handedness. (*End of comment by F. A. Sadeghpour*)]

## 3. Knowledge and Education about Sexuality

### A. Government Policies and Programs for Sex Education

Under the Shah's regime, which ended in 1978, the state school biology curriculum for the second year of high school included a section on human reproduction, showing the mechanics of meiosis, or egg and sperm production. Such information, revealing that males and females both contribute genetic material to the production of a fetus, runs counter to a central underpinning of Islamic law with regard to child custody, i.e., that the child is the product solely of male seed. When Islamic law was reinstated by the Ayatollah Khomeini, it was necessary to suppress any dissemination of the idea that males and females both contribute materially to the production of a child.

Even before the 1978 revolution, and despite the passage of the Compulsory Education Act of 1953, many female children were withdrawn from school before the onset of puberty. The Compulsory Education Act required children to remain in school until age 15. However, the birth of a newborn girl was commonly recorded as having occurred two years prior to her actual birth date among all but the educated elite. The parents then had government documentation in hand that their daughter was 15 and old enough to leave school, when in reality, she may not even have reached puberty. During the Shah's regime, efforts to curb this practice were frustrated by the fact that few births took place in a medical setting with personnel able to provide documentation.

The other chief formal source of information on human sexuality is provided by the compulsory religious instruction curriculum in the public schools. In religious instruction classes, students are taught the format of prayers to be said at the five daily prayer times prescribed by Islam, and the rules of purity and pollution surrounding them. Details of prerequisite ablutions of the genital and other orifices of the body provided information on anatomical differences between the sexes. Information is also given on the measures to be taken prior to prayer to counter the polluting effects of urination, defecation, expectoration, expulsion of nasal mucus, menstruation, childbirth, ejaculation, and penetration of the vagina (human and animal) to restore spiritual purity. These measures require that the student have detailed knowledge of the reproductive organs and sexual practices. The Islamic clergy, or *mullahs*, also disseminate this type of information on television, in the mosque, and in the many informal neighborhood prayer meetings.

The general trend of this information, whether given by lay teachers or *mullahs*, is to present sexual behavior as the most polluting form of elimination, which renders the participant spiritually and physically unclean. Sexual behavior of any kind obstructs spiritual readiness. Whereas the polluting effects on the body and spirit of urination or defecation can be washed away in a bathroom with a sink or a shower, orgasm or sexual contact with a person or animal requires a more ritualized bathing with accompanying spiritually cleansing words.

Television programs in Iran regularly deal with the finer points of Islamic observance, such as determining the readiness or otherwise for prayer in ambiguous situations such as nursing mothers, sufferers from vaginal discharges, and males awaking in a state of sexual arousal. Often, the format of the program is one in which viewers' letters are answered by experts in Islamic practice.

## B. Informal Sources of Sexual Knowledge

### *Sexuality Education Within the Home*

The nature of Iranian family and social life offers a major informal source of sexual knowledge.

There is little coyness about the physical aspects of sex. Because it interrupts fasting and prayer schedules, menstruation is openly mentioned by men and women. Pregnancy's physical aspects are not only discussed in intimate detail, but the taboos against males' touching women are lifted during pregnancy, so that males can feel free to pat a pregnant woman approvingly on the abdomen. Breastfeeding is also subject to few social taboos. Women breastfeed in public places and in mixed company in private houses with no attempt to cover the breasts. A little milk, believed to be stale, is usually expressed quiet openly from each breast before beginning to nurse. So although faces and limbs are assiduously covered, the nursing breast is displayed quite blatantly. [Comment 1997: This is characteristic of provincial and lower-class urban Iranians. (End of comment by F. A. Sadeghpour)]

Little girls of all ages are kept well covered. In many provincial towns, girl babies are hidden completely under their mother's *chador* on the street. Toddler girls wear *chadors* often with only a pacifier protruding from its folds.

Little boys are often bare from the waist down, obviating the need for diapers outside. At any age, males may urinate openly in the street or at the roadside. Older males often seek the partial privacy of a tree or wall. Most, however, orient themselves in a way so as to avoid the sacrilege of urinating while facing Mecca, even if it then means facing an audience. Many men, subsequent to urination, bend down and bathe the head of the penis in any convenient pool or

stream of water, to avoid the spiritual defilement of a drop of urine before prayer. Females' visual knowledge of male anatomy is derived largely from seeing little boys unclad and males of all ages urinating and washing in public.

Prior to puberty, male children gain a much more extensive knowledge of female anatomy at all stages of the lifecycle, and at all stages of pregnancy and lactation, by virtue of the fact that their mothers take them to the public baths with them on "women's day." The public baths consist of waist-deep bathing pools for communal bathing and private shower rooms for families. No one bathes completely alone. Women of all ages are unclad. Most wear loose drawers in the public areas, but are otherwise nude. Within the privacy of the shower rooms, little boys therefore observe their grandmothers, mothers, aunts, sisters, and female cousins taking showers and being depilated of all body hair. Female bath attendants, who assist in applying the leafah and pumice stone, also assist in the removing of facial and leg hair with a kind of scissor made of twisted threads, and in the shaving of the pubic regions and armpits. The bath attendants enter the cubicles wearing a *chador*, which they then remove to work in the nude. They themselves are devoid of all body hair. It is up to the bath attendants to decide, based on their own observations, whether a young boy is too old to be present on women's day. Clearly, men retain in adulthood images of what they saw in the bathhouse during childhood. Many speak openly, with disgust and derision, of the effects of pregnancy and the aging process on the female body. Females, however, lack this kind of longitudinal information on males, because fathers do not take children with them to bathe. [Comment 1997: These observations do not apply to upper- and rich-class families, which commonly have showers in their homes. (End of comment by F. A. Sadeghpour)]

Children are aware from an early age that an intrinsic part of wedding preparations is the setting out of the wedding night sleeping quarters for the bride and groom. The first night after the wedding has to be spent within the supervised setting of the family. Children learn, too, that something painful involving blood is going to happen to the bride, and that for her protection against excessive brutality on the part of the groom, older female kin have their bedding set out within earshot, often with only a curtain separating them from the bridal couple. (The prevalence of voyeurism, mentioned in Section 8, Unconventional Sexual Behaviors, below, also provides a rich informal source of sexual knowledge.)

Another informal source of sexuality information is American and European adult magazines such as *Playboy* and *Penthouse*. Until the crackdown of the Islamic regime, these magazines were on sale everywhere and openly displayed in homes. They were a source of pictures to decorate the walls in private houses, particularly in the kitchen and areas of the house off-limits to formal visitors. Although the magazines can no longer be openly sold, back issues still abound and old centerfolds still adorn some family rooms.

### *Television as a Source of Sexual Information*

In the absence of many other forms of recreation, watching television has become a major urban pastime. Since there are only three Government-run television channels, and since their regular scheduled programming is often supplanted, without announcement, by religious broadcasts, satellite-dish television keeps the general public aware that the position of women, and patterns of courtship, marriage, and sexual behavior, are much more liberal outside Iran. In 1994, Iranian-made satellite antennae cost \$700 and small, low-tech antennae sold through the black market for as little as \$400. An estimated 200,000 Iranian families have dishes,

but it is common for several neighboring families to reduce the cost even more by tying in their television sets to a single jointly purchased dish.

For some years, Iranian satellite dishes were able to bring in everything from late-night soft pornography films from Turkey to the BBC news. Most satellite programs were handled by the Hong Kong-based Star TV. The most popular satellite programs were "Dynasty," "The Simpsons," "Baywatch," "Moonlighting," "Wrestlemania," professional American basketball, and an Asian version of MTV. The Donahue and Oprah Winfrey talk shows, which regularly deal with sexual and relationship issues, were also very popular in a society where a woman's ankle cannot be exposed in public. Until December 1994, when the Government outlawed satellite television antennae, this source of sexuality information encouraged the adoption of Western ideas of fashion and relationships. [*Comment 1997: For the rich, this has always been the norm. (End of comment by F. A. Sadeghpour)*] Of necessity, even before they were outlawed, satellite antennae were carefully hidden from the representatives and enforcers of religiously conservative dictates from the Ministry of Culture and Islamic Guidance.

In 1994, threatened with a loss of their captive audience, the *mullahs* fought back with Government efforts to jam the satellite reception. Members of the popular militia, known as *bassijis*, began barging into homes to smash satellite receivers (Hedges 1994). On December 25, 1994, after months of debate, the Iranian Parliament ratified a ban on satellite dishes. Once the ban is routinely approved by the Guardian Council, dish owners would have 30 days to remove them or face confiscation and trial with unspecified penalties. The Interior Ministry and Secret Service agencies were ordered to prevent the import, distribution, and use of satellite dishes "with all the necessary means." Some lawmakers warned that, if people refused to comply with the ban, the forcible removal of satellite dishes would violate their right to privacy and could lead to serious political repercussions for the Islamic Government.

### *Sexual Information on the Internet*

In addition to their interest in controlling sexual information and sexually explicit material available to Iranians on satellite television, the government has very mixed feelings about allowing access to the Internet. *Sobh*, the monthly newspaper of the most puritanical clergy, has called for a ban on the Internet, similar to the ban on satellite-television antennae enacted in 1994. However, as of late 1996, the Parliament had yet to take up the issue. Rapid upgrading of telephone lines, growing pressure from scientists interested in communicating with colleagues around the world, and clergy interest in spreading the message of Islam by making computerized texts of both Sunni and Shi'ite law available on the World Wide Web are forcing the government to open up some access to the Internet. The government is trying to centralize all access through the Ministry of Posts and Telecommunications, which is struggling to screen the rapidly increasing number of sites on the World Wide Web, and block access to objectionable sites with a "firewall." The Ministry is constantly updating its list of banned Web sites and information, ranging from pornography sources like "playboy.com," to opposition groups like the Mujahedeen Khalq, based in Iraq, and abhorred religious faiths like the Bahai, as well as any information seen as Western propaganda (MacFarquhar 1996b).

Cost remains a major hurdle for most Iranians seeking information on the Internet. The Government charges large initiation fees, and bills Internet use at the same high rates as long-distance phone calls.

Outside the Government, a few services have established Internet links. Since 1994, much of the Iranian university system has depended on a trunk line established by the Institute for the Study of Mathematics and Science to a sister institution in Austria. But with an estimated 30,000 people having accounts, and the trunk line limited to six users at a time, getting through requires patience. There is also an ongoing feud between the universities and the Telecommunications Ministry over whether the universities will be allowed to keep their independent access once the government's system is operational. In 1996, Teheran's energetic Mayor, Gholam Hussein Karbaschi, had a municipal bulletin board and an email system that forwarded messages internationally, but exchanges often took at least 24 hours. Professors and students were suspicious that messages sent and received on this municipal service were screened and deleted when found objectionable, but the Mayor denied messages were vetted, blaming the huge backlog for lost exchanges. Government officials have already admitted they cannot control access to objectionable information on the Internet mechanically, so the future of access to sexuality information on the Internet remains uncertain.

### *[Sexual Information in Iranian Cinema*

[*Update 2001: A report on "Subliminal Sex in Iranian Cinema" by Shakla Haeri describes how Iranian cinema has adapted to strict government censorship while accommodating the general interest of Iranians in sexual issues. The cinema has developed all kinds of symbols and codes so that the cinemagoers may assume sexual contact between lovers without any explicit mention or showing. Riding a motorcycle in tandem is one device. Another movie shows quivering lovers both holding on to the same branch of a tree, fully clothed, the girl neatly head-scarfed despite turbulent weather. The tree branch is briefly submerged in a torrent and emerges to show the lovers still perfectly kempt but devoid of former tension (Anthropology News March 2001). (End of update by R. T. Francoeur)*]

## *4. Autoerotic Behaviors and Patterns*

The subject of self-pleasuring is apparently taboo or unacknowledged, because its only reference appears to be within the context of preprayer ablutions requirements on the male after voluntary ejaculation.

## *5. Interpersonal Heterosexual Behaviors*

### **A. Children**

Children do not play unsupervised. An invitation to a child to play at the house of a neighbor or a schoolmate always includes the mother. Such invitations are in any case rare, as are all social interactions with nonkin. Children, in general, play with their cousins under the watchful eye of all mothers. Female children are watched very carefully. Access to information on sex-rehearsal play would be severely hampered by cultural taboos on admitting anything detrimental about one's children, especially to nonkin.

### **B. Adolescents**

#### *Puberty Rituals*

The male puberty rite of circumcision, which formerly celebrated the onset of manhood, has for many years now been more customarily performed at the age of 5 or 6 for children born at home, and at two days old for those born in a medical setting. Boys circumcised after infancy wear a girl's skirt for several days, ostensibly to prevent chafing of the unhealed penis, but also to proclaim their status to others. By puberty, all Muslim Iranian boys must be circumcised if they are to participate fully in religious activities.

Female circumcision, common in African Muslim cultures, does not occur in Iran. For Iranian girls, there is some ambiguity about her societal status from the age of 9 on. In the Iranian brand of Shi'ite Islam, a girl of 9 is judged to have reached the age of understanding. She is therefore expected to say her prayers and abstain from food during periods of prescribed fasting. As a fully participating Muslima in many layers of society, she is expected to assume modest dress, i.e., the *chador*, if she has not already done so. More-conservative *mullahs* in Iran have construed the phrase "age of understanding" to mean age of readiness for marriage. The Islamic regime of the Ayatollah Khomeini has encouraged a return to this interpretation, promoting child marriages in which the 9-year-old girl joins her husband's household (patrilocal). The marriage, however, is not consummated until after her first menstruation. The child bride often shares a quilt at night with her mother-in-law, who, because of the prevalence of cousin marriage, is more often than not the bride's paternal or maternal aunt.

#### *Premarital Sexual Activities and Relationships*

It can be said that there are no societally approved premarital sexual activities. The sexes are separated by adolescence. Young single males join male kin for most social activities. Young single females stay with the women in the family. Many young girls are married immediately after menarche. [*Comment 1997*: Several commentators questioned this broad generalization. (*End of comment by R. T. Francoeur*)]

A young virgin who joins a household as a live-in maid, is often required by both her parents and her employers to submit to a medical examination to establish whether her hymen is intact. Written into her employment contract is the amount of cash penalty payable by the employer should she lose her virginity (as determined by a second medical examination) during her employment. This contract protects her from the advances of male members of the household, as well as from male visitors to the house, by placing the onus on her employer to protect her and supervise her. In her subordinate capacity, she is extremely vulnerable to rape and seduction. Households employing young girls are also vulnerable to extortion by her parents. Her certificates of pre- and postemployment virginity are also documents that feature in her own prenuptial negotiations. Despite these precautions, young servant girls are usually considered fair game for sexual advances and harassment by males in general.

#### *Teenage Runaways*

[*Update 2000*: There are no official statistics on young Iranians who run away from home, although a November 2000 story in a Tehran newspaper estimated that the police round up close to 100 male and female runaways every day. The report also noted that runaways can be found in Iran's railroad and bus stations and public parks, where they often become prey of criminal gangs. For years, the government chose to ignore the problem of runaway youths, because problems of family honor should be dealt with within the family. But with more and more Iranian youth running away from home and falling prey to prostitution, crime, and addiction to cheap and plentiful heroin, the government has been forced to act. In early 2000, the city of Tehran funded the nation's only shelter for females who run away from their homes because of "divorce, addiction, poverty and the bizarre demands of parents."

[In addition to protecting the runaways from relatives bent on restoring their family honor by punishing or even killing the runaway, the shelter's main problem is to figure out what to do when a reconciliation with the runaway's

family is not possible. If runaway girls are prostitutes, drug addicts, and go bareheaded, pretending that they are boys, they are turned over to the police and arrested. If they are just runaways, they are delivered to the shelter. The shelter has a strict regime, teaching basic math and language skills, a range of crafts, sewing, flower arranging, painting, and candlemaking. The hearty lunch is better than that served at many restaurants, and the girls can watch television, read newspapers, and listen to the radio (Sciolino 2000b). (*End of update by R. T. Francoeur*)]

### **C. Adults**

#### *Premarital Courtship, Dating, and Relationships*

Courtship takes place in a supervised, formalized setting. All marriages are arranged, even those based on love matches and mutual inclination. Since male kin, especially the father, passes on the groom's portion of the family estate when he marries, the bride's kin have to know how much is involved before they consent to their daughter's betrothal. The older generation, therefore, controls all meetings between those seeking to marry each other.

A young man visits the girl he intends to marry accompanied by at least three older members of his family. He will be received in the dining room by her parents and relatives. The girl herself will often appear only fleetingly and not speak unless questioned directly. Marriage often follows betrothal by a matter of days. Often a contract is signed in the presence of a *mullah*, making the couple legally married and all financial agreements legally binding. The wedding celebration for the families is held off for up to a year. In some families, especially in Teheran, the couple is allowed to go out together between the official signing of the marriage contract and the wedding celebration. Sometimes the groom's family and sometimes the bride's family will prohibit such contact because, during negotiations, proof of virginity has been spelled out as a prerequisite to the finalization of property transfers. Urban and landless families usually have no such considerations.

Mild public displays of affection are tolerated between urban middle-class couples during the prewedding period. The couple, however, is seldom completely alone, even when allowed to go to the cinema or an ice cream parlor. Usually, there are siblings on either side in tow as a precaution against anything beyond hand holding or chaste kisses on the cheek.

#### *Marriage and the Family*

*Temporary Marriages*. [*Update 2001*: The custom of "temporary marriage" (*mut'a* or *sigheh*) appears to be unique to Iran. Originally, it was meant to provide female companionship and domestic services for Muslim men on long trips, especially on pilgrimages to Mecca and while serving in the military. During the Shah's regime, it existed for a variety of somewhat similar circumstances. A temporary marriage could provide female companionship and comfort for businessmen traveling outside Iran who preferred to leave their wife or wives at home. In this case, the marriage contract had clearly specified a certain duration of days or weeks after which the marriage ended. While this form of marriage became more and more rare over time, its legal authority was never removed. After the Iran-Iraq war, *mut'a* allowed widowed women to find some financial support as "temporary wives" in a society not structured to deal with widowed women with no family support system. Temporary marriages were publicly approved in the early 1990s, when then-President Hashemi Rafsanjani endorsed it as a way to channel young people's sexual urges under the strict sexual segregation maintained by the Islamic Republic.

[The essence of the *mut'a* contract is its legal and binding character. It may be witnessed by a religious authority (*mullah*), who is paid a fee for his official witness, or it may be less formal, but equally as legal in effect, with anyone reading a verse from the Qur'an in the couple's presence. The *mut'a* contract specifies the legitimacy of any offspring conceived during the time of the contract and the inheritance rights of these legitimate offspring, with a claim to the father's support and a right to his name on the birth certificate. Normally, the woman receives some money for entering the contract.

[In 2001, correspondents in Tehran reported a revival and new application of the "temporary marriage" by unmarried consenting adults who just want to go out together in public without being arrested for doing so. The *mut'a* is particularly popular now for two divorced people who are dating. The *mut'a* allows them to visit areas, such as restaurants and ski resorts, which otherwise would be closed to them as an unmarried couple. (Fathi 2002a; Sciolino 2000). (See also Update 2002 in Section 8B, Significant Unconventional Sexual Behaviors, Prostitution) (*End of update by R. T. Francoeur*)]

*Monogamy and Polygyny.* Monogamy has long been established as the norm for both urban and rural households. Traditionally, newly married couples were given quarters in the household of the groom's parents. This pattern persists in rural areas. Young couples in the cities now often rent an apartment, usually in close proximity to the groom's parent's house. The groom's mother, and sometimes the bride's younger sister, stay with the newlyweds for the first few weeks of marriage. The groom's mother sets her guidelines for the way the house is to be run. From the beginning, everything serves to compartmentalize the aspects of the marriage relationship and prevent any spillover of feeling to be expressed in physical expressions of affection or the companionship of shared daytime activities.

The bride is prepared for her wedding night at a pre-nuptial bath in which her pubic hair is removed for the first time. Her mother-in-law and her own mother will sleep in close proximity to the marriage bed on the first night. Both will inspect the specially prepared handkerchief, which will provide evidence of both a broken hymen and ejaculation. If a honeymoon trip is undertaken, the couple will seldom travel alone, but be accompanied by a couple of younger siblings, or maybe an older sister. Honeymoon companions are particularly common for females of the middle class and among university students.

At home, the couple cannot retire until the groom's mother deems it is a fit hour for everyone. Generally, sleeping arrangements are such that the couple cannot rely on uninterrupted privacy. Iranian houses do not have rooms set aside exclusively as bedrooms. Nothing prevents a mother-in-law from setting up her bedding adjacent to that of her son and his wife, or in such a way that she has an excuse to walk by during the night en route to the kitchen or toilet. A pattern is then set for sex in marriage to be quick and almost furtive with ejaculation of the male as the prime or even sole goal.

*Divorce.* [Update 2002: In August 2002, Iran's reformist Parliament approved a bill that would grant women a right to seek a divorce equal to that of men for the first time since the Islamic revolution in 1979. The bill requires approval by the hard-line Guardian Council to become law. While that approval seems unlikely, Parliament's approval of the bill was considered a major victory both for women and reformist politicians, who have consistently sought the support of women because it creates public pressure on the country's conservative Islamic rulers.

[Under the civil code adopted after the 1979 revolution, "a man can divorce his wife whenever he wishes." The new bill would replace that section of the code with a provision that gives men and women equal right to divorce, but sets the grounds on which a divorce could be sought—addiction, mental illness, or violent behavior. This would make divorce equally difficult for both men and women. Another provision of the bill would require a man to pay for health-care if his wife became ill. At present, if a man refuses to pay for his wife's care, the case is sent to court, and judges have not consistently ruled in favor of the wives.

[Reformist women in Parliament have previously tried to change laws that discriminate against women, but their efforts have been blocked or altered by the clerical establishment. The Guardian Council, for instance, blocked a bill that would have raised the legal marriage age for girls from 9 to 15, contending that it went against *Shar'ia*, or Islamic law. After months of dispute, the Expediency Council, which resolves differences between Parliament and the Guardian Council, approved raising the minimum age, but only to 13. In another instance, women in Parliament proposed that Iran join the United Nations Convention on Elimination of All Forms of Discrimination Against Women, but members abruptly dropped consideration of the plan after hard-line clerics in the religious city of Qum declared that the convention was against Islam. (Fathi 2002ab). (*End of update by R. T. Francoeur*)]

### *Incidence of Oral and Anal*

The general lack of privacy inhibits all but the most perfunctory intercourse. Anal penetration of the female is a common means both of birth control and avoidance of possible contamination with menses. Khomeini's writings provide guidelines for preprayer ablution after penetration of the anus and animals under separate headings, though he considered the latter practice unworthy of practicing Muslims.

## *6. Homoerotic, Homosexual, and Bisexual Behaviors*

In the same way that admissions about sexual behavior in children are impossible, homosexuality in a family member cannot be acknowledged. The derogatory term *cuni* (from *cun* = backside) is used to describe men outside the family, whose gait or voice is considered effeminate. Men who do not marry stay with their natal family all their life. Within the family, some such men are described as *na-mard* (not-men). Implicit in the term is a suggestion of phallic underdevelopment or dysfunction. Other older single men are described as not having found a wife yet, the implication being that they are physically normal but financially ineligible for marriage.

Male homosexuality is condemned by Islam and overt homosexuality is unknown. Just as most heterosexual relationships lack an emotional component, it is to be expected that homosexuality be predominantly physical and without an emotional component. Long-term, companionable homosexual relationships are rare. Two unmarried men (of whatever sexual orientation) would be unlikely to be able to set up house together, because of strong societal pressures against any unmarried person living beyond the pale of family control. However, since there are many exclusively male social arenas—teahouses, political and religious organizations, and men's days at the bathhouse—there are more opportunities both for male-male physical contact and for the setting up of clandestine meetings between males. Women, as noted earlier, do not have similar occasions for privacy in same-gender relationships. Ira-

nian culture also allows men a great deal of public touching, embracing, kissing, and holding hands for prolonged periods while walking or in conversation.

[Update 2003: As indicated in the above comments of Dr. Drew, Iranian men who have sex with men do not fit the Western categories of homosexual or gay. Although somewhat closer to the cultural reality, the descriptor “bisexual” is also not accurate. In the Iranian mind, a man’s masculinity and heterosexuality are not affected by the sexual relations he has, be these with women, men, or animals. As Zarit (1992, 56) notes, *kuni*, one of the Farsi words for “queer,” reveals the importance of the role one plays in any sexual activity. A *kuni* is someone who gives himself in anal intercourse. Farsi has two complementary words for “pimp”: *koskeš* means a procurer of vagina, while *kunkeš* means a procurer of ass (*kun*). Taking the active role in anal intercourse with a male is more acceptable than being the receiver in oral sex, which is better than being the giver of oral sex, though all three are enjoyed almost as much. Oral sex is considered a perversion introduced from the West. The acceptability of being the penetrator in anal intercourse—and oral sex—varies according to social class and religious conviction, according to Zarit. Because premarital virginity is so prized for women, a great many Iranians, particularly among the lower class, regard male-male anal sex as normal, particularly before marriage. The more educated and wealthy classes share this view, but tend to be more hypocritical about doing it, maintaining that sodomy simply does not exist in Iran. Vaginal intercourse, active anal sex, and penetrator in oral sex share one common character in Iran: They are equally and predominantly physical and without an emotional component. Long-term male-male sexual relations are very rare.

Homosexual love hardly exists there, at least with foreigners, without some price tag on it: free meals, free jeans, or possibly help in getting a U.S. visa. In a sexual encounter Iranians rarely kiss, and even more rarely on the lips, never with the tongue. . . . When it comes to oral sex, they find it better to receive than to give. And when they *do* get involved, they often literally ‘come and go’, zip sip. . . . [When an Iranian male was asked about having anal sex], he would respond, “But I was the man.” (Reed 1992, 63, 65)

For the male who is the recipient of anal intercourse or takes the female role in fellatio, money is the lubricant that makes it excusable. (*End of update by R. T. Francoeur*)

Other than among siblings, women do not enjoy an equal freedom. Although a similar situation applies to females with regard to touching and embracing, most are married or have marriages already being arranged for them before they reach a stage of physical/hormonal development at which they are aware of their own sexual orientation. Homosexual orientation in females has, therefore, little chance for expression.

Lesbianism is reported to occur in one of the very few residential situations for unmarried women, nurses’ training hostels. It is possible that homosexually oriented females select a nursing career as one that allows opportunities for intimate contact with other women.

## 7. Gender Diversity and Transgender Issues

Since each person’s behavior is strictly controlled by older family members, no overt expression of gender conflict, such as transvestism, would be tolerated. A child suffering from a physical or emotional deviation from narrow,

accepted norms is generally kept from public view. Expression of any kind of individualism in unconventional dress or hairstyle is almost impossible, because of the power and the control of access to funds of the parent generation throughout the lifecycle of the offspring. The burlesque theater with its morality plays (*tazieh*) performed in the street or market place could provide a niche for gender-conflicted males, because female roles are played by tradesmen. This theater is largely thought of as a disreputable arena for the marginalized, providing a normal social framework for those without kin. This theater plays no part in upper-class mores.

## 8. Significant Unconventional Sexual Behaviors

### A. Coercive Sex

#### *Sexual Abuse*

Since marriages can be contracted at any point after a girl has reached the age of 9, it is legally feasible for a very little girl to be married to a man of any age, and thus be physically at his mercy. This no doubt constitutes the broadest category of potential sexual abuse of children. One of the strongest arguments made in Iran against the custody of children, particularly girls, being given to the mother, is that on her remarriage, the children will be in danger of sexual abuse from the new husband.

Sexual abuse of children, particularly little girls, often occurs at the hands of uncles and cousins staying under the same roof. In such cases, the child’s mother is inevitably blamed for leaving her child unguarded, and little outrage is directed at the abuser. Sexual abuse of children in a family setting is not the concern of the police, nor are there any relevant social agencies to which it could be reported. A young servant boy would be withdrawn from the household by his parents if he were the victim of abuse. Only in the case of a young servant girl could the police be implicated, and then only if her virginity had been certified prior to employment.

#### *Incest*

Incest always requires a cultural definition at two levels. To be considered incestuous behavior within a culture, the sexual behavior must take place between people of the opposite sex who are not allowed to marry because of genetic or affinal relatedness. Secondly, the behavior itself must be considered erotic in nature and somehow shocking by the members of that culture. In Iran, marriage between cousins is the norm. Even the marriage between the offspring of two sisters, considered incestuous in most cultures, is very common in Iran, as it prevents the splitting up of parcels of land inherited jointly by two sisters by passing it on to their children at marriage. Within the same generation in a family, only brothers and sisters are off-limits to each other as marriage partners.

In Western cultures, certain zones of the body are described as erogenous, and any touching of these zones by another person is generally interpreted as sexually motivated behavior. Similarly, slow dancing, with bodies touching and the arms of one partner about the neck of the other, would be assumed to be motivated by either sexual attraction or a desire on the part of one or both of the partners to stimulate themselves or the other. In Iran, however, fairly intimate touching is common between opposite-sex siblings, although such behavior would not be tolerated among those of the opposite sex more distantly related. Teenage siblings of the opposite sex, even those who are married, have the license for close “accidental-on-purpose” body contact in rough-and-tumble play. They often display phys-

ical affection, kissing on the face, lips, and neck that border on the erotic. They may be seen grooming each other and, for example, anointing each other with suntan oil in a sensuous way. Such behavior continues with siblings until late in life. At any age, touching high up on the inner thigh or on the outer periphery of the breasts between opposite-sex siblings is allowable in public as a way of drawing attention to points made in conversation, even though it would be deemed indecent public behavior between nonsiblings.

Similarly, in large family gatherings, weddings for example, Western-style dancing is often mixed with Iranian-style dancing. Married couples, fathers and daughters, brothers and sisters, and occasionally mothers and sons, may be seen dancing together very closely. An Iranian would not interpret this behavior as incestuous or in any way distasteful, and would probably find any such suggestion rather warped on the part of the observer. This, of course, raises very interesting questions about what is and is not sexual behavior.

### Sexual Harassment

The general pattern of sex segregation makes opportunities for sexual harassment rare. Should it occur and be mentioned, the female, and more particularly her mother, would be blamed for affording anyone the opportunity. The most common forms of sexual harassment are those of frottage and furtive pinching in crowded shopping areas.

### Rape

The legal concerns of rape are not connected in Iran with the indignities suffered by the victim, but with the financial damages incurred to the family as a result of rupture of the daughter's hymen.

Opportunities for rape are rare. When it does occur, it is likely to involve the police at the instigation of the girl's parents. The police are empowered to force a man who has robbed a girl of her virginity, with or without her assent, to marry her legally. He is allowed to divorce her immediately if he wishes, but the legal procedures and documentation of marriage must be followed through. A divorced woman is more marriageable than an unmarried girl with a ruptured hymen. In the case of a servant girl, her parents may choose between a cash settlement from her employer or a forced marriage between the employer and their daughter, even if he already has a wife. Under the law, a girl can force into legal marriage any man with whom she claims to have had intercourse. The procedure is swift and uncomplicated, involving simple arrest and handcuffs. However, since the girl must be represented in this by her father, few girls would initiate this procedure frivolously or maliciously. This is especially true because there would be few legal repercussions against a father who killed his daughter for dishonoring the family.

Marital rape is not a legal category, in that a woman is her husband's property. If a woman shows signs of physical abuse, her male kin, especially older brothers, will threaten or assault her husband. In general, it is the duty of different members of the kin group to protect the females in the group. In most instances of sexual violence, punishment will be dealt out by the group without fear of intervention from police.

### B. Prostitution

Prostitution is one of the few subsistence slots available for women marginalized by the death of those kin vital to their functioning in society. Daughters of repudiated women and childless widows are particularly vulnerable. Every village seems to have its "fallen woman," who is rumored to serve as a prostitute. People speak too of brothels in the ba-

zaar area of large towns. Veiled women can be seen at night walking alone on the outskirts of towns. A woman walking alone at any time, particularly after dusk, unless obviously bent on shopping or an urgent errand, would be assumed to be a prostitute. Maids commuting from their place of employment carry large totes, a pair of men's shoes, or a garment on a hanger in a dry cleaning bag, so as not to be mistaken for prostitutes and harassed.

[Update 2002: Despite strong enforcement of anti-prostitution laws enacted after the Islamic revolution deposed the Shah in 1979, Iran's Parliament suggested establishing state-approved "decency houses" or "chastity houses" to reduce the explosion of "kerbcrawlers" (street prostitutes). The proposal surfaced in mid 2002 after eight members of the Iranian national football squad were sentenced to as many as 170 lashes of the whip after incriminating photographs of them turned up in a police raid on a warehouse in the capital.

[About the same time, in a suburb of Tehran, a revolutionary court judge was jailed for ten and a half years for pimping young girls, including a 17-year-old who had been detained against her will. Conservatives, who still run the courts and security services, were quick to condemn the proposals as anything but decent, making it far from certain they will ever be put into practice. However, the very fact that they are being openly aired in the press shattered one of conservative Islam's strongest taboos and turned the proposals into an open discussion.

[The proposals being floated take advantage of the Shiite custom of "temporary marriage"—*mut'a* or *sigheh*. If the proposals are adopted, street prostitutes picked up by the religious police or other security forces would be given a choice: Take the assistance of social services to give up their profession, or accept placement in a state-sponsored "decency house" where they could contract temporary marriages with their clients. Such contracts may be for a few minutes or 99 years. Customers would pay a dowry, rather than a fee, and would be able to set the duration of the "marriage contract." The "decency houses" would only be open to males with identity cards proving they were bachelors, widows, or married to women incapacitated by physical or mental illness. Newspapers reported that certain Tehran hotels had already been earmarked for possible use.

[With Iran in the midst of an economic crisis and an estimated over 300,000 women supporting themselves as "kerbcrawlers," the proposals found some unlikely supporters, including the head of the Imam Khomeini Research Center, named after the revered founder of the Islamic Republic. The proposal for state-tolerated prostitution has precedent in Iran. In the days of the pro-Western Shah, when the country was awash with American advisors, the capital's Shahr-e-no district housed hundreds of brothels, which operated openly and legally. After the revolution, some supported keeping the brothels open and legal instead of driving them underground. Soon, however, the hard-line clergy forced their closure.

[After decades of severe repression by the police, Revolutionary Guard, and the courts, a string of high-profile prostitution cases in 2002 made it clear that the Islamic punishments handed out by the revolutionary courts have been and are ineffective. As conservatives put mounting pressure on the reformist administration of moderate President Mohammad Khatami, the whole question of prostitution was poised to become the keystone in elections to be held in late 2002, with the fate of the proposed "decency houses" being intimately connected to the fate of Khatami's government (Arabia.com 2002). (End of update by R. T. Francoeur)]

### C. Pornography and Erotica

During the Shah's regime, copies of American magazines such as *Playboy* and *Penthouse* were widely sold at newsstands, openly perused by men and women, and left lying around in full view in homes (see Section 3B on informal sources of sexual knowledge). Despite the Khomeini regime's ban on all depictions of the unclad human form and the sale of such magazines, this material is still available.

Displays of belly dancing in restaurants and private weddings and parties were staple entertainment prior to the Islamic regime. Although the dancers often showed great skill, male members of the audience clearly viewed them as prostitutes, or at least women with whom liberties could be openly taken. In mixed family audiences, older males often greeted their performances with exaggerated leering and lip-smacking. Young males would be inhibited by the presence of their parents. Middle-aged men, however, would tuck bills into the spangled brassiere or the low-slung waistband of the fringed skirts of the dancer as she passed their table.

[Update 1997: In December 1993, the Iranian Parliament approved legislation providing for capital punishment for the producers and distributors of pornographic videotapes. First offenders would receive a maximum five years' prison term and \$100,000 in fines; "principal promoters" face the death penalty. Experts doubt that this attack on the "Corrupters of the Earth" will discourage the immensely profitable business. Videotapes of Western and pornographic films are already widely available through a network of unlicensed distributors. Also feeding the trade, according to official statistics, are three million Iranian homes with video recorders and 25,000 satellite dishes—analysts say the real figure is more like six million and 50,000, respectively (Hedges 1994). (End of update by R. T. Francoeur)]

### D. Domestic Sexual Controls

Living quarters in the cities are similar to private homes and apartments found in European countries. However, the traditional architecture of Iranian homes in small villages and the rural areas have curtained alcoves, rather than closets, for storing bedding and clothing. In these more traditional homes, people unroll mattresses and bedding from these alcoves to sleep at any convenient spot on the floor in any of the rooms, or on the roof or balcony. Often the choice seems to be dictated by the opportunity it provides for spying on others as they sleep or disrobe. Females, particularly those in their 30s, 40s, and 50s, seem particularly prone to spying on married couples, as well as on other women as they bathe, undress, or use the bathroom. Women gossip openly about information they have obviously garnered by such spying. Some intimate information is clearly used at times to discredit other females, as it is presented to listeners as if revealed by a male confidant with carnal knowledge.

There appears to be a strong interest, not only in details of other women's bodies and personal hygienic measures, but in the frequency and urgency with which they urinate. One who urinates often is spoken of in disparaging terms. Houses with outhouses often have no doors, with walls that conceal only the midsection of the occupant. It is considered a basic precaution to check that one is not being observed.

It is easy for a female to wander from room to room, from roof to balcony to yard without arousing suspicion as she goes about domestic tasks like rounding up soiled dishes and laundry. There are few internal doors in some Iranian houses and any stealthiness can be explained away as consideration for those engaged in the national pastime of brief and frequent naps.

Males do not have such freedom of movement in the house, and thus male voyeurism is less of a day-to-day

problem in the typical large multigenerational household. Male voyeurism more often takes place outside the home. It usually takes the form of the male wearing a woman's all-concealing veil to insinuate himself into female enclaves or the bathhouse on women's day. While the success of such endeavors appears to be largely hearsay, there seems to be an acceptance of voyeurism as a far-from-infrequent fact of life embedded into the culture.

## 9. Contraception, Abortion, and Population Planning

### A. Contraception and Abortion

Condoms are openly sold on every street corner in the towns in Iran. Itinerant vendors display trays of condoms, together with cigarettes and chewing gum. Anal intercourse and coitus interruptus were previously the main male-initiated forms of contraception before the widespread distribution of condoms.

Abortion remains, in rural areas and among the urban poor, the most common female-initiated form of contraception. Untrained midwives induce abortion by introducing a chicken quill into the cervix. From the 1950s on, abortions were widely available in clinics, hospitals, and doctors' offices, restricted only by a woman's ability to pay. Neither male consent nor religious considerations seemed to be issues raised. The conceptus has neither legal nor spiritual status, nor, for that matter, has an apparently nonviable term-born child. Efforts are often not made to succor a weak newborn in the home. Mothers often abandon sickly babies born in a hospital. Only a viable offspring becomes a male concern and an object of his proprietary rights.

Tubal ligations are the contraceptive method of choice among the urban middle class. Contraceptive pills are freely available without prescription and are in common use by young, urban married couples.

### B. Population Control Efforts

Efforts on the part of the Iranian Women's Organization to educate women about safe contraception since the mid-1960s have been mainly aimed at improving female health rather than affecting the population size. Life for women among the rural and urban poor, until the 1960s, was more often than not one of an endless chain of pregnancies, spaced by prolonged and intensive nursing and unskilled, unsterile abortions. High infant-mortality rates in the villages, rather than contraception, kept the population size stable. The Shah set up a network of rural government clinics in the late 1960s and early 1970s to provide free primary healthcare, which included the distribution of contraceptive pills. This latter measure, together with the sudden widespread availability to all of antibiotics, had a dramatic effect both on the birthrates and the survival of those born.

[Update 1997: Between the Islamic revolution of 1979 and 1996, Iran's population almost doubled, from 35 million to more than 60 million. Faced with internal and external threats to the revolution, including the 1980-1988 war with Iraq, Iran's spiritual leaders regularly extolled large families as a way of preserving the revolution. The legal age of marriage was dropped to 9. Today, at least 43% of the population is under 17. Despite official support for larger families, many Iranians in the early 1980s found themselves faced with soaring inflation and eroding wages, a common deterrent to large families. Dr. Alireza Marandi, then Iran's Deputy Minister of Health and its current Minister of Health, recognized that Iran's population growth rate was rocketing out of control. At the time, considering the very conservative religious climate, Marandi did not deem it wise to bring the population issue into public debate. In-

stead, he quietly kept alive a prerevolutionary program of distributing free condoms and IUD's while maneuvering for an opening. One word from the Ayatollah Ruhollah Khomeini and all contraceptives would disappear throughout the country. In 1988, after the Cabinet approved birth control by a single vote, Marandi asked for a public statement supporting contraception. But the internal opposition was so strong, the Cabinet vote was not announced. Instead Ayatollah Khomeini suggested a public discussion that sent Muslim scholars digging through their texts for religious sanctions that could be cited in support of birth control.

[The debate culminated in a 1993 law that enshrined birth control and lifted subsidized health insurance and food coupons for any child after the third. Condoms, vasectomies, and the birth control pill are free. The state also introduced mandatory prenuptial birth control classes. Couples seeking a marriage license must submit a stamped form documenting their participation in an hour-long lecture on contraception. Abortion, however, remains illegal, except when the mother's health is in danger. As a result, Iran's population growth rate, which in the 1980s was 4%—one of the highest growth rates seen anywhere—declined to about 2.5%. Rural families still tend to have many children. Despite the fact that the nation's growth rate is now below 2.5%, Iran's population will pass the 100 million mark early in the 21st century (MacFarquhar 1996a). (*End of update by R. T. Francoeur*)]

## 10. Sexually Transmitted Diseases and HIV/AIDS

### A. Sexually Transmitted Diseases

The major endemic sexually transmitted disease has for decades been syphilis, although it is suspected that the term "syphilis" has become a generic one in Iran to include all sexually transmitted diseases. It is assumed that men contract syphilis from prostitutes and then infect their wives. Many babies in the villages are born with syphilis, contracted during the birth process. Standard neonatal ward procedure in hospitals involves medicating the eyes of newborns against the onset of syphilis-related infections. Part of the prenuptial inspection of prospective brides by the mother-in-law in the bathhouse is a search for what are thought to be symptoms of syphilis, notably patchy skin and thinning hair. Treatment for syphilis is available in clinics, but there is no government attempt to eliminate or track down sources of infection.

### B. HIV/AIDS

At present, there is no information on the prevalence or otherwise of AIDS in Iran. Although prostitution anywhere can bring about a spread of infection, there are cultural patterns in Iran that would minimize the spread of HIV infections. Consorting with prostitutes is not common for married men because of the strong cultural belief that variety adds nothing to the spice of sexual behavior. Since the main object of sex is seen as the relief of phallic tension, this goal is thought to be more safely achieved with one's wife. Advice to this effect is a common subject of sermons and religious writings. Visits to prostitutes are also seen as signs of immaturity, as "real men" have achieved the financial eligibility prerequisite to marriage and uninterrupted access to a woman.

[*Update 2002*: Until recently, the Health Ministry reported that the HIV virus was transmitted in Iran primarily by the sharing of contaminated needles. In 2002, the Health Ministry reported that HIV was increasingly being spread by sexual contact and prostitutes. This trend prompted Ayatollah Moussavi Bojnourdi to support establishment of "decency or chastity houses" where men could enter into temporary marriages with a prostitute. In August 2002, *Etemad*, a Tehran newspaper, quoted Bojnourdi as saying: "If we want

to be realistic and clear the city of such women, we must use the path that Islam offers us" (Fathi 2002b).

[Public health experts and epidemiologists have been ordered by the religious leaders to fight the spread of AIDS, but promoting AIDS-prevention programs to teach teenagers about safe sex without even whispering the word condom is not very effective. A pamphlet designed for adolescents by the Iranian Center for Disease Control suggests, for instance, that the "best way to avoid AIDS is to be faithful to moral and family obligations and to avoid loose sexual relations. Trust in God in order to resist satanic temptations." In mid 2002, the word condom was introduced to AIDS pamphlets for adults, although it continued to be banned on radio and television talk shows. Condoms are available in pharmacies. But the basic government point of view is that telling teenagers about them will inspire the youngsters to start having sex.

[Added to the limits on the mention of condoms is the fact that homosexuality is illegal. In view of Iranian macho and religious traditions, gay sex remains so deeply in the closet that few patients will even confide to their doctors that it could be the source of their disease. Premarital and extramarital sex are similarly hidden. Although drug addiction is now widely acknowledged, tolerance has limits. The Islamic revolution was supposed to eliminate all these social blemishes. To recommend condoms would be to admit the revolution was not a 100% success.

[Despite these restrictions, a small group of activist doctors are determined to exorcise the taboos that surround AIDS. Through January 2002, Iran had identified 3,438 people who were living with HIV, mostly male drug addicts, 35 persons with full-blown AIDS, and 350 who had died from AIDS. The Centers for Disease Control estimates the actual number of HIV-positive Iranians at 19,000, but other sources suggest higher figures. Although these are not epidemic statistics in a country with a population of 70 million, the potential for disaster looms, given widespread needle-sharing among Iran's 1.2 million confirmed drug addicts. Three years ago, Iran had identified just 300 people with HIV.

[In 2002, an anti-AIDS organization provoked outrage by suggesting that the prisons, where addiction is endemic, start needle exchanges. The idea was officially rejected as encouraging addiction. But the organization persuaded a few wardens individually to try it on the sly because the method has worked in lowering incidence of the disease in other countries.

[Government hospitals treat AIDS patients free, at a cost of \$1,000 a week per patient for the cocktail that suppresses the disease. But Iranian doctors will not give AIDS medications to prisoners, because their compliance with the strict schedule of taking the medications is too random in the chaos of the overcrowded prisons.

[The practice of religiously sanctioned temporary marriage (*mu'ta*) has also been recommended by some clerics and members of Parliament. The hope would be that young men in a temporary marriage would be less likely to visit prostitutes who have a high rate of HIV infection (MacFarquhar 2002). (*End of update by R. T. Francoeur*)]

[*Update 2002*: UNAIDS Epidemiological Assessment: Based on the reported data, the HIV epidemic in the Islamic Republic of Iran appears to be accelerating at an alarming trend. According to reports by the National AIDS Program, the number 1,159 of newly diagnosed HIV infections and AIDS cases in 2001 shows a threefold increase in comparison to both years 2000 and 1999.

[This considerable increase may indicate another outbreak. The previous dramatic increase had occurred in 1997, when the number of HIV/AIDS cases had reached 815 new infections.

[Injecting drug use drives the epidemic in Iran. In 2001, 64% of AIDS cases were injecting drug users. The data on HIV seroprevalence among injecting drug users shows the highest rates of infection compared to all other tested groups. Injecting drug users were tested positive in 1996 and a prevalence was found of 5.7% of the cases in 1996, with 1.7% in 1997. The data are variable, as it relates to occurrence of well-known outbreaks among injecting drug users in prisons. Consequently, it is not surprising to note that HIV rates among prisoners rose up to six times higher in 1999 compared to 1996. Likewise, we observe a high rate of HIV-seropositive tests among attendees of voluntary counseling and testing centers, because these centers mainly serve drug users. The voluntary counseling and testing centers were introduced in 1999 and account for a considerable percentage of all annual HIV infections. The HIV prevalence rate among center attendees was around 3% in 1999 and 4% in 2001. There has been a significant increase of total numbers of reported STD cases in the country during the period of 1995 to 1998. Candidiasis, trichomoniasis, chlamydia and gonorrhea are the four main causes, accounting for over 60% of the total diagnosed cases.

[The estimated number of adults and children living with HIV/AIDS on January 1, 2002, were:

Adults ages 15-49:	20,000	(rate: < 0.1%)
Women ages 15-49:	5,000	
Children ages 0-15:	< 200	

[An estimated 290 adults and children died of AIDS during 2001.

[No estimate is available for the number of Iranian children who had lost one or both parents to AIDS and were under age 15 at the end of 2001. (*End of update by the Editors*)]

## 11. Sexual Dysfunctions, Counseling, and Therapies

### A. Concepts of Sexual Dysfunctions

In Iran, there is generally very little concern and a great deal of impatience with psychological considerations. Children who receive regular meals and are kept clean are considered well looked after, regardless of how happy or unhappy they are. A woman who complains about having nothing to wear would be taken more seriously than one who complains that her husband never talks to her or approaches her sexually. Sexual functioning and satisfaction are similarly measured without regard to the emotional component. Tenderness and attention to the state of arousal of the female are not valid considerations.

A male is judged to be sexually adequate if he is capable of erection and ejaculation, as proven by the presence of both semen and blood from the ruptured hymen of his bride on the nuptial handkerchief used on his wedding night. A female is inspected before marriage by her prospective mother-in-law to check for mammary development, nipples sufficiently protruding for nursing, and the width of pelvis for childbirth. The main proof of sexual adequacy, however, is her ability to conceive. Failure to conceive within two years of marriage is grounds for repudiation.

### B. Availability of Counseling, Diagnosis, and Treatment

Counseling in all marital matters is strictly a family affair. There is a strong taboo against discussing family problems of any kind with a nonfamily member. It is not even acceptable to admit, however casually, to a friend or person outside the circle of close kin, that anything is wrong with family, children, or finances. Iran is thus not

very fertile ground for any kind of psychotherapy. On the one hand, the therapist would be perceived as a stranger and, therefore, not one to whom confidences should be made. Secondly, after long years of dictatorship under the Shah, backed up by the secret police, or S.A.V.A.K., and more than a decade of the repressive Islamic Republic with its brutal guardians of public morals, the Pastoran, no clear line would be seen between professionals of any kind asking questions and government officials collecting incriminating information.

Under the Shah's regime, gynecologists in Teheran and other major cities offered help to women with fertility problems. Western-trained medical personnel, however, for the most part fled from Iran after the ousting of the Shah. Most women in small towns and villages seek herbal and spiritual measures to overcome fertility problems. Bitter infusions, thought to aid conception, are concocted and drunk by the desperate. Large, old trees, thought in this mostly desert area to hold the power of fertility, often have their branches completely covered with little pieces of rag into which are knotted the prayers of supplicants who cannot conceive. Advice on the formulations of such potions and the text of such prayers is perhaps the closest one comes in Iran to therapy for sexual dysfunction.

## 12. Sex Research and Advanced Professional Education

Other than a concern with physical causes of infertility in women during the reign of the Shah, sexual research has been nonexistent in Iran. Surgical measures to correct reproductive dysfunction were widely available under the Shah. The psychosexual component of reproduction and sexuality itself were, even then, seldom considered to be of academic or medical interest.

## Conclusion

Within the family, sexual activity between married people can be alluded to in a jocular way. In mixed company, men may be teased for looking tired as a result of suspected sexual activity. Members of households exchange innuendoes about suspicious sounds heard during the night. However, alluding to extramarital sex is considered to be in extremely bad taste and discussion of one's sex life absolutely taboo. Friendships with nonkin are rare. The composition of marital households and informal networks is such that most social contact involves in-laws within the group. Discussion of anything intimate is thus inhibited. There are strong cultural constraints on revealing anything of a personal nature within the family, and even stronger ones on mentioning anything to strangers. Because of this lack of exchange of information, there tends to be an overestimate of the strength and longevity of the human sex drive, and a wildly exaggerated sense of the amount of sexual behavior that occurs in places, such as the U.S.A. and Europe, where Islamic cultural constraints are not in effect. This belief serves to reinforce the notion that such constraints are vital.
